**Library:** Communications Toolbox / Equalizers

## Description

The Linear Equalizer block uses a tapped delay line filter to equalize a linearly modulated signal through a dispersive channel. Using an estimate of the channel modeled as a finite input response (FIR) filter, the block processes input frames and outputs the estimated signal.

This icon shows the block with all ports enabled for configurations that use the LMS or RLS adaptive algorithm.

This icon shows the block with all ports enabled for configurations that use the CMA adaptive algorithm.

## Ports

### Input

#### **in** — Input signal

column vector

Input signal, specified as a column vector. The vector length of **in** must be equal to an integer multiple of the **Number of input samples per symbol** parameter. For more information, see “Symbol Tap Spacing” on page 3-628.

Data Types: double

Complex Number Support: Yes

#### **Desired** — Training symbols

column vector

Training symbols, specified as a column vector. The vector length of **Desired** must be less than or equal to the length of input **in**. The **Desired** input port is ignored when the **Train** input port is 0.

#### **Dependencies**

To enable this port, set the **Adaptive algorithm** parameter to LMS or RLS.

Data Types: double

Complex Number Support: Yes

#### **Train** — Train equalizer flag

1 | 0

Train equalizer flag, specified as 1 or 0. The block starts training when this value changes from 0 to 1 (at the rising edge). The block trains until all symbols in the **Desired** input port are processed.

#### **Dependencies**

To enable this port, set the **Adaptive algorithm** parameter to LMS or RLS and select the **Enable training control input** parameter.

Data Types: Boolean

#### **Update** — Update tap weights flag

1 | 0

Update tap weights flag, specified as 1 or 0. The tap weights are updated when this value is 1.

#### Dependencies

To enable this port, set the **Adaptive algorithm** parameter to CMA and the **Source of adapt weights flag** parameter to Input port.

Data Types: Boolean

#### Reset — Reset equalizer flag

1 | 0

Reset equalizer flag, specified as 1 or 0. If **Reset** is set to 1, the block resets the tap weights before processing the incoming signal. The block performs initial training until all symbols in the **Desired** input port are processed.

#### Dependencies

To enable this port, select the **Enable reset input** parameter.

Data Types: Boolean

## Output

#### Out — Equalized symbols

column vector

Equalized symbols, returned as a column vector that has the same length as input signal **in**.

This port is unnamed until you select the **Output error signal** or **Output taps weights** parameter.

#### Err — Error signal

column vector

Error signal, returned as a column vector that has the same length as input signal **in**.

#### w — Tap weights

column vector

Tap weights, returned as an  $N_{\text{Taps}}$ -by-1 vector, where  $N_{\text{Taps}}$  is the value of the **Number of Taps** parameter. **w** contains the tap weights from the last tap weight update.

## Parameters

### Structure parameters

#### Number of taps — Number of equalizer taps

5 (default) | positive integer

Number of equalizer taps, specified as a positive integer.

#### Signal constellation — Signal constellation

`pskmod(0:3,4,pi/4)` (default) | vector

Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: `pskmod(0:3,4,pi/4)`.

**Tunable:** Yes

#### Number of input samples per symbol — Number of input samples per symbol

1 (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this parameter to any number greater than 1 effectively creates a fractionally spaced equalizer. For more information, see “Symbol Tap Spacing” on page 3-628.

### Algorithm parameters

#### Adaptive algorithm — Adaptive algorithm

LMS (default) | RLS | CMA

Adaptive algorithm used for equalization, specified as one of these values:

- LMS — Update the equalizer tap weights using the “Least Mean Square (LMS) Algorithm” on page 3-630.
- RLS — Update the equalizer tap weights using the “Recursive Least Square (RLS) Algorithm” on page 3-631.
- CMA — Update the equalizer tap weights using the “Constant Modulus Algorithm (CMA)” on page 3-631.

#### Step size — Step size

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to LMS or CMA.

**Forgetting factor — Forgetting factor**

0.99 (default) | scalar in the range (0, 1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to RLS.

**Initial inverse correlation matrix — Initial inverse correlation matrix**

0.1 (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an  $N_{\text{Taps}}$ -by- $N_{\text{Taps}}$  matrix.  $N_{\text{Taps}}$  is equal to the **Number of Taps** parameter value. If you specify this value as a scalar,  $a$ , the equalizer sets the initial inverse correlation matrix to  $a$  times the identity matrix:  $a(\text{eye}(N_{\text{Taps}}))$ .

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to RLS.

**Control parameters**

**Reference tap — Reference tap**

3 (default) | positive integer

Reference tap, specified as a positive integer less than or equal to the **Number of Taps** parameter value. The equalizer uses the reference tap location to track the main energy of the channel.

**Input signal delay (samples) — Input signal delay**

0 (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the block and to the first call of the block after the **Reset** input port toggles to 1.

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to LMS or RLS.

**Source of adapt weights flag — Source of adapt tap weights request**

Property (default) | Input port

Source of the adapt tap weights request, specified as one of these values:

- **Property** — Specify this value to use the **Adaptive algorithm** parameter to control when the block adapts tap weights.
- **Input port** — Specify this value to use the **Update** input port to control when the block adapts tap weights.

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to CMA.

**Adapt tap weights — Adapt tap weights**

on (default) | off

Select this parameter to adaptively update the equalizer tap weights. If this parameter is cleared, the block keeps the equalizer tap weights unchanged.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to CMA and **Source of adapt weights flag** to Property.

**Initial tap weights source — Source for initial tap weights**

Auto (default) | Property

Source for initial tap weights, specified as one of these values:

- **Auto** — Initialize the tap weights to the algorithm-specific default values, as described in the **Initial weights** parameter.
- **Property** — Initialize the tap weights using the **Initial weights** parameter value.

**Initial weights — Initial tap weights**

0 or [0;0;1;0;0] (default) | scalar | column vector

Initial tap weights used by the adaptive algorithm, specified as a scalar or an  $N_{\text{Taps}}$ -by-1 vector.  $N_{\text{Taps}}$  is equal to the **Number of Taps** parameter value. The default is 0 when the **Adaptive algorithm** parameter is set to LMS or RLS. The default is [0;0;1;0;0] when the **Adaptive algorithm** parameter is set to CMA.

If you specify **Initial weights** as a vector, the vector length must be equal to the **Number of Taps** parameter value. If you specify **Initial weights** as a scalar, the equalizer uses scalar expansion to create a vector of length **Number of Taps** with all values set to **Initial weights**.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Initial tap weights source** to Property.

**Tap weight update period (symbols) — Tap weight update period**

1 (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

**Enable training control input — Enable training control input**

off (default) | on

Select this parameter to enable input port **Train**. If this parameter is cleared, the block does not reenter training mode after the initial tap training.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to LMS or RLS.

**Update tap weights when not training — Update tap weights when not training**

on (default) | off

Select this parameter to use decision directed mode to update equalizer tap weights. If this parameter is cleared, the block keeps the equalizer tap weights unchanged after training.

**Tunable:** Yes**Dependencies**

To enable this parameter, set **Adaptive algorithm** to LMS or RLS.

**Enable reset input — Enable reset input**

off (default) | on

Select this parameter to enable input port **Train**. If this parameter is cleared, the block does not reenter training mode after the initial tap training.

**Tunable:** Yes**Diagnostic parameters****Output error signal — Enable error signal output**

off (default) | on

Select this parameter to enable output port **Err** containing the equalizer error signal.

**Tunable:** Yes**Output taps weights — Enable tap weights output**

off (default) | on

Select this parameter to enable output port **w** containing tap weights from the last tap weight update.

**Tunable:** Yes**Simulate using — Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than **Interpreted execution**.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the **Code generation** method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

## More About

### Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbol-spaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

## Algorithms

### Linear Equalizers

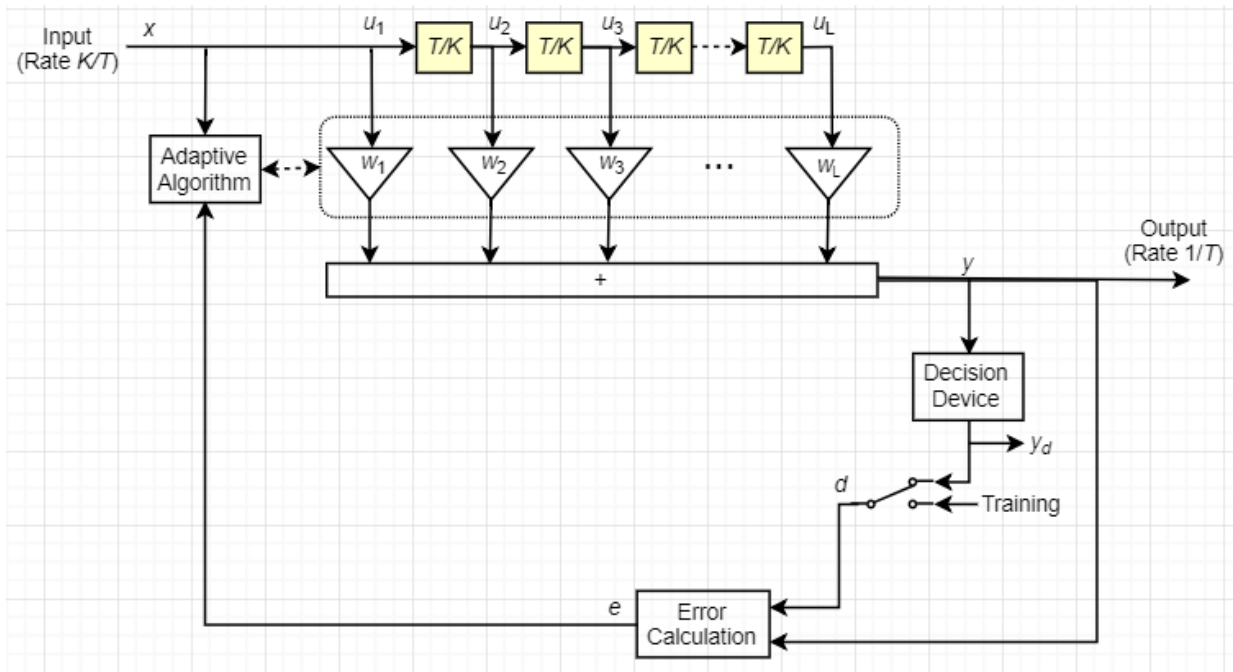

Linear equalizers can remove intersymbol interference (ISI) when the frequency response of a channel has no null. If a null exists in the frequency response of a channel, linear equalizers tend to enhance the noise. In this case, use decision feedback equalizers to avoid enhancing the noise.

A linear equalizer consists of a tapped delay line that stores samples from the input signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

Linear equalizers can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol,  $K$ , is 1. The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol,  $K$ , is an integer greater than 1. Typically,  $K$  is 4 for fractionally spaced equalizers. The output sample rate is  $1/T$  and the input sample rate is  $K/T$ , where  $T$  is the symbol period. Tap-weight updating occurs at the output rate.

This schematic shows a linear equalizer with  $L$  weights, a symbol period of  $T$ , and  $K$  samples per symbol. If  $K$  is 1, the result is a symbol-spaced linear equalizer instead of a fractional symbol-spaced linear equalizer.

In each symbol period, the equalizer receives  $K$  input samples at the tapped delay line. The equalizer then outputs a weighted sum of the values in the tapped delay line and updates the weights to prepare for the next symbol period.

For more information, see “Equalization”.

### Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic,  $w$  is a vector of all weights  $w_i$ , and  $u$  is a vector of all inputs  $u_i$ . Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (\text{StepSize}) u * e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the `maxstep` object function. The  $*$  operator denotes the complex conjugate and the error calculation  $e = d - y$ .

## Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic,  $w$  is the vector of all weights  $w_i$ , and  $u$  is the vector of all inputs  $u_i$ . Based on the current set of inputs,  $u$ , and the inverse correlation matrix,  $P$ , the RLS algorithm first computes the Kalman gain vector,  $K$ , as

$$K = \frac{Pu}{(\text{ForgettingFactor}) + u^H P u}.$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable.  $H$  denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$P_{\text{new}} = \frac{P_{\text{current}}(1 - Ku^H)}{\text{ForgettingFactor}}.$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + K^* e.$$

The  $*$  operator denotes the complex conjugate and the error calculation  $e = d - y$ .

## Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic,  $w$  is the vector of all weights  $w_i$ , and  $u$  is the vector of all inputs  $u_i$ . Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (\text{StepSize}) u^* e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the `maxstep` object function. The  $*$  operator denotes the complex conjugate and the error calculation  $e = y(R - |y|^2)$ , where  $R$  is a constant related to the signal constellation.

# Linearized Baseband PLL

Implement linearized version of baseband phase-locked loop

## Library

Components sublibrary of Synchronization

## Description

The Linearized Baseband PLL block is a feedback control system that automatically adjusts the phase of a locally generated signal to match the phase of an input signal. Unlike the Phase-Locked Loop block, this block uses a baseband model method. Unlike the Baseband PLL block, which uses a nonlinear model, this block simplifies the computations by using  $x$  to approximate  $\sin(x)$ . The baseband PLL model depends on the amplitude of the incoming signal but does not depend on a carrier frequency.

This PLL has these three components:

- An integrator used as a phase detector.
- A filter. You specify the filter's transfer function using the **Lowpass filter numerator** and **Lowpass filter denominator** parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of  $s$ .

To design a filter, you can use functions such as `butter`, `cheby1`, and `cheby2` in Signal Processing Toolbox software. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

```
[num, den] = cheby2(3,40,100,'s')
```

- A voltage-controlled oscillator (VCO). You specify the sensitivity of the VCO signal to its input using the **VCO input sensitivity** parameter. This parameter, measured in Hertz per volt, is a scale factor that determines how much the VCO shifts from its quiescent frequency.

This block accepts a sample-based scalar input signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

## Parameters

### Lowpass filter numerator

The numerator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of  $s$ .

### Lowpass filter denominator

The denominator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of  $s$ .

### VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the VCO's quiescent frequency.

## LMS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with LMS algorithm

## Library

Equalizers

---

**Note** will be removed in a future release. Use Decision Feedback Equalizer instead.

---

## Description

The LMS Decision Feedback Equalizer block uses a decision feedback equalizer and the LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the LMS algorithm to update the weights, once per symbol. If the **Number of samples per symbol** parameter is 1, then the block implements a symbol-spaced equalizer; otherwise, the block implements a fractionally spaced equalizer.

## Input and Output Signals

The **Input** port accepts a column vector input signal. The **Desired** port receives a training sequence with a length that is less than or equal to the number of symbols in the **Input** signal. Valid training symbols are those symbols listed in the **Signal constellation** vector.

Set the **Reference tap** parameter so it is greater than zero and less than the value for the **Number of forward taps** parameter.

The port labeled `Equalized` outputs the result of the equalization process.

You can configure the block to have one or more of these extra ports:

- `Mode` input.
- `Err` output for the error signal, which is the difference between the `Equalized` output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- `Weights` output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see “Equalization”.

## Equalizer Delay

For proper equalization, you should set the **Reference tap** parameter so that it exceeds the delay, in symbols, between the transmitter’s modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer *output* is equal to

$$1 + (\text{Reference tap} - 1) / (\text{Number of samples per symbol})$$

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

### Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

### Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

### Number of samples per symbol

The number of input samples for each symbol.

**Signal constellation**

A vector of complex numbers that specifies the constellation for the modulation.

**Reference tap**

A positive integer less than or equal to the number of forward taps in the equalizer.

**Step size**

The step size of the LMS algorithm.

**Leakage factor**

The leakage factor of the LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

**Initial weights**

A vector that concatenates the initial weights for the forward and feedback taps.

**Mode input port**

If you select this check box, the block has an input port that enables you to toggle between training and decision-directed mode. For training, the mode input must be 1, and for decision directed, the mode must be 0. For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

**Output error**

If you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

**Output weights**

If you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

## LMS Linear Equalizer

(To be removed) Equalize using linear equalizer that updates weights with LMS algorithm

## Library

Equalizers

---

**Note** will be removed in a future release. Use Linear Equalizer instead.

---

## Description

The LMS Linear Equalizer block uses a linear equalizer and the LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the LMS algorithm to update the weights, once per symbol. When you set the **Number of samples per symbol** parameter to 1, then the block implements a symbol-spaced (i.e. T-spaced) equalizer. When you set the **Number of samples per symbol** parameter to a value greater than one, the block updates the weights once every  $N^{\text{th}}$  sample for a T/N-spaced equalizer.

## Input and Output Signals

The **Input** port accepts a column vector input signal. The **Desired** port receives a training sequence with a length that is less than or equal to the number of symbols in the **Input** signal. Valid training symbols are those symbols listed in the **Signal constellation** vector.

Set the **Reference tap** parameter so it is greater than zero and less than the value for the **Number of taps** parameter.

The `Equalized` port outputs the result of the equalization process.

You can configure the block to have one or more of these extra ports:

- `Mode` input.
- `Err` output for the error signal, which is the difference between the `Equalized` output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- `Weights` output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see “Equalization”.

## Equalizer Delay

For proper equalization, you should set the **Reference tap** parameter so that it exceeds the delay, in symbols, between the transmitter’s modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer *output* is equal to

$$1 + (\text{Reference tap} - 1) / (\text{Number of samples per symbol})$$

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap.

## Parameters

### Number of taps

The number of taps in the filter of the linear equalizer.

### Number of samples per symbol

The number of input samples for each symbol.

### Signal constellation

A vector of complex numbers that specifies the constellation for the modulated signal, as determined by the modulator in your model

**Reference tap**

A positive integer less than or equal to the number of taps in the equalizer.

**Step size**

The step size of the LMS algorithm.

**Leakage factor**

The leakage factor of the LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

**Initial weights**

A vector that lists the initial weights for the taps.

**Mode input port**

If you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, and for decision directed, the mode must be 0. For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

**Output error**

If you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

**Output weights**

If you select this check box, the block outputs the current weights.

## Matrix Deinterleaver

Permute input symbols by filling matrix by columns and emptying it by rows

## Library

Block sublibrary of Interleaving

## Description

The Matrix Deinterleaver block performs block deinterleaving by filling a matrix with the input symbols column by column and then sending the matrix contents to the output port row by row. The **Number of rows** and **Number of columns** parameters are the dimensions of the matrix that the block uses internally for its computations.

This block accepts a column vector input signal. The length of the input vector must be **Number of rows** times **Number of columns**.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

### Number of rows

The number of rows in the matrix that the block uses for its computations.

### Number of columns

The number of columns in the matrix that the block uses for its computations.

## Examples

If the **Number of rows** and **Number of columns** parameters are 2 and 3, respectively, then the deinterleaver uses a 2-by-3 matrix for its internal computations. Given an input signal of [1; 2; 3; 4; 5; 6], the block produces an output of [1; 3; 5; 2; 4; 6].

## Matrix Helical Scan Deinterleaver

Restore ordering of input symbols by filling matrix along diagonals

### Library

Block sublibrary of Interleaving

### Description

The Matrix Helical Scan Deinterleaver block performs block deinterleaving by filling a matrix with the input symbols in a helical fashion and then sending the matrix contents to the output port row by row. The **Number of rows** and **Number of columns** parameters are the dimensions of the matrix that the block uses internally for its computations.

Helical fashion means that the block places input symbols along diagonals of the matrix. The number of elements in each diagonal matches the **Number of columns** parameter, after the block wraps past the edges of the matrix when necessary. The block traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

The **Array step size** parameter is the slope of each diagonal, that is, the amount by which the row index increases as the column index increases by one. This parameter must be an integer between zero and the **Number of rows** parameter. If the **Array step size** parameter is zero, then the block does not deinterleave and the output is the same as the input.

This block accepts a column vector input signal. The number of elements of the input vector must be the product of **Number of rows** and **Number of columns**.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

### Number of rows

The number of rows in the matrix that the block uses for its computations.

### Number of columns

The number of columns in the matrix that the block uses for its computations.

### Array step size

The slope of the diagonals that the block writes.

## Matrix Helical Scan Interleaver

Permute input symbols by selecting matrix elements along diagonals

### Library

Block sublibrary of Interleaving

### Description

The Matrix Helical Scan Interleaver block performs block interleaving by filling a matrix with the input symbols row by row and then sending the matrix contents to the output port in a helical fashion. The **Number of rows** and **Number of columns** parameters are the dimensions of the matrix that the block uses internally for its computations.

Helical fashion means that the block selects output symbols by selecting elements along diagonals of the matrix. The number of elements in each diagonal matches the **Number of columns** parameter, after the block wraps past the edges of the matrix when necessary. The block traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

The **Array step size** parameter is the slope of each diagonal, that is, the amount by which the row index increases as the column index increases by one. This parameter must be an integer between zero and the **Number of rows** parameter. If the **Array step size** parameter is zero, then the block does not interleave and the output is the same as the input.

This block accepts a column vector input signal. The number of elements of the input vector must be the product of **Number of rows** and **Number of columns**.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

### Number of rows

The number of rows in the matrix that the block uses for its computations.

### Number of columns

The number of columns in the matrix that the block uses for its computations.

### Array step size

The slope of the diagonals that the block reads.

## Examples

If the **Number of rows** and **Number of columns** parameters are 6 and 4, respectively, then the interleaver uses a 6-by-4 matrix for its internal computations. If the **Array step size** parameter is 1, then the diagonals are as shown in the figure below. Positions with the same color form part of the same diagonal, and diagonals with darker colors precede those with lighter colors in the output signal.

Given an input signal of `[1:24]'`, the block produces an output of

`[1; 6; 11; 16; 5; 10; 15; 20; 9; 14; 19; 24; 13; 18; 23; ...`  
`4; 17; 22; 3; 8; 21; 2; 7; 12]`

# Matrix Interleaver

Permute input symbols by filling matrix by rows and emptying it by columns

## Library

Block sublibrary of Interleaving

## Description

The Matrix Interleaver block performs block interleaving by filling a matrix with the input symbols row by row and then sending the matrix contents to the output port column by column.

The **Number of rows** and **Number of columns** parameters are the dimensions of the matrix that the block uses internally for its computations.

This block accepts a column vector input signal. The number of elements of the input vector must be the product of **Number of rows** and **Number of columns**.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

### Number of rows

The number of rows in the matrix that the block uses for its computations.

### Number of columns

The number of columns in the matrix that the block uses for its computations.

### Examples

If the **Number of rows** and **Number of columns** parameters are 2 and 3, respectively, then the interleaver uses a 2-by-3 matrix for its internal computations. Given an input signal of [1; 2; 3; 4; 5; 6], the block produces an output of [1; 4; 2; 5; 3; 6].

# M-DPSK Demodulator Baseband

Demodulate DPSK-modulated data

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The M-DPSK Demodulator Baseband block demodulates a signal that was modulated using the M-ary differential phase shift keying method. The input is a baseband representation of the modulated signal. The input and output for this block are discrete-time signals. This block accepts a scalar-valued or column vector input signal. For information about the data types each block port supports, see the “Supported Data Types” on page 3-655 table on this page.

The **M-ary number** parameter, M, is the number of possible output symbols that can immediately follow a given output symbol. The block compares the current symbol to the previous symbol. The block's first output is the initial condition of zero (or a group of zeros, if the **Output type** parameter is set to Bit) because there is no previous symbol.

## Integer-Valued Signals and Binary-Valued Signals

If you set the **Output type** parameter to Integer, then the block demodulates a phase difference of

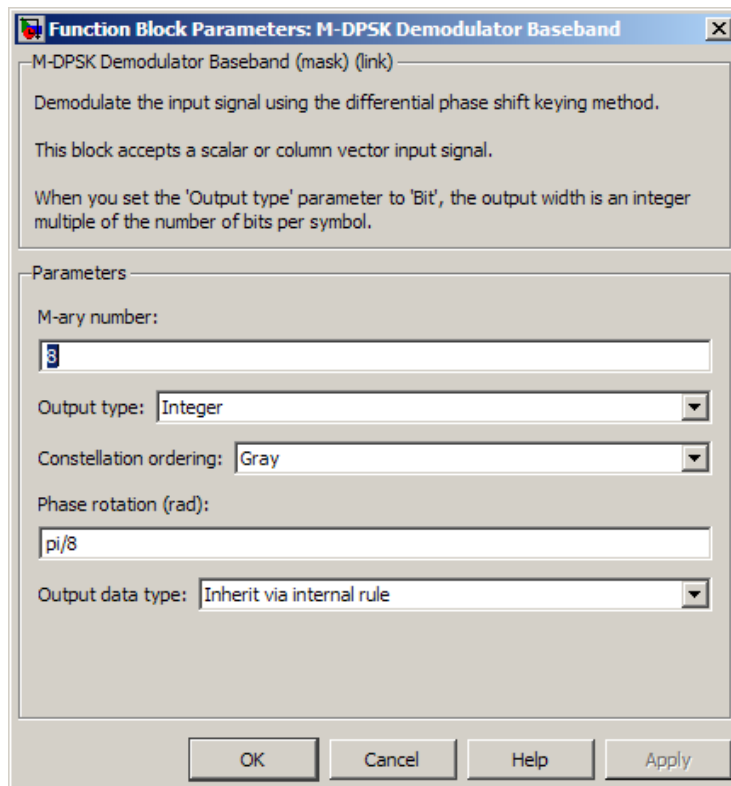

$$\theta + \frac{2\pi k}{M}$$

to  $k$ , where  $\theta$  represents the **Phase rotation** parameter and  $k$  represents an integer between  $\theta$  and  $M-1$ .

When you set the **Output type** parameter to **Bit**, the block outputs binary-valued signals that represent integers. The block represents each integer using a group of  $K = \log_2(M)$  bits, where  $K$  represents the number of bits per symbol. The output vector length must be an integer multiple of  $K$ .

In binary output mode, the symbols can be either binary-demapped or Gray-demapped. The **Constellation ordering** parameter indicates how the block maps an integer to a corresponding group of  $K$  output bits. See the reference pages for the M-DPSK Modulator Baseband and M-PSK Modulator Baseband blocks for details.

## Dialog Box

**M-ary number**

The number of possible modulated symbols that can immediately follow a given symbol.

**Output type**

Determines whether the output consists of integers or groups of bits.

**Constellation ordering**

Determines how the block maps each integer to a group of output bits.

**Phase rotation (rad)**

This phase difference between the current and previous modulated symbols that results in an output of zero.

**Output data type**

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type `single` or `double`.

For integer outputs, this block can output the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `single`, and `double`. For bit outputs, output can be `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, or `double`.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean when <b>Output type</b> set to Bit</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>

# M-DPSK Modulator Baseband

Modulate using M-ary differential phase shift keying method

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The M-DPSK Modulator Baseband block modulates using the M-ary differential phase shift keying method. The output is a baseband representation of the modulated signal. The **M-ary number** parameter,  $M$ , is the number of possible output symbols that can immediately follow a given output symbol.

The input must be a discrete-time signal. For integer inputs, the block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `single`, and `double`. For bit inputs, the block can accept `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, and `double`.

The input can be either bits or integers, which are binary-mapped or Gray-mapped into symbols.

This block accepts column vector input signals. For a bit input, the input width must be an integer multiple of the number of bits per symbol.

## Integer-Valued Signals and Binary-Valued Signals

If you set the **Input type** parameter to `Integer`, then valid input values are integers between 0 and  $M-1$ . In this case, the input can be either a scalar or a frame-based column vector. If the first input is  $k_1$ , then the modulated symbol is

$$\exp\left(j\theta + j2\pi\frac{k_1}{m}\right)$$

where  $\theta$  represents the **Phase rotation** parameter. If a successive input is  $k$ , then the modulated symbol is

$$\exp\left(j\theta + j2\pi\frac{k}{m}\right) \cdot (\text{previous modulated symbol})$$

When you set the **Input type** parameter to **Bit**, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of  $K = \log_2(M)$  bits

where

$K$  represents the number of bits per symbol.

The input vector length must be an integer multiple of  $K$ . In this configuration, the block accepts a group of  $K$  bits and maps that group onto a symbol at the block output. The block outputs one modulated symbol for each group of  $K$  bits.

The input can be a column vector with a length that is an integer multiple of  $K$ .

In binary input mode, the **Constellation ordering** parameter indicates how the block maps a group of  $K$  input bits to a corresponding phase difference. The **Binary** option uses a natural binary-to-integer mapping, while the **Gray** option uses a Gray-coded assignment of phase differences. For example, the following table indicates the assignment of phase difference to three-bit inputs, for both the **Binary** and **Gray** options.  $\theta$  is the **Phase rotation** parameter. The phase difference is between the previous symbol and the current symbol.

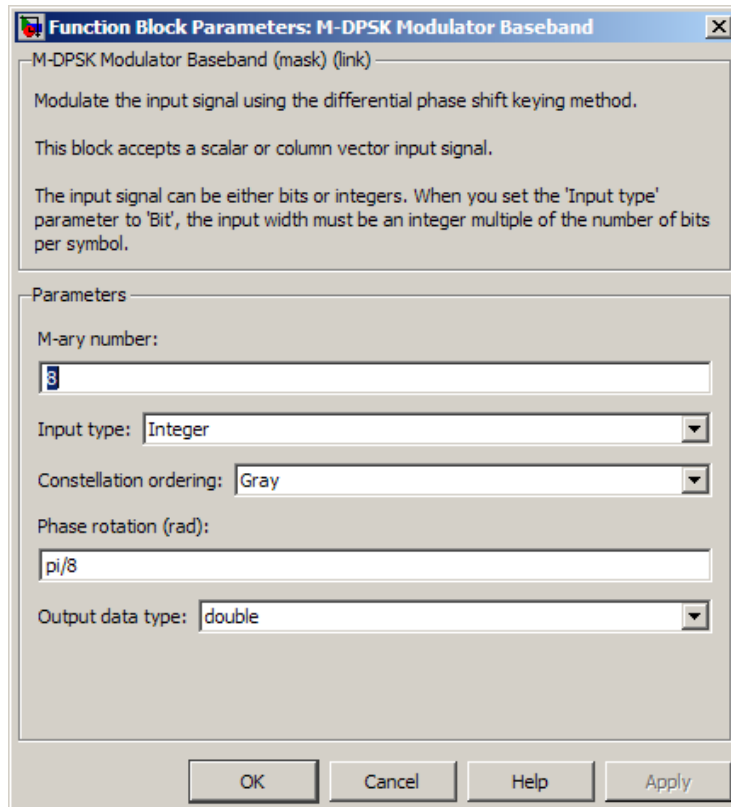

Current Input	Binary-Coded Phase Difference	Gray-Coded Phase Difference
[0 0 0]	$j\theta$	$j\theta$
[0 0 1]	$j\theta + j\pi/4$	$j\theta + j\pi/4$
[0 1 0]	$j\theta + j\pi 2/4$	$j\theta + j\pi 3/4$
[0 1 1]	$j\theta + j\pi 3/4$	$j\theta + j\pi 2/4$
[1 0 0]	$j\theta + j\pi 4/4$	$j\theta + j\pi 7/4$
[1 0 1]	$j\theta + j\pi 5/4$	$j\theta + j\pi 6/4$

Current Input	Binary-Coded Phase Difference	Gray-Coded Phase Difference
[1 1 0]	$j\theta + j\pi 6/4$	$j\theta + j\pi 4/4$
[1 1 1]	$j\theta + j\pi 7/4$	$j\theta + j\pi 5/4$

For more details about the Binary and Gray options, see the reference page for the M-PSK Modulator Baseband block. The signal constellation for that block corresponds to the arrangement of phase differences for this block.

## Dialog Box

**M-ary number**

The number of possible output symbols that can immediately follow a given output symbol.

**Input type**

Indicates whether the input consists of integers or groups of bits. If this parameter is set to `Bit`, then the **M-ary number** parameter must be  $2^K$  for some positive integer  $K$ .

**Constellation ordering**

Determines how the block maps each group of input bits to a corresponding integer.

**Phase rotation (rad)**

The phase difference between the previous and current modulated symbols when the input is zero.

**Output data type**

The output data type can be either `single` or `double`. By default, the block sets this to `double`.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean (binary input mode only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>

## Memoryless Nonlinearity

Apply memoryless nonlinearity to complex baseband signal

## Library

RF Impairments

## Description

The Memoryless Nonlinearity block applies a memoryless nonlinearity to a complex, baseband signal. You can use the block to model radio frequency (RF) impairments to a signal at the receiver.

This block accepts a column vector input signal.

---

**Note** All values of power assume a nominal impedance of 1 ohm.

---

The Memoryless Nonlinearity block provides five different methods for modeling the nonlinearity, which you specify by the **Method** parameter. The options for the **Method** parameter are

- Cubic polynomial
- Hyperbolic tangent
- Saleh model
- Ghorbani model
- Rapp model

The block implements these five methods using subsystems underneath the block mask. For each of the first four methods, the nonlinearity subsystem has the same basic structure, as shown in the following figure.

### Nonlinearity Subsystem

For the first four methods, each subsystem applies a nonlinearity to the input signal as follows:

- 1 Multiply the signal by a gain factor.
- 2 Split the complex signal into its magnitude and angle components.
- 3 Apply an AM/AM conversion to the magnitude of the signal, according to the selected **Method**, to produce the magnitude of the output signal.
- 4 Apply an AM/PM conversion to the phase of the signal, according to the selected **Method**, and adds the result to the angle of the signal to produce the angle of the output signal.
- 5 Combine the new magnitude and angle components into a complex signal and multiply the result by a gain factor, which is controlled by the **Linear gain** parameter.

Each subsystem implements the AM/AM and AM/PM conversions differently, according to the Method you specify. The Rapp model does not apply a phase change to the input signal. The nonlinearity subsystem for Rapp model has following structure:

### Nonlinearity Subsystem for Rapp Model

The Rapp Subsystem applies nonlinearity as follows:

- 1 Multiply the signal by a gain factor.
- 2 Split the complex signal into its magnitude and angle components.
- 3 Apply an AM/AM conversion to the magnitude of the signal, according to the selected **Method**, to produce the magnitude of the output signal.
- 4 Combine the new magnitude and angle components into a complex signal and multiply the result by a gain factor, which is controlled by the **Linear gain** parameter.

If you want to see exactly how the Memoryless Nonlinearity block implements the conversions for a specific method, you can view the AM/AM and AM/PM subsystems that implement these conversions as follows:

- 1 Right-click on the Memoryless Nonlinearity block and select **Mask > Look under mask**. This displays the block's configuration underneath the mask. The block contains five subsystems corresponding to the five nonlinearity methods.
- 2 Double-click the subsystem for the method you are interested in. This displays the subsystem shown in the preceding figure, "Nonlinearity Subsystem" on page 3-663.
- 3 Double-click on one of the subsystems labeled AM/AM or AM/PM to view how the block implements the conversions.

## AM/PM Characteristics of the Cubic Polynomial and Hyperbolic Tangent Methods

The following illustration shows the AM/PM behavior for the Cubic polynomial and Hyperbolic tangent methods:

The AM/PM conversion scales linearly with input power value between the lower and upper limits of the input power level (specified by **Lower input power limit for AM/PM conversion (dBm)** and **Upper input power limit for AM/PM conversion (dBm)**). Beyond these values, AM/PM conversion is constant at the values corresponding to the lower and upper input power limits, which are zero and  $(\text{AM/PM conversion}) \cdot (\text{upper input power limit} - \text{lower input power limit})$ , respectively.

## AM/AM and AM/PM Characteristics of the Saleh Method

The following figure shows, for the Saleh method, plots of

- Output voltage against input voltage for the AM/AM conversion
- Output phase against input voltage for the AM/PM conversion

### Example with 16-ary QAM

You can see the effect of the Memoryless Nonlinearity block on a signal modulated by 16-ary quadrature amplitude modulation (QAM) in a scatter plot. The constellation for 16-ary QAM without the effect of the Memoryless Nonlinearity block is shown in the following figure:

You can generate a scatter plot of the same signal after it passes through the Memoryless Nonlinearity block, with the **Method** parameter set to **Salch Model**, as shown in the following figure.

This plot is generated by the model described in “Illustrate RF Impairments That Distort a Signal” with the following parameter settings for the Rectangular QAM Modulator Baseband block:

- **Normalization method** set to Average Power
- **Average power (watts)** set to  $1e-2$

The following sections discuss parameters specific to the Saleh, Ghorbani, and Rapp models.

## Parameters for the Saleh Model

The **Input scaling (dB)** parameter scales the input signal before the nonlinearity is applied. The block multiplies the input signal by the parameter value, converted from decibels to linear units. If you set the parameter to be the inverse of the input signal amplitude, the scaled signal has amplitude normalized to 1.

The AM/AM parameters, alpha and beta, are used to compute the amplitude gain for an input signal using the following function:

$$F_{AM/AM}(u) = \frac{\alpha * u}{1 + \beta * u^2}$$

where  $u$  is the magnitude of the scaled signal.

The AM/PM parameters,  $\alpha$  and  $\beta$ , are used to compute the phase change for an input signal using the following function:

$$F_{AM/PM}(u) = \frac{\alpha * u^2}{1 + \beta * u^2}$$

where  $u$  is the magnitude of the scaled signal. Note that the AM/AM and AM/PM parameters, although similarly named  $\alpha$  and  $\beta$ , are distinct.

The **Output scaling (dB)** parameter scales the output signal similarly.

## Parameters for the Ghorbani Model

The **Input scaling (dB)** parameter scales the input signal before the nonlinearity is applied. The block multiplies the input signal by the parameter value, converted from decibels to linear units. If you set the parameter to be the inverse of the input signal amplitude, the scaled signal has amplitude normalized to 1.

The AM/AM parameters,  $[x_1 x_2 x_3 x_4]$ , are used to compute the amplitude gain for an input signal using the following function:

$$F_{AM/AM}(u) = \frac{x_1 u^{x_2}}{1 + x_3 u^{x_2}} + x_4 u$$

where  $u$  is the magnitude of the scaled signal.

The AM/PM parameters,  $[y_1 y_2 y_3 y_4]$ , are used to compute the phase change for an input signal using the following function:

$$F_{AM/PM}(u) = \frac{y_1 u^{y_2}}{1 + y_3 u^{y_2}} + y_4 u$$

where  $u$  is the magnitude of the scaled signal.

The **Output scaling (dB)** parameter scales the output signal similarly.

## Parameters for the Rapp Model

The **Linear gain (dB)** parameter scales the input signal before the nonlinearity is applied. The block multiplies the input signal by the parameter value, converted from decibels to linear units. If you set the parameter to be the inverse of the input signal amplitude, the scaled signal has amplitude normalized to 1.

The **Smoothness factor** and **Output saturation level** parameters are used to compute the amplitude gain for the input signal:

$$F_{AM/AM}(u) = \frac{u}{\left(1 + \left(\frac{u}{O_{sat}}\right)^{2S}\right)^{1/2S}}$$

where  $u$  is the magnitude of the scaled signal,  $S$  is the **Smoothness factor**, and  $O_{sat}$  is the **Output saturation level**.

The Rapp model does not apply a phase change to the input signal.

The **Output saturation level** parameter limits the output signal level.

## Parameters

### Method

The nonlinearity method.

The following describes specific parameters for each method.

Parameters

Method:

Linear gain (dB):

IIP3 (dBm):

AM/PM conversion (degrees per dB):

Lower input power limit for AM/PM conversion (dBm):

Upper input power limit for AM/PM conversion (dBm):

**Linear gain (db)**

Scalar specifying the linear gain for the output function.

**IIP3 (dBm)**

Scalar specifying the third order intercept.

**AM/PM conversion (degrees per dB)**

Scalar specifying the AM/PM conversion in degrees per decibel.

**Lower input power limit (dBm)**

Scalar specifying the minimum input power for which AM/PM conversion scales linearly with input power value. Below this value, the phase shift resulting from AM/PM conversion is zero.

**Upper input power limit (dBm)**

Scalar specifying the maximum input power for which AM/PM conversion scales linearly with input power value. Above this value, the phase shift resulting from AM/PM conversion is constant. The value of this maximum shift is given by:

$$(\text{AM/PM conversion}) \cdot (\text{upper input power limit} - \text{lower input power limit})$$

Parameters

Method:

Linear gain (dB):

IIP3 (dBm):

AM/PM conversion (degrees per dB):

Lower input power limit for AM/PM conversion (dBm):

Upper input power limit for AM/PM conversion (dBm):

**Linear gain (db)**

Scalar specifying the linear gain for the output function.

**IIP3 (dBm)**

Scalar specifying the third order intercept.

**AM/PM conversion (degrees per dB)**

Scalar specifying the AM/PM conversion in degrees per decibel.

**Lower input power limit (dBm)**

Scalar specifying the minimum input power for which AM/PM conversion scales linearly with input power value. Below this value, the phase shift resulting from AM/PM conversion is zero.

**Upper input power limit (dBm)**

Scalar specifying the maximum input power for which AM/PM conversion scales linearly with input power value. Above this value, the phase shift resulting from AM/PM conversion is constant. The value of this maximum shift is given by:

$$(\text{AM/PM conversion}) \cdot (\text{upper input power limit} - \text{lower input power limit})$$

The image shows a software parameter dialog box titled "Parameters". It contains several fields and a dropdown menu:

- Method:** A dropdown menu with "Saleh model" selected.
- Input scaling (dB):** A text input field containing "0".
- AM/AM parameters [alpha beta]:** A text input field containing "[2.1587 1.1517]".
- AM/PM parameters [alpha beta]:** A text input field containing "[4.0033 9.1040]".
- Output scaling (dB):** A text input field containing "0".

**Input scaling (dB)**

Number that scales the input signal level.

**AM/AM parameters [alpha beta]**

Vector specifying the AM/AM parameters.

**AM/PM parameters [alpha beta]**

Vector specifying the AM/PM parameters.

**Output scaling (dB)**

Number that scales the output signal level.

Parameters	
Method:	Ghorbani model
Input scaling (dB):	0
AM/AM parameters [x1 x2 x3 x4]:	[8.1081 1.5413 6.5202 -0.0718]
AM/PM parameters [y1 y2 y3 y4]:	[4.6645 2.0965 10.88 -0.003]
Output scaling (dB):	0

**Input scaling (dB)**

Number that scales the input signal level.

**AM/AM parameters [x1 x2 x3 x4]**

Vector specifying the AM/AM parameters.

**AM/PM parameters [y1 y2 y3 y4]**

Vector specifying the AM/PM parameters.

**Output scaling (dB)**

Number that scales the output signal level.

Parameters	
Method:	Rapp model
Linear gain (dB):	0
Smoothness factor:	0.5
Output saturation level:	1

**Linear gain (db)**

Scalar specifying the linear gain for the output function.

**Smoothness factor**

Scalar specifying the smoothness factor

**Output saturation level**

Scalar specifying the output saturation level.

# M-FSK Demodulator Baseband

Demodulate FSK-modulated data

## Library

FM, in Digital Baseband sublibrary of Modulation

## Description

The M-FSK Demodulator Baseband block demodulates a signal that was modulated using the M-ary frequency shift keying method. The input is a baseband representation of the modulated signal. The input and output for this block are discrete-time signals. This block accepts a scalar value or column vector input signal of type `single` or `double`. For information about the data types each block port supports, see “Supported Data Types” on page 3-679.

The **M-ary number** parameter,  $M$ , is the number of frequencies in the modulated signal. The **Frequency separation** parameter is the distance, in Hz, between successive frequencies of the modulated signal.

The M-FSK Demodulator Baseband block implements a non-coherent energy detector. To obtain the same BER performance as that of coherent FSK demodulation, use the CPFSK Demodulator Baseband block.

## Integer-Valued Signals and Binary-Valued Signals

When you set the **Output type** parameter to `Integer`, the block outputs integer values between 0 and  $M-1$ .  $M$  represents the **M-ary number** block parameter.

When you set the **Output type** parameter to `Bit`, the block outputs binary-valued signals that represent integers. The block represents each integer using a group of  $K = \log_2(M)$

bits, where  $K$  represents the number of bits per symbol. The output vector length must be an integer multiple of  $K$ .

The **Symbol set ordering** parameter indicates how the block maps a symbol to a group of  $K$  output bits. When you set the parameter to **Binary**, the block maps the integer,  $I$ , to  $[u(1) u(2) \dots u(K)]$  bits, where the individual  $u(i)$  are given by

$$I = \sum_{i=1}^K u(i)2^{K-i}$$

$u(1)$  is the most significant bit.

For example, if  $M = 8$ , you set **Symbol set ordering** to **Binary**, and the demodulated integer symbol value is 6, then the binary output word is [1 1 0].

When you set **Symbol set ordering** to **Gray**, the block assigns binary outputs from points of a predefined Gray-coded signal constellation. The predefined  $M$ -ary Gray-coded signal constellation assigns the binary representation

```
M = 8; P = [0:M-1]';
de2bi(bitxor(P, floor(P/2)), log2(M), 'left-msb')
```

to the  $P^{\text{th}}$  integer.

The typical Binary to Gray mapping for  $M = 8$  is shown in the following tables.

**Binary to Gray Mapping for Bits**

Binary Code	Gray Code
000	000
001	001
010	011
011	010
100	110
101	111
110	101
111	100

### Binary to Gray Mapping for Integers

Binary Code	Gray Code
0	0
1	1
2	3
3	2
4	6
5	7
6	5
7	4

Whether the output is an integer or a binary representation of an integer, the block maps the highest frequency to the integer 0 and maps the lowest frequency to the integer  $M-1$ . In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

### Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to **Bit**, the output width is  $K$  times the number of input symbols.
- When you set **Output type** to **Integer**, the output width is the number of input symbols.

### Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to **Bit**, the output width equals the number of bits per symbol.

- When you set **Output type** to Integer, the output is a scalar.

To run the M-FSK Demodulator block in multirate mode, clear the **Treat each discrete rate as a separate task** checkbox (in **Simulation > Configuration Parameters > Solver**).

## Parameters

### M-ary number

The number of frequencies in the modulated signal.

### Output type

Determines whether the output consists of integers or groups of bits. If this parameter is set to **Bit**, then the **M-ary number** parameter must be  $2^K$  for some positive integer  $K$ .

### Symbol set ordering

Determines how the block maps each integer to a group of output bits.

### Frequency separation (Hz)

The distance between successive frequencies in the modulated signal.

### Samples per symbol

The number of input samples that represent each modulated symbol.

### Rate options

Select the rate processing method for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample times. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to Integer).
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

**Output data type**

The output type of the block can be specified here as `boolean`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, or `double`. By default, the block sets this to `double`.

**Supported Data Types**

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>

**Introduced before R2006a**

# M-FSK Modulator Baseband

Modulate using M-ary frequency shift keying method

## Library

FM, in Digital Baseband sublibrary of Modulation

## Description

The M-FSK Modulator Baseband block modulates using the M-ary frequency shift keying method. The output is a baseband representation of the modulated signal. For information about the data types each block port supports, see “Supported Data Types” on page 3-685.

To prevent aliasing from occurring in the output signal, set the sampling frequency greater than the product of  $M$  and the **Frequency separation** parameter. Sampling frequency is **Samples per symbol** divided by the input symbol period (in seconds).

## Integer-Valued Signals and Binary-Valued Signals

The input and output signals for this block are discrete-time signals.

When you set the **Input type** parameter to **Integer**, the block accepts integer values between 0 and  $M-1$ .  $M$  represents the **M-ary number** block parameter.

When you set the **Input type** parameter to **Bit**, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of  $K = \log_2(M)$  bits

where

$K$  represents the number of bits per symbol.

The input vector length must be an integer multiple of  $K$ . In this configuration, the block accepts a group of  $K$  bits and maps that group onto a symbol at the block output. The block outputs one modulated symbol, oversampled by the **Samples per symbol** parameter value, for each group of  $K$  bits.

The **Symbol set ordering** parameter indicates how the block maps a group of  $K$  input bits to a corresponding symbol. When you set the parameter to **Binary**, the block maps  $[u(1) u(2) \dots u(K)]$  to the integer

$$\sum_{i=1}^K u(i)2^{K-i}$$

and assumes that this integer is the input value.  $u(1)$  is the most significant bit.

If you set  $M = 8$ , **Symbol set ordering** to **Binary**, and the binary input word is  $[1 \ 1 \ 0]$ , the block converts  $[1 \ 1 \ 0]$  to the integer 6. The block produces the same output when the input is 6 and the **Input type** parameter is **Integer**.

When you set **Symbol set ordering** to **Gray**, the block uses a Gray-coded arrangement and assigns binary inputs to points of a predefined Gray-coded signal constellation. The predefined  $M$ -ary Gray-coded signal constellation assigns the binary representation

```
M = 8; P = [0:M-1]';  
de2bi(bitxor(P, floor(P/2)), log2(M), 'left-msb')
```

to the  $P^{\text{th}}$  integer.

The following tables show the typical Binary to Gray mapping for  $M = 8$ .

### Binary to Gray Mapping for Bits

Binary Code	Gray Code
000	000
001	001
010	011
011	010
100	110
101	111
110	101
111	100

### Binary to Gray Mapping for Integers

Binary Code	Gray Code
0	0
1	1
2	3
3	2
4	6
5	7
6	5
7	4

### Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set **Input type** to **Integer**, the input can be a column vector, the length of which is the number of input symbols.
- When you set **Input type** to **Bit**, the input width must be an integer multiple of  $K$ , the number of bits per symbol.

The output width equals the product of the number of input symbols and the **Samples per symbol** parameter value.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to **Integer**, the input must be a scalar.
- When you set **Input type** to **Bit**, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

To run the M-FSK Modulator block in multirate mode, clear the **Treat each discrete rate as a separate task** checkbox (in **Simulation > Configuration Parameters > Solver**).

## Parameters

### M-ary number

The number of frequencies in the modulated signal.

### Input type

Indicates whether the input consists of integers or groups of bits. If you set this parameter to **Bit**, then the **M-ary number** parameter must be  $2^K$  for some positive integer  $K$ .

### Symbol set ordering

Determines how the block maps each group of input bits to a corresponding integer.

### Frequency separation (Hz)

The distance between successive frequencies in the modulated signal.

### Phase continuity

Determines whether the modulated signal changes phases in a continuous or discontinuous way.

If you set the **Phase continuity** parameter to **Continuous**, then the modulated signal maintains its phase even when it changes its frequency. If you set the **Phase**

**continuity** parameter to **Discontinuous**, then the modulated signal comprises portions of  $M$  sinusoids of different frequencies. Thus, a change in the input value sometimes causes a change in the phase of the modulated signal.

### Samples per symbol

The number of output samples that the block produces for each integer or binary word in the input.

### Rate options

Select the rate processing option for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

### Output data type

You can specify the output type of the block as either a **double** or a **single**. By default, the block sets this value to **double**.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean (bit input mode only)</li> <li>• 8-, 16-, and 32-bit signed integers (integer input mode only)</li> <li>• 8-, 16-, and 32-bit unsigned integers (integer input mode only)</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>

# MIL-188 QAM Demodulator Baseband

MIL-STD-188-110 B/C standard-specific quadrature amplitude demodulation

**Library:** Communications Toolbox / Modulation / Digital  
Baseband Modulation / AM  
Communications Toolbox / Modulation / Digital  
Baseband Modulation / Standard-Compliant

## Description

The MIL-188 QAM Demodulator Baseband block demodulates the input signal using “MIL-STD-188-110” on page 3-692 standard-specific quadrature amplitude modulation (QAM). For a description of MIL-STD-188 compliant demodulation, see “MIL-STD-188-110 QAM Hard Demodulation” on page 3-692 and “MIL-STD-188-110 QAM Soft Demodulation” on page 3-692.

This icon shows the block with all ports enabled:

## Ports

### Input

#### **In — MIL-STD-188 standard-specific QAM modulated signal**

scalar | vector | matrix

MIL-STD-188 standard-specific QAM modulated signal, specified as a scalar, vector, or matrix. When this input is a matrix, each column is treated as an independent channel. This port is unnamed until the Var port is enabled.

Data Types: single | double

Complex Number Support: Yes

**Var — Noise variance**

positive scalar | vector of positive values

Noise variance, specified as a positive scalar or vector of positive values. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “MIL-STD-188-110 QAM Soft Demodulation” on page 3-692 for demodulation decision type considerations.

**Dependencies**

To enable this port set the Noise variance source parameter to Input port.

**Output**

**Out — Demodulated signal**

scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of the demodulated signal depend on the specified Output type and Decision type parameter values. This port is unnamed on the block.

Output type	Decision type	Demodulated Signal Description	Dimensions of Demodulated Signal
Integer	—	Demodulated integer values in the range [0, (M - 1)]	The output signal has the same dimensions as input signal.
Bit	Hard decision	Demodulated bits	The number of rows in the output signal is $\log_2(M)$ times the number of rows in the input signal. Each demodulated symbol is mapped to a group of $\log_2(M)$ elements in a column, where the first element represents the MSB, and the last element represents the LSB.
	Log-likelihood ratio	Log-likelihood ratio value for each bit	
	Approximate log-likelihood ratio	Approximate log-likelihood ratio value for each bit	
<i>M</i> is the value of Modulation order.			

Use Output data type to specify the output data type.

## Parameters

### Modulation order — Modulation order

16 (default) | 32 | 64 | 256

Modulation order,  $M$ , specified as 16, 32, 64, or 256. The modulation order specifies the total number of points in the constellation of the input signal.

### Constellation scaling — Constellation scaling

As specified in standard (default) | Unit average power

Constellation scaling preference, specified as:

- **As specified in standard** - The block scales the constellation based on specifications in the relevant standard [1].
- **Unit average power** - The block scales the constellation to an average power of 1 watt referenced to 1 ohm.

### Output type — Input type

Integer (default) | Bit

Output type, specified as Integer or Bit. To use Integer, the input signal must consist of integers in the range  $[0, (M - 1)]$ . To use Bit, the input signal must contain binary values, and the number of rows must be an integer multiple of  $\log_2(M)$ , where  $M$  is the Modulation order.

### Decision type — Demodulation decision type

Hard decision (default) | Log-likelihood ratio | Approximate log-likelihood ratio

Demodulation decision type, specified as Hard decision, Log-likelihood ratio, or Approximate log-likelihood ratio. See “MIL-STD-188-110 QAM Soft Demodulation” on page 3-692 for algorithm selection considerations.

### Dependencies

This parameter applies when Output type is set to Bit.

### Noise variance source — Noise variance source

Property (default) | Input port

Noise variance source, specified as:

- **Property** — The noise variance is set using the Noise variance parameter.
- **Input port** — The noise variance is set using the Var input port.

**Dependencies**

This parameter applies only when Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.

**Noise variance — Noise variance**

1 (default) | positive scalar | vector of positive values

Noise variance, specified as a positive scalar or vector of positive values.

- When specified as a scalar, that value is used on all elements in the input signal.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal. Each noise variance vector element is applied to its corresponding column in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “MIL-STD-188-110 QAM Soft Demodulation” on page 3-692 for demodulation decision type considerations.

**Dependencies**

This parameter applies only when Noise variance is set to Property and Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.

Data Types: double

**Output data type — Output data type**

double (default) | ...

Output data type, specified as one of the acceptable values from this table. Acceptable Output data type values depend on the Output type and Decision type parameter values.

Output type	Decision type	Output data type Options
Integer	Not applicable	double, single, int8, uint8, int16, uint16, int32, or uint32
Bit	Hard decision	double, single, int8, uint8, int16, uint16, int32, uint32, or logical

Output type	Decision type	Output data type Options
	Log-likelihood ratio or Approximate log-likelihood ratio	The output signal is the same data type as the input signal.

### Dependencies

This parameter applies only when Output type is set to Integer or when Output type is set to Bit and Decision type is set to Hard decision.

### Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

For information on execution speed, see “Tips” on page 3-693.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	yes
<b>Variable-Size Signals</b>	no

## More About

### MIL-STD-188-110

MIL-STD-188-110 is a US Department of Defense standard for HF communications using serial PSK mode of both data and voice signals.

The standard specifies physical layer modulation schemes for tactical and long-haul communications. The modulation scheme specified by the standard is a mix of QAM and APSK. For a detailed description of the modulation scheme, see [1].

### MIL-STD-188-110 QAM Hard Demodulation

The hard demodulation algorithm uses optimum decision region-based demodulation. Since all the constellation points are equally probable, maximum a posteriori probability (MAP) detection reduces to a maximum likelihood (ML) detection. The ML detection rule is equivalent to choosing the closest constellation point to the received symbol. The decision region for each constellation point is designed by drawing perpendicular bisectors between adjacent points. A received symbol is mapped to the proper constellation point based on which decision region it lies in.

Since all MIL-STD constellations are quadrant-based symmetric, for each symbol the optimum decision region-based demodulation:

- Maps the received symbol into the first quadrant
- Chooses the decision region for the symbol
- Maps the constellation point back to its original quadrant using the sign of real and imaginary parts of the received symbol

### MIL-STD-188-110 QAM Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

---

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or -Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

---

## Tips

- For faster execution of the MIL-188 QAM Demodulator Baseband block, set the Simulate using parameter to:
  - Code generation when using hard decision demodulation.
  - Interpreted execution when using soft decision demodulation.

## Description

The MIL-188 QAM Modulator Baseband block modulates the input signal using “MIL-STD-188-110” on page 3-698 standard-specific quadrature amplitude modulation (QAM).

## Ports

### Input

#### In — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The input signal must be binary values or integers in the range  $[0, (M - 1)]$ , where  $M$  is the Modulation order. This port is unnamed on the block.

---

**Note** To process the input signal as binary elements, set the Input type parameter value to Bit. For binary inputs, the number of rows must be an integer multiple of  $\log_2(M)$ . Groups of  $\log_2(M)$  bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

---

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

## Output

### Out — MIL-STD-188 standard-specific QAM modulated signal

scalar | vector | matrix

MIL-STD-188 standard-specific QAM modulated signal, returned as a complex scalar, vector, or matrix. The output signal dimensions depend on the specified Input type parameter value. This port is unnamed on the block.

Input type	Dimensions of Output Signal
Integer	The output signal has the same dimensions as the input signal.
Bit	The number of rows in the output signal equals the number of rows in the input signal divided by $\log_2(M)$ , where $M$ is the Modulation order.

## Parameters

### Modulation order — Modulation order

16 (default) | 32 | 64 | 256

Modulation order,  $M$ , specified as 16, 32, 64, or 256. The modulation order specifies the total number of points in the constellation of the output signal.

### Constellation scaling — Constellation scaling

As specified in standard (default) | Unit average power

Constellation scaling preference, specified as:

- **As specified in standard** - The block scales the constellation based on specifications in the relevant standard [1].
- **Unit average power** - The block scales the constellation to an average power of 1 watt referenced to 1 ohm.

### Input type — Input type

Integer (default) | Bit

Input type, specified as Integer or Bit. To use Integer, the input signal must consist of integers in the range  $[0, (M - 1)]$ . To use Bit, the input signal must contain binary values,

and the number of rows must be an integer multiple of  $\log_2(M)$ , where  $M$  is the Modulation order.

#### **Output data type — Output data type**

double (default) | single

Output data type, specified as double or single.

#### **View Constellation — Plot reference constellation**

button

To plot the reference constellation, click the **View Constellation** button.

#### **Simulate using — Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time, but the speed of the subsequent simulations is comparable to **Interpreted execution**.
- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time and has a simulation speed comparable to **Code generation**. In **Interpreted execution** mode, you can debug the source code of the block.

## **Block Characteristics**

# MIMO Fading Channel

Filter input signal through MIMO multipath fading channel

**Library:** Communications Toolbox / Channels  
Communications Toolbox / MIMO

## Description

The MIMO Fading Channel block filters an input signal using a multi-input/multi-output (MIMO) multipath fading channel. This block models both Rayleigh and Rician fading and employs the Kronecker model for modeling the spatial correlation between the links. For processing details, see the Algorithms on page 3-712 section.

## Signal Dimensions

The availability and dimensions of input and output port signals depends on:

- The Antenna selection parameter setting on the **Main** tab
- The Initial time source parameter setting on the **Realization** tab
- The Output channel path gains selection on the **Realization** tab

Antenna Selection Parameter	Signal Input (in)	Transmit Selection Input (Tx Sel)	Receive Selection Input (Rx Sel)	Initial Time Offset Input (Init Time)	Signal Output (Out1)	Optional Channel Gain Output (Gain)
Off	$N_S$ -by- $N_T$	N/A	N/A	nonnegative scalar	$N_S$ -by- $N_R$	$N_S$ -by- $N_P$ -by- $N_T$ -by- $N_R$
Tx	$N_S$ -by- $N_{ST}$	1-by- $N_T$	N/A		$N_S$ -by- $N_R$	
Rx	$N_S$ -by- $N_T$	N/A	1-by- $N_R$		$N_S$ -by- $N_{SR}$	
Tx and Rx	$N_S$ -by- $N_{ST}$	1-by- $N_T$	1-by- $N_R$		$N_S$ -by- $N_{SR}$	

- $N_S$  represents the number of samples in the input signal.
- $N_T$  represents the number of transmit antennas, as determined by:
  - Transmit spatial correlation when Specify spatial correlation is set to **Separate Tx Rx**
  - Number of transmit antennas when Specify spatial correlation is set to **None or Combined**
- $N_R$  represents the number of receive antennas, as determined by:
  - Receive spatial correlation when Specify spatial correlation is set to **Separate Tx Rx**
  - Number of receive antennas when Specify spatial correlation is set to **None**
  - Combined spatial correlation and Number of transmit antennas when Specify spatial correlation is set to **Combined**
- $N_P$  represents the number of channel paths, as determined by the **Discrete path delays (s)** or **Average path gains (dB)**.
- $N_{ST}$  represents the number of selected transmit antennas, as determined by the number of elements set to **1** in the vector provided to the **Tx Sel** input port.
- $N_{SR}$  represents the number of selected receive antennas, as determined by the number of elements set to **1** in the vector provided to the **Rx Sel** input port.

## Ports

### Input

#### **in** — Input data signal

vector

Input data signal, specified as an  $N_S$ -by- $N_T$  or  $N_S$ -by- $N_{ST}$  matrix.

- $N_S$  represents the number of samples in the input signal.
- $N_T$  represents the number of transmit antennas.
- $N_{ST}$  represents the number of selected transmit antennas.

Data Types: `double` | `single`

Complex Number Support: Yes

**Tx Sel — Select active transmit antennas**

binary vector

Select active transmit antennas, specified as a 1-by- $N_T$  binary vector.  $N_T$  represents the number of transmit antennas. Elements set to 1 identify selected antenna indices and 0 identify nonselected antenna indices.

**Dependencies**

To enable this port, on the **Main** tab, set Antenna selection to Tx or Tx and Rx.

Data Types: double

**Rx Sel — Select active receive antennas**

binary vector

Select active receive antennas, specified as a 1-by- $N_R$  binary vector.  $N_R$  represents the number of receive antennas. Elements set to 1 identify selected antenna indices and 0 identify nonselected antenna indices.

**Dependencies**

To enable this port, on the **Main** tab, set Antenna selection to Rx or Tx and Rx.

Data Types: double

**Init Time — Initial time offset**

nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

**Init Time** must be greater than the last frame end time. When **Init Time** is not a multiple of  $1/\text{Sample Rate}$  (Hz), it is rounded up to the nearest sample position.

**Dependencies**

To enable this port, on the **Realization** tab, set Initial time source to Input port.

Data Types: double

**Output****Out1 — Output data signal for fading channel**

vector

Output data signal for the fading channel, returned as an  $N_S$ -by- $N_R$  or  $N_S$ -by- $N_{SR}$  matrix.

- $N_S$  represents the number of samples in the input signal.
- $N_R$  represents the number of receive antennas.
- $N_{SR}$  represents the number of selected receive antennas.

#### Gain — Discrete path gains

4-D array

Discrete path gains of the underlying fading process, returned as an  $N_S$ -by- $N_P$ -by- $N_T$ -by- $N_R$  array.

- $N_S$  represents the number of samples in the input signal.
- $N_P$  represents the number of channel paths.
- $N_T$  represents the number of transmit antennas.
- $N_R$  represents the number of receive antennas.

Entries for nonselected paths are filled with NaN.

#### Dependencies

To enable this port, on the **Realization** tab, select Output channel path gains.

## Parameters

### Main Tab

#### Multipath parameters (frequency selectivity)

#### Inherit sample rate from input — Option to inherit the sample rate from input

on (default) | off

Select this parameter to use the sample rate of the input signal when processing. When `Inherit sample rate from input` is selected, the sample rate is  $N_S/T_S$ , where  $N_S$  is the number of input samples, and  $T_S$  is the model sample time.

#### Sample rate (Hz) — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate, specified in hertz as a positive scalar. To match the model settings, set the sample rate to  $N_S/T_S$ , where  $N_S$  is the number of input samples, and  $T_S$  is the model sample time.

### Dependencies

This parameter appears when Inherit sample rate from input is not selected.

Data Types: double

### Discrete path delays (s) — Delays for each discrete path

0 (default) | nonnegative scalar | row vector

Delays for each discrete path in seconds, specified as a nonnegative scalar or row vector.

- When you set **Discrete path delays (s)** to a scalar, the MIMO channel is frequency flat.
- When you set **Discrete path delays (s)** to a vector, the MIMO channel is frequency selective.

Data Types: double

### Average path gains (dB) — Average gain for each discrete path

0 (default) | scalar | row vector

Average gain for each discrete path in decibels, specified as a scalar or row vector.

**Average path gains (dB)** must have the same size as Discrete path delays (s).

Data Types: double

### Normalize average path gains to 0 dB — Option to normalize average path gains to 0 dB

on (default) | off

Select this parameter to normalize the fading processes so that the total power of the path gains, averaged over time, is 0 dB.

### Fading distribution — Fading distribution of channel

Rayleigh (default) | Rician

Select the fading distribution of the channel, either Rayleigh or Rician.

### K-factors — K-factor of Rician fading channel

3 (default) | positive scalar | row vector

K-factor of a Rician fading channel, specified as a positive scalar or a 1-by- $N_p$  vector of positive-valued elements.  $N_p$  equals the value of the Discrete path delays (s) parameter.

- If you set **K-factors** to a scalar, the first discrete path is a Rician fading process with a Rician K-factor of **K-factors**. Any remaining discrete paths are independent Rayleigh fading processes.
- If you set **K-factors** to a row vector, the discrete path corresponding to a positive element of the **K-factors** vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to a zero-valued element of the **K-factors** vector is a Rayleigh fading process.

#### Dependencies

This parameter appears when Fading distribution is Rician.

Data Types: double

#### **LOS path Doppler shifts (Hz) — Doppler shifts for line-of-sight components**

0 (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the Rician fading channel in hertz, specified as a scalar or row vector. This parameter must have the same size as K-factors.

- If you set **LOS path Doppler shifts (Hz)** to a scalar, it represents the line-of-sight component Doppler shift of the first discrete path that is a Rician fading process.
- If you set **LOS path Doppler shifts (Hz)** to a row vector, the discrete path that is a Rician fading process has its line-of-sight component Doppler shift specified by the elements of **LOS path Doppler shifts (Hz)** that correspond to positive elements in the K-factors vector.

#### Dependencies

This parameter appears when Fading distribution is Rician.

Data Types: double

#### **LOS path initial phases (rad) — Initial phases for line-of-sight components**

0 (default) | scalar | row vector

Initial phases for the line-of-sight component of the Rician fading channel in radians, specified as a scalar or row vector. This parameter must have the same size as K-factors.

- If you set **LOS path initial phases (rad)** to a scalar, it is the line-of-sight component initial phase of the first discrete path that is a Rician fading process.
- If you set **LOS path initial phases (rad)** to a row vector, the discrete path that is a Rician fading process has its line-of-sight component initial phase specified by the elements of **LOS path initial phases (rad)** that correspond to positive elements in the K-factors vector.

### Dependencies

This parameter appears when Fading distribution is Rician.

Data Types: double

### Doppler parameters (time dispersion)

#### Maximum Doppler shift (Hz) — Maximum Doppler shift for all channel paths

0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths in hertz, specified as a nonnegative scalar.

**Maximum Doppler shift (Hz)** must be smaller than  $(\text{Sample Rate (Hz)}/10)/f_c$  for each path, where  $f_c$  is the cutoff frequency factor of the path. For more information, see “Cutoff Frequency Factor” on page 3-712.

Data Types: double

#### Doppler spectrum — Doppler spectrum shape for all channel paths

doppler('Jakes') (default) | doppler('Flat') | doppler('Rounded', ...) |  
 doppler('Bell', ...) | doppler('Asymmetric Jakes', ...) |  
 doppler('Restricted Jakes', ...) | doppler('Gaussian', ...) |  
 doppler('BiGaussian', ...)

Doppler spectrum shape for all channel paths, specified as a single Doppler spectrum structure returned from the `doppler` function or a 1-by- $N_p$  cell array of such structures. The default value of this parameter is the Jakes Doppler spectrum (`doppler('Jakes')`).

- If you assign a single call to `doppler`, all paths have the same specified Doppler spectrum.
- If you assign a 1-by- $N_p$  cell array of calls to `doppler` using any of the specified syntaxes, each path has the Doppler spectrum specified by the corresponding Doppler spectrum structure in the array. In this case,  $N_p$  equals the value of the Discrete path delays (s) parameter.

#### **Dependencies**

This parameter applies when Maximum Doppler shift (Hz) is greater than zero.

If the Technique for generating fading samples parameter is set to Sum of sinusoids, Doppler spectrum must be doppler('Jakes').

#### **Antenna parameters (spatial dispersion)**

##### **Specify spatial correlation — Spatial correlation mode**

None (default) | Separate Tx Rx | Combined

Select the spatial correlation mode: None, Separate Tx Rx, or Combined.

- Choose 'None' to specify the number of transmit and receive antennas.
- Choose 'Spatial Tx Rx' to specify the transmit and receive spatial correlation matrices separately. The number of transmit ( $N_T$ ) and receive ( $N_R$ ) antennas are derived from the dimensions of the Transmit spatial correlation and Receive spatial correlation parameters, respectively.
- Choose 'Combined' to specify a single correlation matrix for the whole channel. The product of  $N_T$  and  $N_R$  is derived from the dimension of Combined spatial correlation.

##### **Number of transmit antennas — Number of transmit antennas**

2 (default) | positive integer

Number of transmit antennas, specified as a positive integer.

#### **Dependencies**

This parameter appears when Specify spatial correlation is None or Combined.

Data Types: double

##### **Number of receive antennas — Number of receive antennas**

2 (default) | positive integer

Number of receive antennas, specified as a positive integer.

#### **Dependencies**

This parameter appears when Specify spatial correlation is None.

Data Types: double

**Transmit spatial correlation — Spatial correlation of transmitter**

[1 0; 0 1] (default) | matrix | 3-D array

Specify the spatial correlation of the transmitter as an  $N_T$ -by- $N_T$  matrix or  $N_T$ -by- $N_T$ -by- $N_p$  array.  $N_T$  is the number of transmit antennas, and  $N_p$  equals the value of the Discrete path delays (s) parameter.

- If **Discrete path delays (s)** is a scalar, the channel is frequency flat, and **Transmit spatial correlation** is an  $N_T$ -by- $N_T$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If **Discrete path delays (s)** is a vector, the channel is frequency selective, and you can specify **Transmit spatial correlation** as a matrix. Each path has the same transmit spatial correlation matrix.
- Alternatively, you can specify **Transmit spatial correlation** as an  $N_T$ -by- $N_T$ -by- $N_p$  array, where each path can have its own different transmit spatial correlation matrix.

**Dependencies**

This parameter appears when Specify spatial correlation is Separate Tx Rx.

Data Types: double

Complex Number Support: Yes

**Receive spatial correlation — Spatial correlation of receiver**

[1 0; 0 1] (default) | matrix | 3-D array

Specify the spatial correlation of the receiver as an  $N_R$ -by- $N_R$  matrix or  $N_R$ -by- $N_R$ -by- $N_p$  array.  $N_R$  is the number of receive antennas, and  $N_p$  equals the value of the Discrete path delays (s) parameter.

- If **Discrete path delays (s)** is a scalar, the channel is frequency flat, and **Receive spatial correlation** is an  $N_R$ -by- $N_R$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If **Discrete path delays (s)** is a vector, the channel is frequency selective, and you can specify **Receive spatial correlation** as a matrix. Each path has the same receive spatial correlation matrix.
- Alternatively, you can specify **Receive spatial correlation** as an  $N_R$ -by- $N_R$ -by- $N_p$  array, where each path can have its own different receive spatial correlation matrix.

#### Dependencies

This parameter appears when Specify spatial correlation is Separate Tx Rx.

Data Types: double

Complex Number Support: Yes

#### Combined spatial correlation — Combined spatial correlation matrix

[1 0 0 0; 0 1 0 0; 0 0 1 0; 0 0 0 1] (default) | matrix | 3-D array

Specify the combined spatial correlation matrix as an  $N_{TR}$ -by- $N_{TR}$  matrix or  $N_{TR}$ -by- $N_{TR}$ -by- $N_P$  array, where  $N_{TR} = (N_T \times N_R)$ , and  $N_P$  equals the number of delay paths specified by the Discrete path delays (s) parameter.

- If Discrete path delays (s) is a scalar, the channel is frequency flat, and **Combined spatial correlation** is an  $N_{TR}$ -by- $N_{TR}$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If Discrete path delays (s) is a vector, the channel is frequency selective, and you can specify **Combined spatial correlation** as a matrix. Each path has the same spatial correlation matrix.
- Alternatively, you can specify **Combined spatial correlation** as an  $N_{TR}$ -by- $N_{TR}$ -by- $N_P$  array, where each path can have its own different combined spatial correlation matrix.

#### Dependencies

This parameter appears when Specify spatial correlation is Combined.

Data Types: double

#### Normalize outputs by number of receive antennas — Normalize channel output

on (default) | off

Select this parameter to normalize the channel outputs by the number of receive antennas.

#### Simulate using — Compilation type

Interpreted execution (default) | Code generation

Compilation type, specified as Interpreted execution or Code generation.

**Antenna selection — Antenna mode**

Off (default) | Tx | Rx | Tx and Rx

The antenna mode you select corresponds to additional input ports on the block.

Antenna selection Setting	Input Ports Added
Off	None
Tx	Tx Sel
Rx	Rx Sel
Tx and Rx	Tx Sel, Rx Sel

**Realization Tab****Technique for generating fading samples — Channel modeling technique**

Filtered Gaussian noise (default) | Sum of sinusoids

Select the channel modeling technique, either Filtered Gaussian noise or Sum of sinusoids.

**Number of sinusoids — Number of sinusoids used**

48 (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

**Dependencies**

This parameter appears when Technique for generating fading samples is Sum of sinusoids.

**Initial time source — Source of initial time offset**

Property (default) | Input port

Indicate the source of the initial time offset for the fading model, either Property or Input port.

- When you set **Initial time source** to Property, use Initial time (s) to set the initial time offset.
- When you set **Initial time source** to Input port, use the input port Init Time to set the initial time offset.

#### **Dependencies**

This parameter appears when Technique for generating fading samples is Sum of sinusoids.

#### **Initial time (s) — Initial time offset**

0 (default) | nonnegative scalar

Initial time offset for the fading model, specified as a nonnegative scalar.

When Initial time (s) is not a multiple of 1/Sample Rate (Hz), it is rounded up to the nearest sample position.

#### **Dependencies**

This parameter appears when Technique for generating fading samples is Sum of sinusoids and Initial time source is set to Property.

#### **Initial seed — Random number generator initial seed**

73 (default) | nonnegative integer

Random number generator initial seed for this block, specified as a nonnegative integer.

#### **Output channel path gains — Option to output channel path gains**

off (default) | on

Select this parameter to add the Gain output port to the block and output the channel path gains of the underlying fading process.

### **Visualization Tab**

#### **Channel visualization — Select the channel visualization**

Off (default) | Impulse response | Frequency response | Doppler spectrum | Impulse and frequency responses

Select the channel visualization: Off, Impulse response, Frequency response, Doppler spectrum, or Impulse and frequency responses. When visualization is on, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see Channel Visualization.

#### **Antenna pair to display — Transmit-receive antenna pair to display**

[1, 1] (default) | vector

Transmit-receive antenna pair to display, specified as a 1-by-2 vector, where the first element corresponds to the desired transmit antenna and the second corresponds to the desired receive antenna. At this time, only a single pair can be displayed.

#### Dependencies

This parameter appears when Channel visualization is not Off.

#### Percentage of samples to display — Percentage of samples to display

25% (default) | 10% | 50% | 100%

Select the percentage of samples to display: 10%, 25%, 50%, or 100%. Increasing the percentage improves display accuracy at the expense of simulation speed.

#### Dependencies

This parameter appears when Channel visualization is Impulse response, Frequency response, or Impulse and frequency responses.

#### Path for Doppler spectrum display — Path for which Doppler spectrum is displayed

1 (default) | positive integer

Path for which the Doppler spectrum is displayed, specified as a positive integer from 1 to  $N_p$ , where  $N_p$  equals the value of the Discrete path delays (s) parameter.

#### Dependencies

This parameter appears when Channel visualization is Doppler spectrum.

## Block Characteristics

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	yes
<b>Variable-Size Signals</b>	yes

## Algorithms

The fading processing per link is described in Methodology for Simulating Multipath Fading Channels and assumes the same parameters for all ( $N_T \times N_R$ ) links of the MIMO channel. Each link comprises all multipaths for that link.

### The Kronecker Model

The Kronecker model assumes that the spatial correlations at the transmit and receive sides are separable. Equivalently, the direction of departure (DoD) and directions of arrival (DoA) spectra are assumed to be separable. The full correlation matrix is:

$$R_H = E[R_t \otimes R_r]$$

- The  $\otimes$  symbol represents the Kronecker product.
- $R_t$  represents the correlation matrix at the transmit side:  $R_t = E[H^H H]$ , of size  $N_T$ -by- $N_T$ .
- $R_r$  represents the correlation matrix at the receive side:  $R_r = E[H H^H]$ , of size  $N_R$ -by- $N_R$ .

You can obtain a realization of the MIMO channel matrix as:

$$H = R_r^{\frac{1}{2}} A R_t^{\frac{1}{2}}$$

$A$  is an  $N_R$ -by- $N_T$  matrix of independent identically distributed complex Gaussian variables with zero mean and unit variance.

### Cutoff Frequency Factor

The following information explains how the cutoff frequency factor,  $f_c$ , is determined for different Doppler spectrum types:

- For any Doppler spectrum type other than Gaussian and BiGaussian,  $f_c$  equals 1.
- For a doppler('Gaussian') spectrum type,  $f_c$  equals  $\text{NormalizedStandardDeviation} \cdot \text{sqrt}(2 \cdot \log(2))$ .
- For a doppler('BiGaussian') spectrum type:

- If the `PowerGains(1)` and `NormalizedCenterFrequencies(2)` field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \cdot \sqrt{2 \cdot \log(2)}$ .
- If the `PowerGains(2)` and `NormalizedCenterFrequencies(1)` field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(2) \cdot \sqrt{2 \cdot \log(2)}$ .
- If the `NormalizedCenterFrequencies` field value is  $[0, 0]$  and the `NormalizedStandardDeviation` field has two identical elements, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \cdot \sqrt{2 \cdot \log(2)}$ .
- In all other cases,  $f_c$  equals 1.

## Antenna Selection

When the object is in antenna selection mode, it uses the following algorithms to process an input signal:

- All random path gains are always generated and keep evolving for each link, whether or not a given link is selected. The path gain values output for the non-selected links are populated with NaN.
- The spatial correlation only applies to the selected transmit and/or receive antennas, and the correlation coefficients are the corresponding entries in the transmit, receive, or combined correlation matrices. In other words, the spatial correlation matrix for the selected transmit or receive antennas is a submatrix of the transmit, receive, or combined spatial correlation matrix property value.
- For signal paths associated with nonactive antennas, a signal with zero power is transmitted to the channel filter.
- Channel output normalization happens over the number of selected receive antennas.

# MLSE Equalizer

Equalize using Viterbi algorithm

## Library

Equalizer Block

## Description

The MLSE Equalizer block uses the Viterbi algorithm to equalize a linearly modulated signal through a dispersive channel. The block processes input frames and outputs the maximum likelihood sequence estimate (MLSE) of the signal, using an estimate of the channel modeled as a finite input response (FIR) filter.

This block supports `single` and `double` data types.

## Channel Estimates

The channel estimate takes the form of a column vector containing the coefficients of an FIR filter in descending order of powers. The length of this vector is the channel memory, which must be a multiple of the block's **Samples per input symbol** parameter.

To specify the channel estimate vector, use one of these methods:

- Set **Specify channel via** to `Dialog` and enter the vector in the **Channel coefficients** field.
- Set **Specify channel via** to `Input port` and the block displays an additional input port, labeled `Ch`, which accepts a column vector input signal.

## Signal Constellation

The **Signal constellation** parameter specifies the constellation for the modulated signal, as determined by the modulator in your model. **Signal constellation** is a vector of complex numbers, where the  $k$ th complex number in the vector is the constellation point to which the modulator maps the integer  $k-1$ .

---

**Note** The sequence of constellation points must be consistent between the modulator in your model and the **Signal constellation** parameter in this block.

---

For example, to specify the constellation given by the mapping

$$0 \rightarrow +1 + i$$

$$1 \rightarrow -1 + i$$

$$2 \rightarrow -1 - i$$

$$3 \rightarrow +1 - i$$

set **Constellation points** to  $[1+i, -1+i, -1-i, 1-i]$ . Note that the sequence of numbers in the vector indicates how the modulator maps integers to the set of constellation points. The labeled constellation is shown below.

## Preamble and Postamble

If your data is accompanied by a preamble (prefix) or postamble (suffix), then configure the block accordingly:

- If you select **Input contains preamble**, then the **Expected preamble** parameter specifies the preamble that you expect to precede the data in the input signal.
- If you check the **Input contains postamble**, then the **Expected postamble** parameter specifies the postamble that you expect to follow the data in the input signal.

The **Expected preamble** or **Expected postamble** parameter must be a vector of integers between 0 and  $M-1$ , where  $M$  is the number of constellation points. An integer value of  $k-1$  in the vector corresponds to the  $k$ th entry in the **Constellation points** vector and, consequently, to a modulator input of  $k-1$ .

The preamble or postamble must already be included at the beginning or end, respectively, of the input signal to this block. If necessary, you can concatenate vectors in Simulink software using the Matrix Concatenation block.

To learn how the block uses the preamble and postamble, see ““Reset Every Frame” Operation Mode” on page 3-717 below.

### “Reset Every Frame” Operation Mode

One way that the Viterbi algorithm can transition between successive frames is called Reset every frame mode. You can choose this mode using the **Operation mode** parameter.

In Reset every frame mode, the block decodes each frame of data independently, resetting the state metric at the end of each frame. The traceback decoding always starts at the state with the minimum state metric.

The initialization of state metrics depends on whether you specify a preamble and/or postamble:

- If you do not specify a preamble, the decoder initializes the metrics of all states to 0 at the beginning of each frame of data.
- If you specify a preamble, the block uses it to initialize the state metrics at the beginning of each frame of data. More specifically, the block decodes the preamble

and assigns a metric of 0 to the decoded state. If the preamble does not decode to a unique state -- that is, if the length of the preamble is less than the channel memory -- the decoder assigns a metric of 0 to all states that can be represented by the preamble. Whenever you specify a preamble, the traceback path ends at one of the states represented by the preamble.

- If you do not specify a postamble, the traceback path starts at the state with the smallest metric.
- If you specify a postamble, the traceback path begins at the state represented by the postamble. If the postamble does not decode to a unique state, the decoder identifies the smallest of all possible decoded states that are represented by the postamble and begins traceback decoding at that state.

---

**Note** In `Reset every frame` mode, the input to the MLSE Equalizer block must contain at least T symbols, not including an optional preamble, where T is the **Traceback depth** parameter.

---

## Continuous Operation Mode

An alternative way that the Viterbi algorithm can transition between successive frames is called `Continuous with reset option` mode. You can choose this mode using the **Operation mode** parameter.

In `Continuous with reset option` mode, the block initializes the metrics of all states to 0 at the beginning of the simulation. At the end of each frame, the block saves the internal state metric for use in computing the traceback paths in the next frame.

If you select **Enable the reset input port**, the block displays another input port, labeled `Rst`. In this case, the block resets the state metrics whenever the scalar value at the `Rst` port is nonzero.

## Decoding Delay

The MLSE Equalizer block introduces an output delay equal to the **Traceback depth** in the `Continuous with reset option` mode, and no delay in the `Reset every frame` mode.

## Parameters

### Specify channel via

The method for specifying the channel estimate. If you select `Input port`, the block displays a second input port that receives the channel estimate. If you select `Dialog`, you can specify the channel estimate as a vector of coefficients for an FIR filter in the **Channel coefficients** field.

### Channel coefficients

Vector containing the coefficients of the FIR filter that the block uses for the channel estimate. This field is visible only if you set **Specify channel via** to `Dialog`.

### Signal constellation

Vector of complex numbers that specifies the constellation for the modulation.

### Traceback depth

The number of trellis branches (equivalently, the number of symbols) the block uses in the Viterbi algorithm to construct each traceback path.

### Operation mode

The operation mode of the Viterbi decoder. Choices are `Continuous with reset option` and `Reset every frame`.

### Input contains preamble

When checked, you can set the preamble in the **Expected preamble** field. This option appears only if you set **Operation mode** to `Reset every frame`.

### Expected preamble

Vector of integers between 0 and  $M-1$  representing the preamble, where  $M$  is the size of the constellation. This field is visible and active only if you set **Operation mode** to `Reset every frame` and then select **Input contains preamble**.

### Input contains postamble

When checked, you can set the postamble in the **Expected postamble** field. This option appears only if you set **Operation mode** to `Reset every frame`.

### Expected postamble

Vector of integers between 0 and  $M-1$  representing the postamble, where  $M$  is the size of the constellation. This field is visible and active only if you set **Operation mode** to `Reset every frame` and then select **Input contains postamble**.

### Samples per input symbol

The number of input samples for each constellation point.

### Enable the reset input port

When you check this box, the block has a second input port labeled `Rst`. Providing a nonzero input value to this port causes the block to set its internal memory to the initial state before processing the input data. This option appears only if you set **Operation mode** to `Continuous with reset option`.

## MER Measurement

Measure signal-to-noise ratio (SNR) in digital modulation applications

## Library

Utility Blocks

## Description

The MER Measurement block outputs the modulation error ratio (MER). MER is a measure of the signal-to-noise ratio (SNR) in digital modulation applications. The block measures all outputs in dB.

The MER Measurement block accepts a received signal at input port `Rcv`. It may use an ideal input signal at reference port `Ref` or, optionally, a reference constellation. The MER block then outputs a measure of the modulation accuracy by comparing these inputs. The modulation error ratio is the ratio of the average reference signal power to the mean square error. This ratio corresponds to the SNR of the AWGN channel.

The block output always outputs MER in dB, with an option to output minimum MER and  $X$ -percentile MER values. The minimum MER represents the best-case MER value per burst. For the  $X$ -percentile option, you can select to output the number of symbols processed in the percentile computations.

The table shows the output type, the parameter that selects the output type, the computation units, and the corresponding measurement interval.

Output	Activation Parameter	Units	Measurement Interval
MER	None (output by default)	dB	Current length   Entire history   Custom   Custom with periodic reset
Minimum MER	<b>Output minimum MER</b>	dB	Current length   Entire history   Custom   Custom with periodic reset
Percentile MER	<b>Output X-percentile EVM</b>	dB	Entire history
Number of symbols	<b>Output X-percentile EVM and Output the number of symbols processed</b>	None	Entire history

## Data Type

The block accepts double, single, and fixed-point data types. The output of the block is always double.

## Algorithms

## Parameters

### Reference signal

Specifies the reference signal source as either `Input port` or `Estimated from reference constellation`.

### Reference constellation

Specifies the reference constellation points as a vector. This parameter is available only when **Reference signal** is `Estimated from reference constellation`. The default is `constellation(comm.QPSKModulator)`.

**Measurement interval**

Specify the measurement interval as: `Input length`, `Entire history`, `Custom`, or `Custom with periodic reset`. This parameter affects the RMS and minimum MER outputs only.

- To calculate MER using only the current samples, set this parameter to `'Input length'`.
- To calculate MER for all samples, set this parameter to `'Entire history'`.
- To calculate MER over an interval you specify and to use a sliding window, set this parameter to `'Custom'`.
- To calculate MER over an interval you specify and to reset the object each time the measurement interval is filled, set this parameter to `'Custom with periodic reset'`.

**Custom measurement interval**

Specify the custom measurement interval in samples as a real positive integer. This is the interval over which the MER is calculated. This parameter is available when **Measurement interval** is `Custom` or `Custom with periodic reset`. The default is 100.

**Averaging dimensions**

Specify the dimensions over which to average the MER measurements as a scalar or row vector whose elements are positive integers. For example, to average across the rows, set this parameter to 2. The default is 1.

This block supports var-size inputs of the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must be constant. For example, if the input size is `[1000 3 2]` and **Averaging dimensions** is `[1 3]`, then the output size is `[1 3 1]`. The number of elements in the second dimension is fixed at 3.

**Output minimum MER**

Outputs the minimum MER of an input vector or frame.

**Output X-percentile MER**

Enables an output *X*-percentile MER measurement. When you select this option, specify **X-percentile value (%)**.

**X-Percentile value (%)**

This parameter is available only when you select **Output X-percentile MER**. The *X*th percentile is the MER value above which *X*% of all the computed MER values lie. The

parameter defaults to the 95th percentile. That is, 95% of all MER values are above this output.

### **Output the number of symbols processed**

Outputs the number of symbols that the block uses to compute the **Output X-percentile MER**. This parameter is available only when you select **Output X-percentile MER**.

### **Simulate using**

Select the simulation mode.

#### **Code generation**

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is **Code generation**, System objects corresponding to the blocks accept a maximum of nine inputs.

#### **Interpreted execution**

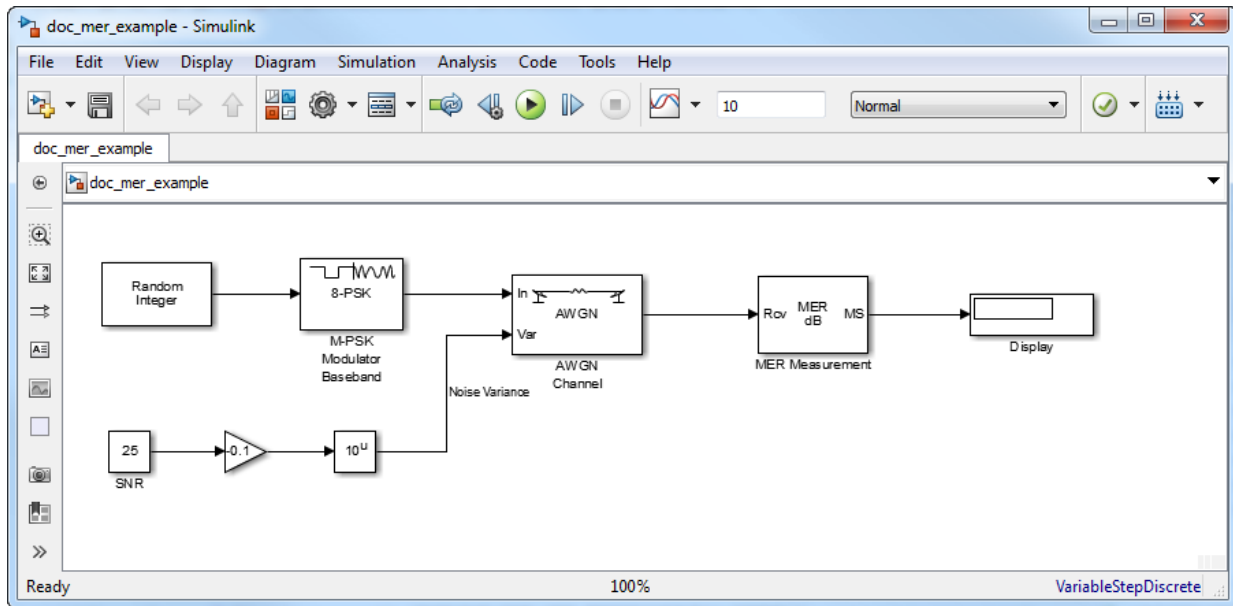

Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## **Examples**

### **Measure MER of Noisy PSK Signal**

Measure the MER of a noisy 8-PSK signal.

Load the model by typing `doc_mer_example` at the command line.

Run the model. The MER is shown in the Display block and is approximately equal to the SNR, which is set by using the Constant block. Experiment with different SNR values, and observe the effect on the estimated MER.

## Algorithms

MER is a measure of the SNR in a modulated signal calculated in dB. The MER over  $N$  symbols is

$$\text{MER} = 10 \cdot \log_{10} \left( \frac{\sum_{n=1}^N (I_k^2 + Q_k^2)}{\sum_{n=1}^N (e_k)} \right) \text{ dB},$$

The MER for the  $k$ th symbol is

$$MER_k = 10 * \log_{10} \left( \frac{\frac{1}{N} \sum_{n=1}^N (I_k^2 + Q_k^2)}{e_k} \right) \text{dB.}$$

The minimum MER represents the minimum MER value in a burst, or

$$MER_{\min} = \min_{k \in [1, \dots, N]} \{MER_k\},$$

where:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- $I_k$  = In-phase measurement of the  $k$ th symbol in the burst
- $Q_k$  = Quadrature phase measurement of the  $k$ th symbol in the burst
- $I_k$  and  $Q_k$  represent ideal (reference) values.  $\tilde{I}_k$  and  $\tilde{Q}_k$  represent measured (received) symbols.

The block computes the  $X$ -percentile MER by creating a histogram of all the incoming  $MER_k$  values. The output provides the MER value above which  $X\%$  of the MER values fall.

# M-APSK Demodulator Baseband

*M*-ary amplitude phase shift keying (APSK) demodulation

**Library:** Communications Toolbox / Modulation / Digital Baseband Modulation / APM

## Description

The M-APSK Demodulator Baseband block demodulates a baseband representation of an *M*-ary amplitude phase shift keying (APSK) modulated signal. *M* is the “Modulation Order for M-APSK” on page 3-735. For a description of *M*-APSK demodulation, see “APSK Hard Demodulation” on page 3-735 and “APSK Soft Demodulation” on page 3-736.

---

**Note** M-APSK Demodulator Baseband specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use M-PSK Demodulator Baseband.

---

This icon shows the block with all ports enabled:

## Ports

### Input

**In — APSK modulated signal**

scalar | vector | matrix

APSK modulated signal, specified as a scalar, vector, or matrix. When this input is a matrix, each column is treated as an independent channel. This port is unnamed until the Var port is enabled.

Data Types: double | single  
Complex Number Support: Yes

**Var — Noise variance**

positive scalar | vector of positive values

Noise variance, specified as a positive scalar or vector of positive values. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “APSK Soft Demodulation” on page 3-736 for demodulation decision type considerations.

**Dependencies**

To enable this port, set Noise variance source to Input port.

Data Types: double | single

**Output**

**Out — Demodulated signal**

scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The data type and dimensions of the demodulated signal depend on the values specified by the Output type and Decision type parameters. This port is unnamed on the block.

Output type	Decision type	Demodulated Signal Description	Dimensions of Demodulated Signal
Integer	—	Demodulated integer values in the range [0, (M - 1)]	The output signal has the same dimensions as the input signal.
Bit	Hard decision	Demodulated bits	The number of rows in the output signal is $\log_2(M)$ times the number of rows in the input signal. Each demodulated symbol is mapped to a group of $\log_2(M)$ elements in a column, where the first element
	Log-likelihood ratio	Log-likelihood ratio value for each bit	

Output type	Decision type	Demodulated Signal Description	Dimensions of Demodulated Signal
	Approximate log-likelihood ratio	Approximate log-likelihood ratio value for each bit	represents the MSB and the last element represents the LSB.
<i>M</i> is the “Modulation Order for M-APSK” on page 3-735.			

Use Output data type to specify the output data type.

Data Types: `single` | `double`

## Parameters

### Constellation points per circle — Constellation points per PSK ring

[4, 12] (default) | vector

Constellation points per PSK ring, specified as a vector with more than one element. Each vector element indicates the number of constellation points in its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. The sum of the elements in **Constellation points per circle** determines the modulation order. Element values must be multiples of four, and the modulation order must be a power of two.

Example: [4, 12, 16] specifies a three PSK ring constellation with a modulation order of 32.

### Radius of each circle — Radius per PSK ring

[0.5, 1] (default) | vector

Radius per PSK ring, specified as a vector with the same length as Constellation points per circle. Each vector element indicates the radius of its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. These element values must be positive values arranged in increasing order.

Example: [0.5, 1, 2] defines radii for three constellation PSK rings. The inner ring has a radius of 0.5, the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.

### Phase offset of each circle (rad) — Phase offset per PSK ring

[pi/4, pi/12] (default) | scalar | vector

Phase offset per PSK ring in radians, specified as a scalar or vector with the same length as Constellation points per circle. Each vector element indicates the phase offset of its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. The **Phase offset of each circle (rad)** can be a scalar only if all the elements of **Constellation points per circle** are the same value.

Example: `[pi/4,pi/12,pi/16]` defines phase offsets for three constellation PSK rings. The inner ring has a phase offset of  $\pi/4$ , the second ring has a phase offset of  $\pi/12$ , and the outer ring has a phase offset of  $\pi/16$ .

### **Symbol mapping — Symbol mapping**

Auto (default) | Contourwise-gray | Gray | User-defined

Symbol mapping, specified as one of the following:

- **Contourwise-gray** — Uses Gray mapping along the contour in the phase dimension for each PSK ring.
- **Gray** — Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all elements in Constellation points per circle must be equal, and all elements in Phase offset of each circle (rad) must be equal. For a description of the Gray mapping used, see [2].
- **User-defined** — See Custom symbol mapping.

The default symbol mapping depends on the **Constellation points per circle** and **Phase offset of each circle (rad)** parameters. When all elements in **Constellation points per circle** are equal, and all elements in **Phase offset of each circle (rad)** are equal, the default is Gray. For all other cases, the default is Contourwise-gray.

### **Custom symbol mapping — Custom symbol mapping**

`[0,4,12,8,1,3,2,6,7,5,13,15,14,10,11,9]` (default) | integer vector

Custom symbol mapping, specified as an integer vector. This vector must consist of  $M$  unique elements with values in the range  $[0, (M - 1)]$ , where  $M$  is the “Modulation Order for M-APSK” on page 3-735. The first element in **Custom symbol mapping** corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

Example: The default value, `[0,4,12,8,1,3,2,6,7,5,13,15,14,10,11,9]`, specifies contourwise-gray symbol mapping. The distribution of constellation points is nonuniform on all contours.

**Dependencies**

To enable this parameter, set Symbol mapping to User-defined.

**Output type — Output type**

Integer (default) | Bit

Output type, specified as Integer or Bit.

Data Types: char | string

**Decision type — Demodulation decision type**

Hard decision (default) | Log-likelihood ratio | Approximate log-likelihood ratio

Demodulation decision type, specified as Hard decision, Log-likelihood ratio, or Approximate log-likelihood ratio. See “APSK Soft Demodulation” on page 3-736 for algorithm selection considerations.

**Dependencies**

This parameter applies only when Output type is set to Bit.

**Noise variance source — Noise variance source**

Property (default) | Input port

Noise variance source, specified as:

- Property — The noise variance is set using the Noise variance parameter.
- Input port — The noise variance is set using the Var input port.

**Dependencies**

This parameter applies only when Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.

**Noise variance — Noise variance**

1 (default) | positive scalar | vector of positive values

Noise variance, specified as a positive scalar or vector of positive values.

- When specified as a scalar, that value is used on all elements in the input signal.

- When specified as a vector, the vector length must be equal to the number of columns in the input signal. Each noise variance vector element is applied to its corresponding column in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “APSK Soft Demodulation” on page 3-736 for Decision type specification considerations.

**Dependencies**

This parameter applies only when Noise variance source is set to Property and Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.

Data Types: double

**Output data type — Output data type**

double (default) | ...

Output data type, specified as one of the acceptable values from this table. Acceptable **Output data type** values depend on the Output type and Decision type parameter values.

Output type	Decision type	Output data type Options
Integer	Not applicable	double, single, int8, uint8, int16, uint16, int32, or uint32
Bit	Hard decision	double, single, int8, uint8, int16, uint16, int32, uint32, or logical
	Log-likelihood ratio or Approximate log-likelihood ratio	The output signal is the same data type as the input signal.

**Dependencies**

This parameter applies only when Output type is set to Integer or when Output type is set to Bit and Decision type is set to Hard decision.

**Simulate using — Type of simulation to run**

Interpreted execution (default) | Code generation

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In **Interpreted execution** mode, you can debug the source code of the block.

For information on execution speed, see “Tips” on page 3-737.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	yes
<b>Variable-Size Signals</b>	no

## More About

### Modulation Order for *M*-APSK

The modulation order,  $M$ , for  $M$ -APSK equals the sum of the vector elements in the Constellation points per circle parameter and is the total number of points in the signal constellation. Element values in **Constellation points per circle** must be multiples of four, and  $M$  must be a power of two.

### APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding, as described in [1].

## APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

---

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or -Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

---

## Tips

- For faster execution of the M-APSK Demodulator Baseband block, set the Simulate using parameter to:
  - Code generation when using hard decision demodulation.
  - Interpreted execution when using soft decision demodulation.

# M-APSK Modulator Baseband

*M*-ary amplitude phase shift keying (APSK) modulation

**Library:** Communications Toolbox / Modulation / Digital Baseband Modulation / APM

## Description

The M-APSK Modulator Baseband block modulates the input signal using *M*-ary amplitude phase shift keying (APSK) modulation. The output is a baseband representation of the modulated signal. *M*, the “Modulation Order for M-APSK” on page 3-743, equals the sum of the elements in Constellation points per circle. For a description of *M*-APSK modulation, see “Algorithms” on page 3-743.

---

**Note** M-APSK Modulator Baseband specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use M-PSK Modulator Baseband.

---

## Ports

### Input

#### In — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The input signal must consist of binary values or integers in the range  $[0, (M - 1)]$ , where *M* is the “Modulation Order for M-APSK” on page 3-743. This port is unnamed on the block.

---

**Note** To process the input signal as binary elements, set the Input type parameter value to Bit. For binary inputs, the number of rows must be an integer multiple of  $\log_2(M)$ .

Groups of  $\log_2(M)$  bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

## Output

### Out — APSK modulated signal

`scalar` | `vector` | `matrix`

APSK modulated signal, returned as a complex scalar, vector, or matrix. The output signal dimensions depend on the specified Input type value. This port is unnamed on the block.

Input type	Dimensions of Output Signal
Integer	The output signal has the same dimensions as the input signal.
Bit	The number of rows in the output signal equals the number of rows in the input signal divided by $\log_2(M)$ , where $M$ is the “Modulation Order for M-APSK” on page 3-743.

Use Output data type to specify the output data type.

## Parameters

### Constellation points per circle — Constellation points per PSK ring

`[4, 12]` (default) | `vector`

Constellation points per PSK ring, specified as a vector with more than one element. Each vector element indicates the number of constellation points in its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. The sum of the elements in **Constellation points per circle** determines the modulation order. Element values must be multiples of four, and the modulation order must be a power of two.

Example: `[4, 12, 16]` specifies a three PSK ring constellation with a modulation order of 32.

### Radius of each circle — Radius per PSK ring

`[0.5, 1]` (default) | `vector`

Radius per PSK ring, specified as a vector with the same length as Constellation points per circle. Each vector element indicates the radius of its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. These element values must be positive and arranged in increasing order.

Example: `[0.5, 1, 2]` defines radii for three constellation PSK rings. The inner ring has a radius of 0.5, the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.

### Phase offset of each circle (rad) — Phase offset per PSK ring

`[pi/4, pi/12]` (default) | scalar | vector

Phase offset per PSK ring in radians, specified as a scalar or vector with the same length as Constellation points per circle. Each vector element indicates the phase offset of its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. The **Phase offset of each circle (rad)** can be a scalar only if all the elements of **Constellation points per circle** are the same value.

Example: `[pi/4, pi/12, pi/16]` defines phase offsets for three constellation PSK rings. The inner ring has a phase offset of  $\pi/4$ , the second ring has a phase offset of  $\pi/12$ , and the outer ring has a phase offset of  $\pi/16$ .

### Symbol mapping — Symbol mapping

Auto (default) | Contourwise-gray | Gray | User-defined

Symbol mapping, specified as one of the following:

- **Contourwise-gray** — Uses Gray mapping along the contour in the phase dimension for each PSK ring.
- **Gray** — Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for Constellation points per circle must be equal and all the values for Phase offset of each circle (rad) must be equal. For a description of the Gray mapping used, see [2].
- **User-defined** — See Custom symbol mapping.

The default symbol mapping depends on **Constellation points per circle** and **Phase offset of each circle (rad)**. When all the elements of **Constellation points per circle** are equal and all the elements of **Phase offset of each circle (rad)** are equal, the default is Gray. For all other cases, the default is Contourwise-gray.

#### **Custom symbol mapping — Custom symbol mapping**

[0, 4, 12, 8, 1, 3, 2, 6, 7, 5, 13, 15, 14, 10, 11, 9] (default) | integer vector

Custom symbol mapping, specified as an integer vector. This vector must consist of  $M$  unique elements with values in the range  $[0, (M - 1)]$ , where  $M$  is the “Modulation Order for M-APSK” on page 3-743. The first element in **Custom symbol mapping** corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

Example: The default value, [0, 4, 12, 8, 1, 3, 2, 6, 7, 5, 13, 15, 14, 10, 11, 9], specifies contourwise-gray symbol mapping. The distribution of constellation points is nonuniform on all contours.

#### **Dependencies**

To enable this parameter, set Symbol mapping to User-defined.

#### **Input type — Input type**

Integer (default) | Bit

Input type, specified as Integer or Bit. To use Integer, the input signal must consist of integers in the range  $[0, (M - 1)]$ . To use Bit, the input signal must contain binary values, and the number of rows must be an integer multiple of  $\log_2(M)$ , where  $M$  is the “Modulation Order for M-APSK” on page 3-743.

#### **Output data type — Output data type**

double (default) | single

Output data type, specified as double or single.

#### **View Constellation — Plot reference constellation**

button

To plot the reference constellation, click the **View Constellation** button.

---

**Tip** Click **Apply** before clicking the **View Constellation** to view latest parameter values.

---

#### **Simulate using — Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	yes
<b>Variable-Size Signals</b>	no

## More About

### Modulation Order for *M*-APSK

The modulation order,  $M$ , for  $M$ -APSK is the total number of points in the signal constellation.  $M$  equals the sum of the elements in Constellation points per circle. The element values in **Constellation points per circle** must be multiples of four.  $M$  must be a power of two.

## Algorithms

The block implements a pure APSK constellation.

A pure  $M$ -APSK constellation is composed of  $N_C$  concentric rings or contours, each with uniformly spaced PSK points. The  $M$ -APSK constellation set is

$$\chi = \begin{cases} R_1 \exp\left(j\left(\frac{2\pi}{M_1}i + \theta_1\right)\right), & i = 0, \dots, M_1 - 1, \\ R_2 \exp\left(j\left(\frac{2\pi}{M_2}i + \theta_2\right)\right), & i = 0, \dots, M_2 - 1, \\ \vdots & \vdots \\ R_{N_C} \exp\left(j\left(\frac{2\pi}{M_{N_C}}i + \theta_{N_C}\right)\right), & i = 0, \dots, M_{N_C} - 1, \end{cases}$$

where

- The modulation order is equal to the sum of all  $M_l$  for  $l = 1, 2, \dots, N_C$ .
- $N_C$  is the number of concentric rings.  $N_C \geq 2$ .
- $M_l$  is the number of constellation points in the  $l$ th ring.
- $R_l$  is the radius of the  $l$ th ring.
- $\theta_l$  is the phase offset of the  $l$ th ring.
- $j = \sqrt{-1}$

## M-PAM Demodulator Baseband

Demodulate PAM-modulated data

### Library

AM, in Digital Baseband sublibrary of Modulation

### Description

The M-PAM Demodulator Baseband block demodulates a signal that was modulated using M-ary pulse amplitude modulation. The input is a baseband representation of the modulated signal.

The signal constellation has  $M$  points, where  $M$  is the **M-ary number** parameter.  $M$  must be an even integer. The block scales the signal constellation based on how you set the **Normalization method** parameter. For details on the constellation and its scaling, see the reference page for the M-PAM Modulator Baseband block.

This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see “Supported Data Types” on page 3-753.

---

**Note** All values of power assume a nominal impedance of 1 ohm.

---

### Integer-Valued Signals and Binary-Valued Signals

When you set the **Output type** parameter to `Integer`, the block outputs integer values between 0 and  $M-1$ .  $M$  represents the **M-ary number** block parameter.

When you set the **Output type** parameter to `Bit`, the block outputs binary-valued signals that represent integers. The block represents each integer using a group of  $K = \log_2(M)$

bits, where  $K$  represents the number of bits per symbol. The output vector length must be an integer multiple of  $K$ .

The **Constellation ordering** parameter indicates how the block assigns binary words to points of the signal constellation. More details are on the reference page for the M-PAM Modulator Baseband block.

## Algorithm

The demodulator algorithm maps received input signal constellation values to M-ary integer symbol indices between 0 and M-1 and then maps these demodulated symbol indices to formatted output values.

The integer symbol index computation is performed by first scaling the real part of the input signal constellation (possibly with noise) by a denormalization factor derived from the **Normalization method** and related parameters. This denormalized value is added to M-1 to translate it into an approximate range between 0 and  $2 \times (M-1)$  plus noise. The resulting value is then rescaled via a divide-by-two (or, equivalently, a right-shift by one bit for fixed-point operation) to obtain a range approximately between 0 and M-1 (plus noise). The noisy index value is rounded to the nearest integer and clipped, via saturation, to the exact range of [0 M-1]. Finally, based on other block parameters, the integer index is mapped to a symbol value that is formatted and cast to the selected **Output data type**.

The following figures contains signal flow diagrams for floating-point and fixed-point algorithm operation. The floating-point diagrams apply when the input signal data type is **double** or **single**. The fixed-point diagrams apply when the input signal is a signed fixed-point data type. Note that the diagram is simplified when using normalized constellations (i.e., denormalization factor is 1).

**Signal-Flow Diagrams with Denormalization Factor Equal to 1**

**Signal-Flow Diagrams with Nonunity Denormalization Factor**

## Parameters

### **M-ary number**

The number of points in the signal constellation. It must be an even integer.

### **Output type**

Determines whether the output consists of integers or groups of bits. If this parameter is set to **Bit**, then the **M-ary number** parameter must be  $2^K$  for some positive integer  $K$ .

### **Constellation ordering**

Determines how the block maps each integer to a group of output bits.

### **Normalization method**

Determines how the block scales the signal constellation. Choices are **Min. distance between symbols**, **Average Power**, and **Peak Power**.

### **Minimum distance**

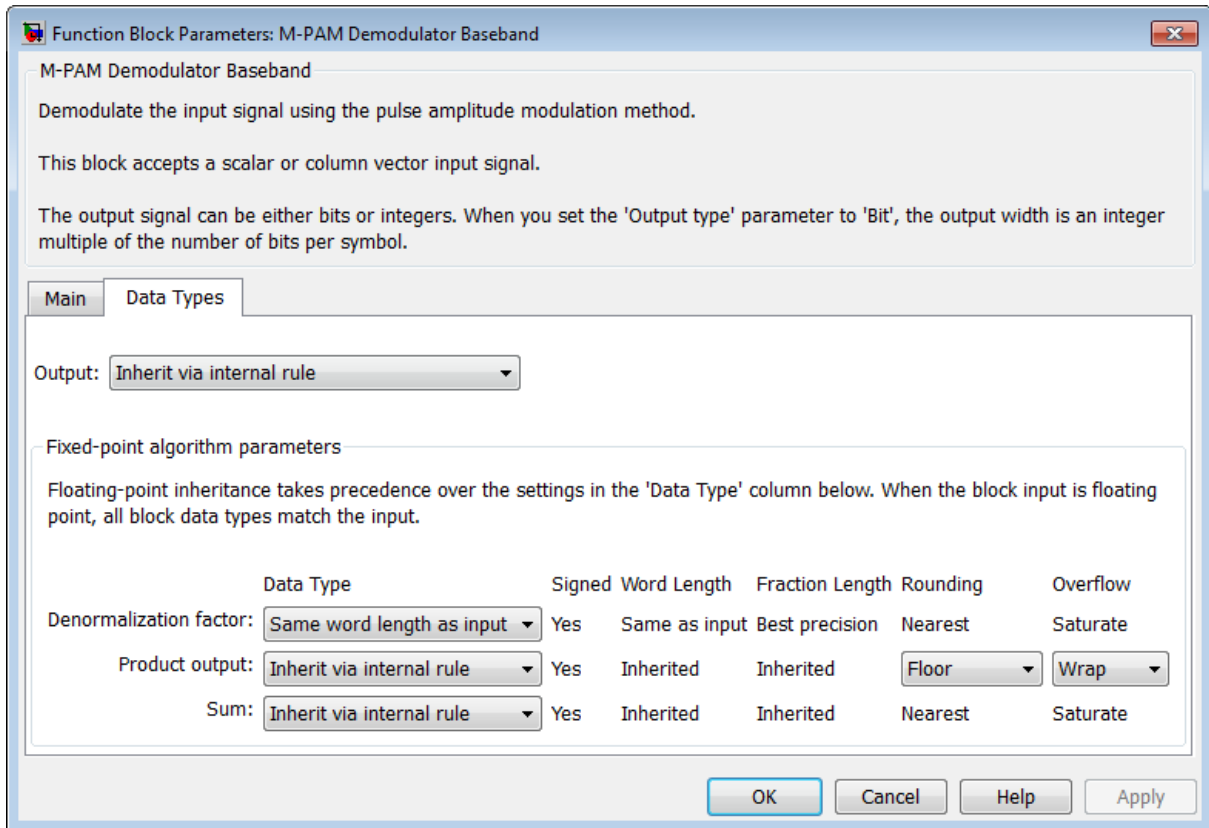

The distance between two nearest constellation points. This field appears only when **Normalization method** is set to **Min. distance between symbols**.

### **Average power, referenced to 1 ohm (watts)**

The average power of the symbols in the constellation, referenced to 1 ohm. This field appears only when **Normalization method** is set to **Average Power**.

### **Peak power, referenced to 1 ohm (watts)**

The maximum power of the symbols in the constellation, referenced to 1 ohm. This field appears only when **Normalization method** is set to **Peak Power**.

## Output

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type `single` or `double`. Otherwise, the output data type will be as if this parameter is set to 'Smallest unsigned integer'.

When the parameter is set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the **Hardware Implementation** pane, the output data type is the ideal minimum size, i.e., `ufix(1)` for bit outputs, and `ufix(ceil(log2(M)))` for integer outputs. For all other selections, it is an unsigned integer with the smallest available word

length large enough to fit the ideal minimum size, usually corresponding to the size of a char (e.g., uint8).

For integer outputs, this parameter can be set to `Smallest unsigned integer`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `single`, and `double`. For bit outputs, the options are `Smallest unsigned integer`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, or `double`.

#### **Denormalization factor**

This parameter applies when a fixed-point input is not normalized. It can be set to `Same word length as input` or `Specify word length`, in which case a field is enabled for user input. A best-precision fraction length is always used.

#### **Product output**

This parameter only applies when the input is a fixed-point signal and there is a nonunity (not equal to 1) denormalized factor. It can be set to `Inherit via internal rule` or `Specify word length`, which enables a field for user input.

Setting to `Inherit via internal rule` computes the full-precision product word length and fraction length. Internal Rule for Product Data Types (DSP System Toolbox) in *DSP System Toolbox User's Guide* describes the full-precision Product output internal rule.

Setting to `Specify word length` allows you to define the word length. The block computes a best-precision fraction length based on the word length specified and the pre-computed worst-case (min/max) real world value **Product output** result. The worst-case **Product output** result is precomputed by multiplying the denormalized factor with the worst-case (min/max) input signal range, purely based on the input signal data type.

The block uses the **Rounding** method when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. For more information, see “Rounding Modes” (DSP System Toolbox) or “Rounding Mode: Simplest” (Fixed-Point Designer).

#### **Sum**

This parameter only applies when the input is a fixed-point signal. It can be set to `Inherit via internal rule`, `Same as product output`, or `Specify word length`, in which case a field is enabled for user input

Setting `Inherit via internal rule` computes the full-precision sum word length and fraction length, based on the two inputs to the Sum in the fixed-point Hard

Decision Algorithm on page 3-747 signal flow diagram. The rule is the same as the fixed-point inherit rule of the internal **Accumulator data type** parameter in the Simulink Sum block.

Setting `Specify word length` allows you to define the word length. A best precision fraction length is computed based on the word length specified in the pre-computed maximum range necessary for the demodulated algorithm to produce accurate results. The signed fixed-point data type that has the best precision fully contains the values in the range  $2 * (M-1)$  for the specified word length.

Setting to `Same as product output` allows the Sum data type to be the same as the **Product output** data type (when **Product output** is used). If the **Product output** is not used, then this setting will be ignored and the `Inherit via internal rule` Sum setting will be used.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed fixed-point</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean when <b>Output type</b> is Bit</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• <code>ufix(1)</code> in ASIC/FPGA when <b>Output type</b> is Bit</li> <li>• <code>ufix(<math>\lceil \log_2 M \rceil</math>)</code> in ASIC/FPGA when <b>Output type</b> is Integer</li> </ul>

**Introduced before R2006a**

# M-PAM Modulator Baseband

Modulate using M-ary pulse amplitude modulation

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The M-PAM Modulator Baseband block modulates using M-ary pulse amplitude modulation. The output is a baseband representation of the modulated signal. The **M-ary number** parameter, M, is the number of points in the signal constellation. It must be an even integer.

---

**Note** All values of power assume a nominal impedance of 1 ohm.

---

## Constellation Size and Scaling

Baseband M-ary pulse amplitude modulation using the block's default signal constellation maps an integer  $m$  between 0 and  $M-1$  to the complex value

$$2m \quad - \quad M \quad + \quad 1$$

---

**Note** This value is actually a real number. The block's output signal is a complex data-type signal whose imaginary part is zero.

---

The block scales the default signal constellation based on how you set the **Normalization method** parameter. The following table lists the possible scaling conditions.

Value of Normalization Method Parameter	Scaling Condition
Min. distance between symbols	The nearest pair of points in the constellation is separated by the value of the <b>Minimum distance</b> parameter
Average Power	The average power of the symbols in the constellation is the <b>Average power</b> parameter
Peak Power	The maximum power of the symbols in the constellation is the <b>Peak power</b> parameter

## Integer-Valued Signals and Binary-Valued Signals

This block accepts a scalar or column vector input signal.

When you set the **Input type** parameter to **Integer**, the block accepts integer values between 0 and  $M-1$ .  $M$  represents the **M-ary number** block parameter.

When you set the **Input type** parameter to **Bit**, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of  $K = \log_2(M)$  bits

where

$K$  represents the number of bits per symbol.

The input vector length must be an integer multiple of  $K$ . In this configuration, the block accepts a group of  $K$  bits and maps that group onto a symbol at the block output. The block outputs one modulated symbol for each group of  $K$  bits.

The **Constellation ordering** parameter indicates how the block assigns binary words to points of the signal constellation.

- If **Constellation ordering** is set to **Binary**, then the block uses a natural binary-coded constellation.
- If **Constellation ordering** is set to **Gray**, then the block uses a Gray-coded constellation.

For details about the Gray coding, see the reference page for the M-PSK Modulator Baseband block.

## Constellation Visualization

The M-PAM Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the Constellation Visualization section of the *Communications Toolbox User's Guide*.

## Parameters

### M-ary number

The number of points in the signal constellation. It must be an even integer.

### Input type

Indicates whether the input consists of integers or groups of bits. If this parameter is set to Bit, then the **M-ary number** parameter must be  $2^K$  for some positive integer K.

### Constellation ordering

Determines how the block maps each group of input bits to a corresponding integer.

### Normalization method

Determines how the block scales the signal constellation. Choices are Min. distance between symbols, Average Power, and Peak Power.

### Minimum distance

The distance between two nearest constellation points. This field appears only when **Normalization method** is set to Min. distance between symbols.

### Average power, referenced to 1 ohm (watts)

The average power of the symbols in the constellation, referenced to 1 ohm. This field appears only when **Normalization method** is set to Average Power.

### Peak power, referenced to 1 ohm (watts)

The maximum power of the symbols in the constellation, referenced to 1 ohm. This field appears only when **Normalization method** is set to Peak Power.

### Output data type

The output data type can be set to double, single, Fixed-point, User-defined, or Inherit via back propagation.

Setting this parameter to **Fixed-point** or **User-defined** enables fields in which you can further specify details. Setting this parameter to **Inherit via back propagation**, sets the output data type and scaling to match the following block.

### **Output word length**

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter.

### **User-defined data type**

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the `sfix`, `sint`, `sfrac`, and `fixdt` functions from Fixed-Point Designer software. This parameter is only visible when you select **User-defined** for the **Output data type** parameter.

### **Set output fraction length to**

Specify the scaling of the fixed-point output by either of the following methods:

- Choose **Best precision** to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose **User-defined** to specify the output scaling in the **Output fraction length** parameter.

This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter or when you select **User-defined** and the specified output data type is a fixed-point data type.

### **Output fraction length**

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select **Fixed-point** or **User-defined** for the **Output data type** parameter and **User-defined** for the **Set output fraction length to** parameter.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean when <b>Input type</b> is Bit</li> <li>• 8-, 16-, 32-bit signed integers</li> <li>• 8-, 16-, 32-bit unsigned integers</li> <li>• <math>ufix(\lceil \log_2 M \rceil)</math> when <b>Input type</b> is Integer</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed fixed-point</li> </ul>

## M-PSK Demodulator Baseband

Demodulate PSK-modulated data

**Library:** Communications Toolbox / Modulation / Digital  
Baseband Modulation / PM  
Communications Toolbox HDL Support / Modulation /  
PM

### Description

The M-PSK Demodulator Baseband block demodulates a baseband representation of a PSK-modulated signal. The modulation order,  $M$ , is equivalent to the number of points in the signal constellation and is determined by the **M-ary number** parameter. The block accepts scalar or column vector input signals.

### Input/Output Ports

#### Input

##### Port\_1 — Input signal

scalar | vector

Input port accepting a baseband representation of a PSK-modulated signal.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

#### Output

##### Port\_1 — Output signal

scalar | vector

Output signal, returned as a scalar or vector. The output is a demodulated version of the PSK-modulated signal.

Data Types: single | double | fixed point

## Parameters

### **M-ary number — Modulation order of the PSK constellation**

8 (default) | scalar

Specify the modulation order as a positive integer power of two.

Example: 2 | 16

### **Output type — Output signal data type**

Integer (default) | Bit

Specify the elements of the input signal as integers or bits. If **Output type** is Bit, the number of samples per frame is an integer multiple of the number of bits per symbol,  $\log_2(M)$ .

### **Decision type — Demodulator output**

Hard decision (default) | Log-likelihood ratio | Approximate log-likelihood ratio

Specify the demodulator output to be hard decision, log-likelihood ratio (LLR), or approximate LLR. The LLR and approximate LLR outputs are used with error decoders that support soft-decision inputs such as a Viterbi decoder, to achieve superior performance. This parameter is available when **Output type** is Bit.

See “Phase Modulation” for algorithm details. The output values for Log-likelihood ratio and Approximate log-likelihood ratio decision types are of the same data type as the input values

### **Noise variance source — Source of noise variance**

Dialog (default) | Port

Specify the source of the noise variance estimate. This parameter is available when **Decision type** is Log-likelihood ratio or Approximate log-likelihood ratio.

- To specify the noise variance from the dialog box, select Dialog.
- To input the noise variance from an input port, select Port.

### **Noise variance — Estimate of noise variance**

1 (default) | positive scalar

Specify the estimate of the noise variance as a positive scalar. This parameter is available when **Noise variance source** is Dialog.

This parameter is tunable in all simulation modes. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. Avoiding recompilation is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

---

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or -Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

---

#### **Constellation ordering — Symbol mapping**

Gray (default) | Binary | User-defined

Specify how the integer or group of  $\log_2(M)$  bits is mapped to the corresponding symbol.

- When **Constellation ordering** is set to Gray, the output symbol is mapped to the input signal using a Gray-encoded signal constellation.
- When **Constellation ordering** is set to Binary, the modulated symbol is  $\exp(j\phi + j2\pi m/M)$ , where  $\phi$  is the phase offset in radians,  $m$  is the integer output such that  $0 \leq m \leq M - 1$ , and  $M$  is the modulation order.
- When **Constellation ordering** is User-defined, specify a vector of size  $M$ , which has unique integer values in the range  $[0, M-1]$ . The first element of this vector corresponds to the constellation point having a value of  $e^{j\phi}$  with subsequent elements running counterclockwise.

Example: [0 3 2 1]

#### **Constellation mapping — User-defined symbol mapping**

[0:7] (default) | vector

Specify the order in which input integers are mapped to output integers. The parameter is available when **Constellation ordering** is User-defined, and must be a row or column vector of size  $M$  having unique integer values in the range  $[0, M - 1]$ .

The first element of this vector corresponds to the constellation point at  $0 + \mathbf{Phase\ offset}$  angle, with subsequent elements running counterclockwise. The last element corresponds to the  $-2\pi/M + \mathbf{Phase\ offset}$  constellation point.

#### **Phase offset (rad) — Phase offset in radians**

`pi/8` (default) | scalar

Specify, in radians, the phase offset of the initial constellation as a real scalar.

Example: `pi/4`

#### **Output data type — Output data type**

Inherit via internal rule (default) | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32

Specify the data type of the demodulated output signal.

## Block Characteristics

<b>Data Types</b>	Boolean   double   fixed point <sup>abc</sup>   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

a.  $M = 2, 4, 8$  only.

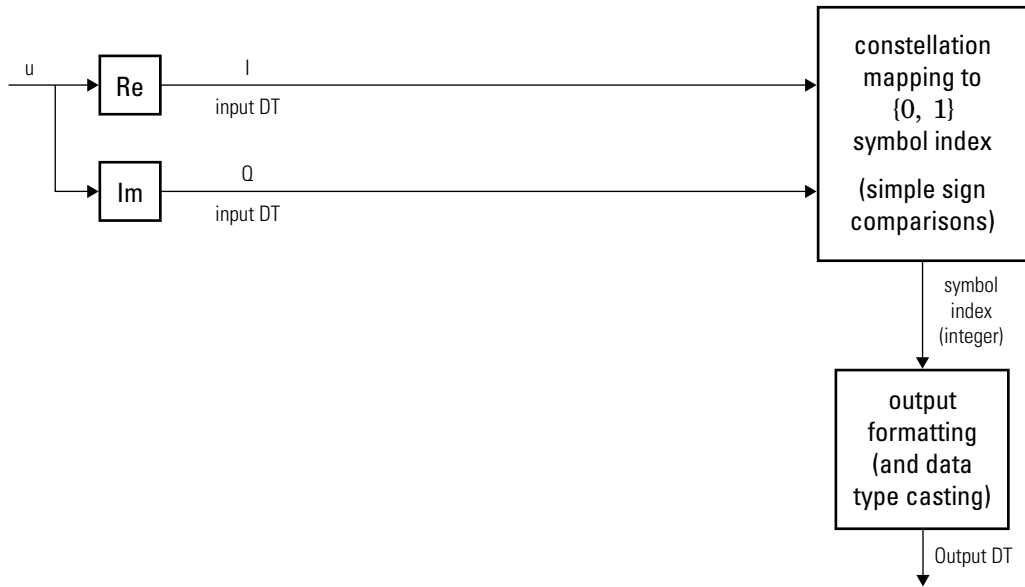

b. Fixed-point inputs must be signed.

c. When ASIC/FPGA is selected in the Hardware Implementation Pane, output is `ufix(1)` for bit outputs, and `ufix(ceil(log2(M)))` for integer outputs.

# M-PSK Modulator Baseband

Modulate using M-ary phase shift keying

**Library:** Communications Toolbox / Modulation / Digital  
Baseband Modulation / PM  
Communications Toolbox HDL Support / Modulation /  
PM

## Description

The M-PSK Modulator Baseband block modulates an input signal using M-ary phase shift keying (PSK) and returns a complex baseband output. The modulation order,  $M$ , which is equivalent to the number of points in the signal constellation, is determined by the **M-ary number** parameter. The block accepts scalar or column vector input signals.

## Input/Output Ports

### Input

#### Port\_1 — Input signal

scalar | vector

Specify the input signal as an integer scalar, integer vector, or binary vector.

- When **Input type** is **Integer**, specify the input signal elements as integers from 0 to  $M - 1$ .
- When **Input type** is **Bit**, specify the input signal as a binary vector in which the number of elements is an integer multiple of the bits per symbol. The bits per symbol is equal to  $\log_2(M)$ .

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

## Output

### Port\_1 — Output signal

scalar | vector

Output signal, returned as a complex scalar or vector. The output is the complex baseband representation of the PSK-modulated signal.

Data Types: single | double | fixed point

## Parameters

### M-ary number — Modulation order of the PSK constellation

8 (default) | scalar

Specify the modulation order as a positive integer power of two.

Example: 2 | 16

### Input type — Type of input signal

Integer (default) | Bit

Specify the elements of the input signal as integers or bits. If **Input type** is Bit, the number of samples per frame must be an integer multiple of the number of bits per symbol. The number of bits per symbol is  $\log_2(M)$ .

### Constellation ordering — Symbol mapping

Gray (default) | Binary | User-defined

Specify how the integer or group of  $\log_2(M)$  bits is mapped to the corresponding symbol.

- When **Constellation ordering** is set to Gray, the input signal is mapped to the output symbols using a Gray-encoded signal constellation.
- When **Constellation ordering** is set to Binary, the modulated symbol is  $\exp(j\phi + j2\pi m/M)$ , where  $\phi$  is the phase offset in radians,  $m$  is the integer input such that  $0 \leq m \leq M - 1$ , and  $M$  is the modulation order.
- When **Constellation ordering** is User-defined, specify a vector of size  $M$ , which has unique integer values in the range  $[0, M-1]$ . The first element of this vector corresponds to the constellation point having an value of  $e^{j\phi}$  with subsequent elements running counterclockwise.

Example: [0 3 2 1]

### Constellation mapping — User-defined symbol mapping

[0:7] (default) | vector

Specify the order in which input integers are mapped to output integers. The parameter is available when **Constellation ordering** is **User-defined**, and must be a row or column vector of size  $M$  having unique integer values in the range  $[0, M - 1]$ .

The first element of this vector corresponds to the constellation point at  $0 + \mathbf{Phase\ offset}$  angle, with subsequent elements running counterclockwise. The last element corresponds to the  $-2\pi/M + \mathbf{Phase\ offset}$  constellation point.

### Phase offset (rad) — Phase offset in radians

pi/8 (default) | scalar

Specify, in radians, the phase offset of the initial constellation as a real scalar.

Example: pi/4

### Output data type — Output data type

double (default) | single | Inherit via back propagation | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the data type of the modulated output signal. Set this parameter to one of the fixed point options or <data type expression> to enable parameters in which you specify additional details. Set this parameter to **Inherit via back propagation**, to match the output data type and scaling to the following block in the model.

## Block Characteristics

<b>Data Types</b>	Boolean   double   fixed point <sup>ab</sup>   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

- ufix(1) at the input if "input type" is set to "bit". ufix(ceil(log2(M))) at input if "input type" is set to "integer" for M-ary modulation.
- Fixed-point outputs must be signed.

## Tips

The M-PSK Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. Clicking the **View Constellation** button allows you to visualize a signal constellation for the specified block parameters.

## Algorithms

The block outputs a baseband signal by mapping input bits or integers to complex symbols according to the following:

$$s_n(t) = \exp\left(j\pi\left(\frac{2n+1}{M}\right)\right); \quad n \in \{0, 1, \dots, M-1\}.$$

This applies when a natural binary ordering is used. Another common mapping is Gray coding, which has the advantage that only one bit changes between adjacent constellation points. This results in better bit error rate performance. For 8-PSK modulation with Gray coding, the mapping between the input and output symbols is shown.

Input	Output
0	0 (000)
1	1 (001)
2	3 (011)
3	2 (010)
4	6 (110)
5	7 (111)
6	5 (101)
7	4 (100)

The corresponding constellation diagram follows.

When the input signal is composed of bits, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of  $\log_2(M)$  bits.

## Extended Capabilities

## M-PSK Phase Recovery

(To be removed) Recover carrier phase using M-Power method

---

**Note** M-PSK Phase Recovery will be removed in a future release. Use the Carrier Synchronizer block instead.

---

### Library

Carrier Phase Recovery sublibrary of Synchronization

### Description

The M-PSK Phase Recovery block recovers the carrier phase of the input signal using the M-Power method. This feedforward, non-data-aided, clock-aided method is suitable for systems that use baseband phase shift keying (PSK) modulation. It is also suitable for systems that use baseband quadrature amplitude modulation (QAM), although the results are less accurate than those for comparable PSK systems. The alphabet size for the modulation must be an even integer.

For PSK signals, the **M-ary number** parameter represents the alphabet size. For QAM signals, the **M-ary number** should be 4 regardless of the alphabet size because the 4-power method is the most appropriate for QAM signals.

The M-Power method assumes that the carrier phase is constant over a series of consecutive symbols, and returns an estimate of the carrier phase for the series. The **Observation interval** parameter is the number of symbols for which the carrier phase is assumed constant. This number must be an integer multiple of the input signal's vector length.

### Input and Output Signals

This block accepts a scalar or column vector input signal of type `double` or `single`. The input signal represents a baseband signal at the symbol rate, so it must be complex-valued and must contain one sample per symbol.

The outputs are as follows:

- The output port labeled **Sig** gives the result of rotating the input signal counterclockwise, where the amount of rotation equals the carrier phase estimate. The **Sig** output is thus a corrected version of the input signal, and has the same sample time and vector size as the input signal.
- The output port labeled **Ph** outputs the carrier phase estimate, in degrees, for all symbols in the observation interval. The **Ph** output is a scalar signal.

---

**Note** Because the block internally computes the argument of a complex number, the carrier phase estimate has an inherent ambiguity. The carrier phase estimate is between  $-180/M$  and  $180/M$  degrees and might differ from the actual carrier phase by an integer multiple of  $360/M$  degrees.

---

## Delays and Latency

The block's algorithm requires it to collect symbols during a period of length **Observation interval** before computing a single estimate of the carrier phase. Therefore, each estimate is delayed by **Observation interval** symbols and the corrected signal has a latency of **Observation interval** symbols, relative to the input signal.

## Parameters

### M-ary number

The number of points in the signal constellation of the transmitted PSK signal. This value as an even integer.

### Observation interval

The number of symbols for which the carrier phase is assumed constant. The observation interval parameter must be an integer multiple of the input signal vector length.

When this parameter is exactly equal to the vector length of the input signal, then the block always works. When the integer multiple is not equal to 1, select **Simulation > Configuration Parameters > Solver** and clear the **Treat each discrete rate as a separate task** checkbox.

## Algorithm

If the symbols occurring during the observation interval are  $x(1)$ ,  $x(2)$ ,  $x(3)$ , ...,  $x(L)$ , then the resulting carrier phase estimate is

$$\frac{1}{M} \arg \left\{ \sum_{k=1}^L (x(k))^M \right\}$$

where the  $\arg$  function returns values between -180 degrees and 180 degrees.

CPM Phase Recovery, M-PSK Modulator Baseband

**Introduced before R2006a**

# M-PSK TCM Decoder

Decode trellis-coded modulation data, modulated using PSK method

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The M-PSK TCM Decoder block uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a PSK signal constellation.

The **M-ary number** parameter represents the number of points in the signal constellation, which also equals the number of possible output symbols from the convolutional encoder. (That is,  $\log_2(\mathbf{M-ary\ number})$  is the number of output bit streams from the convolutional encoder.)

The **Trellis structure** and **M-ary number** parameters in this block should match those in the M-PSK TCM Encoder block, to ensure proper decoding.

## Input and Output Signals

This block accepts a column vector input signal containing complex numbers. The input signal must be `double` or `single`. The reset port signal must be `double` or `Boolean`. For information about the data types each block port supports, see “Supported Data Types” on page 3-787.

If the convolutional encoder described by the trellis structure represents a rate  $k/n$  code, then the M-PSK TCM Decoder block's output is a binary column vector whose length is  $k$  times the vector length of the input signal.

## Operation Modes

The block has three possible methods for transitioning between successive frames. The **Operation mode** parameter controls which method the block uses. This parameter also affects the range of possible values for the **Traceback depth** parameter,  $D$ .

- In **Continuous** mode, the block initializes all state metrics to zero at the beginning of the simulation, waits until it accumulates  $D$  symbols, and then uses a sequence of  $D$  symbols to compute each of the traceback paths.  $D$  can be any positive integer. At the end of each frame, the block saves its internal state metric for use with the next frame.

If you select **Enable the reset input**, the block displays another input port, labeled **Rst**. This port receives an integer scalar signal. Whenever the value at the **Rst** port is nonzero, the block resets all state metrics to zero and sets the traceback memory to zero.

- In **Truncated** mode, the block treats each frame independently. The traceback path starts at the state with the lowest metric.  $D$  must be less than or equal to the vector length of the input.
- In **Terminated** mode, the block treats each frame independently. The traceback path always starts at the all-zeros state.  $D$  must be less than or equal to the vector length of the input. If you know that each frame of data typically ends at the all-zeros state, then this mode is an appropriate choice.

## Decoding Delay

If you set **Operation mode** to **Continuous**, then this block introduces a decoding delay equal to **Traceback depth**\* $k$  bits, for a rate  $k/n$  convolutional code. The decoding delay is the number of zeros that precede the first decoded bit in the output.

The block incurs no delay for other values of **Operation mode**.

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

### M-ary number

The number of points in the signal constellation.

**Traceback depth**

The number of trellis branches (equivalently, the number of symbols) the block uses in the Viterbi algorithm to construct each traceback path.

**Operation mode**

The operation mode of the Viterbi decoder. Choices are Continuous, Truncated, and Terminated.

**Enable the reset input port**

When you check this box, the block has a second input port labeled **Rst**. Providing a nonzero input value to this port causes the block to set its internal memory to the initial state before processing the input data. This option appears only if you set **Operation mode** to Continuous.

**Output data type**

The output type of the block can be specified as a **boolean** or **double**. By default, the block sets this to **double**.

**Supported Data Types**

# M-PSK TCM Encoder

Convolutionally encode binary data and modulate using PSK method

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The M-PSK TCM Encoder block implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a PSK signal constellation.

The **M-ary number** parameter is the number of points in the signal constellation, which also equals the number of possible output symbols from the convolutional encoder. (That is,  $\log_2(\mathbf{M-ary\ number})$  is equal to  $n$  for a rate  $k/n$  convolutional code.)

## Input Signals and Output Signals

If the convolutional encoder described by the trellis structure represents a rate  $k/n$  code, then the block input signal must be a binary column vector with a length of  $L*k$  for some positive integer  $L$ .

This block accepts a binary-valued input signal. The output signal is a complex column vector of length  $L$ .

## Specifying the Encoder

To define the convolutional encoder, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, then use a `poly2trellis` command within the **Trellis structure** field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

- If you have a variable in the MATLAB workspace that contains the trellis structure, then enter its name as the **Trellis structure** parameter. This way is faster because it causes Simulink software to spend less time updating the diagram at the beginning of each simulation, compared to the usage in the previous bulleted item.

The encoder registers begin in the all-zeros state. You can configure the encoder so that it resets its registers to the all-zeros state during the course of the simulation. To do this, set the **Operation mode** to **Reset on nonzero input via port**. The block then opens a second input port, labeled **Rst**. The signal at the **Rst** port is a scalar signal. When it is nonzero, the encoder resets before processing the data at the first input port.

## Signal Constellations

The trellis-coded modulation technique partitions the constellation into subsets called cosets, so as to maximize the minimum distance between pairs of points in each coset. This block internally forms a valid partition based on the value you choose for the **M-ary number** parameter.

The figure below shows the labeled set-partitioned signal constellation that the block uses when **M-ary number** is 8. For constellations of other sizes, see [1].

## Coding Gains

Coding gains of 3 to 6 decibels, relative to the uncoded case can be achieved in the presence of AWGN with multiphase trellis codes [3].

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

### Operation mode

In Continuous mode (default setting), the block retains the encoder states at the end of each frame, for use with the next frame.

In **Truncated (reset every frame)** mode, the block treats each frame independently. I.e., the encoder states are reset to all-zeros state at the start of each frame.

In **Terminate trellis by appending bits** mode, the block treats each frame independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by  $y = n \cdot (x + s)/k$ , where  $x$  is the number of input bits, and  $s = \text{constraint length} - 1$  (or, in the case of multiple constraint lengths,  $s = \text{sum}(\text{ConstraintLength}(i) - 1)$ ). The block supports this mode for column vector input signals.

In **Reset on nonzero input via port** mode, the block has an additional input port, labeled **Rst**. When the **Rst** input is nonzero, the encoder resets to the all-zeros state.

#### **M-ary number**

The number of points in the signal constellation.

#### **Output data type**

The output type of the block can be specified as a **single** or **double**. By default, the block sets this to **double**.

## MSK Demodulator Baseband

Demodulate differentially encoded MSK-modulated data

### Library

CPM, in Digital Baseband sublibrary of Modulation

### Description

The MSK Demodulator Baseband block demodulates a signal that was modulated using the differentially encoded minimum shift keying method. The block expects the input signal to be a baseband representation of a coherent modulated signal with no precoding. The **Phase offset** parameter represents the initial phase of the modulated waveform.

### Pulse Shape Filtering

Differentially encoded minimum shift keying modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function  $q(t)$  is the phase response

obtained from the frequency pulse,  $g(t)$ , through this relation:

$$q(t) = \int_{-\infty}^t g(t) dt$$

The specified frequency pulse shape corresponds to this rectangular pulse shape expression,  $g(t)$ .

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$

- $L_{\text{main}}$  is the main lobe pulse duration in symbol intervals.
- The duration of the pulse,  $LT$ , is the pulse length in symbol intervals.

## Integer-Valued Signals and Binary-Valued Signals

This block accepts a scalar-valued or column vector input signal with a data type of `single` or `double`. If you set the **Output type** parameter to `Integer`, then the block produces values of 1 and -1. If you set the **Output type** parameter to `Bit`, then the block produces values of 0 and 1.

### Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to `Bit`, the output width is  $K$  times the number of input symbols.
- When you set **Output type** to `Integer`, the output width is the number of input symbols.

### Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to `Bit`, the output width equals the number of bits per symbol.
- When you set **Output type** to `Integer`, the output is a scalar.

## Traceback Depth and Output Delays

Internally, this block creates a trellis description of the modulation scheme and uses the Viterbi algorithm. The **Traceback depth** parameter,  $D$ , in this block is the number of trellis branches used to construct each traceback path.  $D$  influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When you set the **Rate options** parameter to `Allow multirate processing`, and the model uses a variable-step solver or a fixed-step solver with the **Tasking Mode** parameter set to `SingleTasking`, then the delay consists of  $D+1$  zero symbols.
- When you set the **Rate options** parameter to `Enforce single-rate processing`, then the delay consists of  $D$  zero symbols.

The optimal **Traceback depth** parameter value is dependent on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the “five-times-the-constraint-length” rule, which corresponds to  $5 \times \log_2(\text{numStates})$ . The number of states is determined by the following equation:

$$\text{numStates} = \begin{cases} p \cdot 2^{(L-1)}, & \text{for even } m \\ 2p \cdot 2^{(L-1)}, & \text{for odd } m \end{cases}$$

where:

- $h = m/p$  is the modulation index proper rational form
  - $m$  = numerator of modulation index
  - $p$  = denominator of modulation index
- $L$  is the Pulse length

## Parameters

### Output type

Determines whether the output consists of bipolar or binary values.

### Phase offset (rad)

The initial phase of the modulated waveform.

### Samples per symbol

The number of input samples that represent each modulated symbol, which must be a positive integer. For more information, see “Upsample Signals and Rate Changes”.

### Rate options

Select the rate processing method for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to Integer).
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

### Traceback depth

The number of trellis branches that the MSK Demodulator Baseband block uses to construct each traceback path.

### Output data type

The output data type can be boolean, int8, int16, int32, or double.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean (When <b>Output type</b> set to Bit)</li> <li>• 8-, 16-, and 32-bit signed integers (When <b>Output type</b> set to Integer)</li> </ul>

# MSK Modulator Baseband

Modulate using differentially encoded minimum shift keying method

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The MSK Modulator Baseband block modulates using the differentially encoded minimum shift keying method. The output is a baseband representation of the modulated signal.

This block accepts a scalar-valued or column vector input signal. For a column vector input signal, the width of the output equals the product of the number of symbols and the value for the **Samples per symbol** parameter.

## Pulse Shape Filtering

Differentially encoded minimum shift keying modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function  $q(t)$  is the phase response

obtained from the frequency pulse,  $g(t)$ , through this relation:

$$q(t) = \int_{-\infty}^t g(t) dt$$

The specified frequency pulse shape corresponds to this rectangular pulse shape expression,  $g(t)$ .

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$

- $L_{\text{main}}$  is the main lobe pulse duration in symbol intervals.
- The duration of the pulse,  $LT$ , is the pulse length in symbol intervals.

## Integer-Valued Signals and Binary-Valued Signals

When you set the **Input type** parameter to **Integer**, then the block accepts values of 1 and -1.

When you set the **Input type** parameter to **Bit**, then the block accepts values of 0 and 1.

For information about the data types each block port supports, see the “Supported Data Types” on page 3-802 table on this page.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set **Input type** to **Integer**, the input can be a column vector, the length of which is the number of input symbols.
- When you set **Input type** to **Bit**, the input width must be an integer multiple of  $K$ , the number of bits per symbol.

The output width equals the product of the number of input symbols and the **Samples per symbol** parameter value.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to `Integer`, the input must be a scalar.
- When you set **Input type** to `Bit`, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

## Parameters

### Input type

Indicates whether the input consists of bipolar or binary values.

### Phase offset (rad)

The initial phase of the output waveform, measured in radians.

### Samples per symbol

The number of output samples that the block produces for each integer or binary word in the input, which must be a positive integer. For all non-binary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes” in *Communications ToolboxUser's Guide*.

### Rate options

Select the rate processing option for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

### Output data type

Specify the block output data type as `double` and `single`. By default, the block sets this to `double`.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Boolean (when <b>Input type</b> set to Bit)</li><li>• 8-, 16-, and 32-bit signed integers (when <b>Input type</b> set to Integer)</li></ul>
Output	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul>

# MSK-Type Signal Timing Recovery

Recover symbol timing phase using fourth-order nonlinearity method

## Library

Timing Phase Recovery sublibrary of Synchronization

## Description

The MSK-Type Signal Timing Recovery block recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This block implements a general non-data-aided feedback method that is independent of carrier phase recovery but requires prior compensation for the carrier frequency offset. This block is suitable for systems that use baseband minimum shift keying (MSK) modulation or Gaussian minimum shift keying (GMSK) modulation.

## Inputs

By default, the block has one input port. The input signal could be (but is not required to be) the output of a receive filter that is matched to the transmitting pulse shape, or the output of a lowpass filter that limits the amount of noise entering this block.

This block accepts a scalar-valued or column vector input signal. The input uses  $N$  samples to represent each symbol, where  $N > 1$  is the **Samples per symbol** parameter.

- For a column vector input signal, the block operates in single-rate processing mode. In this mode, the output signal inherits its sample rate from the input signal. The input length must be a multiple of  $N$ .
- For a scalar input signal, the block operates in multirate processing mode. In this mode, the input and output signals have different sample rates. The output sample rate equals  $N$  multiplied by the input sample rate.

- This block accepts input signals of type Double or Single

If you set the **Reset** parameter to `On nonzero input via port`, then the block has a second input port, labeled `Rst`. The `Rst` input determines when the timing estimation process restarts, and must be a scalar.

- If the input signal is a scalar value, the sample time of the `Rst` input equals the symbol period
- If the input signal is a column vector, the sample time of the `Rst` input equals the input port sample time
- This block accepts reset signals of type Double or Boolean

## Outputs

The block has two output ports, labeled `Sym` and `Ph`:

- The `Sym` output is the result of applying the estimated phase correction to the input signal. This output is the signal value for each symbol, which can be used for decision purposes. The values in the `Sym` output occur at the symbol rate:
  - For a column vector input signal of length  $N \cdot R$ , the `Sym` output is a column vector of length  $R$  having the same sample rate as the input signal.
  - For a scalar input signal, the sample rate of the `Sym` output equals  $N$  multiplied by the input sample rate.
- The `Ph` output gives the phase estimate for each symbol in the input.

The `Ph` output contains nonnegative real numbers less than  $N$ . Noninteger values for the phase estimate correspond to interpolated values that lie between two values of the input signal. The sample time of the `Ph` output is the same as that of the `Sym` output.

---

**Note** If the `Ph` output is very close to either zero or **Samples per symbol**, or if the actual timing phase offset in your input signal is very close to zero, then the block's accuracy might be compromised by small amounts of noise or jitter. The block works well when the timing phase offset is significant rather than very close to zero.

---

- The output signal inherits its data type from the input signal.

## Delays

When the input signal is a vector, this block incurs a delay of two symbols. When the input signal is a scalar, this block incurs a delay of three symbols.

## Parameters

### Modulation type

The type of modulation in the system. Choices are MSK and GMSK.

### Samples per symbol

The number of samples,  $N$ , that represent each symbol in the input signal. This must be greater than 1.

### Error update gain

A positive real number representing the step size that the block uses for updating successive phase estimates. Typically, this number is less than  $1/N$ , which corresponds to a slowly varying phase.

This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. For more information, see Tunable Parameters (Simulink).

### Reset

Determines whether and under what circumstances the block restarts the phase estimation process. Choices are None, Every frame, and On nonzero input via port. The last option causes the block to have a second input port, labeled Rst.

## Algorithm

This block's algorithm extracts timing information by passing the sampled baseband signal through a fourth-order nonlinearity followed by a digital differentiator whose output is smoothed to yield an error signal. The algorithm then uses the error signal to make the sampling adjustments.

More specifically, this block uses a timing error detector whose result for the  $k$ th symbol is  $e(k)$ , given in [2] by

$$e(k) = (-\operatorname{Re}\{r^2(kT - T_s + d_{k-1})r^{*2}((k-1)T - T_s + d_{k-2})\}) \\ - (-\operatorname{Re}\{r^2(kT + T_s + d_{k-1})r^{*2}((k-1)T + T_s + d_{k-1})\})$$

$$e(k) = (-1)^{D+1} \operatorname{Re}\{r^2(kT - T_s + d_{k-1})r^{*2}((k-1)T - T_s + d_{k-2})\} \\ - (-1)^{D+1} \operatorname{Re}\{r^2(kT + T_s + d_{k-1})r^{*2}((k-1)T + T_s + d_{k-1})\}$$

where

- $r$  is the block's input signal
- $T$  is the symbol period
- $T_s$  is the sampling period
- $*$  means complex conjugate
- $d_k$  is the phase estimate for the  $k$ th symbol
- $D$  is 1 for MSK and 2 for Gaussian MSK modulation

# Multipath Rayleigh Fading Channel

(To be removed) Simulate multipath Rayleigh fading propagation channel

## Library

Channels

---

**Note** Multipath Rayleigh Fading Channel will be removed in a future release. Use SISO Fading Channel instead.

---

## Description

The Multipath Rayleigh Fading Channel block implements a baseband simulation of a multipath Rayleigh fading propagation channel. You can use this block to model mobile wireless communication systems. For details about fading channels, see the references listed below.

This block accepts a scalar value or column vector input signal. The block inherits sample time from the input signal. The input signal must have a discrete sample time greater than 0.

Relative motion between the transmitter and receiver causes Doppler shifts in the signal frequency. You can specify the Doppler spectrum of the Rayleigh process using the **Doppler spectrum type** parameter. For channels with multiple paths, you can assign each path a different Doppler spectrum, by entering a vector of `doppler` objects in the **Doppler spectrum** field.

Because a multipath channel reflects signals at multiple places, a transmitted signal travels to the receiver along several paths, each of which may have differing lengths and

associated time delays. In the block's parameter dialog box, the **Discrete path delay vector** specifies the time delay for each path. If you do not check **Normalize gain vector to 0 dB overall gain**, then the **Average path gain vector** specifies the gain for each path. When you check the box, the block uses a multiple of **Average path gain vector** instead of the **Average path gain vector** itself, choosing the scaling factor so that the channel's effective gain, considering all paths, is 0 dB.

The number of paths is implicitly indicated via the number of elements in **Discrete path delay vector** or **Average path gain vector**. If both of these parameters are vectors, then they must have the same length; if exactly one of these parameters contains a scalar value, then the block expands it into a vector whose size matches that of the other vector parameter.

The block multiplies the input signal by samples of a Rayleigh-distributed complex random process. The scalar **Initial seed** parameter seeds the random number generator and the block generates random numbers using the Ziggurat method.

Double-clicking this block during simulation or selecting **Open channel visualization at start of simulation** plots the channel characteristics using the channel visualization tool. For more information, see “Channel Visualization”.

## Parameters

### Maximum Doppler shift (Hz)

A positive scalar value that indicates the maximum Doppler shift.

### Doppler spectrum type

Specifies the Doppler spectrum of the Rayleigh process.

This parameter defaults to Jakes Doppler spectrum. Alternatively, you can also choose any of the following types:

- Flat on page 2-450
- Gaussian on page 2-453
- Rounded on page 2-463
- Restricted Jakes on page 2-459
- Asymmetrical Jakes on page 2-440
- Bi-Gaussian on page 2-446

- Bell on page 2-443

For all Doppler spectrum types except **Jakes** and **Flat**, you can choose one or more parameters to control the shape of the spectrum.

You can also select **Specify as dialog** parameter for the **Doppler spectrum type**. Specify the Doppler spectrum by entering an object in the **Doppler spectrum** field. See the `doppler` function reference for details on how to construct Doppler objects, and also for the meaning of the parameters associated with the various Doppler spectrum types.

**Discrete path delay vector (s)**

A vector that specifies the propagation delay for each path.

**Average path gain vector (dB)**

A vector that specifies the gain for each path.

**Normalize gain vector to 0 dB overall gain**

Checking this box causes the block to scale the **Gain vector** parameter so that the channel's effective gain (considering all paths) is 0 dB.

**Initial seed**

The scalar seed for the Gaussian noise generator.

**Open channel visualization at start of simulation**

Select this check box to open the channel visualization tool when a simulation begins.

**Complex path gains port**

Select this check box to create a port that outputs the values of the complex path gains for each path. In this  $N$ -by- $M$  multichannel output,  $N$  represents the number of samples the input signal contains and  $M$  represents the number of discrete paths (number of delays).

**Channel filter delay port**

Select this check box to create a port that outputs the value of the delay (in samples) that results from the filtering operation of this block. This delay is zero if only one path is simulated, but can be greater than zero if more than one path is present. See "Methodology for Simulating Multipath Fading Channels" for a definition of this delay, where it is denoted as  $N_1$ .

## Algorithm

This implementation is based on the direct-form simulator described in Reference [1]. A detailed explanation of the implementation, including a review of the different Doppler spectra, can be found in [4].

Some wireless applications prefer to specify Doppler shifts in terms of the speed of the mobile. If the mobile moves at speed  $v$  making an angle of  $\theta$  with the direction of wave motion, then the Doppler shift is

$$f_d = (v/c) \cos \theta$$

where  $f$  is the transmission carrier frequency and  $c$  is the speed of light. The Doppler frequency represents the maximum Doppler shift arising from motion of the mobile.

## Example

### Generating Ideal Theoretical BER Results for a Rayleigh Fading Channel

This example illustrates how to generate ideal theoretical BER results for a flat Rayleigh fading channel. The model reproduces known theoretical results and shows the correct BER performance for a flat Rayleigh fading channel. In this example, you will run the model and compare the simulation results to the BERTool theoretical results for verification purposes. Note that the EbNo value for the model's AWGN block is 5 dB. You can change the noise power by double-clicking the AWGN block and entering another numeric value in the EbNo parameter.

#### Opening the Model

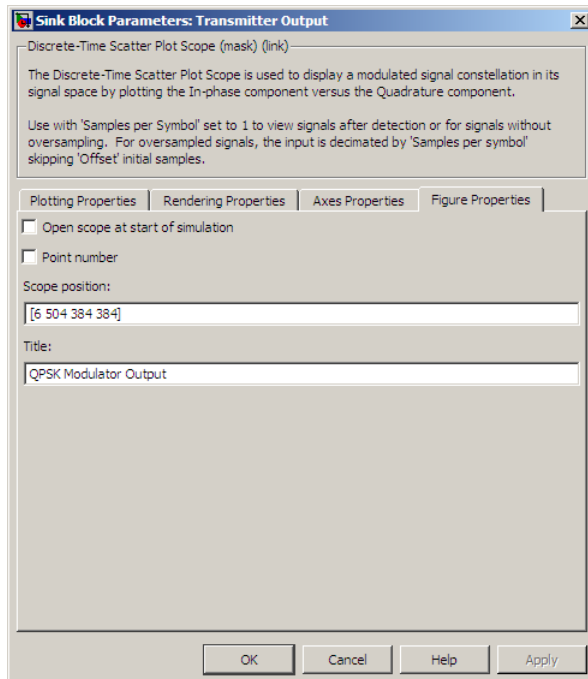

You can open the model by clicking [here](#) in the MATLAB Help browser. Alternatively, you can type `doc_qpsk_rayleigh_derotated` at the MATLAB command line.

#### Running the Model and Comparing Results

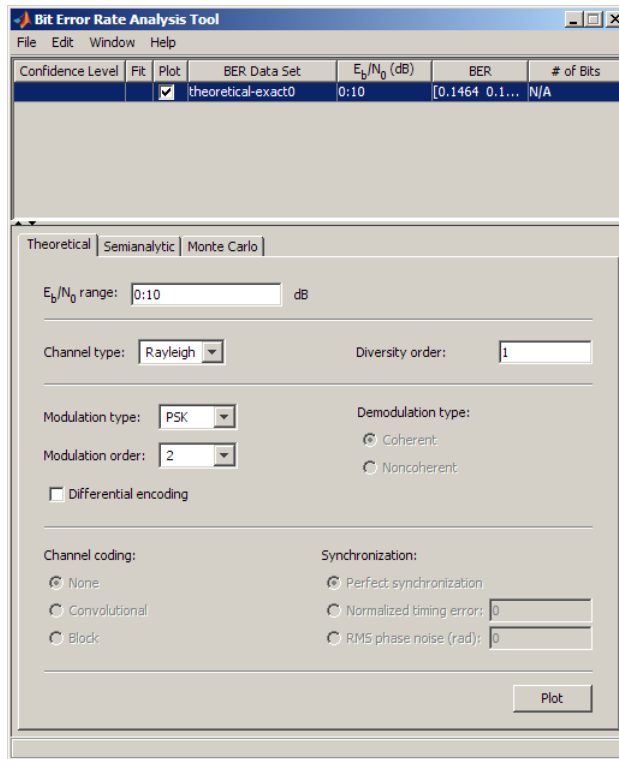

- 1 You can run the example by clicking **Simulation > Run**.
- 2 After the model collects more than 5000 errors, click the stop button.
- 3 Close the three scopes.

- 4 In the Simulink model window, double-click the Transmitter Output block. In the mask window, click the **Figure Properties** tab, uncheck **Open scope at start of Simulation**, then click **OK**.

- 5 In the Simulink model window, double-click the Rayleigh Channel Output block. In the mask window, click the **Figure Properties** tab, uncheck **Open scope at start of Simulation**, then click **OK**.
- 6 In the Simulink model window, double-click the Noisy Rayleigh Channel Output block. In the mask window, click the **Figure Properties** tab, uncheck **Open scope at start of Simulation**, then click **OK**.
- 7 In the Simulink model window, double-click the Error Rate Calculation block, check **Stop simulation**, enter 5000 for **Target number of error**, then click **OK**.
- 8 Click the play button to rerun the example.
- 9 Open BERTool by typing `bertool` at the MATLAB command line.
- 10 In BERTool, click the **Theoretical** tab and make the following selections:

- For **Eb/No range** enter 0 : 10
  - For **Channel type**, select Rayleigh
  - For **Diversity Order** enter 1
  - For **Modulation Type**, select PSK
  - For **Modulation order**, select 4
- 11** Click **Plot**.
- 12** Since the Simulink model uses an EbNo value of 5 dB, verify the probability of error on the BERTool curve at 5 dB. The two values should be approximately equal.

Click the Data Cursor button  (second from right) and click on the BERTool curve at 5dB.

# Multipath Rician Fading Channel

(To be removed) Simulate multipath Rician fading propagation channel

## Library

Channels

---

**Note** Multipath Rician Fading Channel will be removed in a future release. Use SISO Fading Channel instead.

---

## Description

The Multipath Rician Fading Channel block implements a baseband simulation of a multipath Rician fading propagation channel. You can use this block to model mobile wireless communication systems when the transmitted signal can travel to the receiver along a dominant line-of-sight or direct path. For more details, see “Fading Channels”.

This block accepts a scalar value or column vector input signal. The block inherits sample time from the input signal. The input signal must have a discrete sample time greater than 0.

Relative motion between the transmitter and receiver causes Doppler shifts in the signal frequency. You can specify the Doppler spectrum of the Rician process using the **Doppler spectrum type** pop-up menu. For channels with multiple paths, you can assign each path a different Doppler spectrum, by entering a vector of doppler objects in the **Doppler spectrum** field.

Because a multipath channel reflects signals at multiple places, a transmitted signal travels to the receiver along several paths, each of which may have differing lengths and associated time delays. In the block's parameter dialog box, the **Discrete path delay vector** specifies the time delay for each path. If you do not check the **Normalize gain**

**vector to 0 dB overall gain** box, then the **Average path gain vector** specifies the gain for each path. When you check the box, the block uses a multiple of **Average path gain vector** instead of the **Average path gain vector** itself, choosing the scaling factor so that the channel's effective gain considering all paths is 0 dB.

The number of paths is implicitly indicated via the number of elements in **Discrete path delay vector** or **Average path gain vector**. If both of these parameters are vectors, they must have the same length; if exactly one of these parameters contains a scalar value, the block expands it into a vector whose size matches that of the other vector parameter.

Fading causes the signal to become diffuse. The **K-factor** parameter, which is part of the statistical description of the Rician distribution, represents the ratio between the power in the line-of-sight component and the power in the diffuse component. The ratio is expressed linearly, not in decibels. While the **Average path gain vector** parameter controls the overall gain through the channel, the **K-factor** parameter controls the gain's partition into line-of-sight and diffuse components.

You can specify the **K-factor** parameter as a scalar or a vector. If the **K-factor** parameter is a scalar, then the first discrete path of the channel is a Rician fading process (it contains a line-of-sight component) with the specified **K-factor**, while the remaining discrete paths indicate independent Rayleigh fading processes (with no line-of-sight component). If the **K-factor** parameter is a vector of the same size as **Discrete path delay vector**, then each discrete path is a Rician fading process with a **K-factor** given by the corresponding element of the vector. You can attribute the line-of-sight component a Doppler shift, through the **Doppler shift(s) of line-of-sight component(s)** parameter, and an initial phase, through the **Initial phase(s) of line-of-sight component(s)**. The **Doppler shift(s) of line-of-sight component(s)** and **Initial phase(s) of line-of-sight component(s)** parameters must be of the same size as the **K-factor** parameter.

The block multiplies the input signal by samples of a Rician-distributed complex random process. The scalar **Initial seed** parameter seeds the random number generator and the block generates random numbers using the Ziggurat method.

Double-clicking this block during simulation or selecting the block dialog's check box labeled **Open channel visualization at start of simulation** plots the channel characteristics using the channel visualization tool. For more information, see “Channel Visualization”.

## Parameters

### **K-factor**

The ratio of power in the line-of-sight component to the power in the diffuse component. The ratio is expressed linearly, not in decibels. If **K-factor** is a scalar value, then the first discrete path is a Rician fading process (it contains a line-of-sight component) with the specified K-factor, while the remaining discrete paths are independent Rayleigh fading processes (with no line-of-sight component). If **K-factor** is a vector of the same size as **Discrete path delay vector**, then each discrete path is a Rician fading process with a **K-factor** given by the corresponding element of the vector.

### **Doppler shift(s) of line-of-sight component(s) (Hz)**

The Doppler shift of the line-of-sight component. It must be a scalar (if **K-factor** is a scalar) or a vector of the same size as **K-factor**. If this parameter contains a scalar value, then the line-of-sight component of the first discrete path has the specified Doppler shift, while the remaining discrete paths become independent Rayleigh fading processes. If the parameter contains a vector, then the line-of-sight component of each discrete path has a Doppler shift given by the corresponding element of the vector.

### **Initial phase(s) of line-of-sight component(s) (rad)**

The initial phase of the line-of-sight component. It must be either a scalar (if **K-factor** is a scalar value) or a vector of the same size as **K-factor**.

### **Maximum diffuse Doppler shift (Hz)**

A positive scalar value that indicates the maximum diffuse Doppler shift.

### **Doppler spectrum type**

Specifies the Doppler spectrum of the Rician process.

This parameter defaults to Jakes Doppler spectrum. Alternately, you can choose any of the following types:

- Flat on page 2-450
- Gaussian on page 2-453
- Rounded on page 2-463
- Restricted Jakes on page 2-459
- Asymmetrical Jakes on page 2-440

- Bi-Gaussian on page 2-446
- Bell on page 2-443

For all Doppler spectrum types except **Jakes** and **Flat**, You can use one or more parameters to control the shape of the spectrum.

You can also select **Specify as dialog** parameter for the **Doppler spectrum type**. Specify the Doppler spectrum by entering an object in the **Doppler spectrum** field. See the **doppler** function reference for details on how to construct doppler objects, and for the meaning of the parameters associated with the various Doppler spectrum types.

#### **Discrete delay vector(s)**

A vector that specifies the propagation delay for each path.

#### **Average path gain vector (dB)**

A vector that specifies the gain for each path.

#### **Initial seed**

The scalar seed for the Gaussian noise generator.

#### **Open channel visualization at start of simulation**

Select this check box to open the channel visualization tool when a simulation begins. This block supports channel visualization for a column vector input signal.

#### **Complex path gains port**

Select this check box to create a port that outputs the values of the complex path gains for each path. In this  $N$ -by- $M$  multichannel output,  $N$  represents the number of samples the input contains and  $M$  represents the number of discrete paths (number of delays).

#### **Channel filter delay port**

Select this check box to create a port that outputs the value of the delay (in samples) that results from the filtering operation of this block. This delay is zero if only one path is simulated, but can be greater than zero if more than one path is present. See “Methodology for Simulating Multipath Fading Channels” for a definition of this delay, where it is denoted as  $N_1$ .

## Algorithm

This implementation is based on the direct form simulator described in Reference [1]. A detailed explanation of the implementation, including a review of the different Doppler spectra, can be found in [4].

Some wireless applications prefer to specify Doppler shifts in terms of the speed of the mobile. If the mobile moves at speed  $v$  making an angle of  $\theta$  with the direction of wave motion, the Doppler shift is

$$f_d = f \frac{v}{c} \cos \theta$$

where  $f$  is the transmission carrier frequency and  $c$  is the speed of light. The Doppler frequency is the maximum Doppler shift arising from the motion of the mobile.

## Mu-Law Compressor

Implement  $\mu$ -law compressor for source coding

## Library

Source Coding

## Description

The Mu-Law Compressor block implements a  $\mu$ -law compressor for the input signal. The formula for the  $\mu$ -law compressor is

$$y = \frac{V \log(1 + \mu|x|/V)}{\log(1 + \mu)} \operatorname{sgn}(x)$$

where  $\mu$  is the  $\mu$ -law parameter of the compressor,  $V$  is the peak magnitude of  $x$ ,  $\log$  is the natural logarithm, and  $\operatorname{sgn}$  is the signum function (`sign` in MATLAB).

The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

### **mu value**

The  $\mu$ -law parameter of the compressor.

### **Peak signal magnitude**

The peak value of the input signal. This is also the peak value of the output.

## Supported Data Type

## Mu-Law Expander

Implement  $\mu$ -law expander for source coding

## Library

Source Coding

## Description

The Mu-Law Expander block recovers data that the Mu-Law Compressor block compressed. The formula for the  $\mu$ -law expander, shown below, is the inverse of the compressor function.

$$x = \frac{V}{\mu} \left( e^{|y| \log(1 + \mu)^{1/V}} - 1 \right) \text{sgn}(y)$$

The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

### mu value

The  $\mu$ -law parameter of the compressor.

### Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output.

## Normalized LMS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with normalized LMS algorithm

### Library

Equalizer Block

---

**Note** will be removed in a future release. Use Decision Feedback Equalizer instead.

---

### Description

The Normalized LMS Decision Feedback Equalizer block uses a decision feedback equalizer and the normalized LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the normalized LMS algorithm to update the weights, once per symbol. When you set the **Number of samples per symbol** parameter to 1, then the block implements a symbol-spaced (i.e. T-spaced) equalizer. When you set the **Number of samples per symbol** parameter to a value greater than 1, , the weights are updated once every  $N^{\text{th}}$  sample, for a  $T/N$ -spaced equalizer.

### Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the **Signal constellation** vector.

Set the **Reference tap** parameter so it is greater than zero and less than the value for the **Number of forward taps** parameter.

The port labeled `Equalized` outputs the result of the equalization process.

You can configure the block to have one or more of these extra ports:

- `Mode` input.
- `Err` output for the error signal, which is the difference between the `Equalized` output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- `Weights` output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see “Equalization”.

## Equalizer Delay

For proper equalization, you should set the **Reference tap** parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer *output* is equal to

$$1 + (\text{Reference tap} - 1) / (\text{Number of samples per symbol})$$

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

### Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

### Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

**Number of samples per symbol**

The number of input samples for each symbol.

**Signal constellation**

A vector of complex numbers that specifies the constellation for the modulation.

**Reference tap**

A positive integer less than or equal to the number of forward taps in the equalizer.

**Step size**

The step size of the normalized LMS algorithm.

**Leakage factor**

The leakage factor of the normalized LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

**Bias**

The bias parameter of the normalized LMS algorithm, a nonnegative real number. This parameter is used to overcome difficulties when the algorithm's input signal is small.

**Initial weights**

A vector that concatenates the initial weights for the forward and feedback taps.

**Mode input port**

If you select this check box, the block has an input port that enables you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision directed, the mode should be 0. The equalizer will train for the length of the Desired signal. If the mode input is not present, the equalizer will train at the beginning of every frame for the length of the Desired signal.

**Output error**

If you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

**Output weights**

If you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

## Normalized LMS Linear Equalizer

(To be removed) Equalize using linear equalizer that updates weights with normalized LMS algorithm

## Library

Equalizers

---

**Note** will be removed in a future release. Use Linear Equalizer instead.

---

## Description

The Normalized LMS Linear Equalizer block uses a linear equalizer and the normalized LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the normalized LMS algorithm to update the weights, once per symbol. When you set the **Number of samples per symbol** parameter to 1, the block implements a symbol-spaced (i.e. T-spaced) equalizer and updates the filter weights once for each symbol. When you set the **Number of samples per symbol** parameter to a value greater than 1, the weights are updated once every  $N^{\text{th}}$  sample, for a  $T/N$ -spaced equalizer.

## Input and Output Signals

The **Input** port accepts a column vector input signal. The **Desired** port receives a training sequence with a length that is less than or equal to the number of symbols in the **Input** signal. Valid training symbols are those symbols listed in the **Signal constellation** vector.

Set the **Reference tap** parameter so it is greater than zero and less than the value for the **Number of taps** parameter.

The port labeled `Equalized` outputs the result of the equalization process.

You can configure the block to have one or more of these extra ports:

- `Mode` input.
- `Err` output for the error signal, which is the difference between the `Equalized` output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- `Weights` output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see “Equalization”.

## Equalizer Delay

For proper equalization, you should set the **Reference tap** parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer *output* is equal to

$$1 + (\text{Reference tap} - 1) / (\text{Number of samples per symbol})$$

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap.

## Parameters

### Number of taps

The number of taps in the filter of the linear equalizer.

### Number of samples per symbol

The number of input samples for each symbol.

**Signal constellation**

A vector of complex numbers that specifies the constellation for the modulation.

**Reference tap**

A positive integer less than or equal to the number of taps in the equalizer.

**Step size**

The step size of the normalized LMS algorithm.

**Leakage factor**

The leakage factor of the normalized LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

**Bias**

The bias parameter of the normalized LMS algorithm, a nonnegative real number. This parameter is used to overcome difficulties when the algorithm's input signal is small.

**Initial weights**

A vector that lists the initial weights for the taps.

**Mode input port**

When you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision directed, the mode should be 0. For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

**Output error**

If you check this box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

**Output weights**

If you check this box, the block outputs the current weights.

## OFDM Demodulator Baseband

Demodulate orthogonal frequency division modulated data

### Library

OFDM, in Digital Baseband sublibrary of Modulation

### Description

The Orthogonal Frequency Division Modulation (OFDM) Demodulator Baseband block demodulates an OFDM input signal. The block accepts a single input and has one or two output ports, depending on the status of **Pilot output port**.

### Signal Dimensions

Pilot Output Port	Pilot Carrier Indices	Signal Input	Signal Output	Pilot Output
false	N/A	$N_{CPTotal}$	$N_{data}$ -by- $N_{sym}$ -by- $N_r$	N/A
true	2-D	$+ N_{FFT} \times N_{sym}$ -by- $N_r$	$N_r$	$N_{pilot}$ -by- $N_{sym}$ -by- $N_r$
	3-D			$N_{pilot}$ -by- $N_{sym}$ -by- $N_t$ -by- $N_r$

where

- $N_{CP}$  represents the cyclic prefix length as determined by **Cyclic prefix length**.

- $N_{\text{CPTotal}}$  represents the cyclic prefix length over all the symbols. When  $N_{\text{CP}}$  is a scalar,  $N_{\text{CPTotal}} = N_{\text{CP}} \times N_{\text{sym}}$ . When  $N_{\text{CP}}$  is a row vector,  $N_{\text{CPTotal}} = \sum N_{\text{CP}}$ .
- $N_{\text{FFT}}$  represents the number of subcarriers as determined by **FFT length**.
- $N_{\text{sym}}$  represents the number of symbols as determined by **Number of OFDM symbols**.
- $N_{\text{r}}$  represents the number of receive antennas as determined by **Number of receive antennas**.
- $N_{\text{data}}$  represents the number of data subcarriers. For further information on how  $N_{\text{data}}$  is determined, see the `info` reference page.
- $N_{\text{pilot}}$  represents the number of pilot symbols determined by the second dimension in the **Pilot subcarrier indices** array.
- $N_{\text{t}}$  represents the number of transmit antennas. This parameter is derived from the third dimension of the **Pilot subcarrier indices** array.

## Parameters

### FFT Length

Specify the FFT length, which is equivalent to the number of subcarriers. The length of the FFT,  $N_{\text{FFT}}$ , must be greater than or equal to 8.

### Number of guard bands

Assign the number of subcarriers to the left,  $N_{\text{leftG}}$ , and right,  $N_{\text{rightG}}$ , guard bands. The input is a 2-by-1 vector. The number of subcarriers must fall within  $[0, N_{\text{FFT}}/2 - 1]$ .

### Remove DC carrier

Select to remove the DC subcarrier.

### Pilot output port

Select to separate the data from the pilot signal and output the demodulated pilot signal.

### Pilot subcarrier indices

Specify the pilot subcarrier indices. This field is available only when the **Pilot output port** check box is selected. You can assign the indices can be assigned to the same or different subcarriers for each symbol. Similarly, the pilot carrier indices can differ across multiple transmit antennas. Depending on the desired level of control for index assignments, the dimensions of the indices' array vary from 1 to 3. Valid pilot indices fall in the range

$$[N_{\text{leftG}} + 1, N_{\text{FFT}}/2] \cup [N_{\text{FFT}}/2 + 2, N_{\text{FFT}} - N_{\text{rightG}}],$$

where the index value cannot exceed the number of subcarriers. If the number of transmit antennas is greater than one, ensure that the indices per symbol are mutually distinct across antennas to minimize interference.

### Cyclic prefix length

Specify the length of the cyclic prefix. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length  $N_{\text{sym}}$ , the prefix length can vary across symbols but remains the same length through all antennas.

### Number of OFDM symbols

Specify the number of OFDM symbols,  $N_{\text{sym}}$ , in the time-frequency grid.

### Number of receive antennas

Specify the number of receive antennas,  $N_r$ , as a positive integer such that  $N_r \leq 64$ .

### Simulate using

Select the simulation type from these choices:

- Code generation
- Interpreted execution

## Algorithms

This block implements the algorithm, inputs, and outputs described in the [OFDM Demodulator System](#) object reference page. The object properties correspond to the block parameters.

## Supported Data Types

Port	Supported Data Types

## OFDM Modulator Baseband

Modulate using orthogonal frequency division modulation

### Library

OFDM, in Digital Baseband sublibrary of Modulation

### Description

The OFDM Modulator Baseband block applies OFDM modulation to an incoming data signal. The block accepts one or two inputs depending on the state of the **Pilot input port**.

### Signal Dimensions

Pilot Input Port	Signal Input	Pilot Input	Signal Output
false	$N_{\text{data}}\text{-by-}N_{\text{sym}}\text{-by-}N_{\text{t}}$	N/A	$N_{\text{CPTotal}} + N_{\text{FFT}} \times N_{\text{sym}}\text{-by-}N_{\text{t}}$
true		$N_{\text{pilot}}\text{-by-}N_{\text{sym}}\text{-by-}N_{\text{t}}$	

where

- $N_{\text{data}}$  represents the number of data subcarriers. For further information on how  $N_{\text{data}}$  is determined, see the `info` reference page.
- $N_{\text{sym}}$  represents the number of symbols determined by **Number of OFDM symbols**.
- $N_{\text{t}}$  represents the number of transmit antennas determined by **Number of transmit antennas**.

- $N_{\text{pilot}}$  represents the number of pilot symbols determined by the first dimension size in the **Pilot subcarrier indices** array.
- $N_{\text{CP}}$  represents the cyclic prefix length as determined by **Cyclic prefix length**.
- $N_{\text{CPTotal}}$  represents the cyclic prefix length over all the symbols. When  $N_{\text{CP}}$  is a scalar,  $N_{\text{CPTotal}} = N_{\text{CP}} \times N_{\text{sym}}$ . When  $N_{\text{CP}}$  is a row vector,  $N_{\text{CPTotal}} = \sum N_{\text{CP}}$ .
- $N_{\text{FFT}}$  represents the number of subcarriers as determined by **FFT length**.

## Parameters

### FFT Length

Specify the FFT length, which is equivalent to the number of subcarriers. The length of the FFT,  $N_{\text{FFT}}$ , must be greater than or equal to 8.

### Number of guard bands

Assign the number of subcarriers to the left and right guard bands. The input is a 2-by-1 vector. The number of subcarriers must fall within  $[0, N_{\text{FFT}}/2 - 1]$ .

### Insert DC null

Select to insert a null on the DC subcarrier.

### Pilot input port

Select to allow the specifying of pilot subcarrier indices.

### Pilot subcarrier indices

Specify the pilot subcarrier indices. This field is available only when the **Pilot input port** check box is selected. You can assign the indices to the same or different subcarriers for each symbol. Similarly, the pilot carrier indices can differ across multiple transmit antennas. Depending on the desired level of control for index assignments, the dimensions of the indices array vary. Valid pilot indices fall in the range

$$[N_{\text{leftG}} + 1, N_{\text{FFT}}/2] \cup [N_{\text{FFT}}/2 + 2, N_{\text{FFT}} - N_{\text{rightG}}],$$

where the index value cannot exceed the number of subcarriers. When the pilot indices are the same for every symbol and transmit antenna, the property has dimensions  $N_{\text{pilot}}$ -by-1. When the pilot indices vary across symbols, the property has dimensions of  $N_{\text{pilot}}$ -by- $N_{\text{sym}}$ . If there is only one symbol but multiple transmit antennas, the property has dimensions of  $N_{\text{pilot}}$ -by-1-by- $N_t$ . If the indices vary across the number of symbols and transmit antennas, the property will have dimensions of

$N_{\text{pilot}}$ -by- $N_{\text{sym}}$ -by- $N_t$ . If the number of transmit antennas is greater than one, ensure that the indices per symbol are mutually distinct across antennas to minimize interference. The default value is [12; 26; 40; 54].

**Cyclic prefix length**

Specify the length of the cyclic prefix. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length  $N_{\text{sym}}$ , the prefix length can vary across symbols but remains the same through all antennas.

**Apply raised cosine windowing between OFDM symbols**

Select to apply raised cosine windowing. Windowing is the process in which the OFDM symbol is multiplied by a raised cosine window before transmission to reduce the power of out-of-band subcarriers, which serves to reduce spectral regrowth.

**Window length**

Set the length of the raised cosine window. The field is available only when **Apply raised cosine windowing between OFDM symbols** is selected. Use positive integers having a maximum value no greater than the minimum cyclic prefix length. For example, in a configuration in which there are four symbols with cyclic prefix lengths of [12 16 14 18], the window length cannot exceed 12.

**Number of OFDM symbols**

Specify the number of OFDM symbols in the time-frequency grid.

**Number of transmit antennas**

Specify the number of transmit antennas,  $N_t$ , as a positive integer such that  $N_t \leq 64$ .

**Simulate using**

Select the simulation type from these choices:

- Code generation
- Interpreted execution

## Algorithms

This block implements the algorithm, inputs, and outputs described in the **OFDM Modulator System** object reference page. The object properties correspond to the block parameters.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> </ul>
Pilot (optional)	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> </ul>

# OQPSK Demodulator Baseband

Demodulation using OQPSK method

**Library:** Communications Toolbox / Modulation / Digital Baseband Modulation / PM

## Description

The OQPSK Demodulator Baseband block applies pulse shape filtering to the input waveform and demodulates it using the offset quadrature phase shift keying (OQPSK) method. For more information, see “Pulse Shaping Filter” on page 3-848. The input is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 3-846.

## Ports

### Input

#### In — Input baseband waveform

scalar | column vector

Input baseband waveform, specified as a discrete-time complex scalar or column vector.

The block processes the input signal based on the Output type setting.

Data Types: double

Complex Number Support: Yes

### Output

#### Out — Output data

integer column vector | bit column vector

Output data, returned as an integer or bit column vector.

## Parameters

### Modulation

#### **Output type — Output type**

Integer (default) | Bit

Output type, specified as Integer or Bit.

- When you set **Output type** to Integer, the block outputs a vector of integer symbols with values from 0 to 3, the length of which is the number of output symbols.
- When you set **Output type** to Bit, the block outputs a 2-bit binary representation of integers, in a binary-valued, even-length vector.

The input period for each integer or bit pair is the Samples per symbol times the output sample period.

#### **Phase offset (rad) — Phase of zeroth point of signal constellation**

0 (default) | scalar

Phase of zeroth point of the signal constellation in radians, specified as a scalar.

Example: Setting **Phase offset (rad)** to 0 aligns the OQPSK signal constellation points on the axes,  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

#### **Symbol mapping — Signal constellation bit mapping**

Gray (default) | Binary | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as Gray, Binary, or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr><td>1</td><td>0</td></tr> <tr><td>3</td><td>2</td></tr> </table>	1	0	3	2	<table border="1"> <tr><td>01</td><td>00</td></tr> <tr><td>11</td><td>10</td></tr> </table>	01	00	11	10	The signal constellation mapping is Gray-encoded.

## Filtering

### Pulse shape — Filtering pulse shape

Half sine (default) | Normal raised cosine | Root raised cosine | Custom

Select the filtering pulse shape: Half sine, Normal raised cosine, Root raised cosine, or Custom.

### Rolloff factor — Raised cosine filter rolloff factor

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1.

### Dependencies

This property appears when Pulse shape is Normal raised cosine or Root raised cosine.

Data Types: double

**Filter span (in symbols) — Filter length**

10 (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to **Filter span (in symbols)** symbols.

**Dependencies**

This property appears when Pulse shape is Normal raised cosine or Root raised cosine.

Data Types: double

**Filter numerator — Filter numerator**

[0.7071 0.7071] (default) | row vector

Filter numerator, specified as a row vector.

**Dependencies**

This parameter appears when Pulse shape is Custom.

Data Types: double

**Samples per symbol — Number of samples per symbol**

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

**Other Parameters****Rate options — Processing rate option**

Enforce single-rate processing (default) | Allow multirate processing

- **Enforce single-rate processing** — Executes the model, ensuring that the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. For integer outputs, the output width equals 1/Samples per symbol times the input width.

For more information, see Single-Rate Processing with OQPSK Demodulator Block.

- **Allow multirate processing** — Executes the model, allowing the input and output signals to have different port sample times. The output symbol time is Samples per symbol times the input sample time.

For more information, see Multirate Processing with OQPSK Demodulator Block.

### Output data type — Output data type

double (default) | single | uint8

Select the output data type: double, single, or uint8.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### OQPSK Signal Flow Diagram

Every Samples per symbol input samples produce one output symbol. In this figure, the dotted line represents the region comprising the input sample processing.

### Modulation Delays

Digital modulation and demodulation blocks incur delays between their inputs and outputs that result in an offset in the arrival time of the received data. Data that enters a modulation or demodulation block at time  $T$  appears in the output at time  $T + \text{delay}$ . Take system delays into account when comparing transmitted data with received data, such as in overlaid plots or when computing error statistics. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter, input/output data setting, and simulation configuration.

	true (multitasking)	Integer	$2*\text{length}(\text{data}) + \mathbf{Filter\ span\ (in\ symbols) + 2}$	
		Bit	$2*\text{length}(\text{data}) + \mathbf{2*Filter\ span\ (in\ symbols) + 4}$	
(*) The data type parameter is <b>Input type</b> for modulation and <b>Output type</b> for demodulation.				

### **Pulse Shaping Filter**

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

# OQPSK Modulator Baseband

Modulation using OQPSK method

**Library:** Communications Toolbox / Modulation / Digital  
Baseband Modulation / PM

## Description

The OQPSK Modulator Baseband block modulates the input signal using the offset quadrature phase shift keying (OQPSK) method and applies pulse shape filtering to the waveform. For more information, see “Pulse Shaping Filter” on page 3-855. The output is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 3-853.

## Ports

### Input

#### In — Input data

integer column vector | bit column vector

Input data, specified as an integer or bit column vector.

The input signal is processed based on the setting selected for Input type.

Data Types: double

### Output

#### Out — Output baseband waveform

column vector

Output baseband waveform, returned as a column vector of complex data.

## Parameters

### Modulation

#### **Input type — Input type**

Integer (default) | Bit

Input type, specified as Integer or Bit.

- When you set **Input type** to Integer, the input can be a scalar value or column vector, the length of which is the number of input symbols.
- When you set **Input type** to Bit, the input width must be an integer multiple of two.

The output sample period is the period of each integer or bit pair in the input divided by Samples per symbol.

#### **Phase offset (rad) — Phase of zeroth point of signal constellation**

0 (default) | scalar

Phase of zeroth point of the signal constellation in radians, specified as a scalar.

Example: Setting **Phase offset (rad)** to 0 aligns the OQPSK signal constellation points on the axes,  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

#### **Symbol mapping — Signal constellation bit mapping**

Gray (default) | Binary | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as Gray, Binary, or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr> <td>1</td> <td>0</td> </tr> <tr> <td>3</td> <td>2</td> </tr> </table>	1	0	3	2	<table border="1"> <tr> <td>01</td> <td>00</td> </tr> <tr> <td>11</td> <td>10</td> </tr> </table>	01	00	11	10	The signal constellation mapping is Gray-encoded.

c	d										
de2bi(b)	de2bi(a)										
de2bi(c)	de2bi(d)										

## Filtering

### Pulse shape — Filtering pulse shape

Half sine (default) | Normal raised cosine | Root raised cosine | Custom

Select the filtering pulse shape: Half sine, Normal raised cosine, Root raised cosine, or Custom.

### Rolloff factor — Raised cosine filter rolloff factor

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar in the range [0, 1].

### Dependencies

This property appears when Pulse shape is Normal raised cosine or Root raised cosine.

Data Types: double

**Filter span (in symbols) — Filter length**

10 (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to **Filter span (in symbols)** symbols.

**Dependencies**

This property appears when Pulse shape is Normal raised cosine or Root raised cosine.

Data Types: double

**Filter numerator — Filter numerator**

[0.7071 0.7071] (default) | row vector

Filter numerator, specified as a row vector.

**Dependencies**

This parameter appears when Pulse shape is Custom.

Data Types: double

**Samples per symbol — Number of samples per symbol**

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

**Other Parameters****Rate options — Processing rate option**

Enforce single-rate processing (default) | Allow multirate processing

- **Enforce single-rate processing** — Executes the model, ensuring that the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. For integer inputs, the output width equals Samples per symbol times the number of symbols.

For more information, see Single-Rate Processing with OQPSK Modulator Block.

- **Allow multirate processing** — Executes the model, allowing the input and output signals to have different port sample times. The output sample time equals the symbol period divided by Samples per symbol.

For more information, see Single-Rate Processing with OQPSK Modulator Block.

### Output data type — Output data type

`double` (default) | `single`

Select the output data type: `double` or `single`.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### Modulation Delays

Digital modulation and demodulation blocks incur delays between their inputs and outputs that result in an offset in the arrival time of the received data. Data that enters a modulation or demodulation block at time  $T$  appears in the output at time  $T + \text{delay}$ . Take system delays into account when comparing transmitted data with received data, such as in overlaid plots or when computing error statistics. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter, input/output data setting, and simulation configuration.

Pulse Shape	Rate Options	Treat Each Discrete Rate as a Separate Task?	Input/Output Data (*)	End-to-End Delay Incurred by an OQPSK Modulator-Demodulator Block Pair (in samples)

# OSTBC Combiner

Combine inputs for received signals and channel estimate according to orthogonal space-time block code (OSTBC)

## Library

MIMO

## Description

The OSTBC Combiner block combines the input signal (from all of the receive antennas) and the channel estimate signal to extract the soft information of the symbols that were encoded using an OSTBC. The input channel estimate may not be constant during each codeword block transmission and the combining algorithm uses only the estimate for the first symbol period per codeword block. A symbol demodulator or decoder would follow the Combiner block in a MIMO communications system.

The block conducts the combining operation for each symbol independently. The combining algorithm depends on the structure of the OSTBC. For more information, see the OSTBC Combining Algorithms on page 3-859 section of this help page.

## Dimension

Along with the time and spatial domains for OSTBC transmission, the block supports an optional dimension, over which the combining calculation is independent. This dimension can be thought of as the frequency domain for OFDM-based applications. The following illustration indicates the supported dimensions for inputs and output of the OSTBC Combiner block.

The following table describes each variable for the block.

Variable	Description
F	The additional dimension; typically the frequency dimension. The combining calculation is independent of this dimension.
N	Number of transmit antennas.
M	Number of receive antennas.
T	Output symbol sequence length in time domain.
R	Symbol rate of the code.

**Note** On the two inputs, T/R is the symbol sequence length in the time domain.

$F$  can be any positive integers.  $M$  can be 1 through 8, indicated by the **Number of receive antennas** parameter.  $N$  can be 2, 3 or 4, indicated by the **Number of transmit antennas** parameter. The time domain length T/R must be a multiple of the codeword block length (2 for Alamouti; 4 for all other OSTBC). For  $N = 2$ , T/R must be a multiple of 2. When  $N > 2$ , T/R must be a multiple of 4.  $R$  defaults to 1 for 2 antennas.  $R$  can be either  $\frac{3}{4}$  or  $\frac{1}{2}$  for more than 2 antennas.

The supported dimensions for the block depend upon the values of  $F$  and  $M$ . For one receive antenna ( $M = 1$ ), the received signal input must be a column vector or a full 2-D matrix, depending on the value for  $F$ . The corresponding channel estimate input must be a full 2-D or 3-D matrix.

For more than one receive antenna ( $M > 1$ ), the received signal input must be a full 2-D or 3-D matrix, depending on the value for  $F$ . Correspondingly, the channel estimate input must be a 3-D or 4-D matrix, depending on the value for  $F$ .

To understand the block's dimension propagation, refer to the following table.

	<b>Input 1 (Received Signal)</b>	<b>Input 2 (Channel Estimate)</b>	<b>Output</b>
$F = 1$ and $M = 1$	Column vector	2-D	Column vector
$F = 1$ and $M > 1$	2-D	3-D	Column vector
$F > 1$ and $M = 1$	2-D	3-D	2-D
$F > 1$ and $M > 1$	3-D	4-D	2-D

## Data Type

For information about the data types each block port supports, see the “Supported Data Type” on page 3-865 table on this page. The output signal inherits the data type from the inputs. The block supports different fixed-point properties for the two inputs. For fixed-point signals, the output word length and fractional length depend on the block’s mask parameter settings. See Fixed-Point Signals for more information about fixed-point data propagation of this block.

## Frames

The output inherits the frameness of the received signal input. For either column vector or full 2-D matrix input signal, the input can be either frame-based or sample-based. A 3-D or 4-D matrix input signal must have sample-based input.

## OSTBC Combining Algorithms

The OSTBC Combiner block supports five different OSTBC combining computation algorithms. Depending on the selection for **Rate** and **Number of transmit antennas**, you can select one of the algorithms shown in the following table.

Transmit Antenna	Rate	Computational Algorithm per Codeword Block Length
2	1	$\begin{pmatrix} \widehat{s}_1 \\ \widehat{s}_2 \end{pmatrix} = \frac{1}{\ H\ ^2} \sum_{j=1}^M \begin{pmatrix} h_{1,j}^* r_{1,j} + h_{2,j} r_{2,j}^* \\ h_{2,j}^* r_{1,j} - h_{1,j} r_{2,j}^* \end{pmatrix}.$
3	1/2	$\begin{pmatrix} \widehat{s}_1 \\ \widehat{s}_2 \end{pmatrix} = \frac{1}{\ H\ ^2} \sum_{j=1}^M \begin{pmatrix} h_{1,j}^* r_{1,j} + h_{2,j} r_{2,j}^* + h_{3,j}^* r_{3,j} \\ h_{2,j}^* r_{1,j} - h_{1,j} r_{2,j}^* - h_{3,j} r_{4,j}^* \end{pmatrix}.$
3	3/4	$\begin{pmatrix} \widehat{s}_1 \\ \widehat{s}_2 \\ \widehat{s}_3 \end{pmatrix} = \frac{1}{\ H\ ^2} \sum_{j=1}^M \begin{pmatrix} h_{1,j}^* r_{1,j} + h_{2,j} r_{2,j}^* - h_{3,j} r_{3,j}^* \\ h_{2,j}^* r_{1,j} - h_{1,j} r_{2,j}^* - h_{3,j} r_{4,j}^* \\ h_{3,j}^* r_{1,j} + h_{1,j} r_{3,j}^* + h_{2,j} r_{4,j}^* \end{pmatrix}.$
4	1/2	$\begin{pmatrix} \widehat{s}_1 \\ \widehat{s}_2 \end{pmatrix} = \frac{1}{\ H\ ^2} \sum_{j=1}^M \begin{pmatrix} h_{1,j}^* r_{1,j} + h_{2,j} r_{2,j}^* + h_{3,j}^* r_{3,j} + h_{4,j} r_{4,j}^* \\ h_{2,j}^* r_{1,j} - h_{1,j} r_{2,j}^* + h_{4,j}^* r_{3,j} - h_{3,j} r_{4,j}^* \end{pmatrix}.$
4	3/4	$\begin{pmatrix} \widehat{s}_1 \\ \widehat{s}_2 \\ \widehat{s}_3 \end{pmatrix} = \frac{1}{\ H\ ^2} \sum_{j=1}^M \begin{pmatrix} h_{1,j}^* r_{1,j} + h_{2,j} r_{2,j}^* - h_{3,j} r_{3,j}^* - h_{4,j} r_{4,j}^* \\ h_{2,j}^* r_{1,j} - h_{1,j} r_{2,j}^* + h_{4,j}^* r_{3,j} - h_{3,j} r_{4,j}^* \\ h_{3,j}^* r_{1,j} + h_{4,j}^* r_{2,j} + h_{1,j} r_{3,j}^* + h_{2,j} r_{4,j}^* \end{pmatrix}.$

$\widehat{s}_k$  represents the estimated  $k$ th symbol in the OSTBC codeword matrix.  $h_{ij}$  represents the estimate for the channel from the  $i$ th transmit antenna and the  $j$ th receive antenna. The values of  $i$  and  $j$  can range from 1 to  $N$  (the number of transmit antennas) and to  $M$  (the number of receive antennas) respectively.  $r_{lj}$  represents the  $l$ th symbol at the  $j$ th receive antenna per codeword block. The value of  $l$  can range from 1 to the codeword block length.  $\|H\|^2$  represents the summation of channel power per link, i.e.,

$$\|H\|^2 = \sum_{i=1}^N \sum_{j=1}^M \|h_{ij}\|^2$$

### Fixed-Point Signals

Use the following formula for  $\widehat{s}_1$  for Alamouti code with 1 receive antenna to highlight the data types used for fixed-point signals.

$$\widehat{s}_1 = \frac{h_{1,1}^* r_{1,1} + h_{2,1} r_{2,1}^*}{\|H\|^2} = \frac{h_{1,1}^* r_{1,1} + h_{2,1} r_{2,1}^*}{h_{1,1} h_{1,1}^* + h_{2,1} h_{2,1}^*}$$

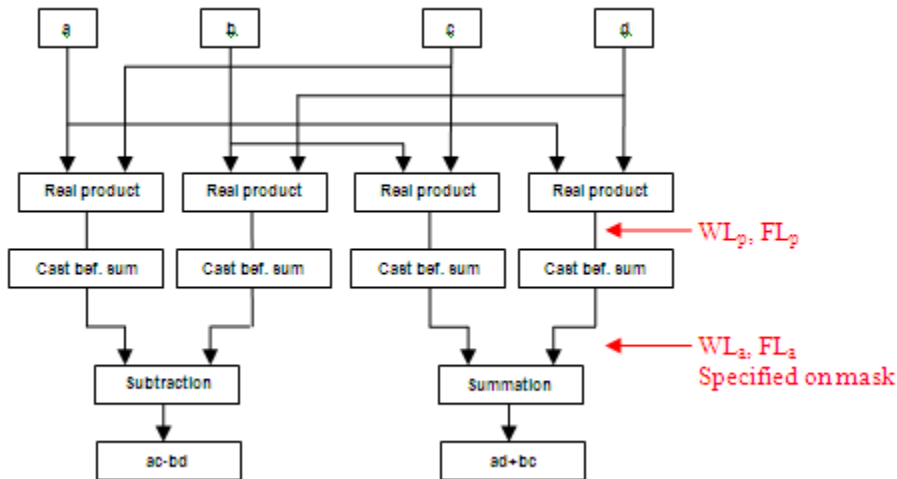

In this equation, the data types for **Product output** and **Accumulator** correspond to the product and summation in the numerator. Similarly, the types for **Energy product output** and **Energy accumulator** correspond to the product and summation in the denominator.

### Signal Flow Diagram for $s_1$ Combining Calculation of Alamouti Code with One Receive Antenna

The following formula shows the data types used within the OSTBC Combiner block for fixed-point signals for more than one receive antenna for Alamouti code, where  $M$  represents the number of receive antennas.

$$\hat{s}_1 = \frac{h_{1,1}^* r_{1,1} + h_{2,1} r_{2,1}^* + h_{1,2}^* r_{1,2} + h_{2,2} r_{2,2}^* + \dots + h_{1,M}^* r_{1,M} + h_{2,M} r_{2,M}^*}{h_{1,1} h_{1,1}^* + h_{2,1} h_{2,1}^* + h_{1,2} h_{1,2}^* + h_{2,2} h_{2,2}^* + \dots + h_{1,M} h_{1,M}^* + h_{2,M} h_{2,M}^*}$$

### Signal Flow Diagram for Complex Multiply of $a + ib$ and $c + id$

For Binary point scaling, you cannot specify  $WL_p$  and  $FL_p$ . Instead, the blocks determine these values implicitly from  $WL_a$  and  $FL_a$

The Internal Rule for **Product output** and **Energy product output** are:

- When you select **Inherit** via internal rule, the internal rule (DSP System Toolbox) determines  $WL_p$  and  $FL_p$ . Therefore,  $WL_a = WL_p + 1$  and  $FL_a = FL_p$
- For Binary point scaling, you specify  $WL_a$  and  $FL_a$ . Therefore,  $WL_p = WL_a - 1$  and  $FL_a = FL_p$ .

For information on how the Internal Rule applies to the **Accumulator** and **Energy Accumulator**, see **Inherit via Internal Rule** (DSP System Toolbox).

## Parameters

### Number of transmit antennas

Sets the number of transmit antennas. The block supports 2, 3, or 4 transmit antennas. This value defaults to 2.

**Rate**

Sets the symbol rate of the code. You can specify either 3/4 or 1/2. This field only appears when you use more than 2 transmit antennas. This field defaults to  $\frac{3}{4}$  for more than 2 transmit antennas. For 2 transmit antennas, there is no rate option and the implicit (default) rate defaults to 1.

**Number of receive antennas**

The number of antennas the block uses to receive signal streams. The block supports from 1 to 8 receive antennas. This value defaults to 1.

**Rounding mode**

Sets the rounding mode for fixed-point calculations. The block uses the rounding mode if a value cannot be represented exactly by the specified data type and scaling. When this occurs, the value is rounded to a representable number. For more information refer to Rounding (Fixed-Point Designer).

**Saturate on integer overflow**

Sets the overflow mode for fixed-point calculations. Use this parameter to specify the method to be used if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result. For more information refer to Precision and Range (DSP System Toolbox).

**Product Output**

Complex product in the numerator for the diversity combining. For more information refer to the Fixed-Point Signals section of this help page.

**Accumulator**

Summation in the numerator for the diversity combining.

Fixed-point Communications Toolbox blocks that must hold summation results for further calculation usually allow you to specify the data type and scaling of the accumulator. Most such blocks cast to the accumulator data type prior to summation:

Use the **Accumulator—Mode** parameter to specify how you would like to designate the accumulator word and fraction lengths:

- When you select **Inherit via internal rule**, the accumulator output word and fraction lengths are automatically calculated for you. Refer to **Inherit via Internal Rule** (DSP System Toolbox) for more information.
- When you select **Same as product output**, these characteristics match those of the product output.
- When you select **Same as input**, these characteristics match those of the first input to the block.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the accumulator. The bias of all signals in DSP System Toolbox software is zero.

### Energy product output

Complex product in the denominator for calculating total energy in the MIMO channel .

### Energy accumulator

Summation in the denominator for calculating total energy in the MIMO channel.

### Division output

Normalized diversity combining by total energy in the MIMO channel.

## Supported Data Type

Port	Supported Data Types
Rx	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed Fixed-point</li> </ul>
cEst	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed Fixed-point</li> </ul>
Out	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed Fixed-point</li> </ul>

## Examples

For an example of this block in use, see OSTBC Over 3x2 Rayleigh Fading Channel. The model shows the use of a rate  $\frac{3}{4}$  OSTBC for 3 transmit and 2 receive antennas with BPSK modulation using independent fading links and AWGN.

You can also see the block in the Concatenated OSTBC with TCM example by typing `commtcmstbc` at the MATLAB command line.

## Extended Capabilities

## See Also

### Blocks

OSTBC Encoder

**Introduced in R2009a**

# OSTBC Encoder

Encode input message using orthogonal space-time block code (OSTBC)

## Library

MIMO

## Description

The OSTBC Encoder block encodes an input symbol sequence using orthogonal space-time block code (OSTBC). The block maps the input symbols block-wise and concatenates the output codeword matrices in the time domain. For more information, see the OSTBC Encoding Algorithms on page 3-869 section of this help page.

## Dimension

The block supports time and spatial domains for OSTBC transmission. It also supports an optional dimension, over which the encoding calculation is independent. This dimension can be thought of as the frequency domain. The following illustration indicates the supported dimensions for the inputs and output of the OSTBC Encoder block.

The following table describes the variables.

Variable	Description
F	The additional dimension; typically the frequency domain. The encoding does not depend on this dimension.
T	Input symbol sequence length for the time domain.
R	Symbol rate of the code.
N	Number of transmit antennas.

---

**Note** On the output,  $T/R$  is the symbol sequence length in time domain.

---

$F$  can be any positive integer.  $N$  can be 2, 3 or 4, indicated by **Number of transmit antennas**. For  $N = 2$ ,  $R$  must be 1. For  $N = 3$  or 4,  $R$  can be  $3/4$  or  $1/2$ , indicated by **Rate**. The time domain length  $T$  must be a multiple of the number of symbols in each codeword matrix. Specifically, for  $N = 2$  or  $R = 1/2$ ,  $T$  must be a multiple of 2 and when  $R = 3/4$ ,  $T$  must be a multiple of 3.

To understand the block’s dimension propagation, refer to the following table.

Dimension	Input	Output
$F = 1$	Column vector	2-D
$F > 1$	2-D	3-D

## Data Type

For information about the data types each block port supports, see the “Supported Data Type” on page 3-871 table on this page. The output signal inherits the data type from the input signal. For fixed-point signals, the complex conjugation may cause overflows which the fixed-point parameter **Saturate on integer overflow** must handle.

## Frames

The output signal inherits frame type from the input signal. A column vector input requires either frame-based or sample-based input; otherwise, the input must be sample-based.

## OSTBC Encoding Algorithms

The OSTBC Encoder block supports five different OSTBC encoding algorithms. Depending on the selection for **Rate** and **Number of transmit antennas**, the block implements one of the algorithms in the following table:

Transmit Antenna	Rate	OSTBC Codeword Matrix
2	1	$\begin{pmatrix} s_1 & s_2 \\ -s_2^* & s_1^* \end{pmatrix}$
3	1/2	$\begin{pmatrix} s_1 & s_2 & 0 \\ -s_2^* & s_1^* & 0 \\ 0 & 0 & s_1 \\ 0 & 0 & -s_2^* \end{pmatrix}$
3	3/4	$\begin{pmatrix} s_1 & s_2 & s_3 \\ -s_2^* & s_1^* & 0 \\ s_3^* & 0 & -s_1^* \\ 0 & s_3^* & -s_2^* \end{pmatrix}$
4	1/2	$\begin{pmatrix} s_1 & s_2 & 0 & 0 \\ -s_2^* & s_1^* & 0 & 0 \\ 0 & 0 & s_1 & s_2 \\ 0 & 0 & -s_2^* & s_1^* \end{pmatrix}$

Transmit Antenna	Rate	OSTBC Codeword Matrix
4	3/4	$\begin{pmatrix} s_1 & s_2 & s_3 & 0 \\ -s_2^* & s_1^* & 0 & s_3 \\ s_3^* & 0 & -s_1^* & s_2 \\ 0 & s_3^* & -s_2^* & -s_1 \end{pmatrix}$

In each matrix, its  $(l, i)$  entry indicates the symbol transmitted from the  $i$ th antenna in the  $l$ th time slot of the block. The value of  $i$  can range from 1 to  $N$  (the number of transmit antennas). The value of  $l$  can range from 1 to the codeword block length.

## Parameters

### Number of transmit antennas

Sets the number of antennas at the transmitter side. The block supports 2, 3, or 4 transmit antennas. The value defaults to 2.

### Rate

Sets the symbol rate of the code. You can specify either 3/4 or 1/2. This field only appears when using more than 2 transmit antennas. This field defaults to  $\frac{3}{4}$  for more than 2 transmit antennas. For 2 transmit antennas, there is no rate option and the rate defaults to 1.

### Saturate on integer overflow

Sets the overflow mode for fixed-point calculations. Use this parameter to specify the method to be used if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result. For more information refer to “Precision and Range” (DSP System Toolbox).

## Supported Data Type

Port	Supported Data Types
In	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed Fixed-point</li> </ul>
Out	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed Fixed-point</li> </ul>

## Examples

For an example of this block in use, see “OSTBC Over 3x2 Rayleigh Fading Channel” . The model shows the use of a rate  $\frac{3}{4}$  OSTBC for 3 transmit and 2 receive antennas with BPSK modulation using independent fading links and AWGN

You can also see the block in the Concatenated OSTBC with TCM example by typing `commtcmstbc` at the MATLAB command line.

## OVSF Code Generator

Generate orthogonal variable spreading factor (OVSF) code from set of orthogonal codes

### Library

Spreading Codes

### Description

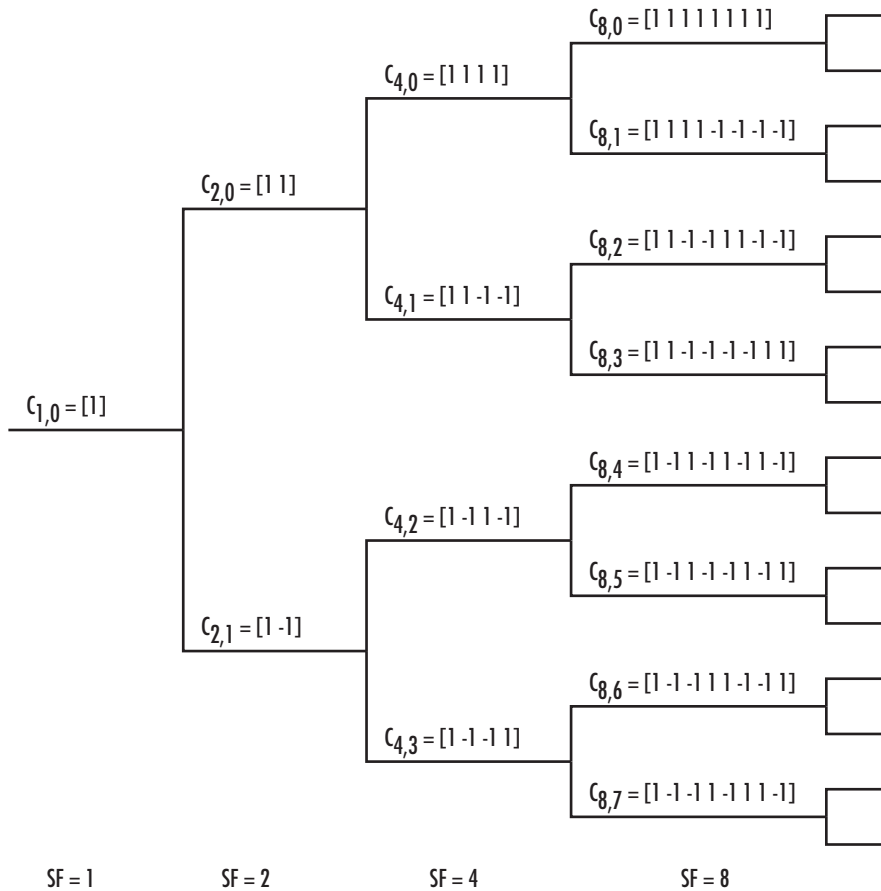

The OVSF Code Generator block generates an OVSF code from a set of orthogonal codes. OVSF codes were first introduced for 3G communication systems. OVSF codes are primarily used to preserve orthogonality between different channels in a communication system.

OVSF codes are defined as the rows of an  $N$ -by- $N$  matrix,  $C_N$ , which is defined recursively as follows. First, define  $C_1 = [1]$ . Next, assume that  $C_N$  is defined and let  $C_N(k)$  denote the  $k$ th row of  $C_N$ . Define  $C_{2N}$  by

$$C_{2N} = \begin{bmatrix} C_N(0) & C_N(0) \\ C_N(0) & -C_N(0) \\ C_N(1) & C_N(1) \\ C_N(1) & -C_N(1) \\ \dots & \dots \\ C_N(N-1) & C_N(N-1) \\ C_N(N-1) & -C_N(N-1) \end{bmatrix}$$

Note that  $C_N$  is only defined for  $N$  a power of 2. It follows by induction that the rows of  $C_N$  are orthogonal.

The OVSF codes can also be defined recursively by a tree structure, as shown in the following figure.

If  $[C]$  is a code length  $2^r$  at depth  $r$  in the tree, where the root has depth 0, the two branches leading out of  $C$  are labeled by the sequences  $[C C]$  and  $[C -C]$ , which have length  $2^{r+1}$ . The codes at depth  $r$  in the tree are the rows of the matrix  $C_N$ , where  $N = 2^r$ .

Note that two OVSF codes are orthogonal if and only if neither code lies on the path from the other code to the root. Since codes assigned to different users in the same cell must be orthogonal, this restricts the number of available codes for a given cell. For example, if the code  $C_{41}$  in the tree is assigned to a user, the codes  $C_{10}$ ,  $C_{20}$ ,  $C_{82}$ ,  $C_{83}$ , and so on, cannot be assigned to any other user in the same cell.

## Block Parameters

You specify the code the OVFS Code Generator block outputs by two parameters in the block's dialog: the **Spreading factor**, which is the length of the code, and the **Code index**, which must be an integer in the range  $[0, 1, \dots, N - 1]$ , where  $N$  is the spreading factor. If the code appears at depth  $r$  in the preceding tree, the **Spreading factor** is  $2^r$ . The **Code index** specifies how far down the column of the tree at depth  $r$  the code appears, counting from 0 to  $N - 1$ . For  $C_{N, k}$  in the preceding diagram,  $N$  is the **Spreading factor** and  $k$  is the **Code index**.

You can recover the code from the **Spreading factor** and the **Code index** as follows. Convert the **Code index** to the corresponding binary number, and then add 0s to the left, if necessary, so that the resulting binary sequence  $x_1 x_2 \dots x_r$  has length  $r$ , where  $r$  is the logarithm base 2 of the **Spreading factor**. This sequence describes the path from the root to the code. The path takes the upper branch from the code at depth  $i$  if  $x_i = 0$ , and the lower branch if  $x_i = 1$ .

To reconstruct the code, recursively define a sequence of codes  $C_i$  for as follows. Let  $C_0$  be the root [1]. Assuming that  $C_i$  has been defined, for  $i < r$ , define  $C_{i+1}$  by

$$C_{i+1} = \begin{cases} C_i C_i & \text{if } x_i = 0 \\ C_i(-C_i) & \text{if } x_i = 1 \end{cases}$$

The code  $C_N$  has the specified **Spreading factor** and **Code index**.

For example, to find the code with **Spreading factor** 16 and **Code index** 6, do the following:

- 1 Convert 6 to the binary number 110.
- 2 Add one 0 to the left to obtain 0110, which has length  $4 = \log_2 16$ .
- 3 Construct the sequences  $C_i$  according to the following table.

$i$	$x_i$	$C_i$
0		$C_0 = [1]$
1	0	$C_1 = C_0 C_0 = [1] [1]$
2	1	$C_2 = C_1 - C_1 = [1 \ 1] [-1 \ -1]$
3	1	$C_3 = C_2 - C_2 = [1 \ 1 \ -1 \ -1] [-1 \ -1 \ 1 \ 1]$
4	0	$C_4 = C_3 C_3 = [1 \ 1 \ -1 \ -1 \ -1 \ -1 \ 1 \ 1] [1 \ 1 \ -1 \ -1 \ -1 \ -1 \ 1 \ 1]$

The code  $C_4$  has **Spreading factor** 16 and **Code index** 6.

## Parameters

### Spreading factor

Positive integer that is a power of 2, specifying the length of the code.

### Code index

Integer in the range  $[0, 1, \dots, N - 1]$  specifying the code, where  $N$  is the **Spreading factor**.

### Sample time

The time between each sample of the output signal. Specify as a nonnegative real scalar.

### Samples per frame

The number of samples per frame in one column of the output signal. Specify as a positive integer scalar.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

---

### Output data type

The output type of the block can be specified as an `int8` or `double`. By default, the block sets this to `double`.

### Simulate using

Select the simulation mode.

#### Code generation

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is `Code generation`, System objects corresponding to the blocks accept a maximum of nine inputs.

Interpreted execution

Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

# Phase/Frequency Offset

Apply phase and frequency offsets to complex baseband signal

## Library

RF Impairments

## Description

The Phase/Frequency Offset block applies phase and frequency offsets to an incoming signal.

The block inherits its output data type from the input signal. If the input signal is  $u(t)$ , then the output signal is:

$$y(t) = u(t) \cdot \left( \cos\left(2\pi \int^t f(\tau) d\tau + \varphi(t)\right) + j \sin\left(2\pi \int^t f(\tau) d\tau + \varphi(t)\right) \right)$$

where

$f(t)$  = Frequency offset

$\varphi(t)$  = Phase offset

The discrete-time output is:

$$y(0) = u(0)(\cos(\varphi(0)) + j \sin(\varphi(0)))$$

$$y(i) = u(i) \left( \cos\left(2\pi \sum_{n=0}^{i-1} f(n)\Delta t + \varphi(i)\right) + j \sin\left(2\pi \sum_{n=0}^{i-1} f(n)\Delta t + \varphi(i)\right) \right) \quad i > 0$$

where

$\Delta t$  = Sample time

This block accepts real and complex inputs of data type `double` or `single`.

## Phase Offset

The block applies a phase offset to the input signal, specified by the **Phase offset** parameter.

## Frequency Offset

The block applies a frequency offset to the input signal, specified by the **Frequency offset** parameter. Alternatively, when you select **Frequency offset from port**, the `Frq` input port provides the offset to the block. The frequency offset must be a scalar value, vector with the same number of rows or columns as the data input, or a matrix with the same size as the data input. For more information, see “Interdependent Parameter-Port Dimensions” on page 3-880.

The effects of changing the block's parameters are illustrated by the following scatter plots of a signal modulated by 16-ary quadrature amplitude modulation (QAM). The usual 16-ary QAM constellation without the effect of the Phase/Frequency Offset block is shown in the first scatter plot:

The following figure shows a scatter plot of an output signal, modulated by 16-ary QAM, from the Phase/Frequency Offset block with **Phase offset** set to  $20^\circ$  and **Frequency offset** set to 0:

Observe that each point in the constellation is rotated by a 20 degree angle counterclockwise.

If you set **Frequency offset** to 2 and **Phase offset** to  $0^\circ$ , the angles of points in the constellation change linearly over time. This causes points in the scatter plot to shift radially, as shown in the following figure:

Note that every point in the scatter plot has magnitude equal to a point in the original constellation.

See “Illustrate RF Impairments That Distort a Signal” for a description of the model that generates this plot.

### Interdependent Parameter-Port Dimensions

Number of Dimensions	Data I/O Dimension	Frame Size	Number of Channels	Frequency/Phase Offset Parameter Dimension	Frequency Offset Input Port Dimension
Any	Scalar	1	1	Scalar	Scalar
2	$M$ -by-1	$M$	1	$M$ -by-1, 1-by- $M$ , 1-by-1	$M$ , $M$ -by-1, 1, 1-by-1
2	1-by- $N$	1	$N$	$N$ -by-1, 1-by- $N$ , 1-by-1	$N$ , 1-by- $N$ , 1, 1-by-1
2	$M$ -by- $N$	$M$	$N$	$M$ -by- $N$ , $N$ -by-1, 1-by- $N$ , $M$ -by-1, 1-by- $M$ , 1-by-1	$M$ -by- $N$ , $N$ , 1-by- $N$ , 1, 1-by-1, $M$ , $M$ -by-1

- When you specify a scalar offset parameter the block applies the same offset to all elements of the input signal

- When you specify a 2-by-1 offset parameter for a 2-by-3 input signal (one offset value per sample), the block applies the same sample offset across the three channels.
- When you specify a 1-by-3 offset parameter for a 2-by-3 input signal (one offset value per channel), the same channel offset is applied across the two samples of a channel.
- When you specify a 2-by-3 offset parameter for a 2-by-3 input signal (one offset value per sample for each channel), the offsets are applied element-wise to the input signal.

## Parameters

### Frequency offset from port

Selecting this option opens a port on the block through which you can input the frequency offset information.

### Frequency offset

Specifies the frequency offset in hertz.

This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. For more information, see Tunable Parameters (Simulink) in the *Simulink User's Guide*.

### Phase offset

Specifies the phase offset in degrees.

This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. For more information, see Tunable Parameters (Simulink) in the *Simulink User's Guide*.

If **Frequency offset** and **Phase offset** are both vectors or both matrices, their dimensions (vector lengths, or number of rows and columns) must be the same.

# Phase-Locked Loop

Implement phase-locked loop to recover phase of input signal

## Library

Components sublibrary of Synchronization

## Description

The Phase-Locked Loop (PLL) block is a feedback control system that automatically adjusts the phase of a locally generated signal to match the phase of an input signal. This block is most appropriate when the input is a narrowband signal.

This PLL has these three components:

- A multiplier used as a phase detector.
- A filter. You specify the filter transfer function using the **Lowpass filter numerator** and **Lowpass filter denominator** parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of  $s$ .

To design a filter, you can use functions such as `butter`, `cheby1`, and `cheby2` in Signal Processing Toolbox software. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

```
[num, den] = cheby2(3,40,100,'s')
```

- A voltage-controlled oscillator (VCO). You specify characteristics of the VCO using the **VCO quiescent frequency**, **VCO initial phase**, and **VCO output amplitude** parameters.

This block accepts a sample-based scalar input signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

## Parameters

### **Lowpass filter numerator**

The numerator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of  $s$ .

### **Lowpass filter denominator**

The denominator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of  $s$ .

### **VCO input sensitivity (Hz/V)**

This value scales the input to the VCO and, consequently, the shift from the **VCO quiescent frequency** value. The units of **VCO input sensitivity** are Hertz per volt.

### **VCO quiescent frequency (Hz)**

The frequency of the VCO signal when the voltage applied to it is zero. This should match the carrier frequency of the input signal.

### **VCO initial phase (rad)**

The initial phase of the VCO signal.

### **VCO output amplitude**

The amplitude of the VCO signal.

## Phase Noise

Apply receiver phase noise to complex baseband signal

**Library:** Communications Toolbox / RF Impairments

### Description

The Phase Noise block adds phase noise to a complex signal. This block emulates impairments introduced by the local oscillator of a wireless communication transmitter or receiver. The block generates filtered phase noise according to the specified spectral mask and adds it to the input signal. For a description of the phase noise modeling, see “Algorithms” on page 3-889.

### Ports

#### Input

**In — Input signal**

complex column vector

Input signal, specified as an  $N_S$ -by-1 vector of complex values.  $N_S$  represents the number of samples in the input signal.

Data Types: double

Complex Number Support: Yes

#### Output

**Out — Output signal**

complex column vector

Output signal, returned as an  $N_S$ -by-1 vector of complex values.  $N_S$  equals the number of samples in the input signal.

Data Types: double  
Complex Number Support: Yes

## Parameters

### **Phase noise level (dBc/Hz) — Phase noise level**

[-60 -80] (default) | vector of negative scalars

Phase noise level in decibels relative to carrier per hertz (dBc/Hz), specified as a vector of negative scalars. The **Phase noise level (dBc/Hz)** and **Frequency offset (Hz)** parameters must have the same length.

**Tunable:** Yes

### **Frequency offset (Hz) — Frequency offset**

[20 200] (default) | vector of positive increasing values

Frequency offset in Hz, specified as a vector of positive increasing values. The **Phase noise level (dBc/Hz)** and **Frequency offset (Hz)** parameters must have the same length.

**Tunable:** Yes

Data Types: double

### **Sample rate (Hz) — Sample rate**

1024 (default) | positive scalar

Sample rate in samples per second, specified as a positive scalar. To avoid aliasing, the sample rate must be greater than twice the largest value specified by **Frequency offset (Hz)**.

**Tunable:** Yes

Data Types: double

### **Initial seed — Initial seed of noise generator**

2137 (default) | positive scalar

Initial seed of noise generator, specified as a positive scalar.

This block uses the Random Source block to generate noise. The block generates random numbers using the Ziggurat method (V5 RANDN algorithm). Every time you rerun the

simulation, the block reuses the same initial seed. That way, the block outputs the same signal each time you run a simulation.

**Tunable:** Yes

Data Types: double

**View Filter Response — Display magnitude response of filter**  
button

Display magnitude response of filter defined by the Phase Noise block. The block uses the `fvtool` function to display the magnitude response.

**Simulate using — Specify type of simulation to run**

Interpreted execution (default) | Code generation

- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time speed, but the speed of the subsequent simulations is slower than **Code generation**. In this mode, you can debug the source code of the block.
- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time, but the speed of the subsequent simulations is faster than **Interpreted execution**.

## Block Characteristics

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## Algorithms

The output signal,  $y_k$ , is related to input sequence  $x_k$  by  $y_k = x_k e^{j\varphi_k}$ , where  $\varphi_k$  is the phase noise. The phase noise is filtered Gaussian noise such that  $\varphi_k = f(n_k)$ , where  $n_k$  is the noise sequence and  $f$  represents a filtering operation.

To model the phase noise, define the power spectrum density (PSD) mask characteristic by specifying scalar or vector values for the frequency offset and phase noise level.

- For a scalar frequency offset and phase noise level specification, an IIR digital filter computes the spectrum mask. The spectrum mask has a  $1/f$  characteristic that passes through the specified point.
- For a vector frequency offset and phase noise level specification, an FIR filter computes the spectrum mask. The spectrum mask is interpolated across  $\log_{10}(f)$ . It is flat from DC to the lowest frequency offset, and from the highest frequency offset to half the sample rate.

### IIR Digital Filter

For the IIR digital filter, the numerator coefficient is

$$\lambda = \sqrt{2\pi f_{\text{offset}} 10^{L/10}},$$

where  $f_{\text{offset}}$  is the frequency offset in Hz and  $L$  is the phase noise level in dBc/Hz. The denominator coefficients,  $\gamma_i$ , are recursively determined as

$$\gamma_i = (i - 2.5) \frac{\gamma_{i-1}}{i - 1},$$

where  $\gamma_i = 1$ ,  $i = \{1, 2, \dots, N_t\}$ , and  $N_t$  is the number of filter coefficients.  $N_t$  is a power of 2, from  $2^7$  to  $2^{19}$ . The value of  $N_t$  grows as the phase noise offset decreases towards 0 Hz.

#### **FIR Filter**

For the FIR filter, the phase noise level is determined through  $\log_{10}(f)$  interpolation for frequency offsets over the range  $[df, f_s / 2]$ , where  $df$  is the frequency resolution and  $f_s$  is the sample rate. The phase noise is flat from 0 Hz to the smallest frequency offset, and from the largest frequency offset to  $f_s / 2$ . The frequency resolution is equal to  $\frac{f_s}{2} \left( \frac{1}{N_t} \right)$ , where  $N_t$  is the number of coefficients, and is a power of 2 less than or equal to  $2^{16}$ . If  $N_t < 2^8$ , a time domain FIR filter is used. Otherwise, a frequency domain FIR filter is used.

The algorithm increases  $N_t$  until these conditions are met:

- The frequency resolution is less than the minimum value of the frequency offset vector.
- The frequency resolution is less than the minimum difference between two consecutive frequencies in the frequency offset vector.
- The maximum number of FIR filter taps is  $2^{16}$ .

## PM Demodulator Passband

Demodulate PM-modulated data

### Library

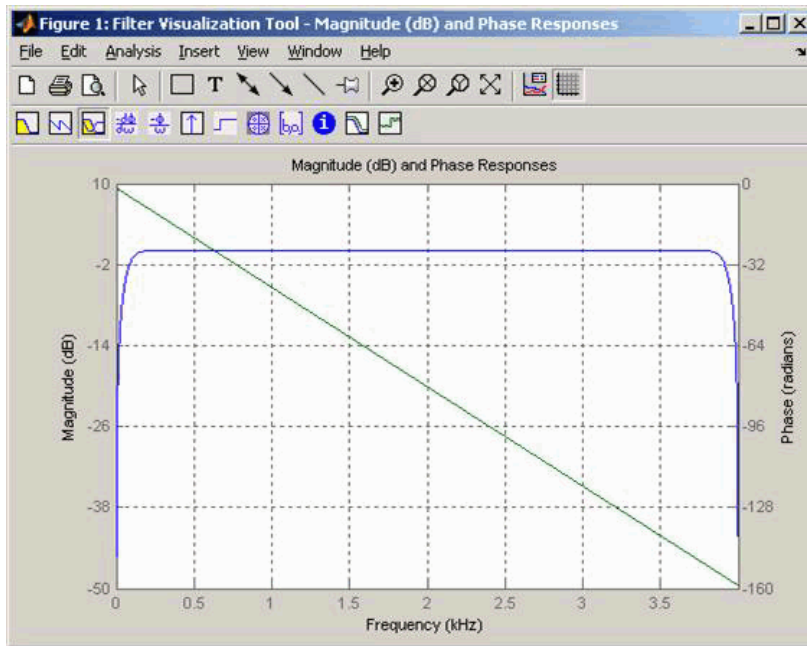

Analog Passband Modulation, in Modulation

### Description

The PM Demodulator Passband block demodulates a signal that was modulated using phase modulation. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

For best results, use a carrier frequency which is estimated to be larger than 10% of your input signal's sample rate. This is due to the implementation of the Hilbert transform by means of a filter.

In the following example, we sample a 10Hz input signal at 8000 samples per second. We then designate a Hilbert Transform filter of order 100. Below is the response of the Hilbert Transform filter as returned by `fvtool`.

Note the bandwidth of the filter's magnitude response. By choosing a carrier frequency larger than 10% (but less than 90%) of the input signal's sample rate (8000 samples per second, in this example) or equivalently, a carrier frequency larger than 400Hz, we ensure that the Hilbert Transform Filter will be operating in the flat section of the filter's magnitude response (shown in blue), and that our modulated signal will have the desired magnitude and form.

Typically, an appropriate **Carrier frequency** value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the **Carrier frequency** parameter.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### **Carrier frequency (Hz)**

The frequency of the carrier.

### **Initial phase (rad)**

The initial phase of the carrier in radians.

### **Phase deviation (rad)**

The phase deviation of the carrier frequency in radians. Sometimes it is referred to as the "variation" in the phase.

### **Hilbert transform filter order**

The length of the FIR filter used to compute the Hilbert transform.

# PM Modulator Passband

Modulate using phase modulation

## Library

Analog Passband Modulation, in Modulation

## Description

The PM Modulator Passband block modulates using phase modulation. The output is a passband representation of the modulated signal. The output signal's frequency varies with the input signal's amplitude. Both the input and output signals are real scalar signals.

If the input is  $u(t)$  as a function of time  $t$ , then the output is

$$\cos(2\pi f_c t + K_c u(t) + \theta)$$

where

- $f_c$  represents the **Carrier frequency** parameter
- $\theta$  represents the **Initial phase** parameter
- $K_c$  represents the **Phase deviation** parameter

An appropriate **Carrier frequency** value is generally much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the **Carrier frequency** parameter.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### **Carrier frequency (Hz)**

The frequency of the carrier.

### **Initial phase (rad)**

The initial phase of the carrier in radians.

### **Phase deviation (rad)**

The phase deviation of the carrier frequency in radians. This is sometimes referred to as the "variation" in the phase.

# PN Sequence Generator

Generate pseudonoise sequence

**Library:** Communications Toolbox / Comm Sources / Sequence Generators  
Communications Toolbox HDL Support / Comm Sources

## Description

The PN Sequence Generator block generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR). Pseudonoise sequences are typically used for pseudorandom scrambling, and in direct-sequence spread-spectrum systems. For more information, see “More About” on page 3-903.

These icons shows the block with all ports enabled.

## Ports

### Input

#### Mask — Output mask

binary vector

Output mask to delay the PN sequence from initial time, specified as a binary vector.

#### Dependencies

To enable this port, set **Output mask source** to Input port.

Data Types: double | uint8 | ufix1

### **oSiz — Output size**

integer

Output size for variable-size output signals, specified as an integer. For information about variable-size signals, see “Variable-Size Signal Basics” (Simulink).

#### **Dependencies**

To enable this port, select **Output variable-size signals** and set **Maximum output size source** to Dialog parameter.

Data Types: double

### **Ref — Reference input**

column vector

Reference input, specified as a column vector that determines the maximum and current output sequence length. The **Ref** input must be a variable-size signal. For information about variable-size signals, see “Variable-Size Signal Basics” (Simulink).

#### **Dependencies**

To enable this port, select **Output variable-size signals** and set **Maximum output size source** to Inherit from reference input.

Data Types: double

### **Rst — Reset sequence generator**

0 | 1

Reset sequence generator, specified as 0 or 1. For more information, see “Resetting a Signal” on page 3-905.

#### **Dependencies**

To enable this port, select **Reset on nonzero input**.

Data Types: Boolean

## **Output**

### **Out — Pseudorandom noise sequence**

binary vector

PN sequence, returned as a binary vector.

## Parameters

### Generator polynomial — Generator polynomial

'z<sup>6</sup> + z + 1' (default) | polynomial character vector | binary row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector that includes the number 1.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The first and last entries must be 1. The length of this vector is  $(N+1)$ , where  $N$  is the degree of the generator polynomial.
- A vector containing the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0.

For more information, see “Character Representation of Polynomials”.

Example: 'z<sup>8</sup> + z<sup>2</sup> + 1', [1 0 0 0 0 0 1 0 1], and [8 2 0] represent the same polynomial,  $p(z) = z^8 + z^2 + 1$ .

### Initial states — Initial shift register states

[0 0 0 0 0 1] (default) | binary row vector

Initial shift register states, specified as a binary row vector of length  $N$ , where  $N$  is the degree of the generator polynomial.

---

**Note** For the block to generate a nonzero sequence, the **Initial states** vector must contain at least one nonzero element.

---

### Output mask source — Output mask source

Dialog parameter (default) | Input port

Output mask source that indicates how the output mask information is given to the block, specified as:

- Dialog parameter to use the Output mask vector (or scalar shift value) parameter setting.
- Input port to add and use the Mask input port.

**Output mask vector (or scalar shift value) — Output mask vector or scalar shift value**

0 (default) | integer scalar | binary vector

Output mask vector or scalar shift value, specified as an integer scalar or binary row vector of length  $N$ , where  $N$  is the degree of the generator polynomial. This parameter determines the delay of the PN sequence from the initial time. For more information, see “Shifting PN Sequence Starting Point” on page 3-905.

**Dependencies**

To enable this parameter, set **Output mask source** to `Dialog` parameter.

**Output variable-size signals — Output variable-size signals**

off (default) | on

Select this parameter to permit variable length output sequences during simulation. When set to `off`, fixed-length sequences are output. When set to `on`, variable-length sequences can be output. For information about variable-size signals, see “Variable-Size Signal Basics” (Simulink).

**Maximum output size source — Maximum output size source**

`Dialog` parameter (default) | `Inherit from reference port`

Maximum output size source, which indicates how the maximum sequence output size is specified.

- `Dialog` parameter configures the block to use the **Maximum output size** parameter setting as the maximum permitted output sequence length.
- `Inherit from reference port` adds the `Ref` input port and configures the block to inherit the sample time and the current output size from the `Ref` input port to set the maximum permitted output sequence length.

**Dependencies**

To enable this parameter, select **Output variable-size signals**.

**Maximum output size — Maximum output size source**

[10 1] (default) | two-element row vector

Maximum output size, specified as a two-element row vector that denotes the maximum output size for the block. The second element of the vector must be 1.

Example: [10 1] gives a 10-by-1 maximum sized output signal.

#### **Dependencies**

To enable this parameter, select **Output variable-size signals**.

#### **Sample time — Time between each sample**

1 (default) | positive scalar

Time between each sample, specified as a positive scalar.

Example: 1 specifies a sample time of 1 second.

#### **Dependencies**

To enable this parameter, clear **Output variable-size signals**.

#### **Samples per frame — Samples per frame**

1 (default) | positive integer

Samples per frame in one channel of the output signal, specified as a positive integer.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

---

#### **Dependencies**

To enable this parameter, clear **Output variable-size signals**.

#### **Reset on nonzero input — Reset on nonzero input**

off (default) | on

Select this parameter to add the Rst input port. For more information, see “Resetting a Signal” on page 3-905.

#### **Enable bit-packed outputs — Enable bit-packed outputs**

off (default) | on

Select this parameter to make the **Number of packed bits** and **Interpret bit-packed values as signed** parameters available.

#### Number of packed bits — Number of packed bits

8 (default) | integer

Number of packed bits, specified as an integer in the range [1,32].

#### Dependencies

To enable this parameter, select **Enable bit-packed outputs**.

#### Interpret bit-packed values as signed — Interpret bit-packed values as signed

off (default) | on

Interpret bit-packed values as signed integer data values when selected or unsigned integer data values when cleared. When selected, a 1 in the most significant bit (sign bit) indicates a negative value.

#### Dependencies

To enable this parameter, select **Enable bit-packed outputs**.

#### Output data type — Output data type

double (default) | boolean | Smallest unsigned integer

Output data type, specified as double, boolean, or Smallest unsigned integer.

- When **Enable bit-packed outputs** is cleared, the output data type can be specified as a double, boolean, or Smallest unsigned integer. When the **Output data type** parameter is set to Smallest unsigned integer, the output data type is selected based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the **Hardware Implementation** pane, the output data type `ufix(1)` = ideal minimum one-bit size. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a char (for example, `uint8`).
- When **Enable bit-packed outputs** is selected, the output data type can be specified as double or Smallest unsigned integer. When the **Output data type** parameter is set to Smallest unsigned integer, the output data type is selected based on the **Interpret bit-packed values as signed** and **Number of packed bits** parameters, and the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the **Hardware Implementation** pane, the output data type is the ideal minimum  $n$ -bit

size, such as `sfix(n)` or `ufix(n)`, based on the **Interpret bit-packed values as signed** parameter. For all other selections, it is a signed or unsigned integer with the smallest available word length large enough to fit  $n$  bits.

<b>Variable-Size Signals</b>	yes

## More About

### Simple Shift Register Generator

A linear-feedback shift register (LFSR), implemented as a simple shift register generator (SSRG), is used to generate PN sequences. This type of shift register is also known as a Fibonacci implementation. For an example, see “Model PN Sequence Generation With Linear Feedback Shift Register”.

The **Generator Polynomial** parameter determines the feedback connections of the shift register. It is a primitive binary polynomial in  $z$ ,  $g_r z^r + g_{r-1} z^{r-1} + g_{r-2} z^{r-2} + \dots + g_0$ . For the coefficient,  $g_{k=0 \text{ to } r}$ , the coefficient  $g_k$  is 1 if there is a connection from the  $k$ th register to the adder. The leading term,  $g_r$ , and the constant term,  $g_0$ , of the **Generator Polynomial** parameter must be 1 because the polynomial must be primitive. The **Initial states** parameter specifies the initial values of the registers. For example, the following table indicates two sets of parameter values that correspond to a generator polynomial of  $p(z) = z^8 + z^2 + 1$ .

Quantity	Example 1	Example 2
<b>Generator polynomial</b>	$g1 = [1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0 \ 1]$	$g2 = [8 \ 2 \ 0]$
Degree of generator polynomial	8, which is $\text{length}(g1) - 1$	8
<b>Initial states</b>	$[1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0]$	$[1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0]$

At each time step, all  $r$  registers in the generator update their values according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The output of the LFSR reflects the sum of all connections in the  $m$  mask vector.

The **Output mask vector (or scalar shift value)** parameter,  $m$ , determines the shift of the PN sequence starting point. For more information, see “Shifting PN Sequence Starting Point” on page 3-905.

## Shifting PN Sequence Starting Point

To shift the starting point of the PN sequence, specify the **Output mask vector (or scalar shift value)** parameter as:

- An integer representing the length of the shift.

The default **Output mask vector (or scalar shift value)** setting of 0 corresponds to no shift. As illustrated in the LFSR shift register diagram in “Simple Shift Register Generator” on page 3-903, there is no shift when the only connection is along the arrow labeled  $m_0$ .

This table shows the shift that occurs when you set **Output mask vector (or scalar shift value)** to 0 versus a positive integer  $d$ .

	<b>T = 0</b>	<b>T = 1</b>	<b>T = 2</b>	...	<b>T = d</b>	<b>T = d+1</b>
<b>Shift = 0</b>	$x_0$	$x_1$	$x_2$	...	$x_d$	$x_{d+1}$
<b>Shift = d</b>	$x_d$	$x_{d+1}$	$x_{d+2}$	...	$x_{2d}$	$x_{2d+1}$

- A binary vector whose length is equal to the degree of the generator polynomial. The LFSR shift register diagram in “Simple Shift Register Generator” on page 3-903 shows **Output mask vector (or scalar shift value)** specified as a mask vector,  $m$ . The binary vector must have  $N$  elements, where  $N$  is the degree of the generator polynomial. To calculate the mask vector, use the `shift2mask` function.

The binary vector corresponds to a polynomial in  $z$ ,  $m_{r-1}z^{r-1} + m_{r-2}z^{r-2} + \dots + m_1z + m_0$ , of degree at most  $r-1$ . The mask vector that correspond to a shift of  $d$  is the vector that represents  $m(z) = z^d$  modulo  $g(z)$ , where  $g(z)$  is the generator polynomial.

For example, if the degree of the generator polynomial is 4, then the mask vector that corresponds to  $d = 2$  is  $[0 \ 1 \ 0 \ 0]$ , which represents the polynomial  $m(z) = z^2$ .

## Resetting a Signal

To reset the PN generator sequence, you must first select **Reset on nonzero input** to add the `Rst` input. Suppose that the PN Sequence Generator block outputs  $[1 \ 0 \ 0 \ 1 \ 1$

0 1 1] when there is no reset. The following table shows the effect on the PN Sequence Generator block output when the reset signal [0 0 0 1] is input to the Rst port. The PN sequence is reset at the fourth bit, because the fourth bit of the reset signal is a 1 and the **Sample time** is 1.

Reset Signal Properties	PN Sequence Generator block	Reset Signal, Output Signal
Sample time = 1	Sample time = 1	

## Sequences of Maximum Length

To generate a maximum length sequence for a generator polynomial that has the degree  $r$ , set **Generator polynomial** to a value from the following table. The maximum sequence length is  $2^r - 1$ .

r	Generator Polynomial	r	Generator Polynomial	r	Generator Polynomial	r	Generator Polynomial
2	[2 1 0]	15	[15 14 0]	28	[28 25 0]	41	[41 3 0]
3	[3 2 0]	16	[16 15 13 4 0]	29	[29 27 0]	42	[42 23 22 1 0]

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

## HDL Architecture

This block has a single, default HDL architecture.

## HDL Block Properties

<b>ConstrainedOutputPipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

## Restrictions

- You can select `Input` port as the **Output mask source** on the block. In this case, the `Mask` input signal must be a vector of data type `ufix1`.
- If you select **Reset on nonzero input**, the input to the `Rst` port must have data type `Boolean`.
- Outputs of type `double` are not supported for HDL code generation. All other output types (including bit-packed outputs) are supported.
- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.
- You cannot generate HDL for this block inside a Triggered Subsystem if the **Use trigger signal as clock** option is selected. See “Using Triggered Subsystems for HDL Code Generation” (HDL Coder).

## Poisson Integer Generator

Generate Poisson-distributed random integers

### Library

Random Data Sources sublibrary of Comm Sources

### Description

The Poisson Integer Generator block generates random integers using a Poisson distribution. The probability of generating a nonnegative integer  $k$  is

$$\lambda^k \exp(-\lambda) / (k!)$$

where  $\lambda$  is a positive number known as the Poisson parameter.

You can use the Poisson Integer Generator to generate noise in a binary transmission channel. In this case, the Poisson parameter **Lambda** should be less than 1, usually much less.

### Attributes of Output Signal

The output signal can be a column or row vector, a two-dimensional matrix, or a scalar. The number of rows in the output signal corresponds to the number of samples in one frame and is determined by the **Samples per frame** parameter. The number of columns in the output signal corresponds to the number of channels and is determined by the number of elements in the **Lambda** parameter. See “Sources and Sinks” in *Communications Toolbox User’s Guide* for more details.

## Parameters

### Lambda

The Poisson parameter  $\lambda$ . Specify  $\lambda$  as a scalar or row vector whose elements are real numbers. If **Lambda** is a scalar, then every element in the output vector shares the same Poisson parameter. If **Lambda** is a row vector, then the number of elements correspond to the number of independent channels output from the block.

### Source of initial seed

The source of the initial seed for the random number generator. Specify the source as either `Auto` or `Parameter`. When set to `Auto`, the block uses the global random number stream.

---

**Note** When **Source of initial seed** is `Auto` in `Code generation` mode, the random number generator uses an initial seed of zero. Therefore, the block generates the same random numbers each time it is started. Use `Interpreted execution` to ensure that the model uses different initial seeds. If `Interpreted execution` is run in `Rapid accelerator` mode, then it behaves the same as `Code generation` mode.

---

### Initial seed

The initial seed value for the random number generator. Specify the seed as a nonnegative integer scalar. **Initial seed** is available when the **Source of initial seed** parameter is set to `Parameter`.

### Sample time

The time between each sample of a column of the output signal.

### Samples per frame

The number of samples per frame in one channel of the output signal. Specify **Samples per frame** as a positive integer scalar.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs an integer every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

---

**Output data type**

The output type of the block can be specified as a `boolean`, `uint8`, `uint16`, `uint32`, `single`, or `double`. The default is `double`.

**Simulate using**

Select the simulation mode.

**Code generation**

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is `Code generation`, System objects corresponding to the blocks accept a maximum of nine inputs.

**Interpreted execution**

Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

# Preamble Detector

Detect preamble in data packet

**Library:** Communications Toolbox / Synchronization

## Description

The Preamble Detector block detects the end of preambles in data packets. A preamble is a set of symbols or bits used in packet-based communications systems to indicate the start of a packet. Packets consist of preamble data and user data. The length of the user data portion of the packet can vary during a simulation run.

This icon shows the block with all ports enabled:

## Input/Output Ports

### Input

#### In — Input data

scalar | column vector

Input data of symbols or bits, specified as a scalar or column vector. The input data can contain multiple packets. This port is unnamed on the block.

Data Types: single | double | Boolean | int8 | uint8

### Output

#### Idx — Index of last preamble symbol

scalar | column vector

Index of the last preamble symbol, returned as a scalar or column vector of the same size and data type as the input data.

- When the Detections parameter is set to `All`, `Idx` outputs the index corresponding to the last element of each detected preamble.
- When the Detections parameter is set to `First`, `Idx` outputs the index corresponding to the last element of the first detected preamble.

This port is unnamed until the `DtMt` port is enabled.

#### **DtMt — Detection metric**

scalar | column vector

Detection metric, returned as a scalar or column vector of the same size and data type as the input data packet.

- If either the preamble or input data is complex, the detection metric is the absolute value of the cross-correlation of the preamble and the input data.
- If both the preamble and input data are real, the detection metric is the cross-correlation of the preamble and the input data.

#### **Dependencies**

To enable this port, set the Input parameter to `Symbol`, and select the Output detection metric parameter.

## **Parameters**

#### **Input — Input type**

`Symbol` (default) | `Bit`

Input type, specified as `Symbol` or `Bit`.

- For binary inputs, set this parameter to `Bit`.
- For all other inputs, set this parameter to `Symbol`.

For information on execution speed, see “Tips” on page 3-916.

#### **Preamble — Preamble sequence**

`[1 + 1i; 1 - 1i]` (default) | column vector

Preamble sequence, specified as a column vector.

- If the **Input** parameter is set to `Bit`, the preamble must be binary.
- If the **Input** parameter is set to `Symbol`, the preamble can be any real or complex sequence.

### Detection threshold — Detection threshold

3 (default) | nonnegative scalar

Detection threshold, specified as a nonnegative scalar. When the detection metric is greater than or equal to the threshold, the block detects the preamble and updates `Idx`.

**Tunable:** Yes

#### Dependencies

To enable this parameter, set the `Input` parameter to `Symbol`.

### Output detection metric — Option to output detection metric

off (default) | on

Select this parameter to output the detection metric and enable the `DtMt` output port.

#### Dependencies

To enable this parameter, set the `Input` parameter to `Symbol`.

### Detections — Detections returned

All (default) | First

Detections returned, specified as `All` or `First`. Specifying `All` returns all detected preambles. Specifying `First` returns only the first detected preamble.

**Tunable:** Yes

### Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as:

- `Code generation` -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.

- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In **Interpreted execution** mode, you can debug the source code of the block.

For information on execution speed, see “Tips” on page 3-916.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

## Tips

- For faster execution of the Preamble Detector block, set the Simulate using parameter to:
  - **Code generation** when the Input parameter is set to **Symbol**
  - **Interpreted execution** when the Input parameter is set to **Bit**

## Algorithms

### Bit Inputs

When the input data is composed of bits, the preamble detector uses an exact pattern match.

### Symbol Inputs

When the input data is composed of symbols, the preamble detector uses a cross-correlation algorithm. A finite impulse response (FIR) filter, in which the coefficients are specified from the preamble, computes the cross-correlation between the input data and the preamble. When a sequence of input samples match the preamble, the filter output

reaches its peak. The index of the peak corresponds to the end of the preamble sequence in the input data. See Discrete FIR Filter for further information on the FIR filter algorithm.

The cross-correlation values that are greater than or equal to the specified threshold are reported as peaks.

- If the detection threshold is too low, the algorithm will detect false peaks, or, in the extreme case, detect as many detected peaks as there are input samples.
- If the detection threshold is too high, the algorithm will miss detecting peaks, or, in the extreme case, detect no peaks.

Consequently, the selection of the detection threshold is critical.

## Puncture

Output elements which correspond to 1s in binary Puncture vector

## Library

Sequence Operations

## Description

The Puncture block creates an output vector by removing selected elements of the input vector and preserving others. This block accepts an input signal that is a real or complex vector of length  $K$ . The block determines which elements to remove and preserve by using the binary **Puncture vector** parameter.

and mod is the modulus function (mod in MATLAB).

- If **Puncture vector**( $n$ ) = 0, then the block removes the  $n^{\text{th}}$  element of the input vector and does not include it as part of the output vector.
- If **Puncture vector**( $n$ ) = 1, then the block preserves the  $n^{\text{th}}$  element of the input vector as part of the output vector.

The input length,  $K$ , must be an integer multiple of the **Puncture vector** parameter length. The block repeats the puncturing pattern, as necessary, to include all input elements. The preserved elements appear in the output vector in the same order in which they appear in the input vector.

The input signal and the puncture vector are both column vectors.

The block accepts signals with the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

### Puncture vector

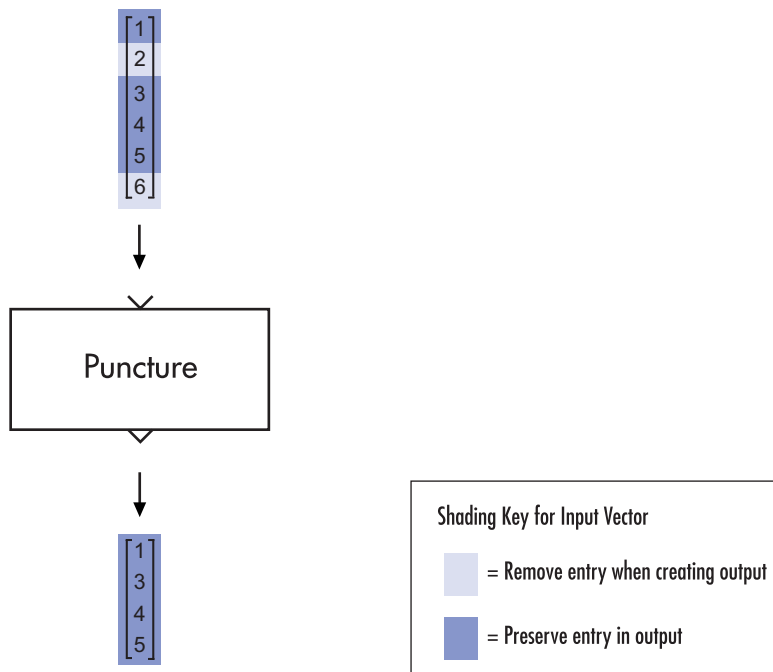

A binary vector whose pattern of 0s (1s) indicates which elements of the input the block should remove (preserve).

## Examples

If the **Puncture vector** parameter is the six-element vector  $[1;0;1;1;1;0]$ , then the block:

- Removes the second and sixth elements from the group of six input elements.
- Sends the first, third, fourth, and fifth elements to the output vector.

The diagram below depicts the block's operation on an input vector of  $[1;2;3;4;5;6]$ , using this **Puncture vector** parameter.

# QPSK Demodulator Baseband

Demodulate QPSK-modulated data

## Library

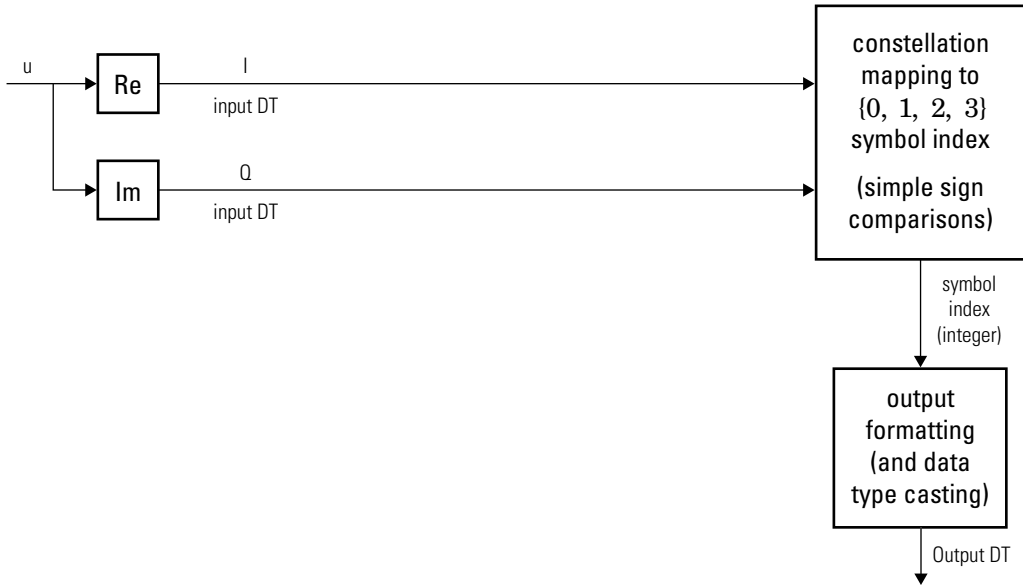

PM, in Digital Baseband sublibrary of Modulation

## Description

The QPSK Demodulator Baseband block demodulates a signal that was modulated using the quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

The input must be a complex signal. This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see “Supported Data Types” on page 3-930.

### Algorithm

**Hard-Decision QPSK Demodulator Signal Diagram for Trivial Phase Offset (odd multiple of  $\pi/4$ )**

**Hard-Decision QPSK Demodulator Floating-Point Signal Diagram for Nontrivial Phase Offset**

**Hard-Decision QPSK Demodulator Fixed-Point Signal Diagram for Nontrivial Phase Offset**

The exact LLR and approximate LLR cases (soft-decision) are described in “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

## Dialog Box

### Phase offset (rad)

The phase of the zeroth point of the signal constellation.

### Constellation ordering

Determines how the block maps each integer to a pair of output bits.

### Output type

Determines whether the output consists of integers or bits.

If the **Output type** parameter is set to Integer and **Constellation ordering** is set to Binary, then the block maps the point

$$\exp(j\theta) + \exp(j(\theta + \pi m/2))$$

to  $m$ , where  $\theta$  is the **Phase offset** parameter and  $m$  is 0, 1, 2, or 3.

The reference page for the QPSK Modulator Baseband block shows the signal constellations for the cases when **Constellation ordering** is set to either Binary or Gray.

If the **Output type** is set to `Bit`, then the output contains pairs of binary values if **Decision type** is set to `Hard decision`. The most significant bit (i.e. the left-most bit in the vector), is the first bit the block outputs.

If the **Decision type** is set to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, then the output contains bitwise LLR or approximate LLR values, respectively.

#### **Decision type**

Specifies the use of hard decision, LLR, or approximate LLR during demodulation. This parameter appears when you select `Bit` from the **Output type** drop-down list. The output values for `Log-likelihood ratio` and `Approximate log-likelihood ratio` decision types are of the same data type as the input values. For integer output, the block always performs `Hard decision` demodulation.

See “Exact LLR Algorithm” and “Approximate LLR Algorithm” for algorithm details.

#### **Noise variance source**

This field appears when `Approximate log-likelihood ratio` or `Log-likelihood ratio` is selected for **Decision type**.

When set to `Dialog`, the noise variance can be specified in the **Noise variance** field. When set to `Port`, a port appears on the block through which the noise variance can be input.

#### **Noise variance**

This parameter appears when the **Noise variance source** is set to `Dialog` and specifies the noise variance in the input signal. This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- `Inf` to `-Inf` if **Noise variance** is very high
- `NaN` if **Noise variance** and signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

## Data Types Pane for Hard-Decision

### Output

For bit outputs, when **Decision type** is set to Hard decision, the output data type can be set to 'Inherit via internal rule', 'Smallest unsigned integer', double, single, int8, uint8, int16, uint16, int32, uint32, or boolean.

For integer outputs, the output data type can be set to 'Inherit via internal rule', 'Smallest unsigned integer', double, single, int8, uint8, int16, uint16, int32, or uint32.

When this parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is a floating-point type (single or double). If the input data type is fixed-point, the output data type will work as if this parameter is set to 'Smallest unsigned integer'.

When this parameter is set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model.

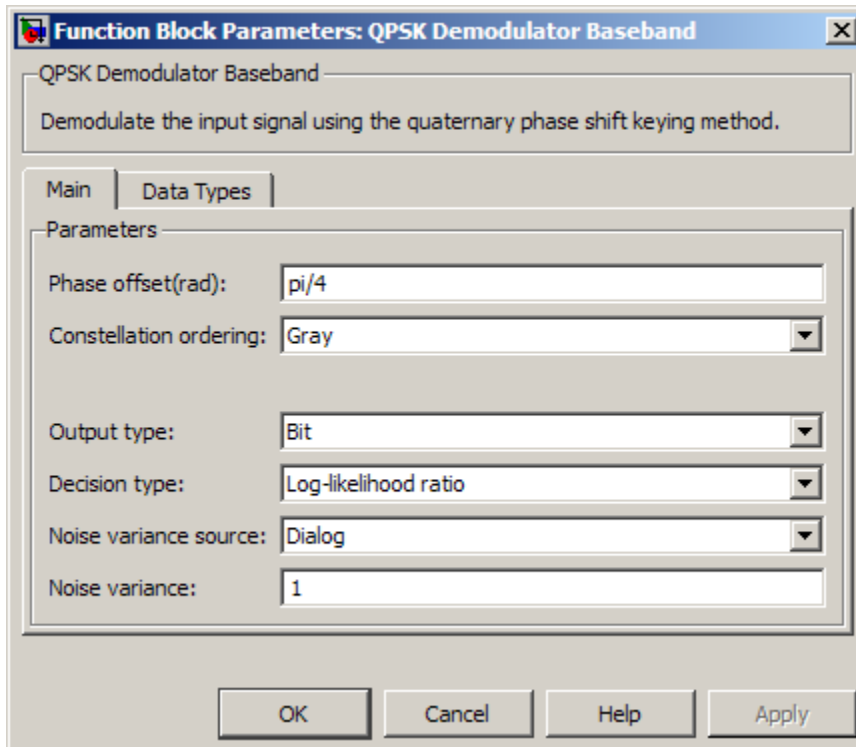

If ASIC/FPGA is selected in the **Hardware Implementation** pane, and **Output type** is **Bit**, the output data type is the ideal minimum one-bit size, i.e., `ufix(1)`. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a char (e.g., `uint8`).

If ASIC/FPGA is selected in the **Hardware Implementation** pane, and **Output type** is **Integer**, the output data type is the ideal minimum two-bit size, i.e., `ufix(2)`. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit two bits, usually corresponding to the size of a char (e.g., `uint8`).

#### **Derotate factor**

This parameter only applies when the input is fixed-point and **Phase offset** is not an even multiple of  $\pi/4$ .

You can select **Same word length as input** or **Specify word length**, in which case you define the word length using an input field.

### Data Types Pane for Soft-Decision

For bit outputs, when **Decision type** is set to Log-likelihood ratio or Approximate log-likelihood ratio, the output data type is inherited from the input (e.g., if the input is of data type double, the output is also of data type double).

## Examples

### Demodulate Noisy QPSK Signal

Modulate and demodulate a noisy QPSK signal.

Open the QPSK demodulation model.

Run the simulation. The results are saved to the base workspace, where the variable `ErrorVec` is a 1-by-3 row vector. The BER is found in the first element.

Display the error statistics. For the  $E_b/N_0$  provided, 4.3 dB, the resultant BER is approximately 0.01. Your results may vary slightly.

ans =

```
0.0112
```

Increase the  $E_b/N_0$  to 7 dB. Rerun the simulation, and observe that the BER has decreased.

ans =

```
1.0000e-03
```

# QPSK Modulator Baseband

Modulate using quadrature phase shift keying method

## Library

PM in Digital Baseband sublibrary of Modulation

## Description

The QPSK Modulator Baseband block modulates using the quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

## Integer-Valued Signals and Binary-Valued Signals

If you set the **Input type** parameter to `Integer`, then valid input values are 0, 1, 2, and 3. When you set **Constellation ordering** to `Binary` for input  $m$  the output symbol is

$$\exp(j\theta) + j\pi m/2$$

where  $\theta$  represents the **Phase offset** parameter (see the following figure for Gray constellation ordering). In this case, the block accepts a scalar or column vector signal.

If you set the **Input type** parameter to `Bit`, then the input contains pairs of binary values. For this configuration, the block accepts column vectors with even lengths. When you set the **Phase offset** parameter to  $\frac{\pi}{4}$ , then the block uses one of the signal constellations in the following figure, depending on whether you set the **Constellation ordering** parameter to `Binary` or `Gray`.

In the previous figure, the most significant bit (i.e. the left-most bit), is the first bit input to the block. For additional information about Gray mapping, see the M-PSK Modulator Baseband help page.

## Constellation Visualization

The QPSK Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the Constellation Visualization section of the *Communications Toolbox User's Guide*.

## Dialog Box

### Phase offset (rad)

The phase of the zeroth point of the signal constellation.

### Constellation ordering

Determines how the block maps each pair of input bits or input integers to constellation symbols.

### Input type

Indicates whether the input consists of integers or pairs of bits.

### Output data type

The output data type can be set to `double`, `single`, `Fixed-point`, `User-defined`, or `Inherit via back propagation`.

Setting this parameter to `Fixed-point` or `User-defined` enables fields in which you can further specify details. Setting this parameter to `Inherit via back propagation`, sets the output data type and scaling to match the following block.

### Output word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

**Set output fraction length to**

Specify the scaling of the fixed-point output by either of the following methods:

- Choose **Best precision** to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose **User-defined** to specify the output scaling in the **Output fraction length** parameter.

This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter or when you select **User-defined** and the specified output data type is a fixed-point data type.

**User-defined data type**

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the `sfix`, `sint`, `sfrac`, and `fixdt` functions from Fixed-Point Designer. This parameter is only visible when you select **User-defined** for the **Output data type** parameter.

**Output fraction length**

For fixed-point output data types, specify the number of fractional bits or bits to the right of the binary point. This parameter is only visible when you select **Fixed-point** or **User-defined** for the **Output data type** parameter and **User-defined** for the **Set output fraction length to** parameter.

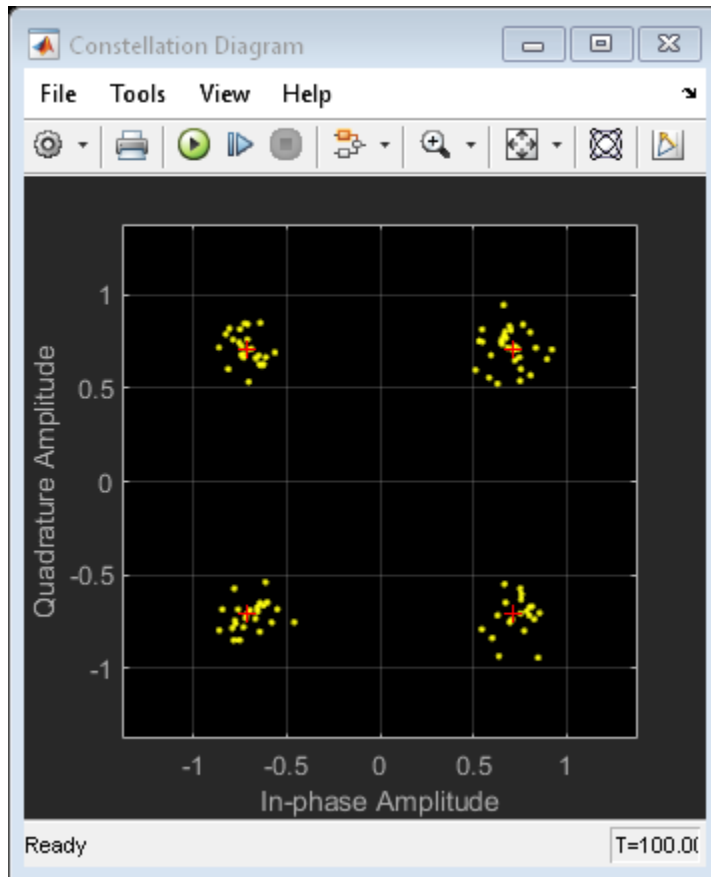

## Examples

**Plot Noisy QPSK Constellation**

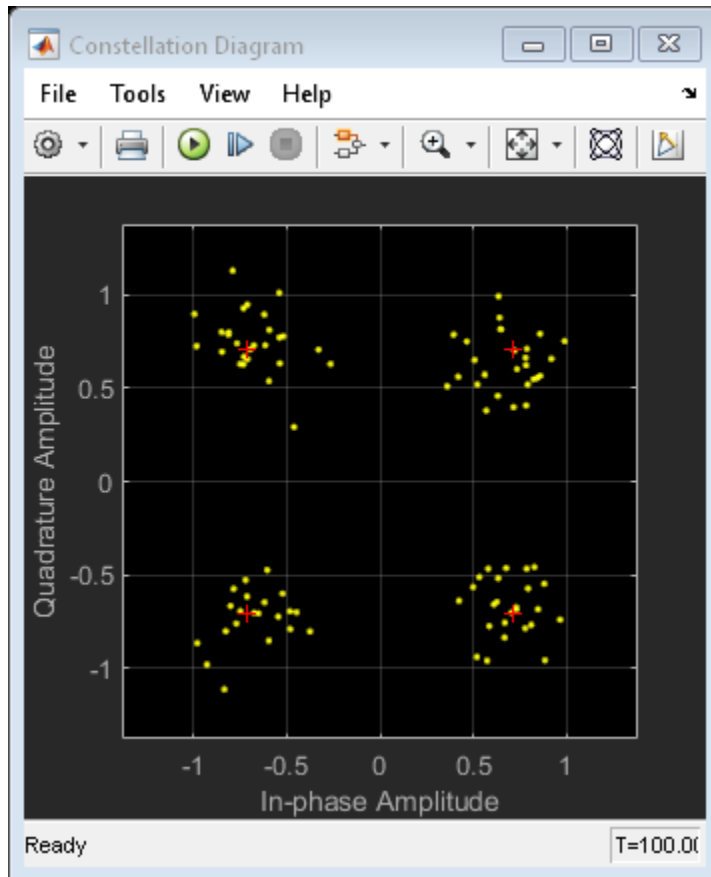

Open the QPSK model. The model generates QPSK data, applies white noise, and displays the resulting constellation diagram.

Run the model.

Change the  $E_b/N_0$  of the AWGN Channel block from 15 dB to 10 dB.

The noise level increases as shown by the greater distance between the samples.

# Quantizing Decoder

Decode quantization index according to codebook

## Library

Source Coding

## Description

The Quantizing Decoder block converts quantization indices to the corresponding codebook values. The **Quantization codebook** parameter, a vector of length  $N$ , prescribes the possible output values. If the input is an integer  $k$  between 0 and  $N-1$ , then the output is the  $(k+1)$ st element of **Quantization codebook**.

The input must be a discrete-time signal. This block processes each vector element independently. For information about the data types each block port supports, see the “Supported Data Type” on page 3-942 table on this page.

---

**Note** The Quantizing Encoder block also uses a **Quantization codebook** parameter. The first output of that block corresponds to the input of Quantizing Decoder, while the second output of that block corresponds to the output of Quantizing Decoder.

---

## Parameters

### Quantization codebook

A real vector that prescribes the output value corresponding to each nonnegative integer of the input.

### Quantized output data type

Select the output data type.

## Supported Data Type

Port	Supported Data Types
Idx	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li><li>• 8-, 16-, and 32-bit signed integers</li><li>• 8-, 16-, and 32-bit unsigned integers</li></ul>

# Quantizing Encoder

Quantize signal using partition and codebook

## Library

Source Coding

## Description

The Quantizing Encoder block quantizes the input signal according to the **Partition** vector and encodes the input signal according to the **Codebook** vector. This block processes each vector element independently. The input must be a discrete-time signal. This block processes each vector element independently. For information about the data types each block port supports, see the “Supported Data Type” on page 3-944 table on this page.

The first output is the quantization index. The second output is the quantized signal. The values for the quantized signal are taken from the **Codebook** vector.

The **Quantization partition** parameter,  $P$ , is a real vector of length  $n$  whose entries are in strictly ascending order. The quantization index (second output signal value) corresponding to an input value of  $x$  is

- 0 if  $x \leq P(1)$
- $m$  if  $P(m) < x \leq P(m+1)$
- $n$  if  $P(n) < x$

The **Quantization codebook** parameter, whose length is  $n+1$ , prescribes a value for each partition in the quantization. The first element of **Quantization codebook** is the value for the interval between negative infinity and the first element of  $P$ . The second output signal from this block contains the quantization of the input signal based on the quantization indices and prescribed values.

Use the `lloydys` function with a representative sample of your data as training data, to obtain appropriate partition and codebook parameters.

## Parameters

### Quantization partition

The vector of endpoints of the partition intervals.

### Quantization codebook

The vector of output values assigned to each partition.

### Index output data type

Select the output data type.

## Raised Cosine Receive Filter

Apply pulse shaping by downsampling signal using raised cosine FIR filter

### Library

Comm Filters

### Description

The Raised Cosine Receive Filter block filters the input signal using a normal raised cosine FIR filter or a square root raised cosine FIR filter. It also downsamples the filtered signal if you set the **Output mode** parameter to `Downsampling`. The FIR Decimation block implements this functionality. The Raised Cosine Receive Filter block's icon shows the filter's impulse response.

### Characteristics of the Filter

Characteristics of the raised cosine filter are the same as in the Raised Cosine Transmit Filter block, except that the length of the filter's input response has a slightly different expression:  $L * \text{Filter span in symbols} + 1$ , where  $L$  is the value of the **Input samples per symbol** parameter (not the **Output samples per symbol** parameter, as in the case of the Raised Cosine Transmit Filter block).

The block normalizes the filter coefficients to unit energy. If you specify a **Linear amplitude filter gain** other than 1, then the block scales the normalized filter coefficients using the gain value you specify.

### Decimating the Filtered Signal

To have the block decimate the filtered signal, set the **Decimation factor** parameter to a value greater than 1.

If  $K$  represents the **Decimation factor** parameter value, then the block retains  $1/K$  of the samples, choosing them as follows:

- If the **Decimation offset** parameter is zero, then the block selects the samples of the filtered signal indexed by  $1, K+1, 2*K+1, 3*K+1$ , etc.
- If the **Decimation offset** parameter is a positive integer less than  $M$ , then the block initially discards that number of samples from the filtered signal and downsamples the remaining data as in the previous case.

To preserve the entire filtered signal and avoid decimation, set **Decimation factor** to 1. This setting is appropriate, for example, when the output from the filter block forms the input to a timing phase recovery block such as Symbol Synchronizer. The timing phase recovery block performs the downsampling in that case.

## Input Signals and Output Signals

This block accepts a column vector or matrix input signal. For information about the data types each block port supports, see the “Supported Data Type” on page 3-952 table on this page.

If you set **Decimation factor** to 1, then the input and output signals share the same sampling mode, sample time, and vector length.

If you set **Decimation factor** to  $K$ , which is greater than 1, then  $K$  and the input sampling mode determine characteristics of the output signal:

## Single-Rate Processing

When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To generate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output ( $M_o$ ) is  $1/K$  times that of the input ( $M_o = M_i/K$ ). In this mode, the input frame size,  $M_i$ , must be a multiple of  $K$ .

## Multirate Processing

When you set the **Rate options** parameter to Allow multirate processing, the input and output of the block are the same size, but the sample rate of the output is  $K$  times slower than that of the input. When the block is in multirate processing mode, you must also specify a value for the **Input processing** parameter:

- When you set the **Input processing** parameter to **Elements as channels (sample based)**, the block treats an  $M$ -by- $N$  matrix input as  $M*N$  independent channels, and processes each channel over time. The output sample period ( $T_{so}$ ) is  $K$  times longer than the input sample period ( $T_{so} = K*T_{si}$ ), and the input and output sizes are identical.
- When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats an  $M_i$ -by- $N$  matrix input as  $N$  independent channels. The block processes each column of the input over time by keeping the frame size constant ( $M_i=M_o$ ), and making the output frame period ( $T_{fo}$ )  $K$  times longer than the input frame period ( $T_{fo} = K*T_{fi}$ ).

## Exporting Filter Coefficients to the MATLAB Workspace

To examine or manipulate the coefficients of the filter that this block designs, select **Export filter coefficients to workspace**. Then set the **Coefficient variable name** parameter to the name of a variable that you want the block to create in the MATLAB workspace. Running the simulation causes the block to create the variable, overwriting any previous contents in case the variable already exists.

## Latency

For information pertaining to the latency of the block, see details in FIR Decimation.

## Parameters

### Filter shape

Specify the filter shape as **Square root** or **Normal**.

### Rolloff factor

Specify the rolloff factor of the filter. Use a real number between 0 and 1.

### Filter span in symbols

Specify the number of symbols the filter spans as an even, integer-valued positive scalar. The default is 10. Because the ideal raised cosine filter has an infinite impulse response, the block truncates the impulse response to the number of symbols that this parameter specifies.

**Input samples per symbol**

An integer greater than 1 representing the number of samples that represent one symbol in the input signal.

**Decimation factor**

Specify the decimation factor the block applies to the input signal. The output samples per symbol equals the value of the input samples per symbol divided by the decimation factor. If the decimation factor is one, then the block only applies filtering. There is no decimation.

**Decimation offset**

Specify the decimation offset in samples. Use a value between 0 and **Decimation factor** -1.

**Linear amplitude filter gain**

Specify a positive scalar value that the block uses to scale the filter coefficients. By default, the block normalizes filter coefficients to provide unit energy gain. If you specify a gain other than 1, the block scales the normalized filter coefficients using the gain value you specify.

**Input processing**

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

**Rate options**

Specify the method by which the block should filter and downsample the input signal. You can select one of the following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the input sample rate and processes the signal by decreasing the output frame size by a factor of  $K$ . To select this option, you must set the **Input processing** parameter to **Columns as channels (frame based)**.
- **Allow multirate processing** — When you select this option, the block processes the signal such that the output sample rate is  $K$  times slower than the input sample rate.

**Export filter coefficients to workspace**

Select this check box to create a variable in the MATLAB workspace that contains the filter coefficients.

**Coefficient variable name**

The name of the variable to create in the MATLAB workspace. This field appears only if **Export filter coefficients to workspace** is selected.

**Visualize filter with FVTool**

If you click this button, then MATLAB launches the Filter Visualization Tool, `fvtool`, to analyze the raised cosine filter whenever you apply any changes to the block's parameters. If you launch `fvtool` for the filter, and subsequently change parameters in the mask, `fvtool` will not update. You will need to launch a new `fvtool` in order to see the new filter characteristics. Also note that if you have launched `fvtool`, then it will remain open even after the model is closed.

**Rounding mode**

Select the rounding mode for fixed-point operations. The block uses the **Rounding mode** when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. The filter coefficients do not obey this parameter; they always round to **Nearest**. For more information, see Rounding Modes (DSP System Toolbox) or “Rounding Mode: Simplest” (Fixed-Point Designer).

**Saturate on integer overflow**

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

**Coefficients**

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator).

See the Coefficients section of the FIR Decimation help page and “Filter Structure Diagrams” (DSP System Toolbox) for illustrations depicting the use of the coefficient data types in this block:

See the Coefficients subsection of the Digital Filter help page for descriptions of parameter settings.

- When you select **Same word length as input**, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that

provides you with the best precision possible given the value and word length of the coefficients.

- When you select **Specify word length**, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the **Rounding mode** and the **Saturate on integer overflow** parameters; they are always saturated and rounded to Nearest.

### **Product output**

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the product output data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

### **Accumulator**

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.

- When you select **Same as product output**, these characteristics match those of the product output.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

### Output

Choose how you specify the output word length and fraction length:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Same as accumulator**, these characteristics match those of the accumulator.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the output, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

# Raised Cosine Transmit Filter

Apply pulse shaping by upsampling signal using raised cosine FIR filter

## Library

Comm Filters

## Description

The Raised Cosine Transmit Filter block upsamples and filters the input signal using a normal raised cosine FIR filter or a square root raised cosine FIR filter. The block's icon shows the filter's impulse response.

## Characteristics of the Filter

The **Filter shape** parameter determines which type of filter the block uses; choices are Normal and Square root.

The impulse response of a normal raised cosine filter with rolloff factor  $R$  and symbol period  $T$  is

$$h(t) = \frac{\sin(\pi t/T)}{(\pi t/T)} \cdot \frac{\cos(\pi R t/T)}{(1 - 4R^2 t^2/T^2)}$$

The impulse response of a square root raised cosine filter with rolloff factor  $R$  is

$$h(t) = 4R \frac{\cos((1 + R)\pi t/T) + \frac{\sin((1 - R)\pi t/T)}{(4Rt/T)}}{\pi\sqrt{T}(1 - (4Rt/T)^2)}$$

The impulse response of a square root raised cosine filter convolved with itself is approximately equal to the impulse response of a normal raised cosine filter.

Because the ideal raised cosine filter has an infinite impulse response, the block truncates the impulse response to the number of symbols that the **Filter span in symbols** parameter specifies. The **Filter span in symbols**,  $N$ , and the **Output samples per symbol**,  $L$ , determine the length of the filter's impulse response, which is  $L * \text{Filter span in symbols} + 1$ .

The **Rolloff factor** parameter is the filter's rolloff factor. It must be a real number between 0 and 1. The rolloff factor determines the excess bandwidth of the filter. For example, a rolloff factor of .5 means that the bandwidth of the filter is 1.5 times the input sampling frequency.

The block normalizes the filter coefficients to unit energy. If you specify a **Linear amplitude filter gain** other than 1, then the block scales the normalized filter coefficients using the gain value you specify.

## Input Signals and Output Signals

The input must be a discrete-time signal. This block accepts a column vector or matrix input signal. For information about the data types each block port supports, see the “Supported Data Type” on page 3-961 table on this page.

The **Rate options** method and the value of the **Output samples per symbol**,  $L$ , parameter determine the characteristics of the output signal:

### Single-Rate Processing

When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. To generate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output ( $M_o$ ) is  $L$  times larger than that of the input ( $M_o = M_i * L$ ), where  $L$  represents the value of the **Output samples per symbol** parameter.

### Multirate Processing

When you set the **Rate options** parameter to `Allow multirate processing`, the input and output of the block are the same size. However, the sample rate of the output is  $L$  times faster than that of the input (i.e. the output sample time is  $1/L$  times the input sample time). When the block is in multirate processing mode, you must also specify a value for the **Input processing** parameter:

- When you set the **Input processing** parameter to **Elements as channels (sample based)**, the block treats an  $M$ -by- $L$  matrix input as  $M*N$  independent channels, and processes each channel over time. The output sample period ( $T_{so}$ ) is  $L$  times shorter than the input sample period ( $T_{so} = T_{si}/L$ ), while the input and output sizes remain identical.
- When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats an  $M_i$ -by- $N$  matrix input as  $N$  independent channels. The block processes each column of the input over time by keeping the frame size constant ( $M_i=M_o$ ), while making the output frame period ( $T_{fo}$ )  $L$  times shorter than the input frame period ( $T_{fo} = T_{fi}/L$ ).

## Exporting Filter Coefficients to the MATLAB Workspace

To examine or manipulate the coefficients of the filter that this block designs, select **Export filter coefficients to workspace**. Then set the **Coefficient variable name** parameter to the name of a variable that you want the block to create in the MATLAB workspace. Running the simulation causes the block to create the variable, overwriting any previous contents in case the variable already exists.

## Parameters

### Filter shape

Specify the filter shape as **Square root** or **Normal**.

### Rolloff factor

Specify the rolloff factor of the filter. Use a real number between 0 and 1.

### Filter span in symbols

Specify the number of symbols the filter spans as an even, integer-valued positive scalar. The default is 10. Because the ideal raised cosine filter has an infinite impulse response, the block truncates the impulse response to the number of symbols that this parameter specifies.

### Output samples per symbol

Specify the number of output samples for each input symbol. The default is 8. This property accepts an integer-valued, positive scalar. The number of taps for the raised cosine filter equals the value of this parameter multiplied by the value of the **Filter span in symbols** parameter.

**Linear amplitude filter gain**

Specify a positive scalar value that the block uses to scale the filter coefficients. By default, the block normalizes filter coefficients to provide unit energy gain. If you specify a gain other than 1, the block scales the normalized filter coefficients using the gain value you specify.

**Input processing**

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

**Rate options**

Specify the method by which the block should upsample and filter the input signal. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and processes the signal by increasing the output frame size by a factor of  $N$ . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block processes the signal such that the output sample rate is  $N$  times faster than the input sample rate.

**Export filter coefficients to workspace**

Select this check box to create a variable in the MATLAB workspace that contains the filter coefficients.

**Visualize filter with FVTool**

If you click this button, then MATLAB launches the Filter Visualization Tool, `fvtool`, to analyze the raised cosine filter whenever you apply any changes to the block's parameters. If you launch `fvtool` for the filter, and subsequently change parameters in the mask, `fvtool` will not update. You will need to launch a new `fvtool` in order to see the new filter characteristics. Also note that if you have launched `fvtool`, then it will remain open even after the model is closed.

### **Rounding mode**

Select the rounding mode for fixed-point operations. The block uses the **Rounding mode** when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. The filter coefficients do not obey this parameter; they always round to **Nearest**. For more information, see Rounding Modes (DSP System Toolbox) or “Rounding Mode: Simplest” (Fixed-Point Designer).

### **Saturate on integer overflow**

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

### **Coefficients**

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See “Filter Structure Diagrams” (DSP System Toolbox) for illustrations depicting the use of the coefficient data types in this block:

- When you select **Same word length as input**, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Specify word length**, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the **Rounding mode** and the **Saturate on integer overflow** parameters; they are always saturated and rounded to **Nearest**.

**Product output**

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the product output data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

**Accumulator**

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Same as product output**, these characteristics match those of the product output.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

**Output**

Choose how you specify the output word length and fraction length:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Same as accumulator**, these characteristics match those of the accumulator.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the output, in bits.

- When you select **Slope** and **bias** scaling, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

# Random Deinterleaver

Restore ordering of input symbols using random permutation

## Library

Block sublibrary of Interleaving

## Description

The Random Deinterleaver block rearranges the elements of its input vector using a random permutation. The **Initial seed** parameter initializes the random number generator that the block uses to determine the permutation. If this block and the Random Interleaver block have the same value for **Initial seed**, then the two blocks are inverses of each other.

This block accepts a column vector input signal. The **Number of elements** parameter indicates how many numbers are in the input vector.

The block accepts the following data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

### Number of elements

The number of elements in the input vector.

### Initial seed

The initial seed value for the random number generator.

# Random Integer Generator

Generate integers randomly distributed in specified range

**Library:** Communications Toolbox / Comm Sources / Random Data Sources

## Description

The Random Integer Generator block generates uniformly distributed random integers in the range  $[0, M-1]$ , where  $M$  is specified by the Set size parameter. Use this block to generate random binary-valued or integer-valued data.

To ensure that the model uses different initial seeds, set the Simulate using parameter to *Interpreted execution*, and run the simulation in Normal or Accelerator mode. For more information, see “Limitations” on page 3-965.

## Limitations

- In Rapid Accelerator simulation mode, when you set Simulate using to *Interpreted execution* and Source of initial seed to *Auto*, the block generates the same numbers every time the simulation runs. This behavior is equivalent to setting Source of initial seed to *Parameter* and setting Initial seed to  $\emptyset$ .
- In all simulation modes (Normal, Accelerator, and Rapid Accelerator), when you set Simulate using to *Code generation* and Source of initial seed to *Auto*, the block generates the same numbers every time the simulation runs. This behavior is equivalent to setting Source of initial seed to *Parameter* and Initial seed to  $\emptyset$ .

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

### Output

#### **Out — Random integer output**

scalar | vector | matrix

Random integer output, returned as a scalar, vector, or matrix. This port is unnamed on the block. The data type is set using the Output data type parameter.

The number of rows in the output data equals the value of the Samples per frame parameter and corresponds to the number of samples in one frame. The number of columns in the output data equals the number of elements in the Set size parameter and corresponds to the number of channels.

## Parameters

#### **Set size — Set size**

8 (default) | positive integer | row vector of positive integers

Set size,  $M$ , specified as a positive integer or row vector of positive integers. The block generates integers in the range  $[0, (M - 1)]$ . The number of elements in **Set size** corresponds to the number of independent channels output from the block.

- If **Set size** is a scalar, then all output random variables are independent and identically distributed (i.i.d.).
- If **Set size** is a vector, then the length of the vector determines the number of output channels. The channels can have differing output ranges.

#### **Source of initial seed — Source of initial seed**

Auto (default) | Parameter

Source of the initial seed for the random number generator, specified as either:

- **Auto** -- the block uses the global random number stream
- **Parameter** -- the block sets the random number generator seed to **Initial seed**

#### **Initial seed — Initial seed value**

0 (default) | nonnegative integer

Initial seed value for the random number generator, specified as a nonnegative integer. If the **Initial seed** parameter is a constant, then the resulting sequence is repeatable.

**Dependencies**

To enable this parameter, set the **Source of initial seed** parameter to `Parameter`.

**Sample time — Sample time**

1 (default) | positive scalar

Sample time in seconds, specified as a positive scalar indicating the time between each sample in a column of the output data.

**Samples per frame — Samples per frame**

1 (default) | positive integer

Samples per frame, specified as a positive integer indicating the number of samples per frame in one channel of the output data.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal 1, the block outputs 1 integer every 1 second. If **Samples per frame** is increased to 10, then a 10-by-1 vector of integers is output every 10 seconds. The equivalent output rate is not dependent on the **Samples per frame** parameter.

---

**Output data type — Output data type**

double (default) | single | uint8 | uint16 | uint32 | boolean

Output data type, specified as `double`, `single`, `uint8`, `uint16`, `uint32`, or `boolean`. If this parameter is set to `boolean`, you must set the `Set size` parameter to 2.

**Simulate using — Type of simulation to run**

Interpreted execution (default) | Code generation

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.

- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In **Interpreted execution** mode, you can debug the source code of the block.

# Rayleigh Noise Generator

(To be removed) Generate Rayleigh distributed noise

---

**Note** Rayleigh Noise Generator will be removed in a future release. Use the MATLAB Function block and `randn` function instead.

---

## Library

Noise Generators sublibrary of Comm Sources

## Description

The Rayleigh Noise Generator block generates Rayleigh distributed noise. The Rayleigh probability density function is given by

$$f(x) = \begin{cases} \frac{x}{\sigma^2} \exp\left(-\frac{x^2}{2\sigma^2}\right) & x \geq 0 \\ 0 & x < 0 \end{cases}$$

where  $\sigma^2$  is known as the *fading envelope* of the Rayleigh distribution.

The block requires you to specify the **Initial seed** for the random number generator. If it is a constant, then the resulting noise is repeatable. The **sigma** parameter can be either a vector of the same length as the **Initial seed**, or a scalar. When **sigma** is a scalar, every element of the output signal shares that same value.

## Initial Seed

The **Initial seed** parameter initializes the random number generator that the Rayleigh Noise Generator block uses to add noise to the input signal. When multiple blocks in a model have the **Initial seed** parameter, you can choose different initial seeds for each block to ensure different random streams are used in each block. Set **Initial seed** to an integer value for repeatable results or use the `randi` function to randomize your results.

## Attributes of Output Signal

The output signal can be a frame-based matrix, a sample-based row or column vector, or a sample-based one-dimensional array. These attributes are controlled by the **Frame-based outputs**, **Samples per frame**, and **Interpret vector parameters as 1-D** parameters. See “Sources and Sinks” for more details.

The number of elements in the **Initial seed** parameter becomes the number of columns in a frame-based output or the number of elements in a sample-based vector output. Also, the shape (row or column) of the **Initial seed** parameter becomes the shape of a sample-based two-dimensional output signal.

## Parameters

### Sigma

Specify  $\sigma$  as defined in the Rayleigh probability density function.

### Initial seed

The initial seed value for the random number generator.

### Sample time

The period of each sample-based vector or each row of a frame-based matrix.

### Frame-based outputs

Determines whether the output is frame-based or sample-based. This box is active only if **Interpret vector parameters as 1-D** is unchecked.

### Samples per frame

The number of samples in each column of a frame-based output signal. This field is active only if **Frame-based outputs** is checked.

### Interpret vector parameters as 1-D

If this box is checked, then the output is a one-dimensional signal. Otherwise, the output is a two-dimensional signal. This box is active only if **Frame-based outputs** is unchecked.

### Output data type

The output can be set to `double` or `single` data types.

## Receiver Thermal Noise

Apply receiver thermal noise to complex baseband signal

## Library

RF Impairments

## Description

The Receiver Thermal Noise block simulates the effects of thermal noise on a complex, baseband signal. You can specify the amount of thermal noise in three ways, according to which **Specification method** you select:

- **Noise temperature** specifies the noise in degrees K.
- **Noise figure** specifies the receiver noise in dB for an input noise temperature of 290 K. This is the decibel equivalent of the noise factor.
- **Noise factor** specifies the receiver noise for an input noise temperature of 290 K. This is the linear equivalent of the noise figure.

The following scatter plot shows the effect of the Receiver Thermal Noise block, with **Specification method** set to **Noise figure** and **Noise figure (dB)** set to 3.01, on a signal modulated by 16-QAM.

This plot is generated by the model described in “Illustrate RF Impairments That Distort a Signal” with the following parameter settings:

- Rectangular QAM Modulator Baseband
  - **Normalization method** set to Average Power
  - **Average power (watts)** set to  $1e-12$
- Receiver Thermal Noise
  - **Specification method** set to Noise figure
  - **Noise figure (dB)** set to 3.01

## Parameters

### Specification method

The method by which you specify the amount of noise. The choices are Noise temperature, Noise figure, and Noise factor.

### Noise temperature (K)

Scalar specifying the amount of noise in degrees K.

#### **Noise figure (dB)**

Scalar specifying the amount of noise in dB relative to a noise temperature of 290 degrees K. This parameter specifies the noise contribution of the receiver circuitry only. To add the effects of antenna noise, select the **Add 290K antenna noise** check box.

#### **Noise factor**

Scalar specifying the amount of noise relative to a noise temperature of 290 degrees K. This parameter specifies the noise contribution of the receiver circuitry only. To add the effects of antenna noise, select the **Add 290K antenna noise** check box.

#### **Add 290K antenna noise**

Select this check box to add 290 K antenna noise to the signal. This parameter is available when **Specification method** is Noise figure or Noise factor.

#### **Initial seed**

The initial seed value for the random number generator that generates the noise.

## **Extended Capabilities**

### **C/C++ Code Generation**

# Rectangular QAM Demodulator Baseband

Demodulate rectangular-QAM-modulated data

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The Rectangular QAM Demodulator Baseband block demodulates a signal that was modulated using quadrature amplitude modulation with a constellation on a rectangular lattice.

---

**Note** All values of power assume a nominal impedance of 1 ohm.

---

The signal constellation has  $M$  points, where  $M$  is the **M-ary number** parameter.  $M$  must have the form  $2^K$  for some positive integer  $K$ . The block scales the signal constellation based on how you set the **Normalization method** parameter. For details, see the reference page for the Rectangular QAM Modulator Baseband block.

This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see the “Supported Data Types” on page 3-986 table on this page.

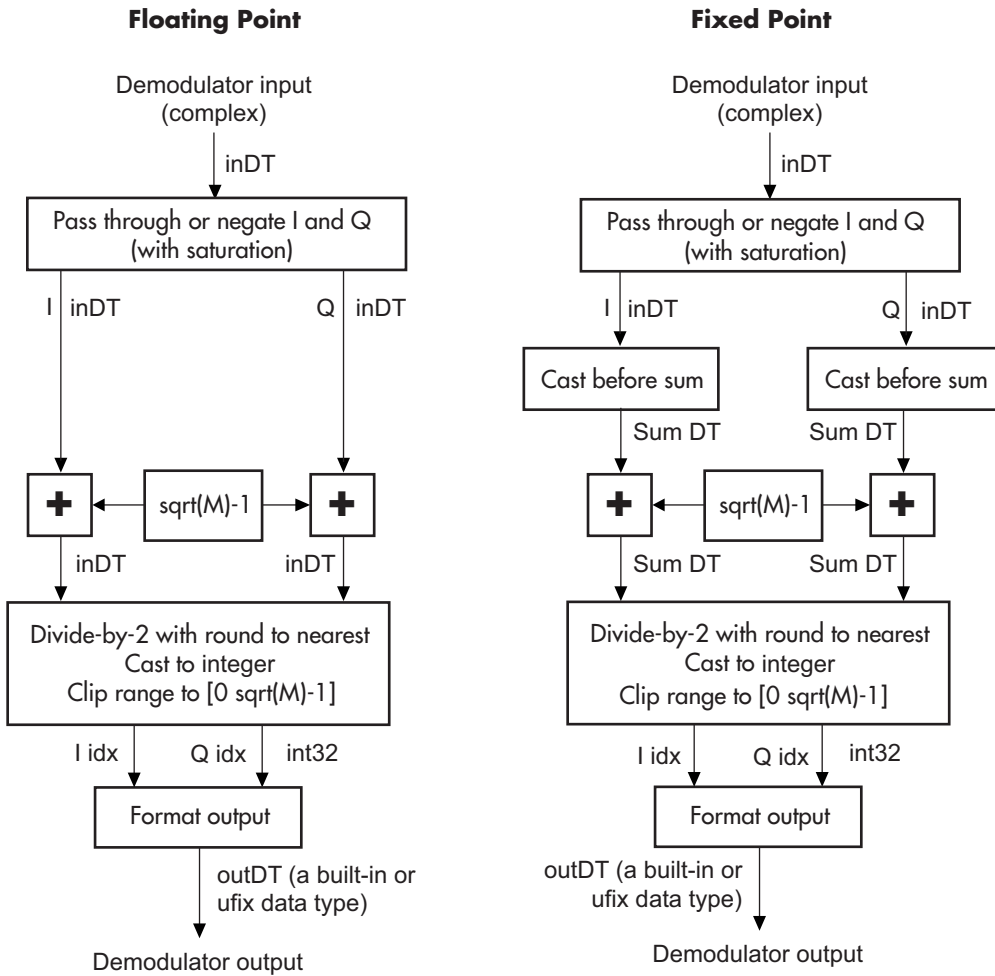

## Hard Decision Algorithm

The demodulator algorithm maps received input signal constellation values to  $M$ -ary integer  $I$  and  $Q$  symbol indices between 0 and  $\sqrt{M} - 1$  and then maps these demodulated symbol indices to formatted output values.

The integer symbol index computation is performed by first derotating and scaling the complex input signal constellation (possibly with noise) by a derotate factor and denormalization factor, respectively. These factors are derived from the **Phase offset**, **Normalization method**, and related parameters. These derotated and denormalized values are added to  $\sqrt{M} - 1$  to translate them into an approximate range between 0 and  $2 \times (\sqrt{M} - 1)$  (plus noise). The resulting values are then rescaled via a divide-by-two (or, equivalently, a right-shift by one bit for fixed-point operation) to obtain a range approximately between 0 and  $\sqrt{M} - 1$  (plus noise) for I and Q. The noisy index values are rounded to the nearest integer and clipped, via saturation, and mapped to integer symbol values in the range [0 M-1]. Finally, based on other block parameters, the integer index is mapped to a symbol value that is formatted and cast to the selected **Output data type**.

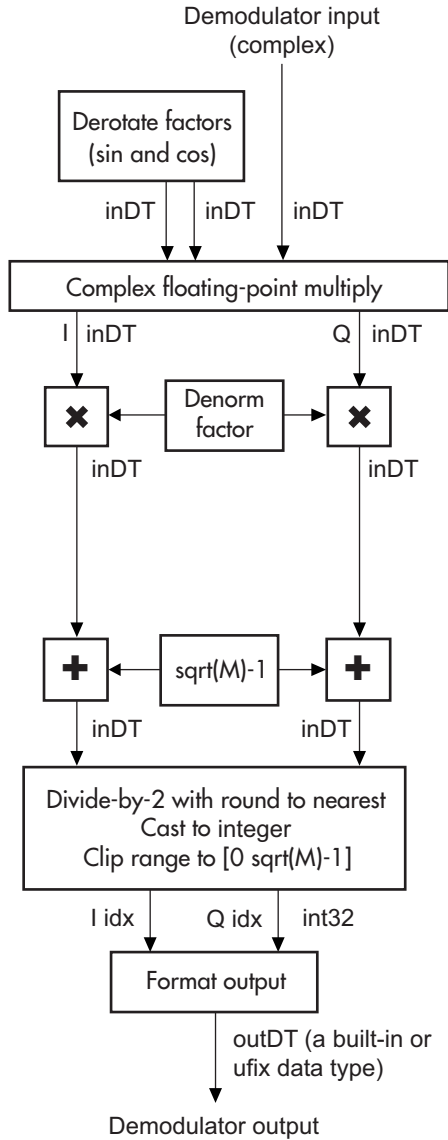

The following figures contains signal flow diagrams for floating-point and fixed-point algorithm operation. The floating-point diagrams apply when the input signal data type is `double` or `single`. The fixed-point diagrams apply when the input signal is a signed fixed-point data type. Note that the diagram is simplified when **Phase offset** is a multiple of  $\pi/2$ , and/or the derived denormalization factor is 1.

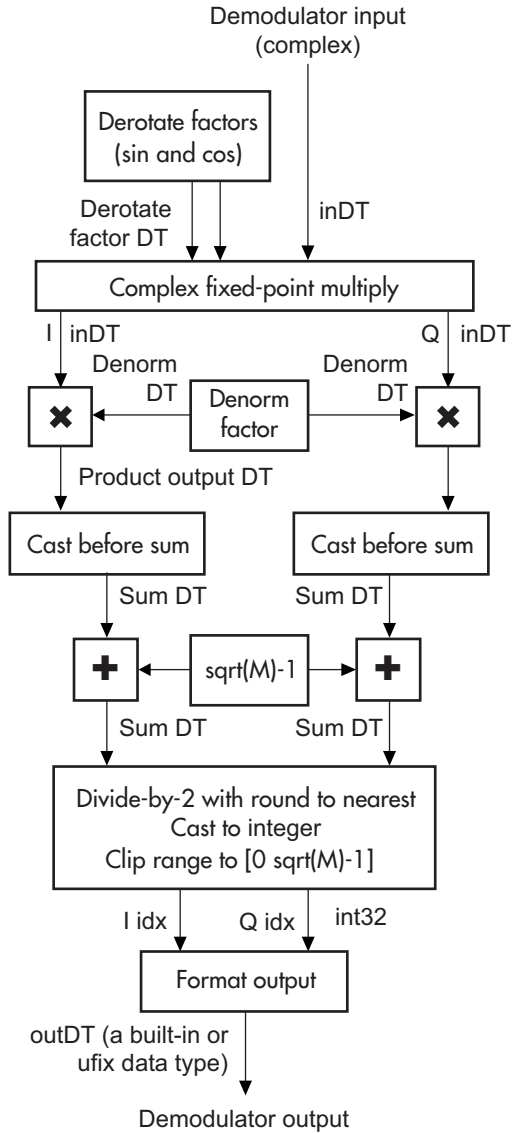

**Signal-Flow Diagrams with Trivial Phase Offset and Denormalization Factor Equal to 1**

**Floating Point**

**Fixed Point**

**Signal-Flow Diagrams with Nontrivial Phase Offset and Nonunity Denormalization Factor**

## Parameters

### M-ary number

The number of points in the signal constellation. It must have the form  $2^K$  for some positive integer  $K$ .

### Normalization method

Determines how the block scales the signal constellation. Choices are `Min. distance between symbols`, `Average Power`, and `Peak Power`.

### Minimum distance

This parameter appears when **Normalization method** is set to `Min. distance between symbols`.

The distance between two nearest constellation points.

### Average power, referenced to 1 ohm (watts)

The average power of the symbols in the constellation, referenced to 1 ohm. This field appears only when **Normalization method** is set to `Average Power`.

### Peak power, referenced to 1 ohm (watts)

The maximum power of the symbols in the constellation, referenced to 1 ohm. This field appears only when **Normalization method** is set to `Peak Power`.

### Phase offset (rad)

The rotation of the signal constellation, in radians.

### Constellation ordering

Determines how the block assigns binary words to points of the signal constellation. More details are on the reference page for the Rectangular QAM Modulator Baseband block.

Selecting `User-defined` displays the field **Constellation mapping**, allowing for user-specified mapping.

### Constellation mapping

This parameter appears when `User-defined` is selected in the pull-down list **Constellation ordering**.

This is a row or column vector of size  $M$  and must have unique integer values in the range  $[0, M-1]$ . The values must be of data type `double`.

The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point.

#### **Output type**

Determines whether the block produces integers or binary representations of integers.

If set to `Integer`, the block produces integers.

If set to `Bit`, the block produces a group of  $K$  bits, called a *binary word*, for each symbol, when **Decision type** is set to `Hard decision`. If **Decision type** is set to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, the block outputs bitwise LLR and approximate LLR, respectively.

#### **Decision type**

This parameter appears when `Bit` is selected in the pull-down list **Output type**.

Specifies the use of hard decision, LLR, or approximate LLR during demodulation. See “Exact LLR Algorithm” and “Approximate LLR Algorithm” in the *Communications Toolbox User's Guide* for algorithm details.

#### **Noise variance source**

This parameter appears when `Approximate log-likelihood ratio` or `Log-likelihood ratio` is selected for **Decision type**.

When set to `Dialog`, the noise variance can be specified in the **Noise variance** field. When set to `Port`, a port appears on the block through which the noise variance can be input.

#### **Noise variance**

This parameter appears when the **Noise variance source** is set to `Dialog` and specifies the noise variance in the input signal. This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- Inf to -Inf if **Noise variance** is very high
- NaN if **Noise variance** and signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

## Output

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type `single` or `double`. Otherwise, the output data type will be as if this parameter is set to 'Smallest unsigned integer'.

When the parameter is set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the **Hardware Implementation** pane, the output data type is the ideal minimum size, i.e., `ufix(1)` for bit outputs, and `ufix(ceil(log2(M)))` for integer outputs. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit the ideal minimum size, usually corresponding to the size of a char (e.g., `uint8`).

For integer outputs, this parameter can be set to `Smallest unsigned integer`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `single`, and `double`. For bit outputs, the options are `Smallest unsigned integer`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, or `double`.

#### **Derotate factor**

This parameter only applies when the input is fixed-point and **Phase offset** is not a multiple of  $\pi/2$ .

This can be set to `Same word length as input` or `Specify word length`, in which case a field is enabled for user input.

#### **Denormalization factor**

This parameter only applies when the input is fixed-point and the derived denormalization factor is nonunity (not equal to 1). This scaling factor is derived from **Normalization method** and other parameter values in the block dialog.

This can be set to `Same word length as input` or `Specify word length`, in which case a field is enabled for user input. A best-precision fraction length is always used.

#### **Product output**

This parameter only applies when the input is a fixed-point signal and there is a nonunity (not equal to 1) denormalized factor. It can be set to `Inherit via internal rule` or `Specify word length`, which enables a field for user input.

Setting to `Inherit via internal rule` computes the full-precision product word length and fraction length. Internal Rule for Product Data Types (DSP System Toolbox) in *DSP System Toolbox User's Guide* describes the full-precision **Product output** internal rule.

Setting to `Specify word length` allows you to define the word length. The block computes a best-precision fraction length based on the word length specified and the

pre-computed worst-case (min/max) real world value **Product output** result. The worst-case **Product output** result is precomputed by multiplying the denormalized factor with the worst-case (min/max) input signal range, purely based on the input signal data type.

The block uses the **Rounding mode** when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. For more information, see “Rounding Modes” (DSP System Toolbox) or “Rounding Mode: Simplest” (Fixed-Point Designer).

## Sum

This parameter only applies when the input is a fixed-point signal. It can be set to `Inherit via internal rule`, `Same as product output`, or `Specify word length`, in which case a field is enabled for user input

Setting to `Inherit via internal rule` computes the full-precision sum word length and fraction length, based on the two inputs to the Sum in the fixed-point Hard Decision Algorithm on page 3-977 signal flow diagram. The rule is the same as the fixed-point inherit rule of the internal **Accumulator data type** parameter in the Simulink Sum block.

Setting to `Specify word length` allows you to define the word length. A best precision fraction length is computed based on the word length specified in the pre-computed maximum range necessary for the demodulated algorithm to produce accurate results. The signed fixed-point data type that has the best precision fully contains the values in the range  $2 * (\sqrt{M} - 1)$  for the specified word length.

Setting to `Same as product output` allows the Sum data type to be the same as the **Product output** data type (when **Product output** is used). If the **Product output** is not used, then this setting will be ignored and the `Inherit via internal rule` Sum setting will be used.

## Examples

### Demodulate Noisy QAM Signal

Modulate and demodulate a noisy QAM signal.

Open the QAM demodulation model.

Run the simulation. The results are saved to the base workspace, where the variable `ErrorVec` is a 1-by-3 row vector. The BER is found in the first element.

Display the error statistics. For the  $E_b/N_0$  provided, 2 dB, the resultant BER is approximately 0.1. Your results may vary slightly.

ans =

```
0.0948
```

Increase the  $E_b/N_0$  to 4 dB. Rerun the simulation, and observe that the BER has decreased.

ans =

```
0.0167
```

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

#### HDL Architecture

This block has a single, default HDL architecture.

#### HDL Block Properties

<b>ConstrainedOutputPipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

#### Restrictions

- The block does not support `single` or `double` data types for HDL code generation.
- HDL Coder supports the following **Output type** options:
  - Integer
  - Bit is supported only if the **Decision Type** is `Hard decision`.
- You must set **Normalization Method** to `Minimum Distance Between Symbols`, with a **Minimum distance** of 2.
- You must set **Phase offset (rad)** to a value that is a multiple of  $\pi/4$ .

## Rectangular QAM Modulator Baseband

Modulate using rectangular quadrature amplitude modulation

### Library

AM, in Digital Baseband sublibrary of Modulation

### Description

The Rectangular QAM Modulator Baseband block modulates using M-ary quadrature amplitude modulation with a constellation on a rectangular lattice. The output is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see “Supported Data Types” on page 3-996.

---

**Note** All values of power assume a nominal impedance of 1 ohm.

---

### Integer-Valued Signals and Binary-Valued Signals

When you set the **Input type** parameter to *Integer*, the block accepts integer values between 0 and  $M-1$ .  $M$  represents the **M-ary number** block parameter.

When you set the **Input type** parameter to *Bit*, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of  $K = \log_2(M)$  bits

where

$K$  represents the number of bits per symbol.

The input vector length must be an integer multiple of  $K$ . In this configuration, the block accepts a group of  $K$  bits and maps that group onto a symbol at the block output. The block outputs one modulated symbol for each group of  $K$  bits.

The **Constellation ordering** parameter indicates how the block assigns binary words to points of the signal constellation. Such assignments apply independently to the in-phase and quadrature components of the input:

- If **Constellation ordering** is set to Binary, the block uses a natural binary-coded constellation.
- If **Constellation ordering** is set to Gray and  $K$  is even, the block uses a Gray-coded constellation.
- If **Constellation ordering** is set to Gray and  $K$  is odd, the block codes the constellation so that pairs of nearest points differ in one or two bits. The constellation is cross-shaped, and the schematic below indicates which pairs of points differ in two bits. The schematic uses  $M = 128$ , but suggests the general case.

For details about the Gray coding, see the reference page for the M-PSK Modulator Baseband block and the paper listed in References on page 3-997. Because the in-phase and quadrature components are assigned independently, the Gray and binary orderings coincide when  $M = 4$ .

## Constellation Size and Scaling

The signal constellation has  $M$  points, where  $M$  is the **M-ary number** parameter.  $M$  must have the form  $2^K$  for some positive integer  $K$ . The block scales the signal constellation based on how you set the **Normalization method** parameter. The following table lists the possible scaling conditions.

Value of Normalization Method Parameter	Scaling Condition
Min. distance between symbols	The nearest pair of points in the constellation is separated by the value of the <b>Minimum distance</b> parameter
Average Power	The average power of the symbols in the constellation is the <b>Average power</b> parameter
Peak Power	The maximum power of the symbols in the constellation is the <b>Peak power</b> parameter

## Constellation Visualization

The Rectangular QAM Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the Constellation Visualization section of the *Communications Toolbox User's Guide*.

## Parameters

### M-ary number

The number of points in the signal constellation. It must have the form  $2^K$  for some positive integer  $K$ .

### Input type

Indicates whether the input consists of integers or groups of bits.

### Constellation ordering

Determines how the block maps each symbol to a group of output bits or integer.

Selecting **User-defined** displays the field **Constellation mapping**, which allows for user-specified mapping.

### Constellation mapping

This parameter is a row or column vector of size  $M$  and must have unique integer values in the range  $[0, M-1]$ . The values must be of data type `double`.

The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point.

This field appears when `User-defined` is selected in the drop-down list **Constellation ordering**.

### **Normalization method**

Determines how the block scales the signal constellation. Choices are `Min. distance between symbols`, `Average Power`, and `Peak Power`.

### **Minimum distance**

The distance between two nearest constellation points. This field appears only when **Normalization method** is set to `Min. distance between symbols`.

### **Average power, referenced to 1 ohm (watts)**

The average power of the symbols in the constellation, referenced to 1 ohm. This field appears only when **Normalization method** is set to `Average Power`.

### **Peak power, referenced to 1 ohm (watts)**

The maximum power of the symbols in the constellation, referenced to 1 ohm. This field appears only when **Normalization method** is set to `Peak Power`.

### **Phase offset (rad)**

The rotation of the signal constellation, in radians.

### **Output data type**

The output data type can be set to `double`, `single`, `Fixed-point`, `User-defined`, or `Inherit via back propagation`.

Setting this parameter to `Fixed-point` or `User-defined` enables fields in which you can further specify details. Setting this parameter to `Inherit via back propagation`, sets the output data type and scaling to match the following block.

### **Output word length**

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

### **User-defined data type**

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the `sfix`, `sint`, `sfrac`, and `fixdt` functions from Fixed-Point Designer software. This parameter is only visible when you select `User-defined` for the **Output data type** parameter.

#### Set output fraction length to

Specify the scaling of the fixed-point output by either of the following methods:

- Choose **Best precision** to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose **User-defined** to specify the output scaling in the **Output fraction length** parameter.

This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter or when you select **User-defined** and the specified output data type is a fixed-point data type.

#### Output fraction length

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select **Fixed-point** or **User-defined** for the **Output data type** parameter and **User-defined** for the **Set output fraction length to** parameter.

## Examples

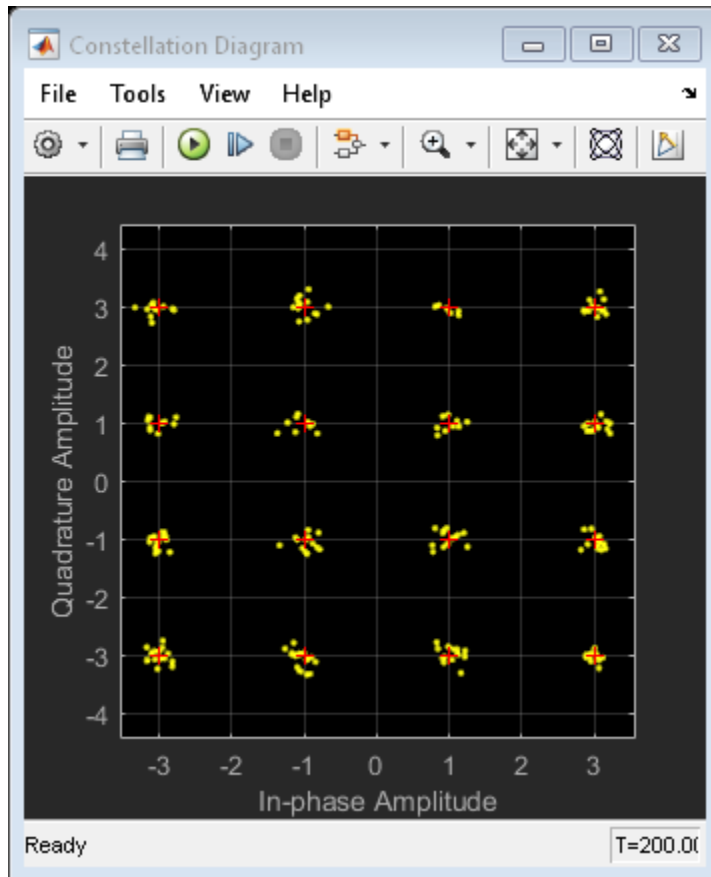

#### Plot Noisy 16-QAM Constellation

Open the 16-QAM model. The model generates a QAM signal, applies white noise, and displays the resulting constellation diagram.

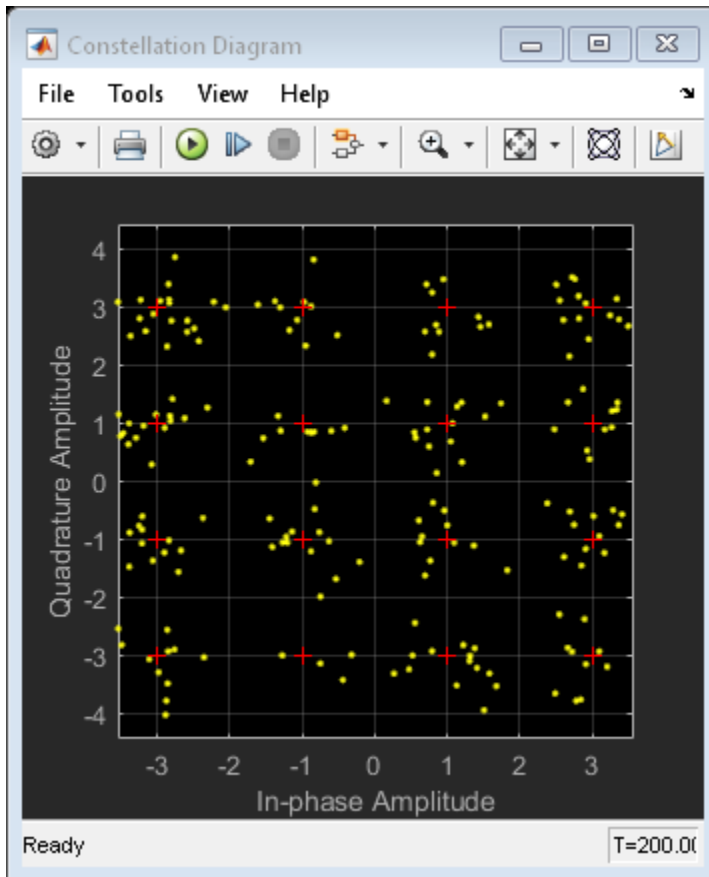

Run the model.

Change the  $E_b/N_0$  of the AWGN Channel block from 20 dB to 10 dB. Observe the increase in the noise.

## Supported Data Types

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### HDL Architecture

This block has a single, default HDL architecture.

### HDL Block Properties

<b>ConstrainedOutputPipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

### Restrictions

- The block does not support `single` or `double` data types for HDL code generation.
- When **Input Type** is set to `Bit`, the block does not support HDL code generation for input types other than `boolean` or `ufix1`.

When the input type is set to `Bit`, but the block input is actually multibit (`uint16`, for example), the Rectangular QAM Modulator Baseband block does not support HDL code generation.

### Blocks

General QAM Modulator Baseband | Rectangular QAM Demodulator Baseband

**Introduced before R2006a**

# Rectangular QAM TCM Decoder

Decode trellis-coded modulation data, modulated using QAM method

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The Rectangular QAM TCM Decoder block uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a QAM signal constellation.

The **M-ary number** parameter represents the number of points in the signal constellation, which also equals the number of possible output symbols from the convolutional encoder. (That is,  $\log_2(\mathbf{M-ary\ number})$  is the number of output bit streams from the convolutional encoder.)

The **Trellis structure** and **M-ary number** parameters in this block should match those in the Rectangular QAM TCM Encoder block, to ensure proper decoding.

## Input and Output Signals

This block accepts a column vector input signal containing complex numbers. For information about the data types each block port supports, see “Supported Data Types” on page 3-1001.

If the convolutional encoder described by the trellis structure represents a rate  $k/n$  code, then the Rectangular QAM TCM Decoder block's output is a binary column vector with a length of  $k$  times the vector length of the input signal.

## Operation Modes

The block has three possible methods for transitioning between successive frames. The **Operation mode** parameter controls which method the block uses. This parameter also affects the range of possible values for the **Traceback depth** parameter,  $D$ .

- In **Continuous** mode, the block initializes all state metrics to zero at the beginning of the simulation, waits until it accumulates  $D$  symbols, and then uses a sequence of  $D$  symbols to compute each of the traceback paths.  $D$  can be any positive integer. At the end of each frame, the block saves its internal state metric for use with the next frame.

If you select **Enable the reset input**, the block displays another input port, labeled **Rst**. This port receives an integer scalar signal. Whenever the value at the **Rst** port is nonzero, the block resets all state metrics to zero and sets the traceback memory to zero.

- In **Truncated** mode, the block treats each frame independently. The traceback path starts at the state with the lowest metric.  $D$  must be less than or equal to the vector length of the input.
- In **Terminated** mode, the block treats each frame independently. The traceback path always starts at the all-zeros state.  $D$  must be less than or equal to the vector length of the input. If you know that each frame of data typically ends at the all-zeros state, then this mode is an appropriate choice.

## Decoding Delay

If you set **Operation mode** to **Continuous**, then this block introduces a decoding delay equal to **Traceback depth**\* $k$  bits, for a rate  $k/n$  convolutional code. The decoding delay is the number of zeros that precede the first decoded bit in the output.

The block incurs no delay for other values of **Operation mode**.

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

### M-ary number

The number of points in the signal constellation.

**Traceback depth**

The number of trellis branches (equivalently, the number of symbols) the block uses in the Viterbi algorithm to construct each traceback path.

**Operation mode**

The operation mode of the Viterbi decoder. Choices are Continuous, Truncated, and Terminated.

**Enable the reset input port**

When you select this check box, the block has a second input port labeled Rst. Providing a nonzero input value to this port causes the block to set its internal memory to the initial state before processing the input data. This option appears only if you set **Operation mode** to Continuous.

**Output data type**

Select the data type for the block output signal as boolean or single. By default, the block sets this to double.

**Supported Data Types**

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>
Reset	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean</li> </ul>

**Introduced before R2006a**

# Rectangular QAM TCM Encoder

Convolutionally encode binary data and modulate using QAM method

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The Rectangular QAM TCM Encoder block implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a QAM signal constellation.

The **M-ary number** parameter is the number of points in the signal constellation, which also equals the number of possible output symbols from the convolutional encoder. (That is,  $\log_2(\mathbf{M}\text{-ary number})$  is equal to  $n$  for a rate  $k/n$  convolutional code.)

## Input Signals and Output Signals

If the convolutional encoder described by the trellis structure represents a rate  $k/n$  code, then the Rectangular QAM TCM Encoder block's input must be a binary column vector with a length of  $L*k$  for some positive integer  $L$ .

The output from the Rectangular QAM TCM Encoder block is a complex column vector of length  $L$ .

## Specifying the Encoder

To define the convolutional encoder, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, then use a `poly2trellis` command within the **Trellis structure** field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

- If you have a variable in the MATLAB workspace that contains the trellis structure, then enter its name as the **Trellis structure** parameter. This way is faster because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage in the previous bulleted item.

The encoder registers begin in the all-zeros state. You can configure the encoder so that it resets its registers to the all-zeros state during the course of the simulation. To do this, set the **Operation mode** to **Reset on nonzero input via port**. The block then opens a second input port, labeled **Rst**. The signal at the **Rst** port is a scalar signal. When it is nonzero, the encoder resets before processing the data at the first input port.

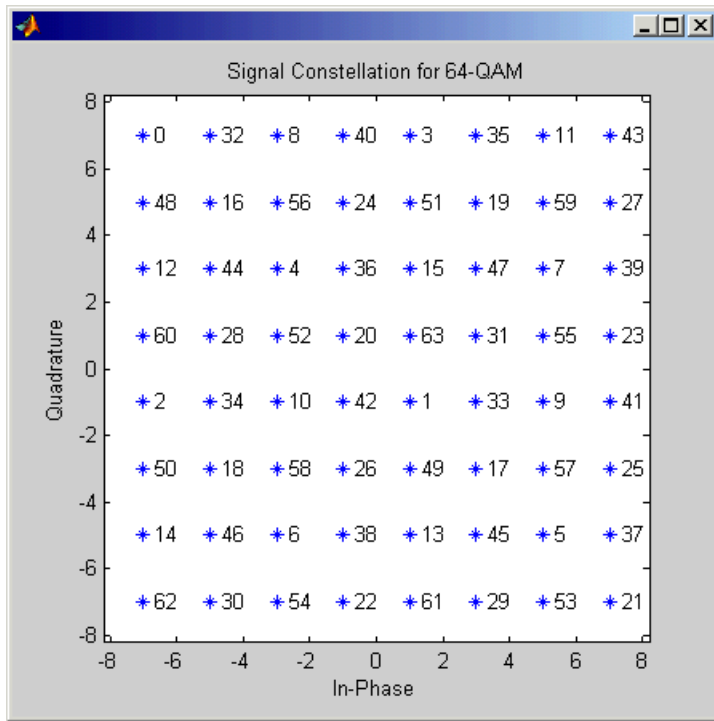

## Signal Constellations

The trellis-coded modulation technique partitions the constellation into subsets called cosets, so as to maximize the minimum distance between pairs of points in each coset. This block internally forms a valid partition based on the value you choose for the **M-ary number** parameter.

The figures below show the labeled set-partitioned signal constellations that the block uses when **M-ary number** is 16, 32, and 64. For constellations of other sizes, see Biglieri, E., D. Divsalar, P. J. McLane and M. K. Simon, *Introduction to Trellis-Coded Modulation with Applications*, New York, Macmillan, 1991.

## Coding Gains

Coding gains of 3 to 6 decibels, relative to the uncoded case can be achieved in the presence of AWGN with multiphase trellis codes. For more information, see Biglieri, E., D. Divsalar, P. J. McLane and M. K. Simon, *Introduction to Trellis-Coded Modulation with Applications*, New York, Macmillan, 1991.

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

### Operation mode

In Continuous mode (default setting), the block retains the encoder states at the end of each frame, for use with the next frame.

In **Truncated (reset every frame)** mode, the block treats each frame independently. I.e., the encoder states are reset to all-zeros state at the start of each frame.

In **Terminate trellis by appending bits** mode, the block treats each frame independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by  $y = n \cdot (x + s)/k$ , where  $x$  is the number of input bits, and  $s = \text{constraint length} - 1$  (or, in the case of multiple constraint lengths,  $s = \text{sum}(\text{ConstraintLength}(i) - 1)$ ). The block supports this mode for column vector input signals.

In **Reset on nonzero input via port** mode, the block has an additional input port, labeled **Rst**. When the **Rst** input is nonzero, the encoder resets to the all-zeros state.

**M-ary number**

The number of points in the signal constellation.

**Output data type**

The output type of the block can be specified as a **single** or **double**. By default, the block sets this to **double**.

## Rician Noise Generator

(To be removed) Generate Rician distributed noise

---

**Note** Rician Noise Generator will be removed in a future release. Use the MATLAB Function block and `randn` function instead.

---

### Library

Noise Generators sublibrary of Comm Sources

### Description

The Rician Noise Generator block generates Rician distributed noise. The Rician probability density function is given by

$$f(x) = \begin{cases} \frac{x}{\sigma^2} I_0\left(\frac{mx}{\sigma^2}\right) \exp\left(-\frac{x^2 + m^2}{2\sigma^2}\right) & x \geq 0 \\ 0 & x < 0 \end{cases}$$

where:

- $\sigma$  is the standard deviation of the Gaussian distribution that underlies the Rician distribution noise
- $m^2 = m_1^2 + m_2^2$ , where  $m_1$  and  $m_2$  are the mean values of two independent Gaussian components
- $I_0$  is the modified 0th-order Bessel function of the first kind given by

$$I_0(y) = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{y \cos t} dt$$

Note that  $m$  and  $\sigma$  are *not* the mean value and standard deviation for the Rician noise.

You must specify the **Initial seed** for the random number generator. When it is a constant, the resulting noise is repeatable. The vector length of the Initial seed parameter

should equal the number of columns in a frame-based output or the number of elements in a sample-based output. The set of numerical parameters above the **Initial seed** parameter in the dialog box can consist of vectors having the same length as the **Initial seed**, or scalars.

## Initial Seed

The scalar **Initial seed** parameter initializes the random number generator that the block uses to generate its Rician-distributed complex random process. When multiple blocks in a model have the **Initial seed** parameter, you can choose different initial seeds for each block to ensure different random streams are used in each block. Set **Initial seed** to an integer value for repeatable results or use the `randi` function to randomize your results.

## Attributes of Output Signal

The output signal can be a frame-based matrix, a sample-based row or column vector, or a sample-based one-dimensional array. These attributes are controlled by the **Frame-based outputs**, **Samples per frame**, and **Interpret vector parameters as 1-D** parameters. See “Sources and Sinks” in *Communications Toolbox User's Guide* for more details.

The number of elements in the **Initial seed** and **Sigma** parameters becomes the number of columns in a frame-based output or the number of elements in a sample-based vector output. Also, the shape (row or column) of the **Initial seed** and **Sigma** parameters becomes the shape of a sample-based two-dimensional output signal.

## Parameters

### Specification method

Either K-factor or Quadrature components.

### Rician K-factor

$K = m^2/(2\sigma^2)$ , where  $m$  is as in the Rician probability density function. This field appears only if **Specification method** is K-factor.

### In-phase component (mean), Quadrature component (mean)

The mean values  $m_I$  and  $m_Q$ , respectively, of the Gaussian components. These fields appear only if **Specification method** is Quadrature components.

### **Sigma**

The variable  $\sigma$  in the Rician probability density function.

### **Initial seed**

The initial seed value for the random number generator.

### **Sample time**

The period of each sample-based vector or each row of a frame-based matrix.

### **Frame-based outputs**

Determines whether the output is frame-based or sample-based. This box is active only if **Interpret vector parameters as 1-D** is unchecked.

### **Samples per frame**

The number of samples in each column of a frame-based output signal. This field is active only if **Frame-based outputs** is checked.

### **Interpret vector parameters as 1-D**

If this box is checked, then the output is a one-dimensional signal. Otherwise, the output is a two-dimensional signal. This box is active only if **Frame-based outputs** is unchecked.

### **Output data type**

The output can be set to `double` or `single` data types.

# RLS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with RLS algorithm

## Library

Equalizers

---

**Note** will be removed in a future release. Use Decision Feedback Equalizer instead.

---

## Description

The RLS Decision Feedback Equalizer block uses a decision feedback equalizer and the RLS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the RLS algorithm to update the weights, once per symbol. When you set the **Number of samples per symbol** parameter to 1, the block implements a symbol-spaced equalizer and updates the filter weights once for each symbol. When you set the **Number of samples per symbol** parameter to a value greater than 1, the weights are updated once every  $N^{\text{th}}$  sample, for a fractionally spaced equalizer.

## Input and Output Signals

The **Input** port accepts a column vector input signal. The **Desired** port receives a training sequence with a length that is less than or equal to the number of symbols in the **Input** signal. Valid training symbols are those symbols listed in the **Signal constellation** vector.

Set the **Reference tap** parameter so it is greater than zero and less than the value for the **Number of forward taps** parameter.

The port labeled `Equalized` outputs the result of the equalization process.

You can configure the block to have one or more of these extra ports:

- `Mode` input.
- `Err` output for the error signal, which is the difference between the `Equalized` output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- `Weights` output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see “Equalization”.

## Equalizer Delay

For proper equalization, you should set the **Reference tap** parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer *output* is equal to

$$1 + (\text{Reference tap} - 1) / (\text{Number of samples per symbol})$$

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

### Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

### Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

**Number of samples per symbol**

The number of input samples for each symbol.

**Signal constellation**

A vector of complex numbers that specifies the constellation for the modulation.

**Reference tap**

A positive integer less than or equal to the number of forward taps in the equalizer.

**Forgetting factor**

The forgetting factor of the RLS algorithm, a number between 0 and 1.

**Inverse correlation matrix**

The initial value for the inverse correlation matrix. The matrix must be N-by-N, where N is the total number of forward and feedback taps.

**Initial weights**

A vector that concatenates the initial weights for the forward and feedback taps.

**Mode input port**

When you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, and for decision directed, the mode must be 0. For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

**Output error**

When you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

**Output weights**

When you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

# Scrambler

Scramble input signal

**Library:** Communications Toolbox / Sequence Operations

## Description

The Scrambler block scrambles a scalar or column vector input signal.

One purpose of scrambling is to reduce the length of consecutive 0s or 1s in a transmitted signal. Long sequences of 0s or 1s can cause transmission synchronization problems. This schematic shows the scrambler operation. All adders perform addition modulo  $N$ , where  $N$  is the value specified by the Calculation base parameter.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Scramble polynomial parameter, you specify the on or off state for each switch in the scrambler.

To achieve repeatable initial scrambler conditions, you can use one of these optional input ports:

- Select the Reset on nonzero input via port parameter and reset the scrambler with Rst.

- Set the Initial states source parameter to Input port and provide the initial states with **ISt**.

This block can accept input sequences that vary in length during simulation. For more information about sequences that vary in length, see [Variable-Size Signal Basics \(Simulink\)](#).

## Ports

### Input

#### **in** — Input data signal

vector

Input data signal, specified as an  $N_S$ -by-1 vector.  $N_S$  represents the number of samples in the input signal. The input values must be integers from 0 to Calculation base - 1.

Data Types: double

#### **Rst** — Reset scrambler

scalar

Reset scrambler, specified as a scalar. The scrambler is reset if a nonzero input is applied to the port.

#### Dependencies

To enable this port, set Initial states source to Dialog Parameter and select Reset on nonzero input via port.

#### **ISt** — Initial states

vector

Initial states of the scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of **ISt** must equal the order of the Scramble polynomial parameter. The vector element values must be integers from 0 to Calculation base - 1.

#### Dependencies

To enable this port, set Initial states source to Input port.

## Output

### Out1 — Output scrambled data

vector

Output scrambled data, returned as an  $N_S$ -by-1 vector.  $N_S$  equals the number of samples in the input signal.

Data Types: double

## Parameters

### Calculation base — Calculation base

4 (default) | nonnegative integer

Calculation base used in the scrambler for modulo operations, specified as a nonnegative integer. The input and output of this block are integers from 0 to **Calculation base** - 1.

### Scramble polynomial — Polynomial that defines connections in scrambler

'1 + z<sup>-1</sup> + z<sup>-2</sup> + z<sup>-4</sup>' (default) | character vector | integer vector | binary vector

Polynomial that defines the connections in the scrambler, specified as a character vector, integer vector, or binary vector. The **Scramble polynomial** parameter defines if each switch in the scrambler is on or off. Specify the polynomial as:

- A character vector, such as '1 + z<sup>-6</sup> + z<sup>-8</sup>'. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0 -6 -8], listing the descrambler coefficients in order of descending powers of  $z^{-1}$ , where  $p(z^{-1}) = 1 + p_1z^{-1} + p_2z^{-2} + \dots$
- A binary vector, such as [1 0 0 0 0 0 1 0 1], listing the powers of  $z$  that appear in the polynomial that has a coefficient of 1. In this case, the order of the scramble polynomial is one less than the binary vector length.

Example: '1 + z<sup>-6</sup> + z<sup>-8</sup>', [0 -6 -8], and [1 0 0 0 0 0 1 0 1] all represent this polynomial:

$$p(z^{-1}) = 1 + z^{-6} + z^{-8}$$

### Initial states source — Set the source for scrambler initial states

Dialog Parameter (default) | Input port

- **Dialog Parameter** - Specify scrambler initial states by using the Initial states parameter.
- **Input port** - Specify scrambler initial states by using the Ist port.

**Initial states — Initial states of scrambler registers**

[0 1 2 3] (default) | nonnegative integer vector

Initial states of scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of **Initial states** must equal the order of the Scramble polynomial parameter. The vector element values must be integers from 0 to Calculation base - 1.

**Dependencies**

This parameter is available when Initial states source is set to Dialog Parameter.

**Reset on nonzero input via port — Reset scrambler via input port**

off (default) | on

Select this parameter to reset the Scrambler block via input port Rst.

**Dependencies**

This parameter is available when Initial states source is set to Dialog Parameter.

## Sign LMS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with signed LMS algorithm

## Library

Equalizers

---

**Note** will be removed in a future release. Use Decision Feedback Equalizer instead.

---

## Description

The Sign LMS Decision Feedback Equalizer block uses a decision feedback equalizer and an algorithm from the family of signed LMS algorithms to equalize a linearly modulated baseband signal through a dispersive channel.

The supported algorithms, corresponding to the **Update algorithm** parameter, are

- Sign LMS
- Sign Regressor LMS
- Sign Sign LMS

During the simulation, the block uses the particular signed LMS algorithm to update the weights, once per symbol. If the **Number of samples per symbol** parameter is 1, then the block implements a symbol-spaced equalizer; otherwise, the block implements a fractionally spaced equalizer.

## Input and Output Signals

The **Input** port accepts a column vector input signal. The **Desired** port receives a training sequence with a length that is less than or equal to the number of symbols in the **Input** signal. Valid training symbols are those symbols listed in the **Signal constellation** vector.

Set the **Reference tap** parameter so it is greater than zero and less than the value for the **Number of forward taps** parameter.

The port labeled **Equalized** outputs the result of the equalization process.

You can configure the block to have one or more of these extra ports:

- **Mode** input.
- **Err** output for the error signal, which is the difference between the **Equalized** output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- **Weights** output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see “Equalization”.

## Equalizer Delay

For proper equalization, you should set the **Reference tap** parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer *output* is equal to

$$1 + (\text{Reference tap} - 1) / (\text{Number of samples per symbol})$$

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

### Update algorithm

The specific type of signed LMS algorithm that the block uses to update the equalizer weights.

### Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

### Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

### Number of samples per symbol

The number of input samples for each symbol.

- When you set this parameter to 1, the filter weights are updated once for each symbol, for a symbol spaced (i.e. T-spaced) equalizer.
- When you set this parameter to a value greater than 1, the weights are updated once every  $N^{\text{th}}$  sample, for a T/N-spaced equalizer.

### Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

### Reference tap

A positive integer less than or equal to the number of forward taps in the equalizer.

### Step size

The step size of the signed LMS algorithm.

### Leakage factor

The leakage factor of the signed LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

### Initial weights

A vector that concatenates the initial weights for the forward and feedback taps.

### Mode input port

When you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision directed, the mode should be 0. For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

**Output error**

When you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

**Output weights**

When you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

# Sign LMS Linear Equalizer

(To be removed) Equalize using linear equalizer that updates weights with signed LMS algorithm

## Library

Equalizers

---

**Note** will be removed in a future release. Use Linear Equalizer instead.

---

## Description

The Sign LMS Linear Equalizer block uses a linear equalizer and an algorithm from the family of signed LMS algorithms to equalize a linearly modulated baseband signal through a dispersive channel. The supported algorithms, corresponding to the **Update algorithm** parameter, are

- Sign LMS
- Sign Regressor LMS
- Sign Sign LMS

During the simulation, the block uses the particular signed LMS algorithm to update the weights, once per symbol. When you set the **Number of samples per symbol** parameter to 1, then the block implements a symbol-spaced equalizer and updates the filter weights once for each symbol. When you set the **Number of samples per symbol** parameter to a value greater than 1, the weights are updated once every  $N^{\text{th}}$  sample, for a  $T/N$ -spaced equalizer.

## Input and Output Signals

The **Input** port accepts a column vector input signal. The **Desired** port receives a training sequence with a length that is less than or equal to the number of symbols in the **Input** signal. Valid training symbols are those symbols listed in the **Signal constellation** vector.

Set the **Reference tap** parameter so it is greater than zero and less than the value for the **Number of taps** parameter.

The **Equalized** port outputs the result of the equalization process.

You can configure the block to have one or more of these extra ports:

- **Mode** input.
- **Err** output for the error signal, which is the difference between the **Equalized** output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- **Weights** output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see “Equalization”.

## Equalizer Delay

For proper equalization, you should set the **Reference tap** parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer *output* is equal to

$$1 + (\text{Reference tap} - 1) / (\text{Number of samples per symbol}) \quad (3-1)$$

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap.

## Parameters

### Update algorithm

The specific type of signed LMS algorithm that the block uses to update the equalizer weights.

### Number of taps

The number of taps in the filter of the linear equalizer.

### Number of samples per symbol

The number of input samples for each symbol.

### Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

### Reference tap

A positive integer less than or equal to the number of taps in the equalizer.

### Step size

The step size of the signed LMS algorithm.

### Leakage factor

The leakage factor of the signed LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

### Initial weights

A vector that lists the initial weights for the taps.

### Mode input port

When you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision directed, the mode should be 0. For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

### Output error

When you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

### Output weights

When you select this check box, the block outputs the current weights.

# SISO Fading Channel

Filter input signal through SISO multipath fading channel

**Library:** Communications Toolbox / Channels

## Description

The SISO Fading Channel block filters an input signal using a single-input/single-output (SISO) multipath fading channel. This block models both Rayleigh and Rician fading. For processing details, see the Algorithms on page 3-1041 section.

## Ports

### Input

**in** — Input data signal

vector

Input data signal, specified as an  $N_S$ -by-1 vector.  $N_S$  represents the number of samples in the input signal.

Data Types: `double` | `single`

Complex Number Support: Yes

### Output

**Out1** — Output data signal for fading channel

vector

Output data signal for the fading channel, returned as an  $N_S$ -by-1 vector.  $N_S$  represents the number of samples in the input signal.

#### Gain — Discrete path gains

matrix

Discrete path gains of the underlying fading process, returned as an  $N_S$ -by- $N_P$  matrix.

- $N_S$  represents the number of samples in the input signal.
- $N_P$  represents the number of channel paths.

#### Dependencies

To enable this port, on the **Main** tab, select Output channel path gains.

#### Delay — Channel filter delay

scalar

Channel filter delay, returned as a scalar.

#### Dependencies

To enable this port, on the **Main** tab, select Output channel filter delay.

## Parameters

### Main Tab

#### Multipath parameters (frequency selectivity)

#### Inherit sample rate from input — Option to inherit the sample rate from input

on (default) | off

Select this parameter to use the sample rate of the input signal when processing. When Inherit sample rate from input is selected, the sample rate is  $N_S/T_S$ , where  $N_S$  is the number of input samples, and  $T_S$  is the model sample time.

#### Sample rate (Hz) — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar. To match the model settings, set the sample rate to  $N_S/T_S$ , where  $N_S$  is the number of input samples, and  $T_S$  is the model sample time.

**Dependencies**

This parameter appears when Inherit sample rate from input is not selected.

Data Types: double

**Discrete path delays (s) — Delays for each discrete path**

0 (default) | nonnegative scalar | row vector

Delays for each discrete path in seconds, specified as a nonnegative scalar or row vector.

- When you set **Discrete path delays (s)** to a scalar, the SISO channel is frequency flat.
- When you set **Discrete path delays (s)** to a vector, the SISO channel is frequency selective.

Data Types: double

**Average path gains (dB) — Average gain for each discrete path**

0 (default) | scalar | row vector

Average gain for each discrete path in decibels, specified as a scalar or row vector.

**Average path gains (dB)** must have the same size as Discrete path delays (s).

Data Types: double

**Normalize average path gains to 0 dB — Option to normalize average path gains to 0 dB**

on (default) | off

Select this parameter to normalize the fading processes so that the total power of the path gains, averaged over time, is 0 dB.

**Fading distribution — Fading distribution of channel**

Rayleigh (default) | Rician

Select the fading distribution of the channel, either Rayleigh or Rician.

**K-factors — K-factor of Rician fading channel**

3 (default) | positive scalar | row vector

K-factor of a Rician fading channel, specified as a positive scalar or a 1-by- $N_p$  vector of positive-valued elements.  $N_p$  equals the value of the Discrete path delays (s) parameter.

- If you set **K-factors** to a scalar, the first discrete path is a Rician fading process with a Rician K-factor of **K-factors**. Any remaining discrete paths are independent Rayleigh fading processes.
- If you set **K-factors** to a row vector, the discrete path corresponding to a positive element of the **K-factors** vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to a zero-valued element of the **K-factors** vector is a Rayleigh fading process.

#### Dependencies

This parameter appears when Fading distribution is Rician.

Data Types: double

#### **LOS path Doppler shifts (Hz) — Doppler shifts for line-of-sight components**

0 (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the Rician fading channel in hertz, specified as a scalar or row vector. This parameter must have the same size as K-factors.

- If you set **LOS path Doppler shifts (Hz)** to a scalar, it represents the line-of-sight component Doppler shift of the first discrete path that is a Rician fading process.
- If you set **LOS path Doppler shifts (Hz)** to a row vector, the discrete path that is a Rician fading process has its line-of-sight component Doppler shift specified by the elements of **LOS path Doppler shifts (Hz)** that correspond to positive elements in the K-factors vector.

#### Dependencies

This parameter appears when Fading distribution is Rician.

Data Types: double

#### **LOS path initial phases (rad) — Initial phases for line-of-sight components**

0 (default) | scalar | row vector

Initial phases for the line-of-sight component of the Rician fading channel in radians, specified as a scalar or row vector. This parameter must have the same size as K-factors.

- If you set **LOS path initial phases (rad)** to a scalar, it is the line-of-sight component initial phase of the first discrete path that is a Rician fading process.
- If you set **LOS path initial phases (rad)** to a row vector, the discrete path that is a Rician fading process has its line-of-sight component initial phase specified by the

elements of **LOS path initial phases (rad)** that correspond to positive elements in the K-factors vector.

### Dependencies

This parameter appears when Fading distribution is Rician.

Data Types: double

### Doppler parameters (time dispersion)

#### Maximum Doppler shift (Hz) — Maximum Doppler shift for all channel paths

0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths in hertz, specified as a nonnegative scalar.

**Maximum Doppler shift (Hz)** must be smaller than  $(f_s/10)/f_c$  for each path.  $f_s$  is the sampling rate at the input to the SISO Fading Channel block.  $f_c$  is the cutoff frequency factor of the path. For more information, see Cutoff Frequency Factor on page 3-712.

Data Types: double

#### Doppler spectrum — Doppler spectrum shape for all channel paths

doppler('Jakes') (default) | doppler('Flat') | doppler('Rounded', ...) |  
 doppler('Bell', ...) | doppler('Asymmetric Jakes', ...) |  
 doppler('Restricted Jakes', ...) | doppler('Gaussian', ...) |  
 doppler('BiGaussian', ...)

Doppler spectrum shape for all channel paths, specified as a single Doppler spectrum structure returned from the `doppler` function or a 1-by- $N_p$  cell array of such structures. The default value of this parameter is the Jakes Doppler spectrum (`doppler('Jakes')`).

- If you assign a single call to `doppler`, all paths have the same specified Doppler spectrum.
- If you assign a 1-by- $N_p$  cell array of calls to `doppler` using any of the specified syntaxes, each path has the Doppler spectrum specified by the corresponding Doppler spectrum structure in the array. In this case,  $N_p$  equals the value of the Discrete path delays (s) parameter.

### Dependencies

This parameter applies when Maximum Doppler shift (Hz) is greater than zero.

### Other parameters

#### Initial seed — Random number generator initial seed

73 (default) | nonnegative integer

Random number generator initial seed for this block, specified as a nonnegative integer.

#### Output channel path gains — Option to output channel path gains

off (default) | on

Select this parameter to add the Gain output port to the block and output the channel path gains of the underlying fading process.

#### Output channel filter delay — Option to output channel filter delay

off (default) | on

Select this parameter to add the Delay output port to the block and output the channel filter delay of the underlying fading process.

#### Simulate using — Compilation type

Interpreted execution (default) | Code generation

Compilation type, specified as Interpreted execution or Code generation.

- **Interpreted execution** — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.
- **Code generation** — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

## Visualization Tab

#### Channel visualization — Select the channel visualization

Off (default) | Impulse response | Frequency response | Doppler spectrum | Impulse and frequency responses

Select the channel visualization: Off, Impulse response, Frequency response, Doppler spectrum, or Impulse and frequency responses. When visualization is

on, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see Channel Visualization.

### Percentage of samples to display — Percentage of samples to display

25% (default) | 10% | 50% | 100%

Select the percentage of samples to display: 10%, 25%, 50%, or 100%. Increasing the percentage improves display accuracy at the expense of simulation speed.

#### Dependencies

This parameter appears when Channel visualization is Impulse response, Frequency response, or Impulse and frequency responses.

### Path for Doppler spectrum display — Path for which Doppler spectrum is displayed

1 (default) | positive integer

Path for which the Doppler spectrum is displayed, specified as a positive integer from 1 to  $N_p$ , where  $N_p$  equals the value of the Discrete path delays (s) parameter.

#### Dependencies

This parameter appears when Channel visualization is Doppler spectrum.

## Block Characteristics

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	yes
<b>Variable-Size Signals</b>	yes

## Algorithms

The fading process for the SISO channel is described in Methodology for Simulating Multipath Fading Channels.

## Cutoff Frequency Factor

The following information explains how the cutoff frequency factor,  $f_c$ , is determined for different Doppler spectrum types:

- For any Doppler spectrum type other than Gaussian and BiGaussian,  $f_c$  equals 1.
- For a doppler( 'Gaussian' ) spectrum type,  $f_c$  equals  $\text{NormalizedStandardDeviation} \cdot \sqrt{2 \cdot \log(2)}$ .
- For a doppler( 'BiGaussian' ) spectrum type:
  - If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \cdot \sqrt{2 \cdot \log(2)}$ .
  - If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(2) \cdot \sqrt{2 \cdot \log(2)}$ .
  - If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \cdot \sqrt{2 \cdot \log(2)}$ .
  - In all other cases,  $f_c$  equals 1.

## Sphere Decoder

Decode input using a sphere decoder

## Library

MIMO

## Description

This block decodes the symbols sent over  $N_t$  antennas using the sphere decoding algorithm.

## Data Type

For information about the data types each block port supports, see the “Supported Data Type” on page 3-1045 table on this page. The output signal inherits the data type from the inputs.

## Algorithm

This block implements the algorithm, inputs, and outputs described on the `comm.SphereDecoder` System object block reference page. The object properties correspond to the block parameters.

## Parameters

### Signal constellation

Specify the number of points in the signal constellation to which the bits are mapped. This value must be a complex column vector. The length of the vector must be a

power of two. The block uses the same constellation for each transmit antenna. The default setting is a QPSK constellation with an average power of 1.

### Bit mapping per constellation point

Specify the bit mapping that the block uses for each constellation point. This value must be a numerical matrix. The matrix size must be [ConstellationLength bitsPerSymbol], where ConstellationLength represents the length of the **Signal constellation** parameter value and bitsPerSymbol represents the number of bits that each symbol encodes. The default matrix size is [0 0; 0 1; 1 0; 1 1], which matches the default value of the **Signal constellation** property.

### Initial search radius

Specify the initial search radius for the decoding algorithm as `Infinity` or `ZF solution`.

When you select `Infinity`, the block sets the initial search radius to `Inf`. When you select `ZF solution`, the block sets the initial search radius to the zero-forcing solution. The zero-forcing solution is calculated by the pseudo-inverse of the input channel when decoding. Large constellations and/or antenna counts can benefit from the initial reduction in the search radius. In most cases, however, the extra computation of the `ZF solution` will not provide a benefit.

### Decision method

Specify the decoding decision method as `Soft` or `Hard`. When you select `Soft` the block outputs log-likelihood ratios (LLRs), or soft bits. When you select set to `Hard`, the block converts the soft LLRs to bits. The hard decision output logical array follows the mapping of a `0` for a negative LLR and `1` for all other values.

### Simulation using

Specify if the block simulates using `Code generation` or `Interpreted execution`. The default is `Interpreted execution`.

## Supported Data Type

Port	Supported Data Types
Rx	<ul style="list-style-type: none"> <li>Double-precision floating point</li> </ul>
cEst	<ul style="list-style-type: none"> <li>Double-precision floating point</li> </ul>

Port	Supported Data Types
Output	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Boolean (Hard-decision method)</li></ul>

## Limitations

- The output LLR values are not scaled by the noise variance. For coded links employing iterative coding (LDPC or turbo) or MIMO OFDM with Viterbi decoding, the output LLR values should be scaled by the channel state information to achieve better performance.

## Algorithms

This block implements the algorithm, inputs, and outputs described on the Sphere Decoder System object reference page. The object properties correspond to the block parameters.

# SSB AM Demodulator Passband

Demodulate SSB-AM-modulated data

## Library

Analog Passband Modulation, in Modulation

## Description

The SSB AM Demodulator Passband block demodulates a signal that was modulated using single-sideband amplitude modulation. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### Carrier frequency (Hz)

The carrier frequency in the corresponding SSB AM Modulator Passband block.

### Initial phase (rad)

The phase offset,  $\theta$ , of the modulated signal.

### Lowpass filter design method

The method used to generate the filter. Available methods are Butterworth, Chebyshev type I, Chebyshev type II, and Elliptic.

### Filter order

The order of the lowpass digital filter specified in the **Lowpass filter design method** field .

**Cutoff frequency**

The cutoff frequency of the lowpass digital filter specified in the **Lowpass filter design method** field in Hertz.

**Passband ripple**

Applies to Chebyshev type I and Elliptic filters only. This is peak-to-peak ripple in the passband in dB.

**Stopband ripple**

Applies to Chebyshev type II and Elliptic filters only. This is the peak-to-peak ripple in the stopband in dB.

# SSB AM Modulator Passband

Modulate using single-sideband amplitude modulation

## Library

Analog Passband Modulation, in Modulation

## Description

The SSB AM Modulator Passband block modulates using single-sideband amplitude modulation with a Hilbert transform filter. The output is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

SSB AM Modulator Passband transmits either the lower or upper sideband signal, but not both. To control which sideband it transmits, use the **Sideband to modulate** parameter.

If the input is  $u(t)$  as a function of time  $t$ , then the output is

$$u(t)\cos(f_c t + \theta) \mp \hat{u}(t)\sin(f_c t + \theta)$$

where:

- $f_c$  is the **Carrier frequency** parameter.
- $\theta$  is the **Initial phase** parameter.
- $\hat{u}(t)$  is the Hilbert transform of the input  $u(t)$ .
- The minus sign indicates the upper sideband and the plus sign indicates the lower sideband.

## Hilbert Transform Filter

This block uses the Analytic Signal block from the DSP System Toolbox Transforms block library.

The Analytic Signal block computes the complex analytic signal corresponding to each channel of the real M-by-N input,  $u$

$$y = u + jH\{u\}$$

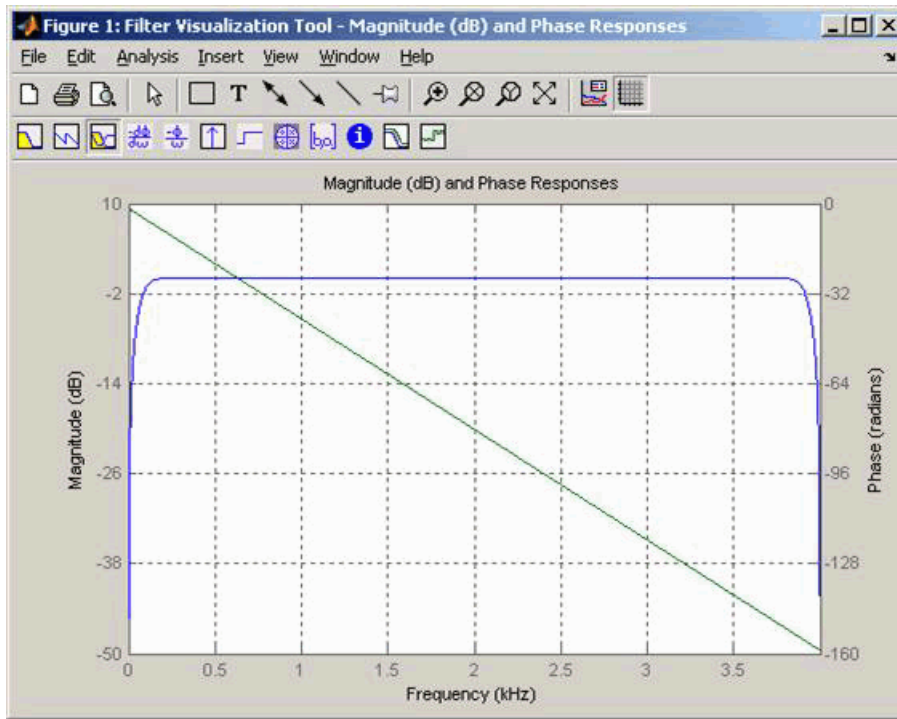

where  $j = \sqrt{-1}$  and  $H\{\}$  denotes the Hilbert transform. The real part of the output in each channel is a replica of the real input in that channel; the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal retains the positive frequency content of the original signal while zeroing-out negative frequencies and doubling the DC component.

The block computes the Hilbert transform using an equiripple FIR filter with the order specified by the Filter order parameter,  $n$ . The linear phase filter is designed using the Remez exchange algorithm, and imposes a delay of  $n/2$  on the input samples.

For best results, use a carrier frequency which is estimated to be larger than 10% of your input signal's sample rate. This is due to the implementation of the Hilbert transform by means of a filter.

In the following example, we sample a 10Hz input signal at 8000 samples per second. We then designate a Hilbert Transform filter of order 100. Below is the response of the Hilbert Transform filter as returned by `fvtool`.

Note the bandwidth of the filter's magnitude response. By choosing a carrier frequency larger than 10% (but less than 90%) of the input signal's sample time (8000 samples per second, in this example) or equivalently, a carrier frequency larger than 400Hz, we ensure that the Hilbert Transform Filter will be operating in the flat section of the filter's magnitude response (shown in blue), and that our modulated signal will have the desired magnitude and form.

Typically, an appropriate **Carrier frequency** value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the **Carrier frequency** parameter.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### Carrier frequency (Hz)

The frequency of the carrier.

### Initial phase (rad)

The phase offset,  $\theta$ , of the modulated signal.

### Sideband to modulate

This parameter specifies whether to transmit the upper or lower sideband.

### Hilbert Transform filter order

The length of the FIR filter used to compute the Hilbert transform.

# Symbol Synchronizer

Correct symbol timing clock skew

**Library:** Communications Toolbox / Synchronization

## Description

The Symbol Synchronizer block corrects symbol timing clock skew for PAM, PSK, QAM, or OQPSK modulation schemes between a single-carrier transmitter and receiver. For more information, see “Symbol Synchronization Overview” on page 3-1057.

---

**Note** The input signal operates on a sample rate basis, while the output signal operates on a symbol rate basis.

---

## Ports

### Input

**samples — Input samples**

scalar (default) | column vector

Input samples, specified as a scalar or column vector of a PAM, PSK, QAM, or OQPSK modulated single-carrier signal. This port is unnamed on the block.

Data Types: double | single

Complex Number Support: Yes

### Output

**Sym — Output signal symbols**

scalar | column vector

Output signal symbols, returned as a variable-size scalar or column vector that has the same data type as the input. For an input with dimensions of  $N_{\text{samp}}$ -by-1, the output at **Sym** has dimensions of  $N_{\text{sym}}$ -by-1.  $N_{\text{sym}}$  is approximately equal to  $N_{\text{samp}}$  divided by the  $N_{\text{sps}}$ .  $N_{\text{sps}}$  is equal to the **Samples per symbol** parameter. If the output exceeds the maximum output size of  $\left\lceil \frac{N_{\text{samp}}}{N_{\text{sps}}} \times 1.1 \right\rceil$ , it is truncated.

This port is unnamed when **Normalized timing error output port** is not selected.

### **Err — Estimated timing error**

scalar | column vector

Estimated timing error for each input sample, returned as a scalar or column vector with values in the range [0, 1]. The estimated timing error is normalized by the input sample time. **Err** has the same data type and size as the input signal.

### **Dependencies**

To enable this port, select **Normalized timing error output port**.

## **Parameters**

### **Modulation type — Modulation type**

PAM/PSK/QAM (default) | OQPSK

Modulation type, specified as PAM/PSK/QAM, or OQPSK.

### **Timing error detector — Type of timing error detector**

Zero-Crossing (decision-directed) (default) | Gardner (non-data-aided) |  
Early-Late (non-data-aided) | Mueller-Muller (decision-directed)

Type of timing error detector, specified as Zero-Crossing (decision-directed), Gardner (non-data-aided), Early-Late (non-data-aided), or Mueller-Muller (decision-directed). This parameter assigns the timing error detection scheme used in the synchronizer.

For more information, see “Timing Error Detection (TED)” on page 3-1058.

### **Samples per symbol — Samples per symbol**

2 (default) | positive integer greater than 1

Samples per symbol, specified as a positive integer greater than 1.

Data Types: double

**Damping factor — Damping factor of the loop filter**

1 (default) | positive scalar

Damping factor of the loop filter, specified as a positive scalar. For more information, see “Loop Filter” on page 3-1062.

**Tunable:** Yes

Data Types: double | single

**Normalized loop bandwidth — Normalized bandwidth of loop filter**

0.01 (default) | positive scalar less than 1

Normalized bandwidth of the loop filter, specified as a positive scalar less than 1. The loop bandwidth is normalized by the sample rate of the input signal. For more information, see “Loop Filter” on page 3-1062.

---

**Note** To ensure that the symbol synchronizer locks, set the **Normalized loop bandwidth** parameter to a value less than 0.1.

---

**Tunable:** Yes

Data Types: double | single

**Detector gain — Phase detector gain**

2.7 (default) | positive scalar

Phase detector gain, specified as a positive scalar.

**Tunable:** Yes

Data Types: double | single

**Normalized timing error output port — Enable normalized timing error output port**

on (default) | off

Select this parameter to output normalized timing error data at the output port **Err**.

**Simulate using — Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as `Code generation` or `Interpreted execution`.

- `Code generation` -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than `Interpreted execution`.
- `Interpreted execution` -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the `Code generation` method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

<b>Variable-Size Signals</b>	yes

## More About

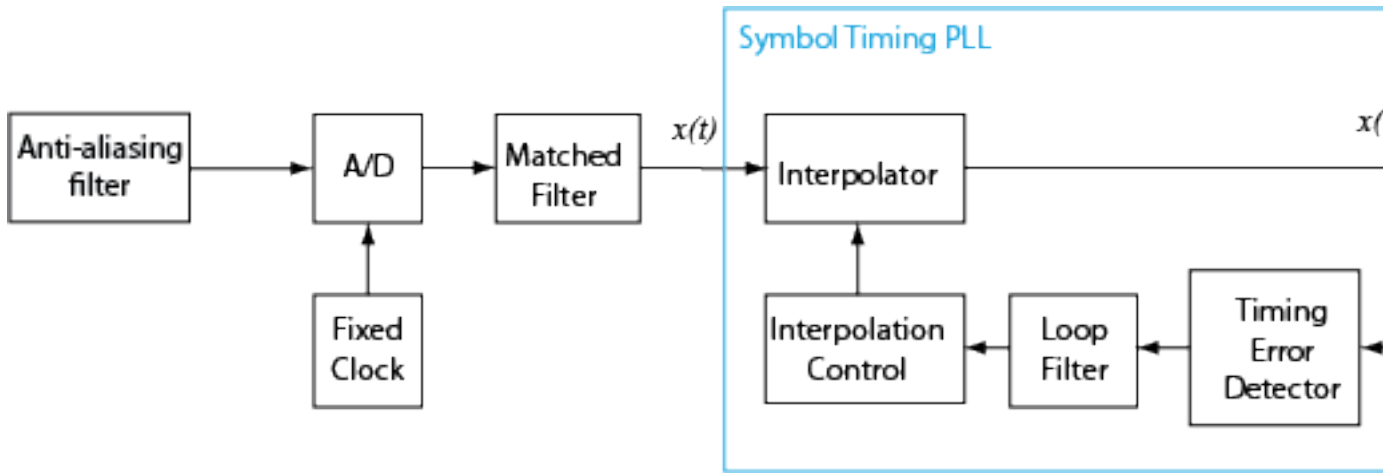

### Symbol Synchronization Overview

The symbol timing synchronizer algorithm is based on a phased lock loop (PLL) algorithm that consists of four components:

- A timing error detector (TED)
- An interpolator
- An interpolation controller
- A loop filter

For OQPSK modulation, the in-phase and quadrature signal components are first aligned (as in QPSK modulation) using a state buffer to cache the last half symbol of the previous input. After initial alignment, the remaining synchronization process is the same as for QPSK modulation.

This block diagram shows an example of a timing synchronizer. In the figure, the symbol timing PLL operates on  $x(t)$ , the received sample signal after matched filtering. The symbol timing PLL outputs the symbol signal,  $x(kT_s + \hat{\tau})$ , after correcting for the clock skew between the transmitter and receiver.

### Timing Error Detection (TED)

The symbol timing synchronizer supports non-data-aided TED and decision-directed TED methods. This table shows the timing estimate expressions for the TED method options.

TED Method	Expression
Zero-crossing (decision-directed)	$e(k) = x((k - 1/2)T_s + \hat{\tau})[\hat{a}_0(k - 1) - \hat{a}_0(k)] + y((k - 1/2)T_s + \hat{\tau})[\hat{a}_1(k - 1) - \hat{a}_1(k)]$

TED Method	Expression
Gardner (non-data-aided)	$e(k) = x((k - 1/2)T_s + \hat{\tau})[x((k - 1)T_s + \hat{\tau}) - x(kT_s + \hat{\tau})] + y((k - 1/2)T_s + \hat{\tau})[y((k - 1)T_s + \hat{\tau}) - y(kT_s + \hat{\tau})]$
Early-late (non-data-aided)	$e(k) = x(kT_s + \hat{\tau})[x((k + 1/2)T_s + \hat{\tau}) - x((k - 1/2)T_s + \hat{\tau})] + y(kT_s + \hat{\tau})[y((k + 1/2)T_s + \hat{\tau}) - y((k - 1/2)T_s + \hat{\tau})]$
Mueller-Muller (decision-directed)	$e(k) = \hat{a}_0(k - 1)x(kT_s + \hat{\tau}) - \hat{a}_0(k)x((k - 1)T_s + \hat{\tau}) + \hat{a}_1(k - 1)y(kT_s + \hat{\tau}) - \hat{a}_1(k)y((k - 1)T_s + \hat{\tau})$

Non-data-aided TED uses received samples without any knowledge of the transmitted signal or the results of the channel estimation. Non-data-aided TED is used to estimate the timing error for signals with modulation schemes that have constellation points aligned with the in-phase or quadrature axis. Examples of signals suitable for the Gardner or early-late methods include QPSK-modulated signals with a zero phase offset that has points at  $\{1+0i, 0+1i, -1+0i, 0-1i\}$  and BPSK-modulated signals with a zero phase offset.

- Gardner method** — The Gardner method is a non-data-aided feedback method that is independent of carrier phase recovery. It is used for baseband systems and modulated carrier systems. More specifically, this method is used for systems that use a linear modulation type with Nyquist pulses that have an excess bandwidth between approximately 40% and 100%. Examples include systems that use PAM, PSK, QAM, or OQPSK modulation and that shape the signal using raised cosine filters whose rolloff factor is between 0.4 and 1. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth increases (or rolloff factor increases in the case of a raised cosine filter). The Gardner method is similar to the early-late gate method.
- Early-late method** — The early-late method is a non-data-aided feedback method. It is used for systems that use a linear modulation type such as PAM, PSK, QAM, or OQPSK modulation. For example, systems using a raised cosine filter with Nyquist pulses. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth of the pulse increases (or rolloff factor increases in the case of a raised cosine filter).

The early-late method is similar to the Gardner method. The Gardner method performs better in systems with high SNR values because it has lower self noise than the early-late method.

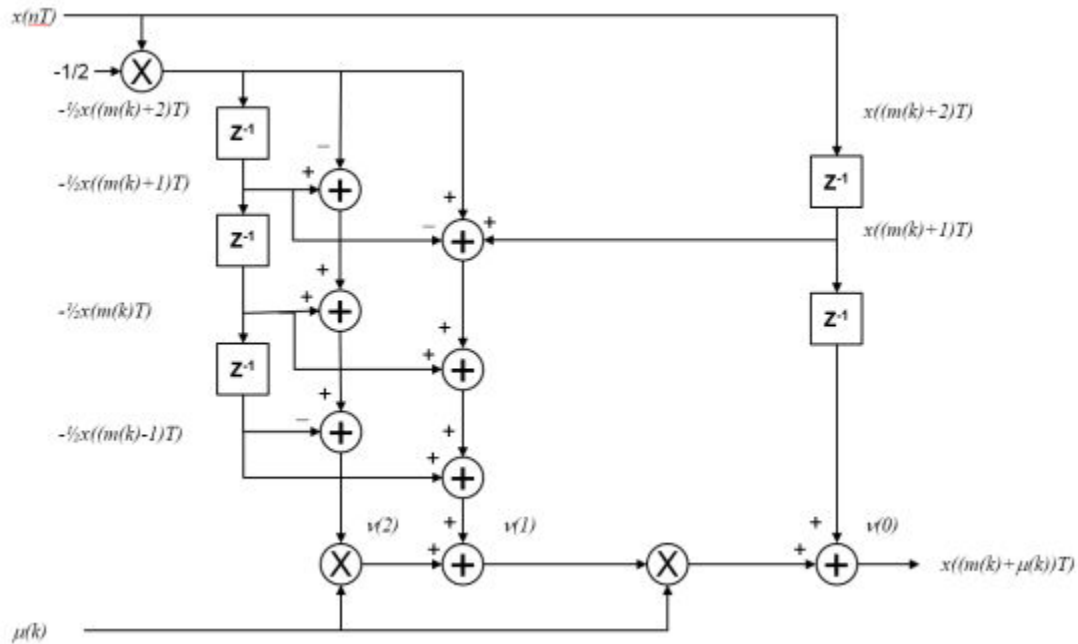

Decision-directed TED uses the `sign` function to estimate the in-phase and quadrature components of received samples, which result in lower computational complexity than non-data-aided TED.

- **Zero-crossing method** — The zero-crossing method is a decision-directed technique that requires 2 samples per symbol at the input to the synchronizer. It is used in low-SNR conditions for all values of excess bandwidth and in moderate-SNR conditions for moderate excess bandwidth factors in the approximate range [0.4, 0.6].
- **Mueller-Muller method** — The Mueller-Muller method is a decision-directed feedback method that requires prior recovery of the carrier phase. When the input signal has Nyquist pulses (for example, when using a raised cosine filter), the Mueller-Muller method has no self noise. For narrowband signaling in the presence of noise, the performance of the Mueller-Muller method improves as the excess bandwidth factor of the pulse decreases.

Because the decision-directed methods (zero-crossing and Mueller-Muller) estimate timing error based on the sign of the in-phase and quadrature components of signals passed to the synchronizer, they are not recommended for constellations that have points with either a zero in-phase or a quadrature component.  $x(kT_s + \hat{\tau})$  and  $y(kT_s + \hat{\tau})$  are the in-phase and quadrature components of the input signals to the timing error detector, where  $\hat{\tau}$  is the estimated timing error. The Mueller-Muller method coefficients  $\hat{a}_0(k)$  and  $\hat{a}_1(k)$  are the estimates of  $x(kT_s + \hat{\tau})$  and  $y(kT_s + \hat{\tau})$ . The timing estimates are made by applying the `sign` function to the in-phase and quadrature components and are used for only the decision-directed TED methods.

## Interpolator

The time delay is estimated from the fixed-rate samples of the matched filter, which are asynchronous with the symbol rate. Because the resulting samples are not aligned with the symbol boundaries, an interpolator is used to "move" the samples. Because the time delay is unknown, the interpolator must be adaptive. Moreover, because the interpolant is a linear combination of the available samples, it can be thought of as the output of a filter.

The interpolator uses a piecewise parabolic interpolator with a Farrow structure and coefficient  $\alpha$  set to  $1/2$  (see Rice, Michael, *Digital Communications: A Discrete-Time Approach*).

## Interpolation Control

Interpolation control provides the interpolator with the basepoint index and fractional interval. The basepoint index is the sample index nearest to the interpolant. The fractional interval is the ratio of the time between the interpolant and its basepoint index and the interpolation interval.

Interpolation is performed for every sample, and a strobe signal is used to determine if the interpolant is output. The synchronizer uses a modulo-1 counter interpolation control to provide the strobe and the fractional interval for use with the interpolator.

## Loop Filter

The synchronizer uses a proportional-plus integrator (PI) loop filter. The proportional gain,  $K_1$ , and the integrator gain,  $K_2$ , are calculated by

$$K_1 = \frac{-4\zeta\theta}{(1 + 2\zeta\theta + \theta^2)K_p}$$

and

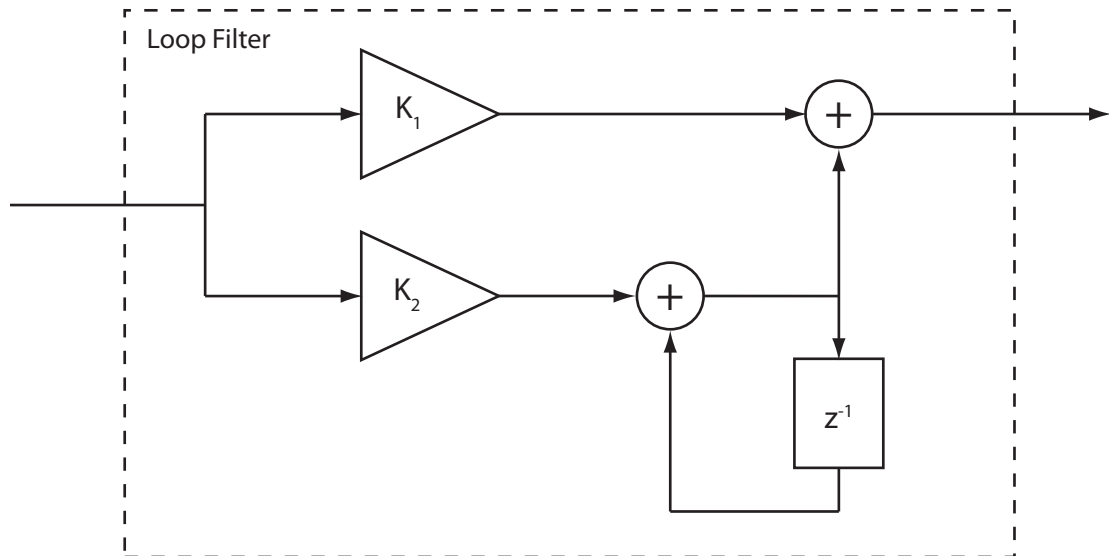

$$K_2 = \frac{-4\theta^2}{(1 + 2\zeta\theta + \theta^2)K_p} .$$

The interim term,  $\theta$ , is given by

$$\theta = \frac{B_n T_s}{\zeta + \frac{1}{4\zeta}} ,$$

where:

- $N$  is the number of samples per symbol.
- $\zeta$  is the damping factor.
- $B_n T_s$  is the normalized loop bandwidth.
- $K_p$  is the detector gain.

# TPC Decoder

Turbo product code (TPC) decoder

**Library:** Communications Toolbox / Error Detection and Correction / Block

## Description

The TPC Decoder block performs 2-D turbo product code (TPC) decoding of the soft input LLRs corresponding to the product code iteratively, using Chase-Pyndiah algorithm. The product code is a 2-D concatenation of linear block codes. The linear block code can be a parity check code, a Hamming code, or a BCH code capable of correcting two errors. Extended and shortened codes can be applied independently on each dimension. For a description of 2-D TPC decoding, see “Algorithms” on page 3-1071.

For information about valid code pairs and the error-correcting capability for each valid code pair, see “Component Code Pairs” on page 3-1070.

## Ports

### Input

#### In — Log likelihood ratios

column vector

Log likelihood ratios, specified as a column vector.

- For full-length input messages, the length of the column vector is the product of Number of rows in code,  $N_R$  and Number of columns in code,  $N_C$ .
- For shortened input messages, the length of the column vector is the product of  $(N_R - K_R + S_R)$  and  $(N_C - K_C + S_C)$ , where:
  - $N_R$  is the value of Number of rows in code,  $N_R$ .

- $K_R$  is the value of Number of rows in message,  $K_r$ .
- $S_R$  is the value of Number of rows in shortened message,  $S_r$ .
- $N_C$  is the value of Number of columns in code,  $N_c$ .
- $K_C$  is the value of Number of columns in message,  $K_c$ .
- $S_C$  is the value of Number of columns in shortened message,  $S_c$ .

Data Types: `double` | `single`

## Output

### **Out — TPC decoded message**

column vector

TPC decoded message, returned as a column vector of binary values.

- For full-length input messages, the length of the column vector is the product of Number of rows in message,  $K_r$  and Number of columns in message,  $K_c$ .
- For shortened input messages, the length of the column vector is the product of Number of rows in shortened message,  $S_r$  and Number of columns in shortened message,  $S_c$ .

Data Types: `Boolean`

### **Iter — Actual number of decoding iterations**

positive integer

Actual number of decoding iterations, returned as a positive integer.

### **Dependencies**

To enable this port, select Output number of iterations executed.

Data Types: `double`

## Parameters

### **Row TPC parameters**

### **Extended codes — Extended codes indicator for TPC row parameters**

`on` (default) | `off`

- When Extended codes is selected, the lists for Number of rows in code,  $N_R$  and Number of rows in message,  $K_R$  contain the valid values for extended individual code pairs  $(N_R, K_R)$ .
- When Extended codes is cleared, the lists for Number of rows in code,  $N_R$  and Number of rows in message,  $K_R$  contain the valid values for nonextended individual code pairs  $(N_R, K_R)$ .

### **Number of rows in code, $N_R$ — Number of rows in product code matrix**

16 (default) | integer

Number of rows in the product code matrix,  $N_R$ . The list of integer values varies depending on the setting for Extended codes.

### **Number of rows in message, $K_R$ — Number of rows in message matrix**

11 (default) | integer

Number of rows in the message matrix,  $K_R$ . The list of integer values varies depending on the setting for Extended codes and Number of rows in code,  $N_R$ .

### **Specify shortened message length — Specify shortened message length for rows**

off (default) | on

Select **Specify shortened message length** to specify a value for Number of rows in shortened message,  $S_R$ .

### **Number of rows in shortened message, $S_R$ — Number of rows in shortened message matrix**

9 (default) | integer

Number of rows in the shortened message matrix,  $S_R$ , specified as an integer less than or equal to  $K_R$ . When you specify this parameter, provide full-length  $N_R$  and  $K_R$  values to specify the  $(N_R, K_R)$  code pair. This code pair is then shortened to the  $(N_R - K_R + S_R, S_R)$  code pair, where:

- $N_R$  is the value of Number of rows in code,  $N_R$ .
- $K_R$  is the value of Number of rows in message,  $K_R$ .
- $S_R$  is the value of Number of rows in shortened message,  $S_R$ .

### **Dependencies**

To enable this parameter, select Specify shortened message length.

Data Types: double

### **Column TPC parameters**

#### **Extended codes — Extended codes indicator for TPC column parameters**

on (default) | off

- When Extended codes is selected, the lists for Number of columns in code,  $N_C$  and Number of columns in message,  $K_C$  contain the valid values for extended individual code pairs  $(N_C, K_C)$ .
- When Extended codes is cleared, the lists for Number of columns in code,  $N_C$  and Number of columns in message,  $K_C$  contain the valid values for nonextended individual code pairs  $(N_C, K_C)$ .

#### **Number of columns in code, $N_C$ — Number of columns in product code matrix**

32 (default) | integer

Number of columns in the product code matrix,  $N_C$ . The list of integer values varies depending on the setting for Extended codes.

#### **Number of columns in message, $K_C$ — Number of columns in message matrix**

26 (default) | integer

Number of columns in the message matrix,  $K_C$ . The list of integer values varies depending on the setting for Extended codes and Number of columns in code,  $N_C$ .

#### **Specify shortened message length — Specify shortened message length for columns**

off (default) | on

Select **Specify shortened message length** to specify a value for Number of columns in shortened message,  $S_C$ .

#### **Number of columns in shortened message, $S_C$ — Number of columns in shortened message matrix**

22 (default) | integer

Number of columns in the shortened message matrix,  $S_C$ , specified as an integer. When you specify this parameter, provide full-length  $N_C$  and  $K_C$  values to specify the  $(N_C, K_C)$  code pair. This code pair is then shortened to the  $(N_C - K_C + S_C, S_C)$  code pair, where:

- $N_C$  is the value of Number of columns in code,  $N_C$ .

- $K_C$  is the value of Number of columns in message,  $K_c$ .
- $S_C$  is the value of Number of columns in shortened message,  $S_c$ .

### Dependencies

To enable this parameter, select Specify shortened message length.

Data Types: double

### Maximum number of iterations – Maximum number of decoding iterations

4 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: double

### Stop iterating when code converges – Stop decoding based on the calculated syndrome or parity-check of the component code

on (default) | off

Select **Stop iterating when code converges** to terminate decoding early if the calculated syndrome or parity-check of the component code evaluates to zero before Maximum number of iterations.

### Output number of iterations executed – Output number of iterations executed

off (default) | on

Select this parameter to add the Iter output port and output the actual number of TPC decoding iterations performed.

### Simulate using – Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the

speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

### Component Code Pairs

This table lists the supported component code pairs for the row ( $N_R, K_R$ ) and column ( $N_C, K_C$ ) parameters.

- $N_R$  and  $K_R$  represent the number of rows in the product code matrix and message matrix, respectively.
- $N_C$  and  $K_C$  represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

<b>Code type</b>	<b>Component Code Pairs</b> ( $N_R, K_R$ ) and ( $N_C, K_C$ )	<b>Error-Correction Capability</b> ( $T$ )

## Algorithms

Turbo product codes (TPC) are a form of concatenated codes used as forward error correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. The TPC decoder achieves near-optimum

decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. For a detailed description, see [1] and [2]. This decoder implements an iterative soft input, soft output 2-D product code decoding, as described in [2], using two “Linear Block Codes”. The decoder expects the soft bit log likelihood ratios (LLRs) obtained from digital demodulation as the input signal.

### TPC Decoding Full-Length Messages

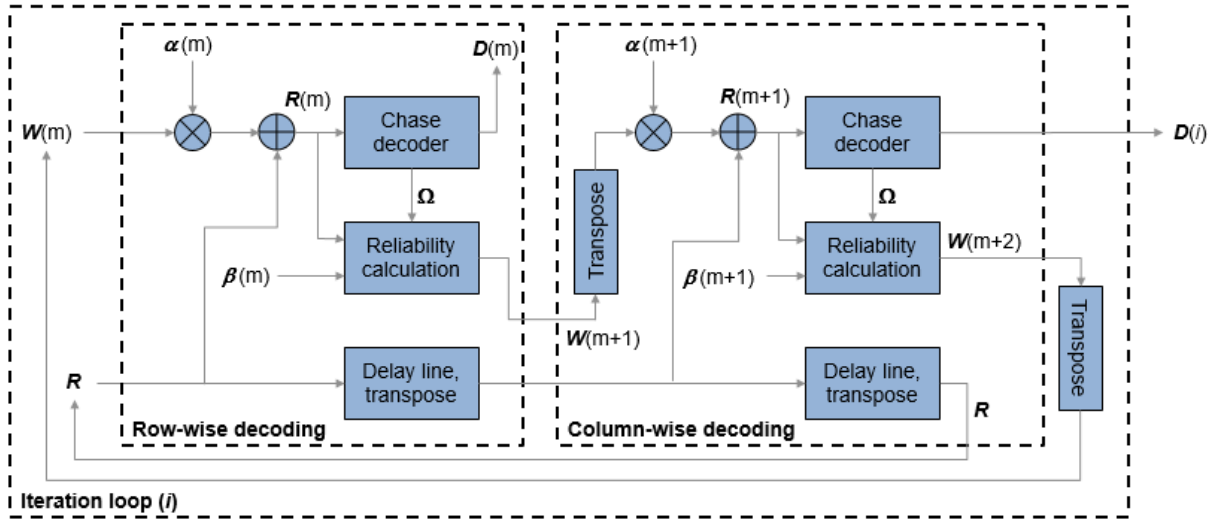

TPC encoded full-length input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the  $(N_C, K_C)$  code pair and column-wise decoding uses the  $(N_R, K_R)$  code pair. The input vector length must be  $N_R \times N_C$ . To perform the 2-D TPC decoding, the column vector of the input LLRs, composed of the message and parity bits, is arranged into an  $N_R$ -by- $N_C$  matrix.

The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. Chase decoding forms a set of possible codewords for each row or column. The Pyndiah algorithm calculates soft information required for the next decoding step.

### Iterative Soft Input, Soft Output Decoder

The iterative soft input, soft output decoding, as shown in the block diagram, carries out two decoding steps for each iteration.

The soft inputs for decoding are  $\mathbf{R}(m) = \mathbf{R} + \alpha(m)\mathbf{W}(m)$ .

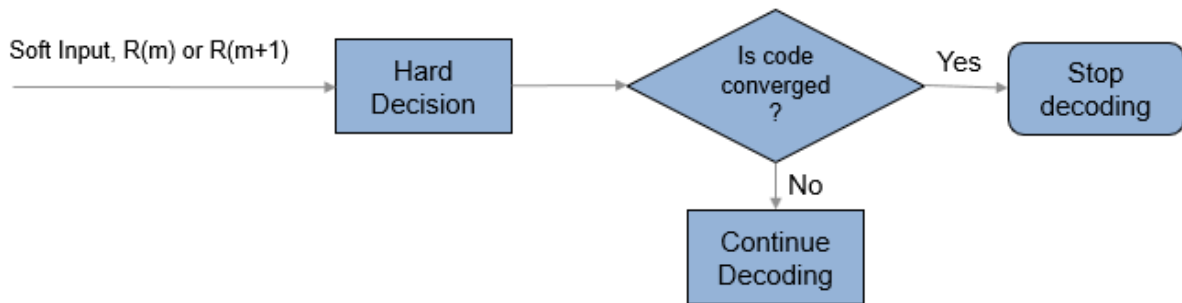

- Iteration loop counter  $i$  increments from  $i = 1$  to the specified number of iterations.
- $m = 2i - 1$  is the decoding step index.
- $\mathbf{R}$  is the received LLR matrix.
- $\mathbf{R}(m)$  is the soft input for the  $m$ th decoding step.
- $\mathbf{W}(m)$  is the input extrinsic information for the  $m$ th decoding step.
- $\alpha(m) = [0, 0.2, 0.3, 0.5, 0.7, 0.9, 1, 1, \dots]$ , where  $\alpha$  is a weighting factor applied based on the decoding step index. For higher decoding steps,  $\alpha = 1$ .
- $\beta(m) = [0.2, 0.4, 0.6, 0.8, 1, 1, \dots]$ , where  $\beta$  is a reliability factor applied based on the decoding step index. For higher decoding steps,  $\beta = 1$ .
- $\mathbf{D}$  contains the decoded message bits. The output message bits are formed from  $\mathbf{D}$  by mapping  $-1$  to  $0$  and  $+1$  to  $1$ , then reshaping the message block into a column vector.

The output message bits are formed after iterating through the specified number of iterations, or, if early termination is enabled, after code convergence.

### Early Termination of TPC Decoding

If early termination is enabled, a code convergence check is performed on the hard decision of the soft input in each row-wise and column-wise decoding step. Early

termination can be triggered after either the row-wise decoding or column-wise decoding converges.

The code is converged if, for all rows or all columns,

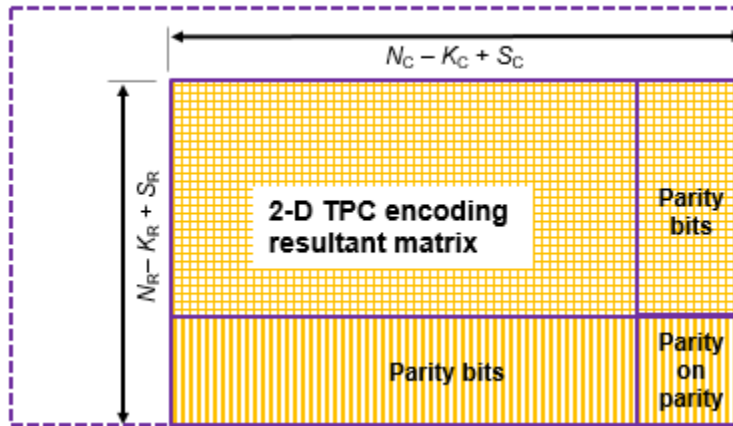

- The syndrome evaluates to zero in the codes (Hamming codes, Extended Hamming codes, BCH codes, or Extended BCH codes).
- The parity check is evaluated to zero in parity check codes.

The reported number of iterations evaluates to the iteration value that is currently in progress. For example, if the code convergence check is satisfied after row-wise decoding in the third iteration (after 2.5 decoding steps), then the number of iteration returned is 3.

### TPC Decoding Shortened Messages

TPC encoded shortened input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the  $(N_C - K_C + S_C, S_C)$  code pair and column-wise decoding uses the  $(N_R - K_R + S_R, S_R)$  code pair. The input vector length must be  $(N_R - K_R + S_R) \times (N_C - K_C + S_C)$ . To perform the 2-D TPC decoding of shortened messages, the column vector of the input LLRs, composed of the shortened message and parity bits, is arranged into an  $(N_R - K_R + S_R)$ -by- $(N_C - K_C + S_C)$  matrix.

The TPC decoder processes the received shortened message LLRs similar to full length codes, with these exceptions:

- The shortened bit positions in the received codeword are set to -1.
- The Chase algorithm does not consider the shortened bit positions while choosing the least reliable bits.

## Ports

### Input

#### In — Message to encode

column vector

Input message bits to encode, specified as a column vector.

- For full-length input messages, the length of the column vector must be the product of Number of rows in message,  $K_r$  and Number of columns in message,  $K_c$ .
- For shortened input messages, the length of the column vector must be the product of Number of rows in shortened message,  $S_r$  and Number of columns in shortened message,  $S_c$ .

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

## Output

### **Out — TPC-encoded message**

column vector

TPC-encoded message, returned as a column vector with the same data type as the input signal.

- For full-length input messages, the length of the column vector is the product of Number of rows in code,  $N_R$  and Number of columns in code,  $N_C$ .
- For shortened input messages, the length of the column vector is the product of  $(N_R - K_R + S_R)$  and  $(N_C - K_C + S_C)$ , where:
  - $N_R$  is the value of Number of rows in code,  $N_R$ .
  - $K_R$  is the value of Number of rows in message,  $K_R$ .
  - $S_R$  is the value of Number of rows in shortened message,  $S_R$ .
  - $N_C$  is the value of Number of columns in code,  $N_C$ .
  - $K_C$  is the value of Number of columns in message,  $K_C$ .
  - $S_C$  is the value of Number of columns in shortened message,  $S_C$ .

## Parameters

### **Row TPC parameters**

#### **Extended codes — Extended codes indicator for TPC row parameters**

on (default) | off

- When Extended codes is selected, the lists for Number of rows in code,  $N_R$  and Number of rows in message,  $K_R$  contain the valid values for extended individual code pairs  $(N_R, K_R)$ .
- When Extended codes is cleared, the lists for Number of rows in code,  $N_R$  and Number of rows in message,  $K_R$  contain the valid values for nonextended individual code pairs  $(N_R, K_R)$ .

#### **Number of rows in code, $N_R$ — Number of rows in product code matrix**

16 (default) | integer

Number of rows in the product code matrix,  $N_R$ . The list of integer values varies depending on the setting for Extended codes.

**Number of rows in message,  $K_R$  — Number of rows in message matrix**

11 (default) | integer

Number of rows in the message matrix,  $K_R$ . The list of integer values varies depending on the setting for Extended codes and Number of rows in code,  $N_r$ .

**Specify shortened message length — Specify shortened message length for rows**

off (default) | on

Select **Specify shortened message length** to specify a value for Number of rows in shortened message,  $S_r$ .

**Number of rows in shortened message,  $S_r$  — Number of rows in shortened message matrix**

9 (default) | integer

Number of rows in the shortened message matrix,  $S_r$ , specified as an integer less than or equal to  $K_R$ . When you specify this parameter, provide full-length  $N_r$  and  $K_R$  values to specify the  $(N_r, K_R)$  code pair. This code pair is then shortened to the  $(N_r - K_R + S_r, S_r)$  code pair, where:

- $N_r$  is the value of Number of rows in code,  $N_r$ .
- $K_R$  is the value of Number of rows in message,  $K_r$ .
- $S_r$  is the value of Number of rows in shortened message,  $S_r$ .

**Dependencies**

To enable this parameter, select Specify shortened message length.

Data Types: double

**Column TPC parameters****Extended codes — Extended codes indicator for TPC column parameters**

on (default) | off

- When Extended codes is selected, the lists for Number of columns in code,  $N_c$  and Number of columns in message,  $K_c$  contain the valid values for extended individual code pairs  $(N_c, K_c)$ .
- When Extended codes is cleared, the lists for Number of columns in code,  $N_c$  and Number of columns in message,  $K_c$  contain the valid values for nonextended individual code pairs  $(N_c, K_c)$ .

**Number of columns in code,  $N_C$  — Number of columns in product code matrix**  
32 (default) | integer

Number of columns in the product code matrix,  $N_C$ . The list of integer values varies depending on the setting for Extended codes.

**Number of columns in message,  $K_C$  — Number of columns in message matrix**  
26 (default) | integer

Number of columns in the message matrix,  $K_C$ . The list of integer values varies depending on the setting for Extended codes and Number of columns in code,  $N_C$ .

**Specify shortened message length — Specify shortened message length for columns**  
off (default) | on

Select **Specify shortened message length** to specify a value for Number of columns in shortened message,  $S_C$ .

**Number of columns in shortened message,  $S_C$  — Number of columns in shortened message matrix**  
22 (default) | integer

Number of columns in the shortened message matrix,  $S_C$ , specified as an integer. When you specify this parameter, provide full-length  $N_C$  and  $K_C$  values to specify the  $(N_C, K_C)$  code pair. This code pair is then shortened to the  $(N_C - K_C + S_C, S_C)$  code pair, where:

- $N_C$  is the value of Number of columns in code,  $N_C$ .
- $K_C$  is the value of Number of columns in message,  $K_C$ .
- $S_C$  is the value of Number of columns in shortened message,  $S_C$ .

#### **Dependencies**

To enable this parameter, select Specify shortened message length.

Data Types: double

**Simulate using — Type of simulation to run**  
Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Algorithms

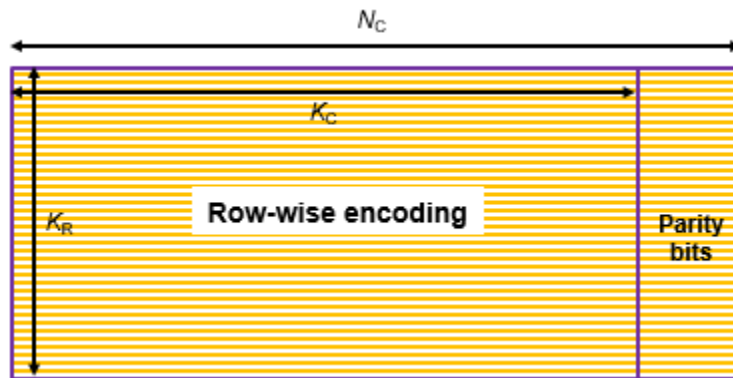

Turbo product codes (TPC) are a form of concatenated codes used as forward error-correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. This encoder implements 2-D product code encoding, as described in [1], using two “Linear Block Codes”.

### Construction of Full-Length Message Product Codes

Full-length input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the  $(N_C, K_C)$  code pair and column-wise encoding uses the  $(N_R, K_R)$  code pair. The input vector length must be  $K_R \cdot K_C$ . The input message bits vector is arranged into a  $K_R$ -by- $K_C$  matrix.

Row-wise encoding uses an  $(N_C, K_C)$  systematic linear block encoder with  $K_C$  bits per row. The row-wise encoding results in a  $K_R$ -by- $N_C$  matrix that includes parity bits added to each row.

Next, column-wise encoding uses an  $(N_R, K_R)$  systematic linear block encoder on each of the  $N_C$  columns. Applying this 2-D TPC encoding to the initial  $K_R$ -by- $K_C$  matrix results in an  $N_R$ -by- $N_C$  matrix that includes parity bits added to each row and column.

The 2-D TPC full-code matrix is reshaped into a column vector of length  $N_R \cdot N_C$  and returned as the TPC-encoded output.

### Construction of Shortened Message Product Codes

Shortened input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the  $(N_C, K_C)$  code pair and column-wise encoding uses an  $(N_R, K_R)$  code pair. The input vector length must be  $S_R \cdot S_C$ . The input shortened message bits vector is arranged into an  $S_R$ -by- $S_C$  matrix. The shortened message matrix prepends two dimensions by padding the beginning of the message matrix with zeros. The resulting matrix is a  $K_R$ -by- $K_C$  matrix.

Row-wise encoding uses an  $(N_C, K_C)$  systematic linear block encoder with  $K_C$  bits per row. The row-wise encoding results in a  $K_R$ -by- $N_C$  matrix that includes parity bits added to each row.

Next, the column-wise encoding uses an  $(N_R, K_R)$  systematic linear block encoder on each of the  $N_C$  columns.

Applying this 2-D TPC encoding to the initial  $K_R$ -by- $K_C$  matrix and excluding the zero-padded bits from the output results in an  $(N_R - K_R + S_R)$ -by- $(N_C - K_C + S_C)$  matrix. This matrix includes parity bits added to each row and column.

The 2-D TPC shortened-code matrix is reshaped into a column vector of length  $(N_R - K_R + S_R) \cdot (N_C - K_C + S_C)$  and returned as the TPC-encoded output.

## Turbo Decoder

Decode input signal using parallel concatenated decoding scheme

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The Turbo Decoder block decodes the input signal using a parallel concatenated decoding scheme. The iterative decoding scheme uses the *a posteriori* probability (APP) decoder as the constituent decoder, an interleaver, and a deinterleaver.

The two constituent decoders use the same trellis structure and decoding algorithm.

## Block Diagram of Iterative Turbo Decoding

The previous block diagram illustrates that the APP decoders (labeled as SISO modules in the previous image) output an updated sequence of log-likelihoods of the encoder input bits,  $\pi(u;O)$ . This sequence is based on the received sequence of log-likelihoods of the channel (coded) bits,  $\pi(c;I)$ , and code parameters.

The decoder block iteratively updates these likelihoods for a fixed number of decoding iterations and then outputs the decision bits. The interleaver ( $\pi$ ) that the decoder uses is identical to the one the encoder uses. The deinterleaver ( $\pi^{-1}$ ) performs the inverse permutation with respect to the interleaver. The decoder does not assume knowledge of the tail bits and excludes these bits from the iterations.

## Dimensions

This block accepts an  $M$ -by-1 column vector input signal and outputs an  $L$ -by-1 column vector signal. For a given trellis,  $L$  and  $M$  are related by:

$$L = \frac{(M - 2 \cdot \text{numTails})}{(2 \cdot n - 1)}$$

and

$$M = L \cdot (2 \cdot n - 1) + 2 \cdot \text{numTails}$$

where

$M$  = decoder input length

$L$  = decoder output length

$n = \log_2(\text{trellis.NumOutputSymbols})$ , for a rate 1/2 trellis,  $n = 2$

$\text{numTails} = \log_2(\text{trellis.numStates}) * n$

## Bit Stream Ordering

The bit ordering subsystem reorganizes the incoming data into the two log likelihood ratio (LLR) streams input to the constituent decoders. This subsystem reconstructs the second systematic stream and reorders the bits so that they match the two constituent encoder outputs at the transmitter. This ordering subsystem is the inverse of the reordering subsystem at the turbo encoder.

## Parameters

### Trellis structure

Trellis structure of constituent convolutional code.

Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. Alternatively, use the `poly2trellis` function to create a custom trellis using the constraint length, code generator (octal), and feedback connection (octal).

The default structure is the result of `poly2trellis(4, [13 15], 13)`.

#### Source of interleaver indices

Specify the source of the interleaver indices as `Property` or `Input port`.

When you set this parameter to `Property`, the block uses the **Interleaver indices** parameter to specify the interleaver indices.

When you set this parameter to `Input port`, the block uses the secondary input port, `IntrInd`, to specify the interleaver indices.

#### Interleaver indices

Specify the mapping that the Turbo encoder block uses to permute the input bits as a column vector of integers. The default is `(64: -1:1)'`. This mapping is a vector with the number of elements equal to  $L$ , the length of the output signal. Each element must be an integer between 1 and  $L$ , with no repeated values.

#### Decoding algorithm

Specify the decoding algorithm that the constituent APP decoders use to decode the input signal as `True APP`, `Max*`, `Max`. When you set this parameter to:

- `True APP` - the block implements true *a posteriori* probability decoding
- `Max*` or `Max` - the block uses approximations to increase the speed of the computations.

#### Number of scaling bits

Specify the number of bits which the constituent APP decoders must use to scale the input data to avoid losing precision during computations. The decoder multiplies the input by  $2^{\text{Number of scaling bits}}$  and divides the pre-output by the same factor. The value for this parameter must be a scalar integer between 0 and 8. This parameter only applies when you set **Decoding algorithm** to `Max*`. The default is 3.

#### Number of decoding iterations

Specify the number of decoding iterations the block uses. The default is 6. The block iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the block is the hard-decision output of the final LLR update.

#### Simulate using

Specify if the block simulates using `Code generation` or `Interpreted execution`. The default is `Interpreted execution`.

# Turbo Encoder

Encode binary data using parallel concatenated encoding scheme

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The Turbo Encoder block encodes a binary input signal using a parallel concatenated coding scheme. This coding scheme employs two identical convolutional encoders and one internal interleaver. Each constituent encoder is independently terminated by tail bits.

## Block Diagram of Parallel Concatenated Convolutional Code

The previous block diagram illustrates that the output of the Turbo Encoder block consists of the systematic and parity bits streams of the first encoder, and only the parity bit streams of the second encoder.

For a rate one-half constituent encoder, the block interlaces the three streams and multiplexes the tail bits to the end of the encoded data streams.

For more information about tail bits, see the terminate **Operation mode** on the Convolutional Encoder block reference page.

## Dimensions

This block accepts an  $L$ -by-1 column vector input signal and outputs an  $M$ -by-1 column vector signal. For a given trellis,  $M$  and  $L$  are related by:

$$M = L \cdot (2 \cdot n - 1) + 2 \cdot numTails$$

and

$$L = \frac{(M - 2 \cdot numTails)}{(2 \cdot n - 1)}$$

where

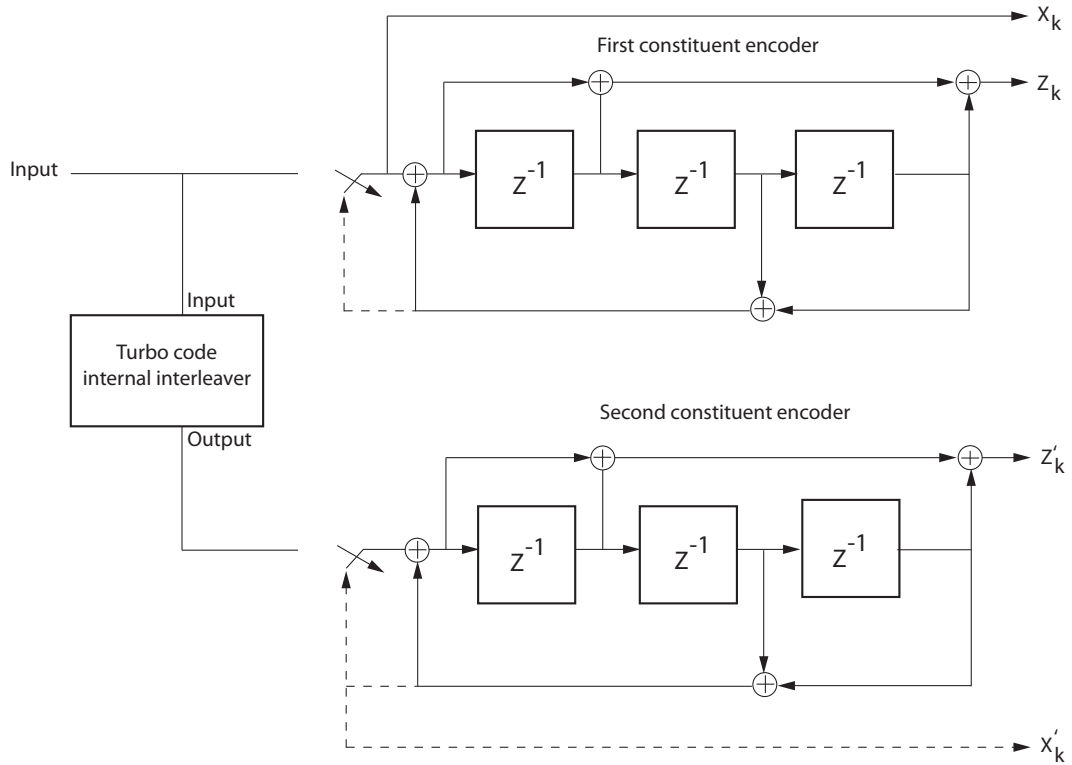

$L$  = encoder input length

$M$  = encoder output length

$n = \log_2(\text{trellis.NumOutputSymbols})$ , for a rate 1/2 trellis,  $n = 2$

$numTails = \log_2(\text{trellis.numStates}) * n$

## Encoder Schematic for Rate 1/3 Turbo Code Example

The previous schematic shows the encoder configuration for a trellis specified by the default value of the **Trellis structure** parameter, `poly2trellis(4, [13 15], 13)`. For an input vector length of 64 bits, the output of the encoder block is 204 bits. The first 192 bits correspond to the three 64 bit streams (systematic ( $X_k$ ) and parity ( $Z_k$ ) bit streams from the first encoder and the parity ( $Z'_k$ ) bit stream of the second encoder), interleaved as per  $X_k, Z_k, Z'_k$ . The last 12 bits correspond to the tail bits from the two encoders, when the switches are in the lower position corresponding to the dashed lines. The first group of six bits (three systematic bits and three parity bits) are the output tail bits from the first constituent encoder. The second group of six bits (three systematic bits and three parity bits) are the output tail bits from the second constituent encoder.

Due to the tail bits, the encoder output code rate is slightly less than 1/3.

## Parameters

### Trellis structure

Trellis structure of constituent convolutional code.

Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. Alternatively, use the `poly2trellis` function to create a custom trellis using the constraint length, code generator (octal), and feedback connections (octal).

This block supports only rate 1-by- $N$  trellises where  $N$  is an integer.

The default structure is the result of `poly2trellis(4, [13 15], 13)`.

### Source of interleaver indices

Specify the source of the interleaver indices as `Property` or `Input port`.

When you set this parameter to `Property`, the block uses the **Interleaver indices** parameter to specify the interleaver indices.

When you set this parameter to `Input port`, the block uses the secondary input port, `IntrInd`, to specify the interleaver indices.

### Interleaver indices

Specify the mapping that the block uses to permute the input bits as a column vector of integers. The default is `(64:-1:1)'`. This mapping is a vector with the number of elements equal to the length,  $L$ , of the input signal. Each element must be an integer between 1 and  $L$ , with no repeated values.

### Simulate using

Specify if the block simulates using `Code generation` or `Interpreted execution`. The default is `Interpreted execution`.

# Uniform Noise Generator

(To be removed) Generate uniformly distributed noise between upper and lower bounds

---

**Note** Uniform Noise Generator will be removed in a future release. Use the MATLAB Function block and rand function instead.

---

## Library

Noise Generators sublibrary of Comm Sources

## Description

The Uniform Noise Generator block generates uniformly distributed noise. The output data of this block is uniformly distributed between the specified lower and upper bounds. The upper bound must be greater than or equal to the lower bound.

You must specify the **Initial seed** in the simulation. When it is a constant, the resulting noise is repeatable.

If all the elements of the output vector are to be independent and identically distributed (i.i.d.), then you can use a scalar for the **Noise lower bound** and **Noise upper bound** parameters. Alternatively, you can specify the range for each element of the output vector individually, by using vectors for the **Noise lower bound** and **Noise upper bound** parameters. If the bounds are vectors, then their length must equal the length of the **Initial seed** parameter.

## Attributes of Output Signal

The output signal can be a frame-based matrix, a sample-based row or column vector, or a sample-based one-dimensional array. These attributes are controlled by the **Frame-based outputs**, **Samples per frame**, and **Interpret vector parameters as 1-D** parameters.

The number of elements in the **Initial seed** parameter becomes the number of columns in a frame-based output or the number of elements in a sample-based vector output. Also,

the shape (row or column) of the **Initial seed** parameter becomes the shape of a sample-based two-dimensional output signal.

## Parameters

### Noise lower bound, Noise upper bound

The lower and upper bounds of the interval over which noise is uniformly distributed.

### Initial seed

The initial seed value for the random number generator.

### Sample time

The period of each sample-based vector or each row of a frame-based matrix.

### Frame-based outputs

Determines whether the output is frame-based or sample-based. This box is active only if **Interpret vector parameters as 1-D** is unchecked.

### Samples per frame

The number of samples in each column of a frame-based output signal. This field is active only if **Frame-based outputs** is checked.

### Interpret vector parameters as 1-D

If this box is checked, then the output is a one-dimensional signal. Otherwise, the output is a two-dimensional signal. This box is active only if **Frame-based outputs** is unchecked.

### Output data type

The output can be set to `double` or `single` data types.

# Unipolar to Bipolar Converter

Map unipolar signal in range [0, M-1] into bipolar signal

## Library

Utility Blocks

## Description

The Unipolar to Bipolar Converter block maps the unipolar input signal to a bipolar output signal. If the input consists of integers between 0 and M-1, where M is the **M-ary number** parameter, then the output consists of integers between -(M-1) and M-1. If M is even, then the output is odd. If M is odd, then the output is even. This block is only designed to work when the input value is within the set {0,1,2...(M-1)}, where M is the **M-ary number** parameter. If the input value is outside of this set of integers the output may not be valid.

The table below shows how the block's mapping depends on the **Polarity** parameter.

Polarity Parameter Value	Output Corresponding to Input Value of k
Positive	$2k-(M-1)$
Negative	$-2k+(M-1)$

## Parameters

### M-ary number

The number of symbols in the bipolar or unipolar alphabet.

#### **Polarity**

A value of **Positive** causes the block to maintain the relative ordering of symbols in the alphabets. A value of **Negative** causes the block to reverse the relative ordering of symbols in the alphabets.

#### **Output Data Type**

The type of bipolar signal produced at the block's output.

The block supports the following output data types:

- `Inherit via internal rule`
- `Same as input`
- `double`
- `int8`
- `int16`
- `int32`

When the parameter is set to its default setting, `Inherit via internal rule`, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either `single` or `double`), the output data type is the same as the input data type.
- If the input data type is not floating-point:
  - Based on the **M-ary** number parameter, an ideal signed integer output word length required to contain the range  $[-(M-1)M-1]$  is computed as follows:

$$\text{ideal word length} = \text{ceil}(\log_2(M))+1$$

---

**Note** The +1 is associated with the need for the sign bit.

---

- The block sets the output data type to be a signed integer, based on the smallest word length (in bits) that can fit best the computed ideal word length.

---

**Note** The selections in the “Hardware Implementation Pane” (Simulink) pertaining to word length constraints do not affect how this block determines output data types.

---

## Examples

If the input is [0; 1; 2; 3], the **M-ary number** parameter is 4, and the **Polarity** parameter is **Positive**, then the output is [-3; -1; 1; 3]. Changing the **Polarity** parameter to **Negative** changes the output to [3; 1; -1; -3].

If the value for the **M-ary number** is  $2^7$  the block gives an output of int8.

If the value for the **M-ary number** is  $2^7+1$  the block gives an output of int16.

## Variable Step LMS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with variable-step-size LMS algorithm

### Library

Equalizers

---

**Note** will be removed in a future release. Use Decision Feedback Equalizer instead.

---

### Description

The Variable Step LMS Decision Feedback Equalizer block uses a decision feedback equalizer and the variable-step-size LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the variable-step-size LMS algorithm to update the weights, once per symbol. When you set the **Number of samples per symbol** parameter to 1, then the block implements a symbol-spaced equalizer and updates the filter weights once for each symbol. When you set the **Number of samples per symbol** parameter to a value greater than 1, the weights are updated once every  $N^{\text{th}}$  sample, for a  $T/N$ -spaced equalizer.

### Input and Output Signals

The **Input** port accepts a column vector input signal. The **Desired** port receives a training sequence with a length that is less than or equal to the number of symbols in the

Input signal. Valid training symbols are those symbols listed in the **Signal constellation** vector.

Set the **Reference tap** parameter so it is greater than zero and less than the value for the **Number of forward taps** parameter.

The port labeled `Equalized` outputs the result of the equalization process.

You can configure the block to have one or more of these extra ports:

- `Mode` input.
- `Err` output for the error signal, which is the difference between the `Equalized` output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- `Weights` output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see “Equalization”.

## Equalizer Delay

For proper equalization, you should set the **Reference tap** parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer *output* is equal to

$$1 + (\text{Reference tap} - 1) / (\text{Number of samples per symbol})$$

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

### Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

**Number of feedback taps**

The number of taps in the feedback filter of the decision feedback equalizer.

**Number of samples per symbol**

The number of input samples for each symbol.

**Signal constellation**

A vector of complex numbers that specifies the constellation for the modulation.

**Reference tap**

A positive integer less than or equal to the number of forward taps in the equalizer.

**Initial step size**

The step size that the variable-step-size LMS algorithm uses at the beginning of the simulation.

**Increment step size**

The increment by which the step size changes from iteration to iteration

**Minimum step size**

The smallest value that the step size can assume.

**Maximum step size**

The largest value that the step size can assume.

**Leakage factor**

The leakage factor of the variable-step-size LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

**Initial weights**

A vector that concatenates the initial weights for the forward and feedback taps.

**Mode input port**

When you select this check box, the block has an input port that enables you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision directed, the mode should be 0. The equalizer will train for the length of the Desired signal. If the mode input is not present, the equalizer will train at the beginning of every frame for the length of the Desired signal.

**Output error**

When you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

### **Output weights**

When you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

# Viterbi Decoder

Decode convolutionally encoded data using Viterbi algorithm

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The Viterbi Decoder block decodes input symbols to produce binary output symbols. This block can process several symbols at a time for faster performance.

This block can output sequences that vary in length during simulation. For more information about sequences that vary in length, or variable-size signals, see “Variable-Size Signal Basics” (Simulink).

## Input and Output Sizes

If the convolutional code uses an alphabet of  $2^n$  possible symbols, this block's input vector length is  $L*n$  for some positive integer  $L$ . Similarly, if the decoded data uses an alphabet of  $2^k$  possible output symbols, this block's output vector length is  $L*k$ .

This block accepts a column vector input signal with any positive integer value for  $L$ . For variable-sized inputs, the  $L$  can vary during simulation. The operation of the block is governed by the operation mode parameter.

For information about the data types each block port supports, see the “Supported Data Types” on page 3-1126 table on this page.

## Input Values and Decision Types

The entries of the input vector are either bipolar, binary, or integer data, depending on the **Decision type** parameter.

Decision type Parameter	Possible Entries in Decoder Input	Interpretation of Values	Branch metric calculation
Unquantized	Real numbers	Positive real: logical zero Negative real: logical one	Euclidean distance
Hard Decision	0, 1	0: logical zero 1: logical one	Hamming distance
Soft Decision	Integers between 0 and $2^b-1$ , where $b$ is the <b>Number of soft decision bits</b> parameter.	0: most confident decision for logical zero $2^b-1$ : most confident decision for logical one Other values represent less confident decisions.	Hamming distance

To illustrate the soft decision situation more explicitly, the following table lists interpretations of values for 3-bit soft decisions.

Input Value	Interpretation
0	Most confident zero
1	Second most confident zero
2	Third most confident zero
3	Least confident zero
4	Least confident one
5	Third most confident one

Input Value	Interpretation
6	Second most confident one
7	Most confident one

## Operation Modes for Inputs

The Viterbi decoder block has three possible methods for transitioning between successive input frames. The **Operation mode** parameter controls which method the block uses:

- In **Continuous** mode, the block saves its internal state metric at the end of each input, for use with the next frame. Each traceback path is treated independently.
- In **Truncated** mode, the block treats each input independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state. This mode is appropriate when the corresponding Convolutional Encoder block has its **Operation mode** set to Truncated (reset every frame).
- In **Terminated** mode, the block treats each input independently, and the traceback path always starts and ends in the all-zeros state. This mode is appropriate when the uncoded message signal (that is, the input to the corresponding Convolutional Encoder block) has enough zeros at the end of each input to fill all memory registers of the feed-forward encoder. If the encoder has  $k$  input streams and constraint length vector  $\text{constr}$  (using the polynomial description), “enough” means  $k \cdot \max(\text{constr} - 1)$ . For feedback encoders, this mode is appropriate if the corresponding Convolutional Encoder block has **Operation mode** set to Terminate trellis by appending bits.

---

**Note** When this block outputs sequences that vary in length during simulation and you set the **Operation mode** to Truncated or Terminated, the block's state resets at every input time step.

---

Use the Continuous mode when the input signal contains only one symbol.

## Traceback Depth and Decoding Delay

The **Traceback depth** parameter,  $D$ , influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

- If you set the **Operation mode** to Continuous, the decoding delay consists of  $D$  zero symbols
- If the **Operation mode** parameter is set to Truncated or Terminated, there is no output delay and the **Traceback depth** parameter must be less than or equal to the number of symbols in each input.

As a general estimate, the **Traceback depth** value is approximately two to three times  $(k - 1)/(1 - r)$ , where  $k$  is the constraint length of the code and  $r$  is the code rate [7]. For example:

- A rate 1/2 code has a **Traceback depth** of  $5(k - 1)$ .
- A rate 2/3 code has a **Traceback depth** of  $7.5(k - 1)$ .
- A rate 3/4 code has a **Traceback depth** of  $10(k - 1)$ .
- A rate 5/6 code has a **Traceback depth** of  $15(k - 1)$ .

## Reset Port

The reset port is usable only when the **Operation mode** parameter is set to Continuous. Selecting **Enable reset input port** gives the block an additional input port, labeled Rst. When the Rst input is nonzero, the decoder returns to its initial state by configuring its internal memory as follows:

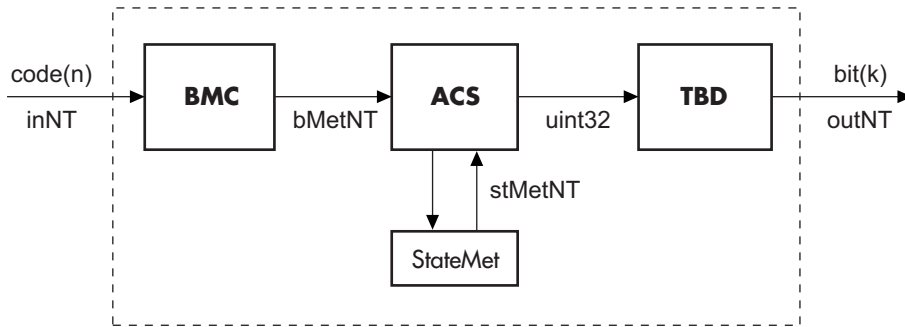

- Sets the all-zeros state metric to zero.
- Sets all other state metrics to the maximum value.
- Sets the traceback memory to zero.

Using a reset port on this block is analogous to setting **Operation mode** in the Convolutional Encoder block to Reset on nonzero input via port.

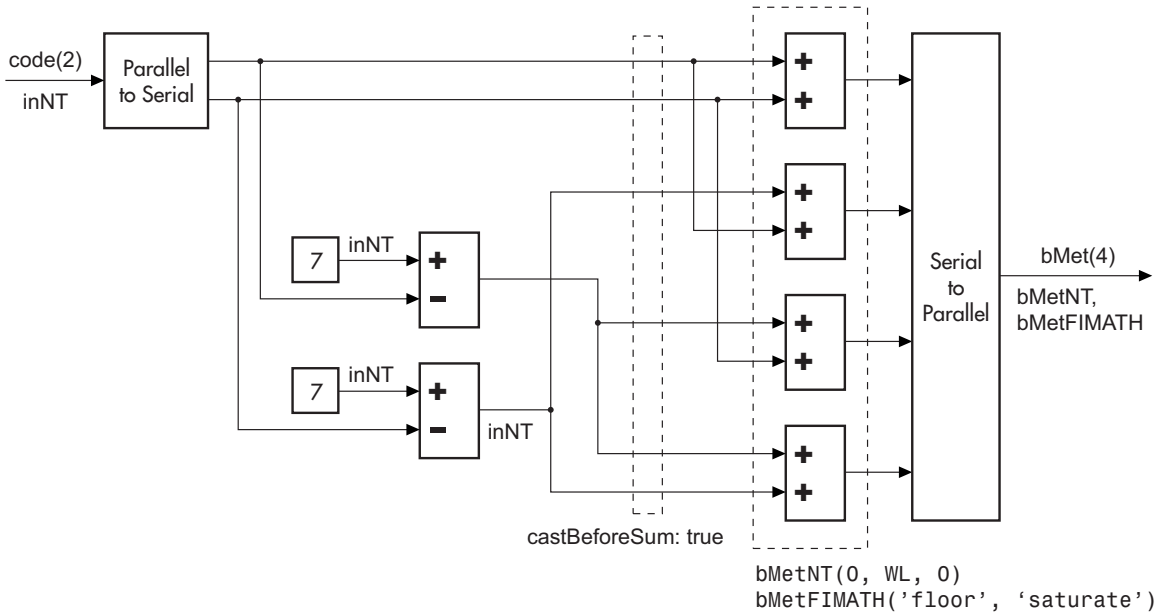

The reset port supports double or boolean typed signals.

## Fixed-Point Signal Flow Diagram

There are three main components to the Viterbi decoding algorithm. They are branch metric computation (BMC), add-compare and select (ACS), and traceback decoding (TBD). The following diagram illustrates the signal flow for a  $k/n$  rate code.

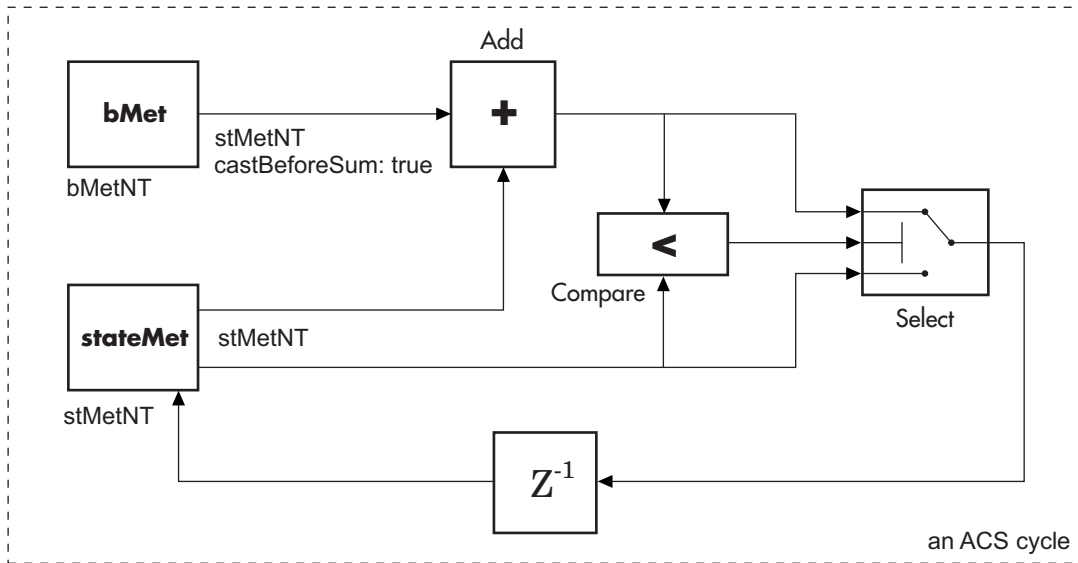

As an example of a BMC diagram, a 1/2 rate,  $nsdec = 3$  signal flow would be as follows.

$$WL = nsdec + n - 1$$

$$n = 2 \Rightarrow WL = 4$$

The ACS component is generally illustrated as shown in the following diagram.

```

stMetNT(0, WL2, 0)
stMetFIMATH('floor', 'saturate')
  
```

Where WL2 is specified on the mask by the user.

In the flow diagrams above, inNT, bMetNT, stMetNT, and outNT are numeric type objects, and bMetFIMATH and stMetFIMATH, are fimath objects.

## Puncture Pattern Examples

For some commonly used puncture patterns for specific rates and polynomials, see the last three references.

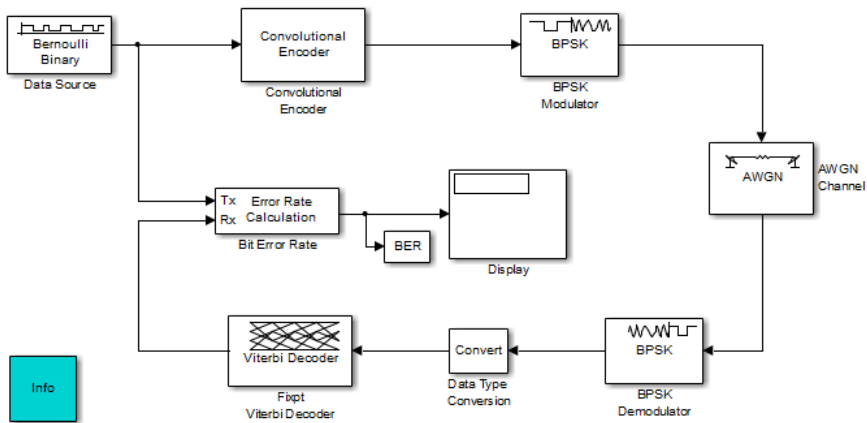

## Fixed-Point Viterbi Decoding Examples

The following two example models showcase the fixed-point Viterbi decoder block used for both hard- and soft-decision convolutional decoding.

If you are reading this reference page in the MATLAB Help Browser, click Fixed-point Hard-Decision Viterbi Decoding and Fixed-point Soft-Decision Viterbi Decoding to open

the models. These can also be found as `doc_fixpt_vitharddec.mdl` and `doc_fixpt_vitsoftdec.mdl` under `help\toolbox\comm\examples`.

### Fixed-point Hard-Decision Viterbi Decoding

### Fixed-point Soft-Decision Viterbi Decoding

The layout of the soft decision model example is also similar to the existing doc example on Soft-Decision Decoding, which can be found at `help\toolbox\comm\examples\doc_softdecision.mdl`

The purpose of this model is to highlight the fixed-point modeling attributes of the Viterbi decoder, using a familiar layout.

## Overview of the Simulations

The two simulations have a similar structure and have most parameters in common. A data source produces a random binary sequence that is convolutionally encoded, BPSK modulated, and passed through an AWGN channel.

The Convolutional encoder is configured as a rate 1/2 encoder. For every 2 bits, the encoder adds another 2 redundant bits. To accommodate this, and add the correct amount of noise, the **Eb/No (dB)** parameter of the AWGN block is in effect halved by subtracting  $10 \cdot \log_{10}(2)$ .

For the hard-decision case, the BPSK demodulator produces hard decisions, at the receiver, which are passed onto the decoder.

For the soft-decision case, the BPSK demodulator produces soft decisions, at the receiver, using the log-likelihood ratio. These soft outputs are 3-bit quantized and passed onto the decoder.

After the decoding, the simulation compares the received decoded symbols with the original transmitted symbols in order to compute the bit error rate. The simulation ends after processing 100 bit errors or 1e6 bits, whichever comes first.

## Fixed-Point Modeling

Fixed-point modeling enables bit-true simulations which take into account hardware implementation considerations and the dynamic range of the data/parameters. For example, if the target hardware is a DSP microprocessor, some of the possible word lengths are 8, 16, or 32 bits, whereas if the target hardware is an ASIC or FPGA, there may be more flexibility in the word length selection.

To enable fixed-point Viterbi decoding, the block input must be of type `ufix1` (unsigned integer of word length 1) for hard decisions. Based on this input (either a 0 or a 1), the internal branch metrics are calculated using an unsigned integer of word length = (number of output bits), as specified by the trellis structure (which equals 2 for the hard-decision example).

For soft decisions, the block input must be of type `ufixN` (unsigned integer of word length N), where N is the number of soft-decision bits, to enable fixed-point decoding. The block

inputs must be integers in the range 0 to  $2^{N-1}$ . The internal branch metrics are calculated using an unsigned integer of word length =  $(N + \text{number of output bits} - 1)$ , as specified by the trellis structure (which equals 4 for the soft-decision example).

The **State metric word length** is specified by the user and usually must be greater than the branch metric word length already calculated. You can tune this to be the most suitable value (based on hardware and/or data considerations) by reviewing the logged data for the system.

Enable the logging by selecting **Analysis > Fixed-Point Tool**. In the Fixed-Point Setting GUI, set the **Fixed-point instruments mode** to **Minimums, maximums and overflows**, and rerun the simulation. If you see overflows, it implies the data did not fit in the selected container. You could either increase the size of the word length (if your hardware allows it) or try scaling the data prior to processing it. Based on the minimum and maximum values of the data, you are also able to determine whether the selected container is of the appropriate size.

Try running simulations with different values of **State metric word length** to get an idea of its effect on the algorithm. You should be able to narrow down the parameter to a suitable value that has no adverse effect on the BER results.

## Comparisons with Double-Precision Data

To run the same model with double precision data, Select **Analysis > Fixed-Point Tool**. In the Fixed-Point Tool GUI, select the **Data type override** to be **Double**. This selection overrides all data type settings in all the blocks to use double precision. For the Viterbi Decoder block, as **Output type** was set to **Boolean**, this parameter should also be set to **double**.

Upon simulating the model, note that the double-precision and fixed-point BER results are the same. They are the same because the fixed-point parameters for the model have been selected to avoid any loss of precision while still being most efficient.

## Comparisons Between Hard and Soft-Decision Decoding

The two models are set up to run from within BERTool to generate a simulation curve that compares the BER performance for hard-decision versus soft-decision decoding.

To generate simulation results for `doc_fixpt_vitharddec.mdl`, do the following:

- 1 Type `bertool` at the MATLAB command prompt.
- 2 Go to the **Monte Carlo** pane.
- 3 Set the **Eb/No range** to 2:5.
- 4 Set the **Simulation model** to `doc_fixpt_vitharddec.mdl`. Make sure that the model is on path.
- 5 Set the **BER variable name** to BER.
- 6 Set the **Number of errors** to 100, and the **Number of bits** to 1e6.
- 7 Press **Run** and a plot is generated.

To generate simulation results for `doc_fixpt_vitsoftdec.mdl`, just change the **Simulation model** in step 4 and press **Run**.

Notice that, as expected, 3-bit soft-decision decoding is better than hard-decision decoding, roughly to the tune of 1.7 dB, and not 2 dB as commonly cited. The difference in the expected results could be attributed to the imperfect quantization of the soft outputs from the demodulator.

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder. Use the same value here and in the corresponding Convolutional Encoder block.

### Punctured code

Select this check box to specify a punctured input code. The field, **Punctured code**, appears.

### Puncture vector

Constant puncture pattern vector used at the transmitter (encoder). The puncture vector is a pattern of 1s and 0s. The 0s indicate the punctured bits. When you select **Punctured code**, the **Punctured vector** field appears.

### Enable erasures input port

When you check this box, the decoder opens an input port labeled Era. Through this port, you can specify an erasure vector pattern of 1s and 0s, where the 1s indicate the erased bits.

For these erasures in the incoming data stream, the decoder does not update the branch metric. The widths and the sample times of the erasure and the input data ports must be the same. The erasure input port can be of data type double or Boolean.

### Decision type

Specifies the use of Unquantized, Hard Decision, or Soft Decision for the branch metric calculation.

- Unquantized decision uses the Euclidean distance to calculate the branch metrics.
- Soft Decision and Hard Decision use the Hamming distance to calculate the branch metrics, where **Number of soft decision bits** equals 1.

#### **Number of soft decision bits**

The number of soft decision bits to represent each input. This field is active only when **Decision type** is set to Soft Decision.

#### **Error if quantized input values are out of range**

Select this check box to throw an error when quantized input values are out of range. This check box is active only when **Decision type** is set to Soft Decision or Hard Decision.

#### **Traceback depth**

The number of trellis branches to construct each traceback path.

#### **Operation mode**

Method for transitioning between successive input frames: Continuous, Terminated, and Truncated.

---

**Note** When this block outputs sequences that vary in length during simulation and you set the **Operation mode** to Truncated or Terminated, the block's state resets at every input time step.

---

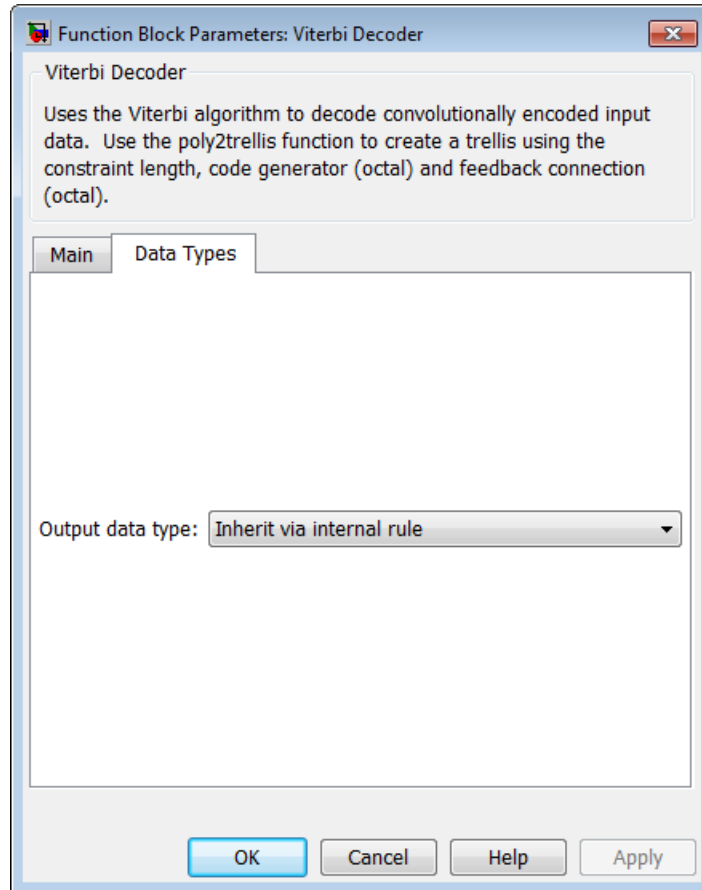

#### **Enable reset input port**

When you check this box, the decoder opens an input port labeled Rst. Providing a nonzero input value to this port causes the block to set its internal memory to the initial state before processing the input data.

#### **Delay reset action to next time step**

When you select this option, the Viterbi Decoder block resets after decoding the encoded data. This option is available only when you set **Operation mode** to Continuous and select **Enable reset input port**. You must enable this option for HDL support.

## Output data type

The output signal's data type can be double, single, boolean, int8, uint8, int16, uint16, int32, uint32, or set to 'Inherit via internal rule' or 'Smallest unsigned integer'.

When set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the **Hardware Implementation** pane, the output data type is `ufix(1)`. For all other selections, it is an unsigned integer with the smallest specified wordlength corresponding to the char value (e.g., uint8).

When set to 'Inherit via internal rule' (the default setting), the block selects double-typed outputs for double inputs, single-typed outputs for single inputs, and behaves similarly to the 'Smallest unsigned integer' option for all other typed inputs.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean for Hard decision mode</li> <li>• 8-, 16-, and 32-bit signed integers (for Hard decision and Soft decision modes)</li> <li>• 8-, 16-, and 32-bit unsigned integers (for Hard decision and Soft decision modes)</li> <li>• ufix(n), where n represents the <b>Number of soft decision bits</b></li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• ufix(1) for ASIC/FPGA mode</li> </ul>

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

---

**Note** For decoding data encoded with truncated or terminated modes, or punctured codes, use the Viterbi Decoder block from LTE HDL Toolbox™.

---

HDL Coder supports the following features of the Viterbi Decoder block:

- Non-recursive encoder/decoder with feed-forward trellis and simple shift register generation configuration
- Continuous mode

- Sample-based input
- Decoder rates from 1/2 to 1/7
- Constraint length from 3 to 9

When **Decision type** is set to `Soft decision`, the HDL implementation of the Viterbi Decoder block supports fixed-point inputs and output. For input, the fixed-point data type must be `ufixN`. `N` is the number of soft-decision bits. Signed built-in data types (`int8`, `int16`, `int32`) are not supported. For output, the HDL implementation of the Viterbi Decoder block supports block-supported output data types.

When **Decision type** is set to `Hard decision`, the block supports input with data types `ufix1` and `Boolean`. For output, the HDL implementation of the Viterbi Decoder block supports block-supported output data types. The HDL implementation of the Viterbi Decoder block does not support double and single input data types. The block does not support floating point output for fixed-point inputs.

The Viterbi Decoder block decodes every bit by tracing back through a traceback depth that you define for the block. The block implements a complete traceback for each decision bit, using registers to store the minimum state index and branch decision in the traceback decoding unit. There are two methods to optimize the traceback logic: a pipelined register-based implementation or a RAM-based architecture. See the “HDL Code Generation for Viterbi Decoder” example.

### Register-Based Traceback

You can specify that the traceback decoding unit be pipelined to improve the speed of the generated circuit. You can add pipeline registers to the traceback unit by specifying the number of traceback stages per pipeline register.

Using the `TracebackStagesPerPipeline` implementation parameter, you can balance the circuit performance based on system requirements. A smaller parameter value indicates the requirement to add more registers to increase the speed of the traceback circuit. Increasing the parameter value results in fewer registers along with a decrease in the circuit speed.

### RAM-Based Traceback

Instead of using registers, you can choose to use RAMs to save the survivor branch information. The coder does not support **Enable reset input port** when using RAM-based traceback.

- 1 Right-click the block and open **HDL Code > HDL Block Properties**. Set the **Architecture** property to RAM-based Traceback.
- 2 Double-click the block and set the **Traceback depth** on the Viterbi Decoder block mask.

RAM-based traceback and register-based traceback differ in the following ways:

- The RAM-based implementation traces back through one set of data to find the initial state to decode the previous set of data. The register-based implementation combines the traceback and decode operations into one step. It uses the best state found from the minimum operation as the decoding initial state.
- RAM-based implementation traces back through M samples, decodes the previous M bits in reverse order, and releases one bit in order at each clock cycle. The register-based implementation decodes one bit after a complete traceback.

Because of the differences in the two traceback algorithms, the RAM-based implementation produces different numerical results than the register-based traceback. A longer traceback depth, for example, 10 times the constraint length, is recommended in the RAM-based traceback. This depth achieves a similar bit error rate (BER) as the register-based implementation. The size of RAM required for the implementation depends on the trellis and the traceback depth.

### HDL Block Properties

<b>ConstrainedOutput Pipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
<b>TracebackStagesPerPipeline</b>	See “Register-Based Traceback” on page 3-1128.

### Restrictions

- **Punctured code:** Do not select this option. Punctured code requires frame-based input, which HDL Coder does not support.
- **Decision type:** The coder does not support the Unquantized decision type.
- **Error if quantized input values are out of range:** The coder does not support this option.
- **Operation mode:** The coder supports only the Continuous mode.
- **Enable reset input port:** When you enable both **Enable reset input port** and **Delay reset action to next time step**, HDL support is provided. You must select Continuous operation mode, and use register-based traceback.
- You cannot use the Viterbi Decoder block inside a Resettable Synchronous Subsystem.

# Walsh Code Generator

Generate Walsh code from orthogonal set of codes

## Library

Sequence Generators sublibrary of Comm Sources

## Description

Walsh codes are defined as a set of  $N$  codes, denoted  $W_j$ , for  $j = 0, 1, \dots, N - 1$ , which have the following properties:

- $W_j$  takes on the values  $+1$  and  $-1$ .
- $W_j[0] = 1$  for all  $j$ .
- $W_j$  has exactly  $j$  zero crossings, for  $j = 0, 1, \dots, N - 1$ .
- $W_j W_k^T = \begin{cases} 0 & j \neq k \\ N & j = k \end{cases}$
- Each code  $W_j$  is either even or odd with respect to its midpoint.

Walsh codes are defined using a Hadamard matrix of order  $N$ . The Walsh Code Generator block outputs a row of the Hadamard matrix specified by the **Walsh code index**, which must be an integer in the range  $[0, \dots, N - 1]$ . If you set **Walsh code index** equal to an integer  $j$ , the output code has exactly  $j$  zero crossings, for  $j = 0, 1, \dots, N - 1$ .

Note, however, that the indexing in the Walsh Code Generator block is different than the indexing in the Hadamard Code Generator block. If you set the **Walsh code index** in the Walsh Code Generator block and the **Code index parameter** in the Hadamard Code Generator block, the two blocks output different codes.

## Parameters

### Code length

Integer scalar that is a power of 2 specifying the length of the output code.

### Code index

Integer scalar in the range [0, 1, ... , N - 1], where N is the **Code length**, specifying the number of zero crossings in the output code.

### Sample time

The time between each sample of the output signal. Specify as a nonnegative real scalar.

### Samples per frame

The number of samples in one column of the output signal. If **Samples per frame** is greater than the **Code length**, the code is cyclically repeated. Specify as a positive integer scalar.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

---

### Output data type

The output type of the block can be specified as an `int8` or `double`. By default, the block sets this to `double`.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Does not support integer only code generation.

### Blocks

Hadamard Code Generator | OVSF Code Generator

**Introduced before R2006a**

## Windowed Integrator

Integrate over time window of fixed length

### Library

Comm Filters

### Description

The Windowed Integrator block creates cumulative sums of the input signal values over a sliding time window of fixed length. If the **Integration period** parameter is  $N$  and the input samples are denoted by  $x(1)$ ,  $x(2)$ ,  $x(3)$ , ..., then the  $n$ th output sample is the sum of the  $x(k)$  values for  $k$  between  $n-N+1$  and  $n$ . In cases where  $n-N+1$  is less than 1, the block uses an initial condition of 0 to represent those samples.

### Input and Output Signals

This block accepts scalar, column vector, and  $M$ -by- $N$  matrix input signals. The block filters an  $M$ -by- $N$  input matrix as follows:

- When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats each column as a separate channel. In this mode, the block creates  $N$  instances of the same filter, each with its own independent state buffer. Each of the  $N$  filters process  $M$  input samples at every Simulink time step.
- When you set the **Input processing** parameter to **Elements as channels (sample based)**, the block treats each element as a separate channel. In this mode, the block creates  $M*N$  instances of the same filter, each with its own independent state buffer. Each filter processes one input sample at every Simulink time step.

The output dimensions always equal those of the input signal. For information about the data types each block port supports, see the “Supported Data Type” on page 3-1137 table on this page.

## Parameters

### Integration period

The length of the interval of integration, measured in samples.

### Input processing

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

### Rounding mode

Select the rounding mode for fixed-point operations. The block uses the **Rounding mode** when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. The filter coefficients do not obey this parameter; they always round to **Nearest**. For more information, see “Rounding Modes” (DSP System Toolbox) or “Rounding Mode: Simplest” (Fixed-Point Designer).

### Saturate on integer overflow

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

### Coefficients

The block implementation uses a Direct-Form FIR filter with all tap weights set to one. The **Coefficients** parameter controls which data type represents the taps (i.e. ones) when the input data is a fixed-point signal.

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See “Filter Structure Diagrams” (DSP System Toolbox) for illustrations depicting the use of the coefficient data types in this block:

- When you select **Same word length as input**, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Specify word length**, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the **Rounding mode** and the **Saturate on integer overflow** parameters; they are always saturated and rounded to Nearest.

#### **Product output**

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the product output data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

#### **Accumulator**

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Binary point scaling`, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

### Output

Choose how you specify the output word length and fraction length:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you are able to enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

### Lock scaling against changes by the autoscaling tool

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

## Supported Data Type

Port	Supported Data Types
In	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed Fixed-point</li> </ul>

Port	Supported Data Types
Out	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li><li>• Signed fixed-point</li></ul>

## Examples

If **Integration period** is 3 and the input signal is a ramp (1, 2, 3, 4,...), then some of the sums that form the output of this block are as follows:

- $0+0+1 = 1$
- $0+1+2 = 3$
- $1+2+3 = 6$
- $2+3+4 = 9$
- $3+4+5 = 12$
- $4+5+6 = 15$
- etc.

The zeros in the first few sums represent initial conditions. With the **Input processing** parameter set to `Elements as channels`, then the values 1, 3, 6,... are successive values of the scalar output signal. With the **Input processing** parameter set to `Columns as channels`, the values 1, 3, 6,... are organized into output frames that have the same vector length as the input signal.

## comm.ACPR

**Package:** comm

Adjacent Channel Power Ratio measurements

### Description

The ACPR System object measures adjacent channel power ratio (ACPR) of an input signal.

To measure adjacent channel power:

- 1 Define and set up your adjacent channel power object. See “Construction” on page 4-2.
- 2 Call `step` to measure the adjacent channel power ratio according to the properties of `comm.ACPR`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.ACPR` creates a System object, `H`, that measures adjacent channel power ratio (ACPR) of an input signal.

`H = comm.ACPR(Name, Value)` creates object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### NormalizedFrequency

Assume normalized frequency values

Specify whether the frequency values are normalized. If you set this property to `true`, the object assumes that frequency values are normalized (in the `[-1 1]` range). The default is `false`. If you set this property to `false`, the object assumes that frequency values are measured in Hertz.

### SampleRate

Sample rate of input signal

Specify the sample rate of the input signal, in samples per second, as a double-precision, positive scalar. The default is `1e6` samples per second. This property applies when you set the `NormalizedFrequency` property to `false`.

### MainChannelFrequency

Main channel center frequency

Specify the main channel center frequency as a double-precision scalar. The default is `0` Hz.

When you set the `NormalizedFrequency` property to `true`, you must specify the center frequency as a normalized value between `-1` and `1`.

When you set the `NormalizedFrequency` property to `false`, you must specify the center frequency in Hertz. The object measures the main channel power in the bandwidth that you specify in the `MainMeasurementBandwidth` property. This measurement is taken at the center of the frequency that you specify in the `MainMeasurementBandwidth` property.

### MainMeasurementBandwidth

Main channel measurement bandwidth

Specify the main channel measurement bandwidth as a double-precision, positive scalar. The default is `50e3` Hz.

When you set the `NormalizedFrequency` property to `true`, you must specify the measurement bandwidth as a normalized value between 0 and 1.

When you set the `NormalizedFrequency` property to `false`, you must specify the measurement bandwidth in Hertz. The object measures the main channel power in the bandwidth that you specify in the `MainMeasurementBandwidth` property. This measurement is taken at the center of the frequency that you specify in the `MainChannelFrequency` property.

### **AdjacentChannelOffset**

Adjacent channel frequency offsets

Specify the adjacent channel offsets as a double-precision scalar or as a row vector comprising frequencies that define the location of adjacent channels of interest. The default is `[-100e3 100e3]` Hz.

When you set the `NormalizedFrequency` property to `true`, you must specify normalized frequency offset values between -1 and 1. When you set the `NormalizedFrequency` property to `false`, you must specify frequency offset values in Hertz. The offset values indicate the distance between the main channel center frequency and adjacent channel center frequencies. Positive offsets indicate adjacent channels to the right of the main channel center frequency. Negative offsets indicate adjacent channels to the left of the main channel center frequency.

### **AdjacentMeasurementBandwidth**

Adjacent channel measurement bandwidths

Specify the measurement bandwidth for each adjacent channel. The default is the scalar, `50e3`. The object assumes that each adjacent bandwidth is centered at the frequency defined by the corresponding frequency offset. You define this offset in the `AdjacentChannelOffset` property. Set this property to a double-precision scalar or row vector of length equal to the number of specified offsets in the `AdjacentChannelOffset` property.

When you set this property to a scalar, the object obtains all adjacent channel power measurements within equal measurement bandwidths. When you set the `NormalizedFrequency` property to `true`, you must specify normalized bandwidth values between 0 and 1. When you set the `NormalizedFrequency` property to `false`, you must specify the adjacent channel bandwidth values in Hertz.

## **MeasurementFilterSource**

Source of the measurement filter

Specify the measurement filter source as one of `None` | `Property`. The default is `None`. When you set this property to `None` the object does not apply filtering to obtain ACPR measurements. When you set this property to `Property`, the object applies a measurement filter to the main channel before measuring the average power. Each of the adjacent channel bands also receives a measurement filter. In this case, you specify the measurement filter coefficients in the `MeasurementFilter` property.

## **MeasurementFilter**

Measurement filter coefficients

Specify the measurement filter coefficients as a double-precision row vector containing the coefficients of an FIR filter in descending order of powers of  $z$ . Center the response of the filter at DC. The ACPR object automatically shifts and applies the filter response at each of the main and adjacent channel center frequencies before obtaining the average power measurements. The internal filter states persist and clear only when you call the `reset` method. This property applies when you set the `MeasurementFilterSource` property to `Property`. The default is `1`, which is an all-pass filter that has no effect on the measurements.

## **SpectralEstimation**

Spectral estimation control

Specify the spectral estimation control as one of `Auto` | `Specify frequency resolution` | `Specify window parameters`. The default is `Auto`.

When you set this property to `Auto`, the object obtains power measurements with a Welch spectral estimator with zero-percent overlap, a Hamming window, and a segment length equal to the length of the input data vector. In this setting, the spectral estimator set should achieve the maximum frequency resolution attainable with the input data length.

When you set this property to `Specify frequency resolution`, you specify the desired spectral frequency resolution, in normalized units or in Hertz, using the `FrequencyResolution` property. In this setting, the object uses the value in the `FrequencyResolution` property to automatically compute the size of the spectral estimator data window.

When you set this property to `Specify window parameters`, several spectral estimator properties become available so that you can control the Welch spectral estimation settings. These properties are: `SegmentLength`, `OverlapPercentage`, `Window`, and `SidelobeAttenuation`. Sidelobe attenuation applies only when you set the `Window` property to `Chebyshev`.

When you set this property to `Specify window parameters`, the `FrequencyResolution` property does not apply, and you control the resolution using the above properties.

### **SegmentLength**

Segment length

Specify the segment length, in samples, for the spectral estimator as a numeric, positive, integer scalar. The default is 64. The length of the segment allows you to make tradeoffs between frequency resolution and variance in the spectral estimates. A long segment length results in better resolution. A short segment length results in more averaging and a decrease in variance. This property applies when you set the `SpectralEstimation` property to `Specify window parameters`.

### **OverlapPercentage**

Overlap percentage

Specify the percentage of overlap between each segment in the spectral estimator as a double-precision scalar in the [0 100] interval. This property applies when you set the `SpectralEstimation` property to `Specify window parameters`. The default is 0 percent.

### **Window**

Window function

Specify a window function for the spectral estimator as one of `Bartlett` | `Bartlett-Hanning` | `Blackman` | `Blackman-Harris` | `Bohman` | `Chebyshev` | `Flat Top` | `Hamming` | `Hann` | `Nuttall` | `Parzen` | `Rectangular` | `Triangular`. The default is `Hamming`. A Hamming window has 42.5dB of sidelobe attenuation. This attenuation may mask spectral content below this value, relative to the peak spectral content. Choosing different windows allows you to make tradeoffs between resolution and sidelobe attenuation. This property applies when you set the `SpectralEstimation` property to `Specify window parameters`.

## SidelobeAttenuation

Sidelobe attenuation for Chebyshev window

Specify the sidelobe attenuation, in decibels, for the Chebyshev window function as a double-precision, nonnegative scalar. The default is 100 dB. This property applies when you set the SpectralEstimation property to Specify window parameters and the Window property to Chebyshev.

## FrequencyResolution

Frequency resolution

Specify the frequency resolution of the spectral estimator as a double-precision scalar. The default is 10625 Hz.

When you set the NormalizedFrequency property to true, you must specify the frequency resolution as a normalized value between 0 and 1. When you set the NormalizedFrequency property to false, you must specify the frequency resolution in Hertz. The object uses the value in the FrequencyResolution property to calculate the size of the data window used by the spectral estimator. This property applies when you set the SpectralEstimation property to Specify frequency resolution.

## FFTLength

FFT length

Specify the FFT length that the Welch spectral estimator uses as one of Next power of 2 | Same as segment length | Custom. The default is Next power of 2.

When you set this property to Custom, the CustomFFTLength property becomes available to specify the desired FFT length.

When you set this property to Next power of 2, the object sets the length of the FFT to the next power of 2. This length is greater than the spectral estimator segment length or 256, whichever is greater.

When you set this property to Same as segment length, the object sets the length of the FFT. This length equals the spectral estimator segment length or 256, whichever is greater.

### **CustomFFTLength**

Custom FFT length

Specify the number of FFT points that the spectral estimator uses as a numeric, positive, integer scalar. This property applies when you set the `FFTLength` property to `Custom`. The default is 256.

### **MaxHold**

Max-hold setting control

Specify the maximum hold setting. The default is `false`.

When you set this property to `true`, the object compares two vectors. One vector compared is the current estimated power spectral density vector (obtained with the current input data frame). The object checks this vector against the previous maximum-hold accumulated power spectral density vector, (obtained at the previous call to the `step` method). The object stores the maximum values at each frequency bin and uses them to compute average power measurements. You clear the maximum-hold spectrum by calling the `reset` method on the object. When you set this property to `false`, the object obtains power measurements using instantaneous power spectral density estimates. This property is tunable.

### **PowerUnits**

Power units

Specify power measurement units as one of `dBm` | `dBW` | `Watts`. The default is `dBm`.

When you set this property to `dBm`, or `dBW`, the `step` method outputs ACPR measurements in a `dBc` scale (adjacent channel power referenced to main channels power). If you set this property to `Watts`, the `step` method outputs ACPR measurements in a linear scale.

### **MainChannelPowerOutputPort**

Enable main channel power measurement output

When you set this property to `true`, the `step` method outputs the main channel power measurement. The default is `false`. The main channel power is the power of the input signal measured in the band that you define with the `MainChannelFrequency` and

MainMeasurementBandwidth properties. The `step` method returns power measurements in the units that you specify in the `PowerUnits` property.

### AdjacentChannelPowerOutputPort

Enable adjacent channel power measurements output

When you set this property to `true`, the `step` method outputs a vector of adjacent channel power measurements. The default is `false`. The adjacent channel powers correspond to the input signal's power measured in the bands that you define with the `AdjacentChannelOffset` and `AdjacentMeasurementBandwidth` properties. The `step` method returns power measurements in the units that you specify in the `PowerUnits` property.

## Methods

`reset`      Reset states of ACPR measurement object  
`step`        Adjacent Channel Power Ratio measurements

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Measure ACPR of a 16-QAM signal with symbol rate of 3.84 Msps

Generate data with an alphabet size of 16 and modulate the data

```
x = randi([0 15],5000,1);
y = qammod(x,16);
```

Upsample the data by  $L = 8$  using a rectangular pulse shape

```
L = 8;
yPulse = rectpulse(y,L);
```

Create an ACPR measurement object and measure the modulated signal

```
acpr = comm.ACPR(...  
    'SampleRate', 3.84e6*8,...  
    'MainChannelFrequency', 0,...  
    'MainMeasurementBandwidth', 3.84e6,...  
    'AdjacentChannelOffset', [-5e6 5e6],...  
    'AdjacentMeasurementBandwidth', 3.84e6,...  
    'MainChannelPowerOutputPort', true,...  
    'AdjacentChannelPowerOutputPort', true);  
[ACPR,mainChnlPwr,adjChnlPwr] = acpr(yPulse)
```

```
ACPR = 1x2
```

```
    -14.3659    -14.3681
```

```
mainChnlPwr = 38.8668
```

```
adjChnlPwr = 1x2
```

```
    24.5010    24.4988
```

## Algorithms

---

**Note** The following conditions must be true, otherwise power measurements fall out of the Nyquist interval.

$$\left| \text{MainChannelFreq} \pm \frac{\text{MainChannelMeasBW}}{2} \right| < F_{\max}$$

$$\left| (\text{MainChannelFreq} + \text{AdjChannelOffset}) \pm \frac{\text{AdjChannelMeasBW}}{2} \right| < F_{\max}$$

$F_{\max} = F_s/2$  if NormalizedFrequency = false

$F_{\max} = 1$  if NormalizedFrequency = true

---

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Package:** comm

Adjacent Channel Power Ratio measurements

## Syntax

```
A = step(H,X)
[A,MAINPOW] = step(H,X)
[A,ADJPOW] = step(H,X)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`A = step(H,X)` returns a vector of the adjacent channel power ratio, `A`, measured in the input data, `X`. The measurements are at the frequency bands that you specify with the `MainChannelFrequency`, `MainMeasurementBandwidth`, `AdjacentChannelOffset`, and `AdjacentMeasurementBandwidth` properties. Input `X` must be a double precision column vector. The length of the output vector, `A`, equals the number of adjacent channels that you specify in the `AdjacentChannelOffset` property.

`[A,MAINPOW] = step(H,X)` returns the measured main channel power, `MAINPOW`, when you set the `MainChannelPowerOutputPort` property to true. The `step` method outputs the main channel power measured within the main channel frequency band of interest that you specify with the `MainChannelFrequency` and `MainMeasurementBandwidth` properties.

`[A,ADJPOW] = step(H,X)` returns a vector of the measured adjacent channel powers, `ADJPOW`, when you set the `AdjacentChannelPowerOutputPort` property to true. The

adjacent channel powers are measured at the adjacent frequency bands of interest that you specify with the `AdjacentChannelOffset` and `AdjacentMeasurementBandwidth` properties. The length of the output vector, `ADJPOW`, equals the length of the vector that you specify in the `AdjacentChannelOffset` property. You can combine optional output arguments when you set their enabling properties. Optional outputs must be listed in the same order as the order of the enabling properties. For example,

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.AGC

**Package:** comm

Adaptively adjust gain for constant signal-level output

## Description

The `comm.AGC` System object creates an automatic gain controller (AGC) that adaptively adjusts its gain to achieve a constant signal level at the output.

To adaptively adjust gain for constant signal-level output:

- 1 Define and set up your automatic gain controller object. See “Construction” on page 4-15.
- 2 Call `step` to adaptively adjust gain and achieve a constant signal level at the output according to the properties of `comm.AGC`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.AGC` creates an AGC System object, `H`, that adaptively adjusts its gain to achieve a constant signal level at the output.

`H = comm.AGC(Name,Value)` creates an AGC object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### **AdaptationStepSize**

Step size for gain updates

Specify the step size as a real positive scalar. The default is `0.01`. Increasing the step size permits the AGC to respond more quickly to changes in the input signal level but increases variation in the output signal level during steady-state operation.

### **DesiredOutputPower**

Target output power level

Specify the desired output power level as a real positive scalar. The power is measured in Watts referenced to 1 ohm. The default is `1`.

### **AveragingLength**

Length of the averaging window

Specify the length of the averaging window in samples as a positive integer scalar. The default is `100`.

---

**Note** If you use the AGC with higher-order QAM signals, inspect the scatter plot at the output of the AGC during steady-state operation and increase the averaging length if you see frequent gain adjustments. An increase in `AveragingLength` reduces execution speed.

---

### **MaxPowerGain**

Maximum power gain in decibels

Specify the maximum gain of the AGC in decibels as a positive scalar. The default is `60`.

Large gain adjustments can cause clipping when a small input signal power suddenly increases. Use `MaxPowerGain` to avoid large gain adjustments by limiting the gain that the AGC applies to the input signal.

## Methods

reset     Reset internal states of automatic gain controller  
 step     Apply adaptive gain to input signal

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Vary AGC Averaging Length

Apply different AGC averaging lengths to QAM modulated signals. Compare the variance and plot of the signals after AGC is applied.

Initialize three AGC System objects with average window length set to 10, 100, and 1000 samples.

```
agc1 = comm.AGC('AveragingLength',10);
agc2 = comm.AGC('AveragingLength',100);
agc3 = comm.AGC('AveragingLength',1000);
```

Generate M-QAM modulated and raised cosine pulse shaped packetized data.

```
M = 16;
d = randi([0 M-1],1000,1);
s = qammod(d,M);
x = 0.1*s;
pulseShaper = comm.RaisedCosineTransmitFilter;
y = awgn(pulseShaper(x),inf);
```

Apply AGC.

```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot and compare the signals.

```
figure(1)
subplot(4,1,1)
```

```
plot(abs(y))
title('AGC input')
subplot(4,1,2)
plot(abs(r1))
axis([0 8000 0 10])
title('AGC output (AveragingLength = 10 samples)')
text(4000, 5, sprintf('Variance = %f',var(r1(3000:end))))
subplot(4,1,3)
plot(abs(r2))
axis([0 8000 0 10])
title('AGC output (AveragingLength = 100 sample)')
text(4000, 5, sprintf('Variance = %f',var(r2(3000:end))))
subplot(4,1,4)
plot(abs(r3))
axis([0 8000 0 10])
title('AGC output (AveragingLength = 1000 samples)')
text(4000, 5, sprintf('Variance = %f',var(r3(3000:end))))
```

As the averaging length increases the variance at the output of the AGC decreases.

### Vary AGC Maximum Gain

Apply different AGC maximum gain level to QPSK modulated signals. With the maximum gain too small the signal after AGC will not reach desired amplitude. With the maximum gain too large the signal after AGC will overshoot and can saturate resulting in signal loss at the start of received packets. With the maximum gain at the optimal level, the signal after AGC reaches the desired amplitude without signal loss due to saturation. Compare the plot of the signals after AGC is applied.

Initialize three AGC System objects with maximum gain values set to 10 dB, 20 dB, and 30 dB.

```
agc1 = comm.AGC('MaxPowerGain', 10);  
agc2 = comm.AGC('MaxPowerGain', 20);  
agc3 = comm.AGC('MaxPowerGain', 30);
```

Generate QPSK modulated and raised cosine pulse shaped packetized data.

```
M = 4;  
pktLen = 10000;  
d = randi([0 M-1],pktLen,1);  
s = pskmod(d,M,pi/4);  
x = repmat([zeros(pktLen,1); 0.3*s],3,1);  
pulseShaper = comm.RaisedCosineTransmitFilter;  
y = awgn(pulseShaper(x),50);
```

Apply AGC and plot.

```
r1 = agc1(y);  
r2 = agc2(y);  
r3 = agc3(y);
```

Plot and compare the signals.

```
figure(1)  
subplot(4,1,1)  
plot(abs(y))  
title('AGC input')  
subplot(4,1,2)  
plot(abs(r1))  
title('AGC output (MaxPowerGain = 10 dB)')  
subplot(4,1,3)  
plot(abs(r2))  
title('AGC output (MaxPowerGain = 20 dB)')  
subplot(4,1,4)  
plot(abs(r3))  
title('AGC output (MaxPowerGain = 30 dB)')
```

This plot compares the signal input to AGC and output from AGC with various maximum gain levels. With the maximum gain set to 10dB, the AGC output cannot reach the desired output power level. With the maximum gain set to 20dB, the AGC output reaches the desired level without saturating. With the maximum gain set to 30dB, the AGC output overshoots risking signal saturation and data loss. Between packets there is only noise in the input signal.

As shown in the plots, with packet transmissions there may be extended periods when no data is received. This results in AGC increasing to the maximum gain setting. If a packet arrives when the AGC gain is too high, the output power overshoots until the AGC can respond to the change in the input power level and reduce its gain.

### Vary AGC Step Size

Apply different AGC step sizes to QPSK modulated signals. Compare the signals after AGC is applied.

Initialize three AGC System objects with step sizes set to 1e-1, 1e-3, and 1e-4.

```
agc1 = comm.AGC('AdaptationStepSize',1e-1);  
agc2 = comm.AGC('AdaptationStepSize',1e-3);  
agc3 = comm.AGC('AdaptationStepSize',1e-4);
```

Generate QPSK modulated data with raised cosine pulse shaping.

```
d = randi([0 3],500,1);  
s = pskmod(d,4,pi/4);  
x = 0.1*s;  
pulseShaper = comm.RaisedCosineTransmitFilter;  
y = pulseShaper(x);
```

Apply AGC.

```
r1 = agc1(y);  
r2 = agc2(y);  
r3 = agc3(y);
```

Plot the signal input to AGC and output after various AGC step sizes.

```
figure  
subplot(4,1,1)  
plot(abs(y))  
title('AGC input')  
subplot(4,1,2)  
plot(abs(r1))  
title('AGC output (AdaptionStepSize = 1e-1)')  
subplot(4,1,3)  
plot(abs(r2))  
title('AGC output (AdaptionStepSize = 1e-3)')  
subplot(4,1,4)  
plot(abs(r3))  
title('AGC output (AdaptionStepSize = 1e-4)')
```

With the step size set to  $1e-1$ , the AGC output overshoot but converges very quickly. With the step size set to  $1e-3$ , the AGC output overshoot disappears and the AGC converges smoothly but more slowly. With the maximum gain set to  $1e-4$ , the AGC takes a very long time to converge.

### **Adaptively Adjust Received Signal Amplitude Using AGC**

Modulate and amplify a QPSK signal. Set the received signal amplitude to approximately 1 volt using an AGC. Then plot the output.

Create a QPSK modulated signal using the QPSK System object.

```
data = randi([0 3],1000,1);  
qpsk = comm.QPSKModulator;  
modData = qpsk(data);
```

Attenuate the modulated signal.

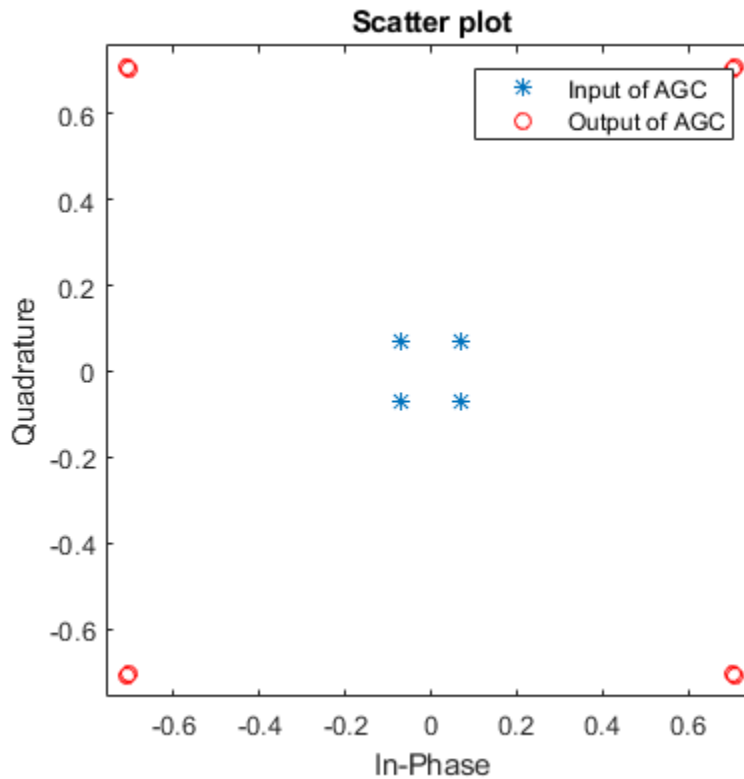

```
txSig = 0.1*modData;
```

Create an AGC System object™ and pass the transmitted signal through it using the step function. The AGC adjusts the received signal power to approximately 1 W.

```
agc = comm.AGC;  
rxSig = agc(txSig);
```

Plot the signal constellations of the transmit and received signals after the AGC reaches steady-state.

```
h = scatterplot(txSig(200:end),1,0,'*');  
hold on  
scatterplot(rxSig(200:end),1,0,'or',h);  
legend('Input of AGC', 'Output of AGC')
```

Measure and compare the power of the transmitted and received signals after the AGC reaches a steady state. The power of the transmitted signal is 100 times smaller than the power of the received signal.

```
txPower = var(txSig(200:end));
rxPower = var(rxSig(200:end));
[txPower rxPower]
```

```
ans = 1x2
```

```
0.0100    0.9970
```

### Plot Effect of Step Size on AGC Performance

Create two AGC System objects™ to adjust the level of the received signal using two different step sizes with identical update periods.

Generate an 8-PSK signal having power equal to 10 W.

```
data = randi([0 7],200,1);  
modData = sqrt(10)*pskmod(data,8,pi/8,'gray');
```

Create a pair of raised cosine matched filters with their Gain property set so that they have unity output power.

```
txfilter = comm.RaisedCosineTransmitFilter('Gain',sqrt(8));  
rxfilter = comm.RaisedCosineReceiveFilter('Gain',sqrt(1/8));
```

Filter the modulated signal through the raised cosine transmit filter object.

```
txSig = txfilter(modData);
```

Create two AGC objects to adjust the received signal level. Select a step size of 0.01 and 0.1, respectively. Set the update period to 10.

```
agc1 = comm.AGC('AdaptationStepSize',0.01);  
agc2 = comm.AGC('AdaptationStepSize',0.1);
```

Pass the modulated signal through the two AGC objects.

```
agcOut1 = agc1(txSig);  
agcOut2 = agc2(txSig);
```

Filter the AGC output signals by using the raised cosine receive filter object.

```
rxSig1 = rxfilter(agcOut1);  
rxSig2 = rxfilter(agcOut2);
```

Plot the power of the filtered AGC responses while accounting for the 10 symbol delay through the transmit-receive filter pair.

```
plot([abs(rxSig1(11:110)).^2 abs(rxSig2(11:110)).^2])  
grid on  
xlabel('Symbols')  
ylabel('Power (W)')  
legend('Step Size 0.01','Step Size 0.1')
```

The signal with the larger step size converges faster to the AGC target power level of 1 W.

Plot the power of the steady-state filtered AGC signals by including only the last 100 symbols.

```
plot((101:200), [abs(rxSig1(101:200)).^2 abs(rxSig2(101:200)).^2])  
grid on  
xlabel('Symbols')  
ylabel('Power (W)')  
legend('Step Size 0.01', 'Step Size 0.1')
```

The larger AGC step size results in less accurate gain correction.

The reduced accuracy suggests a trade off with the `AdaptationStepSize` property. Larger values result in faster convergence at the expense of less accurate gain control.

### **Demonstrate Effect of Maximum AGC Gain on Packet Data**

Pass attenuated QPSK packet data to two AGCs having different maximum gains. Then display the results.

Create two, 200-symbol QSPK data packets. Transmit the packets over a 1200-symbol frame.

```
modData1 = pskmod(randi([0 3],200,1),4,pi/4);  
modData2 = pskmod(randi([0 3],200,1),4,pi/4);  
txSig = [modData1; zeros(400,1); modData2; zeros(400,1)];
```

Attenuate the transmitted burst signal by 20 dB and plot its power.

```
rxSig = 0.1*txSig;  
rxSigPwr = abs(rxSig).^2;  
plot(rxSigPwr)  
grid  
xlabel('Symbols')  
ylabel('Power (W)')
```

Create two AGCs, where `agc1` has a maximum power gain of 30 dB and `agc2` has a maximum power gain of 24 dB.

```
agc1 = comm.AGC('MaxPowerGain',30, ...  
               'AdaptationStepSize',0.02);
```

```
agc2 = comm.AGC('MaxPowerGain',24, ...  
               'AdaptationStepSize',0.02);
```

Pass the attenuated signal through the AGCs and calculate the output power.

```
rxAGC1 = agc1(rxSig);  
rxAGC2 = agc2(rxSig);
```

```
pwrAGC1 = abs(rxAGC1).^2;
pwrAGC2 = abs(rxAGC2).^2;
```

Plot the output power.

```
plot([pwrAGC1 pwrAGC2])
legend('AGC1', 'AGC2')
grid
xlabel('Symbols')
ylabel('Power (W)')
```

Initially, for the second packet, the `agc1` output signal power is too high because the AGC applied its maximum gain during the period when no data was transmitted. The corresponding `agc2` output signal power does not overshoot the target power level of 1 W

by the same amount. It converges to the correct power more quickly due to its smaller maximum gain.

## Algorithms

### Logarithmic Loop AGC

For the logarithmic loop AGC, the output signal is the product of the input signal and the exponential of the loop gain. The error signal is the difference between the reference level and the product of the logarithm of the detector output and the exponential of the loop gain. After multiplying by the step size, the AGC passes the error signal to an integrator.

The logarithmic loop AGC provides good performance for a variety of signal types, including amplitude modulation. Unlike the previous AGC (R2015a and earlier), the detector is applied to the input signal, which results in faster convergence times and increased signal power variation at the detector input. The larger variation is not a problem for floating point systems. A block diagram of the algorithm is shown.

Mathematically, the algorithm is summarized as

$$\begin{aligned}y(n) &= x(n) \cdot \exp(g(n - 1)) \\z(n) &= D(x(n)) \cdot \exp(2g(n - 1)) \\e(n) &= A - \ln(z(n)) \\g(n) &= g(n - 1) + K \cdot e(n),\end{aligned}$$

where

- $x$  represents the input signal.
- $y$  represents the output signal.
- $g$  represents the loop gain.
- $D(\bullet)$  represents the detector function.
- $z$  represents the detector output.
- $A$  represents the reference value.
- $e$  represents the error signal.
- $K$  represents the step size.

## AGC Detector

The AGC detector output,  $z$ , computes a square law detector:

$$z(m) = \frac{1}{N} \sum_{n=mN}^{(m+1)N-1} |y(n)|^2,$$

where  $N$  represents the update period.

## AGC Performance Criteria

- Attack time — The duration it takes the AGC to respond to an increase in the input amplitude.
- Decay time — The duration it takes the AGC to respond to a decrease in the input amplitude.
- Gain pumping — The variation in the gain value during steady-state operation.

Increasing the step size decreases the attack time and decay times, but it also increases gain pumping.

**Package:** comm

Reset internal states of automatic gain controller

## Syntax

reset(H)

## Description

reset(H) resets the filter states of the automatic gain controller filter object, H, to their initial values.

# step

**System object:** `comm.AGC`

**Package:** `comm`

Apply adaptive gain to input signal

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  applies an adaptive gain to the input signal  $X$ , to achieve a reference signal level at the output,  $Y$ . You must specify  $X$  as a double-precision or single-precision column vector. The AGC object uses a square law detector to determine the output signal level.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.AlgebraicDeinterleaver

**Package:** comm

(To be removed) Deinterleave input symbols using algebraically derived permutation vector

## Compatibility

comm.AlgebraicDeinterleaver will be removed in a future release. Use `algdeintrlv` instead. For more information, see “Compatibility Considerations” on page 4-41.

## Description

The `AlgebraicDeinterleaver` object restores the original ordering of a sequence that was interleaved using the `AlgebraicInterleaver` object. In typical usage, the properties of the two objects have the same values.

To deinterleave input symbols using an algebraically derived permutation vector:

- 1 Define and set up your algebraic deinterleaver object. See “Construction” on page 4-38.
- 2 Call `step` to deinterleave the input symbols according to the properties of `comm.AlgebraicDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.AlgebraicDeinterleaver` creates a deinterleaver System object, `H`. This object restores the original ordering of a sequence from the corresponding algebraic interleaver object.

`H = comm.AlgebraicDeinterleaver(Name, Value)` creates an Algebraic deinterleaver System object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### Method

Algebraic method to generate permutation vector

Specify the algebraic method as one of `Takehita-Costello` | `Welch-Costas`. The default is `Takehita-Costello`. The algebraic interleaver performs all computations in modulo  $N$ , where  $N$  equals the length you set in the `Length` property.

For the `Welch-Costas` method, the value of  $(N+1)$  must be a prime number, where  $N$  equals the value you specify in the `Length` property. You must set the `PrimitiveElement` property to an integer,  $A$ , between 1 and  $N$ . This integer represents a primitive element of the finite field  $GF(N+1)$ .

For the `Takehita-Costello` method, you must set the `Length` property to a value equal to  $2^m$ , for any integer  $m$ . You must also set the `MultiplicativeFactor` property to an odd integer that is less than the value of the `Length` property. The `CyclicShift` property requires a nonnegative integer which is less than the value of the `Length` property. The `Takehita-Costello` interleaver method uses a cycle vector of length  $N$ , which you specify in the `Length` property. The cycle vector calculation uses the equation,  $\text{mod}(k \times (n - 1) \times \frac{n}{2}, N) + 1$ , for any integer  $n$ , between 1 and  $N$ . The object creates an intermediate permutation function using the relationship,  $P(c(n)) = c(n+1)$ . You can shift the elements of the intermediate permutation vector to the left by the amount specified by the `CyclicShift` property. Doing so produces the interleaver's actual permutation vector.

## Length

Number of elements in input vector

Specify the number of elements in the input as a positive, integer, scalar. When you set the Method property to `Welch-Costas`, then the value of `Length+1` must equal a prime number. When you set the Method property to `Takeshita-Costello`, then the value of the Length property requires a power of two. The default is 256.

## MultiplicativeFactor

Cycle vector computation factor

Specify the factor the object uses to compute the interleaver's cycle vector as a positive, integer, scalar. This property applies when you set the Method property to `Takeshita-Costello`. The default is 13.

## CyclicShift

Amount of cyclic shift

Specify the amount by which the object shifts indices, when the object creates the final permutation vector, as a nonnegative, integer, scalar. The default is 0. This property applies when you set the Method property to `Takeshita-Costello`.

## PrimitiveElement

Primitive element

Specify the primitive element as an element of order  $N$  in the finite field  $GF(N+1)$ .  $N$  is the value you specify in the `Length` on page 4-0 property. You can express every nonzero element of  $GF(N+1)$  as the value of the `PrimitiveElement` property raised to some integer power. In a `Welch-Costas` interleaver, the permutation maps the integer  $k$  to  $\text{mod}(A^k, N+1)-1$ , where  $A$  represents the value of the `PrimitiveElement` property. This property applies when you set the Method property to `Welch-Costas`. The default is 6.

## Syntax

`Y = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using an algebraic interleaver. An algebraically derived permutation vector based on the algebraic method you specify in the `Method` property forms the base of the output, `Y`. `X` must be a column vector of length specified by the `Length` property. `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# comm.AlgebraicInterleaver

**Package:** comm

(To be removed) Permute input symbols using algebraically derived permutation vector

## Compatibility

comm.AlgebraicInterleaver will be removed in a future release. Use `algintrlv` instead. For more information, see “Compatibility Considerations” on page 4-49.

## Description

The `AlgebraicInterleaver` object rearranges the elements of its input vector using an algebraically derived permutation.

To interleave input symbols using an algebraically derived permutation vector:

- 1 Define and set up your algebraic interleaver object. See “Construction” on page 4-45.
- 2 Call `step` to interleave the input symbols according to the properties of `comm.AlgebraicInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.AlgebraicInterleaver` creates an interleaver System object, `H`, that permutes the symbols in the input signal. This permutation is based on an algebraically derived permutation vector.

`H = comm.AlgebraicInterleaver(Name, Value)` creates an algebraic interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### Method

Algebraic method to generate permutation vector

Algebraic method to generate permutation vector

Specify the algebraic method as one of `Takeshita-Costello` or `Welch-Costas`. The default is `Takeshita-Costello`. The algebraic interleaver performs all computations in modulo  $N$ , where  $N$  is the length you set in the `Length` property.

For the `Welch-Costas` method, the value of  $(N+1)$  must be a prime number, where  $N$  is the value you specify in the `Length` property. You must set the `PrimitiveElement` property to an integer,  $A$ , between 1 and  $N$ . This integer represents a primitive element of the finite field  $GF(N+1)$ .

For the `Takeshita-Costello` method, you must set the `Length` property to a value equal to  $2^m$ , for any integer  $m$ . You must also set the `MultiplicativeFactor` property to an odd integer which is less than the value of the `Length` property. In addition, you must set the `CyclicShift` property to a nonnegative integer which is less than the value of the `Length` property. The `Takeshita-Costello` interleaver method uses a cycle vector of length  $N$ , which you specify in the `Length` property. The cycle vector calculation uses the equation,  $\text{mod}(k \times (n - 1) \times \frac{n}{2}, N) + 1$ , for any integer  $n$ , between 1 and  $N$ . The object creates an intermediate permutation function using the relationship,  $P(c(n)) = c(n+1)$ . You can shift the elements of the intermediate permutation vector to the left by the amount specified by the `CyclicShift` property. Doing so produces the actual permutation vector of the interleaver.

### Length

Number of elements in input vector

Specify the number of elements in the input as a positive, integer, scalar. When you set the `Method` property to `Welch-Costas`, then the value of `Length+1` must equal a prime

number. When you set the `Method` property to `Takeshita-Costello`, then the value of the `Length` property requires a power of two. The default is 256.

### **MultiplicativeFactor**

Cycle vector computation method

Specify the factor the object uses to compute the cycle vector for the interleaver as a positive, integer, scalar. This property applies when you set the `Method` on page 4-0 property to `Takeshita-Costello`. The default is 13.

### **CyclicShift**

Amount of cyclic shift

Specify the amount by which the object shifts indices, when it creates the final permutation vector, as a nonnegative, integer, scalar. This property applies when you set the `Method` on page 4-0 property to `Takeshita-Costello`. The default is 0.

### **PrimitiveElement**

Primitive element

Specify the primitive element as an element of order  $N$  in the finite field  $GF(N+1)$ .  $N$  is the value you specify in the `Length` property. You can express every nonzero element of  $GF(N+1)$  as the value of the `PrimitiveElement` property raised to an integer power. In a Welch-Costas interleaver, the permutation maps the integer  $k$  to  $\text{mod}(A^k, N+1)-1$ , where  $A$  represents the value of the `PrimitiveElement` property. This property applies when you set the `Method` property to `Welch-Costas`. The default is 6.

# comm.APPDecoder

**Package:** comm

Decode convolutional code using the a posteriori probability method

## Description

The APPDecoder object performs a posteriori probability (APP) decoding of a convolutional code.

To perform a posteriori probability (APP) decoding of a convolutional code:

- 1 Define and set up your a posteriori probability decoder object. See “Construction” on page 4-53.
- 2 Call `step` to perform APP decoding according to the properties of `comm.APPDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.APPDecoder` creates an a posteriori probability (APP) decoder System object, `H`, that decodes a convolutional code using the APP method.

`H = comm.APPDecoder(Name, Value)` creates an APP decoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.APPDecoder(TRELLIS, Name, Value)` creates an APP decoder object, `H`, with the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. The default is the result of `poly2trellis(7, [171 133], 171)`. Use the `istrellis` function to check if a structure is a valid trellis structure.

### TerminationMethod

Termination method of encoded frame

Specify how the encoded frame is terminated as one of `Truncated` | `Terminated`. The default is `Truncated`. When you set this property to `Truncated`, the object assumes that the encoder stops after encoding the last symbol in the input frame. When you set this property to `Terminated` the object assumes that the encoder forces the trellis to end each frame in the all-zeros state by encoding additional symbols. If you use the `comm.ConvolutionalEncoder` System object to generate the encoded frame, the `TerminationMethod` values of both encoder and decoder objects must match.

### Algorithm

Decoding algorithm

Specify the decoding algorithm that the object uses as one of `True APP` | `Max*` | `Max`. The default is `Max*`. When you set this property to `True APP`, the object implements true a posteriori probability decoding. When you set the property to any other value, the object uses approximations to increase the speed of the computations.

### NumScalingBits

Number of scaling bits

Specify the number of bits the decoder uses to scale the input data to avoid losing precision during the computations. The default is 3. The decoder multiplies the input by  $2^{\text{NumScalingBits}}$  and divides the pre-output by the same factor. This property must be a scalar integer between 0 and 8. This property applies when you set the `Algorithm` property to `Max*`.

## CodedBitLLROutputPort

Enable coded-bit LLR output

Set this property to `false` to disable the second output of the decoding step method. The default is `true`.

## Methods

`reset` Reset states of APP decoder object

`step` Decode convolutional code using the a posteriori probability method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Decode Convolutional Code Using the APP Decoder

This example shows how to use the APP decoder on a convolutionally encoded 8-PSK-modulated bit stream transmitted through an AWGN channel.

Create convolutional encoder, PSK modulator, and AWGN channel System objects.

```
noiseVar = 2e-1;
frameLength = 300;
hConEnc = comm.ConvolutionalEncoder('TerminationMethod','Truncated');
hMod = comm.PSKModulator('BitInput',true,'PhaseOffset',0);
hChan = comm.AWGNChannel('NoiseMethod','Variance', ...
    'Variance',noiseVar);
```

Create convolutional decoder, PSK demodulator, and error rate System objects.

```
hAPPDec = comm.APPDecoder(...
    'TrellisStructure',poly2trellis(7,[171 133]), ...
    'Algorithm','True APP','CodedBitLLROutputPort',false);
hDemod = comm.PSKDemodulator('BitOutput',true,'PhaseOffset',0, ...
    'DecisionMethod','Approximate log-likelihood ratio', ...
```

```
    'Variance',noiseVar);  
hError = comm.ErrorRate;
```

Transmit a convolutionally encoded 8-PSK-modulated bit stream through an AWGN channel. Demodulate the received signal using soft-decision. Decode the demodulated signal using the APP decoder.

```
for counter = 1:5  
    data = randi([0 1],frameLength,1);  
    encodedData = step(hConEnc,data);  
    modSignal = step(hMod,encodedData);  
    receivedSignal = step(hChan,modSignal);  
    demodSignal = step(hDemod,receivedSignal);  
    % The APP decoder assumes a polarization of the soft inputs that is  
    % inverse to that of the demodulator soft outputs. Change the sign of  
    % demodulated signal.  
    receivedSoftBits = step(hAPPDec,zeros(frameLength,1),-demodSignal);  
    % Convert from soft-decision to hard-decision.  
    receivedBits = double(receivedSoftBits > 0);  
    % Count errors  
    errorStats = step(hError,data,receivedBits);  
end
```

Display the error rate information.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...  
    errorStats(1), errorStats(2))
```

```
Error rate = 0.000000  
Number of errors = 0
```

Decode convolutional code using the a posteriori probability method

## Syntax

[LUD,LCD] = step(H,LU,LC)

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

[LUD,LCD] = `step(H,LU,LC)` performs APP decoding. The input LU is the sequence of log-likelihoods of encoder input data bits. The input LC is the sequence of log-likelihoods of encoded bits. Negative soft inputs are considered to be zeros and positive soft inputs are considered to be ones. The outputs, LUD and LCD, are updated versions of the input LU and LC sequences and are obtained based on information about the encoder. The inputs must be of the same data type, which can be double or single precision. The output data type is the same as the input data type. If the convolutional code uses an alphabet of  $2^N$  symbols, the LC and LCD vector lengths are multiples of N. If the decoded data uses an alphabet of  $2^K$  output symbols, the LU and LUD vector lengths are multiples of K.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.AWGNChannel

**Package:** comm

Add white Gaussian noise to input signal

## Description

comm.AWGNChannel adds white Gaussian noise to the input signal.

When applicable, if inputs to the object have a variable number of channels, the EbNo, EsNo, SNR, BitsPerSymbol, SignalPower, SamplesPerSymbol, and Variance properties must be scalars.

To add white Gaussian noise to an input signal:

- 1 Create the comm.AWGNChannel object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
awgnchan = comm.AWGNChannel  
awgnchan = comm.AWGNChannel(Name,Value)
```

## Description

awgnchan = comm.AWGNChannel creates an additive white Gaussian noise (AWGN) channel System object, awgnchan. This object then adds white Gaussian noise to a real or complex input signal.

`awgnchan = comm.AWGNChannel(Name, Value)` creates a AWGN channel object, `awgnchan`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### NoiseMethod — Noise level method

'Signal to noise ratio (Eb/No)' (default) | 'Signal to noise ratio (Es/No)' | 'Signal to noise ratio (SNR)' | 'Variance'

Noise level method, specified as 'Signal to noise ratio (Eb/No)', 'Signal to noise ratio (Es/No)', 'Signal to noise ratio (SNR)', or 'Variance'. For more information, see *Specifying the Variance Directly or Indirectly* on page 4-82.

Data Types: `char`

### EbNo — Ratio of energy per bit to noise power spectral density

10 (default) | scalar | row vector

Ratio of energy per bit to noise power spectral density (Eb/No) in decibels, specified as a scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Tunable:** Yes

### Dependencies

This property applies when `NoiseMethod` is set to 'Signal to noise ratio (Eb/No)'

Data Types: `double`

### EsNo — Ratio of energy per symbol to noise power spectral density

10 (default) | scalar | row vector

Ratio of energy per symbol to noise power spectral density ( $E_s/N_0$ ) in decibels, specified as a scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Tunable:** Yes

**Dependencies**

This property applies when NoiseMethod is set to 'Signal to noise ratio (Es/No)'.

Data Types: double

**SNR — Ratio of signal power to noise power**

10 (default) | scalar | row vector

Ratio of signal power to noise power in decibels, specified as a scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Tunable:** Yes

**Dependencies**

This property applies when NoiseMethod is set to 'Signal to noise ratio (SNR)'.

Data Types: double

**BitsPerSymbol — Number of bits per symbol**

1 (default) | positive integer

Number of bits per symbol, specified as a positive integer.

**Dependencies**

This property applies when NoiseMethod is set to 'Signal to noise ratio (Eb/No)'.

Data Types: double

**SignalPower — Input signal power**

1 (default) | positive scalar | row vector

Input signal power in watts, specified as a positive scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels. The object assumes a nominal impedance of 1  $\Omega$ .

**Tunable:** Yes

### Dependencies

This property applies when `NoiseMethod` is set to 'Signal to noise ratio (Eb/No)', 'Signal to noise ratio (Es/No)', or 'Signal to noise ratio (SNR)'.

Data Types: double

### SamplesPerSymbol — Number of samples per symbol

1 (default) | positive integer | row vector

Number of samples per symbol, specified as a positive integer or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

### Dependencies

This property applies when `NoiseMethod` is set to 'Signal to noise ratio (Eb/No)' or 'Signal to noise ratio (Es/No)'.

Data Types: double

### VarianceSource — Source of noise variance

'Property' (default) | 'Input port'

Source of noise variance, specified as 'Property' or 'Input port'.

- Set `VarianceSource` to 'Property' to specify the noise variance value using the `Variance` property.
- Set `VarianceSource` to 'Input port' to specify the noise variance value using an input to the object, when you call it as a function.

For more information, see [Specifying the Variance Directly or Indirectly](#) on page 4-82.

### Dependencies

This property applies when `NoiseMethod` is 'Variance'.

Data Types: char

### Variance — White Gaussian noise variance

1 (default) | positive scalar | row vector

White Gaussian noise variance, specified as a positive scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Tunable:** Yes

**Dependencies**

This property applies when `NoiseMethod` is set to 'Variance' and `VarianceSource` is set to 'Property'.

Data Types: double

**RandomStream — Source of random number stream**

'Global stream' (default) | 'mt19937ar with seed'

Source of random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- When you set `RandomStream` to 'Global stream', the object uses the MATLAB default random stream to generate random numbers. To generate reproducible numbers using this object, you can reset the MATLAB default random stream. For example `reset(RandStream.getGlobalStream)`. For more information, see `RandStream`.
- When you set `RandomStream` to 'mt19937ar with seed', the object uses the mt19937ar algorithm for normally distributed random number generation. In this scenario, when you call the `reset` function, the object reinitializes the random number stream to the value of the `Seed` property. You can generate reproducible numbers by resetting the object.

For a complex input signal, the object creates the random data as follows:

```
noise = randn( $N_S$ ,  $N_C$ ) + 1i * randn( $N_S$ ,  $N_C$ )
```

$N_S$  is the number of samples and  $N_C$  is the number of channels.

**Dependencies**

This property applies when `NoiseMethod` is set to 'Variance'.

Data Types: char

**Seed — Initial seed**

67 (default) | nonnegative integer

Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. For each call to the `reset` function, the object reinitializes the mt19937ar random number stream to the `Seed` value.

### Dependencies

This property applies when `RandomStream` is set to `'mt19937ar with seed'`.

Data Types: `double`

## Usage

## Syntax

```
outsignal = awgnchan(insignal)
outsignal = awgnchan(insignal,var)
```

## Description

`outsignal = awgnchan(insignal)` adds white Gaussian noise, as specified by `awgnchan`, to the input signal. The result is returned in `outsignal`.

`outsignal = awgnchan(insignal,var)` specifies the variance of the white Gaussian noise. This syntax applies when you set the `NoiseMethod` to `'Variance'` and `VarianceSource` to `'Input port'`.

For example:

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance','VarianceSource','Input port');
var = 12;
...
outsignal = awgnchan(insignal,var);
```

## Input Arguments

### **insignal** — Input signal

`scalar` | `vector` | `matrix`

Input signal, specified as a scalar, an  $N_S$ -element vector, or an  $N_S$ -by- $N_C$  matrix.  $N_S$  is the number of samples and  $N_C$  is the number of channels.

Data Types: `double`

Complex Number Support: Yes

**var** — Variance of additive white Gaussian noise

positive scalar | row vector

Variance of additive white Gaussian noise, specified as a positive scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels, as determined by the number of columns in the input signal matrix.

**Output Arguments****outsignal** — Output signal

matrix

Output signal, returned with the same dimensions as `insignal`.

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

**Common to All System Objects**

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

**Examples****Create Default AWGN Channel System Object**

Create an AWGN channel System object with the default configuration. Pass signal data through this channel.

Create an AWGN channel object and signal data.

```
awgnchan = comm.AWGNChannel;  
insignal = randi([0 1],100,1);
```

Send the input signal through the channel.

```
outsignal = awgnchan(insignal);
```

### Add White Gaussian Noise to 8-PSK Signal

Modulate an 8-PSK signal, add white Gaussian noise, and plot the signal to observe the effects of noise.

Create a PSK modulator System object™. The default modulation order for the PSK modulator object is 8.

```
pskModulator = comm.PSKModulator;
```

Modulate the signal.

```
modData = pskModulator(randi([0 7],2000,1));
```

Add white Gaussian noise to the modulated signal by passing the signal through an AWGN channel.

```
channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',3);
```

Transmit the signal through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the noiseless and noisy data using scatter plots to observe the effects of noise.

```
scatterplot(modData)
```

```
scatterplot(channelOutput)
```

Change the EbNo property to 10 dB to increase the noise.

```
channel.EbNo = 10;
```

Pass the modulated data through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the channel output. You can see the effects of increased noise.

```
scatterplot(channelOutput)
```

### Process Signals When Number of Channels Changes

Pass a single-channel and multichannel signal through an AWGN channel System object™.

Create an AWGN channel System object with the Eb/No ratio set for a single channel input. In this case, the EbNo property is a scalar.

```
channel = comm.AWGNChannel('EbNo',15);
```

Generate random data and apply QPSK modulation.

```
data = randi([0 3],1000,1);  
modData = pskmod(data,4,pi/4);
```

Pass the modulated data through the AWGN channel.

```
rxSig = channel(modData);
```

Plot the noisy constellation.

```
scatterplot(rxSig)
```

Generate two-channel input data and apply QPSK modulation.

```
data = randi([0 3],2000,2);  
modData = pskmod(data,4,pi/4);
```

Pass the modulated data through the AWGN channel.

```
rxSig = channel(modData);
```

Plot the noisy constellations. Each channel is represented as a single column in `rxSig`. The plots are nearly identical, because the same  $E_b/N_0$  value is applied to both channels.

```
scatterplot(rxSig(:,1))  
title('First Channel')
```

```
scatterplot(rxSig(:,2))  
title('Second Channel')
```

Modify the AWGN channel object to apply a different Eb/No value to each channel. To apply different values, set the `EbNo` property to a 1-by-2 vector. When changing the dimension of the `EbNo` property, you must release the AWGN channel object.

```
release(channel)  
channel.EbNo = [10 20];
```

Pass the data through the AWGN channel.

```
rxSig = channel(modData);
```

Plot the noisy constellations. The first channel has significantly more noise due to its lower Eb/No value.

```
scatterplot(rxSig(:,1))  
title('First Channel')
```

```
scatterplot(rxSig(:,2))  
title('Second Channel')
```

### Add AWGN Using Noise Variance Input Port

Apply the noise variance input as a scalar or a row vector, with a length equal to the number of channels of the current signal input.

Create an AWGN channel System object™ with the `NoiseMethod` property set to `'Variance'` and the `VarianceSource` property set to `'Input port'`.

```
channel = comm.AWGNChannel('NoiseMethod','Variance', ...  
    'VarianceSource','Input port');
```

Generate random data for two channels and apply 16-QAM modulation.

```
data = randi([0 15],10000,2);  
txSig = qammod(data,16);
```

Pass the modulated data through the AWGN channel. The AWGN channel object processes data from two channels. The variance input is a 1-by-2 vector.

```
rxSig = channel(txSig,[0.01 0.1]);
```

Plot the constellation diagrams for the two channels. The second signal is noisier because its variance is ten times larger.

```
scatterplot(rxSig(:,1))
```

```
scatterplot(rxSig(:,2))
```

Repeat the process where the noise variance input is a scalar. The same variance is applied to both channels. The constellation diagrams are nearly identical.

```
rxSig = channel(txSig,0.2);  
scatterplot(rxSig(:,1))
```

```
scatterplot(rxSig(:,2))
```

### Set Random Number Seed for Repeatability

Specify a seed to produce the same outputs when using a random stream in which you specify the seed.

Create an AWGN channel System object™. Set the `NoiseMethod` property to `'Variance'`, the `RandomStream` property to `'mt19937ar with seed'`, and the `Seed` property to 99.

```
channel = comm.AWGNChannel( ...  
    'NoiseMethod','Variance', ...
```

```
'RandomStream','mt19937ar with seed', ...
'Seed',99);
```

Pass data through the AWGN channel.

```
y1 = channel(zeros(8,1));
```

Pass another all-zeros vector through the channel.

```
y2 = channel(zeros(8,1));
```

Because the seed changes between function calls, the output is different.

```
isequal(y1,y2)
```

```
ans = logical
      0
```

Reset the AWGN channel object by calling the `reset` function. The random data stream is reset to the initial seed of 99.

```
reset(channel);
```

Pass the all-zeros vector through the AWGN channel.

```
y3 = channel(zeros(8,1));
```

Confirm that the two signals are identical.

```
isequal(y1,y3)
```

```
ans = logical
      1
```

## Algorithms

### Relationship Among $E_b/N_0$ , $E_s/N_0$ , and SNR Modes

For uncoded complex input signals, `comm.AWGNChannel` relates  $E_b/N_0$ ,  $E_s/N_0$ , and SNR according to these equations:

$$E_s/N_0 = N_{\text{sps}} \times \text{SNR}$$
$$E_s/N_0 = E_b/N_0 + 10\log_{10}(k) \text{ in dB}$$

where

- $E_s$  represents the signal energy in joules.
- $E_b$  represents the bit energy in joules.
- $N_0$  represents the noise power spectral density in watts/Hz.
- $N_{\text{sps}}$  represents the number of samples per symbol, SamplesPerSymbol.
- $k$  represents the number of information bits per input symbol, BitsPerSymbol.

For real signal inputs, the `comm.AWGNChannel` relates  $E_s/N_0$  and SNR according to this equation:

$$E_s/N_0 = 0.5 (N_{\text{sps}}) \times \text{SNR}$$

---

### Note

- All values of power assume a nominal impedance of 1 ohm.
  - The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of  $N_0/2$  watts/Hz for real input signals, versus  $N_0$  watts/Hz for complex signals.
- 

For more information, see AWGN Channel Noise Level.

## Specifying the Variance Directly or Indirectly

To directly specify the variance of the noise generated by `comm.AWGNChannel`, specify `VarianceSource` as:

- `'Property'`, then set `NoiseMethod` to `'Variance'` and specify the variance with the `Variance` property.
- `'Input port'` then specify the variance level for the object as an input with an input argument, `var`.

To specify variance indirectly, that is, to have it calculated by `comm.AWGNChannel`, specify `VarianceSource` as `'Property'` and the `NoiseMethod` as:

- 'Signal to noise ratio (Eb/No)', where the object uses these properties to calculate the variance:
  - EbNo, the ratio of bit energy to noise power spectral density
  - BitsPerSymbol
  - SignalPower, the actual power of the input signal samples
  - SamplesPerSymbol
- 'Signal to noise ratio (Es/No)', where the object uses these properties to calculate the variance:
  - EsNo, the ratio of signal energy to noise power spectral density
  - SignalPower, the actual power of the input signal samples
  - SamplesPerSymbol
- 'Signal to noise ratio (SNR)', where the object uses these properties to calculate the variance:
  - SNR, the ratio of signal power to noise power
  - SignalPower, the actual power of the input signal samples

Changing the number of samples per symbol ( SamplesPerSymbol ) affects the variance of the noise added per sample, which also causes a change in the final error rate.

$$\text{NoiseVariance} = \text{SignalPower} \times \text{SamplesPerSymbol} / 10^{(\text{EsNo})/10}$$

---

**Tip** Select the number of samples per symbol based on what constitutes a symbol and the oversampling applied to it. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see AWGN Channel Noise Level.

# comm.BarkerCode

**Package:** comm

Generate bipolar Barker code

## Description

The `comm.BarkerCode` System object generates a bipolar Barker code. Barker codes have low autocorrelation properties. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. For more information, see “Barker Codes” on page 4-90.

To generate a Barker code:

- 1 Create the `comm.BarkerCode` object and set its properties.
- 2 Call the object, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
barkerCode = comm.BarkerCode  
barkerCode = comm.BarkerCode(Name,Value)
```

## Description

`barkerCode = comm.BarkerCode` creates a bipolar Barker code generator System object to generate a Barker code.

`barkerCode = comm.BarkerCode(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.BarkerCode('Length',11,'SamplesPerFrame','11')` configures a bipolar

Barker code generator System object to output a length 11 Barker code in an 11-sample frame. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### **Length — Length of generated code**

7 (default) | 123451113

Length of the generated code, specified as 1, 2, 3, 4, 5, 7, 11, or 13. For more information, see “Barker Codes” on page 4-90.

Example: `'Length', 2` outputs the Barker code `[-1;1]`.

Data Types: `double`

### **SamplesPerFrame — Samples per output frame**

1 (default) | positive integer

Samples per output frame, specified as a positive integer. If `SamplesPerFrame` is  $M$ , the object outputs a frame containing  $M$  samples comprised of length  $N$  Barker code sequences. If necessary, the object repeats the code sequence to reach  $M$  samples.  $N$  is the length of the generated code, which is set by the `Length` property.

Data Types: `double`

### **OutputDataType — Output data type**

`double` (default) | `int8`

Output data type, specified as `double` or `int8`.

Data Types: `char` | `string`

## Usage

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Syntax

```
y = barkerCode
```

## Description

`y = barkerCode` outputs a Barker code frame, as a column vector. If the frame length exceeds the Barker code length, the object fills the frame by repeating the Barker code.

Set the data type of the output with the `OutputDataType` property.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to comm.BarkerCode

`clone`      Create duplicate System object  
`isLocked`   Determine if System object is in use

### Common to All System Objects

`step`      Run System object algorithm  
`release`   Release resources and allow changes to System object property values and input characteristics  
`reset`     Reset internal states of System object

## Examples

### Generate Barker Code Sequence

Create a Barker code System object with 10 samples per frame.

```
barker = comm.BarkerCode('SamplesPerFrame',10)

barker =
comm.BarkerCode with properties:
    Length: 7
SamplesPerFrame: 10
OutputDataType: 'double'
```

Generate multiple frames by using the default Barker code sequence of length 7. The code wraps within the frame and continues in the next frame.

```
for ii = 1:2
    seq = barker()
end

seq = 10×1

-1
-1
-1
 1
 1

-1
```

### Compute Barker Code Sidelobe Level

Compute the peak sidelobe level for each Barker code.

```
CodeLength = [1 2 3 4 5 7 11 13]';
psl = zeros(length(CodeLength),1);
ac = dsp.Autocorrelator;
barker = comm.BarkerCode;
for ii=1:length(CodeLength)
    spf = CodeLength(ii);
    barker.Length = CodeLength(ii);
    barker.SamplesPerFrame = spf;
    seq = barker();
    sll_dB = 20*log10(abs(ac(seq)));
    psl(ii) = -(max(sll_dB));
    release(barker);
    release(ac);
end
Sidelobe_dB = psl;
T = table(CodeLength,Sidelobe_dB)
```

```
T=8x2 table
   CodeLength   Sidelobe_dB
   _____   _____
         1             0
         2        -6.0206
         3        -9.5424
         4       -12.041
         5       -13.979
         7       -16.902
        11       -20.828
        13       -22.279
```

## More About

### Barker Codes

Barker codes have a maximum autocorrelation sequence, which has off-peak autocorrelations no larger than 1.

A correlation sidelobe is the correlation of a codeword with a time-shifted version of itself. The correlation sidelobe,  $C_k$ , for a  $k$ -symbol shift of an  $N$ -bit code sequence,  $\{X_j\}$ , is

$$C_k = \sum_{j=1}^{N-k} X_j X_{j+k}$$

For  $j=1, 2, 3, \dots, N$ ,  $X_j$  is an individual code symbol that is equal to +1 or -1. The adjacent symbols are assumed to be 0.

The output code is in a bipolar format with 0 and 1 mapped to 1 and -1. The maximum known Barker code length is 13. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. The Barker code generator outputs the Barker codes listed in this table.

Barker Code Length	Barker Code	Sidelobe Level
1	[-1]	0 dB
2	[-1; 1]	-6 dB
3	[-1; -1; 1]	-9.5 dB
4	[-1; -1; 1; -1]	-12 dB
5	[-1; -1; -1; 1; -1]	-14 dB
7	[-1; -1; -1; 1; 1; -1; 1]	-16.9 dB
11	[-1; -1; -1; 1; 1; 1; -1; 1; 1; -1; 1]	-20.8 dB
13	[-1; -1; -1; -1; -1; 1; 1; -1; -1; 1; -1; 1; -1]	-22.3 dB

## comm.BasebandFileReader

**Package:** comm

Read baseband signals from file

### Description

The `comm.BasebandFileReader` object reads a baseband signal from a specific type of binary file written by `comm.BasebandFileWriter`. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz. The `SampleRate` and `CenterFrequency` properties are saved when the file is created. The `comm.BasebandFileReader` object automatically reads the sample rate, center frequency, number of channels, and any descriptive data and saves them to its read-only properties.

To create an input signal from a saved baseband file:

- 1 Create a `comm.BasebandFileReader` object and set the properties of the object.
- 2 Call `step` to generate a baseband signal from saved data.
- 3 Call `release` to close the file.

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

### Construction

`bbr = comm.BasebandFileReader` returns a baseband reader object, `bbr`, using the default properties.

`bbr = comm.BasebandFileReader(fname)` returns a baseband reader object and sets `fname` as the `Filename` property.

`bbr = comm.BasebandFileReader(fname, spf)` also sets `spf` as the `SamplesPerFrame` property.

`bbr = comm.BasebandFileReader( ____, Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

**Example:**

```
bbr = comm.BasebandFileReader('recorded_data',100);
```

## Properties

**Filename — Name of the baseband file to read**

'example.bb' (default) | character vector

Name of the baseband file to read, specified as a character vector. Specify the absolute path only if the file is not on the MATLAB path. Only the absolute path is saved and displayed.

**SampleRate — Sample rate of the saved baseband signal**

1 (default) | positive scalar

This property is read-only.

Sample rate of the saved baseband signal in Hz.

**CenterFrequency — Center frequency of the saved baseband signal**

100000000 (default) | positive scalar | row vector

This property is read-only.

Center frequency of the saved baseband signal in Hz. When this property is a row vector, each element represents the center frequency of a channel in a multichannel signal.

**NumChannels — Number of channels of the saved baseband signal**

1 (default) | positive integer

This property is read-only.

Number of channels of the saved baseband signal.

**Metadata — Data describing the baseband signal**

`struct()` (default) | structure

This property is read-only.

Data describing the baseband signal. If the file has no descriptive data, this property is an empty structure.

### **SamplesPerFrame — Number of samples per output frame**

100 (default) | positive integer

Number of samples per output frame, specified as a positive integer.

Data Types: double

### **CyclicRepetition — Flag to repeatedly read baseband file**

false (default) | true

Flag to repeatedly read baseband file, specified as a logical scalar. To repeatedly read the baseband file specified by `Filename`, set this property to `true`.

## Methods

`info` Characteristic information about baseband file reader

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>step</code>	Generate baseband signal from file
<code>reset</code>	Reset states of baseband file reader object
<code>isDone</code>	Read status of baseband file samples

## Examples

### **Read Baseband Data from File**

Create a baseband file reader object.

```
bbr = comm.BasebandFileReader
```

```
bbr =  
    comm.BasebandFileReader with properties:
```

```
        Filename: 'B:\matlab\toolbox\comm\comm\example.bb'  
        SampleRate: 1  
        CenterFrequency: 100000000  
        NumChannels: 1  
        Metadata: [1x1 struct]  
        SamplesPerFrame: 100  
        CyclicRepetition: false
```

Use the `info` method to gain additional information about `bbr`. The file contains 10000 samples of type 'double'. No samples have been read.

```
info(bbr)
```

```
ans = struct with fields:  
    NumSamplesInData: 10000  
    DataType: 'double'  
    NumSamplesRead: 0
```

Read the entire contents of the `example.bb` file by using the `isDone` method to terminate the loop.

```
y = [];  
while ~isDone(bbr)  
    x = bbr();  
    y = cat(1,y,x);  
end
```

Plot the absolute magnitude of the baseband data.

```
plot(abs(y))
```

Confirm that all the samples have been read.

```
info(bbr)
```

```
ans = struct with fields:  
    NumSamplesInData: 10000  
    DataType: 'double'  
    NumSamplesRead: 10000
```

The total number of samples and the number of samples read are the same.

Release the baseband file reader resources.

```
release(bbr)
```

`comm.BasebandFileWriter`

**Introduced in R2016b**

# info

**System object:** `comm.BasebandFileReader`

**Package:** `comm`

Characteristic information about baseband file reader

## Syntax

```
s = info(bbr)
```

## Description

`s = info(bbr)` returns a structure, `s`, containing characteristic information for the `BasebandFileReader` System object, `bbr`. `s` has these fields:

- `NumSamplesInData` is the total number of baseband data samples in the file, returned as a positive integer.
- `DataType` is the data type of the baseband signal in the file.
- `NumSamplesRead` is the number of samples that have been read from the file, returned as a positive integer. It cannot exceed the `NumSamplesInData` property when `CyclicRepetition` is `false`.

**Introduced in R2016b**

# comm.BasebandFileWriter

**Package:** comm

Write baseband signals to file

## Description

A baseband file is a specific type of binary file written by `comm.BasebandFileWriter`. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz. The `SampleRate` and `CenterFrequency` properties are saved when the file is created.

To save a baseband signal to a file:

- 1 Create a `comm.BasebandFileWriter` object and set the properties of the object.
- 2 Call `step` to save a baseband signal to a file.
- 3 Call `release` to save the baseband signal to a file and to close the file.

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`bbw = comm.BasebandFileWriter` returns a baseband writer object, `bbw`, using the default properties.

`bbw = comm.BasebandFileWriter(fname)` returns `bbw` and sets `fname` as the `Filename` property.

`bbw = comm.BasebandFileWriter(fname, fs)` also sets `fs` as the `SampleRate` property.

`bbw = comm.BasebandFileWriter(fname, fs, fc)` also sets `fc` as the `CenterFrequency` property.

`bbw = comm.BasebandFileWriter(fname, fs, fc, md)` also sets structure `md` as the `MetaData` property.

`bbw = comm.BasebandFileWriter( ____, Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

### Example:

```
bbw = comm.BasebandFileWriter('qpsk_data.bb', 10e6, 2e9);
```

## Properties

### Filename — Name of saved file

'untitled.bb' (default) | character vector

Name of saved file, specified as a character vector. The filename can include a relative or an absolute path.

### SampleRate — Sample rate of output signal

1 (default) | positive scalar

Sample rate of the output signal, specified in Hz as a positive scalar.

### CenterFrequency — Center frequency of the baseband signal

1000000000 (default) | positive integer scalar | row vector

Center frequency of the baseband signal, specified in Hz as a positive integer scalar or row vector. If `CenterFrequency` is a row vector, each element corresponds to a channel.

### Metadata — Data describing the baseband signal

empty structure (default) | structure

Data describing the baseband signal, specified as a structure. The structure can have any number of fields and any field name. The field values can be of any numeric, logical, or character data type and have any number of dimensions.

### NumSamplesToWrite — Number of samples to save

Inf (default) | positive integer

Number of samples to save, specified as a positive integer.

- To write all the baseband signal samples to a file, set NumSamplesToWrite to Inf.
- To write only the last NumSamplesToWrite samples to a file, set NumSamplesToWrite to a finite number.

Data Types: double

## Methods

info Characteristic information about baseband file writer  
 reset Reset states of baseband file writer object  
 step Write baseband signal to file

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Write Baseband Signal to File

Create a baseband file writer object having a sample rate of 1 kHz and a 0 Hz center frequency.

```
bbw = comm.BasebandFileWriter('baseband_data.bb',1000,0);
```

Save today's date in the Metadata structure.

```
bbw.Metadata = struct('Date',date);
```

Generate two channels of QPSK-modulated data.

```
d = randi([0 3],1000,2);
x = pskmod(d,4,pi/4,'gray');
```

Write the baseband data to file 'baseband\_data.bb'.

```
bbw(x)
```

Display information about bbw. Release the object.

```
info(bbw)
```

```
ans = struct with fields:
    Filename: 'C:\TEMP\Bdoc19b_1192687_11188\ib6635F1\3\tp2864cdb7\comm-ex664
    SamplesPerFrame: 1000
    NumChannels: 2
    DataType: 'double'
    NumSamplesWritten: 1000
```

```
release(bbw)
```

Create a baseband file reader object to read the saved data. Read the metadata from the file.

```
bbr = comm.BasebandFileReader('baseband_data.bb', 'SamplesPerFrame', 100);
bbr.Metadata
```

```
ans = struct with fields:
    Date: '28-Aug-2019'
```

Read the data from the file.

```
z = [];

while ~isDone(bbr)
    y = bbr();
    z = cat(1,z,y);
end
```

Display information about `bbr`. Release `bbr`.

```
info(bbr)
```

```
ans = struct with fields:
    NumSamplesInData: 1000
    DataType: 'double'
    NumSamplesRead: 1000
```

```
release(bbr)
```

Confirm the original modulated data, `x`, matches the data read from file `'baseband_data.bb'`, `z`.

```
isequal(x,z)
ans = logical
     1
```

## Tips

- `comm.BasebandFileWriter` writes baseband signals to uncompressed binary files. To share these files, you can compress them to a zip file using the `zip` function. For more information, see “Create and Extract from Zip Archives” (MATLAB).

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`comm.BasebandFileReader`

**Introduced in R2016b**

# info

Characteristic information about baseband file writer

## Syntax

```
s = info(bbw)
```

## Description

`s = info(bbw)` returns a structure, `s`, containing characteristic information for the `BasebandFileWriter` System object, `bbw`. `s` has these fields:

- `Filename` is the name of the baseband data file, returned as a character vector. The filename shows the absolute path.
- `SamplesPerFrame` is the number of samples in each frame, returned as a positive integer.
- `NumChannels` is the number of channels, returned as a positive integer greater than or equal to 1.
- `DataType` is the input data type.
- `NumSamplesWritten` is the number of samples written to the file, returned as a positive integer. This field returns the smaller of the total number of samples processed by the object and the `NumSamplesWritten` property.

---

**Note** All fields are available when the object is locked. When the object is unlocked, only the `Filename` and `NumSamplesWritten` fields are available.

---

## reset

**System object:** comm.BasebandFileWriter

**Package:** comm

Reset states of baseband file writer object

## Syntax

reset(bbw)

## Description

reset(bbw) resets the states of the BasebandFileWriter object, bbw.

**Introduced in R2016b**

# step

**System object:** `comm.BasebandFileWriter`

**Package:** `comm`

Write baseband signal to file

## Syntax

```
step(bbw,x)  
bbw(x)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`step(bbw,x)` writes a baseband signal, `x`, to the file specified by the `Filename` property of the `BasebandFileWriter` object, `bbw`. The number of samples written to the file is determined by the `NumSamplesToWrite` property of `bbw`.

`bbw(x)` is equivalent to the first syntax.

---

**Note** `bbw` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Introduced in R2016b**

## comm.BCHDecoder

**Package:** comm

Decode data using BCH decoder

### Description

The `BCHDecoder` object recovers a binary message vector from a binary BCH codeword vector. For proper decoding, the codeword and message length values in this object must match the properties in the corresponding `BCHEncoder` System object.

To decode a binary message from a BCH codeword:

- 1 Define and set up your BCH decoder object. See “Construction” on page 4-108.
- 2 Call `step` to recover a binary message vector from a binary BCH codeword vector according to the properties of `comm.BCHDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`dec = comm.BCHDecoder` creates a BCH decoder System object, `dec`, that performs BCH decoding.

`dec = comm.BCHDecoder(N,K)` creates a BCH decoder object, `dec`, with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`dec = comm.BCHDecoder(N,K,GP)` creates a BCH decoder object, `dec`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, and the `GeneratorPolynomial` property set to `GP`.

`dec = comm.BCHDecoder(N,K,GP,S)` creates a BCH decoder object, `dec`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and the `ShortMessageLength` property set to `S`.

`dec = comm.BCHDecoder(N,K,GP,S,Name,Value)` creates a BCH decoder object, `dec`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, the `ShortMessageLength` property set to `S`, and each specified property `Name` set to the specified `Value`.

`dec = comm.BCHDecoder(Name,Value)` creates a BCH decoder object, `dec`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### CodewordLength

Codeword length

Specify the codeword length of the BCH code as a double-precision positive integer scalar. The default is 15. The values of the `CodewordLength` and `MessageLength` on page 4-0 properties must produce a valid narrow-sense BCH code. For a full-length BCH code, the value of this property must take the form  $2^M - 1$ , where  $M$  is an integer such that  $3 \leq M \leq 16$ . The default is 15.

### MessageLength

Message length

Specify the message length as a double-precision positive integer scalar. The values of the `CodewordLength` on page 4-0 and `MessageLength` properties must produce a valid narrow-sense BCH code. The default is 5.

### ShortMessageLengthSource

Short message length source

Specify the source of the shortened message as either `Auto` or `Property`. When this property is set to `Auto`, the BCH code is defined by the `CodewordLength` on page 4-0 ,

`MessageLength` on page 4-0 , `GeneratorPolynomial` on page 4-0 , and `PrimitivePolynomial` on page 4-0 properties. When `ShortMessageLengthSource` is set to `Property`, you must specify the `ShortMessageLength` on page 4-0 property, which is used with the other properties to define the BCH code. The default is `Auto`.

### **ShortMessageLength**

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength` on page 4-0 . When `ShortMessageLength` < `MessageLength`, the BCH code is shortened. The default is 5.

### **GeneratorPolynomialSource**

Source of generator polynomial

Specify the source of the generator polynomial as either `Auto` or `Property`. Set this property to `Auto` to create the generator polynomial automatically. Set `GeneratorPolynomialSource` to `Property` to specify a generator polynomial using the `GeneratorPolynomial` on page 4-0 property. The default is `Auto`.

### **GeneratorPolynomial**

Generator polynomial

Specify the generator polynomial as a binary double-precision row vector, a binary Galois field row vector that represents the coefficients of the generator polynomial in order of descending powers, or as a polynomial character vector. The length of the generator polynomial requires a value of `CodewordLength` on page 4-0 -`MessageLength` on page 4-0 +1. This property applies when you set `GeneratorPolynomialSource` on page 4-0 to `Property`. The default is `'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'`, which is the result of `bchgenpoly(15,5,[],'double')` and corresponds to a 15,5 code.

### **CheckGeneratorPolynomial**

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check the first time you call the `step` method. The default is `true`. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check reduces processing time. As a

best practice, perform the check at least once before setting this property to `false`. This property applies when you set `GeneratorPolynomialSource` on page 4-0 to `Property`. The default is `true`.

### **PrimitivePolynomialSource**

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. Set this property to `Auto` to create a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength} + 1))$ . Set `PrimitivePolynomialSource` to `Property` to specify a polynomial using the `PrimitivePolynomial` on page 4-0 property. The default is `Auto`.

### **PrimitivePolynomial**

Primitive polynomial

Specify the primitive polynomial of order  $M$ , that defines the finite Galois field  $GF(2)$ . Use a double-precision, binary row vector with the coefficients of the polynomial in order of descending powers or a polynomial character vector. This property applies when you set the `PrimitivePolynomialSource` on page 4-0 property to `Property`. The default is `'X^4 + X + 1'`, which is the result of `fliplr(de2bi(primpoly(4)))`.

### **PuncturePatternSource**

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. Set this property to `None` to disable puncturing. Set it to `Property` to decode punctured codewords. This decoding is based on a puncture pattern vector you specify in the `PuncturePattern` on page 4-0 property. The default is `None`.

### **PuncturePattern**

Puncture pattern vector

Specify the pattern that the object uses to puncture the encoded data. Use a double-precision binary column vector of length `CodewordLength` on page 4-0 - `MessageLength` on page 4-0 . Zeros in the puncture pattern vector indicate the position of the parity bits that the object punctures or excludes from each codeword. This property applies when you set `PuncturePatternSource` on page 4-0 to `Property`. The default is `[ones(8,1); zeros(2,1)]`.

### **ErasuresInputPort**

Enable erasures input

Set this property to `true` to specify a vector of erasures as a `step` method input. The erasures vector is a double-precision or logical binary column vector that indicates which bits of the input codewords to erase or ignore. Values of 1 in the erasures vector correspond to erased bits in the same position of the (possibly punctured) input codewords. Set this property to `false` to disable erasures. The default is `false`.

### **NumCorrectedErrorsOutputPort**

Output number of corrected errors

Set this property to `true` so that the `step` method outputs the number of corrected errors. The default is `true`.

## **Input and Output Signal Lengths in BCH and RS System Objects**

The notation  $y = c * x$  denotes that  $y$  is an integer multiple of  $x$ .

The number of punctures equals the number of zeros in the puncture vector.

$M$  is the degree of the primitive polynomial. Each group of  $M$  bits represents an integer between 0 and  $2^M-1$  that belongs to the finite Galois field  $GF(2^M)$ .

## Methods

step      Decode data using a BCH decoder

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### Transmit and decode an 8-DPSK-modulated signal, then count errors

% The following code transmits a BCH-encoded, 8-DPSK-modulated bit stream  
% through an AWGN channel. Then, the example demodulates, decodes, and counts errors.

```
enc = comm.BCHEncoder;
mod = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',true);
dec = comm.BCHDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
    data = randi([0 1], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedBits = step(dec, demodSignal);
    errorStats = step(errorRate, data, receivedBits);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.015075
Number of errors = 9
```

### Transmit and receive a BPSK-modulated signal

Transmit and receive a BPSK-modulated signal encoded with a shortened BCH code, then count errors.

Specify the codeword, message, and shortened message lengths.

```
N = 255;  
K = 239;  
S = 63;
```

Create a BCH (255,239) generator polynomial. Use the generator polynomial to create a BCH encoder and decoder pair. The BCH code is based on the AMR standard.

```
gp = bchgenpoly(255,239);  
bchEncoder = comm.BCHEncoder(N,K,gp,S);  
bchDecoder = comm.BCHDecoder(N,K,gp,S);
```

Create an error rate counter.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Main processing loop.

```
for counter = 1:20  
    data = randi([0 1],630,1);           % Generate binary data  
    encodedData = bchEncoder(data);     % BCH encode data  
    modSignal = pskmod(encodedData,2);  % BPSK modulate  
    receivedSignal = awgn(modSignal,5); % Pass through AWGN channel  
    demodSignal = pskdemod(receivedSignal,2); % BSPK demodulate  
    receivedBits = bchDecoder(demodSignal); % BCH decode data  
    errorStats = errorRate(data,receivedBits); % Compute error statistics  
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...  
    errorStats(1), errorStats(2))
```

```
Error rate = 0.000318  
Number of errors = 4
```

## Shorten a BCH Code

Shorten a (31,26) BCH code to an (11,6) BCH code and use it to encode and decode random binary data.

Create a BCH encoder and decoder pair for a (31,26) code. Specify the generator polynomial,  $x^5 + x^2 + 1$ , and a shortened message length of 6.

```
enc = comm.BCHEncoder(31,26,'x5+x2+1',6);  
dec = comm.BCHDecoder(31,26,'x5+x2+1',6);
```

Encode and decode random binary data and verify that the decoded bit stream matches the original data.

```
x = randi([0 1],60,1);  
y = step(enc,x);  
z = step(dec,y);  
isequal(x,z)
```

```
ans = logical  
     1
```

## step

**System object:** comm.BCHDecoder

**Package:** comm

Decode data using a BCH decoder

## Syntax

```
Y = step(H,X)
[Y,ERR] = step(H,X)
Y = step(H,X,ERASURES)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` decodes input binary codewords in `X` using a (`CodewordLength,MessageLength`) BCH decoder with the corresponding narrow-sense generator polynomial. The `step` method returns the estimated message in `Y`. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `false`. The input and output length of the `step` function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 4-112.

`[Y,ERR] = step(H,X)` returns the number of corrected errors in output `ERR` when you set the `NumCorrectedErrorsOutputPort` property to `true`. A non-negative value in the  $i$ -th element of the `ERR` output vector denotes the number of corrected errors in the  $i$ -th input codeword. A value of `-1` in the  $i$ -th element of the `ERR` output indicates that a decoding error occurred for the  $i$ -th input codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the BCH code.

`Y = step(H,X,ERASURES)` uses `ERASURES` as the erasures pattern input when you set the `ErasuresInputPort` property to `true`. The object decodes the binary encoded data

input,  $X$ , and treats as erasures the bits of the input codewords specified by the binary column vector, `ERASURES`. The length of `ERASURES` must equal the length of  $X$ , and its elements must be of data type `double` or `logical`. Values of `1` in the erasures vector correspond to erased bits in the same position of the (possibly punctured) input codewords.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.BCHEncoder

**Package:** comm

Encode data using BCH encoder

## Description

The `BCHEncoder` object creates a BCH code with specified message and codeword lengths.

To encode data using a BCH coding scheme:

- 1 Define and set up your BCH encoder object. See “Construction” on page 4-121.
- 2 Call `step` to create a BCH code with message and codeword lengths specified according to the properties of `comm.BCHEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`enc = comm.BCHEncoder` creates a BCH encoder System object, `enc`, that performs BCH encoding.

`enc = comm.BCHEncoder(N,K)` creates a BCH encoder object, `enc`, with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`enc = comm.BCHEncoder(N,K,GP)` creates a BCH encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K` and the `GeneratorPolynomial` property set to `GP`.

`enc = comm.BCHEncoder(N,K,GP,S)` creates a BCH encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the

GeneratorPolynomial property set to GP and the ShortMessageLength property set to S.

`enc = comm.BCHEncoder(N,K,GP,S,Name,Value)` creates a BCH encoder object, `enc`, with the `CodewordLength` property set to N, the `MessageLength` property set to K, the `GeneratorPolynomial` property set to GP, the `ShortMessageLength` property set to S, and each specified property `Name` set to the specified `Value`.

`enc = comm.BCHEncoder(Name,Value)` creates a BCH encoder object, `enc`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

---

**Note** The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 4-112 on the `comm.BCHDecoder` reference page.

---

### CodewordLength

Codeword length

Specify the codeword length of the BCH code as a double-precision positive integer scalar. The default is 15. The values of the `CodewordLength` and `MessageLength` on page 4-0 properties must produce a valid narrow-sense BCH code. For a full-length BCH code, the value of the property must use the form  $2^M - 1$ , where  $M$  is an integer such that  $3 \leq M \leq 16$ . The default is 15.

### MessageLength

Message length

Specify the message length as a double-precision positive integer scalar. The values of the `CodewordLength` on page 4-0 and `MessageLength` properties must produce a valid narrow-sense BCH code. The default is 5.

### ShortMessageLengthSource

Short message length source

Specify the source of the shortened message as either `Auto` or `Property`. When this property is set to `Auto`, the BCH code is defined by the `CodewordLength` on page 4-0 , `MessageLength` on page 4-0 , `GeneratorPolynomial` on page 4-0 , and `PrimitivePolynomial` on page 4-0 properties. When `ShortMessageLengthSource` is set to `Property`, you must specify the `ShortMessageLength` on page 4-0 property that is used with the other properties to define the RS code. The default is `Auto`.

### **ShortMessageLength**

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength` on page 4-0 . When `ShortMessageLength` < `MessageLength`, the BCH code is shortened. The default is 5.

### **GeneratorPolynomialSource**

Source of generator polynomial

Specify the source of the generator polynomial as either `Auto` or `Property`. Set this property to `Auto` to create the generator polynomial automatically. Set it to `Property` to specify a generator polynomial using the `GeneratorPolynomial` on page 4-0 property. The default is `Auto`.

### **GeneratorPolynomial**

Generator polynomial

Specify the generator polynomial as a binary double-precision row vector, a binary Galois row vector that represents the coefficients of the generator polynomial in order of descending powers, or as a polynomial character vector. The length of the generator polynomial requires a value of `CodewordLength` on page 4-0 -`MessageLength` on page 4-0 +1. This property applies when you set `GeneratorPolynomialSource` on page 4-0 to `Property`. The default is `'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'`, which is the result of `bchgenpoly(15,5, [], 'double')` and corresponds to a (15,5) code.

### **CheckGeneratorPolynomial**

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check the first time you call the `step` method. This check verifies that the specified generator polynomial is valid. For

larger codes, disabling the check reduces processing time. As a best practice, perform the check at least once before setting this property to false. This property applies when you set `GeneratorPolynomialSource` on page 4-0 to `Property`. The default is `true`.

### **PrimitivePolynomialSource**

Source of primitive polynomial

Specify the source of the primitive polynomial as one of `Auto` or `Property`. Set this property to `Auto` to create a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength} + 1))$ . Set it to `Property` to specify a polynomial using the `PrimitivePolynomial` on page 4-0 property. The default is `Auto`.

### **PrimitivePolynomial**

Primitive polynomial

Specify the primitive polynomial of order  $M$ , that defines the finite Galois field  $GF(2)$ . Use a double-precision, binary row vector with the coefficients of the polynomial in order of descending powers or as a polynomial character vector. This property applies when you set the `PrimitivePolynomialSource` on page 4-0 property to `Property`. The default is `'X^4 + X + 1'`, which is the result of `fliplr(de2bi(primpoly(4)))`.

### **PuncturePatternSource**

Source of puncture pattern

Specify the source of the puncture pattern as one of `None` or `Property`. Set this property to `None` to disable puncturing. Set it to `Property` to decode punctured codewords. This decoding is based on a puncture pattern vector you specify in the `PuncturePattern` on page 4-0 property. The default is `None`.

### **PuncturePattern**

Puncture pattern vector

Specify the pattern that the object uses to puncture the encoded data. Use a double-precision binary column vector of length `CodewordLength` on page 4-0 - `MessageLength` on page 4-0 . Zeros in the puncture pattern vector indicate the position of the parity bits that the object punctures or excludes from each codeword. This property applies when you set `PuncturePatternSource` on page 4-0 to `Property`. The default is `[ones(8,1); zeros(2,1)]`.

## Methods

step      Encode data using a BCH encoder

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### Transmit and decode an 8-DPSK-modulated signal, then count errors

% The following code transmits a BCH-encoded, 8-DPSK-modulated bit stream  
% through an AWGN channel. Then, the example demodulates, decodes, and counts errors.

```
enc = comm.BCHEncoder;
mod = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',true);
dec = comm.BCHDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
    data = randi([0 1], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedBits = step(dec, demodSignal);
    errorStats = step(errorRate, data, receivedBits);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.015075
Number of errors = 9
```

### Transmit and receive a BPSK-modulated signal

Transmit and receive a BPSK-modulated signal encoded with a shortened BCH code, then count errors.

Specify the codeword, message, and shortened message lengths.

```
N = 255;  
K = 239;  
S = 63;
```

Create a BCH (255,239) generator polynomial. Use the generator polynomial to create a BCH encoder and decoder pair. The BCH code is based on the AMR standard.

```
gp = bchgenpoly(255,239);  
bchEncoder = comm.BCHEncoder(N,K,gp,S);  
bchDecoder = comm.BCHDecoder(N,K,gp,S);
```

Create an error rate counter.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Main processing loop.

```
for counter = 1:20  
    data = randi([0 1],630,1);           % Generate binary data  
    encodedData = bchEncoder(data);     % BCH encode data  
    modSignal = pskmod(encodedData,2);  % BPSK modulate  
    receivedSignal = awgn(modSignal,5); % Pass through AWGN channel  
    demodSignal = pskdemod(receivedSignal,2); % BSPK demodulate  
    receivedBits = bchDecoder(demodSignal); % BCH decode data  
    errorStats = errorRate(data,receivedBits); % Compute error statistics  
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...  
    errorStats(1), errorStats(2))
```

```
Error rate = 0.000318  
Number of errors = 4
```

## Shorten a BCH Code

Shorten a (31,26) BCH code to an (11,6) BCH code and use it to encode and decode random binary data.

Create a BCH encoder and decoder pair for a (31,26) code. Specify the generator polynomial,  $x^5 + x^2 + 1$ , and a shortened message length of 6.

```
enc = comm.BCHEncoder(31,26,'x5+x2+1',6);
dec = comm.BCHDecoder(31,26,'x5+x2+1',6);
```

Encode and decode random binary data and verify that the decoded bit stream matches the original data.

```
x = randi([0 1],60,1);
y = step(enc,x);
z = step(dec,y);
isequal(x,z)
```

```
ans = logical
     1
```

## step

**System object:** comm.BCHEncoder

**Package:** comm

Encode data using a BCH encoder

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  encodes input binary data,  $X$ , using a (CodewordLength,MessageLength) BCH encoder with the corresponding narrow-sense generator polynomial and returns the result in vector  $Y$ . The input and output length of the `step` function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 4-112.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.BitToInteger

**Package:** comm

(To be removed) Convert vector of bits to vector of integers

---

**Note** will be removed in a future release. Use `bi2de` instead. For more information, see “Compatibility Considerations”.

---

### Description

The `BitToInteger` object maps groups of bits in the input vector to integers in the output vector.

To map bits to integers:

- 1 Define and set up your bit to integer object. See “Construction” on page 4-130.
- 2 Call `step` to map groups of bits in the input vector to integers in the output vector according to the properties of `comm.BitToInteger`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.BitToInteger` creates a bit-to-integer converter System object, `H`, that maps a vector of bits to a corresponding vector of integer values.

`H = comm.BitToInteger(Name,Value)` creates a bit-to-integer converter object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.BitToInteger(NUMBITS, Name, Value)` creates a bit-to-integer converter System object, `H`. This object has the `BitsPerInteger` on page 4-0 property set to `NUMBITS` and the other specified properties set to the specified values.

## Properties

### **BitsPerInteger**

Number of bits per integer

Specify the number of input bits that the object maps to each output integer. You can set this property to a scalar integer between 1 and 32. The default is 3.

### **MSBFirst**

Assume first bit of input bit words is most significant bit

Set this property to `true` to indicate that the first bit of the input bit words is the most significant bit (MSB). The default is `true`. You can set this property to `false` to indicate that the first bit of the input bit words is the least significant bit (LSB).

### **SignedIntegerOutput**

Output signed integers

Set this property to `true` to generate signed integer outputs. The default is `false`. You can set this property to `false` to generate unsigned integer outputs.

When you set this property to `false`, the output values are integers between 0 and  $(2^N) - 1$ . In this case,  $N$  is the value you specified in the `BitsPerInteger` on page 4-0 property.

When you set this property to `true`, the output values are integers between  $-(2^{(N-1)})$  and  $(2^{(N-1)}) - 1$ .

### **OutputDataType**

Data type of output

Specify the output data type. The default is `Full` precision.

When you set the `SignedIntegerOutput` on page 4-0 property to `false`, set this property as one of `Full precision` | `Smallest integer` | `Same as input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`.

When you set this property to `Same as input`, and the input data type is numeric or fixed-point (fi object), the output data has the same type as the input data.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When you set the `SignedIntegerOutput` property to `true`, specify the output data type as one of `Full precision` | `Smallest integer` | `double` | `single` | `int8` | `int16` | `int32`.

When you set this property to `Full precision`, the object determines the output data type based on the input data type. If the input data type is double or single precision, the output data has the same type as the input data. Otherwise, the property determines the output data type in the same way as when you set this property to `Smallest unsigned integer`.

## Methods

`step` (To be removed) Convert vector of bits to vector of integers

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Convert random 4-bit words to integers

```
hBitToInt = comm.BitToInteger(4);
% Generate three 4-bit words
bitData = randi([0 1],3*hBitToInt.BitsPerInteger,1);
intData = step(hBitToInt,bitData)
```

```
intData = 3x1

    13
     9
    13
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Bit To Integer Converter block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

**comm.BitToInteger will be removed in a future release. Use bi2de instead.**

*Not recommended starting in R2019b*

Data types as supported by comm.BitToInteger are not inherently supported by functions. This code shows binary to decimal conversion for various data types using this function.

### Examples Using bi2de for Various Data Types

```
function compbi2de

% Number of integers
n = randi([1 100]);

% Default
h1 = comm.BitToInteger;
bpi = h1.BitsPerInteger;
x = randi([0,1],n*bpi,1);
y1 = h1(x);
y2 = bi2de(reshape(x,bpi,[]),'left-msb');
isequal(y1,y2)

% Right MSB, logical input
h2 = comm.BitToInteger( ...
    'BitsPerInteger',5, ...
    'MSBFirst',false);
bpi = h2.BitsPerInteger;
x = logical(randi([0,1],n*bpi,1));
y1 = h2(x);
y2 = bi2de(reshape(x,bpi,[]),'right-msb');
```

```
isequal(y1,y2)

% Right MSB, signed output, single input
h3 = comm.BitToInteger( ...
    'BitsPerInteger',8, ...
    'MSBFirst',false, ...
    'SignedIntegerOutput',true);
bpi = h3.BitsPerInteger;
x = randi([0,1],n*bpi,1,'single');
y1 = h3(x);
y2 = bi2de(reshape(x,bpi,[]),'right-msb');
N = 2^bpi;
y2 = y2 - (y2>=N/2)*N;
isequal(y1,y2)
end
```

**Introduced in R2012a**

## step

**System object:** `comm.BitToInteger`

**Package:** `comm`

(To be removed) Convert vector of bits to vector of integers

---

**Note** `comm.BitToInteger` will be removed in a future release. Use `bi2de` instead.

---

## Syntax

`Y = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` converts binary input, `X`, to corresponding integers, `Y`. The input must be a scalar or a column vector and the data type can be numeric, `numericType(0,1)`, or logical. The length of input `X` must be an integer multiple of the value you specify in the `BitsPerInteger` property. The object outputs a column vector with a length equal to `length(X)/BitsPerInteger`. When you set the `SignedIntegerOutput` property to `false`, the object maps each group of bits to an integer between 0 and  $(2^{\text{BitsPerInteger}})-1$ . A group of bits contains `N` bits, where `N` is the value of the `BitsPerInteger` property. If you set the `SignedIntegerOutput` property to `true`, the object maps each group of `BitsPerInteger` bits to an integer between  $-2^{(\text{BitsPerInteger}-1)}$  and  $(2^{(\text{BitsPerInteger}-1)})-1$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.BinarySymmetricChannel

**Package:** comm

(To be removed) Introduce binary errors

---

**Note** `comm.BinarySymmetricChannel` will be removed in a future release. Use `bsc` instead.

---

## Description

The `BinarySymmetricChannel` object introduces binary errors to the signal transmitted through this channel.

To introduce binary errors into the transmitted signal:

- 1 Define and set up your binary symmetric channel object. See “Construction” on page 4-137.
- 2 Call `step` to introduces binary errors into the signal transmitted through this channel according to the properties of `comm.ACPR`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.BinarySymmetricChannel` creates a binary symmetric channel System object, `H`, that introduces binary errors to the input signal with a prescribed probability.

`H = comm.BinarySymmetricChannel(Name,Value)` creates a binary symmetric channel object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### ErrorProbability

Probability of binary error

Specify the probability of a binary error as a scalar with a value between 0 and 1. The default is 0.05.

### ErrorVectorOutputPort

Enable error vector output

When you set this property to `true`, the `step` method outputs an error signal, `ERR`. This error signal, in vector form, indicates where errors were introduced in the input signal, `X`. A value of 1 at the  $i$ -th element of `ERR` indicates that an error was introduced at the  $i$ -th element of `X`. Set the property to `false` if you do not want the `ERR` vector at the output of the `step` method. The default is `true`.

### OutputDataType

Data type of output

Specify output data type as one of `double` | `logical`. The default is `double`.

## Methods

`step` (To be removed) Introduce binary errors

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Add Errors to Binary Input Signal

```
% Add binary errors with a probability of 0.2 to a binary input signal.  
p = 0.2;
```

```

binSymChan = comm.BinarySymmetricChannel('ErrorProbability',p);
data = randi([0 1],1000,1);
[~,err1] = binSymChan(data);

% Confirm that the number errors is approximately
% equal to the probability value multiplied by the number of symbols.
[sum(err1) p*length(data)];

% Perform using the bsc function
[~,err2] = bsc(data,p);
[sum(err2) p*length(data)];

ans =

    192    200

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Binary Symmetric Channel block reference page. The object properties correspond to the block parameters, except: This object uses the MATLAB default random stream to generate random numbers. The block uses a random number generator based on the V5 RANDN (Ziggurat) algorithm. An initial seed, set with the **Initial seed** parameter initializes the random number generator. For every system run that contains the block, the block generates the same sequence of random numbers. To generate reproducible numbers using this object, you can reset the MATLAB default random stream using the following code.

```
reset(RandStream.getGlobalStream)
```

For more information, see help for RandStream.

## Compatibility Considerations

### **comm.BinarySymmetricChannel will be removed**

*Warns starting in R2019b*

comm.BinarySymmetricChannel will be removed in a future release. Use bsc instead.

```
% This code provides examples using various syntaxes
% for the comm.BinarySymmetricChannel object versus the |bsc| function.
```

```
%% Simulate BSC with default comm.BinarySymmetricChannel object
```

```
data = randi([0 1],1000,2); % generate binary data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel;
s = rng; % Save default MATLAB random number generator state
outOld = bscObj(data);
% Using bsc function
rng(s) % Restore saved random number generator state
outNew = bsc(data,0.05);

%% Simulate BSC with object and set ErrorProbability property
data = randi([0 1],1000,2); % generate binary data
p = 0.3; % probability
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel('ErrorProbability',p);
s = rng; % Save default MATLAB random number generator state
outOld = bscObj(data);
% Using bsc function
rng(s) % Restore saved random number generator state
outNew = bsc(data,p);

%% Simulate BSC with object and set ErrorVectorOutputPort property
data = randi([0 1],1000,2); % generate binary data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel('ErrorVectorOutputPort', true)
s = rng; % Save default MATLAB random number generator state
[outOld,errOld] = bscObj(data);
% Using bsc function
rng(s) % Restore saved random number generator state
[outNew,errNew] = bsc(data,0.05);

%% Simulate BSC with object and set OutputDataType property to logical
data = randi([0 1],1000,2); % generate binary data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel('OutputDataType','logical');
s = rng; % Save default MATLAB random number generator state
outOld = bscObj(data);
% Using bsc function
rng(s) % Restore saved random number generator state
outNew = logical(bsc(data,0.05));

%% Simulate BSC with object and input is logical
data = logical(randi([0 1],1000,2)); % generate logical data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel;
```

```
s = rng; % Save default MATLAB random number generator state.
outOld = bscObj(data);
% Using bsc function
rng(s) % Restore saved random number generator state
outNew = bsc(double(data),0.05);

%% Simulate BSC with object and input is integer, 'int8'
% Integer datatype options: int8, uint8, int16, uint16, int32, uint32
data = randi([0 1],1000,2,'int8'); % generate integer data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel;
s = rng; % Save default MATLAB random number generator state
outOld = bscObj(int8(data));
% Using bsc function
rng(s) % Restore saved random number generator state
outNew = bsc(double(data),0.05);
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### See Also

`bsc` | `comm.AWGNChannel`

**Introduced in R2012a**

# step

**System object:** `comm.BinarySymmetricChannel`

**Package:** `comm`

(To be removed) Introduce binary errors

---

**Note** `comm.BinarySymmetricChannel` will be removed in a future release. Use `bsc` instead.

---

## Syntax

`Y = step(H,X)`  
`[Y,ERR] = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` adds binary errors to the input signal `X` and returns the modified signal, `Y`. The input signal can be a vector or matrix with numeric, logical, or fixed-point (fi objects) data type elements. The `step` method output, `Y`, has the same dimensions as the input, `X`. If `X` input contains a non-binary value, `V`, the object considers it to be 1 when **abs**(`V`) > 0. This syntax applies when you set the `ErrorVectorOutputPort` property to `false`.

`[Y,ERR] = step(H,X)` returns the error signal vector, `ERR`. A value of 1 at the *i*-th element of `ERR` indicates that an error was introduced at the *i*-th element of `X`. The outputs, `Y` and `ERR`, have the same dimensions as the input, `X`. This syntax applies when you set the `ErrorVectorOutputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# bleATTPDUConfig

Create configuration object for BLE ATT PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Description

The `bleATTPDUConfig` creates a configuration object for a Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU). You can configure a BLE ATT PDU using the applicable properties of `bleATTPDUConfig`.

## Creation

## Syntax

```
cfgATT = bleATTPDUConfig
cfgATT = bleATTPDUConfig(Name,Value)
```

## Description

`cfgATT = bleATTPDUConfig` creates a `bleATTPDUConfig` configuration object, `cfgATT`, for a BLE ATT PDU with default values.

`cfgATT = bleATTPDUConfig(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bleATTPDUConfig('Opcode','Error response')` sets the `Opcode` property of `cfgATT` to `'Error response'`.

## Properties

---

**Note** For more information about BLE ATT PDU properties and their respective values, see volume 3, part F, sections 3.3 and 3.4 of the Bluetooth Core Specification [2].

---

### Opcode — BLE ATT PDU operation code

'Read request' (default) | 'MTU request' | 'Information request' | ...

BLE ATT PDU operation code, specified as one of the values in this list. Each valid value describes a BLE ATT PDU operation code.

- 'MTU request'
- 'Error response'
- 'Information request'
- 'Find by type value request'
- 'Read by type request'
- 'Read request'
- 'Read response'
- 'Read blob request'
- 'Read blob response'
- 'Read by group type request'
- 'Write request'
- 'Write response'
- 'Write command'
- 'Prepare write request'
- 'Prepare write response'
- 'Execute write request'
- 'Execute write response'
- 'Handle value notification'
- 'Handle value indication'
- 'Handle value confirmation'

- 'Information response'
- 'Find by type value response'
- 'Read by type response'
- 'Read by group type response'

Data Types: char | string

### **RequestedOpcode — Opcode of request BLE ATT PDU**

'Read request' (default) | character vector | string scalar

Opcode of request BLE ATT PDU, specified as one of the values in this list. Each valid value describes a request BLE ATT PDU (from a peer device) that caused an error.

- 'MTU request'
- 'Information request'
- 'Find by type value request'
- 'Read by type request'
- 'Read request'
- 'Read blob request'
- 'Read by group type request'
- 'Write request'
- 'Prepare to write request'
- 'Execute write request'

Data Types: char | string

### **Format — Format of information data field**

'16 bit' (default) | '128 bit'

Format of information data field, specified as '16 bit' or '128 bit'. This value specifies the format of information data element in the PDU with opcode 'Information Response'.

Data Types: char | string

### **AttributeHandle — Handle value of attribute**

'0001' (default) | character vector of two-octet hexadecimal

Handle value of attribute, specified as the character vector of a two-octet hexadecimal value in the range [0x0001, 0xFFFF]. This value is a unique identifier. The server dynamically assigns this value.

Data Types: char | string

**ErrorMessage — Error message corresponding to request BLE ATT PDU**

'Invalid handle' (default) | 'Invalid handle' | 'Read not permitted' | ...

Error message corresponding to request BLE ATT PDU, specified as one of the values in this list. Each value indicates the cause of an error corresponding to the request PDU from a peer device.

- 'Invalid handle'
- 'Read not permitted'
- 'Write not permitted'
- 'Invalid PDU'
- 'Insufficient authentication'
- 'Request not supported'
- 'Invalid offset'
- 'Insufficient authorization'
- 'Prepare queue full'
- 'Attribute not found'
- 'Attribute not long'
- 'Insufficient encryption key size'
- 'Invalid attribute value length'
- 'Unlikely error'
- 'Insufficient encryption'
- 'Unsupported group type'
- 'Insufficient resources'

Data Types: char | string

**MaxTransmissionUnit — Maximum size of BLE ATT PDU**

23 (default) | positive integer

Maximum size of BLE ATT PDU, specified as a positive integer in the range [23, 65535]. This value sets the maximum size of the BLE ATT PDU in bytes that a client or server can receive.

Data Types: `uint8`

### **StartHandle — Starting handle of handle range**

'0001' (default) | character vector of two-octet hexadecimal value

Starting handle of handle range, specified as a two-octet hexadecimal value in the range [0x0001, 0xFFFF]. This value indicates the handle value of a service or characteristic declaration or the starting handle of a handle range. This value must be less than the `EndHandle`.

Data Types: `char` | `string`

### **EndHandle — Ending handle of handle range**

'FFFF' (default) | character vector of two-octet hexadecimal value

Ending handle of handle range, specified as a two-octet hexadecimal value in the range [0x0001, 0xFFFF]. This value sets the end handle value of a service declaration or a characteristic declaration or the ending handle of a handle range. This value must be greater than the `StartHandle`.

Data Types: `char` | `string`

### **AttributeType — Type of attribute**

'2800' (Primary service) (default) | four-element or 32-element character vector | 2-octet or 16-octet string scalar

Type of attribute, specified as a four-element or 32-element character vector or a string scalar denoting a two-octet or 16-octet hexadecimal value.

Data Types: `char` | `string`

### **AttributeValue — Value of attribute**

' ' (default) | character vector | string scalar | numeric vector of elements in the range [0, 255] | n-by-2 character array of maximum length 131068

Value of attribute, specified as one of these values:

- Character vector — This vector represent octets in hexadecimal format.
- String scalar — This scalar represent octets in hexadecimal format.

- Numeric vector of elements in the range [0,255] — This vector represent octets in decimal format. The maximum length of the numeric vector is 65534.
- n-by-2 character array — Each row represent an octet in hexadecimal format. The maximum length of the character array is 131068.

**AttributeValue** indicates the value of an attribute to be stored in or read from the attribute database. Specify this value in LSB first format.

Data Types: char | string | double

#### **Offset — Offset of next octet to be read**

0 (default) | integer in the range [0, 65565]

Offset of next octet to be read, specified as an integer in the range [0, 65535]. You can use this value in the BLE ATT PDUs with opcodes 'Read blob request', 'Prepare write request', and 'Prepare write response' to identify an attribute value offset in the attribute database.

Data Types: double

#### **ExecuteWrite — Execute write flag**

'Cancel all prepared writes' (default) | 'Write all pending requests'

Execute write flag, specified as 'Cancel all prepared writes' or 'Write all pending requests'. You can determine the action (discard or write) to be performed when this property is used.

Data Types: char | string

## **Object Functions**

### **Specific to This Object**

bleATTPDU	Generate BLE ATT PDU
bleATTPDUDecode	Decode BLE ATT PDU

## **Examples**

### Create BLE ATT PDU Configuration Objects

Create two unique BLE ATT PDU configuration objects: one of type 'Read by type request' and the other of type 'Error response' using default settings and name-value pairs respectively.

Create a BLE ATT PDU configuration object with default settings.

```
cfgATT = bleATTPDUConfig;
```

Set the BLE ATT PDU opcode as 'Read by type request'. View the applicable properties of the opcode 'Read by type request'.

```
cfgATT.Opcode = 'Read by type request'
```

```
cfgATT =  
    bleATTPDUConfig with properties:  
  
        Opcode: 'Read by type request'  
        StartHandle: '0001'  
        EndHandle: 'FFFF'  
        AttributeType: '2800'
```

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode to 'Error response'. View the applicable properties of the opcode 'Error response'.

```
cfgATT = bleATTPDUConfig('Opcode', 'Error response')
```

```
cfgATT =  
    bleATTPDUConfig with properties:  
  
        Opcode: 'Error response'  
        RequestedOpcode: 'Read request'  
        AttributeHandle: '0001'  
        ErrorMessage: 'Invalid handle'
```

## End-to-End Workflow of BLE ATT PDU

Create a BLE ATT PDU configuration object. Change the value of opcode to 'Read by type request'. View the applicable properties of the specified value of opcode.

```
cfgTx = bleATTPDUConfig;
cfgTx.Opcode = 'Read by type request'

cfgTx =
  bleATTPDUConfig with properties:
      Opcode: 'Read by type request'
      StartHandle: '0001'
      EndHandle: 'FFFF'
      AttributeType: '2800'
```

Generate a BLE ATT PDU from the corresponding configuration object.

```
attPDU = bleATTPDU(cfgTx);
```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode 'Error response'.

```
[status, cfgRx] = bleATTPDUdecode(attPDU)

status =
  Success

cfgRx =
  bleATTPDUConfig with properties:
      Opcode: 'Read by type request'
      StartHandle: '0001'
      EndHandle: 'FFFF'
      AttributeType: '2800'
```

# bleChannelSelection

Select BLE channel index for connection events

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Description

The `bleChannelSelection` System object selects a Bluetooth low energy (BLE) channel index based on the selected algorithm. For more information, see `Algorithm` in property.

To select a BLE channel index:

- 1 Create the `bleChannelSelection` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

## Creation

## Syntax

```
csa = bleChannelSelection  
csa = bleChannelSelection(Name,Value)
```

## Description

`csa = bleChannelSelection` creates a `blechannelselection` System object, `csa`, to select a BLE channel index for connection events or periodic advertising events.

`csa = bleChannelSelection(Name, Value)` sets properties using one or more name-value pairs. For example, `bleChannelSelection('Algorithm', '2')` configures the System object, `csa`, to select a BLE channel index based on 'Algorithm #2'. Enclose each property name in quotes.

## Properties

---

**Note** For more information about BLE channel selection properties and their respective values, see volume 6, part B, section 4.5.8 of the Bluetooth Core Specification [2].

---

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### **Algorithm — Type of BLE channel selection algorithm**

1 (default) | 2

Type of BLE channel selection algorithm, specified as 1 or 2 representing 'Algorithm #1' or 'Algorithm #2' respectively. The property uses this algorithm to select the channel index.

Data Types: double

### **HopIncrement — Hop increment count**

5 (default) | integer in the range [5, 16]

Hop increment count, specified as an integer in the range [5,16]. This property indicates the hop increment count to be used for hopping between data channels. 'Algorithm #1' uses this value as an input.

Data Types: double

### **AccessAddress — Unique connection address**

'8E89BED6' (default) | eight-element character vector | string scalar denoting a four-octet hexadecimal value

Unique connection address, specified as an eight-element character vector or a string scalar denoting a four-octet hexadecimal value. This value indicates a unique 32-bit address for the link layer connection between two devices. 'Algorithm #2' uses this value as an input.

Data Types: `char` | `string`

### **UsedChannels — List of used (good) data channels**

row vector containing all the channel indices [0, 36] (default) | vector of integers in the range [0, 36]

List of used (good) data channels, specified as an integer vector with element values in the range [0, 36]. The vector length must be greater than 1. At least two channels must be set as used (good) channels. This value indicates the set of good channels classified by the master.

Data Types: `double`

## **Usage**

## **Syntax**

```
channelIndex = csa()
```

## **Description**

`channelIndex = csa()` selects a channel index based on the algorithm specified by the `Algorithm` property, the list of used data channels specified by the `UsedChannels` property, and other applicable properties dependant on the selected algorithm. The returned channel index, `channelIndex`, is of data type `double`.

## **Object Functions**

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

### Specific to bleChannelSelection

clone      Create duplicate System object  
isLocked   Determine if System object is in use

### Common to All System Objects

step      Run System object algorithm  
release   Release resources and allow changes to System object property values and input characteristics  
reset     Reset internal states of System object

## Examples

### Select BLE Channel Indices Based on Type of Channel Selection Algorithm

Create a `blechannelselection` System object, 'csa', to select a BLE channel index based on the channel selection algorithm, 'Algorithm #1'. View the corresponding applicable properties.

```
csa = bleChannelSelection  
  
csa =  
    bleChannelSelection with properties:  
  
        Algorithm: 1  
        HopIncrement: 5  
        UsedChannels: [1x37 double]  
        ChannelIndex: 0  
        EventCounter: 0
```

Set the values of 'HopIncrement' to 7 and 'UsedChannels' to [0, 2, 24, 6, 10, 14, 26, 30, 34, 36]. View the corresponding properties.

```
csa.HopIncrement = 7;  
csa.UsedChannels = [0, 2, 24, 6, 10, 14, 26, 30, 34, 36]  
  
csa =  
    bleChannelSelection with properties:  
  
        Algorithm: 1
```

```
HopIncrement: 7
UsedChannels: [0 2 6 10 14 24 26 30 34 36]
ChannelIndex: 0
EventCounter: 0
```

Select a BLE channel index from the corresponding system object using 'Algorithm #1'.

```
channelIndex = csa()
```

```
channelIndex = 30
```

Create another `blechannelselection` System object, 'csa', this time to select a BLE channel index by specifying the type of channel selection algorithm as 'Algorithm #2'. View the corresponding applicable properties.

```
csa2 = bleChannelSelection("Algorithm",2);
```

Change the values of 'AccessAddress' to '8E89BED6' and 'UsedChannels' to [9,10,21,22,23,33,34,35,36]. View the corresponding properties.

```
csa2.AccessAddress = '8E89BED6';
csa2.UsedChannels = [9, 10, 21, 22, 23, 33, 34, 35, 36]
```

```
csa2 =
    bleChannelSelection with properties:
```

```
    Algorithm: 2
    AccessAddress: '8E89BED6'
    UsedChannels: [9 10 21 22 23 33 34 35 36]
    ChannelIndex: 0
    EventCounter: 0
```

Select a BLE channel index from the corresponding system object using 'Algorithm #2'.

```
channelIndex2 = csa2()
```

```
channelIndex2 = 9
```

# bleLLControlPDUConfig

Create configuration object for BLE LL control PDU payload configuration

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Description

The `bleLLControlPDUConfig` creates a configuration object for Bluetooth low energy (BLE) link layer (LL) control protocol data unit (PDU) payload configuration by using the default and specified values. You can configure a BLE LL control PDU payload configuration using the applicable properties of `bleLLControlPDUConfig`.

## Creation

## Syntax

```
cfgControl = bleLLControlPDUConfig
cfgControl = bleLLControlPDUConfig(Name,Value)
```

## Description

`cfgControl = bleLLControlPDUConfig` creates a configuration object, `cfgControl`, for a BLE LL control PDU payload configuration using default values.

`cfgControl = bleLLControlPDUConfig(Name,Value)` sets the properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bleLLControlPDUConfig('Opcode','Version indication')` configures `cfgControl` with the operation code as 'Version indication'

# Properties

---

**Note** For more information about BLE LL control PDU properties and their respective values, see volume 6, part B, section 2.4 of the Bluetooth Core Specification [2].

---

### **Opcode — BLE LL control PDU payload configuration operation code**

'Connection update indication' (default) | 'Channel map indication' | 'Terminate indication' | 'Unknown response' | 'Version indication' | 'Reject indication'

BLE LL control PDU payload configuration operation code, specified as one of the values in this list. Each valid value describes a BLE LL control PDU operation code.

- 'Connection update indication'
- 'Channel map indication'
- 'Terminate indication'
- 'Unknown response'
- 'Version indication'
- 'Reject indication'

Data Types: char | string

### **WindowSize — Transmit window size**

1 (default) | nonnegative integer

Transmit window size, specified as a nonnegative integer in the range [1,  $Mws$ ], where  $Mws$  is the lesser of 8 and  $(ConnectionInterval-1)$ . This property indicates the window size within which the master transmits a data packet and the slave listens for a data packet after the connection is established. Each unit is taken as 1.25 ms so that the window size ( $WindowSize \times 1.25$ ) is in the range of 1.25 ms to the minimum of (10 ms,  $((ConnectionInterval \times 1.25) - 1.25)$  ms).

Data Types: double

### **ConnectionInterval — Connection interval**

6 (7.5 ms) (default) | integer in the range [6, 3200]

Connection interval, specified as an integer in the range [6, 3200]. This property indicates the interval between the start of two consecutive connection events. Each unit is taken as

1.25 ms so that the connection interval ( $\text{ConnectionInterval} \times 1.25$ ) is in the range of 7.5 ms to 4.0 s.

Data Types: double

### **SlaveLatency — Slave latency**

0 (default) | nonnegative integer

Slave latency, specified as a nonnegative integer in the range  $[0, \text{Msl}]$ , where  $\text{Msl}$  is the lesser of 499 and  $((\text{ConnectionTimeout} \times 10) / ((\text{ConnectionInterval} \times 1.25) \times 2)) - 1$ . This property indicates the number of connection events that a slave can ignore.

Data Types: double

### **ConnectionTimeout — Connection supervision timeout**

10 (default) | nonnegative integer

Connection supervision timeout, specified as a nonnegative integer in the range  $[\text{Mct}, 3200]$ , where  $\text{Mct}$  is the larger of 10 and  $((1 + \text{SlaveLatency}) \times (\text{ConnectionInterval} \times 1.25) \times 2) / 10$ . If the slave does not receive a valid packet within this time, this property indicates the connection timeout. Each unit is taken as 10 ms so that the connection timeout ( $\text{ConnectionInterval} \times 10$ ) is in the range of 100 ms to 32.0 s.

Data Types: double

### **Instant — Connection event instant**

0 (default) | integer in the range  $[0, 65535]$

Connection event instant, specified as an integer in the range  $[0, 65535]$ . This property indicates the event count at which specific action must occur, for instance, using updated connection parameters.

Data Types: double

### **UsedChannels — List of used data channels**

row vector containing the channel indices between  $[0:36]$  (default) | integer vector with element values in the range  $[0, 36]$

List of used data channels, specified as an integer vector with element values in the range  $[0, 36]$ . The vector length must be greater than 1. At least two channels must be set as used (good) channels. This property indicates the set of good channels classified by the master.

Data Types: double

### **ErrorCode — Connection termination error code**

'Success' (default) | 'Unknown connection identifier' | 'Hardware failure'  
| ...

Connection termination error code, specified as one of the values in this list. Each valid value describes the error description informing the remote device why the connection is about to be terminated.

- 'Success'
- 'Unknown connection identifier'
- 'Hardware failure'
- 'Memory capacity exceeded'
- 'Connection timeout'
- 'Connection limit exceeded'
- 'Connection already exists'
- 'Command disallowed'
- 'Connection accept timeout exceeded'
- 'Connection rejected due to limited resources'
- 'Invalid LL parameters'
- 'Connection rejected due to unacceptable BD\_ADDR'
- 'Unspecified error'
- 'Unsupported LL parameter value'
- 'Role change not allowed'
- 'LL response timeout'
- 'LL procedure collision'
- 'Instant passed'
- 'Channel classification not supported'
- 'Extended inquiry response too large'
- 'Connection rejected due to no suitable channel found'
- 'Advertising timeout'
- 'Controller busy'

- 'Unacceptable connection parameters'
- 'Connection failed to be established'
- 'Unknown advertising identifier'
- 'Limit reached'
- 'Operation cancelled by host'

Data Types: char | string

#### **UnknownOpcode — Unrecognized or unsupported operation code**

'00' (default) | two-element character vector | string scalar denoting one-octet hexadecimal value

Unrecognized or unsupported operation code, specified as the comma-separated pair consisting of 'UnknownOpcode' and a two-element character vector or string scalar denoting a one-octet hexadecimal value. This property indicates the type of BLE LL control PDU that is not recognized or supported.

Data Types: char | string

#### **VersionNumber — Version number of Bluetooth specification**

'5.0' (default) | string scalar denoting a one-octet hexadecimal value

Version number of Bluetooth specification, specified as a string scalar denoting a one-octet hexadecimal value. You can specify the 'VersionNumber' as '4.0', '4.1', '4.2' or '4.3'. This property indicates the version number of the Bluetooth core specification.

Data Types: string

#### **CompanyIdentifier — Manufacturer ID of Bluetooth controller**

'FFFF' (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Manufacturer ID of Bluetooth controller, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. This property indicates the unique identifier assigned to your organization by Bluetooth Special Interest Group (SIG) [2].

Data Types: char | string

#### **SubVersionNumber — Subversion number of the Bluetooth controller**

'0000' (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Subversion number of the Bluetooth controller, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property indicates the unique value for each implementation or revision of a Bluetooth controller implementation.

Data Types: `char` | `string`

## Object Functions

### Specific to This Object

<code>bleLLDataChannelPDU</code>	Generate BLE LL data channel PDU
<code>bleLLDataChannelPDUDecode</code>	Decode BLE LL data channel PDU
<code>bleLLDataChannelPDUConfig</code>	Create configuration object for BLE LL data channel PDU

## Examples

### Create BLE LL Control PDU Configuration Object Using Default Settings

Create a BLE LL control PDU configuration object, `'cfgControl'`, using default settings. View the corresponding applicable properties.

```
cfgControl = bleLLControlPDUConfig

cfgControl =
    bleLLControlPDUConfig with properties:

        Opcode: 'Connection update indication'
        WindowSize: 1
        WindowOffset: 0
        ConnectionInterval: 6
        SlaveLatency: 0
        ConnectionTimeout: 10
        Instant: 0
```

Change the value of the connection interval to 64. View the configured properties.

```
cfgControl.ConnectionInterval = 64
```

```

cfgControl =
  bleLLControlPDUConfig with properties:
      Opcode: 'Connection update indication'
      WindowSize: 1
      WindowOffset: 0
      ConnectionInterval: 64
      SlaveLatency: 0
      ConnectionTimeout: 10
      Instant: 0

```

### Create BLE LL Control PDU Configuration Object Using Name-Value Pairs

Create two unique BLE LL control PDU configuration objects using name-value pairs: first one of the type 'Terminate indication' and error code 'Connection timeout' and second one of the type 'Channel map indication' with used set of data channels.

Create a BLE LL control PDU configuration object, 'cfgControl', by specifying opcode as 'Terminate indication' and the error code as 'Connection timeout'. View the applicable properties corresponding to the specified opcode.

```

cfgControl = bleLLControlPDUConfig('Opcode','Terminate indication', ...
    'ErrorCode','Connection Timeout')
cfgControl =
  bleLLControlPDUConfig with properties:
      Opcode: 'Terminate indication'
      ErrorCode: 'Connection timeout'

```

Create another BLE LL control PDU payload configuration object, 'cfgControl', this time by setting the value of opcode as 'Channel map indication'. Specify the list of used data channels. View the configured properties corresponding to the specified opcode.

```

cfgControl = bleLLControlPDUConfig('Opcode','Channel map indication');
cfgControl.UsedChannels = [0 3 12 16 18 24]
cfgControl =
  bleLLControlPDUConfig with properties:

```

```
        Opcode: 'Channel map indication'  
        Instant: 0  
UsedChannels: [0 3 12 16 18 24]
```

Create a BLE LL data channel configuration object, 'cfgLLData', by specifying the values of 'LLID' as 'Control' and 'ControlConfig' as 'cfgControl'. View the properties of the configuration object 'cfgLLData'.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID','Control');  
cfgLLData.ControlConfig = cfgControl
```

```
cfgLLData =  
    bleLLDataChannelPDUConfig with properties:  
  
        LLID: 'Control'  
        NESN: 0  
SequenceNumber: 0  
        MoreData: 0  
ControlConfig: [1x1 bleLLControlPDUConfig]
```

### End-to-End Workflow of BLE LL Control PDU

Create a BLE LL data channel PDU configuration object for a control PDU by using default configuration. View the corresponding default properties.

```
cfgControl = bleLLControlPDUConfig  
  
cfgControl =  
    bleLLControlPDUConfig with properties:  
  
        Opcode: 'Connection update indication'  
        WindowSize: 1  
        WindowOffset: 0  
ConnectionInterval: 6  
        SlaveLatency: 0  
ConnectionTimeout: 10  
        Instant: 0
```

Generate a BLE LL data channel PDU using 'cfgTx' by specifying the value of link layer identifier, 'LLID', as 'Control' and 'ControlConfig' as 'cfgControl'. Specify the cyclic redundancy check (CRC) value for the configuration object 'cfgTx'. View the properties of 'cfgTx'.

```
cfgTx = bleLLDataChannelPDUConfig('LLID', 'Control', ...
    'ControlConfig',cfgControl);
cfgTx.CRCInitialization = 'E23456'

cfgTx =
    bleLLDataChannelPDUConfig with properties:
        LLID: 'Control'
        NESN: 0
        SequenceNumber: 0
        MoreData: 0
        ControlConfig: [1x1 bleLLControlPDUConfig]
```

Generate a BLE LL control PDU from 'cfgTx'.

```
pdu = bleLLDataChannelPDU(cfgTx);
```

Decode the generated BLE LL control PDU by initializing the CRC value. The returned status indicates decoding is successful. View the values of 'status', 'cfgRx' and 'llPayload'.

```
crcInit = 'E23456'; % Received during associaton
[status, cfgRx, llPayload] = bleLLDataChannelPDUDecode(pdu, crcInit)

status =
    Success

cfgRx =
    bleLLDataChannelPDUConfig with properties:
        LLID: 'Control'
        NESN: 0
        SequenceNumber: 0
        MoreData: 0
        ControlConfig: [1x1 bleLLControlPDUConfig]

llPayload =
    1x0 empty char array
```

# bleL2CAPFrameConfig

Create configuration object for BLE L2CAP frame

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Description

The `bleL2CAPFrameConfig` creates a configuration object for Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) signaling frame or data frame using the default and specified values. You can configure a BLE L2CAP signaling frame or data frame using the applicable properties of `bleL2CAPFrameConfig`.

## Creation

## Syntax

```
cfgL2CAP = bleL2CAPFrameConfig  
cfgL2CAP = bleL2CAPFrameConfig(Name,Value)
```

## Description

`cfgL2CAP = bleL2CAPFrameConfig` creates a configuration object, `cfgL2CAP`, for a BLE L2CAP signaling command frame or data frame with default values.

`cfgL2CAP = bleL2CAPFrameConfig(Name,Value)` specifies properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bleL2CAPFrameConfig('CommandType','Command reject')` configures `cfgL2CAP` with the type of signaling command frame as 'Command reject'.

# Properties

---

**Note** For more information about BLE L2CAP frame properties and their respective values, see volume 3, part A, section 3 of the Bluetooth Core Specification [2].

---

### **ChannelIdentifier — Identifier for logical channel endpoint**

'0005' (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Identifier for a logical channel endpoint, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. The 'ChannelIdentifier' denotes the local name representing a logical channel endpoint. This property is used to identify the command and data frames. Command frames use '0005' as the 'ChannelIdentifier'. L2CAP B-frames use fixed 'ChannelIdentifier', '0004' for attribute protocol (ATT) and '0006' for security manager protocol (SMP).

Data Types: char | string

### **CommandType — Signaling command type**

'Credit Based Connection request' (default) | 'Command reject' | 'Disconnection request' | ...

Signaling command type, specified as a character vector or a string scalar. You can specify CommandType as one of these values:

- 'Command reject'
- 'Disconnection request'
- 'Disconnection response'
- 'Connection Parameter Update request'
- 'Connection Parameter Update response'
- 'Credit Based Connection request'
- 'Credit Based Connection response'
- 'Flow Control Credit'

This property is applicable only when the value of ChannelIdentifier is set to '0005' (signaling channel identifier).

Data Types: char | string

**SignalIdentifier — Identifier for request-response frame exchange**

'01' (default) | two-element character vector | string scalar denoting one-octet hexadecimal value

Identifier for a request-response frame exchange, specified as a two-element character vector or string scalar denoting a one-octet hexadecimal value. The requesting device sets the value of this property and the responding device uses the same value in its response. The value of this property cannot be set to '00'.

Data Types: char | string

**CommandRejectReason — Reason for rejecting received signaling command frame**

'Command not understood' (default) | 'Signaling MTU exceeded' | 'Invalid CID in request'

Reason for rejecting the received signaling command frame, specified as a character vector or a string scalar. You can specify CommandRejectReason as one of these values:

- 'Command not understood'
- 'Signaling MTU exceeded'
- 'Invalid CID in request'

This property specifies the reason for rejecting a signaling command frame.

Data Types: char | string

**SourceChannelIdentifier — Source logical channel endpoint**

'0040' (default) | four-element character vector | string scalar denoting two-octet hexadecimal value

Source logical channel endpoint, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property specifies the source channel endpoint from which the request is sent or a response is received. When the channel is created using credit-based connection procedure, data packets flowing to the sender of the request are sent to the SourceChannelIdentifier.

Data Types: char | string

**DestinationChannelIdentifier — Destination logical channel endpoint**

'0040' (default) | four-element character vector | string scalar denoting two-octet hexadecimal value

Destination logical channel endpoint, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property specifies the destination channel endpoint from which the request is sent or a response is received. When the channel is created using credit-based connection procedure, data packets flowing to the destination of the request are sent to the `DestinationChannelIdentifier`.

Data Types: `char` | `string`

### **ConnectionIntervalRange — Connection interval range**

[6, 3200] (default) | two-element numeric vector specified as [*MIN*, *MAX*]

Connection interval range, specified as a two-element numeric vector in the form of [*MIN*, *MAX*]. *MIN* and *MAX* specify the minimum and the maximum value of the `ConnectionIntervalRange` respectively. You can specify the value of *MIN* and *MAX* in the range [6, 3200]. *MIN* must be less than or equal to *MAX*. Each unit for *MIN* or *MAX* is taken as 1.25 ms so the resultant value is in the range [7.5 ms, 4.0 s].

Data Types: `double`

### **ConnectionTimeout — Connection supervision timeout**

10 (100 ms) (default) | integer in the range [*Mct*, 3200]

Connection supervision timeout, specified as an integer in the range [*Mct*, 3200], where *Mct* is the larger of 10 and  $((1 + \text{SlaveLatency}) \times (\text{ConnectionInterval} \times 1.25) \times 2) / 10$ . This property indicates the timeout for a connection if no valid packet is received within this time. Each unit is taken as 10 ms so that the resultant connection timeout,  $(\text{ConnectionInterval} \times 10)$ , is in the range [100 ms, 32.0s].

Data Types: `double`

### **SlaveLatency — Number of link layer connection events a slave can ignore**

0 (default) | integer in the range [0, *Msl*]

Number of link layer connection events a slave can ignore, specified as an integer in the range [0, *Msl*], where *Msl* is the lesser of 499 and  $((\text{ConnectionTimeout} \times 10) / ((\text{ConnectionInterval} \times 1.25) \times 2)) - 1$ . This property indicates the number of connection events that a slave can ignore.

Data Types: `double`

### **ParameterUpdateResult — Result of connection parameters update**

'Accepted' (default) | 'Rejected'

Result of the connection parameters update, specified as 'Accepted' or 'Rejected'. This property indicates the response to the 'Connection Parameter Update Request' value of the property CommandType and specifies the result after updating the connection parameters.

Data Types: char | string

### **LEPSM — LE protocol or service multiplexer**

'001F' (default) | four-element character vector | string scalar denoting two-octet hexadecimal value

LE protocol or service multiplexer, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. The value of this property is a unique number specified by the Special Interest Group (SIG) for each protocol. The SIG assigns the value of this property within the range [0x0001, 0x007F] for a set of existing protocols. The SIG dynamically assigns the value of this property in the range [0x0080, 0x00FF] to the implemented protocols.

Data Types: char | string

### **MaxTransmissionUnit — Maximum service data unit (SDU) size**

23 (default) | integer in the range of [23, 65,535]

Maximum service data unit (SDU) size, specified as an integer in the range of [23, 65,535] octets. This property specifies the maximum acceptable SDU size for the upper-layer entity.

Data Types: double

### **MaxPDUPayloadSize — Maximum protocol data unit (PDU) payload size**

23 (default) | integer in the range of [23, 65,535]

Maximum protocol data unit (PDU) payload size, specified as an integer in the range of [23, 65,535] octets. This property specifies the maximum acceptable payload data for the L2CAP layer entity.

Data Types: double

### **Credits — Number of LE-frames peer device can send or receive**

1 (default) | integer in the range of [0, 65,535]

Number of LE-frames peer device can send or receive, specified as an integer in the range of [0, 65,535] octets. This property indicates the number of LE-frames that the peer

device can send or receive. If the value of `CommandType` property is set to `'Flow control credit'`, then this property cannot be set to `0`.

Data Types: `double`

### **ConnectionResult — Result of credit-based connection procedure**

`'Successful'` (default) | `'LEPSM not supported'` | `'No resources available'`  
| ...

Result of the credit-based connection procedure, specified as a character vector or a string scalar. You can specify `ConnectionResult` as one of these values:

- `'Successful'`
- `'LEPSM not supported'`
- `'No resources available'`
- `'Insufficient authentication'`
- `'Insufficient authorization'`
- `'Insufficient encryption key size'`
- `'Insufficient encryption'`
- `'Invalid Source CID'`
- `'Source CID already allocated'`
- `'Unacceptable parameters'`

This property indicates the outcome of the connection request.

Data Types: `char` | `string`

## **Object Functions**

### **Specific to This Object**

<code>bleL2CAPFrame</code>	Generate BLE L2CAP frame
<code>bleL2CAPFrameDecode</code>	Decode BLE L2CAP frame

## **Examples**

## Create BLE L2CAP Frame Configuration Object Using Default Settings

Create a BLE L2CAP frame configuration object, 'cfgL2CAP', using default properties. View the corresponding applicable properties. This configuration object generates a BLE L2CAP signaling frame of type 'Credit based connection request'.

```
cfgL2CAP = bleL2CAPFrameConfig
```

```
cfgL2CAP =  
  bleL2CAPFrameConfig with properties:  
  
    ChannelIdentifier: '0005'  
      CommandType: 'Credit based connection request'  
    SignalIdentifier: '01'  
  SourceChannelIdentifier: '0040'  
    LEPSM: '001F'  
  MaxTransmissionUnit: 23  
  MaxPDUPayloadSize: 23  
  Credits: 1
```

Set the value of credits to 10. View the corresponding properties of 'cfgL2CAP'.

```
cfgL2CAP.Credits          = 10
```

```
cfgL2CAP =  
  bleL2CAPFrameConfig with properties:  
  
    ChannelIdentifier: '0005'  
      CommandType: 'Credit based connection request'  
    SignalIdentifier: '01'  
  SourceChannelIdentifier: '0040'  
    LEPSM: '001F'  
  MaxTransmissionUnit: 23  
  MaxPDUPayloadSize: 23  
  Credits: 10
```

### Create BLE L2CAP Configuration Object Using Name-Value pairs

Create a BLE L2CAP frame configuration object, 'cfgL2CAP', by setting the value of channel identifier as '0004' using name-value pairs. View the corresponding applicable properties. This configuration object generates a BLE L2CAP data frame (B-frame).

```
cfgL2CAP = bleL2CAPFrameConfig('ChannelIdentifier','0004')
```

```
cfgL2CAP =  
    bleL2CAPFrameConfig with properties:  
  
    ChannelIdentifier: '0004'
```

### End-to-End Workflow of BLE L2CAP Frames

Create a BLE L2CAP configuration object, 'bleL2CAPFrameConfig', to generate a BLE L2CAP data frame (B-frame). Set the value of channel identifier as '0004' and view the corresponding applicable properties.

```
cfgTx = bleL2CAPFrameConfig('ChannelIdentifier','0004')
```

```
cfgTx =  
    bleL2CAPFrameConfig with properties:  
  
    ChannelIdentifier: '0004'
```

Generate a BLE L2CAP data frame (B-frame) with service data unit (SDU) from ATT specified as '0A0100'.

```
l2capFrame = bleL2CAPFrame(cfgTx,"0A0100")
```

```
l2capFrame = 7x2 char array  
    '03'  
    '00'  
    '04'  
    '00'  
    '0A'  
    '01'  
    '00'
```

Decode the generated BLE L2CAP data frame (B-frame). The returned status indicates decoding was successful. View the output of 'status', 'cfgRx' and 'SDU'.

```
[status, cfgRx, SDU] = bleL2CAPFrameDecode(l2capFrame)
```

```
status =  
Success
```

```
cfgRx =  
bleL2CAPFrameConfig with properties:
```

```
    ChannelIdentifier: '0004'
```

```
SDU = 3x2 char array  
    '0A'  
    '01'  
    '00'
```

# bleLLDataChannelPDUConfig

Create configuration object for BLE LL data channel PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Description

The `bleLLDataChannelPDUConfig` creates a configuration object for a Bluetooth low energy (BLE) link layer (LL) data channel protocol data unit (PDU) using the default and specified values. You can configure a BLE LL data PDU and a BLE LL control PDU using the applicable properties of `bleLLDataChannelPDUConfig`.

## Creation

## Syntax

```
cfgLLData = bleLLDataChannelPDUConfig
cfgLLData = bleLLDataChannelPDUConfig(Name,Value)
```

## Description

`cfgLLData = bleLLDataChannelPDUConfig` creates a configuration object, `cfgLLData`, for a BLE LL data channel PDU with default values.

`cfgLLData = bleLLDataChannelPDUConfig(Name,Value)` sets properties by using one or more name-value pairs. Enclose each property name in quotes. For example, `bleLLDataChannelPDUConfig('LLID','Data (start fragment/complete)')` configures `cfgLLData` with the type of BLE LL data channel PDU as a data PDU.

# Properties

---

**Note** For more information about BLE LL data channel PDU properties and their respective values, see volume 6, part B, section 2.4 of the Bluetooth Core Specification [2].

---

### **LLID — Link layer identifier**

'Data (continuation fragment/empty)' (default) | 'Data (continuation fragment/empty)' | 'Control'

Link layer identifier, specified as a character vector or a string scalar to describe the type of a BLE LL data channel PDU. You can specify 'LLID' as one of these values:

- 'Data (continuation fragment/empty)'
- 'Data (start fragment/complete)'
- 'Control'

Data Types: char | string

### **NESN — Next expected sequence number**

0 (default) | 1

Next expected sequence number, specified as 0 or 1. This value indicates either an acknowledgment for the last received packet or a request for resending the last transmitted packet from the peer.

Data Types: scalar | logical | double

### **SequenceNumber — Transmitting packet sequence number**

0 (default) | scalar | 1

Transmitting packet sequence number, specified as 0 or 1. This property indicates the sequence number of the packet being transmitted.

Data Types: scalar | logical | double

### **MoreData — Indication for more data**

false or 0 (default) | true or 1

Indication for more data, specified as a numeric or a logical value of 1 (true) or 0 (false). A true or 1 value indicates that the sender has more data to send.

Data Types: `logical`

### **CRCInitialization** — Cyclic redundancy check initialization value

'012345' (default) | six-element character vector | string scalar denoting three-octet hexadecimal value

Cyclic redundancy check initialization value, specified as a six-element character vector or a string scalar denoting a three-octet hexadecimal value.

Data Types: `char` | `string`

### **ControlConfig** — BLE LL control PDU payload configuration object

`bleLLControlPDUConfig` object

BLE LL control PDU payload configuration object, specified as a `bleLLControlPDUConfig` object. The different fields of this value are configured using the settings of `bleLLControlPDUConfig`. The default value of this property is an object of type `bleLLControlPDUConfig` with all properties set to their default values. This property is applicable for generating and decoding a BLE LL control PDU.

## Object Functions

### Specific to This Object

<code>bleLLDataChannelPDU</code>	Generate BLE LL data channel PDU
<code>bleLLDataChannelPDUDecode</code>	Decode BLE LL data channel PDU
<code>bleLLControlPDUConfig</code>	Create configuration object for BLE LL control PDU payload configuration

## Examples

### Create BLE LL Data Channel PDU Configuration Object for Data PDU

Create a BLE LL data channel PDU configuration object for a data PDU and view the corresponding default properties.

```
cfgLLData = bleLLDataChannelPDUConfig
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
```

```
        LLID: 'Data (continuation fragment/empty)'
        NESN: 0
SequenceNumber: 0
        MoreData: 0
```

Specify the value of LLID as 'Data (start fragment/complete)' and view the corresponding properties.

```
cfgLLData.LLID = 'Data (start fragment/complete)'
```

```
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
```

```
        LLID: 'Data (start fragment/complete)'
        NESN: 0
SequenceNumber: 0
        MoreData: 0
```

### Create BLE LL Data Channel PDU Configuration Object for Control PDU

Create two unique BLE LL data channel PDU configuration objects for a control PDU of type 'Channel map indication' and 'Version indication' using name-value pairs.

Create a BLE LL control PDU payload configuration object, 'cfgControl', for a control PDU with opcode 'Channel map indication'. View the applicable properties corresponding to the specified opcode.

```
cfgControl = bleLLControlPDUConfig('Opcode', 'Channel map indication')
```

```
cfgControl =
    bleLLControlPDUConfig with properties:
```

```
        Opcode: 'Channel map indication'
        Instant: 0
UsedChannels: [1x37 double]
```

Create a BLE LL data channel configuration object by specifying the values of 'LLID' as 'Control' and 'ControlConfig' as 'cfgControl'. View the properties of 'cfgLLData'.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID','Control', ...
    'ControlConfig',cfgControl)

cfgLLData =
    bleLLDataChannelPDUConfig with properties:

        LLID: 'Control'
        NESN: 0
    SequenceNumber: 0
        MoreData: 0
    ControlConfig: [1x1 bleLLControlPDUConfig]
```

Create another BLE LL data channel configuration object, 'cfgControl' for a control PDU, this time specifying the opcode as 'Version indication'. View the applicable properties of 'cfgControl' corresponding to the specified opcode.

```
cfgControl.Opcode = 'Version indication';
cfgControl.SubVersionNumber = '008E'

cfgControl =
    bleLLControlPDUConfig with properties:

        Opcode: 'Version indication'
        VersionNumber: '5.0'
    CompanyIdentifier: 'FFFF'
        SubVersionNumber: '008E'
```

Create a BLE LL data channel configuration object, 'cfgLLData', by specifying the values of 'ControlConfig' as 'cfgControl' and view the applicable properties.

```
cfgLLData.ControlConfig = cfgControl

cfgLLData =
    bleLLDataChannelPDUConfig with properties:

        LLID: 'Control'
        NESN: 0
    SequenceNumber: 0
        MoreData: 0
```

```
ControlConfig: [1x1 bleLLControlPDUConfig]
```

### End-to-End Workflow of BLE LL Data Channel PDU

Create a BLE LL data channel PDU configuration object, 'cfgTx', for a data PDU using default configuration. View the corresponding default properties.

```
cfgTx = bleLLDataChannelPDUConfig
```

```
cfgTx =  
    bleLLDataChannelPDUConfig with properties:  
  
        LLID: 'Data (continuation fragment/empty)'  
        NESN: 0  
        SequenceNumber: 0  
        MoreData: 0
```

Initialize the CRC value corresponding to the configuration object 'cfgTx'.

```
cfgTx.CRCInitialization = '123456';
```

Generate a BLE LL data channel PDU by using the data PDU configuration object, 'cfgTx' and the upper-layer payload '030004000A0100'.

```
pdu = bleLLDataChannelPDU(cfgTx, '030004000A0100');
```

Decode the generated BLE LL data channel PDU by initializing the CRC value. The returned status indicates decoding is successful. View the values of 'status', 'cfgRx' and 'llPayload'.

```
crcInit = '123456';  
[status, cfgRx, llPayload] = bleLLDataChannelPDUDecode(pdu, crcInit)  
  
status =  
Success  
  
cfgRx =  
    bleLLDataChannelPDUConfig with properties:
```

```
        LLID: 'Data (continuation fragment/empty)'
```

```
NESN: 0  
SequenceNumber: 0  
MoreData: 0
```

```
llPayload = 7x2 char array  
    '03'  
    '00'  
    '04'  
    '00'  
    '0A'  
    '01'  
    '00'
```

# bleLLAdvertisingChannelPDUConfig

Create configuration object for BLE LL advertising channel PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Description

The `bleLLAdvertisingChannelPDUConfig` creates a configuration object for Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU) using the default and specified values. You can configure a BLE LL advertising channel PDU using the applicable properties of `bleLLAdvertisingChannelPDUConfig`.

## Creation

## Syntax

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig
cfgLLAdv = bleLLAdvertisingChannelPDUConfig(Name,Value)
```

## Description

`cfgLLAdv = bleLLAdvertisingChannelPDUConfig` creates a configuration object, `cfgLLAdv`, for a BLE LL advertising channel PDU with default values.

`cfgLLAdv = bleLLAdvertisingChannelPDUConfig(Name,Value)` creates a BLE LL advertising channel PDU configuration object by specifying properties using one or more name-value pairs. Enclose each property name in quotation marks. For example, `bleLLAdvertisingChannelPDUConfig('PDUType','Scan response')` configures `cfgLLAdv` with the type of BLE LL advertising channel PDU as 'Scan response'.

# Properties

---

**Note** For more information about BLE LL advertising channel PDU properties and their respective values, see volume 6, part B, section 2.3 of the Bluetooth Core Specification [2].

---

### **PDUType — BLE LL advertising channel PDU type**

'Advertising indication' (default) | 'Advertising direct indication' | 'Advertising non connectable indication' | ...

BLE LL advertising channel PDU type, specified as a character vector or a string scalar to describe the type of a BLE LL advertising channel PDU. You can specify 'PDUType' as one of these values:

- 'Advertising indication'
- 'Advertising direct indication'
- 'Advertising non connectable indication'
- 'Scan request'
- 'Scan response'
- 'Connection indication'
- 'Advertising scannable indication'

Data Types: char | string

### **ChannelSelection — Channel selection algorithm**

'Algorithm1' (default) | 'Algorithm2'

Channel selection algorithm, specified as 'Algorithm1' or 'Algorithm2' to indicate the type of algorithm used for hopping between channels.

Data Types: char | string

### **AdvertiserAddressType — Advertiser device address type**

'Random' (default) | 'Public'

Advertiser device address type, specified as 'Random' or 'Public' to indicate the type of advertiser address in the packet.

Data Types: char | string

**AdvertiserAddress — Advertiser device address**

'0123456789AB' (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Advertiser device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the advertiser device address.

Data Types: char | string

**TargetAddressType — Target device address type**

'Random' (default) | 'Public'

Target device address type, specified as 'Random' or 'Public' to indicate the type of target device address when a directed advertisement packet is transmitted.

Data Types: char | string

**TargetAddress — Target device address**

'0123456789CD' (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Target device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the target device address when a directed advertisement packet is transmitted.

Data Types: char | string

**ScannerAddressType — Scanner device address type**

'Random' (default) | 'Public'

Scanner device address type, specified as 'Random' or 'Public' to indicate the type of scanner device address when a scan request packet is transmitted.

Data Types: char | string

**ScannerAddress — Scanner device address**

'0123456789CD' (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Scanner device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the scanner device address when a scan request packet is transmitted.

Data Types: char | string

### **InitiatorAddressType — Initiator device address type**

'Random' (default) | 'Public'

Scanner device address type, specified as 'Random' or 'Public' to indicate the type of initiator device address when a connection indication packet is transmitted.

Data Types: char | string

### **InitiatorAddress — Initiator device address**

'0123456789CD' (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Initiator device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the initiator device address when a connection indication packet is transmitted.

Data Types: char | string

### **AdvertisingData — Advertising data**

'020106' (default) | character vector | string scalar | numeric vector of elements in the range [0,31] | n-by-2 character array

Advertising data, specified as one of these values:

- Character vector — This vector represent octets in hexadecimal format.
- String scalar — This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,31] — This vector represent octets in decimal format.
- n-by-2 character array — Each row represent an octet in hexadecimal format.

This property indicates the advertising data that the device sends out in an advertisement packet.

Data Types: char | string | double

### **ScanResponseData — Scan response data**

'020106' (default) | character vector | string scalar | numeric vector of elements in the range [0,31] | n-by-2 character array

Scan response data, specified as one of these values:

- Character vector — This vector represent octets in hexadecimal format.

- String scalar — This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,31] — This vector represent octets in decimal format.
- n-by-2 character array — Each row represent an octet in hexadecimal format.

This property indicates the scan response data that the device sends out in a scan response packet (when scan request is received).

Data Types: char | string | double

### **AccessAddress — Unique connection address**

'01234567' (default) | eight-element character vector or a string scalar

Unique connection address, specified as an eight-element character vector or a string scalar. This property indicates a unique 32-bit address generated by the LL for the new connection or for a periodic advertisement between two devices.

Data Types: char | string

### **CRCInitialization — CRC initialization value**

'012345' (default) | six-element character vector | three-octet hexadecimal value

CRC initialization value, specified as a six-element character vector or a string scalar denoting a three-octet hexadecimal value. This property is used as initialization value for the CRC calculation.

Data Types: char | string

### **WindowSize — Transmit window size**

1 (default) | nonnegative integer

Transmit window size, specified as a nonnegative integer in the range [1, Mws], where Mws is the lesser of 8 and ConnectionInterval-1. This property indicates the window size within which the master transmits the data packet and slave listens for the data packet after connection establishment. Each unit is taken as 1.25 ms so that the window size (WindowSize×1.25) is in the range of 1.25 ms to the minimum of (10 ms, ((ConnectionInterval×1.25) - 1.25) ms).

Data Types: double

### **WindowOffset — Transmit window offset**

0 (default) | nonnegative integer

Transmit window size, specified as a nonnegative integer in the range  $[0, Mwo]$ , where  $Mwo$  is the lesser of 3200 and `ConnectionInterval`. This property indicates the window offset after which the transmit window starts. Each unit is taken as 1.25 ms so that the resultant window offset ( $WindowOffset \times 1.25$ ) is in the range of 0 ms to  $(ConnectionInterval \times 1.25)$  ms.

Data Types: double

### **ConnectionInterval — Connection interval**

6 (7.5 ms) (default) | positive integer

Connection interval, specified as a positive integer in the range  $[6, 3200]$ . This property indicates the interval between the start of two consecutive connection events. Each unit is taken as 1.25 ms so that the resultant connection interval ( $ConnectionInterval \times 1.25$ ) is in the range of 7.5 ms to 4.0 s.

Data Types: double

### **SlaveLatency — Slave latency**

0 (default) | nonnegative integer

Slave latency, specified as a nonnegative integer in the range  $[0, Msl]$ , where  $Msl$  is the lesser of 499 and  $((ConnectionInterval \times 10) / ((ConnectionInterval \times 1.25) \times 2)) - 1$ . This property indicates the number of connection events that a slave can skip listening for packets from the master.

Data Types: double

### **ConnectionTimeout — Connection supervision timeout**

10 (default) | positive integer

Connection supervision timeout, specified as a positive integer in the range  $[Mct, 3200]$ , where  $Mct$  is the larger of 10 and  $((1 + SlaveLatency) \times (ConnectionInterval \times 1.25) \times 2) / 10$ . This property indicates the timeout for a connection if no valid packet is received within this time. Each unit is taken as 10 ms so that the resultant connection timeout ( $ConnectionInterval \times 10$ ) is in the range of 100 ms to 32.0 s.

Data Types: double

### **UsedChannels — List of used data channels**

row vector containing the channel indices between  $[0:36]$  (default) | integer vector with element values in the range  $[0, 36]$

List of used data channels, specified as an integer vector with element values in the range [0, 36]. The vector length must be greater than 1. At least two channels must be set as used (good) channels. This property indicates the set of good channels classified by the master.

Data Types: double

### **HopIncrement** — Hop increment count

5 (default) | positive integer

Hop increment count, specified as an integer in the range [5, 16]. This property indicates the hop increment count to be used for hopping between data channels.

Data Types: double

### **SleepClockAccuracy** — Master sleep clock accuracy

'251 to 500 ppm' (default) | '151 to 250 ppm' | '101 to 150 ppm' | ...

Master sleep clock accuracy, specified as a character vector or a string scalar indicating the worst case master sleep clock accuracy. You can specify `SleepClockAccuracy` as one of these values:

- '251 to 500 ppm'
- '151 to 250 ppm'
- '101 to 150 ppm'
- '76 to 100 ppm'
- '51 to 75 ppm'
- '31 to 50 ppm'
- '21 to 30 ppm'
- '0 to 20 ppm'

Data Types: char | string

## **Object Functions**

### **Specific to This Object**

bleLLAdvertisingChannelPDU

Generate BLE LL advertising channel PDU

bleLLAdvertisingChannelPDUDecode Decode BLE LL advertising channel PDU

## Examples

### Create BLE LL Advertising Channel PDU Configuration Object Using Default Settings

Create a BLE LL advertising channel configuration object and view the corresponding default properties.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig

cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:

        PDUType: 'Advertising indication'
        ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
        AdvertisingData: [3x2 char]
```

### Create BLE LL Advertising Channel PDU Configuration Object Using Name-Value Pairs

Create two unique BLE LL advertising channel configuration objects of type 'Scan response' and 'Connection indication' using name-value pairs.

Create a BLE LL advertising channel PDU configuration object, 'cfgLLAdv', by setting the values of PDU type as 'Scan response', advertiser address as '1234567890AB', and scan response data as '020106020AD3' using name-value pairs. View the corresponding properties.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig(...
    'PDUType','Scan response', ...
    'AdvertiserAddress','1234567890AB', ...
    'ScanResponseData','020106020AD3')
```

```

cfgLLAdv =
  bleLLAdvertisingChannelPDUConfig with properties:
      PDUType: 'Scan response'
      ChannelSelection: 'Algorithm1'
      AdvertiserAddressType: 'Random'
      AdvertiserAddress: '1234567890AB'
      ScanResponseData: [6x2 char]

```

Create another BLE LL advertising channel PDU configuration object, 'cfgLLAdv', and change the type of PDU to 'Connection indication'. Set the values of the connection interval as 64 and the set of data channels as [0 4 12 16 18 24 25]. View the corresponding properties.

```

cfgLLAdv = bleLLAdvertisingChannelPDUConfig('PDUType', ...
  'Connection indication');
cfgLLAdv.ConnectionInterval = 64;
cfgLLAdv.UsedChannels       = [0 4 12 16 18 24 25]

cfgLLAdv =
  bleLLAdvertisingChannelPDUConfig with properties:
      PDUType: 'Connection indication'
      ChannelSelection: 'Algorithm1'
      AdvertiserAddressType: 'Random'
      AdvertiserAddress: '0123456789AB'
      InitiatorAddressType: 'Random'
      InitiatorAddress: '0123456789CD'
      AccessAddress: '01234567'
      CRCInitialization: '012345'
      WindowSize: 1
      WindowOffset: 0
      ConnectionInterval: 64
      SlaveLatency: 0
      ConnectionTimeout: 10
      UsedChannels: [0 4 12 16 18 24 25]
      HopIncrement: 5
      SleepClockAccuracy: '251 to 500 ppm'

```

### End-to-End Workflow of BLE LL Advertising Channel PDU

Create a BLE LL advertising channel PDU configuration object, 'cfgTx'. Set the values of PDU type as 'Connection indication', the connection interval as 8, and the set of data channels as [0 4 12 16 18 24 25].

```
cfgTx = bleLLAdvertisingChannelPDUConfig('PDUType', ...  
    'Connection indication');  
cfgTx.ConnectionInterval = 8;  
cfgTx.UsedChannels       = [0 4 12 16 18 24 25]
```

```
cfgTx =  
    bleLLAdvertisingChannelPDUConfig with properties:
```

```
        PDUType: 'Connection indication'  
        ChannelSelection: 'Algorithm1'  
AdvertiserAddressType: 'Random'  
AdvertiserAddress: '0123456789AB'  
InitiatorAddressType: 'Random'  
InitiatorAddress: '0123456789CD'  
AccessAddress: '01234567'  
CRCInitialization: '012345'  
WindowSize: 1  
WindowOffset: 0  
ConnectionInterval: 8  
SlaveLatency: 0  
ConnectionTimeout: 10  
UsedChannels: [0 4 12 16 18 24 25]  
HopIncrement: 5  
SleepClockAccuracy: '251 to 500 ppm'
```

Generate a BLE LL advertising channel PDU by using the corresponding configuration object.

```
pdu = bleLLAdvertisingChannelPDU(cfgTx);
```

Decode the generated BLE LL advertising channel PDU. The returned status indicates decoding is successful. View the output of 'status' and 'cfgRx'.

```
[status, cfgRx] = bleLLAdvertisingChannelPDUDecode(pdu)
```

```
status =  
Success
```

```
cfgRx =
  bleLLAdvertisingChannelPDUConfig with properties:
      PDUType: 'Connection indication'
      ChannelSelection: 'Algorithm1'
  AdvertiserAddressType: 'Random'
  AdvertiserAddress: '0123456789AB'
  InitiatorAddressType: 'Random'
  InitiatorAddress: '0123456789CD'
  AccessAddress: '01234567'
  CRCInitialization: '012345'
  WindowSize: 1
  WindowOffset: 0
  ConnectionInterval: 8
  SlaveLatency: 0
  ConnectionTimeout: 10
  UsedChannels: [0 4 12 16 18 24 25]
  HopIncrement: 5
  SleepClockAccuracy: '251 to 500 ppm'
```

### Introduced in R2019b

## bleGAPDataBlockConfig

Create configuration object for BLE GAP data block

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

### Description

The `bleGAPDataBlockConfig` creates a configuration object for a Bluetooth low energy (BLE) generic access profile (GAP) data block of the type advertising data (AD) or scan response data (SRD). You can configure a BLE GAP data block using the applicable properties of `bleGAPDataBlockConfig`.

### Creation

### Syntax

```
cfgGAP = bleGAPDataBlockConfig
cfgGAP = bleGAPDataBlockConfig(Name,Value)
```

### Description

`cfgGAP = bleGAPDataBlockConfig` creates a configuration object, `cfgGAP`, for a BLE GAP data block of the type AD or SRD with default values.

`cfgGAP = bleGAPDataBlockConfig(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bleGAPDataBlockConfig('AdvertisingDataTypes','Tx power level')` configures `cfgGAP` with block data advertising data type as 'Tx power level'.

## Properties

---

**Note** For more information about BLE GAP data block properties and their respective values, see vol 3, part C, section 4 of the Bluetooth Core Specification [2].

---

### AdvertisingDataTypes — Block data advertising data types

'Flags' (default) | 'UUIDs' | 'Local name' | 'Tx power level' | 'Connection interval range' | 'Advertising interval'

Block data advertising data types, specified as a character vector or a string scalar or a cell array, containing the list of advertising data types for BLE GAP data block. You can specify `AdvertisingDataTypes` as one of these values:

- 'Flags'
- 'UUIDs'
- 'Local name'
- 'Tx power level'
- 'Connection interval range'
- 'Advertising interval'

Data Types: char | string | cell

### LEDiscoverability — LE discoverable mode

'General' (default) | 'None' | 'Limited' | 'Limited and general'

LE discoverable mode, specified as a character vector or a string scalar, describing the LE discoverable mode of the device. You can specify `LEDiscoverability` as one of these values:

- 'None'
- 'General'
- 'Limited'
- 'Limited and general'

Data Types: char | string

### BREDR — Basic rate (BR) or enhanced data rate (EDR ) support

false (default) | true

Basic rate (BR) or enhanced data rate (EDR) support, specified as `true` or `false`. A `true` value indicates that BR or EDR is supported. This is used when `AdvertisingDataTypes` is set to `'Flags'`.

Data Types: `logical`

### **LE — Simultaneous LE and BR or EDR support**

`'None'` (default) | `'Host'` | `'Controller'` | `'Host and controller'`

Simultaneous LE and BR/EDR support, specified as a character vector or a string scalar. You can specify `'LE'` as one of these values:

- `'None'`
- `'Host'`
- `'Controller'`
- `'Host and controller'`

This property is applicable only when `BREDR` is set to `true`. Set this property to `'Host'` or `'Controller'` to specify simultaneous LE and BR or EDR support at the host or the controller respectively. Set this property to `'Host and Controller'` for simultaneous LE and BR or EDR support at the host and the controller.

Data Types: `char` | `string`

### **LocalNameShortening — Enable shortening of local name**

`false` (default) | `true`

Local name shortened used, specified as a scalar logical value of `false` or `true`. Set this value to `true` value indicates that the name of the device is shortened.

Data Types: `logical`

### **LocalName — UTF-8 encoded user-friendly descriptive name**

`'Bluetooth'` (default) | character vector or a string scalar consisting of UTF-8 characters

UTF-8 encoded user-friendly descriptive name, specified as a character vector or a string scalar consisting of UTF-8 characters. This property specifies the local name assigned to the device.

Data Types: `char` | `string`

**IdentifierType — Type of 16-bit service or service class identifiers**

'Incomplete' (default) | 'Complete'

Type of 16-bit service or service class identifiers, specified as 'Incomplete' or 'Complete'. If this value is 'Incomplete', then the list of 16-bit service or service class identifiers list is incomplete.

Data Types: char | string

**Identifiers — List of 16-bit service or service class identifiers**

' ' (empty) (default) |  $n$ -by-4 character array

List of 16-bit service or service class identifiers, specified as an  $n$ -by-4 character array. The value of  $n$  must be in the range [0, 127]. Each row in the  $n$ -by-4 character array is represented as a four-element character vector or string scalar denoting a two-octet (16-bit) hexadecimal value of a service or service class universally unique identifier (UUID). These UUIDs are assigned by the Bluetooth Special Interest Group (SIG).

Data Types: char

**AdvertisingInterval — Advertising interval**

32 (default) | integer in the range [32, 65,535]

Advertising interval, specified as an integer in the range [32, 65,535]. This property denotes the interval between the start of two consecutive advertising events. Incremental units are 0.625 ms steps, so the resultant range for [32, 65,535] is [20, 40.959375].

Data Types: double

**TxPowerLevel — Packet transmit power level**

0 (dBm) (default) | integer in the range [-127, 127]

Packet transmit power level, in dBm, specified as an integer in the range [-127, 127]. This property calculates the pathloss as  $pathloss = Tx\ Power\ Level - RSSI$ , where  $RSSI$  is the received signal strength indicator.

Data Types: double

**ConnectionIntervalRange — Connection interval range**

[6, 3200] (default) | two-element numeric vector [MIN, MAX]

Connection interval range, specified as a two-element numeric vector [MIN, MAX], where MIN and MAX must be in the range [6,3200]. MIN and MAX specify the minimum and maximum value for the connection interval respectively. MIN must be less than or equal

to *MAX*. Incremental units are 1.25 ms steps, so that the resultant range for [6, 3200] is [7.5, 4.0].

Data Types: double

## Object Functions

### Specific to This Object

bleGAPDataBlock           Generate BLE GAP data block  
bleGAPDataBlockDecode   Decode BLE GAP data block

## Examples

### Create BLE GAP AD Block Configuration Object Using Default Settings

Create two unique BLE GAP AD configuration objects: one with AD types 'Flags' and 'Tx power level' and the other with AD type 'Flags' and simultaneous LE and BR or EDR support at the host.

Create a BLE GAP AD block configuration object using default settings. Set the values of AD types as 'Flags' and 'Tx power level', LE discoverability as 'Limited' and Tx power level as 45. View the properties of the corresponding configuration object.

```
cfgGAP = bleGAPDataBlockConfig;  
cfgGAP.AdvertisingDataTypes = {'Flags'; 'Tx power level'};  
cfgGAP.LEDiscoverability = 'Limited';  
cfgGAP.TxPowerLevel = 45
```

```
cfgGAP =  
  bleGAPDataBlockConfig with properties:
```

```
  AdvertisingDataTypes: {2x1 cell}  
  LEDiscoverability: 'Limited'  
  BREDR: 0  
  TxPowerLevel: 45
```

Create another BLE GAP AD block configuration object using default settings, this time with AD type 'Flags' and having simultaneous support for LE and BR/EDR. Set the

values of LE discoverability as 'Limited', enable BR or EDR support as true and enable simultaneous support for LE and BR or EDR as 'Host'. View the properties of the corresponding configuration object.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.LEDiscoverability = 'Limited and general';
cfgGAP.BREDR = true;
cfgGAP.LE = 'Host'

cfgGAP =
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {'Flags'}
    LEDiscoverability: 'Limited and general'
    BREDR: 1
    LE: 'Host'
```

### Create BLE GAP AD Block Configuration Object Using Name-Value Pairs

Create a configuration object for a BLE GAP AD block using name-value pairs. Set the values of AD types as 'Advertising interval' and 'Local name', advertising interval as 48, local name as 'MathWorks' and local name shortening as true. View the properties of the corresponding configuration object.

```
cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
    {'Advertising interval', ...
    'Local name'});
cfgGAP.AdvertisingInterval = 48;
cfgGAP.LocalName = 'MathWorks';
cfgGAP.LocalNameShortening = true

cfgGAP =
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
    LocalName: 'MathWorks'
    LocalNameShortening: 1
    AdvertisingInterval: 48
```

### End-to-End Workflow of BLE GAP AD Blocks

Create a configuration object for a BLE GAP AD block using name-value pairs. Set the values of AD types as 'Advertising interval' and 'Local name', advertising interval as 48, local name as 'MathWorks', and local name shortening as true. View the properties of the corresponding configuration object.

```
cfgTx = bleGAPDataBlockConfig('AdvertisingDataTypes',{ 'Advertising interval', 'Local name' }, ...  
cfgTx.AdvertisingInterval = 48;  
cfgTx.LocalName = 'MathWorks';  
cfgTx.LocalNameShortening = true
```

```
cfgTx =  
    bleGAPDataBlockConfig with properties:
```

```
    AdvertisingDataTypes: {2x1 cell}  
        LocalName: 'MathWorks'  
    LocalNameShortening: 1  
    AdvertisingInterval: 48
```

Create a BLE GAP AD block using the configuration object 'cfgTx'.

```
dataBlock = bleGAPDataBlock(cfgTx);
```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful. View the output of 'status' and 'cfgRx'.

```
[status, cfgRx] = bleGAPDataBlockDecode(dataBlock)
```

```
status =  
Success
```

```
cfgRx =  
    bleGAPDataBlockConfig with properties:
```

```
    AdvertisingDataTypes: {2x1 cell}  
        LocalName: 'MathWorks'  
    LocalNameShortening: 1  
    AdvertisingInterval: 48
```

### Functions

`bleGAPDataBlock` | `bleGAPDataBlockDecode`

### Topics

"Bluetooth Protocol Stack"

**Introduced in R2019b**

## comm.BlockDeinterleaver

**Package:** comm

(To be removed) Deinterleave input symbols using permutation vector

### Compatibility

comm.BlockDeinterleaver will be removed in a future release. Use `deintrlv` instead. For more information, see “Compatibility Considerations” on page 4-209.

### Description

The `BlockDeinterleaver` object, which can process variable-sized signals, rearranges the elements of its input vector without repeating or omitting any elements. The input can be real or complex.

To deinterleave the input vector:

- 1 Define and set up your block deinterleaver object. See “Construction” on page 4-206.
- 2 Call `step` to rearrange the elements of the input vector according to the properties of `comm.BlockDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.BlockDeinterleaver` creates a block deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the block interleaver System object.

`H = comm.BlockDeinterleaver(Name, Value)` creates object, `H`, with the specified property set to the specified value.

## Properties

### PermutationVectorSource

Permutation vector source

Specify the source of the permutation vector as either `Property` or `Input port`. The default value is `Property`.

### PermutationVector

Permutation vector

Specify the mapping used to permute the input symbol as a column vector of integers. The default is `[5;4;3;2;1]`. The mapping is a column vector of integers where the number of elements is equal to the length,  $N$ , of the input to the step method. Each element must be an integer, between 1 and  $N$ , with no repeated values. The `PermutationVector` property is available only when the `PermutationVectorSource` property is set to `Property`.

## Methods

`step` (To be removed) Deinterleave input symbols using permutation vector

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Block Interleaving and Deinterleaving

Create interleaver and deinterleaver objects.

```
interleaver = comm.BlockInterleaver([3 4 1 2]');
```

Warning: COMM.BLOCKINTERLEAVER will be removed in a future release. Use INTRLV instead.

```
deinterleaver = comm.BlockDeinterleaver([3 4 1 2]');
```

Warning: COMM.BLOCKDEINTERLEAVER will be removed in a future release. Use DEINTRLV instead.

Pass random data through the interleaver and deinterleaver.

```
data = randi(7,4,1);  
intData = interleaver(data);  
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data, intData, deIntData]
```

```
ans = 4×3
```

```
     6     1     6  
     7     7     7  
     1     6     1  
     7     7     7
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical  
     1
```

Generate a random vector of unique integers as a permutation vector.

```
permVec = randperm(7)';
```

Specify permVec as the permutation vector for the interleaver and deinterleaver objects.

```
interleaver = comm.BlockInterleaver(permVec);
```

Warning: COMM.BLOCKINTERLEAVER will be removed in a future release. Use INTRLV instead.

```
deinterleaver = comm.BlockDeinterleaver(permVec);
```

Warning: COMM.BLOCKDEINTERLEAVER will be removed in a future release. Use DEINTRLV instead.

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,7,1);  
intData = interleaver(data);  
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical  
     1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General Block Deinterleaver block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

### **comm.BlockDeinterleaver will be removed**

*Not recommended starting in R2019b*

comm.BlockDeinterleaver will be removed in a future release. Use `deintrlv` instead.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## See Also

### Functions

`deintrlv` | `intrlv`

**Introduced in R2012a**

## step

**System object:** `comm.BlockDeinterleaver`

**Package:** `comm`

(To be removed) Deinterleave input symbols using permutation vector

## Compatibility

`step` will be removed in a future release. Use `deintrlv` instead.

## Syntax

`Y = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a block interleaver. The `step` method forms the output, `Y`, based on the mapping specified by the `PermutationVector` property as

**Output**(`PermutationVector(k)`)=**Input**(`k`), for  $k = 1:N$ , where  $N$  is the length of the permutation vector. The input `X` must be a column vector of the same length,  $N$ . The data type of `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.BlockInterleaver

**Package:** comm

(To be removed) Permute input symbols using permutation vector

## Compatibility

comm.BlockInterleaver will be removed in a future release. Use `intrlv` instead. For more information, see “Compatibility Considerations” on page 4-216.

## Description

The `BlockInterleaver` object permutes the symbols in the input signal. Internally, it uses a set of shift registers, each with its own delay value. This object processes variable-size signals.

To interleave the input signal:

- 1 Define and set up your block interleaver object. See “Construction” on page 4-213.
- 2 Call `step` to reorder the input symbols according to the properties of `comm.BlockInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.BlockInterleaver` creates a block interleaver System object, `H`. This object permutes the symbols in the input signal based on a permutation vector.

`H = comm.BlockInterleaver(Name, Value)` creates object, `H`, with specified property set to the specified value.

## Properties

### PermutationVectorSource

Permutation vector source

Specify the source of the permutation vector as either `Property` or `Input port`. The default value is `Property`.

### PermutationVector

Permutation vector

Specify the mapping used to permute the input symbols as an integer column vector. The default is `[5;4;3;2;1]`. The number of elements of the permutation vector property must equal the length of the input vector. The `PermutationVector` property indicates the indices, in order, of the input elements that form the output vector. The relationship **Output**( $k$ )=**Input**(`PermutationVector`( $k$ )) describes this order. Each integer,  $k$ , must be between 1 and  $N$ , where  $N$  is the number of elements in the permutation vector. The elements in the `PermutationVector` property must be integers between 1 and  $N$  with no repetitions. The `PermutationVector` property is available only when the `PermutationVectorSource` property is set to `Property`.

## Methods

`step` (To be removed) Permute input symbols using a permutation vector

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

## Block Interleaving and Deinterleaving

Create interleaver and deinterleaver objects.

```
interleaver = comm.BlockInterleaver([3 4 1 2]');
```

Warning: COMM.BLOCKINTERLEAVER will be removed in a future release. Use INTRLV instead.

```
deinterleaver = comm.BlockDeinterleaver([3 4 1 2]');
```

Warning: COMM.BLOCKDEINTERLEAVER will be removed in a future release. Use DEINTRLV instead.

Pass random data through the interleaver and deinterleaver.

```
data = randi(7,4,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data, intData, deIntData]
```

```
ans = 4x3
```

```

     6     1     6
     7     7     7
     1     6     1
     7     7     7
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical
      1
```

Generate a random vector of unique integers as a permutation vector.

```
permVec = randperm(7)';
```

Specify permVec as the permutation vector for the interleaver and deinterleaver objects.

```
interleaver = comm.BlockInterleaver(permVec);
```

Warning: COMM.BLOCKINTERLEAVER will be removed in a future release. Use INTRLV instead.

```
deinterleaver = comm.BlockDeinterleaver(permVec);
```

Warning: COMM.BLOCKDEINTERLEAVER will be removed in a future release. Use DEINTRLV instead.

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,7,1);  
intData = interleaver(data);  
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical  
     1
```

## Algorithms

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.BPSKDemodulator

**Package:** comm

Demodulate using BPSK method

### Description

The `BPSKDemodulator` object demodulates a signal that was modulated using the binary phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a binary phase shift signal:

- 1 Define and set up your BPSK demodulator object. See “Construction” on page 4-220.
- 2 Call `step` to demodulate a signal according to the properties of `comm.BPSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.BPSKDemodulator` creates a demodulator System object, `H`, that demodulates the input signal using the binary phase shift keying (BPSK) method.

`H = comm.BPSKDemodulator(Name,Value)` creates a BPSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.BPSKDemodulator(PHASE,Name,Value)` creates a BPSK demodulator object, `H`, with the `PhaseOffset` property set to `PHASE`, and the other specified properties set to the specified values.

## Properties

### PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a finite, real scalar. The default is 0.

### DecisionMethod

Demodulation decision method

Specify the decision method the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`.

### VarianceSource

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

### Variance

Noise variance

Specify the variance of the noise as a nonzero, real scalar. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations can yield `Inf` or `-Inf`. This variance occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite precision arithmetic. As a best practice in such cases, use approximate LLR because this option's algorithm does not compute exponentials. This property applies when you set the `VarianceSource` on page 4-0 property to `Property`. This property is tunable.

### OutputDataType

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `logical`.

The default is `Full precision`. This property applies only when you set the `DecisionMethod` on page 4-0 property to `Hard decision`. Thus, when you set the `OutputDataType` on page 4-0 property to `Full precision`, and the input data type is single or double precision, the output data has the same data type as the input. If the input data is of a fixed-point type, then the output data type behaves as if you had set the `OutputDataType` property to `Smallest unsigned integer`. If you set the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, the output data type is the same as that of the input. In this case, that data type can only be single or double precision.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

### **Fixed-Point Properties**

#### **DerotateFactorDataType**

Data type of derotate factor

Specify the derotate factor data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property applies when you set the `DecisionMethod` on page 4-0 property to `Hard decision`. The object uses the derotate factor in the computations only when certain conditions exist. The step method input must be of a fixed-point type, and the `PhaseOffset` on page 4-0 property must have a value that is not a multiple of  $\pi/2$ .

#### **CustomDerotateFactorDataType**

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an unscaled, `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `DecisionMethod` on page 4-0 property to `Hard decision` and the `DerotateFactorDataType` on page 4-0 property to `Custom`.

## Methods

constellation	Calculate or plot ideal signal constellation
step	Demodulate using BPSK method

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Demodulate BPSK Signal and Calculate Errors

Generate a BPSK signal, pass it through an AWGN channel, demodulate the signal, and compute the error statistics.

Create BPSK modulator and demodulator System objects.

```
bpskModulator = comm.BPSKModulator;
bpskDemodulator = comm.BPSKDemodulator;
```

Create an error rate calculator System object.

```
errorRate = comm.ErrorRate;
```

Generate 50-bit random data frames, apply BPSK modulation, pass the signal through an AWGN channel, demodulate the received data, and compile the error statistics.

```
for counter = 1:100
    % Transmit a 50-symbol frame
    txData = randi([0 1],50,1);           % Generate data
    modSig = bpskModulator(txData);      % Modulate
    rxSig = awgn(modSig,5);              % Pass through AWGN
    rxData = bpskDemodulator(rxSig);     % Demodulate
    errorStats = errorRate(txData,rxData); % Collect error stats
end
```

Display the cumulative error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.005600  
Number of errors = 28
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the BPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

# constellation

**System object:** comm.BPSKDemodulator

**Package:** comm

Calculate or plot ideal signal constellation

## Syntax

```
y = constellation(h)  
constellation(h)
```

## Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

## Examples

### Calculate Reference Signal Constellation for BPSK Demodulator

Create BPSK Demodulator System object™ and calculate its reference constellation.

Create a `comm.BPSKDemodulator` System object.

```
h = comm.BPSKDemodulator;
```

Calculate and display the reference signal constellation by calling the `constellation` function.

```
refC = constellation(h)
```

```
refC = 2×1 complex
```

```
1.0000 + 0.0000i  
-1.0000 + 0.0000i
```

### Plot BPSK Demodulator Reference Signal Constellation

Create a BPSK Demodulator System object™ and then plot the reference signal constellation.

Create a `comm.BPSKDemodulator` System object.

```
h = comm.BPSKDemodulator;
```

Plot the reference constellation by calling the `constellation` function.

```
constellation(h)
```

# step

**System object:** comm.BPSKDemodulator

**Package:** comm

Demodulate using BPSK method

## Syntax

`Y = step(H,X)`

`Y = step(H,X,VAR)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` demodulates input data, `X`, with the BPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. When you set the `DecisionMethod` property to `Hard decision`, the data type of the input can also be signed integer, or signed fixed point (fi objects).

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio` and the `VarianceSource` property to `Input port`. The data type of input `VAR` must be double or single precision.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.IQImbalanceCompensator

**Package:** comm

Compensate for I/Q imbalance

### Description

The `IQImbalanceCompensator` System object compensates for the imbalance between the in-phase and quadrature components of a modulated signal.

To compensate for I/Q imbalance:

- 1 Define and set up the `IQImbalanceCompensator` object. See “Construction” on page 4-231.
- 2 Call `step` to compensate for the I/Q imbalance according to the properties of `comm.IQImbalanceCompensator`. The behavior of `step` is specific to each object in the toolbox.

The adaptive algorithm inherent to the I/Q imbalance compensator is compatible with M-PSK, M-QAM, and OFDM modulation schemes, where  $M > 2$ .

---

**Note** The output of the compensator might be scaled and rotated, that is, multiplied by a complex number, relative to the reference constellation. In practice, this is not an issue as receivers correct for this prior to demodulation through the use of channel estimation.

---

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.IQImbalanceCompensator` creates a compensator System object, `H`, that compensates for the imbalance between the in-phase and quadrature components of the input signal.

`H = comm.IQImbalanceCompensator(Name, Value)` creates an I/Q imbalance compensator object, `H`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### CoefficientSource

Source of compensator coefficients

Specify either `Estimated from input signal` or `Input port`. If the `CoefficientSource` property is set to `Estimated from input signal`, the compensator uses an adaptive algorithm to estimate the compensator coefficient from the input signal. If the `CoefficientSource` property is set to `Input port`, all other properties are disabled and the compensator coefficients must be provided to the step function as an input argument. The default value is `Estimated from input signal`. This property is nontunable.

### InitialCoefficient

Initial coefficient used to compensate for I/Q imbalance

The initial coefficient is a complex scalar that can be either single or double precision. The default value is  $0+0i$ . This property is nontunable.

### StepSizeSource

Source of step size for coefficient adaptation

Specify either `Property` or `Input port`. If `StepSizeSource` is set to `Property`, you specify the step size through the `StepSize` property. Otherwise, the step size is provided to the step function as an input argument. The default value is `Property`. This property is nontunable.

### StepSize

Adaptation step size

Specifies the step size used by the algorithm in estimating the I/Q imbalance. This property is accessible only when `StepSizeSource` is set to `Property`. The default value is `1e-5`. This property is tunable.

### AdaptInputPort

Creates input port to control compensator coefficient adaptation

When this logical property is `true`, an input port is created to enable or disable coefficient adaptation. If `AdaptInputPort` is `false`, the coefficients update after each output sample. The default value is `false`. This property is nontunable.

### CoefficientOutputPort

Create port to output compensator coefficients

When this logical property is `true`, the I/Q imbalance compensator coefficients are made available through an output argument of the step function. The default value is `false`. This property is nontunable.

## Methods

`step`    Compensate I/Q Imbalance

`reset`    Reset states of the `IQImbalanceCompensator` System object

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

## Remove I/Q Imbalance from a QPSK Signal

Mitigate the impacts of amplitude and phase imbalance on a QPSK modulated signal by using the comm.IQImbalanceCompensator System object?

Create a constellation diagram object. Specify name-value pairs to ensure that the constellation diagram displays only the last 100 data symbols.

```
constDiagram = comm.ConstellationDiagram(...
    'SymbolsToDisplaySource','Property', ...
    'SymbolsToDisplay',100);
```

Create an I/Q imbalance compensator.

```
iqImbComp = comm.IQImbalanceCompensator;
```

Generate random data symbols and apply QPSK modulation.

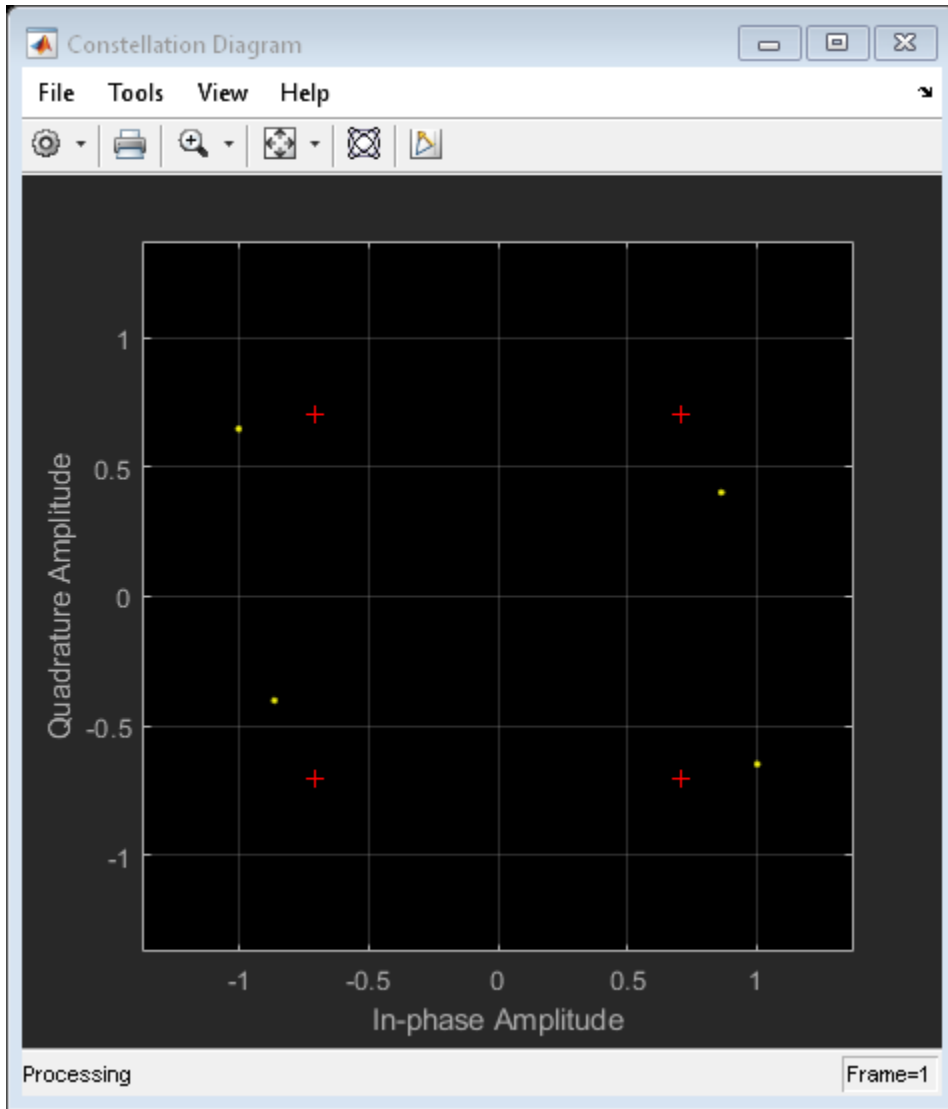

```
data = randi([0 3],1e7,1);
txSig = pskmod(data,4,pi/4);
```

Apply amplitude and phase imbalance to the transmitted signal.

```
ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

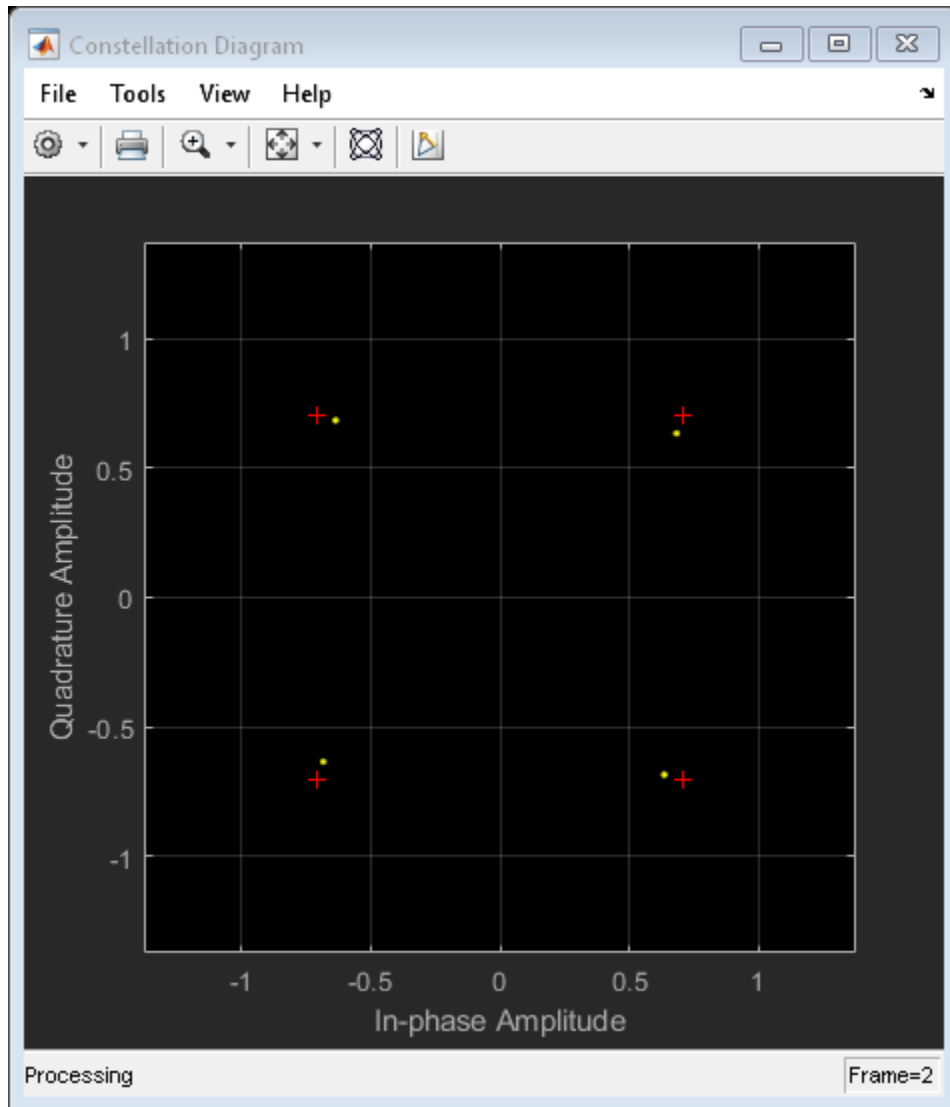

Plot the constellation diagram of the received signal. Observe that the received signal experienced an amplitude and phase shift.

```
constDiagram(rxSig)
```

Apply the I/Q compensation algorithm and view the constellation. The compensated signal constellation is nearly aligned with the reference constellation.

```
compSig = iqImbComp(rxSig);
constDiagram(compSig)
```

### Remove I/Q Imbalance from an 8-PSK Signal using External Coefficients

Compensate for an amplitude and phase imbalance on an 8-PSK signal by using the `comm.IQImbalanceCompensator` System object™ with external coefficients.

Create 8-PSK modulator and constellation diagram System objects. Use name-value pairs to ensure that the constellation diagram displays only the last 100 data symbols and to provide the reference constellation.

```
hMod = comm.PSKModulator(8);  
refC = constellation(hMod);  
hScope = comm.ConstellationDiagram(...  
    'SymbolsToDisplaySource','Property', ...  
    'SymbolsToDisplay',100, ...  
    'ReferenceConstellation',refC);
```

Create an I/Q imbalance compensator object with an input port for the algorithm coefficients.

```
hIQComp = comm.IQImbalanceCompensator('CoefficientSource','Input port');
```

Generate random data symbols and apply 8-PSK modulation.

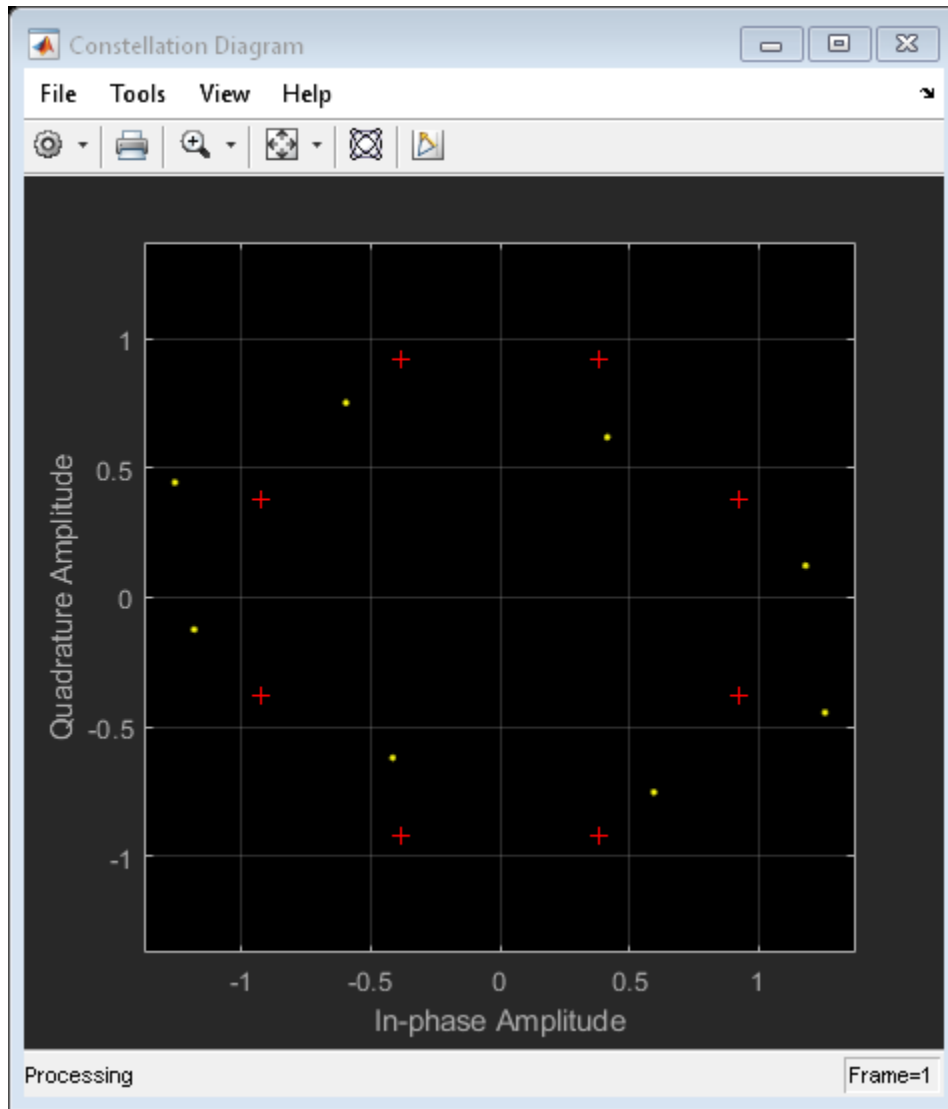

```
data = randi([0 7],1000,1);  
txSig = step(hMod,data);
```

Apply amplitude and phase imbalance to the transmitted signal.

```
ampImb = 5; % dB  
phImb = 15; % deg  
gainI = 10.^(0.5*ampImb/20);  
gainQ = 10.^(-0.5*ampImb/20);  
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);  
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));  
rxSig = imbI + imbQ;
```

Plot the constellation diagram of the received signal. Observe that the received signal experienced an amplitude and phase shift.

```
step(hScope,rxSig);
```

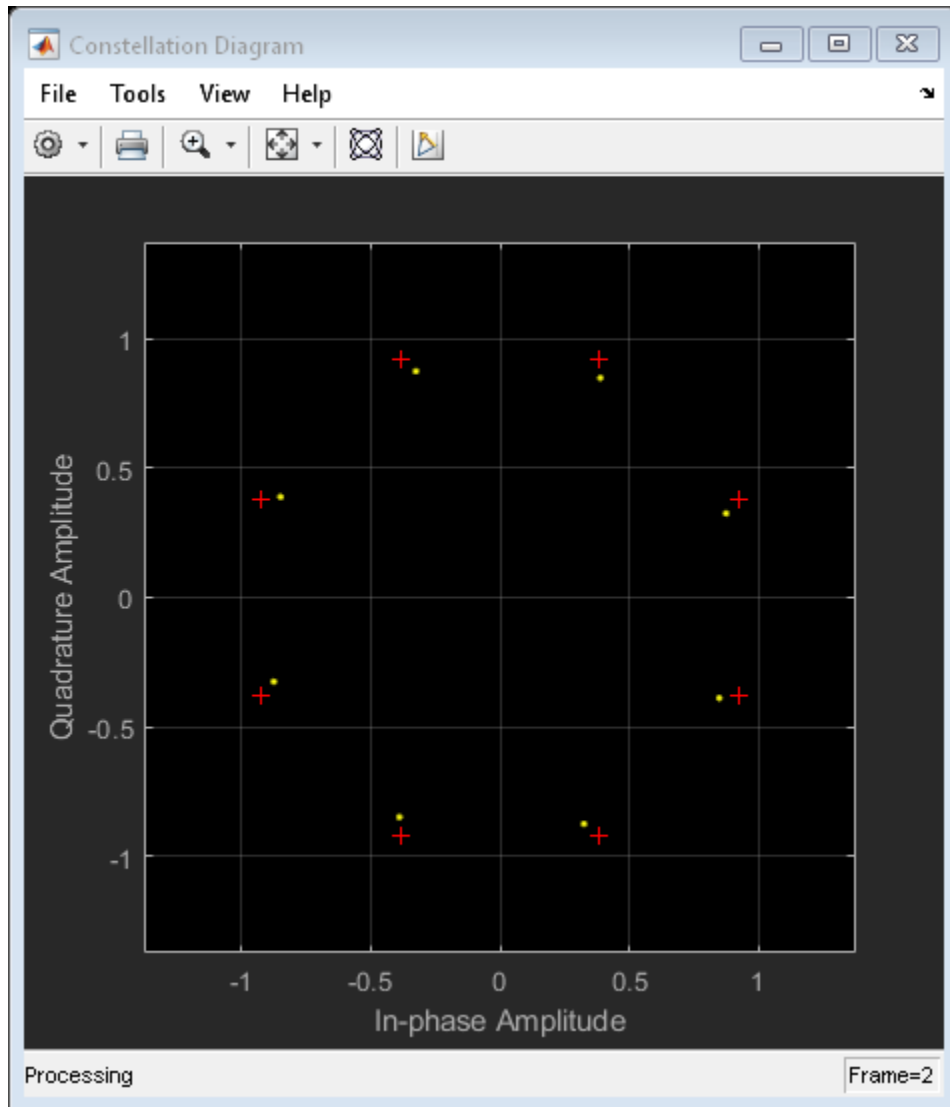

Use the `iqimbal2coef` function to determine the compensation coefficient given the amplitude and phase imbalance.

```
compCoef = iqimbal2coef(ampImb,phImb);
```

Apply the compensation coefficient to the received signal using the `step` function of the `comm.IQImbalanceCompensator` object and view the resultant constellation. You can see that the compensated signal constellation is now nearly aligned with the reference constellation.

```
compSig = step(hIQComp,rxSig,compCoef);  
step(hScope,compSig)
```

### Remove I/Q Imbalance from a QAM Signal

Remove an I/Q imbalance from a 64-QAM signal and to make the estimated coefficients externally available while setting the algorithm step size from an input port.

Create a constellation diagram object. Use name-value pairs to ensure that the constellation diagram displays only the last 256 data symbols, set the axes limits, and specify the reference constellation.

```
M = 64;
refC = qammod(0:M-1,M);
constDiagram = comm.ConstellationDiagram(...
    'SymbolsToDisplaySource','Property', ...
    'SymbolsToDisplay',256, ...
    'XLimits',[-10 10],'YLimits',[-10 10], ...
    'ReferenceConstellation',refC);
```

Create an I/Q imbalance compensator System object in which the step size is specified as an input argument and the estimated coefficients are made available through an output port.

```
iqImbComp = comm.IQImbalanceCompensator('StepSizeSource','Input port', ...
    'CoefficientOutputPort',true);
```

Generate random data symbols and apply 64-QAM modulation.

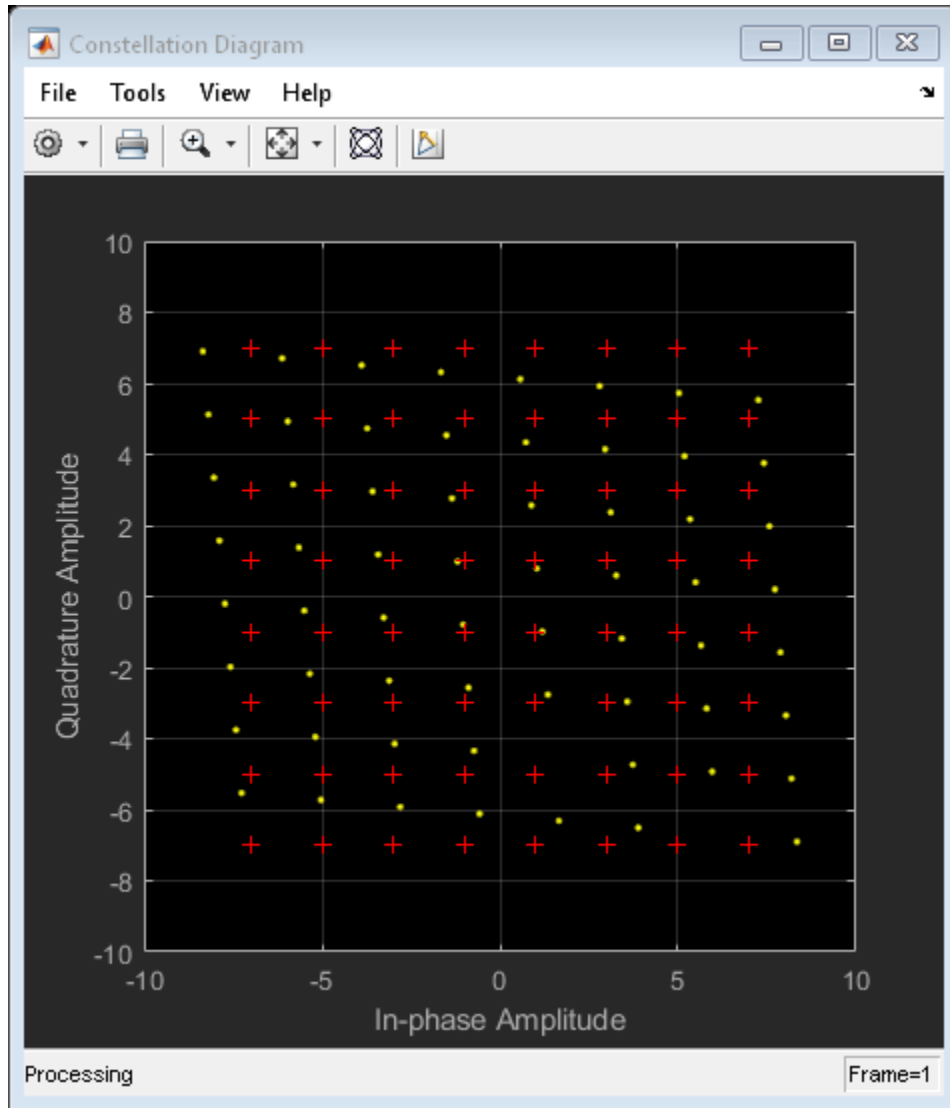

```
nSym = 25000;
data = randi([0 M-1],nSym,1);
txSig = qammod(data,M);
```

Apply amplitude and phase imbalance to the transmitted signal.

```
ampImb = 2; % dB
phImb = 10; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Plot the constellation diagram of the received signal.

```
constDiagram(rxSig);
```

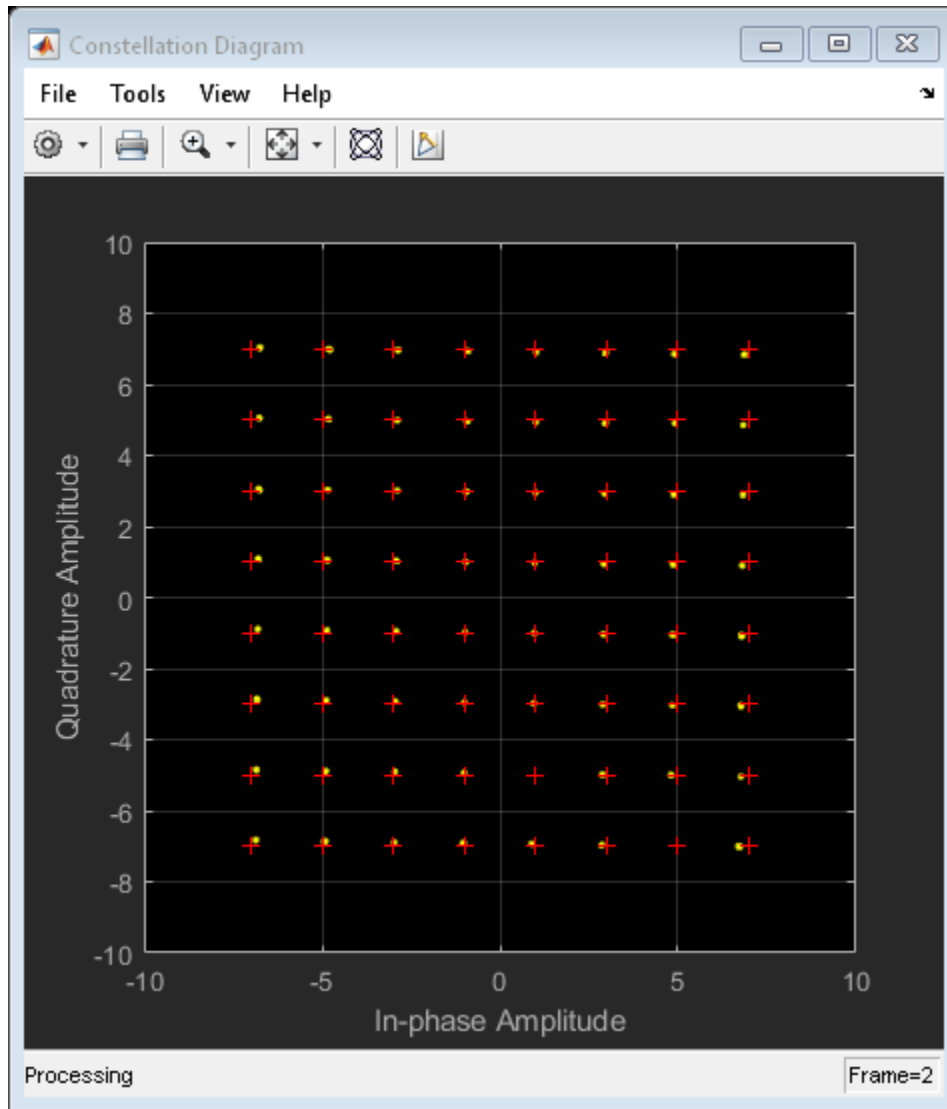

Specify the step size parameter for the I/Q imbalance compensator.

```
stepSize = 1e-5;
```

Compensate for the I/Q imbalance while setting the step size via an input argument. You can see that the compensated signal constellation is now nearly aligned with the reference constellation.

```
[compSig,estCoef] = iqImbComp(rxSig,stepSize);  
constDiagram(compSig)
```

Plot the real and imaginary values of the estimated coefficients. You can see that they reach a steady-state solution.

```
plot((1:nSym)'/1000,[real(estCoef),imag(estCoef)])  
grid
```

```
xlabel('Symbols (thousands)')  
ylabel('Coefficient Value')  
legend('Real', 'Imag', 'location', 'best')
```

### Control Adaptation Algorithm for I/Q Imbalance Compensator

Control the adaptation algorithm of the I/Q imbalance compensator using an external argument.

Apply QPSK modulation to random data symbols.

```
data = randi([0 3],600,1);  
txSig = pskmod(data,4,pi/4,'gray');
```

Create an I/Q imbalance compensator in which the adaptation algorithm is controlled through an input port, the step size is specified through the `StepSize` property, and the estimated coefficients are made available through an output port.

```
iqImbComp = comm.IQImbalanceCompensator('AdaptInputPort',true, ...
    'StepSize',0.001,'CoefficientOutputPort',true);
```

Apply amplitude and phase imbalance to the transmitted signal.

```
ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Break the compensation operation into three segments in which the compensator is enabled for the first 200 symbols, disabled for the next 200 symbols, and enabled for the last 200 symbols. Save the coefficient data in three vectors.

```
[~,estCoef1] = iqImbComp(rxSig(1:200),true);
[~,estCoef2] = iqImbComp(rxSig(201:400),false);
[~,estCoef3] = iqImbComp(rxSig(401:600),true);
```

Concatenate the complex algorithm coefficients and plot their real and imaginary parts.

```
estCoef = [estCoef1; estCoef2; estCoef3];
plot((1:600)',[real(estCoef) imag(estCoef)])
grid
xlabel('Symbols')
ylabel('Coefficient Value')
legend('Real','Imaginary','location','best')
```

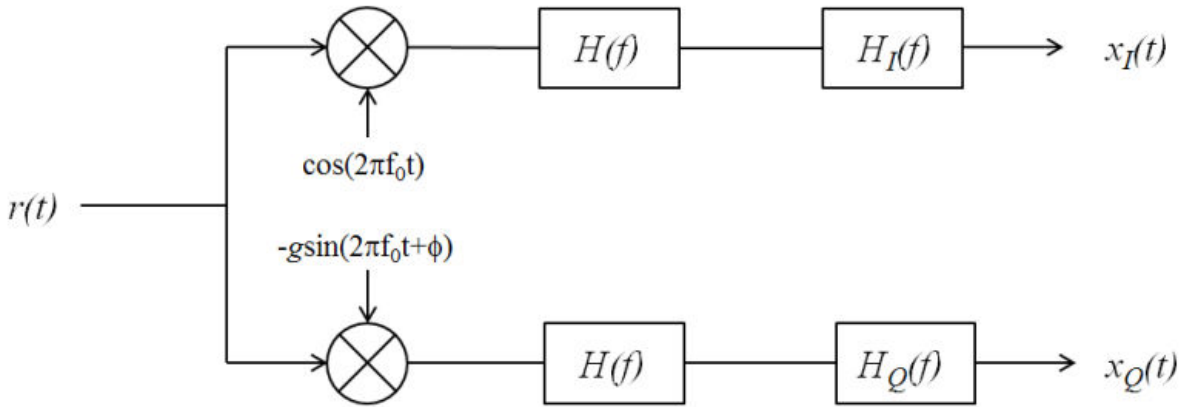

Observe that the coefficients do not adapt during the time in which the compensator is disabled.

## Algorithms

One of the major impairments affecting direct conversion receivers is the imbalance between the received signal's in-phase and quadrature components. Rather than improving the front-end, analog hardware, it is more cost effective to tolerate a certain level of I/Q imbalance and then implement compensation methods. A circularity-based blind compensation algorithm is used as the basis for the I/Q Imbalance Compensator.

A generalized I/Q imbalance model is shown, where  $g$  is the amplitude imbalance and  $\phi$  is the phase imbalance (ideally,  $g = 1$  and  $\phi = 0$ ). In the figure,  $H(f)$  is the nominal frequency response of the branches due to, for example, lowpass filters.  $H_I(f)$  and  $H_Q(f)$  represent the portions of the in-phase and quadrature amplitude and phase responses that differ from the nominal response. With perfect matching,  $H_I(f) = H_Q(f) = 1$ .

Let  $z(t)$  be the ideal baseband equivalent signal of the received signal,  $r(t)$ , where its Fourier transform is denoted as  $Z(f)$ . Given the generalized I/Q imbalance model, the Fourier transform of the imbalanced signal,  $x(t) = x_I(t) + x_Q(t)$ , is

$$X(f) = G_1(f)Z(f) + G_2(f)Z^*(-f)$$

where  $G_1(f)$  and  $G_2(f)$  are the direct and conjugate components of the I/Q imbalance. These components are defined as

$$G_1(f) = [H_I(f) + H_Q(f)g \exp(-j\phi)]/2$$

$$G_2(f) = [H_I(f) + H_Q(f)g \exp(j\phi)]/2$$

Applying the inverse Fourier transform to  $X(f)$ , the signal model becomes  $x(t) = g_1(t) * z(t) + g_2(t) * z^*(t)$ .

This suggests the compensator structure as shown in which discrete-time notation is used to express the variables. The compensated signal is expressed as  $y(n) = x(n) + wx^*(n)$ .

A simple algorithm of the form

$$\begin{cases} y(n) = x(n) + w(n)x^*(n) \\ w(n+1) = w(n) - My^2(n) \end{cases}$$

is used to determine the weights, because it ensures that the output is “proper”, that is,  $E[y^2(n)] = 0$  [1]. The initial value of  $w$  is determined by the `InitialCoefficient` property, which has a default value of  $\theta + \theta i$ .  $M$  is the step size, as specified in the `StepSize` property.

**Package:** comm

Compensate I/Q Imbalance

## Syntax

$Y = \text{step}(H, X)$

$Y = \text{step}(H, X, \text{COEF})$

$Y = \text{step}(H, X, \text{STEP SIZE})$

$Y = \text{step}(H, \dots, \text{ADAPT})$

$[Y, \text{ESTCOEF}] = \text{step}(H, X)$

$[Y, \text{ESTCOEF}] = \text{step}(H, X, \text{STEP SIZE})$

$[Y, \text{ESTCOEF}] = \text{step}(H, X, \text{STEP SIZE}, \text{ADAPT})$

$[Y, \text{ESTCOEF}] = \text{step}(H, X, \text{ADAPT})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  estimates the I/Q imbalance in the input signal,  $X$ , and returns a compensated signal,  $Y$ . The input  $X$  can take real or complex values and can be either a scalar or a column vector. Double- and single-precision data types are supported. The output  $Y$  has the same properties as  $X$ .

$Y = \text{step}(H, X, \text{COEF})$  accepts input coefficients,  $\text{COEF}$ , instead of generating them internally. This syntax applies when the `CoefficientSource` property of  $H$  is set to `Input port`. The input coefficients,  $\text{COEF}$ , are complex and can be either double or single precision.  $\text{COEF}$  has the same dimensions as  $X$ . At each time instant,  $\text{COEF}$  is a complex scalar.

---

$Y = \text{step}(H, X, \text{STEP SIZE})$  accepts a step size input, `STEP SIZE`. This syntax applies when the `StepSizeSource` property of `H` is set to `Input port`. The step size is a real scalar supporting either double or single precision.

$Y = \text{step}(H, \dots, \text{ADAPT})$  accepts a control signal, `ADAPT`, to enable or disable coefficient updates. This syntax applies when the `AdaptInputPort` property of `H` is `true`. The adaptation control signal is a logical scalar.

$[Y, \text{ESTCOEF}] = \text{step}(H, X)$  outputs the estimated coefficients, `ESTCOEF`, when the `CoefficientOutputPort` property of `H` is `true`. `ESTCOEF` has the same data properties and dimensionality as the input signal, `X`.

$[Y, \text{ESTCOEF}] = \text{step}(H, X, \text{STEP SIZE})$  outputs the estimated coefficients, `ESTCOEF`, and accepts a step size input, `STEP SIZE`. This syntax applies when the properties of `H` are set so that `CoefficientOutputPort` is `true` and `StepSizeSource` is `Input port`.

$[Y, \text{ESTCOEF}] = \text{step}(H, X, \text{STEP SIZE}, \text{ADAPT})$  outputs the estimated coefficients, `ESTCOEF`, and accepts a step size input, `STEP SIZE`, and a control signal input, `ADAPT`. This syntax applies when the properties of `H` are set so that `CoefficientOutputPort` is `true`, `StepSizeSource` is `Input port`, and `AdaptInputPort` is `true`.

$[Y, \text{ESTCOEF}] = \text{step}(H, X, \text{ADAPT})$  outputs the estimated coefficients, `ESTCOEF`, and accepts a control signal input, `ADAPT`. This syntax applies when the properties of `H` are set so that `CoefficientOutputPort` is `true` and `AdaptInputPort` is `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## **reset**

**System object:** comm.IQImbalanceCompensator

**Package:** comm

Reset states of the IQImbalanceCompensator System object

## **Syntax**

reset(H)

## **Description**

reset(H) resets the states of the IQImbalanceCompensator object, H.

This method resets the windowed suffix from the last symbol in the previously processed frame.

# comm.BPSKModulator

**Package:** comm

Modulate using BPSK method

## Description

The `BPSKModulator` object modulates using the binary phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a binary phase shift signal:

- 1 Define and set up your BPSK modulator object. See “Construction” on page 4-253.
- 2 Call `step` to modulate a signal according to the properties of `comm.BPSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.BPSKModulator` creates a modulator System object, `H`, that modulates the input signal using the binary phase shift keying (BPSK) method.

`H = comm.BPSKModulator(Name,Value)` creates a BPSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.BPSKModulator(PHASE,Name,Value)` creates a BPSK modulator object, `H`. The object's `PhaseOffset` property is set to `PHASE`, and the other specified properties are set to the specified values.

## Properties

### PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a finite, real scalar. The default is 0.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

### Fixed-Point Properties

#### CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a `Signedness` of `Auto`. The default is `numericType([ ], 16)`. This property applies when you set the `OutputDataType` on page 4-0 property to `Custom`.

## Methods

<code>constellation</code>	Calculate or plot ideal signal constellation
<code>step</code>	Modulate using BPSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### **BPSK Data Scatter Plot**

This example creates binary data, modulates it, and then displays the data using a scatter plot.

Create binary data symbols

```
data = randi([0 1],100,1);
```

Create a BPSK modulator System object

```
bpskModulator = comm.BPSKModulator;
```

Change the phase offset to  $\pi/16$

```
bpskModulator.PhaseOffset = pi/16;
```

Modulate and plot the data

```
modData = bpskModulator(data);  
scatterplot(modData)
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the BPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

# constellation

**System object:** `comm.BPSKModulator`

**Package:** `comm`

Calculate or plot ideal signal constellation

## Syntax

```
y = constellation(h)  
constellation(h)
```

## Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

## Examples

### Calculate BPSK Modulator Reference Constellation

Create a BPSK Modulator System object™ and calculate the reference constellation values.

Create a `comm.BPSKModulator` System object.

```
h = comm.BPSKModulator;
```

Calculate and display the reference constellation values by calling the `constellation` function.

```
refC = constellation(h)
```

```
refC = 2×1 complex
```

```
1.0000 + 0.0000i  
-1.0000 + 0.0000i
```

## Plot BPSK Modulator Reference Constellation

Create a BPSK Modulator System object™ and plot the reference constellation.

Create a `comm.BPSKModulator System` object.

```
bpsk = comm.BPSKModulator;
```

Plot the reference constellation by calling the `constellation` function.

```
constellation(bpsk)
```

---

## step

**System object:** comm.BPSKModulator

**Package:** comm

Modulate using BPSK method

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  modulates input data,  $X$ , with the BPSK modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . The input must be a column vector of bits. The data type of the input can be numeric, logical, or unsigned fixed point of word length 1 (fi object).

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.OFDMModulator

**Package:** comm

Modulate using OFDM method

### Description

The `OFDMModulator` object modulates using the orthogonal frequency division modulation method. The output is a baseband representation of the modulated signal.

To modulate an OFDM signal:

- 1 Define and set up the OFDM modulator object. See “Construction” on page 4-262.
- 2 Call `step` to modulate a signal according to the properties of `comm.OFDMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.OFDMModulator` creates a modulator System object, `H`, that modulates the input signal using the orthogonal frequency division modulation (OFDM) method.

`H = comm.OFDMModulator(Name, Value)` creates a OFDM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.OFDMModulator(hDemod)` creates an OFDM modulator object, `H`, whose properties are determined by the corresponding OFDM demodulator object, `hDemod`.

## Properties

### FFTLength

The length of the FFT,  $N_{\text{FFT}}$ , is equivalent to the number of subcarriers used in the modulation process. FFTLength must be  $\geq 8$ .

Specify the number of subcarriers. The default is 64.

### NumGuardBandCarriers

The number of guard band subcarriers allocated to the left and right guard bands.

Specify the number of left and right subcarriers as nonnegative integers from 0 to  $(\text{floor}(\text{FFTLength} / 2) - 1)$  where you specify the left,  $N_{\text{leftG}}$ , and right,  $N_{\text{rightG}}$ , guard bands independently in a 2-by-1 column vector. The default values are [6; 5].

### InsertDCNull

This is a logical variable that controls whether a DC null is inserted. The default value is false.

The DC subcarrier is the center of the frequency band and has the index value:

- $(\text{FFTLength} / 2) + 1$  when FFTLength is even
- $(\text{FFTLength} + 1) / 2$  when FFTLength is odd

### PilotInputPort

This is a logical property that controls whether you can specify the pilot carrier indices. If true, you can assign individual subcarriers for pilot transmission; otherwise, pilot information will be assumed to be embedded in the input data. The default value is false.

### PilotCarrierIndices

If the `comm.OFDMModulator.PilotInputPort` property is set to true, you can specify the indices of the pilot subcarriers. You can assign the indices to the same or different subcarriers for each symbol. Similarly, the pilot carrier indices can differ across multiple transmit antennas. Depending on the desired level of control for index assignments, the dimensions of the property vary. Valid pilot indices fall in the range

$$[N_{\text{leftG}} + 1, N_{\text{FFT}}/2] \cup [N_{\text{FFT}}/2 + 2, N_{\text{FFT}} - N_{\text{rightG}}],$$

where the index value cannot exceed the number of subcarriers. When the pilot indices are the same for every symbol and transmit antenna, the property has dimensions  $N_{\text{pilot}}\text{-by-1}$ , where  $N_{\text{pilot}}$  is the number of pilot subcarriers. When the pilot indices vary across symbols, the property has dimensions of  $N_{\text{pilot}}\text{-by-}N_{\text{sym}}$ , where  $N_{\text{sym}}$  is the number of symbols. If there is only one symbol but multiple transmit antennas, the property has dimensions of  $N_{\text{pilot}}\text{-by-1-by-}N_{\text{T}}$ , where  $N_{\text{T}}$  is the number of transmit antennas. If the indices vary across the number of symbols and transmit antennas, the property has dimensions of  $N_{\text{pilot}}\text{-by-}N_{\text{sym}}\text{-by-}N_{\text{T}}$ . It is desirable that when the number of transmit antennas is greater than one, the indices per symbol should be mutually distinct across antennas to avoid interference. The default value is [12; 26; 40; 54].

### CyclicPrefixLength

The `CyclicPrefixLength` property specifies the length of the OFDM cyclic prefix. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length  $N_{\text{sym}}$ , the prefix length can vary across symbols but remains the same length through all antennas. The default value is 16.

### Windowing

This is a `logical` property whose state enables or disables windowing. Windowing is the process in which the OFDM symbol is multiplied by a raised cosine window before transmission to more quickly reduce the power of out-of-band subcarriers. This serves to reduce spectral regrowth. The default value is `false`.

### WindowLength

This property specifies the length of the raised cosine window when `comm.OFDMModulator.Windowing` is `true`. Use positive integers with a maximum value no greater than the minimum cyclic prefix length. For example, in a configuration having four symbols with cyclic prefix lengths of [12 16 14 18], the window length cannot exceed 12. The default value is 1.

### NumSymbols

This property specifies the number of symbols,  $N_{\text{sym}}$ . `NumSymbols` must be a positive integer. The default value is 1.

## NumTransmitAntennas

This property determines the number of antennas,  $N_T$ , used to transmit the OFDM modulated signal. The property is a positive integer. The default value is 1.

## Methods

info	Provide dimensioning information for the OFDM method
reset	Reset states of the OFDMModulator System object
showResourceMapping	Show the subcarrier mapping of the OFDM symbols created by the OFDM modulator System object.
step	Modulate using OFDM method

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### Construct and Modify OFDM Modulator

An OFDM modulator System object™ can be constructed using default properties. Once constructed, these properties can be modified.

Construct an OFDM modulator.

```
ofdmMod = comm.OFDMModulator;
```

Display the properties of the modulator.

```
disp(ofdmMod)
```

```
comm.OFDMModulator with properties:
```

```
    FFTLength: 64
 NumGuardBandCarriers: [2x1 double]
   InsertDCNull: false
   PilotInputPort: false
```

```
CyclicPrefixLength: 16
    Windowing: false
    NumSymbols: 1
NumTransmitAntennas: 1
```

Modify the number of subcarriers and symbols.

```
ofdmMod.FFTLength = 128;
ofdmMod.NumSymbols = 2;
```

Verify that the number of subcarriers and the number of symbols changed.

```
disp(ofdmMod)
```

```
comm.OFDMModulator with properties:
```

```
    FFTLength: 128
NumGuardBandCarriers: [2x1 double]
    InsertDCNull: false
    PilotInputPort: false
    CyclicPrefixLength: 16
    Windowing: false
    NumSymbols: 2
NumTransmitAntennas: 1
```

The `showResourceMapping` method shows the mapping of data, pilot, and null subcarriers in the time-frequency space. Apply the `showResourceMapping` method.

```
showResourceMapping(ofdmMod)
```

### Construct OFDM Modulator from OFDM Demodulator

An OFDM modulator System object™ can be constructed from an existing OFDM demodulator System object.

Construct an OFDM demodulator, `ofdmDemod` and specify pilot indices for a single symbol and two transmit antennas.

Note: You can set the `PilotCarrierIndices` property in the demodulator object, which then changes the number of transmit antennas in the modulator object. The number of

receive antennas in the demodulator is uncorrelated with the number of transmit antennas.

```
ofdmDemod = comm.OFDMDemodulator;  
ofdmDemod.PilotOutputPort = true;  
ofdmDemod.PilotCarrierIndices = cat(3,[12; 26; 40; 54],...  
    [13; 27; 41; 55]);
```

Use the demodulator, `ofdmDemod`, to construct the OFDM modulator.

```
ofdmMod = comm.OFDMModulator(ofdmDemod);
```

Display the properties of the modulator and verify that they match those of the demodulator.

```
disp(ofdmMod)
```

```
comm.OFDMModulator with properties:  
  
    FFTLength: 64  
NumGuardBandCarriers: [2x1 double]  
    InsertDCNull: false  
    PilotInputPort: true  
PilotCarrierIndices: [4x1x2 double]  
    CyclicPrefixLength: 16  
    Windowing: false  
    NumSymbols: 1  
NumTransmitAntennas: 2
```

```
disp(ofdmDemod)
```

```
comm.OFDMDemodulator with properties:  
  
    FFTLength: 64  
NumGuardBandCarriers: [2x1 double]  
    RemoveDCCarrier: false  
    PilotOutputPort: true  
PilotCarrierIndices: [4x1x2 double]  
    CyclicPrefixLength: 16  
    NumSymbols: 1  
NumReceiveAntennas: 1
```

### Visualize Time-Frequency Resource Assignments for OFDM Modulator

The `showResourceMapping` method displays the time-frequency resource mapping for each transmit antenna.

Construct an OFDM modulator.

```
mod = comm.OFDMModulator;
```

Apply the `showResourceMapping` method.

```
showResourceMapping(mod)
```

Insert a DC null.

```
mod.InsertDCNull = true;
```

Show the resource mapping after adding the DC null.

```
showResourceMapping(mod)
```

### Create Modulator and Specify Pilots

The OFDM modulator enables you to specify the subcarrier indices for the pilot signals. The indices can be specified for each symbol and transmit antenna. When there is more than one transmit antenna, ensure that the pilot indices for each symbol differ between antennas.

Construct an OFDM modulator that has two symbols and insert a DC null.

```
mod = comm.OFDMModulator('FFTLength',128,'NumSymbols',2,...  
    'InsertDCNull',true);
```

Turn on the pilot input port so you can specify the pilot indices.

```
mod.PilotInputPort = true;
```

Specify the same pilot indices for both symbols.

```
mod.PilotCarrierIndices = [12; 56; 89; 100];
```

Visualize the placement of the pilot signals and nulls in the OFDM time-frequency grid using the `showResourceMapping` method.

```
showResourceMapping(mod)
```

Concatenate a second column of pilot indices to the `PilotCarrierIndices` property to specify different indices for the second symbol.

```
mod.PilotCarrierIndices = cat(2, mod.PilotCarrierIndices, ...
    [17; 61; 94; 105]);
```

Verify that the pilot subcarrier indices differ between symbols.

```
showResourceMapping(mod)
```

Increase the number of transmit antennas to two.

```
mod.NumTransmitAntennas = 2;
```

Specify the pilot indices for each of the two transmit antennas. To provide indices for multiple antennas while minimizing interference among the antennas, populate the `PilotCarrierIndices` property as a 3-D array such that the indices for each symbol differ among antennas.

```
mod.PilotCarrierIndices = cat(3,[20; 50; 70; 110], ...
    [15; 60; 75; 105]);
```

Display the resource mapping for the two transmit antennas. The gray lines denote the insertion of custom nulls. The nulls are created by the object to minimize interference among the pilot symbols from different antennas.

`showResourceMapping(mod)`

### Create Modulator with Varying Cyclic Prefix Lengths

Specify the length of the cyclic prefix for each OFDM symbol.

Construct an OFDM modulator having five symbols, four left guard-band subcarriers, and three right guard-band subcarriers. Specify the cyclic prefix length for each OFDM symbol.

```
mod = comm.OFDMModulator('NumGuardBandCarriers',[4;3],...
    'NumSymbols',5,...
    'CyclicPrefixLength',[12 10 14 11 13]);
```

Display the properties of the modulator and verify that the cyclic prefix length changes across symbols.

```
disp(mod)
```

```
comm.OFDMModulator with properties:
    FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
    InsertDCNull: false
    PilotInputPort: false
    CyclicPrefixLength: [12 10 14 11 13]
    Windowing: false
    NumSymbols: 5
    NumTransmitAntennas: 1
```

### Info Method to Determine OFDM Modulator Data Dimensions

Determine the OFDM modulator data dimensions by using the `info` method.

Construct an OFDM modulator System object™ with user-specified pilot indices, insert a DC null, and specify two transmit antennas.

```
hMod = comm.OFDMModulator('NumGuardBandCarriers',[4;3], ...
    'PilotInputPort',true, ...
    'PilotCarrierIndices',cat(3,[12; 26; 40; 54], ...
    [11; 25; 39; 53]), ...
    'InsertDCNull',true, ...
    'NumTransmitAntennas',2);
```

Use the `info` method to find the modulator input data, pilot input data, and output data sizes.

```
info(hMod)
```

```
ans = struct with fields:
    DataInputSize: [48 1 2]
    PilotInputSize: [4 1 2]
    OutputSize: [80 2]
```

## Create OFDM Modulated Data

Generate OFDM modulated symbols for use in link-level simulations.

Construct an OFDM modulator with an inserted DC null, seven guard-band subcarriers, and two symbols having different pilot indices for each symbol.

```
mod = comm.OFDMModulator('NumGuardBandCarriers',[4;3],...
    'PilotInputPort',true, ...
    'PilotCarrierIndices',[12 11; 26 27; 40 39; 54 55], ...
    'NumSymbols',2, ...
    'InsertDCNull',true);
```

Determine input data, pilot, and output data dimensions.

```
modDim = info(mod);
```

Generate random data symbols for the OFDM modulator. The structure variable, `modDim`, determines the number of data symbols.

```
dataIn = complex(randn(modDim.DataInputSize),randn(modDim.DataInputSize));
```

Create a pilot signal that has the correct dimensions.

```
pilotIn = complex(rand(modDim.PilotInputSize),rand(modDim.PilotInputSize));
```

Apply OFDM modulation to the data and pilot signals.

```
modData = step(mod,dataIn,pilotIn);
```

Use the OFDM modulator object to create the corresponding OFDM demodulator.

```
demod = comm.OFDMDemodulator(mod);
```

Demodulate the OFDM signal and output the data and pilot signals.

```
[dataOut, pilotOut] = step(demod,modData);
```

Verify that, within a tight tolerance, the input data and pilot symbols match the output data and pilot symbols.

```
isSame = (max(abs([dataIn(:) - dataOut(:); ...
    pilotIn(:) - pilotOut(:)])) < 1e-10)
```

```
isSame = logical  
1
```

## Algorithms

Orthogonal frequency division modulation (OFDM) divides a high-rate transmit data stream into  $N$  lower-rate streams, each of which has a symbol duration larger than the channel delay spread. This serves to mitigate intersymbol interference (ISI). The individual substreams are sent over  $N$  parallel subchannels which are orthogonal to each other. Through the use of an inverse fast Fourier transform (IFFT), OFDM can be transmitted using a single radio. Specifically, the OFDM Modulator System object modulates an input signal using orthogonal frequency division modulation. The output is a baseband representation of the modulated signal:

$$v(t) = \sum_{k=0}^{N-1} X_k e^{j2\pi k \Delta f t}, \quad 0 \leq t \leq T,$$

where  $\{X_k\}$  are data symbols,  $N$  is the number of subcarriers, and  $T$  is the OFDM symbol time. The subcarrier spacing of  $\Delta f = 1/T$  makes them orthogonal over each symbol period. This is expressed as:

$$\frac{1}{T} \int_0^T (e^{j2\pi m \Delta f t})^* (e^{j2\pi n \Delta f t}) dt = \frac{1}{T} \int_0^T e^{j2\pi(m-n)\Delta f t} dt = 0 \quad \text{for } m \neq n.$$

The data symbols,  $X_k$ , are usually complex and can be from any modulation alphabet, e.g., QPSK, 16-QAM, or 64-QAM.

The figure shows an OFDM modulator. It consists of a bank of  $N$  complex modulators, where each corresponds to one OFDM subcarrier.

## Guard Bands and Intervals

There are three types of OFDM subcarriers: data, pilot, and null. Data subcarriers are used for transmitting data while pilot subcarriers are used for channel estimation. There is no transmission on null subcarriers, which provide a DC null and provide buffers between OFDM resource blocks. These buffers are referred to as guard bands whose purpose is to prevent inter-symbol interference. The allocation of nulls and guard bands vary depending upon the applicable standard, e.g., 802.11n differs from LTE. Consequently, the OFDM modulator object allows the user to assign subcarrier indices.

Analogous to the concept of guard bands, the OFDM modulator object supports guard intervals which are used to provide temporal separation between OFDM symbols so that the signal does not lose orthogonality due to time-dispersive channels. As long as the guard interval is longer than the delay spread, each symbol does not interfere with other symbols. Guard intervals are created by using cyclic prefixes in which the last part of an OFDM symbol is copied and inserted as the first part of the OFDM symbol. The benefit of cyclic prefix insertion is maintained as long as the span of the time dispersion does not exceed the duration of the cyclic prefix. The OFDM modulator object enables the setting of the cyclic prefix length. The drawback in using a cyclic prefix is the penalty from increased overhead.

## Raised Cosine Windowing

While the cyclic prefix creates guard period in time domain to preserve orthogonality, an OFDM symbol rarely begins with the same amplitude and phase exhibited at the end of the prior OFDM symbol. This causes spectral regrowth, which is the spreading of signal bandwidth due to intermodulation distortion. To limit this spectral regrowth, it is desired to create a smooth transition between the last sample of a symbol and the first sample of the next symbol. This can be done by using a cyclic suffix and raised cosine windowing.

To create the cyclic suffix, the first  $N_{\text{WIN}}$  samples of a given symbol are appended to the end of that symbol. However, in order to comply with the 802.11g standard, for example, the length of a symbol cannot be arbitrarily lengthened. Instead, the cyclic suffix must overlap in time and is effectively summed with the cyclic prefix of the following symbol. This overlapped segment is where windowing is applied. Two windows are applied, one of which is the mathematical inverse of the other. The first raised cosine window is applied to the cyclic suffix of symbol  $k$ , and decreases from 1 to 0 over its duration. The second raised cosine window is applied to the cyclic prefix of symbol  $k+1$ , and increases from 0 to 1 over its duration. This provides a smooth transition from one symbol to the next.

The raised cosine window,  $w(t)$ , in the time domain can be expressed as:

$$w(t) = \begin{cases} 1, & 0 \leq |t| < \frac{T - T_W}{2} \\ \frac{1}{2} \left\{ 1 + \cos \left[ \frac{\pi}{T_W} \left( |t| - \frac{T - T_W}{2} \right) \right] \right\}, & \frac{T - T_W}{2} \leq |t| \leq \frac{T + T_W}{2} \\ 0, & \text{otherwise} \end{cases}$$

where

- $T$  represents the OFDM symbol duration including the guard interval.
- $T_W$  represents the duration of the window.

Adjust the length of the cyclic suffix via the window length setting property, with suffix lengths set between 1 and the minimum cyclic prefix length. While windowing improves spectral regrowth, it does so at the expense of multipath fading immunity. This occurs because redundancy in the guard band is reduced because the guard band sample values are compromised by the smoothing.

The following figures display the application of raised cosine windowing.

## info

**System object:** comm.OFDMModulator

**Package:** comm

Provide dimensioning information for the OFDM method

## Syntax

`Y = info(H)`

## Description

`Y = info(H)` provides data dimensioning information for the OFDM modulator System object, H. It returns the expected dimensions for the:

- Input data array
- Pilot data array
- Output data array

The output, Y, is a structure containing the following three fields.

Y.DataInputSize

Dimensions of the modulator input data,  $N_{\text{data}}$ -by- $N_{\text{sym}}$ -by- $N_t$ , where  $N_{\text{data}}$  is the number of data subcarriers such that  $N_{\text{data}} = N_{\text{FFT}} - N_{\text{leftG}} - N_{\text{rightG}} - N_{\text{DCNull}} - N_{\text{pilot}} - N_{\text{custNull}}$ .

### Variable Definitions

Variable	Description
$N_{\text{FFT}}$	Number of subcarriers
$N_{\text{leftG}}$	Number of subcarriers in the left guard band
$N_{\text{rightG}}$	Number of subcarriers in the right guard band
$N_{\text{DCNull}}$	Number of subcarriers in the DC null (either 0 or 1)
$N_{\text{pilot}}$	Number of pilot subcarriers
$N_{\text{custNull}}$	Number of subcarriers used for custom nulls (applies only when the pilot indices property is a 3-D array)
$N_{\text{t}}$	Number of transmit antennas

#### Y.PilotInputSize

Dimensions of the pilot input array,  $N_{\text{pilot}}$ -by- $N_{\text{sym}}$ -by- $N_{\text{t}}$ .

#### Y.OutputSize

Dimensions of the modulator output data,  $(N_{\text{FFT}} + N_{\text{CP}}) \times N_{\text{sym}}$ -by- $N_{\text{t}}$ , where  $N_{\text{CP}}$  is the length of the cyclic prefix.

## **reset**

**System object:** comm.OFDMModulator

**Package:** comm

Reset states of the OFDMModulator System object

## **Syntax**

reset(H)

## **Description**

reset(H) resets the states of the OFDMModulator object, H.

This method resets the windowed suffix from the last symbol in the previously processed frame.

# showResourceMapping

**System object:** comm.OFDMModulator

**Package:** comm

Show the subcarrier mapping of the OFDM symbols created by the OFDM modulator System object.

## Syntax

showResourceMapping(H)  
showResourceMapping(H,CI)

## Description

showResourceMapping(H) shows a visualization of the subcarrier mapping for the OFDM symbols used by the OFDM modulator System object, H. The subcarrier indices are numbered from 1 to  $N_{FFT}$ .

showResourceMapping(H,CI) shows the resource mapping where the optional argument, CI, is used to number the subcarrier indices that will be displayed. CI is a 1x2 integer row vector such that  $\text{diff}(CI) = N_{FFT} - 1$ .

# step

**System object:** comm.OFDMModulator

**Package:** comm

Modulate using OFDM method

## Syntax

$Y = \text{step}(H, X)$

$Y = \text{step}(H, X, \text{PILOT})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  modulates input data,  $X$ , with the OFDM modulator System object,  $H$ , and returns the baseband modulated output,  $Y$ , which is a double-precision, 2-D array with complex values. The input,  $X$ , is a numeric, real or complex 3-D array of symbols (typically created with a baseband demodulator, e.g., QPSK). Its dimensions are a function of the number of subcarriers, the number of guard band subcarriers, the number of pilot subcarriers, and whether or not there is a DC null. You can determine the dimensions by using the `info` method.

$Y = \text{step}(H, X, \text{PILOT})$  maps the `PILOT` signal onto the subcarriers specified by the `PilotCarrierIndices` property of  $H$ . The input `PILOT` is a numeric, real or complex 3-D array. This syntax applies when the `PilotInputPort` property of  $H$  is true. The `info` method provides the dimensions of the `PILOT` array.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.OFDMDemodulator

**Package:** comm

Demodulate using OFDM method

### Description

The `OFDMDemodulator` object demodulates using the orthogonal frequency division demodulation method. The output is a baseband representation of the modulated signal, which was input into the `OFDMModulator` companion object.

To demodulate an OFDM signal:

- 1 Define and set up the OFDM demodulator object. See “Construction” on page 4-290.
- 2 Call `step` to demodulate a signal according to the properties of `comm.OFDMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.OFDMDemodulator` creates a demodulator System object, `H`, that demodulates an input signal by using the orthogonal frequency division demodulation method.

`H = comm.OFDMDemodulator(Name, Value)` creates an OFDM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.OFDMDemodulator(hMod)` creates an OFDM demodulator object, `H`, whose properties are determined by the corresponding OFDM modulator object, `hMod`.

## Properties

### FFTLength

The length of the FFT,  $N_{\text{FFT}}$ , is equivalent to the number of subcarriers used in the modulation process. `FFTLength` must be  $\geq 8$ .

Specify the number of subcarriers. The default is 64.

### NumGuardBandCarriers

The number of guard band subcarriers allocated to the left and right guard bands.

Specify the number of left and right subcarriers as nonnegative integers in  $[0, N_{\text{FFT}}/2 - 1]$  where you specify the left,  $N_{\text{leftG}}$ , and right,  $N_{\text{rightG}}$ , guard bands independently in a 2-by-1 column vector. The default values are [6; 5].

### RemoveDCCarrier

A logical variable that when `true`, mandates removal of a DC subcarrier. The default value is `false`.

### PilotOutputPort

A logical property that controls whether to separate the pilot signals and make them available at an additional output port. The location of each pilot output symbol is determined by the pilot subcarrier indices specified in the `PilotCarrierIndices` property. When `false`, pilot symbols may be present but embedded in the data. The default value is `false`.

### PilotCarrierIndices

If the `PilotOutputPort` property is `true`, output separate pilot signals located at the indices specified by the `PilotCarrierIndices` property. If the indices are a 2-D array, the pilot carriers across all the transmit antennas per symbol are the same. If there is more than one transmit antenna (this information is not known by the demodulator), the pilots from different transmit antennas may interfere with each other. To avoid this, specify the pilot carrier indices as a 3-D array with different pilot indices for each symbol across the antennas. This avoids interference between pilots from different transmit antennas, since, on a per-symbol basis, each transmit antenna has different pilot carriers and the OFDM modulator creates custom nulls at the appropriate locations. The size of

the third dimension of the `PilotCarrierIndices` property gives the number of transmit antennas.

### **CyclicPrefixLength**

The cyclic prefix length property specifies the length of the OFDM cyclic prefix. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length  $N_{\text{sym}}$ , the prefix length can vary across symbols but remains the same length through all antennas. The default value is 16.

### **NumSymbols**

This property specifies the number of symbols,  $N_{\text{sym}}$ . Specify  $N_{\text{sym}}$  as a positive integer. The default value is 1.

### **NumReceiveAntennas**

This property determines the number of antennas,  $N_{\text{R}}$ , used to receive the OFDM modulated signal. Specify  $N_{\text{R}}$  as a positive integer. The default value is 1.

## **Methods**

<code>info</code>	Provide dimensioning information for the OFDM method
<code>reset</code>	Reset states of the <code>OFDMDemodulator</code> System object
<code>showResourceMapping</code>	Show the subcarrier mapping of the OFDM symbols created by the OFDM demodulator System object
<code>step</code>	Demodulate using OFDM method

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## **Examples**

## Create and Modify OFDM Demodulator

Construct an OFDM demodulator System object™ with default properties. Modify some of the properties.

Construct the OFDM demodulator.

```
demod = comm.OFDMDemodulator

demod =
  comm.OFDMDemodulator with properties:
      FFTLength: 64
  NumGuardBandCarriers: [2x1 double]
      RemoveDCCarrier: false
      PilotOutputPort: false
  CyclicPrefixLength: 16
      NumSymbols: 1
  NumReceiveAntennas: 1
```

Modify the number of subcarriers and symbols.

```
demod.FFTLength = 128;
demod.NumSymbols = 2;
```

Verify that the number of subcarriers and the number of symbols changed.

```
demod

demod =
  comm.OFDMDemodulator with properties:
      FFTLength: 128
  NumGuardBandCarriers: [2x1 double]
      RemoveDCCarrier: false
      PilotOutputPort: false
  CyclicPrefixLength: 16
      NumSymbols: 2
  NumReceiveAntennas: 1
```

### Create OFDM Demodulator from OFDM Modulator

Create an OFDM demodulator System object™ from an existing OFDM modulator System object.

Construct an OFDM modulator using default parameters.

```
mod = comm.OFDMModulator('NumTransmitAntennas',4);
```

Construct the corresponding OFDM demodulator from the modulator, mod.

```
demod = comm.OFDMDemodulator(mod);
```

Display the properties of the modulator and verify that they match those of the demodulator.

```
mod
```

```
mod =  
  comm.OFDMModulator with properties:  
    FFTLength: 64  
  NumGuardBandCarriers: [2x1 double]  
    InsertDCNull: false  
    PilotInputPort: false  
  CyclicPrefixLength: 16  
    Windowing: false  
    NumSymbols: 1  
  NumTransmitAntennas: 4
```

```
demod
```

```
demod =  
  comm.OFDMDemodulator with properties:  
    FFTLength: 64  
  NumGuardBandCarriers: [2x1 double]  
    RemoveDCCarrier: false  
    PilotOutputPort: false  
  CyclicPrefixLength: 16  
    NumSymbols: 1  
  NumReceiveAntennas: 1
```

Note that the number of transmit antennas is independent of the number of receive antennas.

### **Visualize Time-Frequency Resource Assignments**

The `showResourceMapping` method shows the time-frequency resource mapping for each transmit antenna.

Construct an OFDM demodulator.

```
demod = comm.OFDMDemodulator;
```

Apply the `showResourceMapping` method.

```
showResourceMapping(demod)
```

Remove the DC subcarrier.

```
demod.RemoveDCCarrier = true;
```

Show the resource mapping after removing the DC subcarrier.

```
showResourceMapping(demod)
```

### Demodulate OFDM Data

Construct an OFDM modulator with an inserted DC null, seven guard-band subcarriers, and two symbols that have different pilot indices for each symbol.

```
mod = comm.OFDMModulator('NumGuardBandCarriers',[4;3],...
    'PilotInputPort',true,'PilotCarrierIndices',cat(2,[12; 26; 40; 54],...
    [11; 27; 39; 55]),'NumSymbols',2,'InsertDCNull',true);
```

Determine input data, pilot, and output data dimensions.

```
modDim = info(mod)
```

```
modDim = struct with fields:
    DataInputSize: [52 2]
    PilotInputSize: [4 2]
    OutputSize: [160 1]
```

Generate random data symbols for the OFDM modulator. Determine the number of data symbols by using the structure variable, `modDim`.

```
dataIn = complex(randn(modDim.DataInputSize), randn(modDim.DataInputSize));
```

Create a pilot signal that has the correct dimensions.

```
pilotIn = complex(rand(modDim.PilotInputSize), rand(modDim.PilotInputSize));
```

Apply OFDM modulation to the data and pilot signals.

```
modSig = step(mod, dataIn, pilotIn);
```

Use the OFDM modulator object to create the corresponding OFDM demodulator.

```
demod = comm.OFDMDemodulator(mod);
```

Demodulate the OFDM signal and output the data and pilot signals.

```
[dataOut, pilotOut] = step(demod, modSig);
```

Verify that the input data and pilot symbols match the output data and pilot symbols.

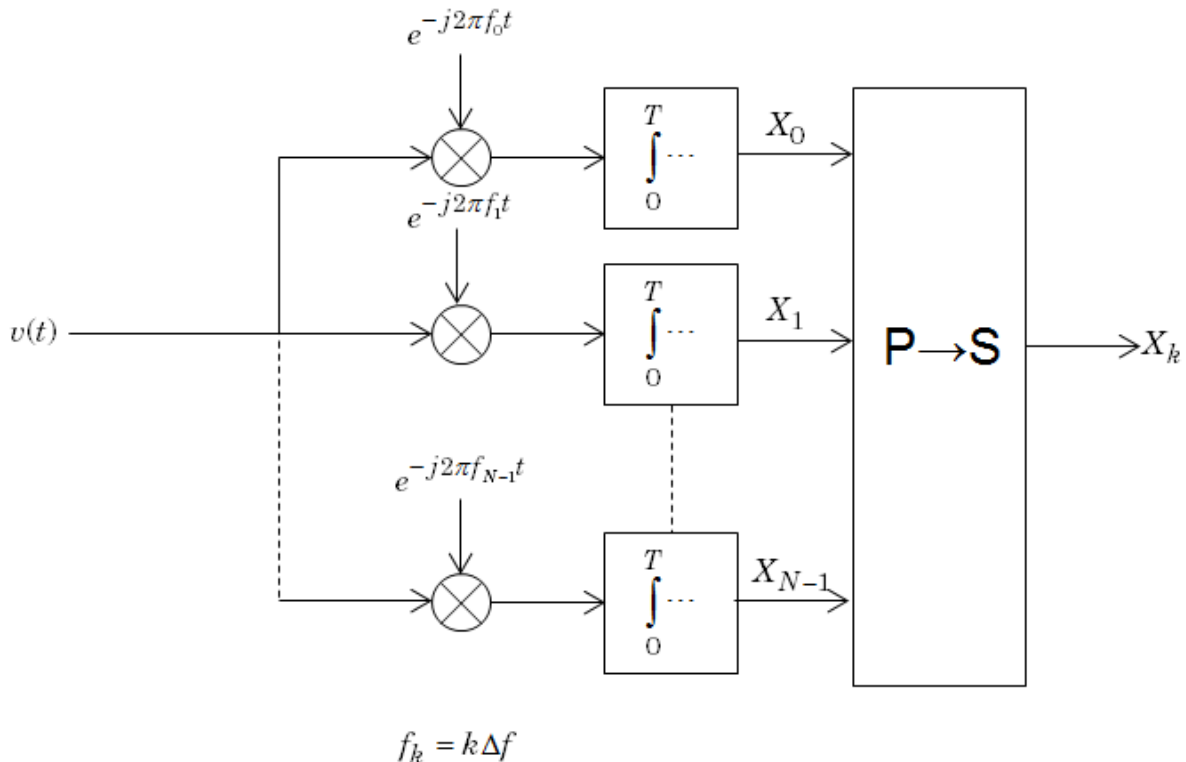

```
isSame = (max(abs([dataIn(:) - dataOut(:); ...
    pilotIn(:) - pilotOut(:)])) < 1e-10)
```

```
isSame = logical
    1
```

## Algorithms

The Orthogonal Frequency Division Modulation (OFDM) Demodulator System object demodulates an OFDM input signal by using an FFT operation that results in  $N$  parallel data streams.

The figure shows an OFDM demodulator. It consists of a bank of  $N$  correlators with one assigned to each OFDM subcarrier followed by a parallel-to-serial conversion.

## Guard Bands and Intervals

There are three types of OFDM subcarriers: data, pilot, and null. Data subcarriers are used for transmitting data while pilot subcarriers are used for channel estimation. There is no transmission on null subcarriers, which are used to provide a DC null as well as to provide buffers between OFDM resource blocks. These buffers are referred to as guard bands whose purpose is to prevent inter-symbol interference. The allocation of nulls and guard bands varies depending upon the standard, e.g., 802.11n differs from LTE. Consequently, the OFDM modulator object allows the user to assign subcarrier indices as required.

Analogous to the concept of guard bands, the OFDM modulator object supports guard intervals that provide temporal separation between OFDM symbols so that the signal does not lose orthogonality due to time-dispersive channels. As long as the guard interval is longer than the delay spread, each symbol does not interfere with other symbols. Guard intervals are created by using cyclic prefixes in which the last part of an OFDM symbol is copied and inserted as the first part of the OFDM symbol. The benefit of cyclic prefix insertion is maintained as long as the span of the time dispersion does not exceed the duration of the cyclic prefix. The OFDM modulator object enables the cyclic prefix length to be set. The drawback in using a cyclic prefix is increased overhead.

Provide dimensioning information for the OFDM method

## Syntax

`Y = info(H)`

## Description

`Y = info(H)` provides data dimensioning information for the OFDM demodulator System object, `H`. It returns the expected dimensions for data input into the OFDM demodulator, for the pilot output, and for the data output from the demodulator. The output, `Y`, is a structure containing three fields: `InputSize`, `DataOutputSize`, and `PilotOutputSize`.

### `Y.InputSize`

Gives the dimensions of the demodulator input data,  $[(N_{\text{FFT}} + N_{\text{CP}}) \times N_{\text{sym}}]$ -by- $N_r$ , where  $N_{\text{FFT}}$  is the number of subcarriers,  $N_{\text{CP}}$  is the length of the cyclic prefix,  $N_{\text{sym}}$  is the number of symbols, and  $N_r$  is the number of receive antennas.

### `Y.DataOutputSize`

Shows the dimensions of the demodulator output data,  $N_{\text{data}}$ -by- $N_{\text{sym}}$ -by- $N_r$ , where  $N_{\text{data}}$  is the number of data subcarriers such that  $N_{\text{data}} = N_{\text{FFT}} - N_{\text{leftG}} - N_{\text{rightG}} - N_{\text{DCNull}} - N_{\text{pilot}} - N_{\text{custNull}}$ . The variables are defined as follows:

$N_{\text{FFT}}$	Number of subcarriers
$N_{\text{leftG}}$	Number of subcarriers in the left guard band
$N_{\text{rightG}}$	Number of subcarriers in the right guard band

---

$N_{\text{DCNull}}$	Number of subcarriers in the DC null (either 0 or 1)
$N_{\text{pilot}}$	Number of pilot subcarriers
$N_{\text{custNull}}$	Number of subcarriers used for custom nulls

#### Y.PilotOutputSize

Provides the dimensions of the pilot signal output array,  $N_{\text{pilot}}$ -by- $N_{\text{sym}}$ -by- $N_r$  or  $N_{\text{pilot}}$ -by- $N_{\text{sym}}$ -by- $N_t$ -by- $N_r$ , depending on the number of transmit antennas.

## **reset**

**System object:** comm.OFDMDemodulator

**Package:** comm

Reset states of the OFDMDemodulator System object

## **Syntax**

reset(H)

## **Description**

reset(H) resets the states of the OFDMDemodulator object, H.

This method resets the windowed suffix from the last symbol in the previously processed frame.

# showResourceMapping

**System object:** comm.OFDMDemodulator

**Package:** comm

Show the subcarrier mapping of the OFDM symbols created by the OFDM demodulator System object

## Syntax

showResourceMapping(H)  
showResourceMapping(H,CI)

## Description

showResourceMapping(H) shows a visualization of the subcarrier mapping for the OFDM symbols used by the OFDM demodulator System object, H. The subcarrier indices are numbered from 1 to  $N_{FFT}$ .

showResourceMapping(H,CI) shows the resource mapping where the optional argument, CI, is used to number the subcarrier indices that will be displayed. CI is a 1x2 integer row vector such that  $\text{diff}(CI) = N_{FFT} - 1$ .

# step

**System object:** comm.OFDMDemodulator

**Package:** comm

Demodulate using OFDM method

## Syntax

$Y = \text{step}(H,X)$   
 $[Y,\text{PILOT}] = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates input data,  $X$ , with the OFDM demodulator System object,  $H$ , and returns the baseband demodulated output,  $Y$ . The input is a double-precision, real or complex, 2-D matrix of symbols whose dimensions are a function of the number of subcarriers, the cyclic prefix length, and the number of receive antennas. You can determine the dimensions by using the `info` method. The output,  $Y$ , is a double-precision, complex, 3-D array.

$[Y,\text{PILOT}] = \text{step}(H,X)$  separates the PILOT signal on the subcarriers specified by the `PilotCarrierIndices` property value of  $H$ . This syntax applies when the `PilotOutputPort` property of  $H$  is true. PILOT is a double-precision, complex, 3-D array.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.CarrierSynchronizer

**Package:** comm

Compensate for carrier frequency offset

### Description

The `comm.CarrierSynchronizer` System object compensates for carrier frequency and phase offsets in signals that use single-carrier modulation schemes. The carrier synchronizer algorithm is compatible with BPSK, QPSK, OQPSK, 8-PSK, PAM, and rectangular QAM modulation schemes.

---

#### Note

- This System object does not resolve phase ambiguities created by the synchronization algorithm. As indicated in this table, the potential phase ambiguity introduced by the synchronizer depends on the modulation type:

Modulation	Phase Ambiguity (degrees)
'BPSK' or 'PAM'	0, 180
'OQPSK', 'QPSK', or 'QAM'	0, 90, 180, 270
'8PSK'	0, 45, 90, 135, 180, 225, 270, 315

The “Examples” on page 4-0 demonstrate carrier synchronization and resolution of phase ambiguity.

- For best results, apply carrier synchronization to non-oversampled signals, as demonstrated in “Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization” on page 4-318.

---

To compensate for frequency and phase offsets in signals that use single-carrier modulation schemes:

- 1 Create the `comm.CarrierSynchronizer` object and set its properties.

- 2 Call the object, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

### Syntax

```
carrSynch = comm.CarrierSynchronizer  
carrSynch = comm.CarrierSynchronizer(Name,Value)
```

### Description

`carrSynch = comm.CarrierSynchronizer` creates a System object that compensates for carrier frequency offset and phase offset in signals that use single-carrier modulation schemes.

`carrSynch = comm.CarrierSynchronizer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

### Modulation — Modulation type

'QAM' (default) | '8PSK' | 'BPSK' | 'OQPSK' | 'PAM' | 'QPSK'

Modulation type, specified as 'QAM', '8PSK', 'BPSK', 'OQPSK', 'PAM', or 'QPSK'.

Example: `comm.CarrierSynchronizer('Modulation','QPSK')` creates a carrier synchronizer System object to use with a QPSK modulated signal.

**Tunable:** No

**ModulationPhaseOffset — Modulation phase offset method**

'Auto' (default) | 'Custom'

Modulation phase offset method, specified as 'Auto' or 'Custom'.

- 'Auto' — Apply the traditional offset for the specified modulation type.

Modulation	Phase Offset (radians)
'BPSK', 'QAM', or 'PAM'	0
'OQPSK' or 'QPSK'	$\pi/4$
'8PSK'	$\pi/8$

- 'Custom' — Specify a user-defined phase offset with the CustomPhaseOffset property.

**Tunable:** Yes

**CustomPhaseOffset — Custom phase offset**

0 (default) | scalar

Custom phase offset in radians, specified as a scalar.

**Dependencies**

This property applies when the ModulationPhaseOffset property is set to 'Custom'.

Data Types: double

**SamplesPerSymbol — Number of samples per symbol**

2 (default) | positive integer

Number of samples per symbol, specified as a positive integer.

**Tunable:** Yes

Data Types: double

**DampingFactor — Damping factor of loop**

0.707 (default) | positive scalar

Damping factor of the loop, specified as a positive scalar.

**Tunable:** Yes

Data Types: double

### **NormalizedLoopBandwidth — Normalized bandwidth of loop**

0.01 (default) | scalar

Normalized bandwidth of the loop, specified as a scalar in the range (0,1]. The loop bandwidth is normalized by the sample rate of the synchronizer.

Decreasing the loop bandwidth reduces the synchronizer convergence time but also reduces the pull-in range of the synchronizer.

**Tunable:** Yes

Data Types: double

## **Usage**

## **Syntax**

```
[outSig,phErr] = carrSynch(inSig)
```

## **Description**

[outSig,phErr] = carrSynch(inSig) compensates for frequency offset and phase offset in the input signal. This System object returns a compensated output signal and an estimate of the phase error.

## **Input Arguments**

### **inSig — Input signal**

scalar | column vector

Input signal, specified as a complex scalar or a column vector of complex values.

Data Types: double | single

Complex Number Support: Yes

### Output Arguments

#### **outSig — Output signal**

scalar (default) | column vector

Output signal, returned as a scalar or column vector with the same data type and length as `inSig`. The output signal adjusts the input signal compensating for carrier frequency and phase offsets in signals that use single-carrier modulation schemes.

#### **phErr — Phase error estimate**

scalar (default) | column vector

Phase error estimate in radians, returned as a scalar or column vector with the same length as `inSig`.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

#### **Specific to comm.CarrierSynchronizer**

`info`      Characteristic information about carrier synchronizer  
`clone`     Create duplicate System object  
`isLocked` Determine if System object is in use

#### **Common to All System Objects**

`step`      Run System object algorithm  
`release`   Release resources and allow changes to System object property values and input characteristics  
`reset`     Reset internal states of System object

### Examples

## Correct Phase and Frequency Offset in QPSK Link

Correct phase and frequency offsets of a QPSK signal passed through an AWGN channel. Using preambles, resolve phase ambiguity.

Define the simulation parameters.

```
M = 4; % Modulation order
rng(1993) % For repeatable results
barker = comm.BarkerCode(...
    'Length',13,'SamplesPerFrame',13); % For preamble
msgLen = 1e4;
numFrames = 10;
frameLen = msgLen/numFrames;
```

Add preambles to each frame, which are used later when performing phase ambiguity resolution. Generate random data symbols, and apply QPSK modulation.

```
preamble = (1+barker())/2; % Length 13, unipolar
data = zeros(msgLen,1);
for idx = 1 : numFrames
    payload = randi([0 M-1],frameLen-barker.Length,1);
    data((idx-1)*frameLen + (1:frameLen)) = [preamble; payload];
end

modSig = pskmod(data,4,pi/4);
```

Create a `comm.PhaseFrequencyOffset` System object™ to introduce phase and frequency offsets to the modulated input signal. Set the phase offset to 45 degrees, frequency offset to 1 kHz, and sample rate to 10 kHz. The frequency offset is set to 1% of the sample rate.

```
pfo = comm.PhaseFrequencyOffset('PhaseOffset',45, ...
    'FrequencyOffset',1e4,'SampleRate',1e6);
```

Create a carrier synchronizer System object to use for correcting the phase and frequency offsets with samples per symbol set to 1.

```
carrierSync = comm.CarrierSynchronizer(...
    'SamplesPerSymbol',1,'Modulation','QPSK');
```

Apply phase and frequency offsets using the `pfo` System object, and then pass the signal through an AWGN channel to add white Gaussian noise.

```
modSigOffset = pfo(modSig);  
rxSig = awgn(modSigOffset,12);
```

Display the scatter plot of the received signal. The data appear in a circle instead of being grouped around the reference constellation points due to the frequency offset.

```
scatterplot(rxSig)
```

Use the `carrierSync` System object to correct the phase and frequency offset in the received signal.

```
syncSignal = carrierSync(rxSig);
```

Use a constellation diagram to display the first and last 1000 symbols of the synchronized signal. Before convergence of the synchronizer loop, the plotted symbols are not grouped

around the reference constellation points. After convergence, the plotted symbols are grouped around the reference constellation points.

```
constDiag = comm.ConstellationDiagram( ...
'SymbolsToDisplaySource','Property','SymbolsToDisplay',300, ...
'ChannelNames',{ 'Before convergence', 'After convergence'}, 'ShowLegend',true, ...
'Position',[400 400 400 400]);
```

```
constDiag([syncSignal(1:1000) syncSignal(9001:10000)]);
```

Demodulate the synchronized signal. Compute and display the total bit errors and BER.

```
syncData = pskdemod(syncSignal,4,pi/4);  
[syncDataTtlErr,syncDataBER] = biterr(data(6000:end),syncData(6000:end))  
  
syncDataTtlErr = 3990  
syncDataBER = 0.4986
```

Phase ambiguity in the received signal might cause bit errors. Using the preamble, determine phase ambiguity. Remove this phase ambiguity from the synchronized signal to reduce bit errors.

```
idx = 9000 + (1:barker.Length);  
phOffset = angle(modSig(idx) .* conj(syncSignal(idx)));  
phOffset = round((2/pi) * phOffset); % -1, 0, 1, +/-2  
phOffset(phOffset==-2) = 2; % Prep for mean operation  
phOffset = mean((pi/2) * phOffset); % -pi/2, 0, pi/2, or pi  
disp(['Estimated mean phase offset = ',num2str(phOffset*180/pi),' degrees'])  
  
Estimated mean phase offset = 180 degrees  
  
resPhzSig = exp(1i*phOffset) * syncSignal;
```

Demodulate the signal after resolving the phase ambiguity. Recompute and display the updated total bit errors and BER. Removing the phase ambiguity reduces the BER dramatically.

```
resPhzData = pskdemod(resPhzSig,4,pi/4);  
[resPhzTtlErr, resPhzBER] = biterr(data(6000:end),resPhzData(6000:end))  
  
resPhzTtlErr = 403  
resPhzBER = 0.0504
```

### Estimate Frequency Offset in an 8-PSK Link

Estimate the frequency offset introduced into a noisy 8-PSK signal using a carrier synchronizer System object™.

Define the simulation parameters.

```
M = 8; % Modulation order  
fs = 1e6; % Sample rate (Hz)
```

```

foffset = 1000;           % Frequency offset (Hz)
phaseoffset = 15;        % Phase offset (deg)
snrdb = 20;              % Signal-to-noise ratio (dB)

```

Create a `comm.PhaseFrequencyOffset` System object to introduce phase and frequency offsets to a modulated signal.

```

pfo = comm.PhaseFrequencyOffset('PhaseOffset',phaseoffset, ...
    'FrequencyOffset',foffset,'SampleRate',fs);

```

Create a carrier synchronizer System object to use for correcting the phase and frequency offsets. Set the `Modulation` property to 8PSK.

```

carrierSync = comm.CarrierSynchronizer('Modulation','8PSK');

```

Generate random data and apply 8-PSK modulation.

```

data = randi([0 M-1],5000,1);
modSig = pskmod(data,M,pi/M);

```

Apply phase and frequency offsets using the `pfo` System object, and pass the signal through an AWGN channel to add Gaussian white noise.

```

modSigOffset = pfo(modSig);
rxSig = awgn(modSigOffset,snrdb);

```

Use the carrier synchronizer to estimate the phase offset of the received signal.

```

[~,phError] = carrierSync(rxSig);

```

Determine the frequency offset by using the `diff` function to compute an approximate derivative of the phase error. The derivative must be scaled by  $2\pi$  because the phase error is measured in radians.

```

estFreqOffset = diff(phError)*fs/(2*pi);

```

Plot the running mean of the estimated frequency offset. After the synchronizer converges to a solution, the mean value of the estimate is approximately equal to the input frequency offset value of 1000 Hz.

```

rmean = cumsum(estFreqOffset)./(1:length(estFreqOffset));
plot(rmean)
xlabel('Symbols')
ylabel('Estimated Frequency Offset (Hz)')
grid

```

### Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization

Compensation of significant phase and frequency offsets for a 16-QAM signal in an AWGN channel is accomplished in two steps. First, correct the coarse frequency offset using the estimate provided by the coarse frequency compensator, and then fine-tune the correction using carrier synchronization. Because of the coarse frequency correction, the carrier synchronizer converges quickly even though the normalized bandwidth is set to a low value. Lower normalized bandwidth values enable better correction for small residual

carrier offsets. After applying phase and frequency offset corrections to the received signal, resolve phase ambiguity using the preambles.

Define the simulation parameters.

```
fs = 10000;      % Sample rate (Hz)
sps = 4;        % Samples per symbol
M = 16;         % Modulation order
k = log2(M);    % Bits per symbol
rng(1996)       % Set seed for repeatable results
barker = comm.BarkerCode(...
    'Length',13,'SamplesPerFrame',13); % For preamble
msgLen = 1e4;
numFrames = 10;
frameLen = msgLen/numFrames;
```

Generate data payloads and add the preamble to each frame. The preamble is later used for phase ambiguity resolution.

```
preamble = (1+barker())/2; % Length 13, unipolar
data = zeros(msgLen, 1);
for idx = 1 : numFrames
    payload = randi([0 M-1],frameLen-barker.Length,1);
    data((idx-1)*frameLen + (1:frameLen)) = [preamble; payload];
end
```

Create a System object for the transmit pulse shape filtering, the receive pulse shape filtering, the QAM coarse frequency compensation, the carrier synchronization, and a constellation diagram.

```
txFilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
rxFilter = comm.RaisedCosineReceiveFilter(...
    'InputSamplesPerSymbol',sps,'DecimationFactor',sps);
coarse = comm.CoarseFrequencyCompensator('SampleRate',fs, ...
    'FrequencyResolution',10);
fine = comm.CarrierSynchronizer( ...
    'DampingFactor',0.4,'NormalizedLoopBandwidth',0.001, ...
    'SamplesPerSymbol',1,'Modulation','QAM');
axislimits = [-6 6];
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',qammod(0:M-1,M), ...
    'ChannelNames',{'Before convergence','After convergence'}, ...
    'ShowLegend',true,'XLimits',axislimits,'YLimits',axislimits);
```

Also create a System object for the AWGN channel, and the phase and frequency offset to add impairments to the signal. A phase offset greater than 90 degrees is added to induce a phase ambiguity that results in a constellation quadrant shift.

```
ebn0 = 8;
freqoffset = 110;
phaseoffset = 110;
awgnChannel = comm.AWGNChannel('EbNo',ebn0, ...
    'BitsPerSymbol',k,'SamplesPerSymbol',sps);
pfo = comm.PhaseFrequencyOffset('FrequencyOffset',freqoffset, ...
    'PhaseOffset',phaseoffset,'SampleRate',fs);
```

Generate random data symbols, apply 16-QAM modulation, and pass the modulated signal through the transmit pulse shaping filter.

```
txMod = qammod(data,M);
txSig = txFilter(txMod);
```

Apply phase and frequency offsets using the pfo System object, and then pass the signal through an AWGN channel to add white Gaussian noise.

```
txSigOffset = pfo(txSig);
rxSig = awgnChannel(txSigOffset);
```

The coarse frequency compensator System object provides a rough correction for the frequency offset. For the conditions in this example, correcting the frequency offset of the received signal correction to within 10 Hz of the transmitted signal is sufficient.

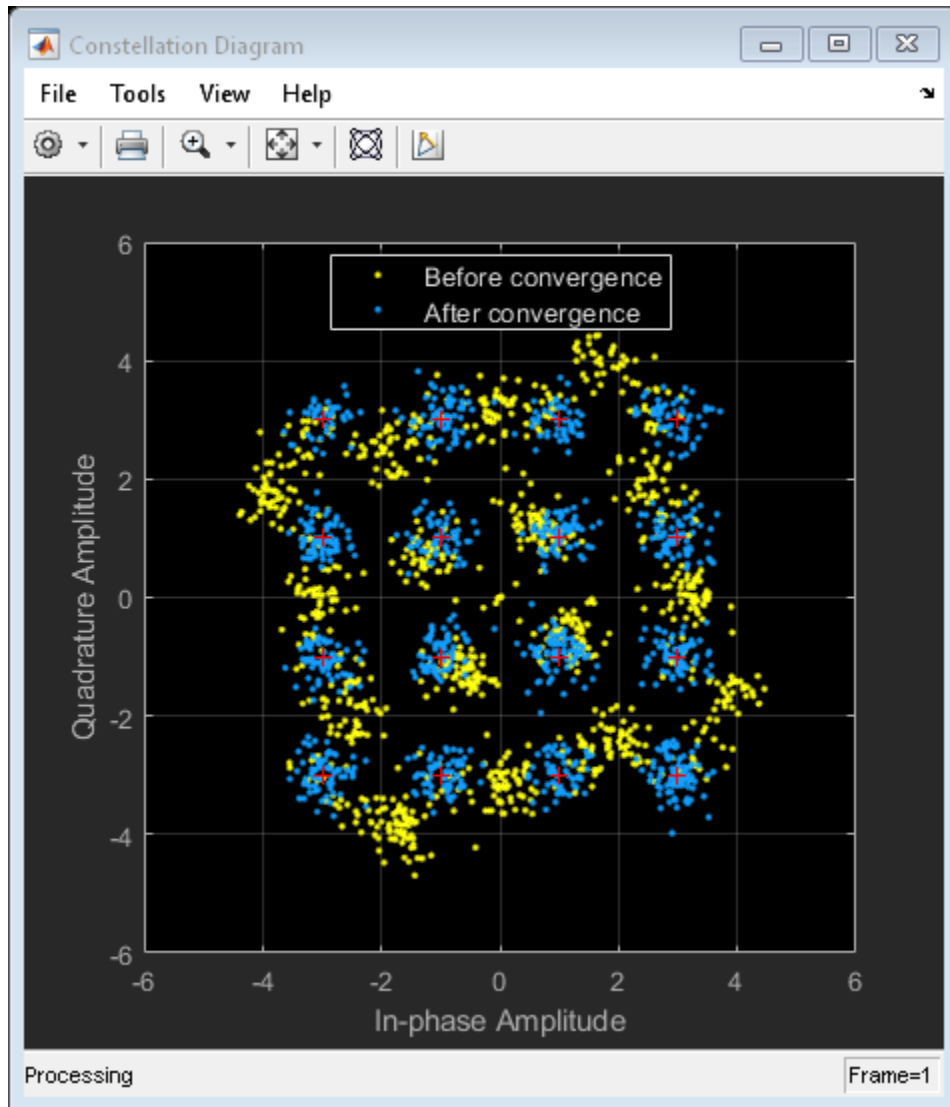

```
syncCoarse = coarse(rxSig);
```

Pass the signal through the receive pulse shaping filter, and apply fine frequency correction.

```
rxFiltSig = fine(rxFilter(syncCoarse));
```

Display the constellation diagram of the first and last 1000 symbols in the signal. Before convergence of the synchronization loop, the spiral nature of the diagram indicates that the frequency offset is not corrected. After the carrier synchronizer has converged to a solution, the symbols are aligned with the reference constellation.

```
constDiagram([rxFiltSig(1:1000) rxFiltSig(9001:end)])
```

Demodulate the signal. Account for the signal delay caused by the transmit and receive filters to align the received data with the transmitted data. Compute and display the total bit errors and BER. When checking the bit errors, use the later portion of the received signal to be sure the synchronization loop has converged.

```
rxData = qamdemod(rxFiltSig,M);
delay = (txFilter.FilterSpanInSymbols + rxFilter.FilterSpanInSymbols) / 2;
idxSync = 2000; % Check BER for the received signal after the synchronization loop has
[syncDataTtlErr,syncDataBER] = biterr(data(idxSync:end-delay),rxData(idxSync+delay:end));

syncDataTtlErr = 16116

syncDataBER = 0.5042
```

Depending on the random data used, there may be bit errors resulting from phase ambiguity in the received signal after the synchronization loop converges and locks. In this case, you can use the preamble to determine and then remove the phase ambiguity from the synchronized signal to reduce bit errors. If phase ambiguity is minimal, the number of bit errors may be unchanged.

```
idx = 9000 + (1:barker.Length);
phOffset = angle(txMod(idx) .* conj(rxFiltSig(idx+delay)));

phOffsetEst = mean(phOffset);
disp(['Phase offset = ',num2str(rad2deg(phOffsetEst)),' degrees'])

Phase offset = -90.1401 degrees

resPhzSig = exp(1i*phOffsetEst) * rxFiltSig;

Demodulate the signal after resolving the phase ambiguity. Recompute the total bit errors
and BER.

resPhzData = qamdemod(resPhzSig,M);
[resPhzTtlErr,resPhzBER] = biterr(data(idxSync:end-delay),resPhzData(idxSync+delay:end));

resPhzTtlErr = 5

resPhzBER = 1.5643e-04
```

### MSK Signal Recovery

Model channel impairments such as timing phase offset, carrier frequency offset, and carrier phase offset for a minimum shift keying (MSK) signal. Use `comm.MSKTimingSynchronizer` and `comm.CarrierSynchronizer` System objects to synchronize such signals at the receiver. The MSK timing synchronizer recovers the timing offset, while a carrier synchronizer recovers the carrier frequency and phase offsets.

Initialize system variables by running the MATLAB script `configureMSKSignalRecoveryEx`. Define the logical control variable `recoverTimingPhase` to enable timing phase recovery, and `recoverCarrier` to enable carrier frequency and phase recovery.

```
configureMSKSignalRecoveryEx;
recoverTimingPhase = true;
recoverCarrier = true;
```

### Modeling Channel Impairments

Specify the sample delay, `timingOffset`, that the channel model applies. Create a variable fractional delay object to introduce the timing delay to the transmitted signal.

```
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
```

Create a `comm.PhaseFrequencyOffset` System object to introduce carrier phase and frequency offsets to a modulated signal. Because the MSK modulator upsamples the transmitted symbols, set the `SampleRate` property to the ratio of the `samplesPerSymbol` and the sample time, `Ts`.

```
freqOffset = 50;
phaseOffset = 30;
pfo = comm.PhaseFrequencyOffset(...
    'FrequencyOffset',freqOffset, ...
    'PhaseOffset',phaseOffset, ...
    'SampleRate',samplesPerSymbol/Ts);
```

Create a `comm.AWGNChannel` System object to add white Gaussian noise to the modulated signal. The noise power is determined by the `EbNo` property, that is the bit energy to noise power spectral density ratio. Because the MSK modulator generates symbols with 1 Watt of power, set the signal power property of the AWGN channel System object to 1.

```
EbNo = 20 + 10*log10(samplesPerSymbol);
chAWGN = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (Eb/No)', ...
    'EbNo',EbNo,...
    'SignalPower',1, ...
    'SamplesPerSymbol',samplesPerSymbol);
```

### Timing Phase, Carrier Frequency, and Carrier Phase Synchronization

Create an MSK timing synchronizer to recover symbol timing phase using a fourth-order nonlinearity method.

```
timeSync = comm.MSKTimingSynchronizer(...  
    'SamplesPerSymbol',samplesPerSymbol, ...  
    'ErrorUpdateGain',0.02);
```

Create a carrier synchronizer to recover both carrier frequency and phase. Because the MSK constellation is QPSK with a 0-degree phase offset, set the `comm.CarrierSynchronizer` accordingly.

```
phaseSync = comm.CarrierSynchronizer(...  
    'Modulation','QPSK', ...  
    'ModulationPhaseOffset','Custom', ...  
    'CustomPhaseOffset',0, ...  
    'SamplesPerSymbol',1);
```

### Stream Processing Loop

The simulation modulates data using MSK modulation. The modulated symbols pass through the channel model, which applies timing delay, carrier frequency and phase shift, and additive white Gaussian noise. The receiver performs timing phase and carrier frequency and phase recovery. Finally, the signal symbols are demodulated and the bit error rate is calculated. The `plotResultsMSKSignalRecoveryEx` script generates scatter plots in this order to show these effects:

- 1 Channel impairments
- 2 Timing synchronization
- 3 Carrier synchronization

At the end of the simulation, the example displays the timing phase, frequency, and phase estimates as a function of simulation time.

```
for p = 1:numFrames  
    %-----  
    % Generate and modulate data  
    %-----  
    txBits = randi([0 1],samplesPerFrame,1);  
    txSym = modem(txBits);  
    %-----  
    % Transmit through channel
```

```

%-----
%
% Add timing offset
rxSigTimingOff = varDelay(txSym,timingOffset*samplesPerSymbol);
%
% Add carrier frequency and phase offset
rxSigCFO = pfo(rxSigTimingOff);
%
% Pass the signal through an AWGN channel
rxSig = chAWGN(rxSigCFO);
%
% Save the transmitted signal for plotting
plot_rx = rxSig;
%
%-----
% Timing recovery
%-----
if recoverTimingPhase
    % Recover symbol timing phase using fourth-order nonlinearity
    % method
    [rxSym,timEst] = timeSync(rxSig);
    % Calculate the timing delay estimate for each sample
    timEst = timEst(1)/samplesPerSymbol;
else
    % Do not apply timing recovery and simply downsample the received
    % signal
    rxSym = downsample(rxSig,samplesPerSymbol);
    timEst = 0;
end

% Save the timing synchronized received signal for plotting
plot_rxTimeSync = rxSym;

%-----
% Carrier frequency and phase recovery
%-----
if recoverCarrier
    % The following script applies carrier frequency and phase recovery
    % using a second order phase-locked loop (PLL), and removes phase ambiguity
    [rxSym,phEst] = phaseSync(rxSym);
    removePhaseAmbiguityMSKSignalRecoveryEx;
    freqShiftEst = mean(diff(phEst)/(Ts*2*pi));
    phEst = mod(mean(phEst),360); % in degrees
else

```

```
        freqShiftEst = 0;
        phEst = 0;
end

% Save the phase synchronized received signal for plotting
plot_rxPhSync = rxSym;
%-----
% Demodulate the received symbols
%-----
rxBits = demod(rxSym);
%-----
% Calculate the bit error rate
%-----
errorStats = BERCalc(txBits,rxBits);
%-----
% Plot results
%-----
plotResultsMSKSignalRecoveryEx;
end
```

Display the bit error rate and the total number of symbols processed by the error rate calculator.

```
BitErrorRate = errorStats(1)
TotalNumberOfSymbols = errorStats(3)
```

```
BitErrorRate =
    4.0001e-06
```

```
TotalNumberOfSymbols =
```

499982

### Conclusion and Further Experimentation

The recovery algorithms are demonstrated by using constellation plots taken after timing, carrier frequency, and carrier phase synchronization.

Open the script to create a writable copy of this example and its supporting files. Then, to show the effects of the recovery algorithms, you can enable and disable the logical control variables `recoverTimingPhase` and `recoverCarrier` and rerun the simulation.

### Appendix

This example uses these scripts:

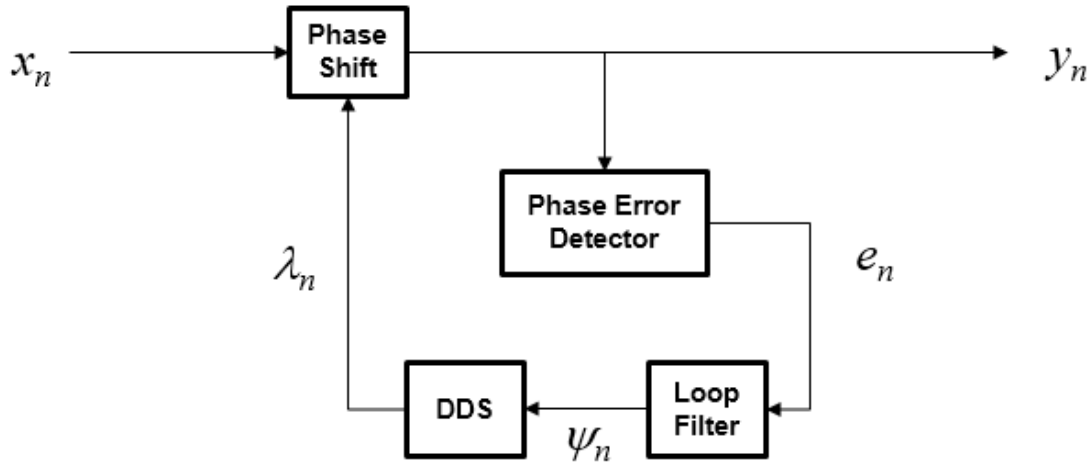

- `configureMSKSignalRecoveryEx`
- `plotResultsMSKSignalRecoveryEx`
- `removePhaseAmbiguityMSKSignalRecoveryEx`

## Algorithms

The `comm.CarrierSynchronizer` System object is a closed-loop compensator that uses the PLL-based algorithm described in [1]. The output of the synchronizer,  $y_n$ , is a frequency-shifted version of the complex input signal,  $x_n$ , for the  $n$ th sample. The synchronizer output is

$$y_n = x_n e^{i\lambda_n},$$

where  $\lambda_n$  is the output of the direct digital synthesizer (DDS). The DDS is the discrete-time version of a voltage-controlled oscillator and is a core component of discrete-time phase locked loops. In the context of this System object, the DDS works as an integration filter.

To correct for the frequency offset, first the algorithm determines the phase error,  $e_n$ . The value of the phase error depends on the modulation scheme.

Modulation	Phase Error
QAM or QPSK	$e_n = \text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\} - \text{sgn}(\text{Im}\{x_n\}) \times \text{Re}\{x_n\}$ <p>For a detailed description of this equation, see [1].</p>
BPSK or PAM	$e_n = \text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\}$ <p>For a detailed description of this equation, see [1].</p>

Modulation	Phase Error
8-PSK	$e_n = \begin{cases} \text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\} - (\sqrt{2} - 1)\text{sgn}(\text{Im}\{x_n\}) \times \text{Re}\{x_n\}, \\ (\sqrt{2} - 1)\text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\} - \text{sgn}(\text{Im}\{x_n\}) \times \text{Re}\{x_n\}, \end{cases}$ <p>For a detailed description of this equation, see [2].</p>
OQPSK	$e_n = \text{sgn}\left(\text{Re}\{x_{n-\text{SamplePerSymbol}/2}\}\right) \times \text{Im}\{x_{n-\text{SamplePerSymbol}/2}\}$

To ensure system stability, the phase error passes through a biquadratic loop filter governed by

$$\psi_n = g_I e_n + \psi_{n-1},$$

where  $\psi_n$  is the output of the loop filter at sample  $n$ , and  $g_I$  is the integrator gain. The integrator gain is determined from the equation

$$g_I = \frac{4(\theta^2/d)}{K_p K_0},$$

where  $\theta$ ,  $d$ ,  $K_0$ , and  $K_p$  are determined from the System object properties. Specifically,

$$\theta = \frac{B_n}{\left(\zeta + \frac{1}{4\zeta}\right)} \text{ and } d = 1 + 2\zeta\theta + \theta^2,$$

where  $B_n$  is the normalized loop bandwidth, and  $\zeta$  is the damping factor. The phase recovery gain,  $K_0$ , is equal to the number of samples per symbol. The modulation type determines the phase error detector gain,  $K_p$ .

Modulation	$K_p$
BPSK, PAM, QAM, QPSK, or OQPSK	2
8-PSK	1

The output of the loop filter is then passed to the DDS. The DDS is another biquadratic loop filter whose expression is based on the forward Euler integration rule

$$\lambda_n = (g_p e_{n-1} + \psi_{n-1}) + \lambda_{n-1},$$

where  $g_p$  is the proportional gain that is expressed as

$$g_p = \frac{4\zeta(\theta/d)}{K_p K_0}.$$

The `info` object function of this System object returns estimates of the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay. The normalized pull-in range,  $(\Delta f)_{\text{pull-in}}$ , is expressed in radians and estimated as

$$(\Delta f)_{\text{pull-in}} \approx \min(1, 2\pi\sqrt{2}\zeta B_n).$$

The expression for  $(\Delta f)_{\text{pull-in}}$  becomes less accurate as  $2\pi\sqrt{2}\zeta B_n$  approaches 1.

The maximum frequency lock delay,  $T_{\text{FL}}$ , and phase lock delay,  $T_{\text{PL}}$ , are expressed in samples and estimated as

$$T_{\text{FL}} \approx 4 \frac{(\Delta f)_{\text{pull-in}}^2}{B_n^3} \text{ and } T_{\text{PL}} \approx \frac{1.3}{B_n}.$$

## info

**Package:** comm

Characteristic information about carrier synchronizer

## Syntax

```
infostruct = info(carrSynch)
```

## Description

`infostruct = info(carrSynch)` returns a structure containing characteristic information for the `CarrierSynchronizer` System object.

## Examples

### Determine Carrier Synchronizer Loop Parameters

Create a carrier synchronizer object.

```
csync = comm.CarrierSynchronizer;
```

Determine the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay by using the `info` method.

```
syncInfo = info(csync)
```

```
syncInfo = struct with fields:  
    NormalizedPullInRange: 0.0628  
    MaxFrequencyLockDelay: 1.5787e+04  
    MaxPhaseLockDelay: 130
```

The normalized pull-in range is 0.0628 rad/sec. Convert the pull-in range to Hz. This represents the maximum normalized frequency offset that can be corrected by the carrier synchronizer.

```
foffsetmax = syncInfo.NormalizedPullInRange/(2*pi)
```

```
foffsetmax = 0.0100
```

The time to acquire a frequency lock is 15787 s, and the time to acquire a phase lock is 130 s.

The overall acquisition time,  $T_{lock}$ , is well approximated by the sum of the frequency and phase lock terms.

```
Tlock = syncInfo.MaxFrequencyLockDelay + syncInfo.MaxPhaseLockDelay
```

```
Tlock = 1.5917e+04
```

## Input Arguments

**carrSynch** — System object to get information from

System object

System object to get information from.

## Output Arguments

**infostruct** — Structure containing object information

struct

Structure containing these fields with information about the System object.

**NormalizedPullInRange** — Normalized pull in range

scalar

Normalized pull in range in radians, returned as a scalar. `NormalizedPullInRange` is the largest frequency offset (rad), normalized by the loop bandwidth, for which the synchronizer can acquire lock.

**MaxFrequencyLockDelay — Maximum frequency lock delay**

positive integer

Maximum frequency lock delay, returned as a positive integer. `MaxFrequencyLockDelay` is the number of samples required for the synchronizer to acquire frequency lock.

**MaxPhaseLockDelay — Maximum phase lock delay**

positive integer

Maximum phase lock delay, returned as a positive integer. `MaxPhaseLockDelay` is the number of samples required for the synchronizer to acquire phase lock.

## comm.CCDF

**Package:** comm

Measure complementary cumulative distribution function

### Description

The CCDF object measures the probability of a signal's instantaneous power to be a specified level above its average power.

To measure complementary cumulative distribution of a signal:

- 1 Define and set up your CCDF object. See “Construction” on page 4-338 .
- 2 Call `step` to measure complementary cumulative distribution according to the properties of `comm.CCDF`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.CCDF` creates a complementary cumulative distribution function measurement (CCDF) System object, `H`, that measures the probability of a signal's instantaneous power to be a specified level above its average power.

`H = comm.CCDF(Name,Value)` creates a CCDF object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### NumPoints

Number of CCDF points

Specify the number of CCDF points that the object calculates. This property requires a numeric, positive, integer scalar. The default is 1000. Use this property with the `MaximumPowerLimit` on page 4-0 property to control the size of the histogram bins. The object uses these bins to estimate CCDF curves. This controls the resolution of the curves. All input channels must have the same number of CCDF points.

### MaximumPowerLimit

Maximum expected input signal power

Specify the maximum expected input signal power limit for each input channel. The default is 50. Set this property to a numeric scalar or row vector length equal to the number of input channels. When you set this property to a scalar, the object assumes that the signals in all input channels have the same expected maximum power. When you set this property to a row vector length equal to the number of input channels, the object assumes that the *i*-th element of the vector is the maximum expected power for the signal at the *i*-th input channel. When you call the `step` method, the object displays the value of this property in the units that you specify in the `PowerUnits` on page 4-0 property. For each input channel, the object obtains CCDF results by integrating a histogram of instantaneous input signal powers. The object sets the bins of the histogram so that the last bin collects all power occurrences that are equal to, or greater than the power that you specify in this property. The object issues a warning if any input signal exceeds its specified maximum power limit. Use this property with the `NumPoints` on page 4-0 property to control the size of the histogram bins that the object uses to estimate CCDF curves (such as control the resolution of the curves).

### PowerUnits

Power units

Specify the power measurement units as one of `dBm` | `dBW` | `Watts`. The default is `dBm`. The `step` method outputs power measurements in the units specified in the `PowerUnits` on page 4-0 property. When you set this property to `dBm` or `dBW`, the `step` method outputs relative power values in a dB scale. When you set this property to `Watts`, the `step` method outputs relative power values in a linear scale. When you call the `step`

method, the object assumes that the units of `MaximumPowerLimit` on page 4-0 have the same value you specified in the `PowerUnits` property.

### **AveragePowerOutputPort**

Enable average power measurement output

When you set this property to `true`, the `step` method outputs running average power measurements. The default is `false`.

### **PeakPowerOutputPort**

Enable peak power measurement output

When you set this property to `true`, the `step` method outputs running peak power measurements. The default is `false`.

### **PAPROutputPort**

Enable PAPR measurement output

When you set this property to `true`, the `step` method outputs running peak-to-average-power measurements. The default is `false`.

## **Methods**

<code>getPercentileRelativePower</code>	Get relative power value for a given probability
<code>getProbability</code>	Get the probability for a given relative power value
<code>plot</code>	Plot CCDF curves
<code>reset</code>	Reset states of CCDF measurement object
<code>step</code>	Measure complementary cumulative distribution function

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## **Examples**

### Obtain CCDF curves for 16-QAM and QPSK signals

Create a CCDF System object and specify that it output average power and peak power measurements.

```
ccdf = comm.CCDF('AveragePowerOutputPort',true, ...  
                'PeakPowerOutputPort',true);
```

Generate 16-QAM and QPSK modulated signals.

```
qamTxSig = qammod(randi([0 15],20e3,1),16,'UnitAveragePower',true);  
qpskTxSig = pskmod(randi([0 3],20e3,1),4,pi/4);
```

Pass the signals through an AWGN channel.

```
qamRxSig = awgn(qamTxSig,15);  
qpskRxSig = awgn(qpskTxSig,15);
```

Measure the CCDF of the two waveforms. Plot the CCDF using the `plot` method of `comm.CCDF`.

```
[CCDFy,CCDFx,AvgPwr,PeakPwr] = ccdf([qamRxSig qpskRxSig]);  
  
plot(ccdf)  
legend('16-QAM','QPSK')
```

## Extended Capabilities

## getPercentileRelativePower

**System object:** comm.CCDF

**Package:** comm

Get relative power value for a given probability

### Syntax

`R = getPercentileRelativePower(H,P)`

### Description

`R = getPercentileRelativePower(H,P)` finds the relative power values, *R*. The power of the signal of interest is above its average power by *R* dB (if `PowerUnits` equals 'dBW', or 'dBm') or by a factor of *R* (in linear scale if `PowerUnits` equals 'Watts') with a probability *P*.

The method output *R*, is a column vector with the *i*-th element corresponding to the relative power for the *i*-th input channel. The method input *P* can be a double precision scalar, or a vector with a number of elements equal to the number of input channels. If *P* is a scalar, then all the relative powers in *R* correspond to the same probability value specified in *P*. If *P* is a vector, then the *i*-th element of *R* corresponds to a power value that occurs in the *i*-th input channel, with a probability specified in the *i*-th element of *P*.

For the *i*-th input channel, this method evaluates the inverse CCDF curve at probability value  $P(i)$ .

### Examples

Obtain CCDF curves for a unit variance AWGN signal and a dual- tone signal. The AWGN signal is *RPW1* dB above its average power one percent of the time, and the dual-tone signal is *RPW2* dB above its average power 10 percent of the time. This example finds the values of *RPW1* and *RPW2*.

```
n = [0:5e3-1].';
s1 = randn(5e3,1);           % AWGN signal
s2 = sin(0.01*pi*n)+sin(0.03*pi*n); % dual-tone signal
hCCDF = comm.CCDF;          % create a CCDF object
step(hCCDF,[s1 s2]);        % step the CCDF measurements
plot(hCCDF)                 % plot CCDF curves
legend('AWGN','Dual-tone')
RPW = getPercentileRelativePower(hCCDF,[1 10]);
RPW1 = RPW(1)
RPW2 = RPW(2)
```

## getProbability

**System object:** comm.CCDF

**Package:** comm

Get the probability for a given relative power value

### Syntax

```
P = getProbability(H,R)
```

### Description

`P = getProbability(H,R)` finds the probability,  $P$ , of the power level of the signal of interest being  $R$  dBs (if `PowerUnits` equals 'dBW', or 'dBm') or Watts (if `PowerUnits` equals 'Watts') above its average power.  $P$  is a column vector with the  $i$ -th element corresponding to the probability value for the  $i$ -th input channel. Input  $R$  can be a double precision scalar or a vector with a number of elements equal to the number of input channels. If  $R$  is a scalar, then all the probability values in  $P$  correspond to the same relative power specified in  $R$ . If  $R$  is a vector, then the  $i$ th element of  $P$  contains a probability value for the  $i$ -th channel and for the relative power specified in the  $i$ -th element of  $R$ .

For the  $i$ -th input channel, this method evaluates the CCDF curve at relative power value  $R(i)$

### Examples

Obtain CCDF curves for a unit variance AWGN signal and a dual-tone signal. Find the probability that the AWGN signal power is 5 dB above its average power and that the dual-tone signal power is 3 dB above its average power.

```
n = [0:5e3-1].';  
s1 = randn(5e3,1);           % AWGN signal  
s2 = sin(0.01*pi*n)+sin(0.03*pi*n); % dual-tone signal  
hCCDF = comm.CCDF;  
step(hCCDF,[s1 s2]);
```

```
plot(hCCDF)                % plot CCDF curves
legend('AWGN','Dual-tone')
P = getProbability(hCCDF,[5 3]) % get probabilities
```

# plot

**System object:** `comm.CCDF`

**Package:** `comm`

Plot CCDF curves

## Syntax

```
D = plot(H)
```

## Description

`D = plot(H)` plots CCDF measurements in the CCDF System object, `H`. The `plot` method returns the plot handles as an output, `D`. This method plots the same number of curves as there are input channels. The `H` input can be followed by parameter-value pairs to specify additional properties of the curves. For example, `plot(H,LineWidth,2)` will create curves with line widths of 2 points.

The `comm.CCDF` System object does not support C code generation for this method.

## reset

**System object:** comm.CCDF

**Package:** comm

Reset states of CCDF measurement object

## Syntax

reset(H)

## Description

reset(H) resets the states of the CCDF object, H.

# step

**System object:** `comm.CCDF`

**Package:** `comm`

Measure complementary cumulative distribution function

## Syntax

```
[CCDFY,CCDFX] = step(H,X)
[CCDFY,CCDFX,AVG] = step(H,X)
[CCDFY,CCDFX,PEAK] = step(H,X)
[CCDFY,CCDFX,PAPR] = step(H,X)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`[CCDFY,CCDFX] = step(H,X)` updates CCDF, average power, and peak power measurements for input `X` using the CCDF System object, `H`. It outputs the y-axis, `CCDFY`, and x-axis, `CCDFX`, CCDF points. `X` must be a double precision,  $M$ -by- $N$  matrix, where  $M$  is the number of time samples and  $N$  is the number of input channels. The `step` method outputs `CCDFY` as a matrix whose  $i$ -th column contains updated probability values measured from the  $i$ -th column of input matrix `X`. `CCDFY` contains the y-axis points of the CCDF curves of each channel. The `step` method outputs `CCDFX` as a matrix containing, in its  $i$ -th column, the corresponding updated instantaneous-to-average power ratios for the  $i$ th column of input matrix `X`. `CCDFX` contains the x-axis points of the CCDF curves of each channel. The object sets the number of rows in `CCDFY` and `CCDFX` equal to `NumPoints` property + 1. The probability values are percentages in the `[0 100]` interval. When you set the `PowerUnits` property to `dBW` or `dBm`, the relative powers are in dB scale. When you set the `PowerUnits` property to `Watts`, the relative powers are in linear scale.

---

Measurements are updated each time you call the `step` method until you reset the object. You call the `plot` method to plot CCDF curves for each channel.

`[CCDFY, CCDFX, AVG] = step(H, X)` returns updated average power measurements, `AVG`, when you set the `AveragePowerOutputPort` property to `true`. The `step` method outputs `AVG` as a column vector with the `ith` element corresponding to an updated average power measurement for the signal available in the `ith` column of input matrix `X`. You specify the units for `AVG` in the `PowerUnits` property.

`[CCDFY, CCDFX, PEAK] = step(H, X)` returns updated peak power measurements, `PEAK`, when you set the `PeakPowerOutputPort` property to `true`. The `step` method outputs `PEAK` as a column vector with the `ith` element corresponding to an updated peak power measurement for the signal available in the `ith` column of input matrix `X`. You specify the units for `PEAK` in the `PowerUnits` property.

`[CCDFY, CCDFX, PAPR] = step(H, X)` returns updated peak-to-average power ratio measurements, `PAPR`, when you set the `PAPROutputPort` property to `true`. The `step` methods outputs `PAPR` as a column vector with the `ith` element corresponding to an updated peak-to-average power ratio measurement for the signal available in the `ith` column of input matrix `X`. When you set the `PowerUnits` property to `dBW` or `dBm`, the method outputs `PAPR` in a dB scale. When you set the `PowerUnits` property to `Watts`, the method outputs `PAPR` in a linear scale. You can combine optional output arguments when you set their enabling properties. Optional outputs must be listed in the same order as the order of the enabling properties. For example,

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.CoarseFrequencyCompensator

**Package:** comm

Compensate for frequency offset for PAM, PSK, or QAM

### Description

The `CoarseFrequencyCompensator` System object compensates for the frequency offset of received signals.

To compensate for the frequency offset of a PAM, PSK, or QAM signal:

- 1 Define and set up your coarse frequency compensator object. See “Construction” on page 4-352.
- 2 Call `step` to compensate for the frequency offset of a PAM, PSK, or QAM signal according to the properties of `comm.CoarseFrequencyCompensator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`CFC = comm.CoarseFrequencyCompensator` creates a coarse frequency offset compensator object, `CFC`. This object uses an open-loop technique to estimate and compensate for the carrier frequency offset in a received signal.

`CFC = comm.CoarseFrequencyCompensator(Name,Value)` creates a coarse frequency offset compensator object, `CFC`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Properties

### Modulation

Modulation type

Specify the signal modulation type as BPSK, QPSK, OQPSK, 8PSK, PAM, or QAM. The default is QAM. This property is nontunable.

### Algorithm

Algorithm used to estimate frequency offset

Specify the estimation algorithm as one of FFT-based or Correlation-based. The default is FFT-based. This property is nontunable.

The table shows the allowable combinations of the modulation type and the estimation algorithm.

Modulation	FFT-Based Algorithm	Correlation-Based Algorithm
BPSK, QPSK, 8PSK, PAM	✓	✓
OQPSK, QAM	✓	

Use the correlation-based algorithm for HDL implementations and for other situations in which you want to avoid using an FFT.

This property appears when Modulation is 'BPSK', 'QPSK', '8PSK', or 'PAM'.

### FrequencyResolution

Frequency resolution (Hz)

Specify the frequency resolution for the offset frequency estimation as a positive, real scalar of data type `double`. This property establishes the FFT length used to perform spectral analysis and must be less than the sample rate. The default is 0.001. This property is nontunable.

### MaximumFrequencyOffset

Maximum measurable frequency offset (Hz)

Specify the maximum measurable frequency offset as a positive, real scalar of data type `double`.

The value of this property must be less than  $f_{samp} / M$ , where  $f_{samp}$  is the sample rate and  $M$  is the modulation order. As a best practice, set `MaximumOffset` to less than  $r / (4M)$ . This property applies only if `Algorithm` is `Correlation-based`. The default is `0.05`. This property is nontunable.

### **SampleRate**

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type `double`. The default is `1`. This property is nontunable.

### **SamplesPerSymbol**

Samples per symbol

Specify the number of samples per symbol,  $s$ , as a real positive finite integer scalar, such that  $s \geq 2$ . The default value is `4`. This property is nontunable.

This property appears when `Modulation` is `'OQPSK'`.

## **Methods**

- `info` Characteristic information about coarse frequency compensator
- `reset` Reset states of the `CoarseFrequencyCompensator` object
- `step` Compensate for frequency offset

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## **Examples**

## Compensate for Frequency Offset in a QPSK Signal

Compensate for a 4 kHz frequency offset imposed on a noisy QPSK signal.

Set the example parameters.

```
nSym = 2048;      % Number of input symbols
sps = 4;         % Samples per symbol
nSamp = nSym*sps; % Number of samples
fs = 80000;     % Sampling frequency (Hz)
```

Create a square root raised cosine transmit filter.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'RolloffFactor',0.2, ...
    'FilterSpanInSymbols',8, ...
    'OutputSamplesPerSymbol',sps);
```

Create a phase frequency offset object to introduce the 4 kHz frequency offset.

```
freqOffset = comm.PhaseFrequencyOffset(...
    'FrequencyOffset',-4000, ...
    'SampleRate',fs);
```

Create a coarse frequency compensator object to compensate for the offset.

```
freqComp = comm.CoarseFrequencyCompensator(...
    'Modulation','QPSK', ...
    'SampleRate',fs, ...
    'FrequencyResolution',1);
```

Generate QPSK symbols, filter the modulated data, pass the signal through an AWGN channel, and apply the frequency offset.

```
data = randi([0 3],nSym,1);
modData = pskmod(data,4,pi/4);
txSig = txfilter(modData);
rxSig = awgn(txSig,20,'measured');
offsetData = freqOffset(rxSig);
```

Compensate for the frequency offset using `freqComp`. When the frequency offset is high, it is beneficial to do coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.

```
[compensatedData,estFreqOffset] = freqComp(offsetData);
```

Display the estimate of the frequency offset.

```
estFreqOffset
```

```
estFreqOffset =  
-3.9999e+03
```

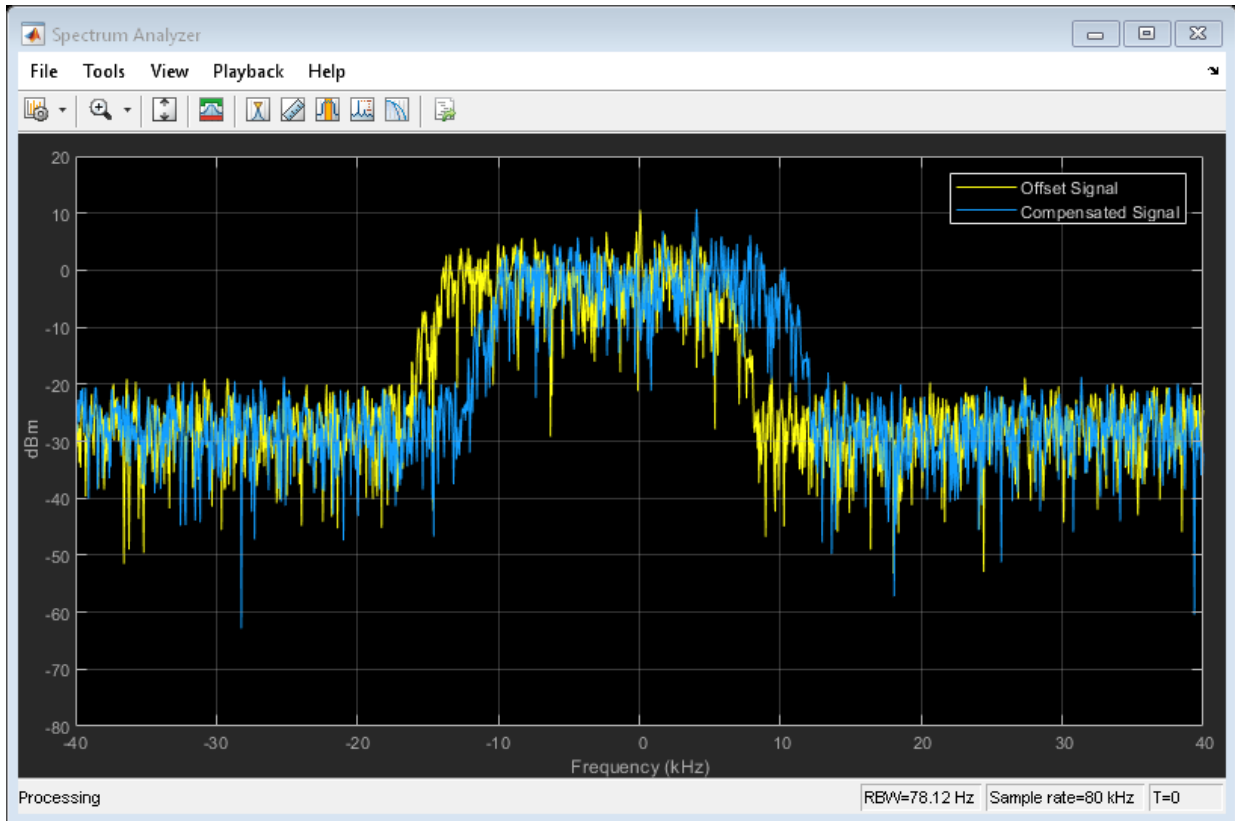

Return information about the `freqComp` object. To obtain the FFT length, you must call `freqComp` prior to calling the `info` method.

```
freqCompInfo = info(freqComp)
```

```
freqCompInfo =  
struct with fields:  
    FFTLength: 131072  
    Algorithm: 'FFT-based'
```

Create a spectrum analyzer object and plot the offset and compensated spectra. Verify that the compensated signal has a center frequency at 0 Hz and that the offset signal has a center frequency at -4 kHz.

```
specAnal = dsp.SpectrumAnalyzer('SampleRate',fs,'ShowLegend',true, ...  
    'ChannelNames',{'Offset Signal' 'Compensated Signal'});  
specAnal([offsetData compensatedData])
```

### Compensate for Frequency Offset Using Coarse and Fine Compensation

Correct for a phase and frequency offset in a noisy QAM signal using a carrier synchronizer. Then correct for the offsets using both a carrier synchronizer and a coarse frequency compensator.

Set the example parameters.

```
fs = 10000;           % Symbol rate (Hz)
sps = 4;             % Samples per symbol
M = 16;              % Modulation order
k = log2(M);         % Bits per symbol
```

Create a QAM modulator and an AWGN channel.

```
channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',k,'SamplesPerSymbol',sps);
```

Create a constellation diagram object to visualize the effects of the offset compensation techniques. Specify the constellation diagram to display only the last 4000 samples.

```
constdiagram = comm.ConstellationDiagram(...  
    'ReferenceConstellation',qammod(0:M-1,M), ...  
    'SamplesPerSymbol',sps, ...  
    'SymbolsToDisplaySource','Property','SymbolsToDisplay',4000, ...  
    'XLimits',[-5 5],'YLimits',[-5 5]);
```

Introduce a frequency offset of 400 Hz and a phase offset of 30 degrees.

```
phaseFreqOffset = comm.PhaseFrequencyOffset(...  
    'FrequencyOffset',400,...  
    'PhaseOffset',30,...  
    'SampleRate',fs);
```

Generate random data symbols and apply 16-QAM modulation.

```
data = randi([0 M-1],10000,1);  
modSig = qammod(data,M);
```

Create a raised cosine filter object and filter the modulated signal.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps, ...  
    'Gain',sqrt(sps));  
txSig = txfilter(modSig);
```

Apply the phase and frequency offset, and then pass the signal through the AWGN channel.

```
freqOffsetSig = phaseFreqOffset(txSig);  
rxSig = channel(freqOffsetSig);
```

Apply fine frequency correction to the signal by using the carrier synchronizer.

```
fineSync = comm.CarrierSynchronizer('DampingFactor',0.7, ...  
    'NormalizedLoopBandwidth',0.005, ...  
    'SamplesPerSymbol',sps, ...  
    'Modulation','QAM');  
rxData = fineSync(rxSig);
```

Display the constellation diagram of the last 4000 symbols.

Repeat the process with a coarse frequency compensator inserted before the carrier synchronizer.

Create a coarse frequency compensator to reduce the frequency offset to a manageable level.

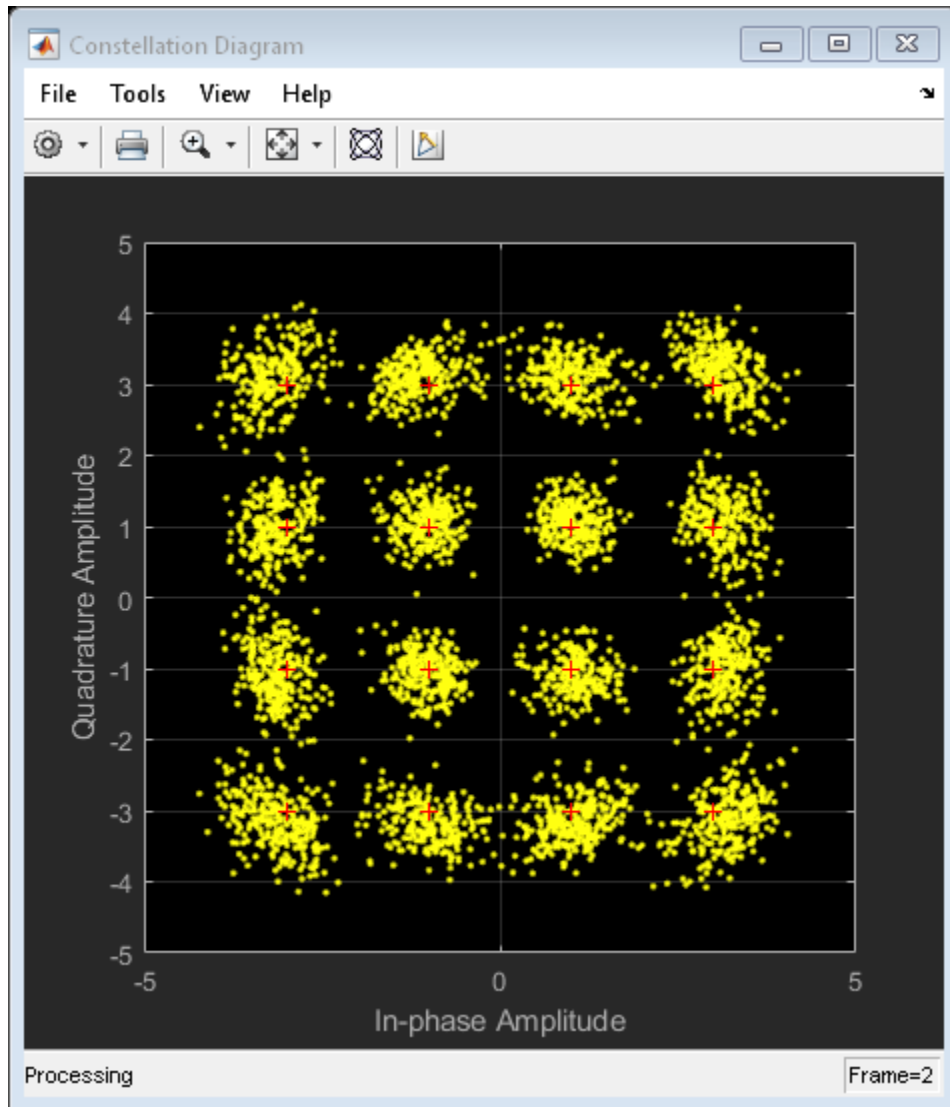

```
coarseSync = comm.CoarseFrequencyCompensator('Modulation','QAM','FrequencyResolution', ...
```

Pass the received signal to the coarse frequency compensator and then to the carrier synchronizer.

```
syncCoarse = coarseSync(rxSig);  
rxData = fineSync(syncCoarse);
```

Plot the constellation diagram of the signal after coarse and fine frequency compensation.

```
constdiagram(rxData)
```

The received data now aligns with the reference constellation.

## Algorithms

### Correlation-Based

The correlation-based estimation algorithm, which can be used to estimate the frequency offset for PSK and PAM signals, is described in [1]. To determine the frequency offset,  $\Delta f$ , the algorithm performs a maximum likelihood (ML) estimation of the complex-valued oscillation  $\exp(j2\pi\Delta ft)$ . The observed signal,  $r_k$ , is represented as

$$r_k = e^{j(2\pi\Delta f k T_s + \theta)}, \quad 1 \leq k \leq N,$$

where  $T_s$  is the sampling interval,  $\theta$  is an unknown random phase, and  $N$  is the number of samples. The maximum likelihood estimation of the frequency offset is equivalent to seeking the maximum of the likelihood function,  $\Lambda(\Delta f)$ ,

$$\Lambda(\Delta f) \approx \left| \sum_{i=1}^N r_i e^{-j2\pi\Delta f i T_s} \right|^2 = \sum_{k=1}^N \sum_{m=1}^N r_k r_m^* e^{-j2\pi\Delta f T_s(k-m)}.$$

After simplifying, the problem is expressed as a discrete Fourier transform, weighted by a parabolic windowing function. It is expressed as

$$\text{Im} \left\{ \sum_{k=1}^{N-1} k(N-k) R(k) e^{j2\pi\Delta \hat{f} T_s} \right\} = 0,$$

where  $R(k)$  denotes the estimated autocorrelation of the sequence  $r_k$  and is represented as

$$R(k) \triangleq \frac{1}{N-k} \sum_{i=k+1}^N r_i r_{i-k}^*, \quad 0 \leq k \leq N-1.$$

The term  $k(N-k)$  is the parabolic windowing function. In [1], it is shown that  $R(k)$  is a poor estimate of the autocorrelation of  $r_k$  when  $k = 0$  or when  $k$  is close to  $N$ . Consequently, the windowing function can be expressed as a rectangular sequence of 1s for  $k = 1, 2, \dots, L$ , where  $L \leq N-1$ . The results is a modified ML estimation strategy in which

$$\text{Im} \left\{ \sum_{k=1}^L R(k) e^{-j2\pi\Delta\hat{f}kT_s} \right\} = 0 .$$

This results in an estimate of  $\Delta\hat{f}$  in which

$$\Delta\hat{f} \cong \frac{f_{\text{samp}}}{\pi(L+1)} \arg \left\{ \sum_{k=1}^L R(k) \right\} .$$

The sampling frequency,  $f_{\text{samp}}$ , is the reciprocal of  $T_s$ . The number of elements used to compute the autocorrelation sequence,  $L$ , are determined as

$$L = \text{round} \left( \frac{f_{\text{samp}}}{f_{\text{max}}} \right) - 1 ,$$

where  $f_{\text{max}}$  is the maximum expected frequency offset and  $\text{round}$  is the nearest integer function. The frequency offset estimate improves when  $L \geq 7$  and leads to the recommendation that  $f_{\text{max}} \leq f_{\text{samp}} / (4M)$ .

## FFT-Based

FFT-based algorithms can be used to estimate the frequency offset for all modulation types. Two variations are used in comm.CoarseFrequencyCompensator.

- For BPSK, QPSK, 8PSK, PAM, or QAM modulations the FFT-based algorithm used is described in [2]. The algorithm estimates  $\Delta\hat{f}$  by using a periodogram of the  $m^{\text{th}}$  power of the received signal and is given as

$$\Delta\hat{f} = \frac{f_{\text{samp}}}{N \cdot m} \arg \max_f \left| \sum_{k=0}^{N-1} r^m(k) e^{-j2\pi kt/N} \right|, \quad \left( -\frac{R_{\text{sym}}}{2} \leq f \leq \frac{R_{\text{sym}}}{2} \right),$$

where  $m$  is the modulation order,  $r(k)$  is the received sequence,  $R_{\text{sym}}$  is the symbol rate, and  $N$  is the number of samples. The algorithm searches for a frequency that maximizes the time average of the  $m^{\text{th}}$  power of the received signal multiplied by various frequencies in the range of  $[-R_{\text{sym}}/2, R_{\text{sym}}/2]$ . As the form of the algorithm is the definition of the discrete Fourier transform of  $r^m(t)$ , searching for a frequency that maximizes the time average is equivalent to searching for a peak line in the spectrum of  $r^m(t)$ . The number of points required by the FFT is

$$N = 2 \left\lceil \log_2 \left( \frac{f_{\text{samp}}}{f_r} \right) \right\rceil ,$$

where  $f_r$  is the desired frequency resolution.

- For OQPSK modulation the FFT-based algorithm used is described in [4]. The algorithm searches for spectral peaks at +/- 200 kHz around the symbol rate. This technique locates desired peaks in the presence of interference from spectral content around baseband frequencies due to filtering.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## **See Also**

`comm.CarrierSynchronizer` | `comm.PhaseFrequencyOffset` | `dsp.FFT`

**Introduced in R2015b**

### info

**System object:** `comm.CoarseFrequencyCompensator`

**Package:** `comm`

Characteristic information about coarse frequency compensator

### Syntax

```
S = info(CFC)
```

### Description

`S = info(CFC)` returns a structure, `S`, containing characteristic information for the `CoarseFrequencyCompensator` System object, `CFC`. `S` has fields `FFTLength`, `Algorithm`, and `MaxLag`. `Algorithm` is the type of algorithm used in estimating the frequency offset. `FFTLength` is the number of samples used in the FFT and is provided when the algorithm is FFT-based. `MaxLag` is the number of samples used in estimating the autocorrelation and is provided when the algorithm is Correlation-based.

---

**Note** The `step` method must be run once to determine the `FFTLength`.

---

## reset

**System object:** `comm.CoarseFrequencyCompensator`

**Package:** `comm`

Reset states of the `CoarseFrequencyCompensator` object

## Syntax

`reset(CFC)`

## Description

`reset(CFC)` resets the internal states of the `CoarseFrequencyCompensator` object, `CFC`.

# step

**System object:** `comm.CoarseFrequencyCompensator`

**Package:** `comm`

Compensate for frequency offset

## Syntax

`Y = step(CFC,X)`

`[Y,EST] = step(CFC,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(CFC,X)` compensates for the carrier frequency offset of the input `X` and returns the result in `Y`. `X` must be a column vector. The `step` method outputs the compensated signal `Y` as a complex column vector having the same dimensions and data type as `X`.

`[Y,EST] = step(CFC,X)` returns a scalar estimate of the frequency offset, `EST`.

---

**Note** `CFC` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.ConstellationDiagram

**Package:** comm

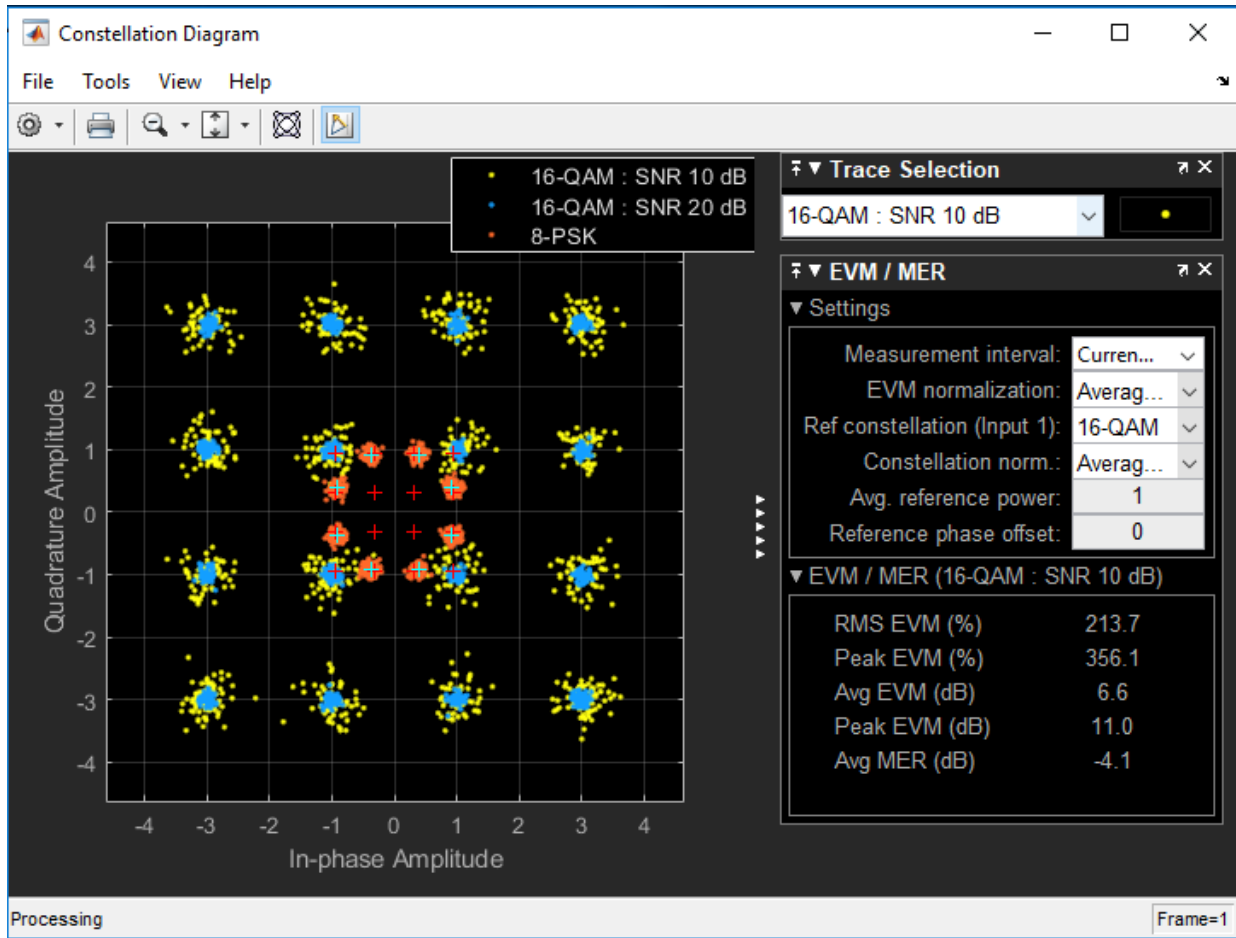

Display constellation diagram for input signals

## Description

The `comm.ConstellationDiagram` System object displays real and complex-valued floating and fixed-point signals in the IQ plane. Use this System object to perform qualitative and quantitative analysis on modulated single-carrier signals.

In the constellation diagram window you can:

- Input and plot multiple signals on a single constellation diagram. You can define one reference constellation for each input signal. For more information, see `ReferenceConstellation`.
- Choose which channels are displayed by selecting signals in the legend. Use the `ShowLegend` property to display the legend. For a multichannel signal, specify the input as a matrix with individual signals defined in the columns of the matrix.
- Display the “EVM / MER Measurements” on page 4-387 panel, which displays calculated error vector magnitude (EVM) and modulation error ratio (MER) measurements. When multiple signals are input to a `comm.ConstellationDiagram` System object, use the **Trace Selection** pane to choose the signal being measured.

To display constellation diagrams:

- 1 Create the `comm.ConstellationDiagram` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
constdiag = comm.ConstellationDiagram  
constdiag = comm.ConstellationDiagram(Name, Value)
```

## Description

`constdiag = comm.ConstellationDiagram` returns a `comm.ConstellationDiagram` System object that displays real and complex-valued floating and fixed-point signals in the IQ plane.

`constdiag = comm.ConstellationDiagram(Name, Value)` set the properties of the System object using one or more name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Example: `constdiag = comm.ConstellationDiagram('SampleOffset', 1e3)` specifies that the first 1000 samples received will not be displayed.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see `System Design in MATLAB Using System Objects` (MATLAB).

### **Name — Title of Constellation Diagram window**

'Constellation Diagram' (default) | character vector

Title of the Constellation Diagram window, specified as a character vector.

### **SamplesPerSymbol — Number of samples used to represent each symbol**

1 (default) | positive integer

Number of samples used to represent each symbol, specified as a positive integer. When the `SamplesPerSymbol` property is greater than 1, the signal is downsampled before it is plotted.

**Tunable:** Yes

### **SampleOffset — Number of samples to skip before plotting points**

0 (default) | nonnegative integer

Number of samples to skip before plotting points, specified as a nonnegative integer less than `SamplesPerSymbol`. This property specifies the number of samples to skip when downsampling the input signal.

**Tunable:** Yes

### **SymbolsToDisplaySource — Source of symbols to display**

'Input frame length' (default) | 'Property'

Source of symbols to display, specified as:

- 'Input frame length' — The number of symbols to display is equal to the input frame length divided by `SamplesPerSymbol`.
- 'Property' — `SymbolsToDisplay` specifies the maximum number of symbols to display.

**Tunable:** Yes

### **SymbolsToDisplay — Maximum number of symbols to display**

256 (default) | positive integer

Maximum number of symbols to display, specified as a positive integer. Use `SymbolsToDisplay` to limit the maximum number of symbols displayed when long signals are input. Symbols plotted are the most recent symbols received.

**Tunable:** Yes

### **Dependencies**

This property applies when `SymbolsToDisplaySource` is set to 'Property'.

### **ReferenceConstellation — Reference constellations**

[0.7071+0.7071i -0.7071+0.7071i -0.7071-0.7071i 0.7070-0.7071i]  
(default) | row vector | cell array

Reference constellations for the input signals, specified as a row vector or cell array of vectors defining the ideal constellation points for each input signal. Input signals can be single channel or multichannel. You can define one reference constellation for each input signal. For multichannel input signals, one reference constellation specification applies to all the individual signals in that input signal. To obtain the “EVM / MER Measurements” on page 4-387, you must set the **ReferenceConstellation** property.

**Tunable:** Yes

Data Types: double

Complex Number Support: Yes

### ReferenceMarker — Marker for reference display

'+' (default) | string | cell array

Specify the marker for the reference display as a string or cell array of strings. Select the marker symbol as one of the markers in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

**Tunable:** Yes

Data Types: string

### **ReferenceColor — Color for reference display constellation**

`[1 0 0]` (red) (default) | row vector | cell array

Color for reference display constellation, specified as a three-element row vector indicating RGB component colors or as a cell array containing RGB component colors for each input signal.

Data Types: double

### **ShowReferenceConstellation — Display the reference constellation**

`true` (default) | `false`

Display the reference constellation, specified as `true` or `false`.

**Tunable:** Yes

Data Types: logical

### **ShowTrajectory — Turn on signal trajectory plot**

`false` (default) | `true`

Turn on signal trajectory plot, specified as `false` or `true`. The signal trajectory is a plot of the in-phase component versus the quadrature component of a modulated signal. See the Show Signal Trajectory button on the toolbar in the “Signal Display” on page 4-385.

**Tunable:** Yes

Data Types: logical

### **Position — Scope window position and size**

410-by-300 pixel window at center of screen (default) | four-element vector

Scope window position and size in pixels, specified as a four-element vector of the form [*left bottom width height*]. The first two elements in the vector indicate the location of the lower left corner and the last two specify the size of the window. The default value for the location depends on the screen resolution. By default, the window is positioned in the center of the screen with a width and height of 410 and 300 pixels, respectively.

**Tunable:** Yes

Data Types: double

### **NumInputPorts — Number of input ports**

1 (default) | integer in the range [1, 20]

Specify the number of input ports, as an integer in the range [1, 20]. Each input signal, whether it is a multichannel signal or a single channel signal, becomes a separate input port in the scope.

When multichannel input signals are specified, the maximum number of input ports is limited by the total number of input signals defined. The total number of input signals cannot exceed 20.

### ShowGrid — Turn on grid

true (default) | false

Turn on the grid, specified as true or false.

**Tunable:** Yes

Data Types: logical

### ChannelNames — Names for input channels

empty cell (default) | cell array of strings or character vectors

Names for input channels, specified as a cell array of strings or character vectors. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

The names assigned to input channels appear in the legend and the **Measurements > Trace Selection** pane.

To show the legend, set ShowLegend to true. The legend displays after you provide an input signal to the comm.ConstellationDiagram System object.

To show the **Trace Selection** pane, select **Tools > Measurements > Trace Selection**. To enable the **Trace Selection** pane, you must first provide an input signal to the comm.ConstellationDiagram System object.

Example: `constDiag = comm.ConstellationDiagram('ChannelNames',{ '8-QAM', '8-PSK' })` assigns names for two input channels to 8-QAM and 8-PSK.

**Tunable:** Yes

### ShowLegend — Display legend

false (default) | true

Display the legend, specified as false or true. The names listed in the legend are the signal names specified by the ChannelNames property.

From the legend, you can control which signals to plot. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal and hide all other signals, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

Data Types: `logical`

### **ColorFading — Add color fading effect**

`false` (default) | `true`

Add color fading effect, specified as `false` or `true`. When you set this property to `true`, the points in the display fade as the interval of time after they are first plotted increases. This animation resembles an oscilloscope display.

Data Types: `logical`

### **Title — Plot title**

`blank` (default) | character vector | string

Plot title, specified as a character vector or string.

**Tunable:** Yes

### **XLimits — x-axis limits**

`[-1.375 1.375]` (default) | two-element numeric vector

x-axis limits, specified as a two-element numeric vector of the form `[xmin xmax]`.

**Tunable:** Yes

### **YLimits — y-axis limits**

`[-1.375 1.375]` (default) | two-element numeric vector

y-axis limits, specified as a two-element numeric vector of the form `[ymin ymax]`.

**Tunable:** Yes

### **XLabel — x-axis label**

'In-phase Amplitude' (default) | character vector | string

x-axis label, specified as a character vector or string.

**Tunable:** Yes

**YLabel — y-axis label**

'Quadrature Amplitude' (default) | character vector | string

y-axis label, specified as a character vector or string.

**Tunable:** Yes

**EnableMeasurements — Display measurements pane**

false (default) | true

Display measurements pane, specified as false or true. To compute and display EVM or MER measurements, activate this pane.

**Tunable:** Yes

Data Types: logical

**MeasurementInterval — Measurement interval**

'Current Display' (default) | 'All displays' | positive integer

Measurement interval, specified as 'Current Display', 'All displays', or a positive integer in the range [2 SymbolsToDisplay]. This property specifies the window length for the EVM and MER measurements.

When the input signal contains one sample per symbol and the reference constellation is provided, the constellation diagram display can measure the signal quality in terms of EVM and MER. The “EVM / MER Measurements” on page 4-387 pane can be displayed by clicking the Signal Quality button. See the toolbar in the “Signal Display” on page 4-385. After the number of input data samples is greater than MeasurementInterval, the EVM and MER measurements are computed.

**Tunable:** Yes

**EVMNormalization — EVM normalization method**

'Average constellation power' (default) | 'Peak constellation power'

EVM normalization method, specified as 'Average constellation power' or 'Peak constellation power'. For more information, see “EVM / MER Measurements” on page 4-387.

**Tunable:** Yes

### Usage

### Syntax

```
constdiag(signal1,signal2,...,signalN)
```

### Description

`constdiag(signal1,signal2,...,signalN)` displays up to `NumInputPorts` signals in one constellation diagram.

### Input Arguments

#### **signal** — Input signal or signals to plot

column vector | matrix

Specify one or more signals to be plotted in the `comm.ConstellationDiagram`. Signals can have different data types and dimensions. To create a multichannel signal, specify a matrix with individual signals defined in the columns of the matrix.

Example: `constDiag([signal1_1,signal1_2],signal2)` displays the multichannel and multi-input constellation diagram. First input is two concatenated column vectors of length `N` to make an `N-by-2` matrix input signal and the second input is a single channel signal.

Data Types: `double`

Complex Number Support: Yes

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

#### **Specific to Scopes**

`show`      Show scope window

hide        Hide scope window  
isVisible   Determine visibility of scope window

### Common to All System Objects

step        Run System object algorithm  
release     Release resources and allow changes to System object property values and input characteristics  
reset       Reset internal states of System object

## Examples

### Plot Amplitude-Imbalanced QPSK Constellation

QPSK modulate random data symbols and apply an amplitude imbalance to the signal. Pass the signal through a noisy channel. Plot the resultant constellation.

Create a constellation diagram object. Because the default reference constellation for the `comm.ConstellationDiagram` System object is QPSK, it is not necessary to set additional properties.

```
constDiagram = comm.ConstellationDiagram;
```

Generate random data symbols and apply QPSK modulation.

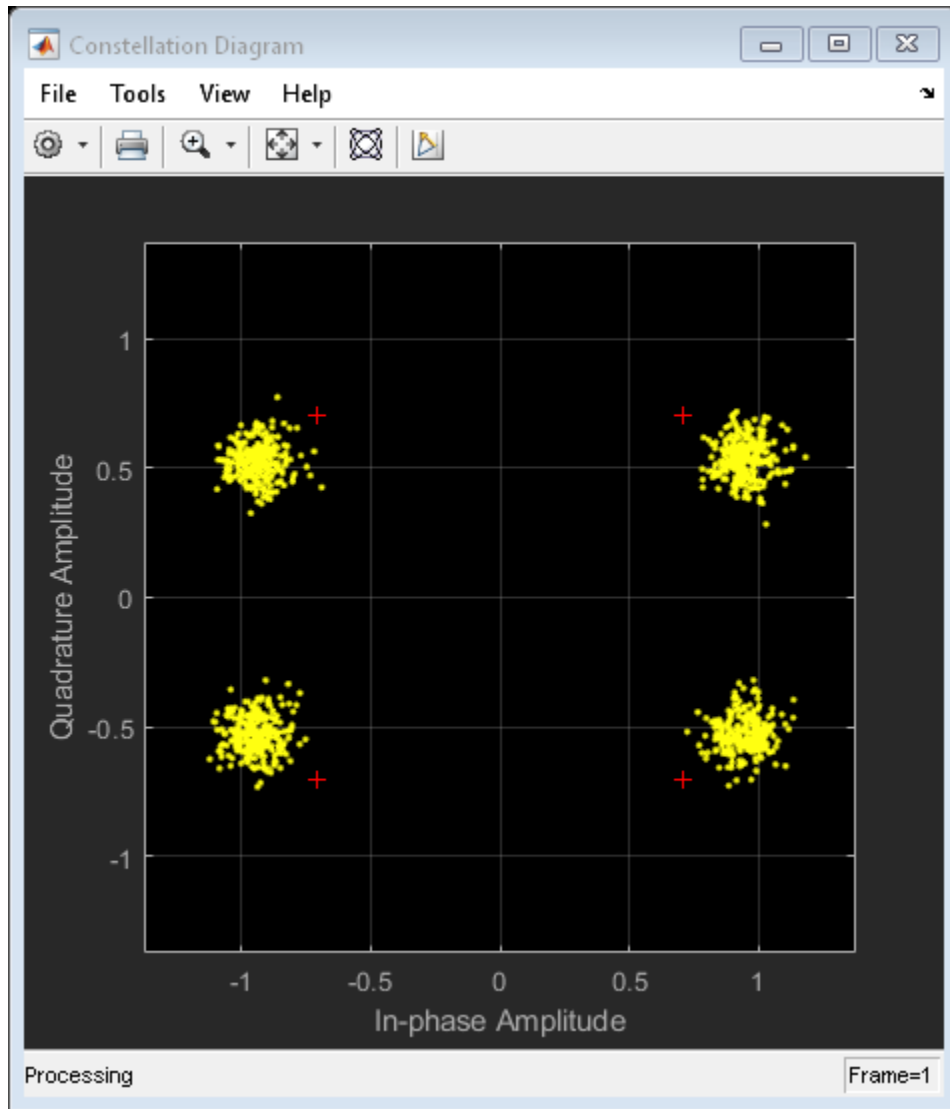

```
data = randi([0 3],1000,1);  
modData = pskmod(data,4,pi/4);
```

Apply an amplitude imbalance to the modulated signal.

```
txSig = iqimbal(modData,5);
```

Pass the transmitted signal through an AWGN channel and display the constellation diagram. Observe that the data points have shifted from their ideal locations.

```
rxSig = awgn(txSig,20);  
constDiagram(rxSig)
```

### Plot 16-QAM Constellation

Apply 16-QAM modulation, transmit data using an AWGN channel, and plot the signal constellation.

Create a 16-QAM reference constellation.

```
M = 16;  
refC = qammod(0:M-1,M);
```

Create a `comm.ConstellationDiagram` System object. Specify the constellation reference points and axes limits using name-value pairs.

```
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refC, ...  
    'XLimits',[-4 4], 'YLimits',[-4 4]);
```

Generate random, 16-ary data symbols.

```
data = randi([0 M-1],1000,1);
```

Apply 16-QAM modulation.

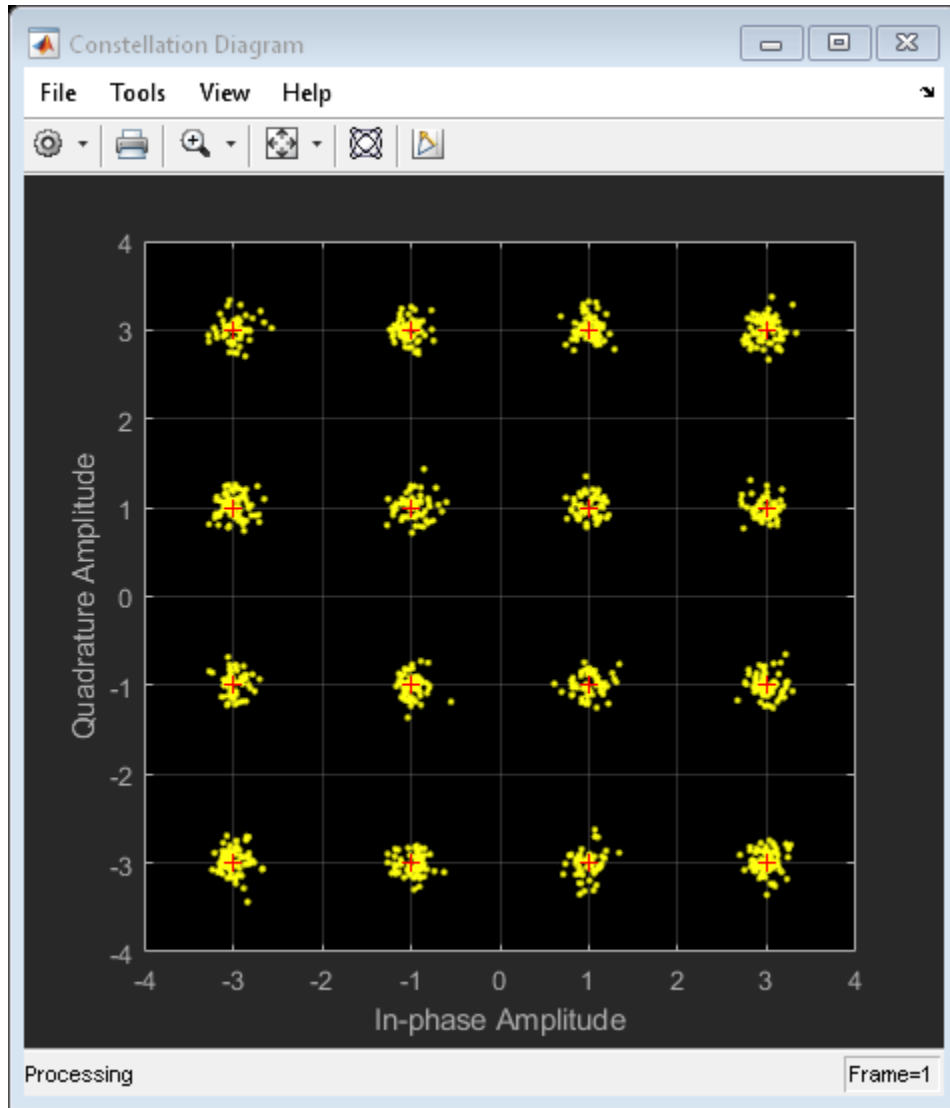

```
sym = qammod(data,M);
```

Pass the modulated signal through an AWGN channel.

```
rcv = awgn(sym,15);
```

Display the constellation diagram.

```
constDiagram(rcv)
```

## View Multi-Input Signals Constellation

Use the `comm.ConstellationDiagram` System object to visualize the constellation of multi-input and multichannel modulated signals. Plot a multichannel signal with two 16-QAM signals with SNR 10 and 20 for the first input, and one 8-PSK signal for the second input.

Create a 16-QAM and a 8-PSK reference constellation.

```
M = 16;
refQAM = qammod(0:M-1,M);
S = 8;
refPSK = pskmod(0:S-1,S,pi/8);
```

Create a `comm.ConstellationDiagram` object™.

```
constDiag = comm.ConstellationDiagram(2,...
    'ReferenceConstellation',{refQAM,refPSK},'ShowLegend',true,...
    'XLimits',[-6 6],'YLimits',[-6 6], ...
    'ChannelNames',{'16-QAM , SNR 10 dB','16-QAM , SNR 20 dB','8-PSK'});
```

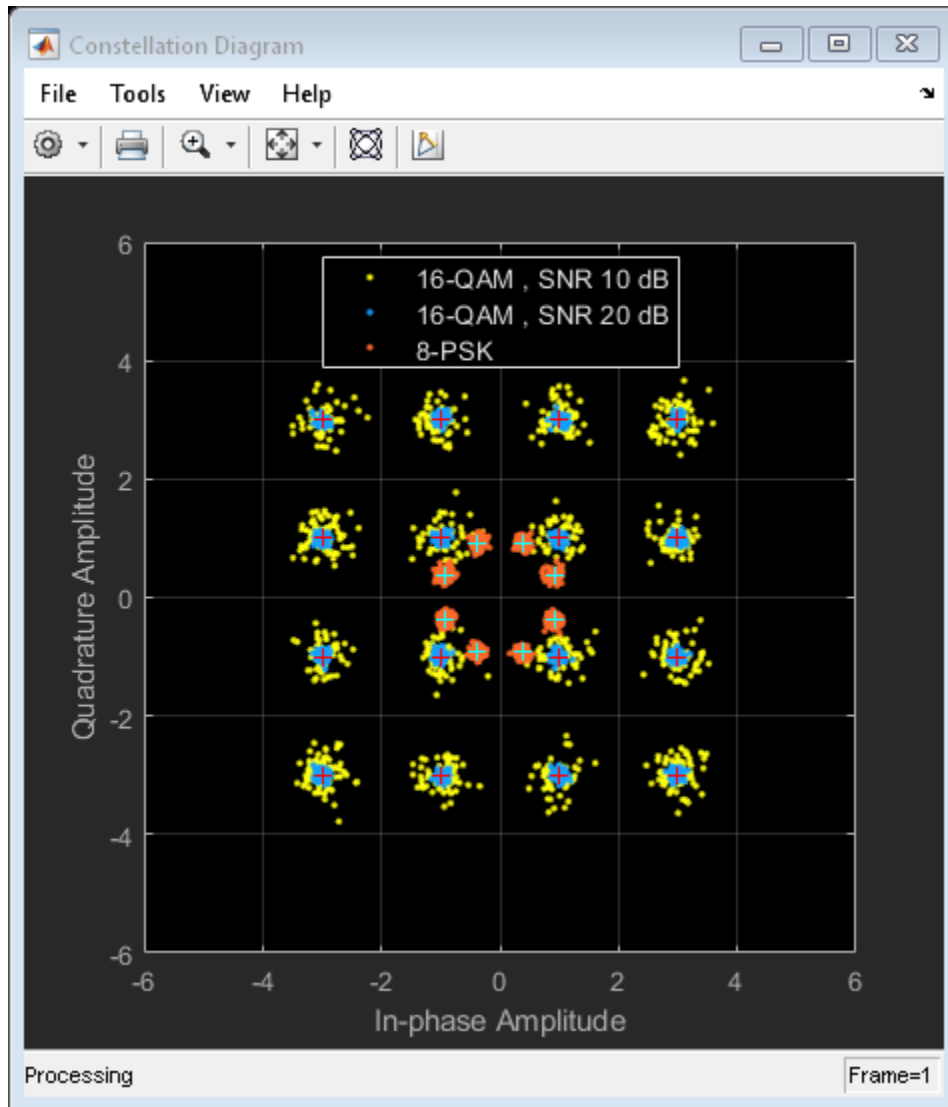

Generate random data symbols, modulate the symbols, and add AWGN with two different SNRs to yield two received signals.

```
d = randi([0 M-1],1000,1);
dQAM = qammod(d,M);
rcv1_1 = awgn(dQAM,10);
rcv1_2 = awgn(dQAM,20);
d = randi([0 S-1],1000,1);
dPSK = pskmod(d,S,pi/8);
rcv2 = awgn(dPSK,20);
```

For the first input, create a multichannel signal by concatenating the two received 16-QAM signals. A single reference constellation is applied for all the multichannel signals of one input. Second input uses a single channel 8-PSK signal. This input has a separate reference constellation.

View the multi-input and multichannel signals .

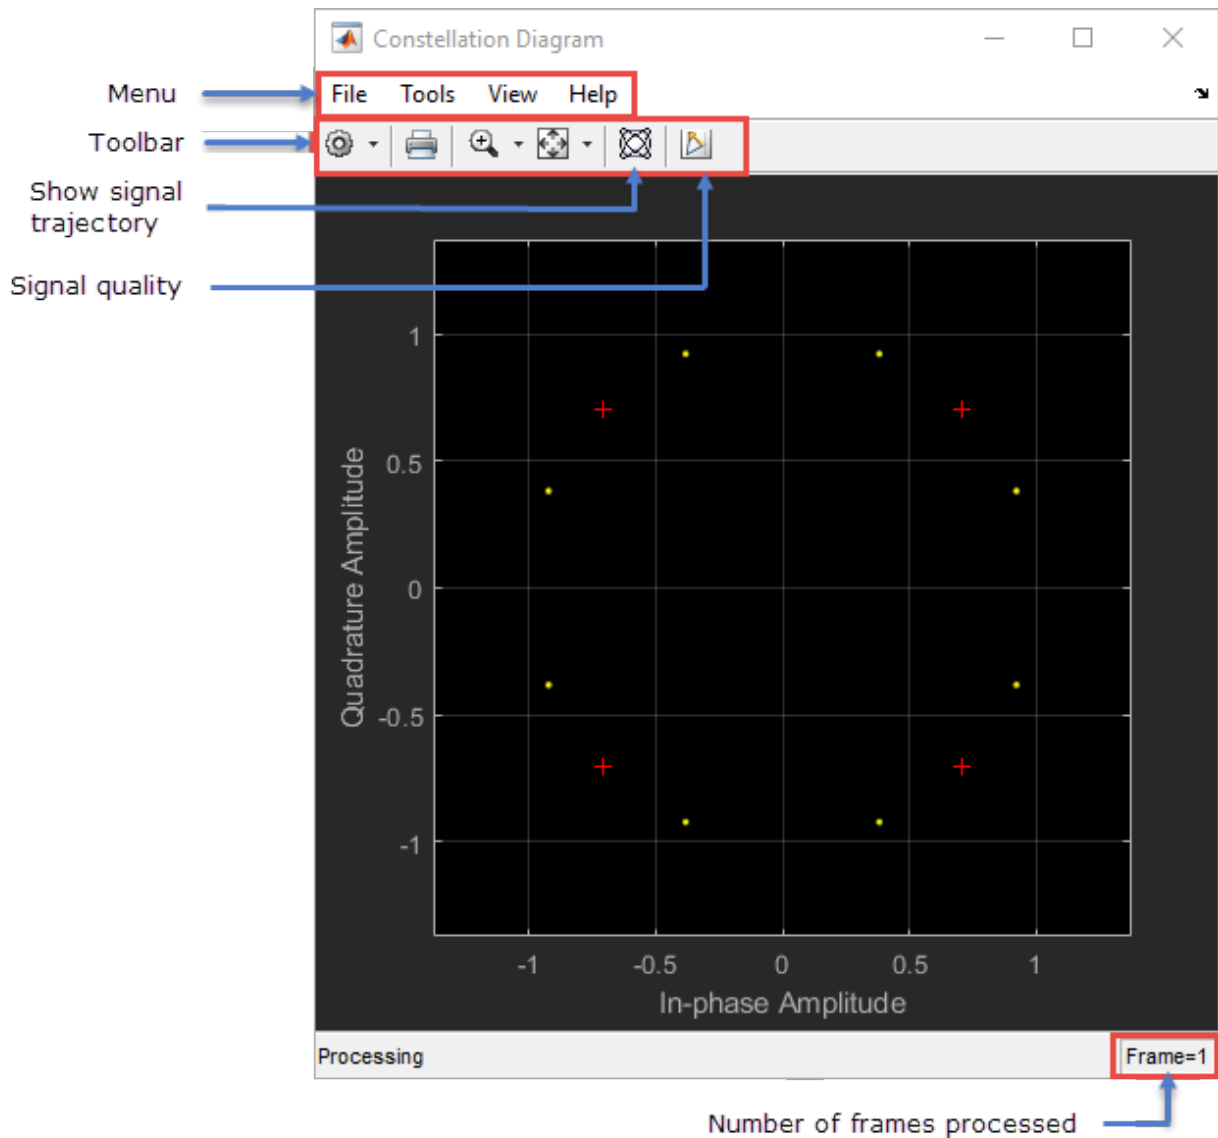

```
constDiag([rcv1_1,rcv1_2],rcv2);
```

## More About

### Signal Display

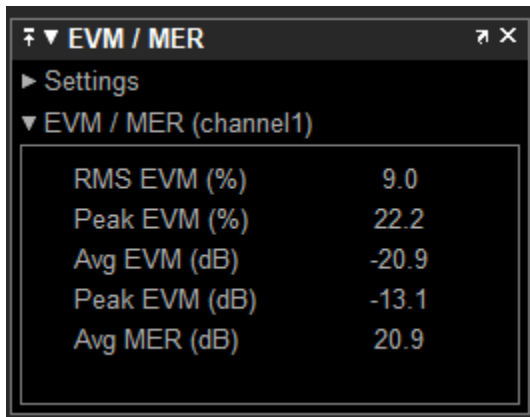

To communicate simulation data that corresponds to the current display, the scope uses the **Frames** indicator on the scope window. This figure highlights important aspects of the Constellation Diagram window.

To change the Constellation Diagram window settings, select menu options under **File**, **Tools**, and **View**. Changes made via menu options adjust the property settings of the System object accordingly.

## EVM / MER Measurements

The **EVM / MER** signal quality pane displays the measurement settings, and error vector magnitude (EVM) and modulation error ratio (MER) measurement calculation results for the specified trace selection.

EVM / MER (channel1)	
RMS EVM (%)	9.0
Peak EVM (%)	22.2
Avg EVM (dB)	-20.9
Peak EVM (dB)	-13.1
Avg MER (dB)	20.9

- **EVM** — An error vector is a vector in the IQ plane from the ideal constellation point to the actual point at the receiver. The root mean square error vector magnitude,  $EVM_{RMS}$ , is measured for the average and peak constellation power.

On the constellation diagram, you can display the  $EVM_{RMS}$  measurements normalized by either the Average constellation power or Peak constellation power method as computed using these algorithms.

EVM Normalization Method	Algorithm
Average constellation power	<p>Average constellation power normalization:</p> $EVM_k = 100\sqrt{\frac{e_k}{P_{avg}}}$ <p><math>EVM_{RMS}</math>, in percent, for average constellation power normalization:</p> $EVM_{RMS}(\%) = 100\sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{avg}}}$
Peak constellation power	<p>Peak constellation power normalization</p> $EVM_k = 100\sqrt{\frac{e_k}{P_{max}}}$ <p><math>EVM_{RMS}</math>, in percent, for peak constellation power normalization</p> $EVM_{RMS}(\%) = 100\sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{max}}}$

The **EVM / MER** pane shows the average and peak  $EVM_{RMS}$  in both percent and decibels for the selected trace. The EVM reported in decibels is computed as  $EVM$  (dB) = 10-log10( $EVM_{MS}$ ) = 20-log10( $EVM_{RMS}$ ), where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- $I_k$  is the in-phase value of the  $k$ th symbol in the input vector.
- $Q_k$  is the quadrature phase value of the  $k$ th symbol in the input vector.
- $I_k$  and  $Q_k$  represent ideal (reference) symbol values.  $\tilde{I}_k$  and  $\tilde{Q}_k$  represent measured (received) symbol values.
- $N$  is the input vector length.

- $P_{\text{avg}}$  is the value for Average constellation power.
- $P_{\text{max}}$  is the value for Peak constellation power.
- $\text{EVM}_{\text{RMS}} = \sqrt{\text{EVM}_{\text{MS}}}$

The maximum EVM value in a vector is  $\text{EVM}_{\text{max}} = \max_{k \in [1, \dots, N]} \{\text{EVM}_k\}$ , where  $k$  is the  $k$ th symbol in a vector of length  $N$ .

For more information, see `comm.EVM`.

- **MER** — MER is the ratio of the average power of the transmitted signal to the average power of the error vector. The **EVM / MER** pane indicates average MER measurement result in decibels for the selected trace.

MER is a measure of the SNR in a modulated signal, calculated in dB. The MER over  $N$  symbols is

$$\text{MER} = 10 \cdot \log_{10} \left( \frac{\sum_{n=1}^N (I_k^2 + Q_k^2)}{\sum_{n=1}^N (e_k)} \right) \text{dB},$$

where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- $I_k$  is the in-phase value of the  $k$ th symbol in the input vector.
- $Q_k$  is the quadrature phase value of the  $k$ th symbol in the input vector.
- $I_k$  and  $Q_k$  represent ideal (reference) values.  $\tilde{I}_k$  and  $\tilde{Q}_k$  represent measured (received) symbols.

For more information, see `comm.MER`.

## Tips

- If you want any of these features, use a `comm.ConstellationDiagram` System object.

- Measurements
- Basic reference constellations
- Signal trajectory plots
- Maintaining state between calls
- If you want a simple signal constellation snapshot, use the `scatterplot` function.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## See Also

### Blocks

Constellation Diagram

### Objects

`comm.EyeDiagram`

### Functions

`scatterplot`

**Introduced in R2013a**

# comm.ConvolutionalDeinterleaver

**Package:** comm

Restore ordering of symbols using shift registers

## Description

The `ConvolutionalDeinterleaver` object recovers a signal that was interleaved using the convolutional Interleaver object. The parameters in the two blocks should have the same values.

To recover convolutionally interleaved binary data:

- 1 Define and set up your convolutional deinterleaver object. See “Construction” on page 4-391.
- 2 Call `step` to convolutionally deinterleave according to the properties of `comm.ConvolutionalDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.ConvolutionalDeinterleaver` creates a convolutional deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the convolutional interleaver System object.

`H = comm.ConvolutionalDeinterleaver(Name,Value)` creates a convolutional deinterleaver System object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### NumRegisters

Number of internal shift registers

Specify the number of internal shift registers as a scalar, positive integer. The default is 6.

### RegisterLengthStep

Symbol capacity difference of each successive shift register

Specify the difference in symbol capacity of each successive shift register, where the last register holds zero symbols as a positive, scalar integer. The default is 2.

### InitialConditions

Initial conditions of shift registers

Specify the values that are initially stored in each shift register as a numeric scalar or vector, except the last shift register, which has zero delay. If you set this property to a scalar, then all shift registers, except the last one, store the same specified value. You can also set this property to a column vector with length equal to the value of the NumRegisters property. With this setting, the  $i$ -th shift register stores the  $(N-i+1)$ -th element of the specified vector. The value of the first element of this property is unimportant because the last shift register has zero delay. The default is 0.

## Methods

reset    Reset states of the convolutional deinterleaver object

step    Restore ordering of symbols using shift registers

Common to All System Objects	
release	Allow System object property value changes

## Examples

## Convolutional Interleaving and Deinterleaving

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans = 21x3
```

```

0     0     0
1     0     0
2     2     0
3     0     0
4     4     0
5     0     0
6     6     0
7     1     1
8     8     2
9     3     3
:
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep
intrlvDelay = 6
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
numSymErrors = 0
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Deinterleaver block reference page. The object properties correspond to the block parameters.

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

`comm.ConvolutionalInterleaver` | `comm.MultiplexedInterleaver`

**Introduced in R2012a**

## reset

**System object:** `comm.ConvolutionalDeinterleaver`

**Package:** `comm`

Reset states of the convolutional deinterleaver object

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the `ConvolutionalDeinterleaver` object, `H`.

# step

**System object:** `comm.ConvolutionalDeinterleaver`

**Package:** `comm`

Restore ordering of symbols using shift registers

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  restores the original ordering of the sequence,  $X$ , that was interleaved using a convolutional interleaver and returns  $Y$ . The input  $X$  must be a column vector. The data type can be numeric, logical, or fixed-point (fi objects).  $Y$  has the same data type as  $X$ . The convolutional deinterleaver object uses a set of  $N$  shift registers, where  $N$  is the value specified by the `NumRegisters` property. The object sets the delay value of the  $k$ -th shift register to the product of  $(k-1)$  and `RegisterLengthStep` property value. With each new input symbol, a commutator switches to a new register and the new symbol shifts in while the oldest symbol in that register shifts out. When the commutator reaches the  $N$ -th register and the next new input occurs, it returns to the first register.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.ConvolutionalEncoder

**Package:** comm

Convolutionally encode binary data

### Description

The `ConvolutionalEncoder` object encodes a sequence of binary input vectors to produce a sequence of binary output vectors.

To convolutionally encode a binary signal:

- 1 Define and set up your convolutional encoder object. See “Construction” on page 4-398.
- 2 Call `step` to encode a sequence of binary input vectors to produce a sequence of binary output vectors according to the properties of `comm.ConvolutionalEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.ConvolutionalEncoder` creates a System object, `H`, that convolutionally encodes binary data.

`H = comm.ConvolutionalEncoder(Name,Value)` creates a convolutional encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.ConvolutionalEncoder(TRELLIS,Name,Value)` creates a convolutional encoder object, `H`. This object has the `TrellisStructure` on page 4-0 property set to `TRELLIS`, and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the result of `poly2trellis(7, [171 133])`.

### TerminationMethod

Termination method of encoded frame

Specify how the encoded frame is terminated as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`. When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector. When you set this property to `Truncated`, the object treats each input vector independently. The encoder states are reset at the start of each input vector. If you set the `InitialStateInputPort` on page 4-0 property to `false`, the object resets its states to the all-zeros state. If you set the `InitialStateInputPort` property to `true`, the object resets the states to the values you specify in the initial states `step` method input. When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to all-zeros states at the end of the vector. For a rate  $K/N$  code, the `step` method outputs a vector with length  $N \times (L + S)/K$ , where  $S = \text{constraintLength}-1$  (or, in the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i)-1)$ ).  $L$  is the length of the input to the `step` method.

### ResetInputPort

Enable encoder reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous`.

### DelayedResetAction

Delay output reset

Set this property to `true` to delay resetting the object output. The default is `false`. When you set this property to `true`, the reset of the internal states of the encoder occurs after the object computes the encoded data. When you set this property to `false`, the reset of the internal states of the encoder occurs before the object computes the encoded data. This property applies when you set the `ResetInputPort` on page 4-0 property to `true`.

### **InitialStateInputPort**

Enable initial state input

Set this property to `true` to enable a `step` method input that allows the specification of the initial state of the encoder for each input vector. The default is `false`. This property applies when you set the `TerminationMethod` on page 4-0 property to `Truncated`.

### **FinalStateOutputPort**

Enable final state output

Set this property to `true` to obtain the final state of the encoder via a `step` method output. The default is `false`. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous` or `Truncated`.

### **PuncturePatternSource**

Source of puncture pattern

Specify the source of the puncture pattern as one of `None` | `Property`. The default is `None`. When you set this property to `None` the object does not apply puncturing. When you set this property to `Property`, the object punctures the code. This puncturing is based on the puncture pattern vector that you specify in the `PuncturePattern` on page 4-0 property. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous` or `Truncated`.

### **PuncturePattern**

Puncture pattern vector

Specify the puncture pattern used to puncture the encoded data as a column vector. The default is `[1; 1; 0; 1; 0; 1]`. The vector contains 1s and 0s, where the 0 indicates the punctured, or excluded, bits. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous` or `Truncated` and the `PuncturePatternSource` on page 4-0 property to `Property`.

## Examples

### Encode and Decode 8-DPSK Modulated Data

Transmit a convolutionally encoded 8-DPSK modulated bit stream through an AWGN channel. Then, demodulate and decode using a Viterbi decoder.

Create the necessary System objects.

```
hConEnc = comm.ConvolutionalEncoder;
hMod = comm.DPSKModulator('BitInput',true);
hChan = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)',...
    'SNR',10);
hDemod = comm.DPSKDemodulator('BitOutput',true);
hDec = comm.ViterbiDecoder('InputFormat','Hard');
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);
```

Process the data using the following steps:

- 1   Generate random bits
- 2   Convolutionally encode the data
- 3   Apply DPSK modulation
- 4   Pass the modulated signal through AWGN
- 5   Demodulate the noisy signal
- 6   Decode the data using a Viterbi algorithm
- 7   Collect error statistics

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = step(hConEnc, data);
    modSignal = step(hMod, encodedData);
    receivedSignal = step(hChan, modSignal);
    demodSignal = step(hDemod, receivedSignal);
    receivedBits = step(hDec, demodSignal);
    errors = step(hError, data, receivedBits);
end
```

Display the number of errors.

```
errors(2)
```

```
ans = 3
```

### Convolutional Encoding and Viterbi Decoding with a Puncture Pattern Matrix

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical

Define a puncture pattern matrix and reshape it into vector form for use with the Encoder and Decoder objects.

```
pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);
```

Create convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by pPatternVec.

```
ENC = comm.ConvolutionalEncoder(...
    'PuncturePatternSource','Property', ...
    'PuncturePattern',pPatternVec);

DEC = comm.ViterbiDecoder('InputFormat','Hard', ...
    'PuncturePatternSource','Property',...
    'PuncturePattern',pPatternVec);
```

Create an error rate counter with the appropriate receive delay.

```
ERR = comm.ErrorRate('ReceiveDelay',DEC.TracebackDepth);
```

Encode and decode a sequence of random bits.

```
dataIn = randi([0 1],600,1);  
dataEncoded = step(ENC,dataIn);  
dataOut = step(DEC,dataEncoded);
```

Verify that there are no errors in the output data.

```
errStats = step(ERR,dataIn,dataOut);  
errStats(2)  
  
ans = 0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Encoder block reference page. The object properties correspond to the block parameters, except:

The operation mode **Reset on nonzero input via port** block parameter corresponds to the ResetInputPort on page 4-0 property.

## Extended Capabilities

Reset states of the convolutional encoder object

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the `ConvolutionalEncoder` object, `H`.

## step

**System object:** comm.ConvolutionalEncoder

**Package:** comm

Convolutionally encode binary data

## Syntax

```
Y = step(H,X)
Y = step(H,X,INITSTATE)
Y = step(H,X,R)
[Y,FSTATE] = step(H,X)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` encodes the binary data, `X`, using the convolutional encoding that you specify in the `TrellisStructure` property. It returns the encoded data, `Y`. Both `X` and `Y` are column vectors of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector equals  $K \times L$ , for some positive integer,  $L$ . The `step` method sets the length of the output vector, `Y`, to  $L \times N$ .

`Y = step(H,X,INITSTATE)` uses the initial state specified in the `INITSTATE` input when you set the `TerminationMethod` property to 'Truncated' and the `InitialStateInputPort` property to `true`. `INITSTATE` must be an integer scalar.

`Y = step(H,X,R)` resets the internal states of the encoder when you input a non-zero reset signal, `R`. `R` must be a double precision or logical scalar. This syntax applies when

you set the `TerminationMethod` property to `Continuous` and the `ResetInputPort` property to `true`.

`[Y, FSTATE] = step(H, X)` returns the final state of the encoder in the integer scalar output `FSTATE` when you set the `FinalStateOutputPort` property to `true`. This syntax applies when you set the `TerminationMethod` property to `Continuous` or `Truncated`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.ConvolutionalInterleaver

**Package:** comm

Permute input symbols using shift registers with same property values

### Description

The `ConvolutionalInterleaver` object permutes the symbols in the input signal. Internally, this class uses a set of shift registers.

To convolutionally interleave binary data:

- 1 Define and set up your convolutional interleaver object. See “Construction” on page 4-408.
- 2 Call `step` to convolutionally interleave according to the properties of `comm.ConvolutionalInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.ConvolutionalInterleaver` creates a convolutional interleaver System object, `H`, that permutes the symbols in the input signal using a set of shift registers.

`H = comm.ConvolutionalInterleaver(Name,Value)` creates a convolutional interleaver System object, `H`. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### NumRegisters

Number of internal shift registers

Specify the number of internal shift registers as a scalar, positive integer. The default is 6.

### RegisterLengthStep

Number of additional symbols that fit in each successive shift register

Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2. The first register holds zero symbols.

### InitialConditions

Initial conditions of shift registers

Specify the values that are initially stored in each shift register as a numeric scalar or vector. You do not need to specify a value for the first shift register, which has zero delay. The default is 0. The value of the first element of this property is unimportant because the first shift register has zero delay. If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the NumRegisters on page 4-0 property, then the  $i$ -th shift register stores the  $i$ -th element of the specified vector.

## Methods

reset    Reset states of the convolutional interleaver object  
 step    Permute input symbols using shift registers

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Convolutional Interleaving and Deinterleaving

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.ConvolutionalInterleaver('NumRegisters',2, ...  
      'RegisterLengthStep',3);  
deinterleaver = comm.ConvolutionalDeinterleaver('NumRegisters',2, ...  
      'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';  
intrlvData = interleaver(data);  
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans = 21×3
```

```
0     0     0  
1     0     0  
2     2     0  
3     0     0  
4     4     0  
5     0     0  
6     6     0  
7     1     1  
8     8     2  
9     3     3  
:  
:
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep  
intrlvDelay = 6  
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))  
numSymErrors = 0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Interleaver block reference page. The object properties correspond to the block parameters.

# comm.CPFSKDemodulator

**Package:** comm

Demodulate using CPFSK method and Viterbi algorithm

## Description

The `CPFSKDemodulator` object demodulates a signal that was modulated using the continuous phase frequency shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the continuous phase frequency shift keying method:

- 1 Define and set up your CPFSK demodulator object. See “Construction” on page 4-415 .
- 2 Call `step` to demodulate the signal according to the properties of `comm.CPFSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.CPFSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input continuous phase frequency shift keying (CPFSK) modulated data using the Viterbi algorithm.

`H = comm.CPFSKDemodulator(Name,Value)` creates a CPFSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.CPFSKDemodulator(M,Name,Value)` creates a CPFSK demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

## Properties

### **ModulationOrder**

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is 4.

### **BitOutput**

Output data as bits

Specify whether the output consists of groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector of length equal to `N/SamplesPerSymbol` on page 4-0 and with elements that are integers between `-(ModulationOrder on page 4-0 -1)` and `ModulationOrder-1`. In this case, `N`, is the length of the input signal, which indicates the number of input baseband modulated symbols.

When you set this property to `true`, the `step` method outputs a binary column vector of length equal to  $P \times (N/SamplesPerSymbol)$ , where  $P = \mathbf{\log_2}(\mathbf{ModulationOrder})$ . The output contains length- $P$  bit words. In this scenario, the object first maps each demodulated symbol to an odd integer value,  $K$ , between `-(ModulationOrder-1)` and `ModulationOrder-1`. The object then maps  $K$  to the nonnegative integer  $(K + \mathbf{ModulationOrder}-1)/2$ . Finally, the object maps each nonnegative integer to a length- $P$  binary word, using the mapping specified in the `SymbolMapping` on page 4-0 property.

### **SymbolMapping**

Symbol encoding

Specify the mapping of the modulated symbols as one of `Binary | Gray`. The default is `Binary`. This property determines how the object maps each demodulated integer symbol

value (in the range 0 and `ModulationOrder` on page 4-0 -1) to a  $P$ -length bit word, where  $P = \text{ModulationOrder}$  on page 4-0 (`ModulationOrder`).

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitOutput` on page 4-0 property to `true`.

### **ModulationIndex**

Modulation index

Specify the modulation index. The default is `0.5`. The value of this property can be a scalar,  $h$ , or a column vector,  $[h_0, h_1, \dots, h_{H-1}]$

where  $H-1$  represents the length of the column vector.

When  $h_i$  varies from interval to interval, the object operates in multi-h. When the object operates in multi-h,  $h_i$  must be a rational number.

### **InitialPhaseOffset**

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar. The default is `0`.

### **SamplesPerSymbol**

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar. The default is `8`.

### **TracebackDepth**

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar. The default is `16`. The value of this property is also the value of the output delay. That value is the number of zero symbols that precede the first meaningful demodulated symbol in the output.

## OutputDataType

Data type of output

Specify the output data type as one of `int8` | `int16` | `int32` | `double`, when you set the `BitOutput` on page 4-0 property to `false`. The default is `double`.

When you set the `BitOutput` property to `true`, specify the output data type as one of `logical` | `double`.

## Methods

`reset`    Reset states of CPFSK demodulator object  
`step`     Demodulate using CPFSK method and Viterbi algorithm

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

### Demodulate a signal using CPFSK modulation with Gray mapping

```
% Create a CPFSK modulator, an AWGN channel, and a CPFSK demodulator
hMod = comm.CPFSKModulator(8, 'BitInput', true, ...
    'SymbolMapping', 'Gray');
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.CPFSKDemodulator(8, 'BitOutput', true, ...
    'SymbolMapping', 'Gray');

% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
hError = comm.ErrorRate('ReceiveDelay', delay);
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1], 300, 1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
```

```
        receivedData = step(hDemod, noisySignal);  
        errorStats = step(hError, data, receivedData);  
    end  
  
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...  
        errorStats(1), errorStats(2))
```

```
Error rate = 0.004006  
Number of errors = 120
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPFSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For CPFSK the phase shift per symbol is  $\pi \times h$ , where  $h$  is the modulation index.

## Extended Capabilities

Reset states of CPFSK demodulator object

## **Syntax**

reset(H)

## **Description**

reset(H) resets the states of the CPFSKDemodulator object, H.

---

## step

**System object:** comm.CPFSKDemodulator

**Package:** comm

Demodulate using CPFSK method and Viterbi algorithm

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates input data,  $X$ , with the CPFSK demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a double or single precision, column vector with a length equal to an integer multiple of the number of samples per symbol specified in the `SamplesPerSymbol` property. Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.CPFSKModulator

**Package:** comm

Modulate using CPFSK method

### Description

The `CPFSKModulator` object modulates using the continuous phase frequency shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using the continuous phase frequency shift keying method:

- 1 Define and set up your CPFSK modulator object. See “Construction” on page 4-422.
- 2 Call `step` to modulate the signal according to the properties of `comm.CPFSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.CPFSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the continuous phase frequency shift keying (CPFSK) modulation method.

`H = comm.CPFSKModulator(Name, Value)` creates a CPFSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.CPFSKModulator(M, Name, Value)` creates a CPFSK modulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is 4.

### BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `false`, the `step` method input must be a double-precision or signed integer data type column vector. This vector comprises odd integer values between  $-(\text{ModulationOrder} - 1)$  and  $\text{ModulationOrder} - 1$ .

When you set this property to `true`, the `step` method input must be a column vector of  $P$ -length bit words, where  $P = \log_2(\text{ModulationOrder})$ . The input data must be double precision or logical data type. The object maps each bit word to an integer  $K$  between  $0$  and  $\text{ModulationOrder} - 1$ , using the mapping specified in the `SymbolMapping` on page 4-0 property. The object then maps the integer  $K$  to the intermediate value  $2^{K - (\text{ModulationOrder} - 1)}$  and proceeds as in the case when you set the `BitInput` on page 4-0 property to `false`.

### SymbolMapping

Symbol encoding

Specify the mapping of bit inputs as one of `Binary | Gray`. The default is `Binary`. This property determines how the object maps each input  $P$ -length bit word, where  $P = \log_2(\text{ModulationOrder})$  on page 4-0, to an integer between  $0$  and  $\text{ModulationOrder} - 1$ .

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitInput` on page 4-0 property to `true`.

### **ModulationIndex**

Modulation index

Specify the modulation index. The default is `0.5`. The value of this property can be a scalar,  $h$ , or a column vector,  $[h_0, h_1, \dots, h_{H-1}]$

where  $H-1$  represents the length of the column vector. The phase shift over a symbol is  $\pi \times h$ .

When  $h_i$  varies from interval to interval, the object operates in multi-h. When the object operates in multi-h,  $h_i$  must be a rational number.

### **InitialPhaseOffset**

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar. The default is `0`.

### **SamplesPerSymbol**

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar. The default is `8`. The upsampling factor is the number of output samples that the step method produces for each input sample.

### **OutputDataType**

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

## **Methods**

<code>reset</code>	Reset states of CPFSK modulator object
<code>step</code>	Modulate using CPFSK method

**Common to All System Objects**

release	Allow System object property value changes
---------	--

## Examples

### Demodulate a signal using CPFSK modulation with Gray mapping

```
% Create a CPFSK modulator, an AWGN channel, and a CPFSK demodulator
hMod = comm.CPFSKModulator(8, 'BitInput', true, ...
    'SymbolMapping', 'Gray');
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.CPFSKDemodulator(8, 'BitOutput', true, ...
    'SymbolMapping', 'Gray');

% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
hError = comm.ErrorRate('ReceiveDelay', delay);
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1], 300, 1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPFSK Modulator Baseband block reference page. The object properties correspond to the block parameters. For CPFSK the phase shift per symbol is  $\pi \times h$ , where  $h$  is the modulation index.

## **Extended Capabilities**

### **C/C++ Code Generation**

**System object:** comm.CPFSKModulator

**Package:** comm

Modulate using CPFSK method

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

$Y = \text{step}(H, X)$  modulates input data,  $X$ , with the CPFSK modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be an integer or bit valued column vector with data types double, signed integer, or logical. The length of output vector,  $Y$ , is equal to the number of input samples times the number of samples per symbol specified in the `SamplesPerSymbol` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.CPMCarrierPhaseSynchronizer

**Package:** comm

(To be removed) Recover carrier phase of baseband CPM signal

---

**Note** comm.CPMCarrierPhaseSynchronizer will be removed in a future release. Use comm.CarrierSynchronizer instead.

---

## Description

The CPMCarrierPhaseSynchronizer object recovers the carrier phase of the input signal using the 2P-Power method. This feedforward method is clock aided, but not data aided. The method is suitable for systems that use certain types of baseband modulation. These types include: continuous phase modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), and Gaussian minimum shift keying (GMSK).

To recover the carrier phase of the input signal:

- 1 Define and set up your CPM carrier phase synchronizer object. See “Construction” on page 4-429.
- 2 Call `step` to recover the carrier phase of the input signal using the 2P-Power method according to the properties of `comm.CPMCarrierPhaseSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.CPMCarrierPhaseSynchronizer` creates a CPM carrier phase synchronizer System object, `H`. This object recovers the carrier phase of a baseband continuous phase

modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), or Gaussian minimum shift keying (GMSK) modulated signal using the 2P-power method.

`H = comm.CPMCarrierPhaseSynchronizer(Name, Value)` creates a CPM carrier phase synchronizer object, `H`. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.CPMCarrierPhaseSynchronizer(HALFPOW, Name, Value)` creates a CPM carrier phase synchronizer object, `H`. This object has the `P` on page 4-0 property set to `HALFPOW`, and the other specified properties set to the specified values.

## Properties

### P

Denominator of CPM modulation index

Specify the denominator of the CPM modulation index of the input signal as a real positive scalar integer value of data type single or double. The default is 2. This property is tunable.

### ObservationInterval

Number of symbols where carrier phase assumed constant

Specify the observation interval as a real positive scalar integer value of data type single or double. The default is 100.

## Methods

`reset` Reset states of the CPM carrier phase synchronizer object

`step` Recover carrier phase of baseband CPM signal

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

Recover carrier phase of a CPM signal using 2P-power method.

```
M = 16;
P = 2;
phOffset = 10 *pi/180; % in radians
numSamples = 100;
% Create CPM modulator System object
hMod = comm.CPModulator(M, 'InitialPhaseOffset',phOffset, ...
    'BitInput',true, 'ModulationIndex',1/P, 'SamplesPerSymbol',1);
% Create CPM carrier phase synchronizer System object
hSync = comm.CPMCarrierPhaseSynchronizer(P,...
    'ObservationInterval',numSamples);
% Generate random binary data
data = randi([0 1],numSamples*log2(M),1);
% Modulate random data and add carrier phase
modData = step(hMod, data);
% Recover the carrier phase
[recSig phEst] = step(hSync, modData);
fprintf('The carrier phase is estimated to be %g degrees.\n', phEst);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Phase Recovery block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

# step

**System object:** `comm.CPMCarrierPhaseSynchronizer`

**Package:** `comm`

Recover carrier phase of baseband CPM signal

## Syntax

`[Y,PH] = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`[Y,PH] = step(H,X)` recovers the carrier phase of the input signal, `X`, and returns the phase corrected signal, `Y`, and the carrier phase estimate (in degrees), `PH`. `X` must be a complex scalar or column vector input signal of data type `single` or `double`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# comm.CPMDemodulator

**Package:** comm

Demodulate using CPM method and Viterbi algorithm

## Description

The `CPMDemodulator` object demodulates a signal that was modulated using continuous phase modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using continuous phase modulation:

- 1 Define and set up your CPM demodulator object. See “Construction” on page 4-435.
- 2 Call `step` to demodulate a signal according to the properties of `comm.CPMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.CPMDemodulator` creates a demodulator System object, `H`. This object demodulates the input continuous phase modulated (CPM) data using the Viterbi algorithm.

`H = comm.CPMDemodulator(Name, Value)` creates a CPM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.CPMDemodulator(M, Name, Value)` creates a CPM demodulator object, `H`, with the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is 4.

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer values. The default is false.

When you set this property to false, the `step` method outputs a column vector of length equal to  $N/\text{SamplesPerSymbol}$  on page 4-0 and with elements that are integers between  $-(\text{ModulationOrder}$  on page 4-0  $-1)$  and  $\text{ModulationOrder}-1$ . Here,  $N$ , is the length of the input signal which indicates the number of input baseband modulated symbols.

When you set this property to true, the `step` method outputs a binary column vector of length equal to  $P \times (N/\text{SamplesPerSymbol})$ , where  $P = \mathbf{\log_2}(\text{ModulationOrder})$ . The output contains length- $P$  bit words. In this scenario, the object first maps each demodulated symbol to an odd integer value,  $K$ , between  $-(\text{ModulationOrder}-1)$  and  $\text{ModulationOrder}-1$ . The object then maps  $K$  to the nonnegative integer  $(K + \text{ModulationOrder}-1)/2$ . Finally, the object maps each nonnegative integer to a length- $P$  binary word, using the mapping specified in the `SymbolMapping` on page 4-0 property.

### SymbolMapping

Symbol encoding

Specify the mapping of the demodulated symbols as one of `Binary | Gray`. The default is `Binary`. This property determines how the object maps each demodulated integer symbol value (in the range 0 and  $\text{ModulationOrder}$  on page 4-0  $-1$ ) to a  $P$ -length bit word, where  $P = \mathbf{\log_2}(\text{ModulationOrder})$ .

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitOutput` on page 4-0 property to `true`.

### **ModulationIndex**

Modulation index

Specify the modulation index. The default is `0.5`. The value of this property can be a scalar,  $h$ , or a column vector,  $[h_0, h_1, \dots, h_{H-1}]$

where  $H-1$  represents the length of the column vector.

When  $h_i$  varies from interval to interval, the object operates in multi-h. When the object operates in multi-h,  $h_i$  must be a rational number.

### **FrequencyPulse**

Frequency pulse shape

Specify the type of pulse shaping that the modulator has used to smooth the phase transitions of the input modulated signal as one of `Rectangular` | `Raised Cosine` | `Spectral Raised Cosine` | `Gaussian` | `Tamed FM`. The default is `Rectangular`.

### **MainLobeDuration**

Main lobe duration of spectral raised cosine pulse

Specify, in number of symbol intervals, the duration of the largest lobe of the spectral raised cosine pulse. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is `1`. This property requires a real, positive, integer scalar. This property applies when you set the `FrequencyPulse` on page 4-0 property to `Spectral Raised Cosine`.

### **RolloffFactor**

Rolloff factor of spectral raised cosine pulse

Specify the roll off factor of the spectral raised cosine pulse. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is `0.2`. This property requires a real scalar between `0` and `1`. This property applies when you set the `FrequencyPulse` on page 4-0 property to `Spectral Raised Cosine`.

### **BandwidthTimeProduct**

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of bandwidth and symbol time for the Gaussian pulse shape. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is 0.3. This property requires a real, positive scalar. This property applies when you set the `FrequencyPulse` on page 4-0 property to `Gaussian`.

### **PulseLength**

Pulse length

Specify the length of the frequency pulse shape in symbol intervals. The value of this property requires a real positive integer. The default is 1.

### **SymbolPrehistory**

Symbol prehistory

Specify the data symbols used by the modulator prior to the first call to the `step` method. The default is 1. This property requires a scalar or vector with odd integer elements between  $-(\text{ModulationOrder on page 4-0} - 1)$  and  $(\text{ModulationOrder}-1)$ . If the value is a vector, then its length must be one less than the value in the `PulseLength` on page 4-0 property.

### **InitialPhaseOffset**

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar. The default is 0.

### **SamplesPerSymbol**

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar. The default is 8.

### **TracebackDepth**

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar. The default is 16. The value of this property is also the output delay, which is the number of zero symbols that precede the first meaningful demodulated symbol in the output.

### OutputDataType

Data type of output

Specify the output data type as one of `int8` | `int16` | `int32` | `double`, when you set the `BitOutput` on page 4-0 property to false. When you set the `BitOutput` property to true, specify the output data type as one of `logical` | `double`. The default is `double`.

## Methods

`reset`    Reset states of CPM demodulator object  
`step`     Demodulate using CPM method and Viterbi algorithm

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

### Demodulate a CPM signal with Gray mapping and bit inputs

```
% Create a CPM modulator, an AWGN channel, and a CPM demodulator.
hMod = comm.CPModulator(8, 'BitInput', true, ...
    'SymbolMapping', 'Gray');
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.CPMDemodulator(8, 'BitOutput', true, ...
    'SymbolMapping', 'Gray');
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
hError = comm.ErrorRate('ReceiveDelay', delay);
for counter = 1:100
    % Transmit 100 3-bit words
```

```
data = randi([0 1],300,1);
modSignal = step(hMod, data);
noisySignal = step(hAWGN, modSignal);
receivedData = step(hDemod, noisySignal);
errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

### Apply GFSK Modulation and Demodulation

Using the `comm.CPModulator` and `comm.CPMDemodulator` System objects apply GFSK modulation and demodulation to random bit data.

Create a GFSK modulator and demodulator object pair.

```
gfskMod = comm.CPModulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
                          'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
                          'BitInput', true);
gfskDemod = comm.CPMDemodulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ..
                               'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
                               'BitOutput', true);
```

Generate random bit data and apply GFSK modulation. Use a scatter plot to view the constellation.

```
numSym = 100;
x = randi([0 1],numSym*gfskMod.SamplesPerSymbol,1);
y = gfskMod(x);
eyediagram(y,16)
```

Demodulate the GFSK modulated data. To verify that the demodulated signal data is equal to the original data, you must account for the delay introduced by the Gaussian filtering in the GFSK modulation and demodulation processing.

```
z = gfskDemod(y);  
delay = finddelay(x,z);  
isequal(x(1:end-delay),z(delay+1:end))  
  
ans = logical  
     1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Demodulator Baseband block reference page. The object properties correspond to the block parameters. For CPM the phase shift per symbol is  $\pi \times h$ , where  $h$  is the modulation index.

**Package:** comm

Demodulate using CPM method and Viterbi algorithm

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates input data,  $X$ , with the CPM demodulator System object,  $H$ , and returns  $Y$ .  $X$  must be a double or single precision, column vector with a length equal to an integer multiple of the number of samples per symbol specified in the `SamplesPerSymbol` property. Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.CPMModulator

**Package:** comm

Modulate using CPM method

## Description

The `CPMModulator` object modulates using continuous phase modulation. The output is a baseband representation of the modulated signal.

To modulate a signal using continuous phase modulation:

- 1 Define and set up your CPM modulator object. See “Construction” on page 4-445.
- 2 Call `step` to modulate a signal according to the properties of `comm.CPMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.CPMModulator` creates a modulator System object, `H`. This object modulates the input signal using the continuous phase modulation (CPM) method.

`H = comm.CPMModulator(Name, Value)` creates a CPM modulator object, `H`. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.CPMModulator(M, Name, Value)` creates a CPM modulator object, `H`, with the `ModulationOrder` property set to `M` and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property must be a power of two, real, integer scalar. The default is 4.

### BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input requires double-precision or signed integer data type column vector. This vector must comprise odd integer values between  $-(\text{ModulationOrder on page 4-0} - 1)$  and  $\text{ModulationOrder}-1$ .

When you set this property to `true`, the `step` method input requires a column vector of  $P$ -length bit words, where  $P = \mathbf{\log_2}(\text{ModulationOrder})$ . The input data must have a double-precision or logical data type. The object maps each bit word to an integer  $K$  between 0 and  $\text{ModulationOrder}-1$ , using the mapping specified in the `SymbolMapping on page 4-0` property. The object then maps the integer  $K$  to the intermediate value  $2^{K-(\text{ModulationOrder}-1)}$  and proceeds as in the case when `BitInput` is `false`.

### SymbolMapping

Symbol encoding

Specify the mapping of bit inputs as one of `Binary | Gray`. The default is `Binary`. This property determines how the object maps each input  $P$ -length bit word, where  $P = \mathbf{\log_2}(\text{ModulationOrder on page 4-0})$ , to an integer between 0 and  $\text{ModulationOrder}-1$ .

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitInput on page 4-0` property to `true`.

## ModulationIndex

Modulation index

Specify the modulation index. The default is 0.5. The value of this property can be a scalar,  $h$ , or a column vector,  $[h_0, h_1, \dots, h_{H-1}]$

where  $H-1$  represents the length of the column vector. The phase shift over a symbol is  $\pi \times h$ .

When  $h_i$  varies from interval to interval, the object operates in multi-h. When the object operates in multi-h,  $h_i$  must be a rational number.

## FrequencyPulse

Frequency pulse shape

Specify the type of pulse shaping that the modulator uses to smooth the phase transitions of the modulated signal. Choose from Rectangular | Raised Cosine | Spectral Raised Cosine | Gaussian | Tamed FM. The default is Rectangular.

## MainLobeDuration

Main lobe duration of spectral raised cosine pulse

Specify, in number of symbol intervals, the duration of the largest lobe of the spectral raised cosine pulse. The default is 1. This property requires a real, positive, integer scalar. This property applies when you set the FrequencyPulse on page 4-0 property to Spectral Raised Cosine.

## RolloffFactor

Rolloff factor of spectral raised cosine pulse

Specify the rolloff factor of the spectral raised cosine pulse. The default is 0.2. This property requires a real scalar between 0 and 1. This property applies when you set the FrequencyPulse on page 4-0 property to Spectral Raised Cosine.

## BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of bandwidth and symbol time for the Gaussian pulse shape. The default is 0.3. This property requires a real, positive scalar. This property applies when you set the `FrequencyPulse` on page 4-0 property to `Gaussian`.

### **PulseLength**

Pulse length

Specify the length of the frequency pulse shape in symbol intervals. The value of this property requires a real, positive integer. The default is 1.

### **SymbolPrehistory**

Symbol prehistory

Specify the data symbols used by the modulator prior to the first call to the `step` method in reverse chronological order. The default is 1. This property requires a scalar or vector with odd integer elements between  $-(\text{ModulationOrder} - 1)$  and  $(\text{ModulationOrder} - 1)$ . If the value is a vector, then its length must be one less than the value in the `PulseLength` on page 4-0 property.

### **InitialPhaseOffset**

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar. The default is 0.

### **SamplesPerSymbol**

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar. The default is 8. The upsampling factor is the number of output samples that the `step` method produces for each input sample.

### **OutputDataType**

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

## Methods

reset      Reset states of CPM modulator object  
 step      Modulate using CPM method

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### Modulate a CPM signal with Gray mapping and bit inputs

```
% Create a CPM modulator, an AWGN channel, and a CPM demodulator.
hMod = comm.CPMModulator(8, 'BitInput', true, ...
    'SymbolMapping', 'Gray');
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.CPMDemodulator(8, 'BitOutput', true, ...
    'SymbolMapping', 'Gray');
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
hError = comm.ErrorRate('ReceiveDelay', delay);
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1], 300, 1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

### Apply GFSK Modulation and Demodulation

Using the `comm.CPModulator` and `comm.CPMDemodulator` System objects apply GFSK modulation and demodulation to random bit data.

Create a GFSK modulator and demodulator object pair.

```
gfskMod = comm.CPModulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...  
    'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...  
    'BitInput', true);  
gfskDemod = comm.CPMDemodulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ..  
    'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...  
    'BitOutput', true);
```

Generate random bit data and apply GFSK modulation. Use a scatter plot to view the constellation.

```
numSym = 100;  
x = randi([0 1], numSym*gfskMod.SamplesPerSymbol, 1);  
y = gfskMod(x);  
eyediagram(y, 16)
```

Demodulate the GFSK modulated data. To verify that the demodulated signal data is equal to the original data, you must account for the delay introduced by the Gaussian filtering in the GFSK modulation and demodulation processing.

```
z = gfskDemod(y);
delay = finddelay(x,z);
isequal(x(1:end-delay),z(delay+1:end))

ans = logical
     1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Modulator Baseband block reference page. The object properties correspond to the block parameters. For CPM the phase shift per symbol is  $\pi \times h$ , where  $h$  is the modulation index.

## Extended Capabilities

## Syntax

reset(H)

## Description

reset(H) resets the states of the CPModulator object, H.

# step

**System object:** comm.CPModulator

**Package:** comm

Modulate using CPM method

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

$Y = \text{step}(H, X)$  modulates input data,  $X$ , with the CPM modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be an integer or bit valued column vector with data types double, signed integer, or logical. The length of output vector,  $Y$ , is equal to the number of input samples times the number of samples per symbol specified in the `SamplesPerSymbol` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.CRCDetector

**Package:** comm

Detect errors in input data using CRC

## Description

The `comm.CRCDetector` System object computes cyclic redundancy check (CRC) checksums for an entire received codeword. For successful CRC detection in a communications system link, you must align the property settings of the `comm.CRCDetector` System object with the paired `comm.CRCGenerator` System object. For more information, see “CRC Syndrome Detector Operation” on page 4-463.

To detect errors in the received codeword containing CRC sequence bits:

- 1 Create the `comm.CRCDetector` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
crcdetector = comm.CRCDetector  
crcdetector = comm.CRCDetector(Name,Value)  
crcdetector = comm.CRCDetector(poly,Name,Value)
```

## Description

`crcdetector = comm.CRCDetector` creates a CRC code detector System object. This object detects errors in the received codewords according to a specified generator polynomial.

`crcdetector = comm.CRCDetector(Name, Value)` sets properties using one or more name-value pairs. For example, `comm.CRCDetector('Polynomial', 'z^16 + z^14 + z + 1')` configures the CRC code detector System object to use the CRC-16 cyclic redundancy check bits when checking for CRC code errors in the received codewords. Enclose each property name in quotes.

`crcdetector = comm.CRCDetector(poly, Name, Value)` creates a CRC code detector System object. This object has the `Polynomial` property set to `poly`, and the other specified properties set to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### Polynomial — Generator polynomial

'z^16 + z^12 + z^5 + 1' (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as 'z^3 + z^2 + 1'.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is  $(N+1)$ , where  $N$  is the degree of the generator polynomial. For example, `[1 1 0 1]` represents the polynomial  $x^3 + z^2 + 1$ .
- An integer row vector containing the exponents of  $z$  for the nonzero terms in the polynomial in descending order. For example, `[3 2 0]` represents the polynomial  $z^3 + z^2 + 1$ .

For more information, see “Character Representation of Polynomials”.

Some commonly used generator polynomials include:

<b>CRC method</b>	<b>Generator polynomial</b>
CRC-32	'z <sup>32</sup> + z <sup>26</sup> + z <sup>23</sup> + z <sup>22</sup> + z <sup>16</sup> + z <sup>12</sup> + z <sup>11</sup> + z <sup>10</sup> + z <sup>8</sup> + z <sup>7</sup> + z <sup>5</sup> + z <sup>4</sup> + z <sup>2</sup> + z + 1'
CRC-24	'z <sup>24</sup> + z <sup>23</sup> + z <sup>14</sup> + z <sup>12</sup> + z <sup>8</sup> + 1'
CRC-16	'z <sup>16</sup> + z <sup>15</sup> + z <sup>2</sup> + 1'
Reversed CRC-16	'z <sup>16</sup> + z <sup>14</sup> + z + 1'
CRC-8	'z <sup>8</sup> + z <sup>7</sup> + z <sup>6</sup> + z <sup>4</sup> + z <sup>2</sup> + 1'
CRC-4	'z <sup>4</sup> + z <sup>3</sup> + z <sup>2</sup> + z + 1'

Example: 'z<sup>7</sup> + z<sup>2</sup> + 1', [1 0 0 0 0 1 0 1], and [7 2 0] represent the same polynomial,  $p(z) = z^7 + z^2 + 1$ .

Data Types: double | char

#### **InitialConditions** — Initial states of internal shift register

0 (default) | 1 | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

Data Types: logical

#### **DirectMethod** — Use direct algorithm for CRC checksum calculations

false (default) | true

Use direct algorithm for CRC checksum calculations, specified as false or true.

When you set this property to true, the object uses the direct algorithm for CRC checksum calculations. When you set this property to false, the object uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see “Error Detection and Correction”.

Data Types: logical

#### **ReflectInputBytes** — Reflect input bytes

false (default) | true

Reflect input bytes, specified as `false` or `true`. Set this property to `true` to flip the received codeword on a bitwise basis before entering the data into the shift register.

When you set this property to `true`, the received codeword length divided by the value of the `ChecksumsPerFrame` property must be an integer and a multiple of 8.

Data Types: `logical`

### **ReflectChecksums — Reflect checksums before final XOR**

`false` (default) | `true`

Reflect checksums before final XOR, specified as `false` or `true`. Set this property to `true` to flip the CRC checksums around their centers after the received codeword is completely through the shift register.

When you set this property to `true`, the object flips the CRC checksums around their centers before the final XOR.

Data Types: `logical`

### **FinalXOR — Final XOR**

0 (default) | binary scalar | binary vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the `FinalXOR` property and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of 0 is equivalent to no XOR operation.

Data Types: `logical`

### **ChecksumsPerFrame — Number of checksums calculated**

1 (default) | positive integer

Number of checksums calculated for each received codeword frame, specified as a positive integer. For more information, see “CRC Syndrome Detector Operation” on page 4-463.

Data Types: `double`

## Usage

## Syntax

```
out = crcdetector(codeword)
[msg, err] = crcdetector(codeword)
```

## Description

`out = crcdetector(codeword)` checks CRC code bits for each received codeword frame, removes the checksums, and then concatenates subframes to the output frame.

`[msg, err] = crcdetector(codeword)` also returns the checksum error signal computed when checking CRC code bits for each codeword subframe.

## Input Arguments

### **codeword** — Received codeword

binary column vector

Received codeword, specified as a binary column vector.

Data Types: `double` | `logical`

## Output Arguments

### **out** — Output frame

binary column vector

Output frame, returned as a binary column vector that inherits the data type of the input signal. The message word output contains the received codeword with the checksums removed.

The length of the output frame is  $n - k * r$  bits, where  $n$  is the size of the received codeword,  $k$  is the number of checksums per frame, and  $r$  is the degree of the generator polynomial.

### **err** — Checksum error signal

binary column vector

Checksum error signal, returned as a binary column vector that inherits the data type of the input signal. The length of `Err` equals the value of `ChecksumsPerFrame`. For each checksum computation, an element value of 0 in `err` indicates no checksum error, and an element value of 1 in `err` indicates a checksum error.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### CRC Detection of Errors in a Random Message

Pass binary data through a CRC generator, introduce a bit error, and detect the error using a CRC detector.

Create a random binary vector.

```
x = randi([0 1],12,1);
```

Encode the input message frame using a CRC generator with the `ChecksumsPerFrame` property set to 2. This subdivides the incoming frame into two equal-length subframes.

```
crcgenerator = comm.CRCGenerator([1 0 0 1], 'ChecksumsPerFrame',2);  
codeword = crcgenerator(x);
```

Decode the codeword and verify that there are no errors in either subframe.

```
crcdetector = comm.CRCDetector([1 0 0 1], 'ChecksumsPerFrame',2);  
[~, err] = crcdetector(codeword)
```

```
err = 2×1
```

```
0
0
```

Introduce an error in the second subframe by inverting the last element of subframe 2. Pass the corrupted codeword through the CRC detector and verify that the error is detected in the second subframe.

```
codeword(end) = not(codeword(end));
[~,err] = crcdetector(codeword)
```

```
err = 2×1
```

```
0
1
```

### Cyclic Redundancy Check of Noisy BPSK Data Frames

Use a CRC code to detect frame errors in a noisy BPSK signal.

Create a CRC generator and detector pair using a standard CRC-4 polynomial,  $z^4 + z^3 + z^2 + z + 1$ .

```
poly = 'z4+z3+z2+z+1';
crcgenerator = comm.CRCGenerator(poly);
crcdetector = comm.CRCDetector(poly);
```

Generate 12-bit frames of binary data and append the CRC bits. Based on the degree of the polynomial, 4 bits are appended to each frame. Apply BPSK modulation and pass the signal through an AWGN channel. Demodulate and use the CRC detector to determine if the frame is in error.

```
numFrames = 20;
frmError = zeros(numFrames,1);
```

```
for k = 1:numFrames
    data = randi([0 1],12,1);           % Generate binary data
    encData = crcgenerator(data);      % Append CRC bits
```

```
modData = pskmod(encData,2);           % BPSK modulate
rxSig = awgn(modData,5);               % AWGN channel, SNR = 5 dB
demodData = pskdemod(rxSig,2);        % BPSK demodulate
[~,frmError(k)] = crcdetector(demodData); % Detect CRC errors
end
```

Identify the frames in which CRC code bit errors are detected.

```
find(frmError)
```

```
ans = 6
```

## More About

### Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the *checksum* or *syndrome*, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see “Cyclic Redundancy Check Codes”.

## CRC Syndrome Detector Operation

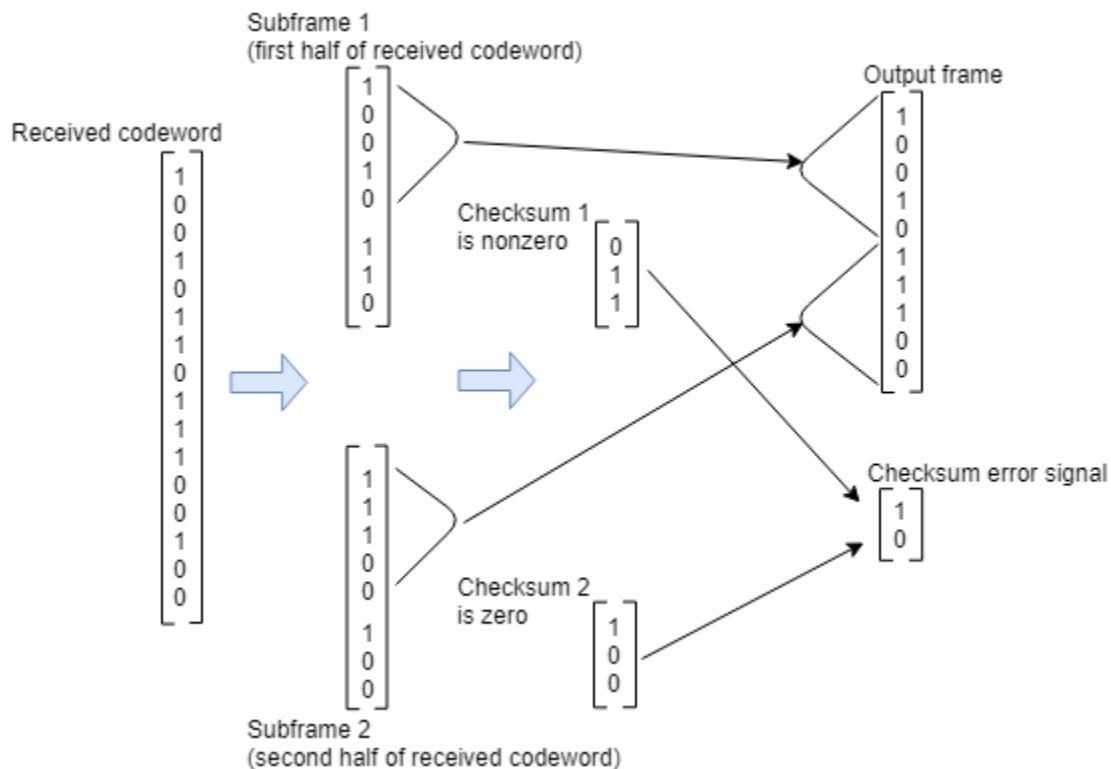

The CRC syndrome detector outputs the received message frame and a checksum error vector according to the specified generator polynomial and number of checksums per frame.

The checksum bits are removed from each subframe, so that the resulting the output frame length is  $n - k \times r$ , where  $n$  is the size of the received codeword,  $k$  is the number of checksums per frame, and  $r$  is the degree of the generator polynomial. The input frame must be evenly divisible by  $k$ .

For a specific initial state of the internal shift register:

- 1** The received codeword is divided into  $k$  equal sized subframes.
- 2** The CRC is removed from each of the  $k$  subframes and compared to the checksum calculated on the received codeword subframes.
- 3** The output frame is assembled by concatenating the subframe bits of the  $k$  subframes and then output as a column vector.
- 4** The checksum error is output as a binary column vector of length  $k$ . An element value of 0 indicates an error-free received subframe, and an element value of 1 indicates an error occurred in the received subframe.

For the scenario shown here, a 16-bit codeword is received, a third degree generator polynomial computes the CRC checksum, the initial state is 0, and the number of checksums per frame is 2.

Since the number of checksums per frame is 2 and the generator polynomial degree is 3, the received codeword is split in half and two checksums of size 3 are computed, one for each half of the received codeword. The initial states are not shown, because an initial state of  $[0]$  does not affect the output of the CRC algorithm. The output frame contains the concatenation of the two halves of the received codeword as a single vector of size 10. The checksum error signal output contains a 2-by-1 binary frame vector whose entries depend on whether the computed checksums are zero. As shown in the figure, the first checksum is nonzero and the second checksum is zero, indicating an error occurred in reception of the first half of the codeword.

**Package:** comm

Generate CRC code bits and append to input data

### Description

The `comm.CRCGenerator` System object generates cyclic redundancy check (CRC) code bits for each input frame and appends them to the frame. For more information, see “CRC Generator Operation” on page 4-477.

To generate CRC code bits for each input frame and append them to the frame:

- 1 Create the `comm.CRCGenerator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

### Creation

### Syntax

```
crcgenerator= comm.CRCGenerator  
crcgenerator = comm.CRCGenerator(Name,Value)  
crcgenerator = comm.CRCGenerator(poly,Name,Value)
```

### Description

`crcgenerator= comm.CRCGenerator` creates a CRC code generator System object. This object generates CRC bits according to a specified generator polynomial and appends them to the input frame.

`crcgenerator = comm.CRCGenerator(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.CRCGenerator('Polynomial','z^16 +`

$z^{14} + z + 1$ ) configures the CRC generator System object to append CRC-16 cyclic redundancy check bits to the input frame. Enclose each property name in quotes.

`crcgenerator = comm.CRCGenerator(poly, Name, Value)` creates a CRC code generator System object. This object has the `Polynomial` property set to `poly`, and the other specified properties set to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

### Polynomial — Generator polynomial

' $z^{16} + z^{12} + z^5 + 1$ ' (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as ' $z^3 + z^2 + 1$ '.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is  $(N+1)$ , where  $N$  is the degree of the generator polynomial. For example, `[1 1 0 1]` represents the polynomial  $x^3 + z^2 + 1$ .
- An integer row vector containing the exponents of  $z$  for the nonzero terms in the polynomial in descending order. For example, `[3 2 0]` represents the polynomial  $z^3 + z^2 + 1$ .

For more information, see “Character Representation of Polynomials”.

Some commonly used generator polynomials include:

CRC method	Generator polynomial
CRC-32	'z <sup>32</sup> + z <sup>26</sup> + z <sup>23</sup> + z <sup>22</sup> + z <sup>16</sup> + z <sup>12</sup> + z <sup>11</sup> + z <sup>10</sup> + z <sup>8</sup> + z <sup>7</sup> + z <sup>5</sup> + z <sup>4</sup> + z <sup>2</sup> + z + 1'
CRC-24	'z <sup>24</sup> + z <sup>23</sup> + z <sup>14</sup> + z <sup>12</sup> + z <sup>8</sup> + 1'
CRC-16	'z <sup>16</sup> + z <sup>15</sup> + z <sup>2</sup> + 1'
Reversed CRC-16	'z <sup>16</sup> + z <sup>14</sup> + z + 1'
CRC-8	'z <sup>8</sup> + z <sup>7</sup> + z <sup>6</sup> + z <sup>4</sup> + z <sup>2</sup> + 1'
CRC-4	'z <sup>4</sup> + z <sup>3</sup> + z <sup>2</sup> + z + 1'

Example: 'z<sup>7</sup> + z<sup>2</sup> + 1', [1 0 0 0 0 1 0 1], and [7 2 0] represent the same polynomial,  $p(z) = z^7 + z^2 + 1$ .

Data Types: double | char

**InitialConditions — Initial states of internal shift register**

0 (default) | 1 | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

Data Types: logical

**DirectMethod — Use direct algorithm for CRC checksum calculations**

false (default) | true

Use direct algorithm for CRC checksum calculations, specified as false or true.

When you set this property to true, the object uses the direct algorithm for CRC checksum calculations. When you set this property to false, the object uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see “Error Detection and Correction”.

Data Types: logical

**ReflectInputBytes — Reflect input bytes**

false (default) | true

Reflect input bytes, specified as `false` or `true`. Set this property to `true` to flip the input frame on a bitwise basis before entering the data into the shift register.

When you set this property to `true`, the input frame length divided by the value of the `ChecksumsPerFrame` property must be an integer and a multiple of 8.

Data Types: `logical`

### **ReflectChecksums — Reflect checksums before final XOR**

`false` (default) | `true`

Reflect checksums before final XOR, specified as `false` or `true`. Set this property to `true` to flip the CRC checksums around their centers after the input data are completely through the shift register.

Data Types: `logical`

### **FinalXOR — Final XOR**

0 (default) | binary scalar | binary vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the `FinalXOR` property and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of 0 is equivalent to no XOR operation.

Data Types: `logical`

### **ChecksumsPerFrame — Number of checksums calculated for each frame**

1 (default) | positive integer

Number of checksums calculated for each frame, specified as a positive integer. For more information, see “CRC Generator Operation” on page 4-477.

Data Types: `double`

## **Usage**

## **Syntax**

`codeword = crcgenerator(x)`

### Description

`codeword = crcgenerator(x)` generates CRC code bits for each input frame and appends them to the frame.

### Input Arguments

#### **x — Input signal**

binary column vector

Input signal, specified as a binary column vector. The length of the input frame must be a multiple of the value of the `ChecksumsPerFrame` property. If the input data type is `double`, the least significant bit is used as the binary value. For more information, see “CRC Generator Operation” on page 4-477.

Data Types: `double` | `logical`

### Output Arguments

#### **codeword — Output codeword frame**

binary column vector

Output codeword frame, returned as a binary column vector that inherits the data type of the input signal. The output contains the input frames with the CRC code sequence bits appended.

The length of the output codeword frame is  $m + k * r$ , where  $m$  is the size of the input message,  $k$  is the number of checksums per input frame, and  $r$  is the degree of the generator polynomial. For more information, see “CRC Generator Operation” on page 4-477.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

step     Run System object algorithm  
 release   Release resources and allow changes to System object property values and  
           input characteristics  
 reset     Reset internal states of System object

## Examples

### Generate CRC-8 Checksum

Generate a CRC-8 checksum for the example shown in 802.11™-2016[1] on page 4-0 , section 21.3.10.3 and compare with the expected CRC.

Create a CRC Generator System object™. To align with the CRC calculation in 802.11-20016, the System object™ sets the generator polynomial as  $z^8 + z^2 + z + 1$ , initial states to 1, direct method, and final XOR to 1.

```
crc8 = comm.CRCGenerator('Polynomial','z^8 + z^2 + z + 1', ...
    'InitialConditions',1,'DirectMethod',true,'FinalXOR',1)
```

```
crc8 =
comm.CRCGenerator with properties:

    Polynomial: 'z^8 + z^2 + z + 1'
InitialConditions: 1
    DirectMethod: true
ReflectInputBytes: false
ReflectChecksums: false
        FinalXOR: 1
ChecksumsPerFrame: 1
```

Process one input frame according to the example from the 802.11-2016 standard in section 21.3.10.3. In the example, the input bit stream  $\{m_0, \dots, m_{22}\}$  is  $\{1\ 0\ 0\ 1\ 1\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 1\ 1\}$  and the expected CRC checksum  $\{c_7, \dots, c_0\}$  is  $\{0\ 0\ 0\ 1\ 1\ 1\ 0\ 0\}$ .

```
x = [1 0 0 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1]';
expectedChecksum = [0 0 0 1 1 1 0 0]';
checksumLength = length(expectedChecksum);
```

The generated CRC checksum is compared to the expected checksum.

```
codeword = crc8(x);  
checksum = codeword(end-checksumLength+1:end);  
isequal(checksum,expectedChecksum)
```

```
ans = logical  
     1
```

### CRC Detection of Errors in a Random Message

Pass binary data through a CRC generator, introduce a bit error, and detect the error using a CRC detector.

Create a random binary vector.

```
x = randi([0 1],12,1);
```

Encode the input message frame using a CRC generator with the `ChecksumsPerFrame` property set to 2. This subdivides the incoming frame into two equal-length subframes.

```
crcgenerator = comm.CRCGenerator([1 0 0 1], 'ChecksumsPerFrame', 2);  
codeword = crcgenerator(x);
```

Decode the codeword and verify that there are no errors in either subframe.

```
crcdetector = comm.CRCDetector([1 0 0 1], 'ChecksumsPerFrame', 2);  
[~, err] = crcdetector(codeword)
```

```
err = 2×1  
  
     0  
     0
```

Introduce an error in the second subframe by inverting the last element of subframe 2. Pass the corrupted codeword through the CRC detector and verify that the error is detected in the second subframe.

```
codeword(end) = not(codeword(end));
[~,err] = crcdetector(codeword)
```

```
err = 2×1
```

```
0
1
```

### Cyclic Redundancy Check of Noisy BPSK Data Frames

Use a CRC code to detect frame errors in a noisy BPSK signal.

Create a CRC generator and detector pair using a standard CRC-4 polynomial,  $z^4 + z^3 + z^2 + z + 1$ .

```
poly = 'z4+z3+z2+z+1';
crcgenerator = comm.CRCGenerator(poly);
crcdetector = comm.CRCDetector(poly);
```

Generate 12-bit frames of binary data and append the CRC bits. Based on the degree of the polynomial, 4 bits are appended to each frame. Apply BPSK modulation and pass the signal through an AWGN channel. Demodulate and use the CRC detector to determine if the frame is in error.

```
numFrames = 20;
frmError = zeros(numFrames,1);

for k = 1:numFrames
    data = randi([0 1],12,1);           % Generate binary data
    encData = crcgenerator(data);      % Append CRC bits
    modData = pskmod(encData,2);      % BPSK modulate
    rxSig = awgn(modData,5);          % AWGN channel, SNR = 5 dB
    demodData = pskdemod(rxSig,2);    % BPSK demodulate
    [~,frmError(k)] = crcdetector(demodData); % Detect CRC errors
end
```

Identify the frames in which CRC code bit errors are detected.

```
find(frmError)
```

```
ans = 6
```

### CRC-16-CCITT Generator for X.25

Create a CRC-16-CCITT generator as described in Section 2.2.7.4 of ITU-T Recommendation X-25[1] on page 4-0 using the input data and expected frame check sequence (FCS) from Example 2 in Appendix I, I.1.

Create an unnumbered acknowledgement (UA) response frame where address = B and F = 1.

```
Address = [1 0 0 0 0 0 0 0];
UA = [1 1 0 0 1 1 1 0];
input = [Address UA]';
expectedChecksum = [1 1 0 0 0 0 0 1 1 1 1 0 1 0 1 0]'; % Expected FCS
checksumLength = 16;
```

```
crcGen = comm.CRCGenerator(...
    'Polynomial','X^16 + X^12 + X^5 + 1',...
    'InitialConditions',1,...
    'DirectMethod',true,...
    'FinalXOR',1);
crcSeq = crcGen(input);
checksum = crcSeq(end-checksumLength+1:end);
```

Compare calculated checksum with the expected checksum.

```
isequal(expectedChecksum,checksum)
```

```
ans = logical
     1
```

## CRC-32 Generator for Ethernet

Create a CRC-32 code for the frame check sequence (FCS) field for Ethernet as described in Section 3.2.9 of the IEEE Standard for Ethernet[1] on page 4-0 .

```
rng(1865); % Seed the random number generator for repeatable results
```

Initialize a message with random data to represent the protected fields of the MAC frame, specifically the destination address, source address, length or type field, MAC client data, and padding.

```
data = randi([0,1],100,1);
```

Specify the CRC-32 generating polynomial used for encoding Ethernet messages.

```
poly = [32,26,23,22,16,12,11,10,8,7,5,4,2,1,0];
```

Calculate the CRC by following the steps specified in the standard and using the nondirect method to generate the CRC code.

```
dataN = [not(data(1:32));data(33:end)]; % Section 3.2.9 step a) and b)
crcGen1 = comm.CRCGenerator(...
    'Polynomial', poly, ...
    'InitialConditions', 0, ...
    'DirectMethod', false, ...
    'FinalXOR', 1);
seq = crcGen1(dataN); % Section 3.2.9 step c), d) and e)
csNondirect = seq(end-31:end);
```

Calculate the CRC by following the steps specified in the standard and using the direct method to generate the CRC code.

```
crcGen2 = comm.CRCGenerator(...
    'Polynomial', poly, ...
    'InitialConditions', 1, ...
    'DirectMethod', true, ...
    'FinalXOR', 1);
txSeq = crcGen2(data);
csDirect = txSeq(end-31:end);
```

Compare the generated CRC codes by using the nondirect and direct methods.

```
disp([csNondirect';csDirect']);
```

```
Columns 1 through 13
```

```
    1    1    1    0    1    1    0    0    1    0    0    1    0
    1    1    1    0    1    1    0    0    1    0    0    1    0
```

Columns 14 through 26

```
    1    0    0    1    0    1    0    1    1    0    0    0    1
    1    0    0    1    0    1    0    1    1    0    0    0    1
```

Columns 27 through 32

```
    1    1    0    0    1    0
    1    1    0    0    1    0
```

```
isequal(csNondirect,csDirect)
```

```
ans = logical
      1
```

```
rng('default'); % Reset the random number generator
```

## More About

### Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the *checksum* or *syndrome*, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see “Cyclic Redundancy Check Codes”.

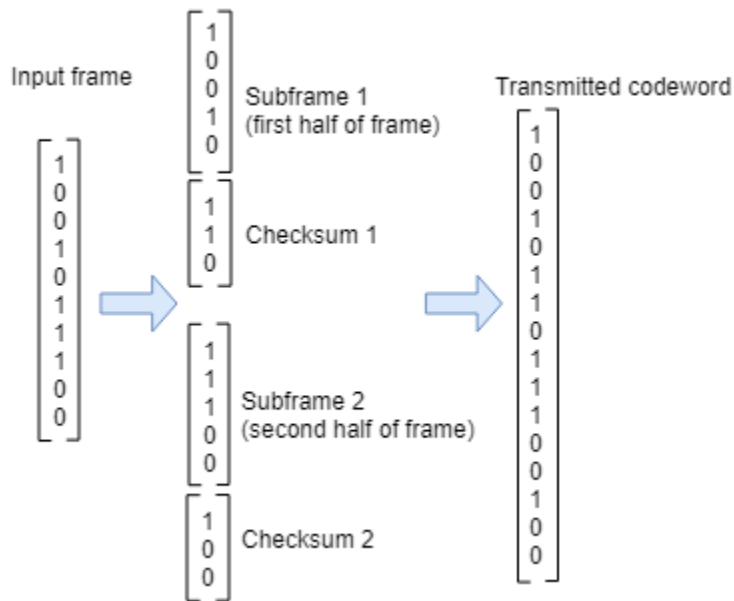

## **CRC Generator Operation**

The CRC generator appends CRC checksums to the input frame according to the specified generator polynomial and number of checksums per frame.

For a specific initial state of the internal shift register and  $k$  checksums per input frame:

- 1** The input signal is divided into  $k$  subframes of equal size.
- 2** Each of the  $k$  subframes are prefixed with the initial states vector.
- 3** The CRC algorithm is applied to each subframe.
- 4** The resulting checksums are appended to the end of each subframe.
- 5** The subframes are concatenated and output as a column vector.

For the scenario shown here, a 10-bit frame is input, a third degree generator polynomial computes the CRC checksum, the initial state is 0, and the number of checksums per frame is 2.

The input frame is divided into two subframes of size 5 and checksums of size 3 are computed and appended to each subframe. The initial states are not shown, because an initial state of  $[0]$  does not affect the output of the CRC algorithm. The output transmitted codeword frame has the size  $5 + 3 + 5 + 3 = 16$ .

## comm.DBPSKDemodulator

**Package:** comm

Demodulate using DBPSK method

### Description

The `DBPSKDemodulator` object demodulates a signal that was modulated using the differential binary phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using differential binary phase shift keying:

- 1 Define and set up your DBPSK demodulator object. See “Construction” on page 4-480.
- 2 Call `step` to demodulate a signal according to the properties of `comm.DBPSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.DBPSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the differential binary phase shift keying (DBPSK) method.

`H = comm.DBPSKDemodulator(Name, Value)` creates a DBPSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.DBPSKDemodulator(PHASE, Name, Value)` creates a DBPSK demodulator object, `H`. This object has the `PhaseRotation` property set to `PHASE` and the other specified properties set to the specified values.

## Properties

### PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated bits in radians as a real scalar. The default is `0`. This value corresponds to the phase difference between previous and current modulated bits when the input is zero.

### OutputDataType

Data type of output

Specify output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `logical`. The default is `Full precision`. When you set this property to `Full precision`, the output data type has the same data type as the input. In this case, that value must be a double- or single-precision data type.

## Methods

`reset`      Reset states of DBPSK demodulator object  
`step`        Demodulate using DBPSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### DBPSK Signal in AWGN

Create a DBPSK modulator and demodulator pair.

```
dbpskmod = comm.DBPSKModulator(pi/4);  
dpskdemod = comm.DBPSKDemodulator(pi/4);
```

Create an error rate calculator. Set the `ComputationDelay` property to 1 to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50-bit frames
- DBPSK modulate
- Pass through AWGN channel
- DBPSK demodulate
- Collect error statistics

```
for counter = 1:100  
    txData = randi([0 1],50,1);  
    modSig = dbpskmod(txData);  
    rxSig = awgn(modSig,7);  
    rxData = dpskdemod(rxSig);  
    errorStats = errorRate(txData,rxData);  
end
```

Display the error statistics.

```
ber = errorStats(1)  
  
ber = 0.0040  
  
numErrors = errorStats(2)  
  
numErrors = 20  
  
numBits = errorStats(3)  
  
numBits = 4999
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the DBPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Reset states of DBPSK demodulator object

## **Syntax**

reset(H)

## **Description**

reset(H) resets the states of the DBPSKDemodulator object, H.

---

## step

**System object:** comm.DBPSKDemodulator

**Package:** comm

Demodulate using DBPSK method

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  demodulates input data,  $X$ , with the DBPSK demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a double or single precision data type scalar or column vector.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.DBPSKModulator

**Package:** comm

Modulate using DBPSK method

### Description

The `DBPSKModulator` object modulates using the differential binary phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential binary phase shift keying:

- 1 Define and set up your DBPSK modulator object. See “Construction” on page 4-486.
- 2 Call `step` to modulate a signal according to the properties of `comm.DBPSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.DBPSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the differential binary phase shift keying (DBPSK) method.

`H = comm.DBPSKModulator(Name,Value)` creates a DBPSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.DBPSKModulator(PHASE,Name,Value)` creates a DBPSK modulator object, `H`. This object has the `PhaseRotation` property set to `PHASE`, and the other specified properties set to the specified values.

## Properties

### PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated bits in radians as a real scalar value. The default is 0. This value corresponds to the phase difference between previous and current modulated bits when the input is zero.

### OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

## Methods

`reset`      Reset states of DBPSK modulator object  
`step`        Modulate using DBPSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### DBPSK Signal in AWGN

Create a DBPSK modulator and demodulator pair.

```
dbpskmod = comm.DBPSKModulator(pi/4);
dppbskdemod = comm.DBPSKDemodulator(pi/4);
```

Create an error rate calculator. Set the `ComputationDelay` property to 1 to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50-bit frames
- DBPSK modulate
- Pass through AWGN channel
- DBPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],50,1);
    modSig = dbpskmod(txData);
    rxSig = awgn(modSig,7);
    rxData = dpbpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
ber = 0.0040
numErrors = errorStats(2)
numErrors = 20
numBits = errorStats(3)
numBits = 4999
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the DBPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

## comm.Descrambler

**Package:** comm

Descramble input signal

### Description

The `comm.Descrambler` object descrambles a scalar or column vector input signal. The `comm.Descrambler` object is the inverse of the `comm.Scrambler` object. If you use the `comm.Scrambler` object in a transmitter, then you use the `comm.Descrambler` object in the related receiver.

This schematic shows the descrambler operation. The adders and subtracter operate modulo  $N$ , where  $N$  is the value specified by the Calculation base property.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the descrambler. To make the `comm.Descrambler` object reverse the operation of the `comm.Scrambler` object, use the same property settings in both objects. If there is no signal delay between the scrambler and the descrambler, then the InitialConditions in the two objects must be the same.

To descramble an input signal:

- 1 Create the `comm.Descrambler` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

### Syntax

```
descrambler = comm.Descrambler  
descrambler = comm.Descrambler(base,poly,cond)  
descrambler = comm.Descrambler( ___,Name,Value)
```

### Description

`descrambler = comm.Descrambler` creates a descrambler System object. This object descrambles the input data by using a linear feedback shift register that you specify with the `Polynomial` property.

`descrambler = comm.Descrambler(base,poly,cond)` creates the descrambler object with the `CalculationBase` property set to `base`, the `Polynomial` property set to `poly`, and the `InitialConditions` property set to `cond`.

Example: `comm.Descrambler(8,'1 + z^-2 + z^-3 + z^-5 + z^-7',[0 3 2 2 5 1 7])` sets the calculation base to 8, and the descrambler polynomial and initial conditions as specified.

`descrambler = comm.Descrambler( ___,Name,Value)` sets properties using one or more name-value pairs and either of the previous syntaxes. Enclose each property name in single quotes.

Example: `comm.Descrambler('CalculationBase',2)`

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

### **CalculationBase — Range of input data**

4 (default) | nonnegative integer

Range of input data used in the descrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from 0 to `CalculationBase - 1`.

Data Types: double

### **Polynomial — Connections for linear feedback shift registers**

'1 + z<sup>-1</sup> + z<sup>-2</sup> + z<sup>-4</sup>' (default) | character vector | integer vector | binary vector

Connections for linear feedback shift registers in the descrambler, specified as a character vector, integer vector, or binary vector. The `Polynomial` property defines if each switch in the descrambler is on or off. Specify the polynomial as:

- A character vector, such as '1 + z<sup>-6</sup> + z<sup>-8</sup>'. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0 -6 -8], listing the descrambler coefficients in order of descending powers of  $z^{-1}$ , where  $p(z^{-1}) = 1 + p_1z^{-1} + p_2z^{-2} + \dots$
- A binary vector, such as [1 0 0 0 0 0 1 0 1], listing the powers of  $z$  that appear in the polynomial that have a coefficient of 1. In this case, the order of the descramble polynomial is one less than the binary vector length.

Example: '1 + z<sup>-6</sup> + z<sup>-8</sup>', [0 -6 -8], and [1 0 0 0 0 0 1 0 1] all represent this polynomial:

$$p(z^{-1}) = 1 + z^{-6} + z^{-8}$$

Data Types: double | char

### **InitialConditionsSource — Initial conditions source**

'Property' (default) | 'Input port'

- 'Property' - Specify descrambler initial conditions by using the `InitialConditions` property.
- 'Input port' - Specify descrambler initial conditions by using an additional input argument, `initcond`, when calling the object.

Data Types: char

### **InitialConditions — Initial conditions of descrambler registers**

[0 1 2 3] (default) | nonnegative integer vector

Initial conditions of descrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of `InitialConditions` must equal the order of the Polynomial property. The vector element values must be integers from 0 to `CalculationBase - 1`.

### Dependencies

This property is available when `InitialConditionsSource` is set to 'Property'.

### ResetInputPort — Descrambler state reset port

`false` (default) | `true`

Descrambler state reset port, specified as `false` or `true`. If `ResetInputPort` is `true`, you can reset the descrambler object by using an additional input argument, `reset`, when calling the object.

### Dependencies

This property is available when `InitialConditionsSource` is set to 'Property'.

## Usage

## Syntax

```
descrambledOut = descrambler(signal)
descrambledOut = descrambler(signal,initcond)
descrambledOut = descrambler(signal,reset)
```

## Description

`descrambledOut = descrambler(signal)` descrambles the input signal. The output is the same data type and length as the input vector.

`descrambledOut = descrambler(signal,initcond)` provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the `InitialConditionsSource` property of the object to 'Input port'.

`descrambledOut = descrambler(signal, reset)` provides an additional input indicating whether to reset the state of the descrambler.

This syntax applies when you set the `InitialConditionsSource` property of the object to 'Property' and the `ResetInputPort` to `true`.

### Input Arguments

#### **signal** — Input signal

column vector

Input signal, specified as a column vector.

Example: `descrambledOut = descrambler([0 1 1 0 1 0])`

Data Types: `double` | `logical`

#### **initcond** — Initial register condition

nonnegative integer column vector

Initial descrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of `initcond` must equal the order of the `Polynomial` property. The vector element values must be integers from 0 to `CalculationBase - 1`.

Example: `descrambledOut = descrambler(signal, [0 1 1 0])` corresponds to possible initial register states for a descrambler with a polynomial order of 4 and a calculation base of 2 or higher.

Data Types: `double`

#### **reset** — Reset initial state of descrambler

scalar

Reset initial state of the descrambler when the simulation starts, specified as a scalar. When the value of `reset` is nonzero, the object is reset before it is called.

Example: `descrambledOut = descrambler(signal, 0)` descrambles the input signal without resetting the descrambler states.

Data Types: `double`

## Output Arguments

### **out** — Descrambled output

column vector

Descrambled output, returned as a column vector with the same data type and length as signal.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Scramble and Descramble Data

Scramble and descramble 8-ary data using `comm.Scrambler` and `comm.Descrambler` System objects™ having a calculation base of 8.

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.

```
N = 8;
scrambler = comm.Scrambler(N, '1 + z^-2 + z^-3 + z^-5 + z^-7', ...
    [0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N, [1 0 1 1 0 1 0 1], ...
    [0 3 2 2 5 1 7]);
```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.

```
data = randi([0 N-1],5,1);
scrData = scrambler(data);
deScrData = descrambler(scrData);
[data scrData deScrData]
```

```
ans = 5×3
```

```
    6    7    6
    7    5    7
    1    7    1
    7    0    7
    5    3    5
```

Verify that the descrambled data matches the original data.

```
isequal(data,deScrData)
```

```
ans = logical
      1
```

### Scramble and Descramble Data with Changing Initial Conditions

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the `InitialConditionsSource` property to 'Input port' so you can set the initial conditions as an argument to the object.

```
N = 4;
scrambler = comm.Scrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
descrambler = comm.Descrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
```

Preallocate memory for the error vector which will be used to store errors output by the `symerr` function.

```
errVec = zeros(10,1);
```

Scramble and descramble random integers while changing the initial conditions, `initCond`, each time the loop executes. Use the `symerr` function to determine if the scrambling and descrambling operations result in symbol errors.

```
for k = 1:10
    initCond = randperm(3)';
    data = randi([0 N-1],5,1);
    scrData = scrambler(data,initCond);
    deScrData = descrambler(scrData,initCond);
    errVec(k) = symerr(data,deScrData);
end
```

Examine `errVec` to verify that the output from the descrambler matches the original data.

**Introduced in R2012a**

# comm.DifferentialDecoder

**Package:** comm

Decode binary signal using differential decoding

## Description

The `DifferentialDecoder` object decodes the binary input signal. The output is the logical difference between the consecutive input element within a channel.

To decode a binary signal using differential decoding:

- 1 Define and set up your differential decoder object. See “Construction” on page 4-501.
- 2 Call `step` to decode a binary signal according to the properties of `comm.DifferentialDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.DifferentialDecoder` creates a differential decoder System object, `H`. This object decodes a binary input signal that was previously encoded using a differential encoder.

`H = comm.DifferentialDecoder(Name,Value)` creates object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### InitialCondition

Initial value used to generate initial output

Specify the initial condition as a real scalar. This property can have a logical, numeric, or fixed-point (embedded.fi object) data type. The default is 0. The object treats nonbinary values as binary signals.

## Methods

reset     Reset states of differential decoder object  
step     Decode binary signal using differential decoding

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Decode Differentially Encoded Signal

Create a differential encoder and decoder pair.

```
diffEnc = comm.DifferentialEncoder;  
diffDec = comm.DifferentialDecoder;
```

Generate random binary data. Differentially encode and decode the data.

```
data = randi([0 1],100,1);  
encData = diffEnc(data);  
decData = diffDec(encData);
```

Determine the number of errors between the original data and the decoded data.

```
numErrors = biterr(data,decData)  
  
numErrors = 0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Differential Decoder block reference page. The object properties correspond to the block parameters, except:

The object only supports single channel, column vector inputs.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

## **reset**

**System object:** `comm.DifferentialDecoder`

**Package:** `comm`

Reset states of differential decoder object

## **Syntax**

`reset(H)`

## **Description**

`reset(H)` resets the states of the `DifferentialDecoder` object, `H`.

---

## step

**System object:** `comm.DifferentialDecoder`

**Package:** `comm`

Decode binary signal using differential decoding

## Syntax

`Y = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` decodes the differentially encoded input data, `X`, and returns the decoded data, `Y`. The input `X` must be a column vector of data type logical, numeric, or fixed-point (embedded.fi objects). `Y` has the same data type as `X`. The object treats non-binary inputs as binary signals. The object computes the initial output value by performing an Xor operation of the value in the `InitialCondition` property and the first element of the vector you input the first time you call the `step` method.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.DifferentialEncoder

**Package:** comm

Encode binary signal using differential coding

### Description

The `DifferentialEncoder` object encodes the binary input signal within a channel. The output is the logical difference between the current input element and the previous output element.

To encode a binary signal using differential coding:

- 1 Define and set up your differential encoder object. See “Construction” on page 4-506.
- 2 Call `step` to encode a binary signal according to the properties of `comm.DifferentialEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.DifferentialEncoder` creates a differential encoder System object, `H`. This object encodes a binary input signal by calculating its logical difference with the previously encoded data.

`H = comm.DifferentialEncoder(Name,Value)` creates object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

# comm.DiscreteTimeVCO

**Package:** comm

Generate variable frequency sinusoid

## Description

The `DiscreteTimeVCO` (voltage-controlled oscillator) object generates a signal whose frequency shift from the quiescent frequency property is proportional to the input signal. The input signal is interpreted as a voltage.

To generate a variable frequency sinusoid:

- 1 Define and set up your discrete time voltage-controlled oscillator object. See “Construction” on page 4-511 .
- 2 Call `step` to generate a variable frequency sinusoid according to the properties of `comm.DiscreteTimeVCO`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.DiscreteTimeVCO` creates a discrete-time voltage-controlled oscillator (VCO) System object, `H`. This object generates a sinusoidal signal with the frequency shifted from the specified quiescent frequency to a value proportional to the input signal.

`H = comm.DiscreteTimeVCO(Name,Value)` creates a discrete-time VCO object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### **OutputAmplitude**

Amplitude of output signal

Specify the amplitude of the output signal as a double- or single-precision, scalar value. The default is 1. This property is tunable.

### **QuiescentFrequency**

Frequency of output signal when input is zero

Specify the quiescent frequency of the output signal in Hertz, as a double- or single-precision, real, scalar value. The default is 10. This property is tunable.

### **Sensitivity**

Sensitivity of frequency shift of output signal

Specify the sensitivity of the output signal frequency shift to the input as a double- or single-precision, real, scalar value. The default is 1. This value scales the input voltage and, consequently, the shift from the quiescent frequency value. The property measures Sensitivity in Hertz per volt. This property is tunable.

### **InitialPhase**

Initial phase of output signal

Specify the initial phase of the output signal, in radians, as a double or single precision, real, scalar value. The default is 0.

### **SampleRate**

Sample rate of input

Specify the sample rate of the input, in Hertz, as a double- or single-precision, positive, scalar value. The default is 100.

## Methods

reset      Reset states of discrete-time VCO object  
 step      Generate variable frequency sinusoid

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Generate FSK Signal Using Discrete Time VCO

Create a signal source System object™.

```
reader = dsp.SignalSource;
```

Generate random data and apply rectangular pulse shaping.

```
reader.Signal = randi([0 7],10,1);
reader.Signal = rectpulse(reader.Signal,100);
```

Create a signal logger and discrete time VCO System objects.

```
logger = dsp.SignalSink;
discreteVCO = comm.DiscreteTimeVCO('OutputAmplitude',8,'QuiescentFrequency',1);
```

Generate an FSK signal.

```
while(~isDone(reader))
    sig = reader();
    y = discreteVCO(sig);
    logger(y);
end
```

```
oscsig = logger.Buffer;
```

Plot the generated FSK signal.

```
t = (0:length(oscsig)-1)/discreteVCO.SampleRate;
plot(t,reader.Signal,'--r','LineWidth',3)
hold on
```

```
plot(t,oscsig,'-b');  
hold off  
xlabel('Time (s)')  
ylabel('Amplitude (V)')  
legend('Input Signal','FSK Signal','location','se')
```

## Algorithms

This object implements the algorithm, inputs, and outputs as described on the Discrete-Time VCO block reference page. However, this object and the corresponding block may

not generate the exact same outputs for single-precision inputs or property values due to the following differences in casting strategies and arithmetic precision issues:

- The block always casts the result of intermediate mathematical operations to the input data type. The object does not cast intermediate results and MATLAB decides the data type. The object casts the final output to the input data type.
- You can specify the `SampleRate` object property in single-precision or double-precision. The block does not allow this.
- In arithmetic operations with more than two operands with mixed data types, the result may differ depending on the order of operation. Thus, the following calculation may also contribute to the difference in the output of the block and the object:

`input * sensitivity * sampleTime`

- The block performs this calculation from left to right. However, since `sensitivity * sampleTime` is a one-time calculation, the object calculates this in the following manner:

`input * (sensitivity * sampleTime)`

## Extended Capabilities

**Package:** comm

Generate variable frequency sinusoid

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  generates a sinusoidal signal,  $Y$ , with frequency shifted, from the value you specify in the `QuiescentFrequency` property, to a value proportional to the input signal,  $X$ . The input,  $X$ , must be a double or single precision, real, scalar value. The output,  $Y$ , has the same data type and size as the input,  $X$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.DPD

**Package:** comm

Digital predistorter

## Description

The `comm.DPD` System object applies digital predistortion (DPD) to a complex baseband signal by using a memory polynomial to compensate for nonlinearities in a power amplifier. For more information, see “Digital Predistortion” on page 4-524.

To predistort signals:

- 1 Create the `comm.DPD` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
dpd = comm.DPD
dpd = comm.DPD(Name, Value)
```

## Description

`dpd = comm.DPD` creates a digital predistorter System object to predistort a signal.

`dpd = comm.DPD(Name, Value)` sets properties using one or more name-value pairs. For example, `comm.DPD('PolynomialType', 'Cross-term memory polynomial')` configures the predistorter System object to predistort the input signal by using a memory polynomial with cross terms. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects* (MATLAB).

### PolynomialType — Polynomial type

'Memory polynomial' (default) | 'Cross-term memory polynomial'

Polynomial type used for predistortion, specified as one of these values:

- 'Memory polynomial' — Predistorts the input signal by using a memory polynomial without cross terms.
- 'Cross-term memory polynomial' — Predistorts the input signal by using a memory polynomial with cross terms.

For more information, see “Digital Predistortion” on page 4-524.

### Coefficients — Memory-polynomial coefficients

`complex([1 0 0 0 0; 0 0 0 0 0; 0 0 0 0 0])` (default) | matrix

Memory-polynomial coefficients, specified as a matrix. The number of rows in the matrix must equal the memory depth of the memory polynomial.

- If `PolynomialType` is 'Memory polynomial', the number of columns in the matrix is the degree of the memory polynomial.
- If `PolynomialType` is 'Cross-term memory polynomial', the number of columns in the matrix must equal  $m(n-1)+1$ .  $m$  is the memory depth of the polynomial, and  $n$  is the degree of the memory polynomial.

For more information, see “Digital Predistortion” on page 4-524.

Data Types: double

Complex Number Support: Yes

### Usage

### Syntax

```
out = dpd(in)
```

### Description

`out = dpd(in)` predistorts a complex baseband signal by using a memory polynomial to compensate for nonlinearities in a power amplifier.

### Input Arguments

**in** — Input baseband signal

column vector

Input baseband signal, specified as a column vector.

Data Types: `double`

Complex Number Support: Yes

### Output Arguments

**out** — Predistorted baseband signal

column vector

Predistorted baseband signal, returned as a column vector of the same length as the input signal.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

## Examples

### Predistort Power Amplifier Input Signal

Apply digital predistortion (DPD) to a power amplifier input signal. The DPD coefficient estimator System object uses a captured signal containing power amplifier input and output signals to determine the predistortion coefficient matrix.

Load a file containing the input and output signals for the power amplifier.

```
load('commpowamp_dpd_data.mat','PA_input','PA_output')
```

Generate a DPD coefficient estimator System object and a raised cosine transmit filter System object.

```
estimator = comm.DPDCoefficientEstimator( ...
    'DesiredAmplitudeGaindB',10, ...
    'PolynomialType','Memory polynomial', ...
    'Degree',5,'MemoryDepth',3,'Algorithm','Least squares');

rctFilt = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',2);
```

Estimate the digital predistortion memory-polynomial coefficients.

```
coef = estimator(PA_input,PA_output);
```

Generate a DPD System object using `coef`, the estimated coefficients output from the DPD coefficient estimator, as for the coefficient matrix.

```
dpd = comm.DPD('PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate 2000 random symbols and apply 16-QAM modulation to the signal. Apply raised cosine transmit filtering to the modulated signal.

```
s = randi([0,15],2000,1);  
u = qammod(s,16);  
x = rctFilt(u);
```

Apply digital predistortion to the data. The DPD System object returns a predistorted signal to provide as input to the power amplifier.

```
y = dpd(x);
```

### Format of Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistortion System object configured using a memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the memory-polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the memory-polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to 1. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,5);  
coef(1,1) = 1;  
coef = coef + 0.01*(randn(3,5)+1j*randn(3,5));
```

Create a DPD System object using the memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD('PolynomialType','Memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);  
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```

u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u.*abs(u) u.*(abs(u).^2) u.*(abs(u).^3) u.*(abs(u).^4]
ans = logical
      1

```

### Format of Cross-Term Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistorter System object configured using a cross-term memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the cross-term memory polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the cross-term memory polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to 1. Add small random complex nonlinear terms to the coefficient matrix.

```

coef = zeros(3,3*(5-1)+1);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,13) + 1j*randn(3,13));

```

Create a DPD System object using the cross-term memory polynomial coefficient matrix, `coef`.

```

dpd = comm.DPD('PolynomialType','Cross-term memory polynomial','Coefficients',coef);

```

Generate an input signal and predistort it using the `dpd` System object.

```

x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);

```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));  
isequal(y(18),sum(sum(coef.*[u u*abs(u.' ) u*(abs(u.').^2) u*(abs(u.').^3) u*(abs(u.').^4  
ans = logical  
1
```

## More About

### Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.

The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is  $x(n)$ , and the predistortion function is  $f(u(n))$ , where  $u(n)$  is the true signal to be amplified, the PA output is approximately equal to  $G \times u(n)$ , where  $G$  is the desired amplitude gain of the PA.

The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} c_m \times u(n-m) + \sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{mjk} \times u(n-m) \times |u(n-j)|^k.$$

The memory polynomial with cross terms has  $(M+M \times M \times (K-1))$  coefficients for  $c_m$  and  $a_{mjk}$ .

- The memory polynomial without cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{mk} \times u(n-m) \times |u(n-m)|^k.$$

The polynomial without cross terms has  $M \times K$  coefficients for  $a_{mk}$ .

### Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function  $f(u(n))$  to predistort input signal  $u(n)$  which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain,  $\{y(n)/G\}$ , to the PA input,  $\{x(n)\}$ , provides a good approximation to the function  $f(u(n))$ , needed to predistort  $\{u(n)\}$  to produce  $\{x(n)\}$ .

Referring to the memory polynomial equations above, estimates are computed for the memory-polynomial coefficients:

- $c_m$  and  $a_{mjk}$  for a memory polynomial with cross terms
- $a_{mk}$  for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing  $\{u(n)\}$  with  $\{y(n)/G\}$ . The function order and

dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see “Power Amplifier Characterization with DPD for Reduced Signal Distortion”.

For background reference material, see the works listed in [1] and [2].

Estimate memory-polynomial coefficients for digital predistortion

## Description

The `comm.DPDCoefficientEstimator` System object estimates the coefficients of a memory polynomial for digital pre-distortion (DPD) of a nonlinear power amplifier, given the baseband equivalent input and baseband equivalent output of the power amplifier. For more information, see “Digital Predistortion” on page 4-537.

To compute predistortion coefficients:

- 1 Create the `comm.DPDCoefficientEstimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
estimator = comm.DPDCoefficientEstimator  
estimator = comm.DPDCoefficientEstimator(Name,Value)
```

## Description

`estimator = comm.DPDCoefficientEstimator` creates a digital predistortion coefficient estimator System object to estimate the coefficients of a memory polynomial for digital predistortion (DPD) of a nonlinear power amplifier.

`estimator = comm.DPDCoefficientEstimator(Name,Value)` sets properties using one or more name-value pairs. For example,

`comm.DPDCoefficientEstimator('PolynomialType','Cross-term memory polynomial')` configures the predistortion coefficient estimator System object to estimate the coefficients for a memory-polynomial with cross terms. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects* (MATLAB).

### **DesiredAmplitudeGaindB** — Desired amplitude gain

10 (default) | scalar

Desired amplitude gain in dB, specified as a scalar. This property value expresses the desired signal gain at the compensated amplifier output.

**Tunable:** Yes

Data Types: double

### **PolynomialType** — Polynomial type

'Memory polynomial' (default) | 'Cross-term memory polynomial'

Polynomial type used for predistortion, specified as one of these values:

- 'Memory polynomial' — Computes predistortion coefficients by using a memory polynomial without cross terms
- 'Cross-term memory polynomial' — Computes predistortion coefficients by using a memory polynomial with cross terms

For more information, see “Digital Predistortion” on page 4-537.

### **Degree** — Memory-polynomial degree

5 (default) | positive integer

Memory-polynomial degree, specified as a positive integer.

Data Types: double

### **MemoryDepth — Memory-polynomial depth**

3 (default) | positive integer

Memory-polynomial depth in samples, specified as a positive integer.

Data Types: double

### **Algorithm — Estimation algorithm**

'Least squares' (default) | 'Recursive least squares'

Adaptive algorithm used for equalization, specified as one of these values:

- 'Least squares' — Estimate the memory polynomial coefficients by using a least squares algorithm
- 'Recursive least squares' — Estimate the memory polynomial coefficients by using a recursive least squares algorithm

For algorithm reference material, see the works listed in [1] and [2].

Data Types: char | string

### **ForgettingFactor — Forgetting factor**

0.99 (default) | scalar in the range (0, 1]

Forgetting factor used by the recursive least squares algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the convergence time but causes the output estimates to be less stable.

**Tunable:** Yes

### **Dependencies**

To enable this property, set Algorithm to 'Recursive least squares'.

Data Types: double

### **InitialCoefficientEstimate — Initial coefficient estimate**

[] (default) | matrix

Initial coefficient estimate for the recursive least squares algorithm, specified as a matrix.

- If `InitialCoefficientEstimate` is an empty matrix, the initial coefficient estimate for the recursive least squares algorithm is chosen automatically to correspond to a memory polynomial that is an identity function, so that the output is equal to input.
- If `InitialCoefficientEstimate` is a nonempty matrix, the number of rows must be equal to `MemoryDepth`.
  - If `PolynomialType` is 'Memory polynomial', the number of columns is the degree of the memory polynomial.
  - If `PolynomialType` is 'Cross-term memory polynomial', the number of columns must equal  $m(n-1)+1$ .  $m$  is the memory depth of the polynomial, and  $n$  is the degree of the memory polynomial.

For more information, see “Digital Predistortion” on page 4-537.

### Dependencies

To enable this property, set `Algorithm` to 'Recursive least squares'.

Data Types: `double`

Complex Number Support: Yes

## Usage

## Syntax

```
coef = estimator(paIn,paOut)
```

## Description

`coef = estimator(paIn,paOut)` estimates the coefficients of a memory polynomial for use by the `comm.DPD` System object to predistort a complex baseband signal by using a memory-polynomial to compensate for nonlinearities in a power amplifier.

## Input Arguments

**paIn — Power amplifier baseband equivalent input**

column vector

Power amplifier baseband equivalent input, specified as a column vector.

Data Types: `double`

Complex Number Support: Yes

### **paOut — Power amplifier baseband equivalent output**

column vector

Power amplifier baseband equivalent output, specified as a column vector of the same length as `paIn`.

Data Types: `double`

Complex Number Support: Yes

## **Output Arguments**

### **coef — Memory-polynomial coefficients**

matrix

Memory-polynomial coefficients, returned as a matrix. For more information, see “Digital Predistortion” on page 4-537.

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Common to All System Objects**

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## **Examples**

### **Predistort Power Amplifier Input Signal**

Apply digital predistortion (DPD) to a power amplifier input signal. The DPD coefficient estimator System object uses a captured signal containing power amplifier input and output signals to determine the predistortion coefficient matrix.

Load a file containing the input and output signals for the power amplifier.

```
load('commpowamp_dpd_data.mat','PA_input','PA_output')
```

Generate a DPD coefficient estimator System object and a raised cosine transmit filter System object.

```
estimator = comm.DPDCoefficientEstimator( ...  
    'DesiredAmplitudeGaindB',10, ...  
    'PolynomialType','Memory polynomial', ...  
    'Degree',5,'MemoryDepth',3,'Algorithm','Least squares');  
  
rctFilt = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',2);
```

Estimate the digital predistortion memory-polynomial coefficients.

```
coef = estimator(PA_input,PA_output);
```

Generate a DPD System object using `coef`, the estimated coefficients output from the DPD coefficient estimator, as for the coefficient matrix.

```
dpd = comm.DPD('PolynomialType','Memory polynomial', ...  
    'Coefficients',coef);
```

Generate 2000 random symbols and apply 16-QAM modulation to the signal. Apply raised cosine transmit filtering to the modulated signal.

```
s = randi([0,15],2000,1);  
u = qammod(s,16);  
x = rctFilt(u);
```

Apply digital predistortion to the data. The DPD System object returns a predistorted signal to provide as input to the power amplifier.

```
y = dpd(x);
```

## Format of Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistortion System object configured using a memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the memory-polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the memory-polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to 1. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,5);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,5)+1j*randn(3,5));
```

Create a DPD System object using the memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD('PolynomialType','Memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u.*abs(u) u.*(abs(u).^2) u.*(abs(u).^3) u.*(abs(u).^4)])));
ans = logical
     1
```

### Format of Cross-Term Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistorter System object configured using a cross-term memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the cross-term memory polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the cross-term memory polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to 1. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,3*(5-1)+1);  
coef(1,1) = 1;  
coef = coef + 0.01*(randn(3,13) + 1j*randn(3,13));
```

Create a DPD System object using the cross-term memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD('PolynomialType','Cross-term memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);  
y = dpd(x);
```

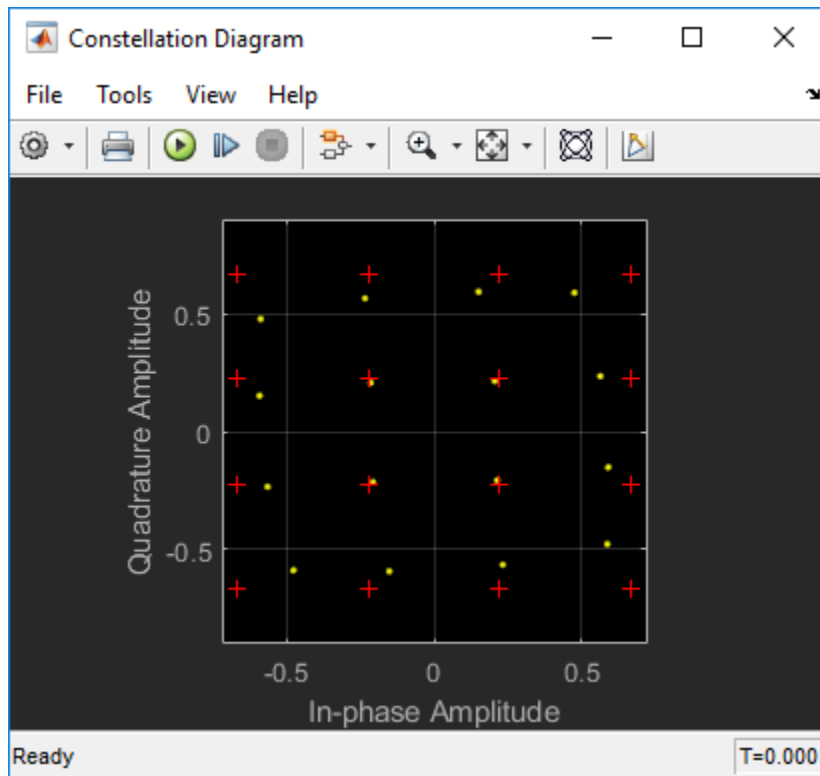

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));  
isequal(y(18),sum(sum(coef.*[u u*abs(u.') u*(abs(u.').^2 u*(abs(u.').^3 u*(abs(u.').^4  
ans = logical  
1
```

## More About

### Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.

The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When

the PA input is  $x(n)$ , and the predistortion function is  $f(u(n))$ , where  $u(n)$  is the true signal to be amplified, the PA output is approximately equal to  $G \times u(n)$ , where  $G$  is the desired amplitude gain of the PA.

The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} c_m \times u(n-m) + \sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{mjk} \times u(n-m) \times |u(n-j)|^k.$$

The memory polynomial with cross terms has  $(M+M \times M \times (K-1))$  coefficients for  $c_m$  and  $a_{mjk}$ .

- The memory polynomial without cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{mk} \times u(n-m) \times |u(n-m)|^k.$$

The polynomial without cross terms has  $M \times K$  coefficients for  $a_{mk}$ .

### Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function  $f(u(n))$  to predistort input signal  $u(n)$  which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain,  $\{y(n)/G\}$ , to the PA input,  $\{x(n)\}$ , provides a good approximation to the function  $f(u(n))$ , needed to predistort  $\{u(n)\}$  to produce  $\{x(n)\}$ .

Referring to the memory polynomial equations above, estimates are computed for the memory-polynomial coefficients:

- $c_m$  and  $a_{mjk}$  for a memory polynomial with cross terms
- $a_{mk}$  for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing  $\{u(n)\}$  with  $\{y(n)/G\}$ . The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see "Power Amplifier Characterization with DPD for Reduced Signal Distortion".

For background reference material, see the works listed in [1] and [2].

**Package:** comm

Demodulate using M-ary DPSK method

## Description

The `DPSKDemodulator` object demodulates a signal that was modulated using the M-ary differential phase shift keying method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. This object accepts a scalar-valued or column vector input signal.

To demodulate a signal that was modulated using differential phase shift keying:

- 1 Define and set up your DPSK modulator object. See “Construction” on page 4-541.
- 2 Call `step` to demodulate a signal according to the properties of `DPSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.DPSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the M-ary differential phase shift keying (M-DPSK) method.

`H = comm.DPSKDemodulator(Name,Value)` creates an M-DPSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.DPSKDemodulator(M,PHASE,Name,Value)` creates an M-DPSK demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, the

PhaseRotation property set to PHASE, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8.

### PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is  $\pi/8$ . This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`. When you set this property to `true` the `step` method outputs a column vector of bit values. The length of this column vector is equal to  $\log_2(\text{ModulationOrder})$  times the number of demodulated symbols.

When you set this property to `false`, the `step` method outputs a column vector. The length of this column vector is equal to that of the input data vector. The output contains integer symbol values between 0 and `ModulationOrder-1`.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder})$  bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer  $m$ , between  $(0 \leq m \leq$

ModulationOrder-1) maps to the current symbol. This mapping uses  $\exp(j \times \text{PhaseRotation} + j \times 2 \times \pi \times m / \text{ModulationOrder}) \times (\text{previously modulated symbol})$ .

### OutputDataType

Data type of output

Specify the output data type as one of Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32. The default is Full precision. When you set this property to Full precision, the input data type is single or double precision, the output data is the same as that of the input. When you set the BitOutput on page 4-0 property to true, logical data type becomes a valid option.

## Methods

reset      Reset states of M-DPSK demodulator object  
step        Demodulate using M-ary DPSK method

Common to All System Objects	
release	Allow System object property value changes

## Examples

### 8-DPSK Signal in AWGN

Create a DPSK modulator and demodulator pair. Create an AWGN channel object having three bits per symbol.

```
dpskmod = comm.DPSKModulator(8,pi/8,'BitInput',true);
dpskdemod = comm.DPSKDemodulator(8,pi/8,'BitOutput',true);
channel = comm.AWGNChannel('EbNo',10,'BitsPerSymbol',3);
```

Create an error rate calculator. Set the ComputationDelay property to 1 to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 3-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],150,1);
    modSig = dpskmod(txData);
    rxSig = channel(modSig);
    rxData = dpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0098
```

```
numErrors = errorStats(2)
```

```
numErrors = 147
```

```
numBits = errorStats(3)
```

```
numBits = 14999
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-DPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### See Also

`comm.DBPSKDemodulator` | `comm.DPSKModulator` | `comm.DQPSKDemodulator`

**Introduced in R2012a**

## **reset**

**System object:** comm.DPSKDemodulator

**Package:** comm

Reset states of M-DPSK demodulator object

## **Syntax**

reset(H)

## **Description**

reset(H) resets the states of the DPSKDemodulator object, H.

---

## step

**System object:** comm.DPSKDemodulator

**Package:** comm

Demodulate using M-ary DPSK method

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  demodulates input data,  $X$ , with the DPSK demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a double or single precision data type scalar or column vector. Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.DPSKModulator

**Package:** comm

Modulate using M-ary DPSK method

### Description

The `DPSKModulator` object modulates using the M-ary differential phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential phase shift keying:

- 1 Define and set up your DPSK modulator object. See “Construction” on page 4-548.
- 2 Call `step` to modulate a signal according to the properties of `comm.DPSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.DPSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the M-ary differential phase shift keying (M-DPSK) method.

`H = comm.DPSKModulator(Name, Value)` creates an M-DPSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.DPSKModulator(M, PHASE, Name, Value)` creates an M-DPSK modulator object, `H`. This object has the `ModulationOrder` property set to `M`, the `PhaseRotation` property set to `PHASE`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8.

### PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is  $\pi/8$ . This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

### BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `true`, the `step` method input must be a column vector of bit values whose length is an integer multiple of  $\log_2(\text{ModulationOrder on page 4-0})$ . This vector contains bit representations of integers between 0 and  $\text{ModulationOrder}-1$ . When you set this property to `false`, the `step` method input requires a column vector of integer symbol values between 0 and  $\text{ModulationOrder}-1$ .

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder on page 4-0})$  input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer  $m$ , between  $(0 \leq m \leq \text{ModulationOrder}-1)$  shifts the output phase. This shift is  $(\text{PhaseRotation on page 4-0} + 2 \times \pi \times m / \text{ModulationOrder})$  radians from the previous output phase. The output symbol uses  $\exp(j \times \text{PhaseRotation} + j \times 2 \times \pi \times m / \text{ModulationOrder}) \times$  (previously modulated symbol).

### OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

## Methods

`reset`      Reset states of M-DPSK modulator object  
`step`        Modulate using M-ary DPSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### 8-DPSK Signal in AWGN

Create a DPSK modulator and demodulator pair. Create an AWGN channel object having three bits per symbol.

```
dpskmod = comm.DPSKModulator(8,pi/8,'BitInput',true);  
dpskdemod = comm.DPSKDemodulator(8,pi/8,'BitOutput',true);  
channel = comm.AWGNChannel('EbNo',10,'BitsPerSymbol',3);
```

Create an error rate calculator. Set the `ComputationDelay` property to 1 to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 3-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate

- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],150,1);
    modSig = dpskmod(txData);
    rxSig = channel(modSig);
    rxData = dpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
ber = 0.0098
numErrors = errorStats(2)
numErrors = 147
numBits = errorStats(3)
numBits = 14999
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-DPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Package:** comm

Reset states of M-DPSK modulator object

## Syntax

reset(H)

## Description

reset(H) resets the states of the DPSKModulator object, H.

# step

**System object:** `comm.DPSKModulator`

**Package:** `comm`

Modulate using M-ary DPSK method

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  modulates input data,  $X$ , with the DPSK modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be an integer or bit valued column vector with numeric or logical data types.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.DQPSKDemodulator

**Package:** comm

Demodulate using DQPSK method

## Description

The `DQPSKDemodulator` object demodulates a signal that was modulated using the differential quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using differential quadrature phase shift keying:

- 1 Define and set up your DQPSK modulator object. See “Construction” on page 4-555.
- 2 Call `step` to demodulate a signal according to the properties of `DQPSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.DQPSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the differential quadrature phase shift keying (DQPSK) method.

`H = comm.DQPSKDemodulator(Name,Value)` creates a DQPSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.DQPSKDemodulator(PHASE, Name, Value)` creates a DQPSK demodulator object, `H`. This object has the `PhaseRotation` property set to `PHASE` and the other specified properties set to the specified values.

## Properties

### PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar. The default is  $\pi/4$ . This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`. When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to twice the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector, of length equal to the input data vector, that contains integer symbol values between 0 and 3.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of 2 bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer  $m$ , between  $0 \leq m \leq 3$  maps to the current symbol as  $\exp(j \times \text{PhaseRotation} \times (2^m - 1))$  on page 4-0.

### OutputDataType

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The

default is `Full precision`. When you set this property to `Full precision` the output has the same data type as that of the input. In this case, the input data type is single- or double-precision value. When you set the `BitOutput` on page 4-0 property to `true`, logical data type becomes a valid option.

## Methods

`reset`      Reset states of DQPSK demodulator object  
`step`        Demodulate using DQPSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### DQPSK Signal in AWGN

Create a DQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
dqpskmod = comm.DQPSKModulator('BitInput',true);
dqpskdemod = comm.DQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',6,'BitsPerSymbol',2);
```

Create an error rate calculator. Set the `ComputationDelay` property to 1 to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 2-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate

- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],100,1);
    modSig = dqpskmod(txData);
    rxSig = channel(modSig);
    rxData = dqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
ber = 0.0170
numErrors = errorStats(2)
numErrors = 170
numBits = errorStats(3)
numBits = 9999
```

## Algorithms

## comm.DQPSKModulator

**Package:** comm

Modulate using DQPSK method

### Description

The `DQPSKModulator` object modulates using the differential quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential quadrature phase shift keying:

- 1 Define and set up your DQPSK modulator object. See “Construction” on page 4-562.
- 2 Call `step` to modulate a signal according to the properties of `comm.DQPSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.DQPSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the differential quadrature phase shift keying (DQPSK) method.

`H = comm.DQPSKModulator(Name,Value)` creates a DQPSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.DQPSKModulator(PHASE,Name,Value)` creates a DQPSK modulator object, `H`. This object has the `PhaseRotation` property set to `PHASE` and the other specified properties set to the specified values.

## Properties

### PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is  $\pi/4$ . This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

### BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `true`, the `step` method input must be a column vector of bit values. The length of this vector is an integer multiple of two. This vector contains bit representations of integers between 0 and 3. When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between 0 and 3.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of two input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer  $m$ , between  $0 \leq m \leq 3$  shifts the output phase. This shift is  $(\text{PhaseRotation on page 4-0} + 2 \times \pi \times m/4)$  radians from the previous output phase. The output symbol is  $\exp(j \times \text{PhaseRotation} + j \times 2 \times \pi \times m/4) \times (\text{previously modulated symbol})$ .

### OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

## Methods

reset      Reset states of DQPSK modulator object  
step        Modulate using DQPSK method

Common to All System Objects	
release	Allow System object property value changes

## Examples

### DQPSK Signal in AWGN

Create a DQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
dqpskmod = comm.DQPSKModulator('BitInput',true);  
dqpskdemod = comm.DQPSKDemodulator('BitOutput',true);  
channel = comm.AWGNChannel('EbNo',6,'BitsPerSymbol',2);
```

Create an error rate calculator. Set the `ComputationDelay` property to 1 to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 2-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100  
    txData = randi([0 1],100,1);  
    modSig = dqpskmod(txData);  
    rxSig = channel(modSig);  
    rxData = dqpskdemod(rxSig);
```

```
        errorStats = errorRate(txData,rxData);  
end
```

Display the error statistics.

```
ber = errorStats(1)  
ber = 0.0170  
numErrors = errorStats(2)  
numErrors = 170  
numBits = errorStats(3)  
numBits = 9999
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the DQPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.ErrorRate

**Package:** comm

Compute bit or symbol error rate of input data

## Description

The `ErrorRate` object compares input data from a transmitter with input data from a receiver and calculates the error rate as a running statistic. To obtain the error rate, the object divides the total number of unequal pairs of data elements by the total number of input data elements from one source.

To obtain the error rate:

- 1 Define and set up your error rate object. See “Construction” on page 4-569.
- 2 Call `step` to compare input data from a transmitter with input data from a receiver and calculate the error rate according to the properties of `comm.ErrorRate`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the `System` object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.ErrorRate` creates an error rate calculator `System` object, `H`. This object computes the error rate of the received data by comparing it to the transmitted data.

`H = comm.ErrorRate(Name, Value)` creates an error rate calculator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### ReceiveDelay

Number of samples to delay transmitted signal

Specify the number of samples by which the received data lags behind the transmitted data. This value must be a real, nonnegative, double-precision, integer scalar. Use this property to align the samples for comparison in the transmitted and received input data vectors. Specify the delay in number of samples, regardless of whether the input is a scalar or a vector. The default is 0.

### ComputationDelay

Computation delay

Specify the number of data samples that the object should ignore at the beginning of the comparison. This value must be a real, nonnegative, double-precision, integer scalar. Use this property to ignore the transient behavior of both input signals. The default is 0.

### Samples

Samples to consider

Specify samples to consider as one of `Entire frame` | `Custom` | `Input port`. The property defines whether the object should consider all or only part of the input frames when computing error statistics. The default is `Entire frame`. Select `Entire frame` to compare all the samples of the RX frame to those of the TX frame. Select `Custom` or `Input port` to list the indices of the RX frame elements that the object should consider when making comparisons. When you set this property to `Custom`, you can list the indices as a scalar or a column vector of double-precision integers through the `CustomSamples` on page 4-0 property. When you set this property to `Input port`, you can list the indices as an input to the `step` method.

### CustomSamples

Selected samples from frame

Specify a scalar or a column vector of double-precision, real, positive integers. This value lists the indices of the elements of the RX frame vector that the object uses when making comparisons. This property applies when you set the `Samples` on page 4-0 property to `Custom`. The default is an empty vector, which specifies that all samples are used.

## ResetInputPort

Enable error rate reset input

Set this property to `true` to reset the error statistics via an input to the `step` method. The default is `false`.

## Methods

`reset`     Reset states of error rate calculator object  
`step`     Compute bit or symbol error rate of input data

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

### Calculate Error Statistics

Create two binary vectors and determine the error statistics.

Create a bit error rate counter object.

```
errorRate = comm.ErrorRate;
```

Create an arbitrary binary data vector.

```
x = [1 0 1 0 1 0 1 0 1 0]';
```

Introduce errors to the first and last bits.

```
y = x;
y(1) = ~y(1);
y(end) = ~y(end);
```

Calculate the error statistics.

```
z = errorRate(x,y);
```

The first element of the vector `z` is the bit error rate.

```
z(1)
ans = 0.2000
```

The second element of `z` is the total error count.

```
z(2)
ans = 2
```

The third element of `z` is the total number of bits.

```
z(3)
ans = 10
```

### Calculate BER between Transmitted and Received Signal

Create an 8-DPSK modulator and demodulator pair that work with binary data.

```
dpskModulator = comm.DPSKModulator('ModulationOrder',8,'BitInput',true);
dpskDemodulator = comm.DPSKDemodulator('ModulationOrder',8,'BitOutput',true);
```

Create an error rate calculator, accounting for the three bit (one symbol) transient caused by the differential modulation.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Calculate the BER for 10 frames.

```
BER = zeros(10,1);

for i= 1:10
    txData = randi([0 1],96,1);           % Generate binary data
    modData = dpskModulator(txData);     % Modulate
    rxSig = awgn(modData,7);             % Pass through AWGN channel
    rxData = dpskDemodulator(rxSig);     % Demodulate
    errors = errorRate(txData,rxData);   % Compute error statistics
    BER(i) = errors(1);                  % Save BER data
end
```

Display the BER.

BER

BER = 10×1

```
0.1613
0.1640
0.1614
0.1496
0.1488
0.1309
0.1405
0.1399
0.1370
0.1411
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Error Rate Calculation block reference page. The object properties correspond to the block parameters, except:

- The **Output data** and **Variable name** block parameters do not have a corresponding properties. The object always returns the result as an output.
- The **Stop simulation** block parameter does not have a corresponding property. To implement similar behavior, use the output of the `step` method in a while loop, to programmatically stop the simulation. See the Gray Coded 8-PSK.
- The **Computation mode** parameter corresponds to the `Samples` on page 4-0 and `CustomSamples` on page 4-0 properties.

## Extended Capabilities

## reset

**System object:** comm.ErrorRate

**Package:** comm

Reset states of error rate calculator object

## Syntax

reset(H)

## Description

reset(H) resets the states of the ErrorRate object, H.

# step

**System object:** `comm.ErrorRate`

**Package:** `comm`

Compute bit or symbol error rate of input data

## Syntax

`Y = step(H, TX, RX)`

`Y = step(H, TX, RX, SEL)`

`Y = step(H, TX, RX, RST)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H, TX, RX)` counts the number of differences between the transmitted data vector, `TX`, and received data vector, `RX`. The `step` method outputs a three-element vector consisting of the error rate, followed by the number of errors detected and the total number of samples compared. `TX` and `RX` inputs can be either scalars or column vectors of the same data type. Valid data types are `single`, `double`, `integer` or `logical`. If `TX` is a scalar and `RX` is a vector, or vice-versa, then the block compares the scalar with each element of the vector.

`Y = step(H, TX, RX, SEL)` calculates the errors based on selected samples from the input frame specified by the `SEL` input. `SEL` must be a real, double-precision integer-valued scalar or a column vector. The vector lists the indices of the elements of the `RX` input vector that the object should consider when making comparisons. This syntax applies when you set the `Samples` property to 'Input Port'.

`Y = step(H, TX, RX, RST)` resets the error count whenever the input `RST` is non-zero. `RST` must be a real, double, or logical scalar. When you set the `RST` input to a nonzero

value, the object clears its error statistics and then recomputes them based on the current TX and RX inputs. This syntax applies when you set the `ResetInputPort` property to true. You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as the order of the enabling properties.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## **comm.LinearEqualizer**

**Package:** comm

Equalize modulated signals using linear filtering

### **Description**

The `comm.LinearEqualizer` System object uses a linear filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. The equalizer object adaptively adjusts tap weights based on the selected algorithm. For more information, see “Algorithms” on page 4-621.

To equalize modulated signals using a linear filter:

- 1 Create the `comm.LinearEqualizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

### **Creation**

### **Syntax**

```
lineq = comm.LinearEqualizer  
lineq = comm.LinearEqualizer(Name,Value)
```

### **Description**

`lineq = comm.LinearEqualizer` creates a linear equalizer System object to adaptively equalize a signal.

`lineq = comm.LinearEqualizer(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.LinearEqualizer('Algorithm','RLS')`

configures the equalizer object to update tap weights using the recursive least squares (RLS) algorithm. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### Algorithm — Adaptive algorithm

'LMS' (default) | 'RLS' | 'CMA'

Adaptive algorithm used for equalization, specified as one of these values:

- 'LMS' — Update the equalizer tap weights using the “Least Mean Square (LMS) Algorithm” on page 4-622.
- 'RLS' — Update the equalizer tap weights using the “Recursive Least Square (RLS) Algorithm” on page 4-623.
- 'CMA' — Update the equalizer tap weights using the “Constant Modulus Algorithm (CMA)” on page 4-623.

Data Types: `char` | `string`

### NumTaps — Number of equalizer taps

5 (default) | positive integer

Number of equalizer taps, specified as a positive integer.

Data Types: `double`

### StepSize — Step size

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

---

**Tip** To determine the maximum step size allowed, use the `maxstep` object function.

---

**Tunable:** Yes

**Dependencies**

To enable this property, set `Algorithm` to 'LMS' or 'CMA'.

Data Types: double

**ForgettingFactor — Forgetting factor**

0.99 (default) | scalar in the range (0, 1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

**Tunable:** Yes

**Dependencies**

To enable this property, set `Algorithm` to 'RLS'.

Data Types: double

**InitialInverseCorrelationMatrix — Initial inverse correlation matrix**

0.1 (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an  $N_{\text{Taps}}$ -by- $N_{\text{Taps}}$  matrix.  $N_{\text{Taps}}$  is equal to the `NumTaps` property value. If you specify `InitialInverseCorrelationMatrix` as a scalar,  $a$ , the equalizer sets the initial inverse correlation matrix to  $a$  times the identity matrix:  $a(\text{eye}(N_{\text{Taps}}))$ .

**Tunable:** Yes

**Dependencies**

To enable this property, set `Algorithm` to 'RLS'.

Data Types: double

**Constellation — Signal constellation**

`pskmod(0:3,4,pi/4)` (default) | vector

Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: `pskmod(0:3,4,pi/4)`.

**Tunable:** Yes

Data Types: double

### **ReferenceTap — Reference tap**

3 (default) | positive integer

Reference tap, specified as a positive integer less than or equal to the NumTaps property value. The equalizer uses the reference tap location to track the main energy of the channel.

Data Types: double

### **InputDelay — Input signal delay**

0 (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the System object and to the first call of the System object after calling the release or reset object function.

Data Types: double

### **InputSamplesPerSymbol — Number of input samples per symbol**

1 (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this property to any number greater than one effectively creates a fractionally spaced equalizer. For more information, see “Symbol Tap Spacing” on page 4-620.

Data Types: double

### **TrainingFlagInputPort — Enable training control input**

false (default) | true

Enable training control input, specified as false or true. Setting this property to true enables the equalizer training flag input tf.

**Tunable:** Yes

Data Types: logical

### **AdaptAfterTraining — Update tap weights when not training**

true (default) | false

Update tap weights when not training, specified as `true` or `false`. If this property is set to `true`, the System object uses decision directed mode to update equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged after training.

**Tunable:** Yes

Data Types: logical

### **AdaptWeightsSource — Source of adapt tap weights request**

'Property' (default) | 'Input port'

Source of adapt tap weights request, specified as one of these values:

- 'Property' — Specify this value to use the AdaptWeights property to control when the System object adapts tap weights.
- 'Input port' — Specify this value to use the aw input to control when the System object adapts tap weights.

### **Dependencies**

To enable this property, set Algorithm to 'CMA'.

Data Types: char | string

### **AdaptWeights — Adapt tap weights**

true (default) | false

Adapt tap weights, specified as `true` or `false`. If this property is set to `true`, the System object updates the equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged.

**Tunable:** Yes

### **Dependencies**

To enable this property, set AdaptWeightsSource to 'Property' and set AdaptAfterTraining to `true`.

Data Types: logical

**InitialWeightsSource — Source for initial tap weights**

'Auto' (default) | 'Property'

Source for initial tap weights, specified as

- 'Auto' — Initialize the tap weights to the algorithm-specific default values, as described in the InitialWeights property.
- 'Property' — Initialize the tap weights using the InitialWeights property value.

Data Types: char | string

**InitialWeights — Initial tap weights**

0 or [0;0;1;0;0] (default) | scalar | column vector

Initial tap weights used by the adaptive algorithm, specified as a scalar or vector. The default is 0 when the Algorithm property is set to 'LMS' or 'RLS'. The default is [0;0;1;0;0] when the Algorithm property is set to 'CMA'.

If you specify InitialWeights as a vector, the vector length must be equal to the NumTaps property value. If you specify InitialWeights as a scalar, the equalizer uses scalar expansion to create a vector of length NumTaps with all values set to InitialWeights.

**Tunable:** Yes**Dependencies**

To enable this property, set InitialWeightsSource to 'Property'.

Data Types: double

**WeightUpdatePeriod — Tap weight update period**

1 (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

Data Types: double

## Usage

## Syntax

```
y = lineq(x,tsym)
y = lineq(x,tsym,tf)
```

```
y = lineq(x)
y = lineq(x,aw)
```

## Description

`y = lineq(x,tsym)` equalizes input signal `x` by using training symbols `tsym`. The output is the equalized symbols. To enable this syntax, set the Algorithm property to 'LMS' or 'RLS'.

`y = lineq(x,tsym,tf)` also specifies training flag `tf`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`. To enable this syntax, set the Algorithm property to 'LMS' or 'RLS' and TrainingFlagInputPort property to `true`.

`y = lineq(x)` equalizes input signal `x`. To enable this syntax, set the Algorithm property to 'CMA'.

`y = lineq(x,aw)` also specifies adapts weights flag `aw`. The System object adapts the equalizer tap weights when `aw` is `true`. If `aw` is `false`, the System object keeps the weights unchanged. To enable this syntax, set the Algorithm property to 'CMA' and AdaptWeightsSource property to 'Input port'.

`[y,err] = lineq( ___ )` also returns error signal `err` using input arguments from any of the previous syntaxes.

`[y,err,weights] = lineq( ___ )` also returns `weights`, the tap weights from the last tap weight update, using input arguments from any of the previous syntaxes.

## Input Arguments

### **x** — Input signal

column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the `InputSamplesPerSymbol` property value. For more information, see “Symbol Tap Spacing” on page 4-620.

Data Types: `double`

Complex Number Support: Yes

### **tsym** — Training symbols

column vector

Training symbols, specified as a column vector of length less than or equal to the length of input `x`. The input `tsym` is ignored when `tf` is `false`.

### Dependencies

To enable this argument, set the `Algorithm` property to `'LMS'` or `'RLS'`.

Data Types: `double`

Complex Number Support: Yes

### **tf** — Training flag

`true` | `false`

Training flag, specified as `true` or `false`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`.

### Dependencies

To enable this argument, set the `Algorithm` property to `'LMS'` or `'RLS'` and `TrainingFlagInputPort` property to `true`.

Data Types: `logical`

### **aw** — Adapt weights flag

`true` | `false`

Adapt weights flag, specified as `true` or `false`. If `aw` is `true`, the System object adapts weights. If `aw` is `false`, the System object keeps the weights unchanged.

### Dependencies

To enable this argument, set the Algorithm property to 'CMA' and AdaptWeightsSource property to 'Input port'.

Data Types: `logical`

### Output Arguments

#### **y** — Equalized symbols

column vector

Equalized symbols, returned as a column vector that has the same length as input signal `x`.

#### **err** — Error signal

column vector

Error signal, returned as a column vector that has the same length as input signal `x`.

#### **weights** — Tap weights

column vector

Tap weights, returned as a column vector that has NumTaps elements. `weights` contains the tap weights from the last tap weight update.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `comm.LinearEqualizer`

<code>isLocked</code>	Determine if System object is in use
<code>clone</code>	Create duplicate System object
<code>info</code>	Characteristic information about the equalizer object
<code>maxstep</code>	Maximum step size for LMS equalizer convergence
<code>mmseweights</code>	Linear equalizer MMSE tap weights

## Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

## Examples

### Linearly Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a linear LMS equalizer having eight taps and a step size of 0.03.

```
bpsk = comm.BPSKModulator;
eqlms = comm.LinearEqualizer('Algorithm','LMS','NumTaps',8,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqlms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqlms,rxsig)
```

```
mxStep = 0.1384
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqlms(rxsig,x(1:200));
```

### Linearly Equalize QPSK-Modulated Signal

Apply linear equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through a multipath AWGN channel.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
```

Generate QPSK-modulated symbols. Apply multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object and display the default configuration. Adjust the reference tap to 1. Check the maximum permitted step size. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer
eq =
    comm.LinearEqualizer with properties:
        Algorithm: 'LMS'
        NumTaps: 5
        StepSize: 0.0100
        Constellation: [1x4 double]
        ReferenceTap: 3
        InputDelay: 0
        InputSamplesPerSymbol: 1
        TrainingFlagInputPort: false
        AdaptAfterTraining: true
        InitialWeightsSource: 'Auto'
        WeightUpdatePeriod: 1
```

```
eq.ReferenceTap = 1;
```

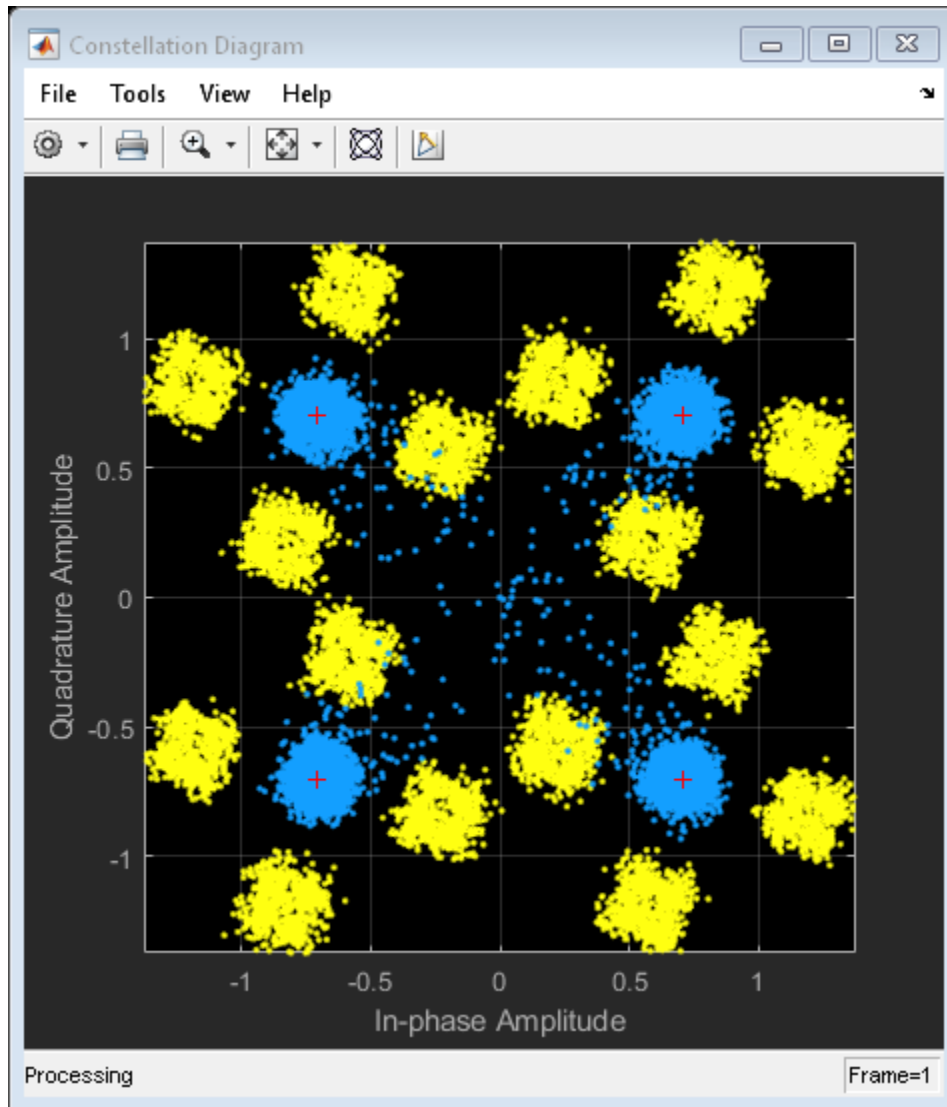

```
mxStep = maxstep(eq,rx)
```

```
mxStep = 0.3154
```

```
[y,err,weights] = eq(rx,tx(1:numTrainingSymbols));
```

Plot the constellation of the impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);  
constell(rx,y)
```

Plot the equalizer error signal and compute the error vector magnitude (EVM) of the equalized symbols.

```
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|');title('Equalizer Error Signal')
```

```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 11.7710
```

Plot the equalizer tap weights.

```
subplot(3,1,1);
stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1]);
title('Equalizer Tap Weights')
subplot(3,1,2);
stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1]);
```

```
subplot(3,1,3);  
stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1])
```

### Linearly Equalize System By Using Different Training Schemes

Demonstrate linear equalization by using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Apply different equalizer training schemes and show the symbol error magnitude.

## System Setup

Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a linear LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
lineq = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',5,'ReferenceTap',3,'StepSize',0.01);
```

## Train the Equalizer at the Beginning of Each Packet With Reset

Use prepended training symbols when processing each packet. After processing each packet, reset the equalizer. This reset forces the equalizer to train the taps with no previous knowledge. Equalizer error signal plots for the first, second, and last packet show higher symbol errors at the start of each packet.

```
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    rx = awgn(packet,SNR);
    [~,err] = lineq(rx,trainingSymbols);
    reset(lineq)
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols')
        ylabel('Error Magnitude')
        axis([0,length(packet),0,1])
        grid on;
        jj = jj+1;
    end
end
```

### Train the Equalizer at the Beginning of Each Packet Without Reset

Process each packet using prepended training symbols. Do not reset the equalizer after each packet is processed. By not resetting after each packet, the equalizer retains tap weights from training prior packets. Equalizer error signal plots for the first, second, and last packet show that after the initial training on the first packet, subsequent packets have less symbol errors at the start of each packet.

```
release(lineq)
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
```

```
packet = [trainingSymbols;dataSym];
channel = 1;
rx = awgn(packet*channel,SNR);
[~,err] = lineq(rx,trainingSymbols);
if (ii ==1 || ii == 2 ||ii == numPkts)
    subplot(3,1,jj)
    plot(abs(err))
    title(['Packet # ',num2str(ii)])
    xlabel('Symbols')
    ylabel('Error Magnitude')
    axis([0,length(packet),0,1])
    grid on;
    jj = jj+1;
end
end
```

### Train the Equalizer Periodically

Systems with signals subject to time-varying channels require periodic equalizer training to maintain lock on the channel variations. Specify a system that has 200 symbols of training for every 1800 data symbols. Between training, the equalizer does not update tap weights. The equalizer processes 200 symbols per packet.

```
Rs = 1e6;
fd = 20;
spp = 200; % Symbols per packet
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols; dataSym];
stream = repmat(packet,10,1);
```

```
tx = (0:length(stream)-1)'/Rs;  
channel = exp(1i*2*pi*fd*tx);  
rx = awgn(stream.*channel,SNR);
```

Set the `AdaptAfterTraining` property to `false` to stop the equalizer tap weight updates after the training phase.

```
release(lineq)  
lineq.AdaptAfterTraining = false  
  
lineq =  
    comm.LinearEqualizer with properties:  
  
        Algorithm: 'LMS'  
        NumTaps: 5  
        StepSize: 0.0100  
        Constellation: [1x4 double]  
        ReferenceTap: 3  
        InputDelay: 0  
        InputSamplesPerSymbol: 1  
        TrainingFlagInputPort: false  
        AdaptAfterTraining: false  
        InitialWeightsSource: 'Auto'  
        WeightUpdatePeriod: 1
```

Equalize the impaired data. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output does not remove the channel effects. The output constellation rotates out of sync, resulting in bit errors.

```
[y,err] = lineq(rx,trainingSymbols);  
  
figure  
subplot(2,1,1)  
plot(tx, unwrap(angle(channel)))  
xlabel('Time (sec)')  
ylabel('Channel Angle (rad)')  
title('Angular Error Over Time')  
subplot(2,1,2)  
plot(abs(err))  
xlabel('Symbols')  
ylabel('Error Magnitude')  
grid on  
title('Time-Varying Channel Without Retraining')
```

```
scatterplot(y)
```

Set the `TrainingInputPort` property to `true` to configure the equalizer to retrain the taps when signaled by the `trainFlag` input. The equalizer trains only when `trainFlag` is `true`. After every 2000 symbols, the equalizer retrains the taps and keeps lock on variations of the channel. Plot the angular error from the channel, equalizer error signal, and signal constellation. As the channel varies, the equalizer output removes the channel effects. The output constellation does not rotate out of sync and bit errors are reduced.

```
release(lineq)
lineq.TrainingFlagInputPort = true;
symbolCnt = 0;
numPackets = length(rx)/spp;
trainFlag = true;
trainingPeriod = 2000;
eVec = zeros(size(rx));
```

```
yVec = zeros(size(rx));
for p=1:numPackets
    [yVec((p-1)*spp+1:p*spp,1),eVec((p-1)*spp+1:p*spp,1)] = ...
        lineq(rx((p-1)*spp+1:p*spp,1),trainingSymbols,trainFlag);
    symbolCnt = symbolCnt + spp;
    if symbolCnt >= trainingPeriod
        trainFlag = true;
        symbolCnt = 0;
    else
        trainFlag = false;
    end
end
figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('t (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(eVec))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel With Retraining')
```

scatterplot(yVec)

### Linearly Equalize Delayed Signal

Simulate a system with delay between the transmitted symbols and received samples. Typical systems have transmitter and receiver filters that result in a delay. This delay must be accounted for to synchronize the system. In this example, the system delay is introduced without transmit and receive filters. Linear equalization, using the least mean squares (LMS) algorithm, recovers QPSK symbols.

Initialize simulation variables.

```
M = 4; % QPSK  
numSymbols = 10000;
```

```
numTrainingSymbols = 1000;  
mpChan = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];  
systemDelay = dsp.Delay(20);  
snr = 24;
```

Generate QPSK-modulated symbols. Apply multipath channel filtering, a system delay, and AWGN to the transmitted symbols.

```
data = randi([0 M-1],numSymbols,1);  
tx = pskmod(data,M,pi/4); % QPSK  
delayedSym = systemDelay(filter(mpChan,1,tx));  
rx = awgn(delayedSym,snr,'measured');
```

Create equalizer and EVM System objects. The equalizer System object specifies a linear equalizer that uses the LMS algorithm.

```
lineq = comm.LinearEqualizer('Algorithm','LMS', ...  
    'NumTaps',9,'ReferenceTap',5);  
evm = comm.EVM('ReferenceSignalSource', ...  
    'Estimated from reference constellation');
```

### Equalize Without Adjusting Input Delay

Equalize the received symbols.

```
[y1,err1,wts1] = lineq(rx,tx(1:numTrainingSymbols,1));
```

Find the delay between the received symbols and the transmitted symbols by using the `finddelay` function.

```
rxDelay = finddelay(tx,rx)
```

```
rxDelay = 20
```

Display the equalizer information. The latency value indicates the delay introduced by the equalizer. Calculate the total delay as the sum of `rxDelay` and the equalizer latency.

```
eqInfo = info(lineq)
```

```
eqInfo = struct with fields:  
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
```

Until the equalizer output converges, the symbol error rate is high. Plot the error output, `err1`, to determine when the equalized output converges.

```
plot(abs(err1))  
xlabel('Symbols')  
ylabel('Error Magnitude')  
title('Equalizer Error Signal')
```

The plot shows excessive errors beyond the 1000 symbols training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 2000 symbols.

```
dataRec1 = pskdemod(y1(2000+totalDelay:end),M,pi/4);
symErrWithDelay = symerr(data(2000:end-totalDelay),dataRec1)

symErrWithDelay = 5999

evmWithDelay = evm(y1)

evmWithDelay = 29.5795
```

The error rate and EVM are high because the receive delay was not accounted for in the equalizer System object.

### Adjust Input Delay in Equalizer

Equalize the received data by using the delay value to set the `InputDelay` property. Because `InputDelay` is a nontunable property, you must release the `lineq` System object to reconfigure the `InputDelay` property. Equalize the received symbols.

```
release(lineq)
lineq.InputDelay = rxDelay

lineq =
  comm.LinearEqualizer with properties:
        Algorithm: 'LMS'
        NumTaps: 9
        StepSize: 0.0100
        Constellation: [1x4 double]
        ReferenceTap: 5
        InputDelay: 20
        InputSamplesPerSymbol: 1
        TrainingFlagInputPort: false
        AdaptAfterTraining: true
        InitialWeightsSource: 'Auto'
        WeightUpdatePeriod: 1
```

```
[y2,err2,wts2] = lineq(rx,tx(1:numTrainingSymbols,1));
```

Plot the tap weights and equalized error magnitude. A stem plot shows the equalizer tap weights before and after the system delay is removed. A 2-D line plot shows the slower equalizer convergence for the delayed signal as compared to the signal with the delay removed.

```
subplot(2,1,1)
stem([real(wts1),real(wts2)])
```

```

xlabel('Taps')
ylabel('Tap Weight Real')
legend('rxDelayed', 'rxDelayRemoved')
grid on
subplot(2,1,2)
stem([imag(wts1),imag(wts2)])
xlabel('Taps')
ylabel('Tap Weight Imaginary')
legend('rxDelayed', 'rxDelayRemoved')
grid on

```

```

figure
plot([abs(err1),abs(err2)])
xlabel('Symbols')

```

```
ylabel('Error Magnitude')  
legend('rxDelayed', 'rxDelayRemoved')  
grid on
```

Plot error output of the equalized signals, `rxDelayed` and `rxDelayRemoved`. For the signal that has the delay removed, the equalizer converges during the 1000 symbol training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 500 symbols. Reconfiguring the equalizer to account for the system delay enables better equalization of the signal, and reduces symbol errors and the EVM.

```
eqInfo = info(lineq)
```

```

eqInfo = struct with fields:
    Latency: 4

totalDelay = rxDelay + eqInfo.Latency;
dataRec2 = pskdemod(y2(500+totalDelay:end),M,pi/4);
symErrDelayRemoved = symerr(data(500:end-totalDelay),dataRec2)

symErrDelayRemoved = 0

evmDelayRemoved = evm(y2(500+totalDelay:end))

evmDelayRemoved = 9.4435

```

### Linearly Equalize Symbols By Using EVM-Based Training

Recover QPSK symbols with a linear equalizer by using the constant modulus algorithm (CMA) and EVM-based taps training. When using blind equalizer algorithms, such as CMA, train the equalizer taps by using the `AdaptWeights` property to start and stop training. Helper functions are used to generate plots and apply phase correction.

Initialize system variables.

```

rng(123456);
M = 4; % QPSK
numSymbols = 100;
numPackets = 5000;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -12], 'MaximumDopplerShift',1e-5);
SNR = 50;
adaptWeights = true;

```

Create the equalizer and EVM System objects. The equalizer System object specifies a linear equalizer by using the CMA adaptive algorithm. Call the helper function to initialize figure plots.

```

lineq = comm.LinearEqualizer('Algorithm','CMA', ...
    'NumTaps',5,'ReferenceTap',3, ...
    'StepSize',0.03,'AdaptWeightsSource','Input port')

lineq =
    comm.LinearEqualizer with properties:

```

```
        Algorithm: 'CMA'  
        NumTaps: 5  
        StepSize: 0.0300  
        Constellation: [1x4 double]  
        ReferenceTap: 3  
InputSamplesPerSymbol: 1  
    AdaptWeightsSource: 'Input port'  
    InitialWeightsSource: 'Auto'  
    WeightUpdatePeriod: 1
```

```
info(lineq)
```

```
ans = struct with fields:  
    Latency: 2
```

```
evm = comm.EVM('ReferenceSignalSource', ...  
    'Estimated from reference constellation');  
[errPlot, evmPlot, scatSym, adaptState] = initFigures(numPackets, lineq);
```

### Equalization Loop

To implement the equalization loop:

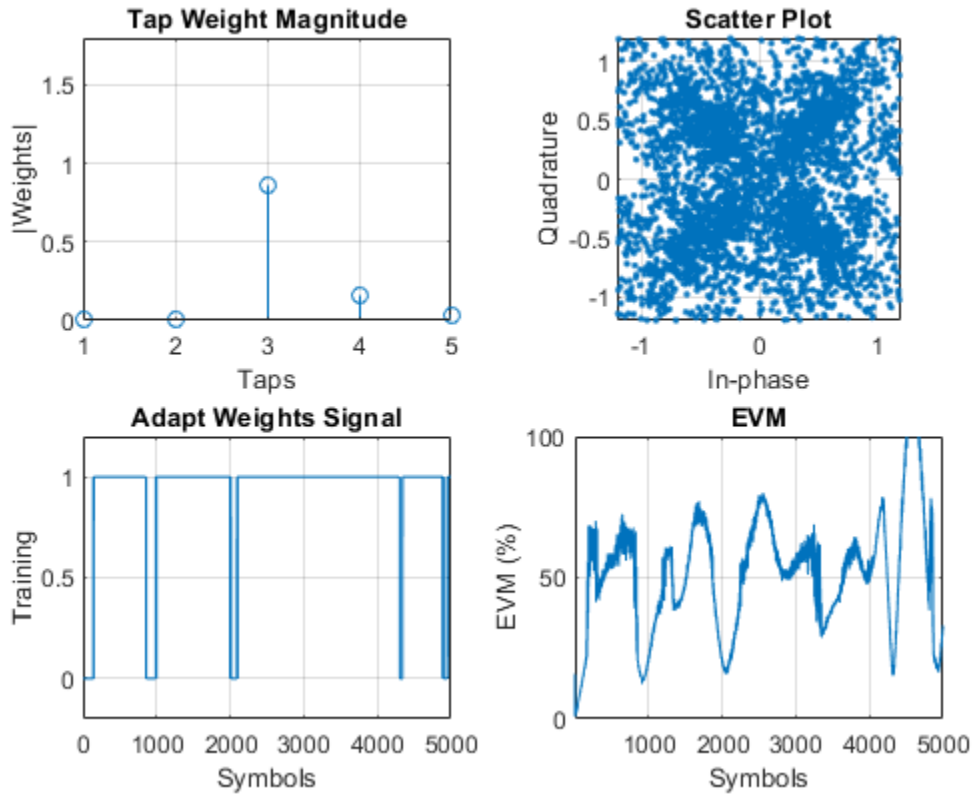

- 1 Generate PSK data packets.
- 2 Apply Rayleigh fading and AWGN to the transmission data.
- 3 Apply equalization to the received data and phase correction to the equalizer output.
- 4 Estimate the EVM and toggle the `adaptWeights` flag to true or false based on the EVM level.
- 5 Update the figure plots.

```
for p=1:numPackets  
    data = randi([0 M-1], numSymbols, 1);  
    tx = pskmod(data, M, pi/4);  
    rx = awgn(raylChan(tx), SNR);  
    rxDelay = finddelay(rx, tx);  
    [y, err, wts] = lineq(rx, adaptWeights);  
    y = phaseCorrection(y);  
    evmEst = evm(y);  
    adaptWeights = (evmEst > 20);
```

```

updateFigures(errPlot, evmPlot, scatSym, adaptState, ...
    wts, y(end), evmEst, adaptWeights, p, numPackets)
end

```

```
rxDelay
```

```
rxDelay = 0
```

The figure plots show that, as the EVM varies, the equalizer toggles in and out of decision-directed weight adaptation mode.

### Helper Functions

This helper function initializes figures that show a quad plot of simulation results.

```

function [errPlot, evmPlot, scatter, adaptState] = initFigures(numPkts, lineq)
yVec = nan(numPkts,1);
evmVec = nan(numPkts,1);
wVec = zeros(lineq.NumTaps,1);
adaptVec = nan(numPkts,1);

figure
subplot(2,2,1)
evmPlot = stem(wVec);
grid on; axis([1 lineq.NumTaps 0 1.8])
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')

subplot(2,2,2)
scatter = plot(yVec, '.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on
xlabel('In-phase'); ylabel('Quadrature'); title('Scatter Plot');
subplot(2,2,3)
adaptState = plot(adaptVec);
grid on; axis([0 numPkts -0.2 1.2])
ylabel('Training'); xlabel('Symbols'); title('Adapt Weights Signal')
subplot(2,2,4)
errPlot = plot(evmVec);
grid on; axis([1 numPkts 0 100])
xlabel('Symbols'); ylabel('EVM (%)'); title('EVM')
end

```

This helper function updates figures.

```

function updateFigures(errPlot, evmPlot, scatSym, ...
    adaptState, w, y, evmEst, adaptWts, p, numFrames)
persistent yVec evmVec adaptVec

if p == 1
    yVec = nan(numFrames,1);
    evmVec = nan(numFrames,1);
    adaptVec = nan(numFrames,1);
end

yVec(p) = y;
evmVec(p) = evmEst;
adaptVec(p) = adaptWts;

errPlot.YData = abs(evmVec);
evmPlot.YData = abs(w);
scatSym.XData = real(yVec);

```

```

scatSym.YData = imag(yVec);
adaptState.YData = adaptVec;
drawnow limitrate
end

```

This helper function applies phase correction.

```

function y = phaseCorrection(y)
a = angle(y((real(y) > 0) & (imag(y) > 0)));
a(a < 0.1) = a(a < 0.1) + pi/2;
theta = mean(a) - pi/4;
y = y * exp(-1i*theta);
end

```

## Linearly Equalize Packetized Signals in Fading Environments

Recover QPSK symbols in fading environments with a linear equalizer, using the least mean squares (LMS) algorithm. Use the `reset` object function to equalize independent packets. Use helper functions to generate plots. This example also shows symbol-based processing and frame-based processing.

### Setup

Initialize system variables, create an equalizer System object, and initialize the plot figures.

```

M = 4; % QPSK
numSym = 1000;
numTrainingSym = 100;
numPackets = 5;
numTaps = 9;
ttlNumSym = numSym + numTrainingSym;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -9], ...
    'MaximumDopplerShift',0, ...
    'PathGainsOutputPort',true);
SNR = 35;
rxVec = zeros(ttlNumSym,numPackets);
txVec = zeros(ttlNumSym,numPackets);
yVec = zeros(ttlNumSym,1);
eVec = zeros(ttlNumSym,1);

lineq1 = comm.LinearEqualizer('Algorithm','LMS', ...

```

```
'NumTaps',numTaps,'ReferenceTap',5, ...  
'StepSize',0.01,'TrainingFlagInputPort',true);  
  
[errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,lineq1, ...  
    raylChan.AveragePathGains);
```

### Symbol-Based Processing

For symbol-based processing, provide one symbol at the input of the equalizer. Reset the equalizer state and channel after processing each packet.

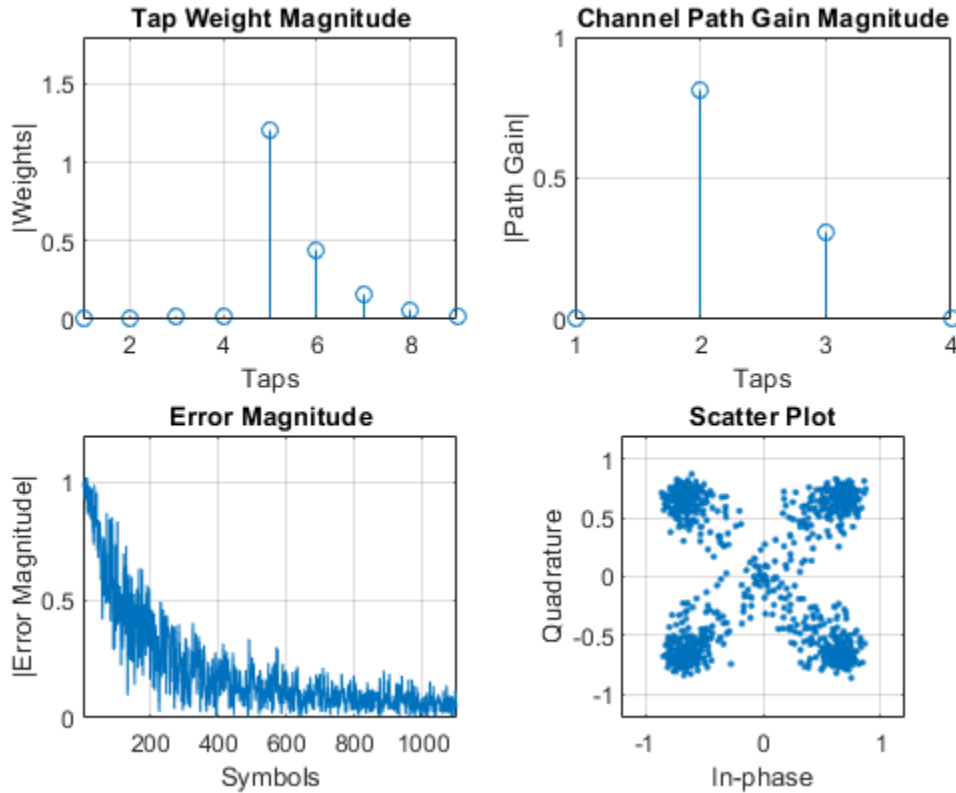

```
for p = 1:numPackets  
    trainingFlag = true;  
    for q=1:ttlNumSym  
        data = randi([0 M-1],1,1);  
        tx = pskmod(data,M,pi/4);  
        [xc,pg] = raylChan(tx);  
        rx = awgn(xc,25);  
        [y,err,wts] = lineq1(rx,tx,trainingFlag);
```

Disable training after processing numTrainingSym training symbols.

```
        if q == numTrainingSym  
            trainingFlag = false;  
        end  
        updateFigures(errPlot,wStem,hStem,scatPlot,err,wts,y,pg,q,ttlNumSym);  
        txVec(q,p) = tx;  
        rxVec(q,p) = rx;  
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```
        reset(raylChan)  
        reset(lineq1)  
    end
```

### Packet-Based Processing

For packet-based processing, provide one packet at the input of the equalizer. Each packet contains `tllNumSym` symbols. Because the training duration is less than the packet length, you do not need to specify the `start-training` input.

```

yVecPkt = zeros(tllNumSym,numPackets);
errVecPkt = zeros(tllNumSym,numPackets);
wgtVecPkt = zeros(numTaps,numPackets);
lineq2 = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',9,'ReferenceTap',6,'StepSize',0.01);
for p = 1:numPackets
    [yVecPkt(:,p),errVecPkt(:,p),wgtVecPkt(:,p)] = ...
        lineq2(rxVec(:,p),txVec(1:numTrainingSym,p));

```

```

for q=1:t1lNumSym
    updateFigures(errPlot,wStem,hStem,scatPlot, ...
        errVecPkt(q,p),wgtVecPkt(:,p),yVecPkt(q,p),pg,q,t1lNumSym);
end

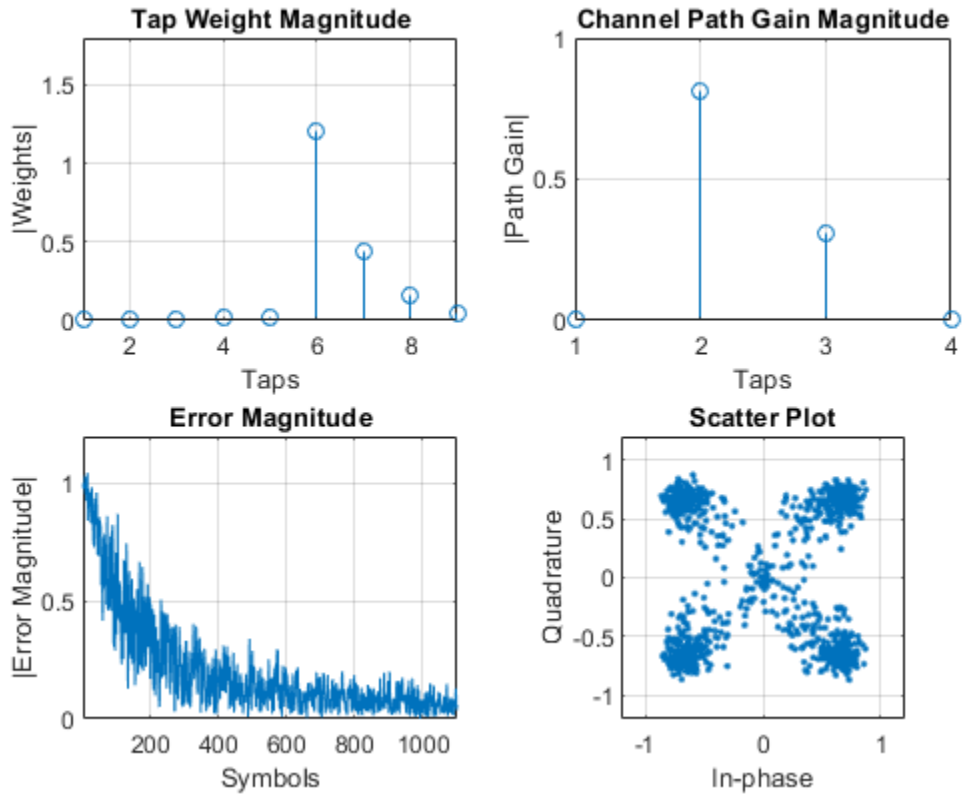

```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```

reset(raylChan)
reset(lineq2)
end

```

### Helper Functions

The helper function initializes the figures.

```

function [errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,lineq,pg)
yVec = nan(ttlNumSym,1);
eVec = nan(ttlNumSym,1);
wVec = zeros(lineq.NumTaps,1);
figure;
subplot(2,2,1);
wStem = stem(wVec);
axis([1 lineq.NumTaps 0 1.8]); grid on
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')
subplot(2,2,2);
hStem = stem([0 abs(pg) 0]);
grid on;
xlabel('Taps'); ylabel('|Path Gain|'); title('Channel Path Gain Magnitude')
subplot(2,2,3);
errPlot = plot(eVec);
axis([1 ttlNumSym 0 1.2]); grid on
xlabel('Symbols'); ylabel('|Error Magnitude|'); title('Error Magnitude')
subplot(2,2,4);
scatPlot = plot(yVec, '.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on;
xlabel('In-phase'); ylabel('Quadrature'); title(sprintf('Scatter Plot'));
end

```

This helper function updates the figures.

```

function updateFigures(errPlot,wStem,hStem,scatPlot, ...
    err,wts,y,pg,p,ttlNumSym)
persistent yVec eVec
if p == 1
    yVec = nan(ttlNumSym,1);
    eVec = nan(ttlNumSym,1);
end
yVec(p) = y;
eVec(p) = abs(err);
errPlot.YData = abs(eVec);
wStem.YData = abs(wts);
hStem.YData = [0 abs(pg) 0];
scatPlot.XData = real(yVec);
scatPlot.YData = imag(yVec);
drawnow limitrate
end

```

## Nonadaptive Linear Equalization

Use the linear equalizer in nonadaptive mode. Use the `mmseweights` object function to calculate the minimum mean squared error (MMSE) solution and use the weights for the linear equalizer taps weights.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object configured to use CMA algorithm, set the `AdaptWeights` property to `false`, and the `InitialWeightsSource` property to `Property`. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer('Algorithm','CMA','AdaptWeights',false,'InitialWeightsSource
```

```
eq =
comm.LinearEqualizer with properties:
```

```
    Algorithm: 'CMA'
    NumTaps: 5
    StepSize: 0.0100
    Constellation: [1x4 double]
    InputSamplesPerSymbol: 1
    AdaptWeightsSource: 'Property'
    AdaptWeights: false
    InitialWeightsSource: 'Property'
    InitialWeights: [5x1 double]
    WeightUpdatePeriod: 1
```

```
wgts = mmseweights(eq,chtaps,EbN0)
```

```
wgts = 5×1 complex
```

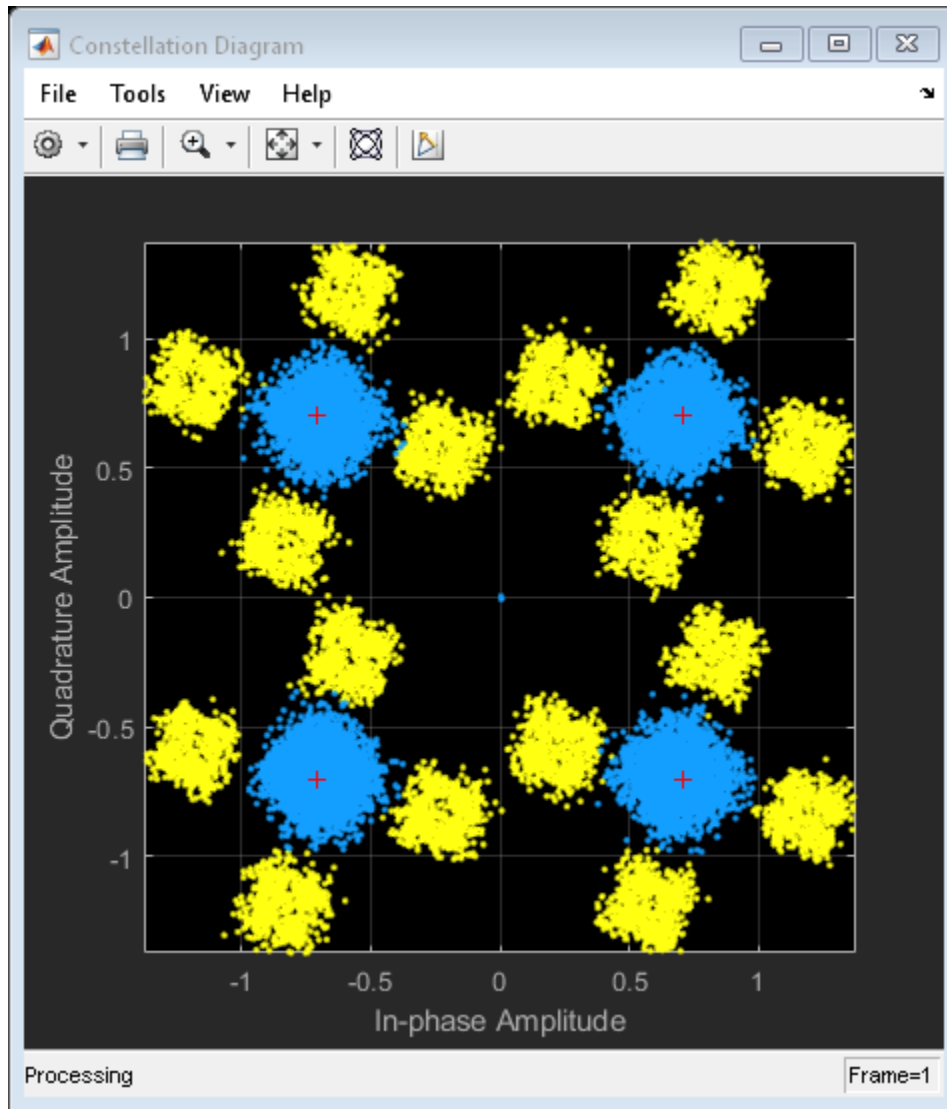

```
0.0005 - 0.0068i  
0.0103 + 0.0117i  
0.9694 - 0.0019i  
-0.3987 + 0.2186i  
0.0389 - 0.1756i
```

```
eq.InitialWeights = wgts;
```

```
[y,err,weights] = eq(rx);
```

Plot constellation of impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);  
constell(rx,y)
```

Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))  
grid on; xlabel('Symbols'); ylabel('|e|')
```

```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 140.6177
```

Plot equalizer tap weights.

```
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on;
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on;
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
subplot(3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on;
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
```

## More About

### Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbol-spaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.

- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

## Algorithms

### Linear Equalizers

Linear equalizers can remove intersymbol interference (ISI) when the frequency response of a channel has no null. If a null exists in the frequency response of a channel, linear equalizers tend to enhance the noise. In this case, use decision feedback equalizers to avoid enhancing the noise.

A linear equalizer consists of a tapped delay line that stores samples from the input signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

Linear equalizers can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol,  $K$ , is 1. The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol,  $K$ , is an integer greater than 1. Typically,  $K$  is 4 for fractionally spaced equalizers. The output sample rate is  $1/T$  and the input sample rate is  $K/T$ , where  $T$  is the symbol period. Tap-weight updating occurs at the output rate.

This schematic shows a linear equalizer with  $L$  weights, a symbol period of  $T$ , and  $K$  samples per symbol. If  $K$  is 1, the result is a symbol-spaced linear equalizer instead of a fractional symbol-spaced linear equalizer.

In each symbol period, the equalizer receives  $K$  input samples at the tapped delay line. The equalizer then outputs a weighted sum of the values in the tapped delay line and updates the weights to prepare for the next symbol period.

For more information, see “Equalization”.

## Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic,  $w$  is a vector of all weights  $w_i$ , and  $u$  is a vector of all inputs  $u_i$ . Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (\text{StepSize}) u * e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the `maxstep` object function. The  $*$  operator denotes the complex conjugate and the error calculation  $e = d - y$ .

## Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic,  $w$  is the vector of all weights  $w_i$ , and  $u$  is the vector of all inputs  $u_i$ . Based on the current set of inputs,  $u$ , and the inverse correlation matrix,  $P$ , the RLS algorithm first computes the Kalman gain vector,  $K$ , as

$$K = \frac{Pu}{(\text{ForgettingFactor}) + u^H Pu}.$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable.  $H$  denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$P_{\text{new}} = \frac{P_{\text{current}}(1 - Ku^H)}{\text{ForgettingFactor}}.$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + K^*e.$$

The \* operator denotes the complex conjugate and the error calculation  $e = d - y$ .

## Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic,  $w$  is the vector of all weights  $w_i$ , and  $u$  is the vector of all inputs  $u_i$ . Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (\text{StepSize}) u^*e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the `maxstep` object function. The \* operator denotes the complex conjugate and the error calculation  $e = y(R - |y|^2)$ , where  $R$  is a constant related to the signal constellation.

**Package:** comm

Equalize modulated signals using decision feedback filtering

## Description

The `comm.DecisionFeedbackEqualizer` System object uses a decision feedback filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. The equalizer object adaptively adjusts tap weights based on the selected algorithm. For more information, see “Algorithms” on page 4-664.

To equalize modulated signals using a decision feedback filter:

- 1 Create the `comm.DecisionFeedbackEqualizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
dfc = comm.DecisionFeedbackEqualizer  
dfc = comm.DecisionFeedbackEqualizer(Name,Value)
```

## Description

`dfc = comm.DecisionFeedbackEqualizer` creates a decision feedback equalizer System object to adaptively equalize a signal.

`dfc = comm.DecisionFeedbackEqualizer(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.DecisionFeedbackEqualizer('Algorithm','RLS')` configures the equalizer

object to update tap weights using the recursive least squares (RLS) algorithm. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### Algorithm — Adaptive algorithm

'LMS' (default) | 'RLS' | 'CMA'

Adaptive algorithm used for equalization, specified as one of these values:

- 'LMS' — Update the equalizer tap weights using the “Least Mean Square (LMS) Algorithm” on page 4-666.
- 'RLS' — Update the equalizer tap weights using the “Recursive Least Square (RLS) Algorithm” on page 4-666.
- 'CMA' — Update the equalizer tap weights using the “Constant Modulus Algorithm (CMA)” on page 4-667.

Data Types: `char` | `string`

### NumForwardTaps — Number of forward equalizer taps

5 (default) | positive integer

Number of forward equalizer taps, specified as a positive integer.

Data Types: `double`

### NumFeedbackTaps — Number of feedback equalizer taps

3 (default) | positive integer

Number of feedback equalizer taps, specified as a positive integer.

Data Types: `double`

**StepSize — Step size**

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

---

**Tip** To determine the maximum step size allowed, use the `maxstep` object function.

---

**Tunable:** Yes

**Dependencies**

To enable this property, set `Algorithm` to 'LMS' or 'CMA'.

Data Types: double

**ForgettingFactor — Forgetting factor**

0.99 (default) | scalar in the range (0, 1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

**Tunable:** Yes

**Dependencies**

To enable this property, set `Algorithm` to 'RLS'.

Data Types: double

**InitialInverseCorrelationMatrix — Initial inverse correlation matrix**

0.1 (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an  $N_{\text{Taps}}$ -by- $N_{\text{Taps}}$  matrix.  $N_{\text{Taps}}$  is equal to the sum of the `NumForwardTaps` and `NumFeedbackTaps` property values. If you specify `InitialInverseCorrelationMatrix` as a scalar,  $a$ , the equalizer sets the initial inverse correlation matrix to  $a$  times the identity matrix:  $a(\text{eye}(N_{\text{Taps}}))$ .

**Tunable:** Yes

### Dependencies

To enable this property, set Algorithm to 'RLS'.

Data Types: double

### Constellation — Signal constellation

`pskmod(0:3,4,pi/4)` (default) | vector

Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: `pskmod(0:3,4,pi/4)`.

**Tunable:** Yes

Data Types: double

### ReferenceTap — Reference tap

3 (default) | positive integer

Reference tap, specified as a positive integer less than or equal to the NumForwardTaps property value. The equalizer uses the reference tap location to track the main energy of the channel.

Data Types: double

### InputDelay — Input signal delay

0 (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the System object and to the first call of the System object after calling the `release` or `reset` object function.

Data Types: double

### InputSamplesPerSymbol — Number of input samples per symbol

1 (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this property to any number greater than one effectively creates a fractionally spaced equalizer.

Data Types: double

**TrainingFlagInputPort — Enable training control input**`false (default) | true`

Enable training control input, specified as `false` or `true`. Setting this property to `true` enables the equalizer training flag input `tf`.

**Tunable:** Yes

Data Types: `logical`

**AdaptAfterTraining — Update tap weights when not training**`true (default) | false`

Update tap weights when not training, specified as `true` or `false`. If this property is set to `true`, the System object uses decision directed mode to update equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged after training.

**Tunable:** Yes

Data Types: `logical`

**AdaptWeightsSource — Source of adapt tap weights request**`'Property' (default) | 'Input port'`

Source of adapt tap weights request, specified as one of these values:

- `'Property'` — Specify this value to use the `AdaptWeights` property to control when the System object adapts tap weights.
- `'Input port'` — Specify this value to use the `aw` input to control when the System object adapts tap weights.

**Dependencies**

To enable this property, set `Algorithm` to `'CMA'`.

Data Types: `char` | `string`

**AdaptWeights — Adapt tap weights**`true (default) | false`

Adapt tap weights, specified as `true` or `false`. If this property is set to `true`, the System object updates the equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged.

**Tunable:** Yes

### Dependencies

To enable this property, set `AdaptWeightsSource` to 'Property' and set `AdaptAfterTraining` to `true`.

Data Types: `logical`

### InitialWeightsSource — Source for initial tap weights

'Auto' (default) | 'Property'

Source for initial tap weights, specified as one of these values:

- 'Auto' — Initialize the tap weights to the algorithm-specific default values, as described in the `InitialWeights` property.
- 'Property' — Initialize the tap weights using the `InitialWeights` property value.

Data Types: `char` | `string`

### InitialWeights — Initial weights

0 or [0;0;1;0;0] (default) | scalar | vector

Initial weights used by the adaptive algorithm, specified as a scalar or vector. The default is 0 when the `Algorithm` property is set to 'LMS' or 'RLS'. The default is [0;0;1;0;0] when the `Algorithm` property is set to 'CMA'.

If you specify `InitialWeights` as a scalar, the equalizer uses scalar expansion to create a vector of length  $N_{\text{Taps}}$  with all values set to `InitialWeights`.  $N_{\text{Taps}}$  is equal to the sum of the `NumForwardTaps` and `NumFeedbackTaps` property values. If you specify `InitialWeights` as a vector, the vector length must be  $N_{\text{Taps}}$ .

**Tunable:** Yes

Data Types: `double`

### WeightUpdatePeriod — Tap weight update period

1 (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

Data Types: `double`

## Usage

## Syntax

```
y = dfe(x,tsym)
y = dfe(x,tsym,tf)
y = dfe(x)
y = dfe(x,aw)
[y,err] = dfe( ___ )
[y,err,weights] = dfe( ___ )
```

## Description

`y = dfe(x,tsym)` equalizes input signal `x` by using training symbols `tsym`. The output is the equalized symbols. To enable this syntax, set the Algorithm property to 'LMS' or 'RLS'.

`y = dfe(x,tsym,tf)` also specifies training flag `tf`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`. To enable this syntax, set the Algorithm property to 'LMS' or 'RLS' and TrainingFlagInputPort property to `true`.

`y = dfe(x)` equalizes input signal `x`. To enable this syntax, set the Algorithm property to 'CMA'.

`y = dfe(x,aw)` also specifies adapts weights flag `aw`. The System object adapts the equalizer tap weights when `aw` is `true`. If `aw` is `false`, the System object keeps the weights unchanged. To enable this syntax, set the Algorithm property to 'CMA' and AdaptWeightsSource property to 'Input port'.

`[y,err] = dfe( ___ )` also returns error signal `err` using input arguments from any of the previous syntaxes.

`[y,err,weights] = dfe( ___ )` also returns `weights`, the tap weights from the last tap weight update, using input arguments from any of the previous syntaxes.

## Input Arguments

### **x — Input signal**

column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the `InputSamplesPerSymbol` property value. For more information, see “Symbol Tap Spacing” on page 4-664.

Data Types: `double`

Complex Number Support: Yes

### **tsym — Training symbols**

column vector

Training symbols, specified as a column vector of length less than or equal to the length of input `x`. The input `tsym` is ignored when `tf` is `false`.

#### **Dependencies**

To enable this argument, set the `Algorithm` property to `'LMS'` or `'RLS'`.

Data Types: `double`

### **tf — Training flag**

`true` | `false`

Training flag, specified as `true` or `false`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`.

#### **Dependencies**

To enable this argument, set the `Algorithm` property to `'LMS'` or `'RLS'` and `TrainingFlagInputPort` property to `true`.

Data Types: `logical`

### **aw — Adapt weights flag**

`true` | `false`

Adapt weights flag, specified as `true` or `false`. If `aw` is `true`, the System object adapts weights. If `aw` is `false`, the System object keeps the weights unchanged.

## Dependencies

To enable this argument, set the Algorithm property to 'CMA' and AdaptWeightsSource property to 'Input port'.

Data Types: logical

## Output Arguments

### **y** — Equalized symbols

column vector

Equalized symbols, returned as a column vector that has the same length as input signal  $x$ .

### **err** — Error signal

column vector

Error signal, returned as a column vector that has the same length as input signal  $x$ .

### **weights** — Tap weights

column vector

Tap weights, returned as a column vector that has  $N_{\text{Taps}}$  elements.  $N_{\text{Taps}}$  is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. **weights** contains the tap weights from the last tap weight update.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to comm.DecisionFeedbackEqualizer

isLocked	Determine if System object is in use
clone	Create duplicate System object
info	Characteristic information about the equalizer object
maxstep	Maximum step size for LMS equalizer convergence

mmseweights Linear equalizer MMSE tap weights

### Common to All System Objects

step Run System object algorithm  
release Release resources and allow changes to System object property values and input characteristics  
reset Reset internal states of System object

## Examples

### Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03.

```
bpsk = comm.BPSKModulator;  
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...  
    'NumForwardTaps',8, 'NumFeedbackTaps',5, 'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqdfe_lms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));  
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms,rxsig)  
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig,x(1:200));
```

## Decision Feedback Equalize QPSK-Modulated Signal

Apply decision feedback equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through a delayed multipath AWGN channel.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
```

Generate QPSK-modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a decision feedback equalizer System object and display the default configuration. Adjust the reference tap to 1. Check the maximum permitted step size. Equalize the impaired symbols.

```
eq = comm.DecisionFeedbackEqualizer
eq =
    comm.DecisionFeedbackEqualizer with properties:
        Algorithm: 'LMS'
        NumForwardTaps: 5
        NumFeedbackTaps: 3
        StepSize: 0.0100
        Constellation: [1x4 double]
        ReferenceTap: 3
        InputDelay: 0
        InputSamplesPerSymbol: 1
        TrainingFlagInputPort: false
        AdaptAfterTraining: true
        InitialWeightsSource: 'Auto'
        WeightUpdatePeriod: 1
```

```
eq.ReferenceTap = 1;
```

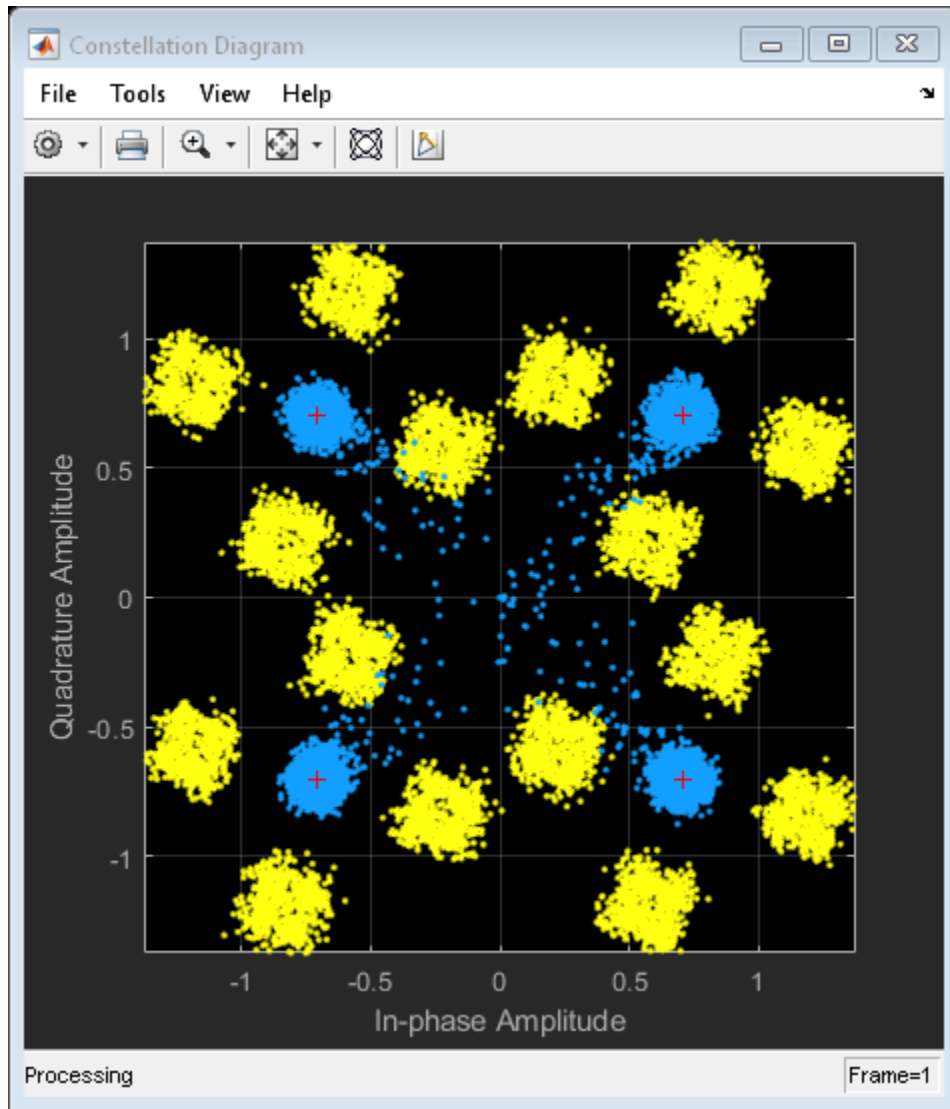

```
mxStep = maxstep(eq,rx)
```

```
mxStep = 0.2141
```

```
[y,err,weights] = eq(rx,tx(1:numTrainingSymbols));
```

Plot the constellation of the impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);  
constell(rx,y)
```

Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))  
grid on; xlabel('Symbols'); ylabel('|e|')
```

```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 10.1621
```

Plot the equalizer tap weights.

```
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; a
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth
title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; a
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth
subplot(3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; ax
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth
```

### Decision Feedback Equalize System Using Different Training Schemes

Demonstrate decision feedback equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Apply different equalizer training schemes and show the symbol error magnitude.

#### System Setup

Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a decision feedback LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',5,'NumFeedbackTaps',4,'ReferenceTap',3,'StepSize',0.01);
```

### **Train the Equalizer at the Beginning of Each Packet With Reset**

Process each packet using prepended training symbols. Reset the equalizer after processing each packet. Resetting the equalizer after each packet forces the equalizer to train taps with no a priori knowledge. Equalizer error signal plots for the first, second, and last packet show higher symbol errors at the start of each packet.

```
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    rx = awgn(packet,SNR);
    [~,err] = dfeq(rx,trainingSymbols);
    reset(dfeq)
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        ylim([0 1])
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols');
        ylabel('Error Magnitude');
        grid on;
        jj = jj+1;
    end
end
```

### Train the Equalizer at the Beginning of Each Packet Without Reset

Process each packet using prepended training symbols. Do not reset the equalizer after each packet is processed. By not resetting after each packet, the equalizer retains tap weights from training prior packets. Equalizer error signal plots for the first, second, and last packet show that after the initial training on the first packet, subsequent packets have less symbol errors at the start of each packet.

```
release(dfec)
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
```

```
packet = [trainingSymbols;dataSym];
channel = 1;
rx = awgn(packet*channel,SNR);
[~,err] = dfreq(rx,trainingSymbols);
if (ii ==1 || ii == 2 ||ii == numPkts)
    subplot(3,1,jj)
    plot(abs(err))
    ylim([0 1])
    title(['Packet # ',num2str(ii)])
    xlabel('Symbols');
    ylabel('Error Magnitude');
    grid on;
    jj = jj+1;
end
end
```

### Train the Equalizer Periodically

Systems with signals subject to time-varying channels require periodic equalizer training to maintain lock on the channel variations. Specify a system that has 200 symbols of training for every 1800 data symbols. Between training, the equalizer does not update tap weights. The equalizer processes 200 symbols per packet.

```
Rs = 1e6;
fd = 20;
spp = 200; % Symbols per packet
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols; dataSym];
stream = repmat(packet,10,1);
```

```
tx = (0:length(stream)-1)/Rs;  
channel = exp(1i*2*pi*fd*tx);  
rx = awgn(stream.*channel,SNR);
```

Set the `AdaptAfterTraining` property to `false` to stop the equalizer tap weight updates after the training phase.

```
release(dfreq)  
dfreq.AdaptAfterTraining = false  
  
dfreq =  
    comm.DecisionFeedbackEqualizer with properties:  
  
        Algorithm: 'LMS'  
        NumForwardTaps: 5  
        NumFeedbackTaps: 4  
        StepSize: 0.0100  
        Constellation: [1x4 double]  
        ReferenceTap: 3  
        InputDelay: 0  
        InputSamplesPerSymbol: 1  
        TrainingFlagInputPort: false  
        AdaptAfterTraining: false  
        InitialWeightsSource: 'Auto'  
        WeightUpdatePeriod: 1
```

Equalize the impaired data. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output does not remove the channel effects. Also, the output constellation rotates out of sync, resulting in bit errors.

```
[y,err] = dfreq(rx,trainingSymbols);  
  
figure  
subplot(2,1,1)  
plot(tx, unwrap(angle(channel)))  
xlabel('Time (sec)')  
ylabel('Channel Angle (rad)')  
title('Angular Error Over Time')  
subplot(2,1,2)  
plot(abs(err))  
xlabel('Symbols')  
ylabel('Error Magnitude')
```

```
grid on  
title('Time-Varying Channel Without Retraining')
```

```
scatterplot(y)
```

Set the `TrainingInputPort` property to `true` to configure the equalizer to retrain the taps when signaled by the `trainFlag` input. The equalizer trains only when `trainFlag` is `true`. After every 2000 symbols, the equalizer retrains the taps and keeps lock on variations of the channel. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output removes the channel effects. Also, the output constellation does not rotate out of sync, and bit errors are reduced.

```
release(dfreq)
dfreq.TrainingFlagInputPort = true;
symbolCnt = 0;
numPackets = length(rx)/spp;
trainFlag = true;
```

```
trainingPeriod = 2000;
eVec = zeros(size(rx));
yVec = zeros(size(rx));
for p=1:numPackets
    [yVec((p-1)*spp+1:p*spp,1),eVec((p-1)*spp+1:p*spp,1)] = ...
        dfreq(rx((p-1)*spp+1:p*spp,1),trainingSymbols,trainFlag);
    symbolCnt = symbolCnt + spp;
    if symbolCnt >= trainingPeriod
        trainFlag = true;
        symbolCnt = 0;
    else
        trainFlag = false;
    end
end
figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('t (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(eVec))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel With Retraining')
```

scatterplot(yVec)

### Decision Feedback Equalize Delayed Signal

Simulate a system with delay between the transmitted symbols and received samples. Typical systems have transmitter and receiver filters that result in a delay. This delay must be accounted for to synchronize the system. In this example, the system delay is introduced without transmit and receive filters. Decision feedback equalization, using the least mean squares (LMS) algorithm, recovers QPSK symbols.

Initialize simulation variables.

```
M = 4; % QPSK  
numSymbols = 10000;
```

```
numTrainingSymbols = 1000;  
mpChan = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];  
systemDelay = dsp.Delay(20);  
snr = 24;
```

Generate QPSK-modulated symbols. Apply multipath channel filtering, a system delay, and AWGN to the transmitted symbols.

```
data = randi([0 M-1],numSymbols,1);  
tx = pskmod(data,M,pi/4); % QPSK  
delayedSym = systemDelay(filter(mpChan,1,tx));  
rx = awgn(delayedSym,snr,'measured');
```

Create equalizer and EVM System objects. The equalizer System object specifies a decision feedback equalizer using the LMS algorithm.

```
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...  
    'NumForwardTaps',9,'NumFeedbackTaps',6,'ReferenceTap',5);  
evm = comm.EVM('ReferenceSignalSource', ...  
    'Estimated from reference constellation');
```

### Equalize Without Adjusting Input Delay

Equalize the received symbols.

```
[y1,err1,wts1] = dfeq(rx,tx(1:numTrainingSymbols,1));
```

Find the delay between the received symbols and the transmitted symbols by using the `finddelay` function.

```
rxDelay = finddelay(tx,rx)
```

```
rxDelay = 20
```

Display the equalizer information. The latency value indicates the delay introduced by the equalizer. Calculate the total delay as the sum of `rxDelay` and the equalizer latency.

```
eqInfo = info(dfreq)
```

```
eqInfo = struct with fields:  
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
```

Until the equalizer output converges, the symbol error rate is high. Plot the error output, `err1`, to determine when the equalized output converges.

```
plot(abs(err1))  
xlabel('Symbols')  
ylabel('Error Magnitude')  
title('Equalizer Error Signal')
```

The plot shows excessive errors for the first 2000 symbols. When demodulating symbols and computing symbol errors, account for the unconverged output and the system delay between the equalizer output and transmitted symbols.

```
dataRec1 = pskdemod(y1(2000+totalDelay:end),M,pi/4);  
symErrWithDelay = symerr(data(2000:end-totalDelay),dataRec1)
```

```
symErrWithDelay = 6001
evmWithDelay = evm(y1)
evmWithDelay = 25.6868
```

The error rate and EVM are high because the receive delay was not accounted for in the equalizer System object.

### Adjust Input Delay in Decision Feedback Equalizer

Equalize the received data by using the delay value to set the `InputDelay` property. Since `InputDelay` is a nontunable property, you must release the `dfeq` System object to reconfigure the `InputDelay` property. Equalize the received symbols.

```
release(dfreq)
dfreq.InputDelay = rxDelay

dfreq =
    comm.DecisionFeedbackEqualizer with properties:
        Algorithm: 'LMS'
        NumForwardTaps: 9
        NumFeedbackTaps: 6
        StepSize: 0.0100
        Constellation: [1x4 double]
        ReferenceTap: 5
        InputDelay: 20
        InputSamplesPerSymbol: 1
        TrainingFlagInputPort: false
        AdaptAfterTraining: true
        InitialWeightsSource: 'Auto'
        WeightUpdatePeriod: 1
```

```
[y2,err2,wts2] = dfreq(rx,tx(1:numTrainingSymbols,1));
```

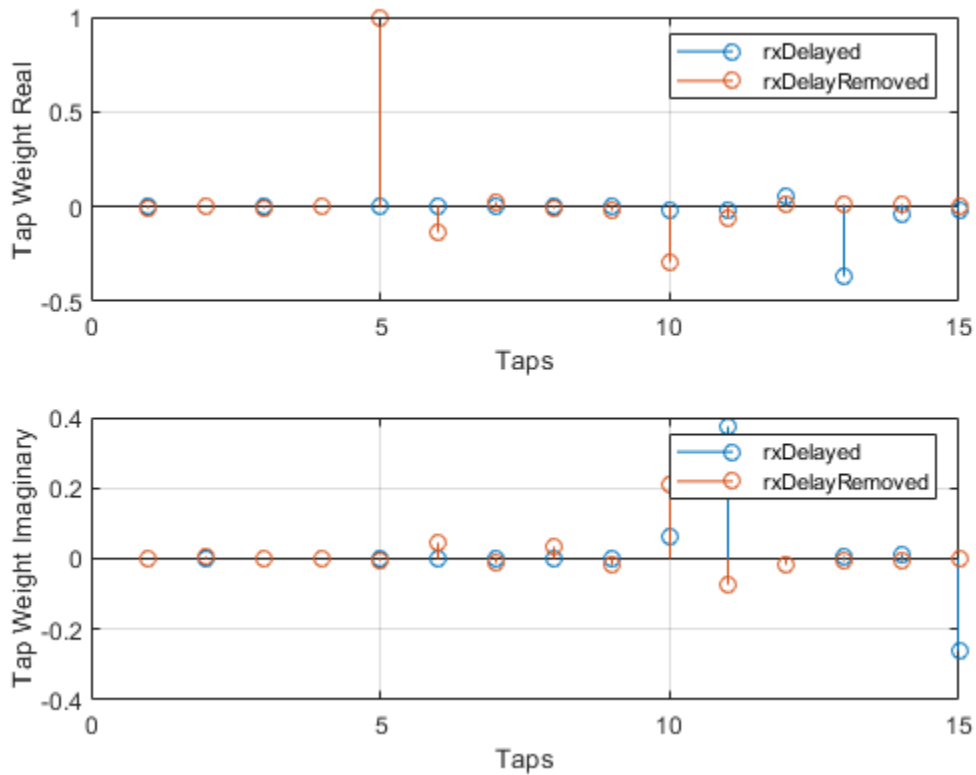

Plot the tap weights and equalized error magnitude. A stem plot shows the equalizer tap weights before and after the system delay is removed. A 2-D line plot shows the slower equalizer convergence for the delayed signal, as compared to the signal with the delay removed.

```
subplot(2,1,1)
stem([real(wts1),real(wts2)])
xlabel('Taps')
```

```

ylabel('Tap Weight Real')
legend('rxDelayed', 'rxDelayRemoved')
grid on
subplot(2,1,2)
stem([imag(wts1),imag(wts2)])
xlabel('Taps')
ylabel('Tap Weight Imaginary')
legend('rxDelayed', 'rxDelayRemoved')
grid on

```

```

figure
plot([abs(err1),abs(err2)])
xlabel('Symbols')

```

```
ylabel('Error Magnitude')  
legend('rxDelayed', 'rxDelayRemoved')  
grid on
```

Plot error output of the equalized signals, `rxDelayed` and `rxDelayRemoved`. For the signal that has the delay removed, the equalizer converges during the 1000 symbol training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 500 symbols. Reconfiguring the equalizer to account for the system delay enables better equalization of the signal, and reduces symbol errors and the EVM.

```
eqInfo = info(dfreq)
```

```

eqInfo = struct with fields:
    Latency: 4

totalDelay = rxDelay + eqInfo.Latency;
dataRec2 = pskdemod(y2(500+totalDelay:end),M,pi/4);
symErrDelayRemoved = symerr(data(500:end-totalDelay),dataRec2)

symErrDelayRemoved = 0

evmDelayRemoved = evm(y2(500+totalDelay:end))

evmDelayRemoved = 7.5147

```

## Decision Feedback Equalize Symbols Using EVM-Based Training

Recover QPSK symbols with a decision equalizer, using the constant modulus algorithm (CMA) and EVM-based taps training. When using blind equalizer algorithms, such as CMA, you can train the equalizer taps using the `AdaptWeights` property to start and stop training. Use helper functions to generate plots and apply phase correction.

Initialize system variables.

```

rng(123456);
M = 4; % QPSK
numSymbols = 100;
numPackets = 5000;
refTap = 3;
nFwdTaps = 5;
nFdbkTaps = 4;
ttlTaps = nFwdTaps + nFdbkTaps;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -12], 'MaximumDopplerShift',1e-5);
SNR = 50;
adaptWeights = true;

```

Create the equalizer and EVM System objects. The equalizer System object specifies a decision feedback equalizer using the CMA adaptive algorithm. Call the helper function to initialize figure plots.

```

dfeq = comm.DecisionFeedbackEqualizer('Algorithm','CMA', ...
    'NumForwardTaps',nFwdTaps,'NumFeedbackTaps',nFdbkTaps,'ReferenceTap',refTap, ...
    'StepSize',0.03,'AdaptWeightsSource','Input port')

```

```
dfeq =  
comm.DecisionFeedbackEqualizer with properties:
```

```
    Algorithm: 'CMA'  
    NumForwardTaps: 5  
    NumFeedbackTaps: 4  
        StepSize: 0.0300  
    Constellation: [1x4 double]  
    ReferenceTap: 3  
    InputSamplesPerSymbol: 1  
    AdaptWeightsSource: 'Input port'  
    InitialWeightsSource: 'Auto'  
    WeightUpdatePeriod: 1
```

```
info(dfeq)
```

```
ans = struct with fields:  
    Latency: 2
```

```
evm = comm.EVM('ReferenceSignalSource', ...  
    'Estimated from reference constellation');  
[errPlot, evmPlot, scatSym, adaptState] = initFigures(numPackets, ttlTaps);
```

### Equalization Loop

Follow these steps to implement the equalization loop.

- 1 Generate OQPSK data packets.
- 2 Apply Rayleigh fading and AWGN to the transmission data.
- 3 Apply equalization to the received data and phase correction to the equalizer output.
- 4 Estimate the EVM and toggle the `adaptWeights` flag to `true` or `false` based on the EVM level.
- 5 Update the figure plots.

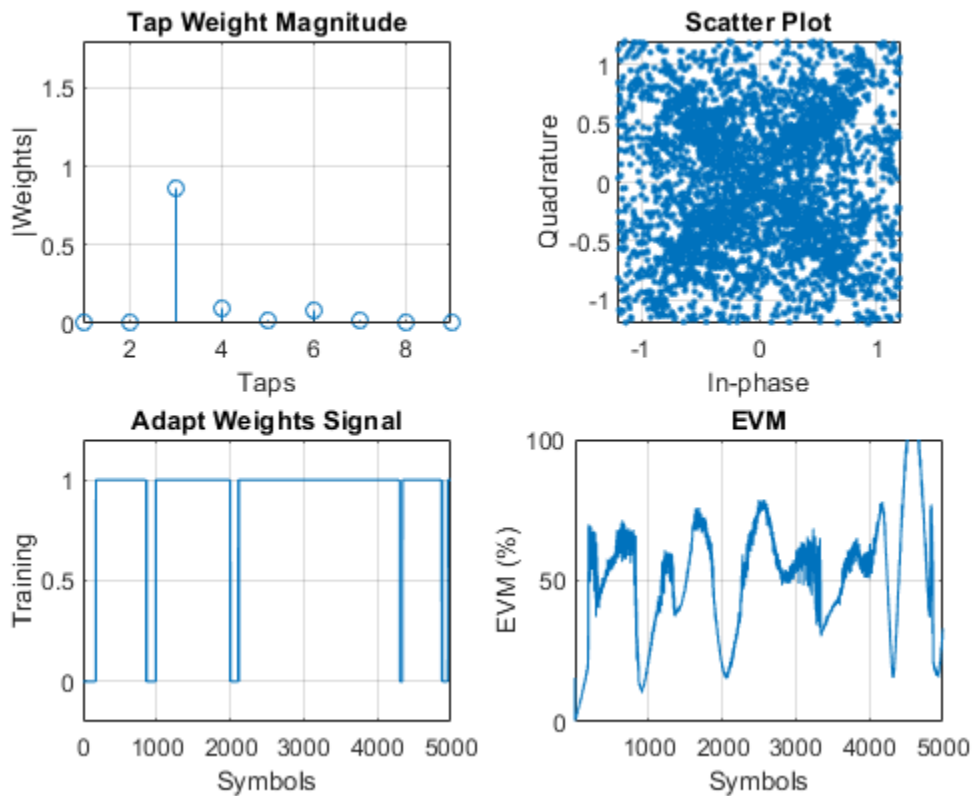

```
for p=1:numPackets  
    data = randi([0 M-1], numSymbols, 1);  
    tx = pskmod(data, M, pi/4);  
    rx = awgn(raylChan(tx), SNR);  
    rxDelay = finddelay(rx, tx);  
    [y, err, wts] = dfreq(rx, adaptWeights);
```

```

y = phaseCorrection(y);
evmEst = evm(y);
adaptWeights = (evmEst > 20);

updateFigures(errPlot, evmPlot, scatSym, adaptState, ...
    wts, y(end), evmEst, adaptWeights, p, numPackets)
end

```

```
rxDelay
```

```
rxDelay = 0
```

The figure plots show that, as the EVM varies, the equalizer toggles in and out of decision-directed weight adaptation mode.

## Helper Functions

This helper function initializes figures that show a quad plot of simulation results.

```
function [errPlot, evmPlot, scatter, adaptState] = initFigures(numPkts, ttlTaps)
yVec = nan(numPkts,1);
evmVec = nan(numPkts,1);
wVec = zeros(ttlTaps,1);
adaptVec = nan(numPkts,1);

figure
subplot(2,2,1)
evmPlot = stem(wVec);
grid on; axis([1 ttlTaps 0 1.8])
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')

subplot(2,2,2)
scatter = plot(yVec, '.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on
xlabel('In-phase'); ylabel('Quadrature'); title('Scatter Plot');
subplot(2,2,3)
adaptState = plot(adaptVec);
grid on; axis([0 numPkts -0.2 1.2])
ylabel('Training'); xlabel('Symbols'); title('Adapt Weights Signal')
subplot(2,2,4)
errPlot = plot(evmVec);
grid on; axis([1 numPkts 0 100])
xlabel('Symbols'); ylabel('EVM (%)'); title('EVM')
end
```

This helper function updates the figures.

```
function updateFigures(errPlot, evmPlot, scatSym, ...
    adaptState, w, y, evmEst, adaptWts, p, numFrames)
persistent yVec evmVec adaptVec

if p == 1
    yVec = nan(numFrames,1);
    evmVec = nan(numFrames,1);
    adaptVec = nan(numFrames,1);
end

yVec(p) = y;
evmVec(p) = evmEst;
adaptVec(p) = adaptWts;
```

```

errPlot.YData = abs(evmVec);
evmPlot.YData = abs(w);
scatSym.XData = real(yVec);
scatSym.YData = imag(yVec);
adaptState.YData = adaptVec;
drawnow limitrate
end

```

This helper function applies phase correction.

```

function y = phaseCorrection(y)
a = angle(y((real(y) > 0) & (imag(y) > 0)));
a(a < 0.1) = a(a < 0.1) + pi/2;
theta = mean(a) - pi/4;
y = y * exp(-1i*theta);
end

```

## Decision Feedback Equalize Packetized Signals in Fading Environments

Recover QPSK symbols in fading environments with a decision feedback equalizer, using the least mean squares (LMS) algorithm. Use the `reset` object function to equalize independent packets. Use helper functions to generate plots. This example also shows symbol-based processing and frame-based processing.

### Setup

Initialize system variables, create the equalizer System object, and initialize the plot figures.

```

M = 4; % QPSK
numSym = 1000;
numTrainingSym = 100;
numPackets = 5;
refTap = 5;
nFwdTaps = 9;
nFdbkTaps = 4;
ttlTaps = nFwdTaps + nFdbkTaps;
stepsz = 0.01;
ttlNumSym = numSym + numTrainingSym;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -9], ...
    'MaximumDopplerShift',0, ...

```

```

    'PathGainsOutputPort',true);
SNR = 35;
rxVec = zeros(ttlNumSym,numPackets);
txVec = zeros(ttlNumSym,numPackets);
yVec = zeros(ttlNumSym,1);
eVec = zeros(ttlNumSym,1);

dfeq1 = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',nFwdTaps,'NumFeedbackTaps',nFdbkTaps,'ReferenceTap',refTap, ...
    'StepSize',stepsz,'TrainingFlagInputPort',true);

[errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,ttlTaps, ...
    raylChan.AveragePathGains);

```

### Symbol-Based Processing

For symbol-based processing, provide one symbol at the input of the equalizer. Reset the equalizer state and channel after processing each packet.

```

for p = 1:numPackets
    trainingFlag = true;
    for q=1:ttlNumSym
        data = randi([0 M-1],1,1);
        tx = pskmod(data,M,pi/4);
        [xc,pg] = raylChan(tx);
        rx = awgn(xc,25);
        [y,err,wts] = dfeq1(rx,tx,trainingFlag);
    end
end

```

Disable training after processing numTrainingSym training symbols.

```

    if q == numTrainingSym
        trainingFlag = false;
    end
    updateFigures(errPlot,wStem,hStem,scatPlot,err,wts,y,pg,q,ttlNumSym);
    txVec(q,p) = tx;
    rxVec(q,p) = rx;
end

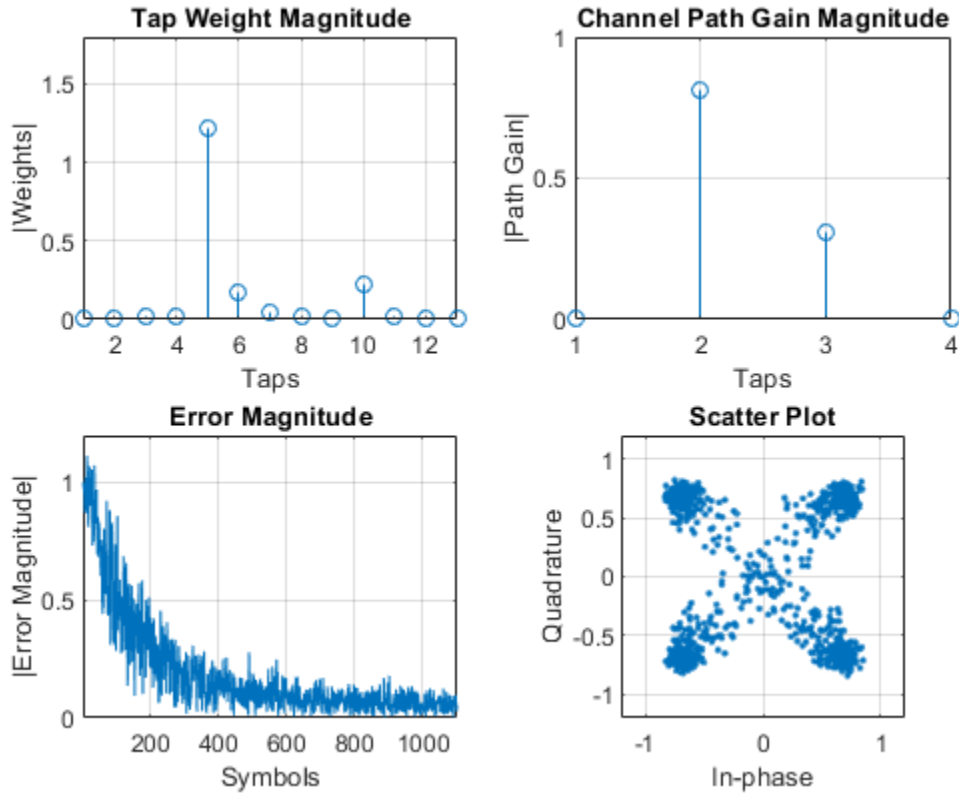

```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```

    reset(raylChan)
    reset(dfreq1)
end

```

### Packet-Based Processing

For packet-based processing, provide one packet at the input of the equalizer. Each packet contains `tllNumSym` symbols. Because the training duration is less than the packet length, you do not need to specify the start-training input.

```
yVecPkt = zeros(tllNumSym,numPackets);
errVecPkt = zeros(tllNumSym,numPackets);
wgtVecPkt = zeros(tllTaps,numPackets);
dfeq2 = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',nFwdTaps,'NumFeedbackTaps',nFdbkTaps,'ReferenceTap',refTap, ...
    'StepSize',stepsz);
for p = 1:numPackets
    [yVecPkt(:,p),errVecPkt(:,p),wgtVecPkt(:,p)] = ...
```

```

dfeq2(rxVec(:,p),txVec(1:numTrainingSym,p));
for q=1:t1NumSym
    updateFigures(errPlot,wStem,hStem,scatPlot, ...
        errVecPkt(q,p),wgtVecPkt(:,p),yVecPkt(q,p),pg,q,t1NumSym);
end

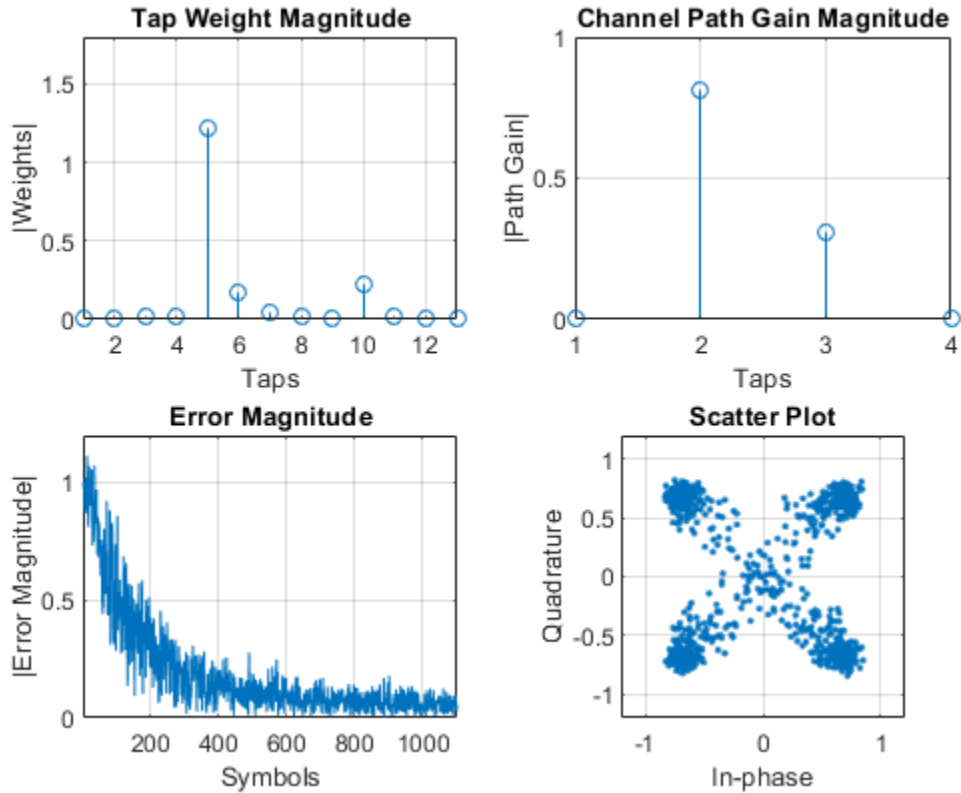

```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```

reset(raylChan)
reset(dfreq2)
end

```

## Helper Functions

This helper function initializes the figures.

```
function [errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,tllTap,pg)
yVec = nan(ttlNumSym,1);
eVec = nan(ttlNumSym,1);
wVec = zeros(tllTap,1);
figure;
subplot(2,2,1);
wStem = stem(wVec);
axis([1 tllTap 0 1.8]); grid on
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')
subplot(2,2,2);
hStem = stem([0 abs(pg) 0]);
grid on;
xlabel('Taps'); ylabel('|Path Gain|'); title('Channel Path Gain Magnitude')
subplot(2,2,3);
errPlot = plot(eVec);
axis([1 ttlNumSym 0 1.2]); grid on
xlabel('Symbols'); ylabel('|Error Magnitude|'); title('Error Magnitude')
subplot(2,2,4);
scatPlot = plot(yVec, '.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on;
xlabel('In-phase'); ylabel('Quadrature'); title(sprintf('Scatter Plot'));
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,wStem,hStem,scatPlot, ...
    err,wts,y,pg,p,ttlNumSym)
persistent yVec eVec
if p == 1
    yVec = nan(ttlNumSym,1);
    eVec = nan(ttlNumSym,1);
end
yVec(p) = y;
eVec(p) = abs(err);
errPlot.YData = abs(eVec);
wStem.YData = abs(wts);
hStem.YData = [0 abs(pg) 0];
scatPlot.XData = real(yVec);
scatPlot.YData = imag(yVec);
```

```
drawnow limitrate  
end
```

## More About

### Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbol-spaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

## Algorithms

### Decision Feedback Equalizers

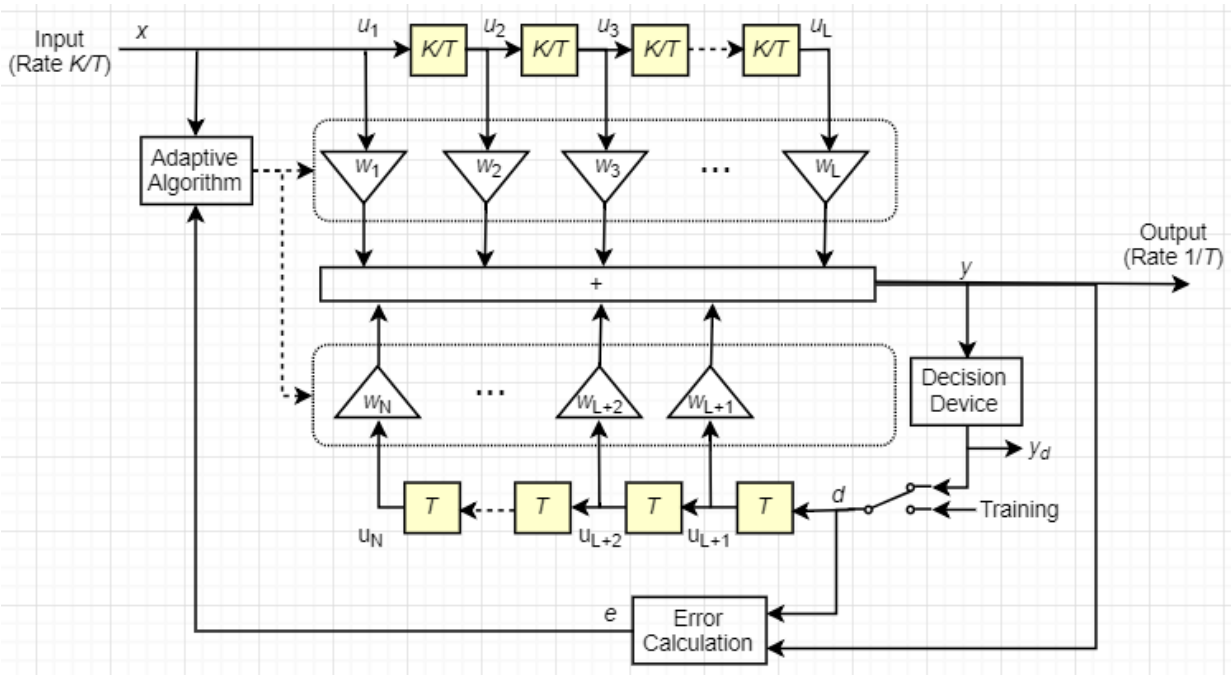

A decision feedback equalizer (DFE) is a nonlinear equalizer that reduces intersymbol interference (ISI) in frequency-selective channels. If a null exists in the frequency response of a channel, DFEs do not enhance the noise. A DFE consists of a tapped delay line that stores samples from the input signal and contains a forward filter and a feedback filter. The forward filter is similar to a linear equalizer. The feedback filter contains a tapped delay line whose inputs are the decisions made on the equalized signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

DFEs can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol,  $K$ , is 1. The output sample rate equals the input sample rate.

- For a fractional symbol-spaced equalizer, the number of samples per symbol,  $K$ , is an integer greater than 1. Typically,  $K$  is 4 for fractional symbol-spaced equalizers. The output sample rate is  $1/T$  and the input sample rate is  $K/T$ . Tap weight updating occurs at the output rate.

This schematic shows a fractional symbol-spaced DFE with a total of  $N$  weights, a symbol period of  $T$ , and  $K$  samples per symbol. The filter has  $L$  forward weights and  $N-L$  feedback weights. The forward filter is at the top, and the feedback filter is at the bottom. If  $K$  is 1, the result is a symbol-spaced DFE instead of a fractional symbol-spaced DFE.

In each symbol period, the equalizer receives  $K$  input samples at the forward filter and one decision or training sample at the feedback filter. The equalizer then outputs a weighted sum of the values in the forward and feedback delay lines and updates the weights to prepare for the next symbol period.

**Note** The algorithm for the Adaptive Algorithm block in the schematic jointly optimizes the forward and feedback weights. Joint optimization is especially important for convergence in the recursive least square (RLS) algorithm.

For more information, see “Equalization”.

## Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic,  $w$  is a vector of all weights  $w_i$ , and  $u$  is a vector of all inputs  $u_i$ . Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (\text{StepSize}) u^*e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the `maxstep` object function. The  $*$  operator denotes the complex conjugate and the error calculation  $e = d - y$ .

## Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic,  $w$  is the vector of all weights  $w_i$ , and  $u$  is the vector of all inputs  $u_i$ . Based on the current set of inputs,  $u$ , and the inverse correlation matrix,  $P$ , the RLS algorithm first computes the Kalman gain vector,  $K$ , as

$$K = \frac{Pu}{(\text{ForgettingFactor}) + u^H Pu}.$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable.  $H$  denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$P_{\text{new}} = \frac{P_{\text{current}}(1 - Ku^H)}{\text{ForgettingFactor}}.$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + K^*e.$$

The  $*$  operator denotes the complex conjugate and the error calculation  $e = d - y$ .

## Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic,  $w$  is the vector of all weights  $w_i$ , and  $u$  is the vector of all inputs  $u_i$ . Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (\text{StepSize}) u^*e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the `maxstep` object function. The `*` operator denotes the complex conjugate and the error calculation  $e = y(R - |y|^2)$ , where  $R$  is a constant related to the signal constellation.

# info

**Package:** comm

Characteristic information about the equalizer object

## Syntax

```
infostruct = info(obj)
```

## Description

`infostruct = info(obj)` returns a structure containing characteristic information for the System object.

## Input Arguments

**obj** — System object to get information from

System object

System object to get information from.

## Output Arguments

**infostruct** — Structure containing object information

struct

Structure containing fields with information about the System object.

**Latency** — Equalizer latency

scalar

Equalizer latency, returned as a scalar.

## maxstep

**Package:** comm

Maximum step size for LMS equalizer convergence

## Syntax

```
mumax = maxstep(eq,x)
```

## Description

`mumax = maxstep(eq,x)` predicts a bound on the step size to provide convergence of the mean values of the coefficients of the equalizer defined by the `eq` System object. The set input signal sequences in `x` are assumed to have zero mean or nearly so.

## Examples

### Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03.

```
bpsk = comm.BPSKModulator;  
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...  
      'NumForwardTaps',8,'NumFeedbackTaps',5,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqdfe_lms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));  
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms, rxsig)
```

```
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig, x(1:200));
```

## Input Arguments

### **eq** — Equalizer object

System object

Equalizer object, specified as a `comm.LinearEqualizer` or `comm.DecisionFeedbackFEqualizer` System object.

### **x** — Input signal

column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the `InputSamplesPerSymbol` property. For more information, see “Symbol Tap Spacing” on page 4-664.

Data Types: `double`

Complex Number Support: Yes

## Output Arguments

### **mumax** — Prediction of maximum step size for LMS equalizer convergence

scalar

Prediction of maximum step size for LMS equalizer convergence, returned as a scalar.

# mmseweights

**Package:** comm

Linear equalizer MMSE tap weights

## Syntax

```
weights = mmse(eq,chTaps,EbN0)
```

## Description

`weights = mmse(eq,chTaps,EbN0)` calculated minimum mean squared error (MMSE) solution for the linear equalizer, `eq` System object given the channel delay taps, `chTaps`, and signal to noise ratio, `EbN0`.

## Examples

### Calculate MMSE Weights for Linear Equalizer

Calculate the minimum mean squared error (MMSE) solution and use the weights for the linear equalizer taps weights.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(cktaps,1,tx),25,'measured');
```

Create a linear equalizer System object configured to use CMA algorithm and input the taps weights. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer('Algorithm','CMA','AdaptWeights',false,'InitialWeightsSource
```

```
eq =
comm.LinearEqualizer with properties:
```

```
    Algorithm: 'CMA'
    NumTaps: 5
    StepSize: 0.0100
    Constellation: [1x4 double]
    InputSamplesPerSymbol: 1
    AdaptWeightsSource: 'Property'
    AdaptWeights: false
    InitialWeightsSource: 'Property'
    InitialWeights: [5x1 double]
    WeightUpdatePeriod: 1
```

```
wgts = mmseweights(eq,cktaps,EbN0)
```

```
wgts = 5x1 complex
```

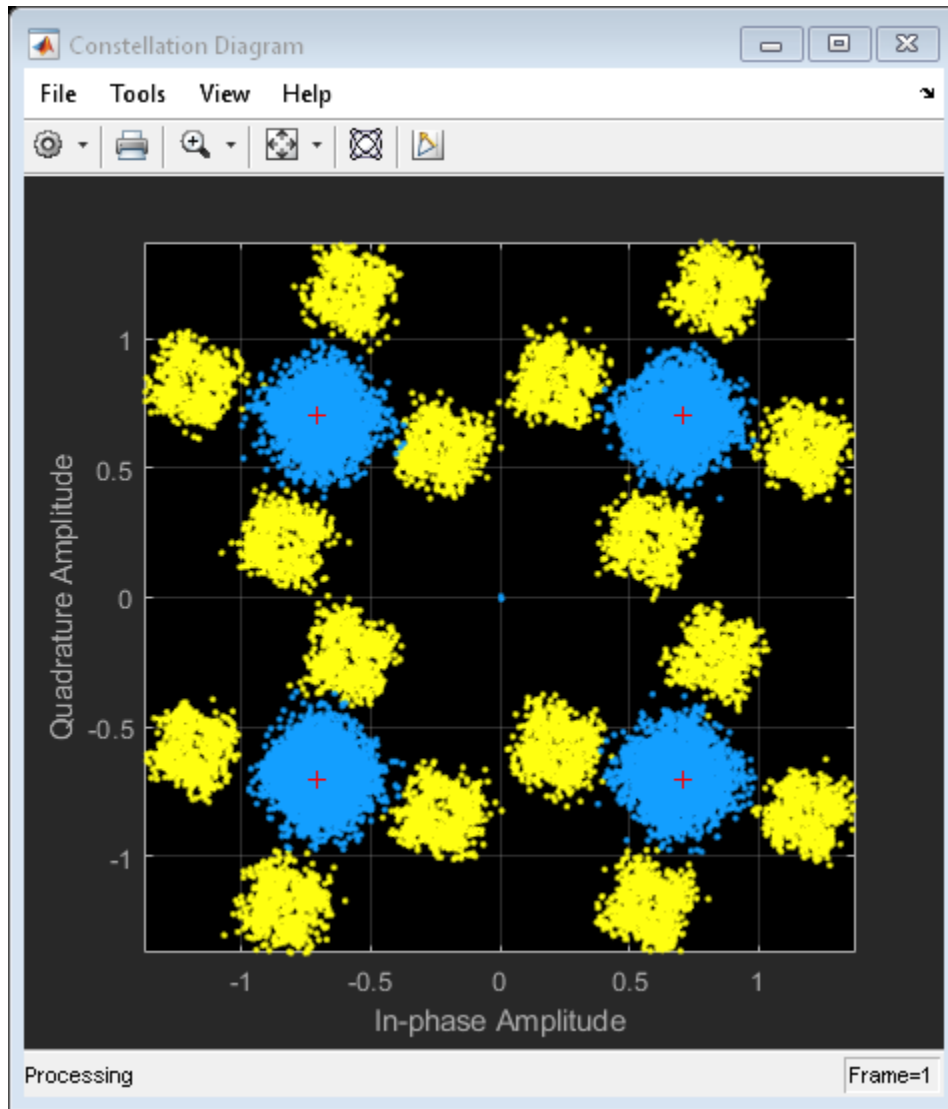

```
0.0005 - 0.0068i
0.0103 + 0.0117i
0.9694 - 0.0019i
-0.3987 + 0.2186i
0.0389 - 0.1756i
```

```
eq.InitialWeights = wgts;
```

```
[y,err,weights] = eq(rx);
```

Plot constellation of impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y)
```

Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))  
grid on; xlabel('Symbols'); ylabel('|e|')
```

```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 140.6177
```

Plot equalizer tap weights.

```
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on;
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on;
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
subplot(3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on;
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
```

## Input Arguments

### **eq** — Equalizer object

System object

Equalizer object, specified as a `comm.LinearEqualizer` System object.

### **chTaps** — Channel delay taps

vector

Channel delay taps, specified as a vector.

Data Types: double  
Complex Number Support: Yes

**EbN0 — Signal to noise ratio**  
scalar

Signal to noise ratio of the channel, specified as a scalar.

Data Types: double

## Output Arguments

**weights — Weights for linear equalizer**  
vector

Weights for linear equalizer, returned as a vector.

# comm.EVM

**Package:** comm

Measure error vector magnitude

## Description

The `comm.EVM` (error vector magnitude) System object measures the modulator or demodulator performance of an impaired signal.

To measure error vector magnitude:

- 1 Define and set up your EVM object. See “Construction” on page 4-679.
- 2 Call `step` to measure the modulator or demodulator performance according to the properties of `comm.EVM`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`EVM = comm.EVM` creates an error vector magnitude object, `EVM`. This object measures the amount of impairment in a modulated signal.

`EVM = comm.EVM(Name, Value)` creates an EVM object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

**Example:** `EVM = comm.EVM('ReferenceSignalSource', 'Estimated from reference constellation')` creates an object, `EVM`, that measures the RMS EVM of a received signal by using a reference constellation.

## Properties

### Normalization

Normalization method

Normalization method used in EVM calculation, specified as one of the following: 'Average reference signal power' (default), 'Average constellation power', or 'Peak constellation power'.

### AverageConstellationPower

Average constellation power

Average constellation power, specified in watts as a positive real scalar. This property is available when Normalization is 'Average constellation power'. The default is 1.

### PeakConstellationPower

Peak constellation power

Peak constellation power, specified in watts as a positive real scalar. This property is available when Normalization is 'Peak constellation power'. The default is 1.

### ReferenceSignalSource

Reference signal source

Reference signal source, specified as either 'Input port' (default) or 'Estimated from reference constellation'. To provide an explicit reference signal against which the input signal is measured, set this property to 'Input port'. To measure the EVM of the input signal against a reference constellation, set this property to 'Estimated from reference constellation'.

### ReferenceConstellation

Reference constellation

Reference constellation, specified as a vector. This property is available when the ReferenceSignalSource property is 'Estimated from reference constellation'.

The default is  $[0.7071 - 0.7071i; -0.7071 - 0.7071i; -0.7071 + 0.7071i; 0.7071 + 0.7071i]$ , which corresponds to a standard QPSK constellation. You can derive constellation points by using modulation functions or objects. For example, to derive the reference constellation for a 16-QAM signal, you can use `qammod(0:15,16)`.

### **MeasurementIntervalSource**

Measurement interval source

Measurement interval source, specified as one of the following: 'Input length' (default), 'Entire history', 'Custom', or 'Custom with periodic reset'. This property affects the RMS and maximum EVM outputs only.

- To calculate EVM using only the current samples, set this property to 'Input length'.
- To calculate EVM for all samples, set this property to 'Entire history'.
- To calculate EVM over an interval you specify and to use a sliding window, set this property to 'Custom'.
- To calculate EVM over an interval you specify and to reset the object each time the measurement interval is filled, set this property to 'Custom with periodic reset'.

### **MeasurementInterval**

Measurement interval

Measurement interval over which the EVM is calculated, specified in samples as a real positive integer. This property is available when `MeasurementIntervalSource` is 'Custom' or 'Custom with periodic reset'. The default is 100.

### **AveragingDimensions**

Averaging dimensions

Averaging dimensions, specified as a positive integer or row vector of positive integers. This property determines the dimensions over which the averaging is performed. For example, to average across the rows, set this property to 2. The default is 1.

The object supports variable-size inputs over the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must remain constant between step calls. For example, if the input has size  $[4 \ 3 \ 2]$  and `Averaging`

dimensions is [1 3], the output size is [1 3 1], and the second dimension must remain fixed at 3.

### **MaximumEVMOutputPort**

Maximum EVM measurement output port

Maximum EVM measurement output port, specified as a logical scalar. To create an output port for maximum EVM measurements, set this property to `true`. The default is `false`.

### **XPercentileEVMOutputPort**

X-percentile EVM measurement output port

X-percentile EVM measurement output port, specified as a logical scalar. To create an output port for X-percentile EVM measurements, set this property to `true`. The X-percentile EVM measurements persist until you reset the object. These measurements are calculated by using all of the input frames since the last reset. The default is `false`.

### **XPercentileValue**

X-percentile value

X-percentile value below which X% of the EVM measurements fall, specified as a real scalar from 0 to 100. This property is available when `XPercentileEVMOutputPort` is `true`. The default is 95.

### **SymbolCountOutputPort**

Symbol count output port

Symbol count output port, specified as a logical scalar. To output the number of accumulated symbols used to calculate the X-percentile EVM measurements, set this property to `true`. This property is available when `XPercentileEVMOutputPort` is `true`. The default is `false`.

## Methods

reset      Reset states of EVM measurement object  
 step        Measure error vector magnitude

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Measure EVM of Noisy 16-QAM Modulated Signal

Create an EVM object. Configure it using name-value pairs to output maximum EVM, 90th percentile EVM, and the symbol count.

```
evm = comm.EVM('MaximumEVMOutputPort',true,...
              'XPercentileEVMOutputPort',true, 'XPercentileValue',90,...
              'SymbolCountOutputPort',true);
```

Generate random data symbols. Apply 16-QAM modulation. The modulated signal serves as the reference for the subsequent EVM measurements.

```
data = randi([0 15],1000,1);
refSym = qammod(data,16,'UnitAveragePower',true);
```

Pass the modulated signal through an AWGN channel.

```
rxSym = awgn(refSym,20);
```

Measure the EVM of the noisy signal.

```
[rmsEVM,maxEVM,pctEVM,numSym] = evm(refSym,rxSym)
```

```
rmsEVM = 9.8775
```

```
maxEVM = 26.8385
```

```
pctEVM = 14.9750
```

```
numSym = 1000
```

### Estimate Received EVM

Generate filtered QAM data and pass it through an AWGN channel. Compute the symbol error rate, and estimate the EVM of the received signal.

Create channel and filter System objects™.

```
M = 16;
refConst = qammod(0:M-1,M);
channel = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)',...
    'SNR',15,'SignalPower',10);

txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',4);
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',4, ...
    'DecimationFactor',4);
```

Create an EVM object to output RMS and maximum EVM measurements.

```
evm = comm.EVM('MaximumEVMOutputPort',true, ...
    'ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst);
```

Create an error rate object and account for the signal delay through the transmit and receive filters. For a filter, the group delay is equal to 1/2 of the FilterSpanInSymbols property.

```
rxd = (txfilter.FilterSpanInSymbols + rxfilter.FilterSpanInSymbols)/2;
errorRate = comm.ErrorRate('ReceiveDelay',rxd);
```

Perform the following channel operations:

- Generate random data symbols.
- Apply 16-QAM modulation.
- Filter the modulated data through a raised cosine Tx filter.
- Pass the transmitted signal through an AWGN channel.
- Filter the received data through a raised cosine Rx filter.
- Demodulate the filtered data.

```
txData = randi([0 15],1000,1);
modData = qammod(txData,M);
```

```
txSig = txfilter(modData);
rxSig = channel(txSig);
filtSig = rxfilter(rxSig);
rxData = qamdemod(filtSig,M);
```

Calculate the error statistics and display the symbol error rate.

```
errStats = errorRate(txData,rxData);
symErrRate = errStats(1)
```

```
symErrRate = 0.0222
```

Measure and display the received RMS EVM and maximum EVM values. Take the filter delay into account by deleting the first `rxd+1` symbols. Because there are symbol errors, the EVM may not be totally accurate.

```
[rmsEVM,maxEVM] = evm(filtSig(rxd+1:end))
```

```
rmsEVM = 17.2966
```

```
maxEVM = 40.1595
```

## Measure EVM Using Reference Constellation

Generate random data symbols, and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);
txSig = pskmod(d,8,pi/8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,30);
```

Create an EVM object. Measure the RMS EVM using the transmitted signal as the reference.

```
evm = comm.EVM;
rmsEVM1 = evm(txSig,rxSig);
```

Release the EVM object. Configure the object to estimate the EVM of the received signal against a reference constellation.

```
release(evm)
evm.ReferenceSignalSource = 'Estimated from reference constellation';
evm.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Measure the RMS EVM using only the received signal as an input. Verify that it matches the result obtained when using a reference signal.

```
rmsEVM2 = evm(rxSig);
[rmsEVM1 rmsEVM2]
```

```
ans = 1×2
```

```
    3.1524    3.1524
```

### Measure EVM Using Custom Measurement Interval

Measure the EVM of a noisy 8-PSK signal using two types of custom measurement intervals. Display the results.

Set the number of frames,  $M$ , and the number of subframes per frame,  $K$ .

```
M = 2;
K = 5;
```

Set the number of symbols in a subframe. Calculate the corresponding frame length.

```
sfLen = 100;
frmLen = K*sfLen
```

```
frmLen = 500
```

Create an EVM object. Configure the object to use a custom measurement interval equal to the frame length.

```
evm1 = comm.EVM('MeasurementIntervalSource','Custom', ...
    'MeasurementInterval',frmLen);
```

Configure the object to measure EVM using an 8-PSK reference constellation.

```
evm1.ReferenceSignalSource = 'Estimated from reference constellation';
evm1.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Create an EVM object, and configure it use a 500-symbol measurement interval with a periodic reset. Configure the object to measure EVM using an 8-PSK reference constellation.

```
evm2 = comm.EVM('MeasurementIntervalSource','Custom with periodic reset', ...
    'MeasurementInterval',frmLen);
evm2.ReferenceSignalSource = 'Estimated from reference constellation';
evm2.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Initialize the EVM and signal-to-noise arrays.

```
rmsEVM1 = zeros(K,M);
rmsEVM2 = zeros(K,M);
snrdB = zeros(K,M);
```

Measure the EVM for a noisy 8-PSK signal using both objects. The SNR increases by 1 dB from subframe to subframe. For `evm1`, the 500 most recent symbols are used to compute the estimate. In this case, a sliding window is used so that an entire frame of data is always processed. For `evm2`, the symbols are cleared each time a new frame is encountered.

```
for m = 1:M
    for k = 1:K
        data = randi([0 7],sfLen,1);
        txSig = pskmod(data,8,pi/8);
        snrdB(k,m) = k+(m-1)*K+7;
        rxSig = awgn(txSig,snrdB(k,m));
        rmsEVM1(k,m) = evm1(rxSig);
        rmsEVM2(k,m) = evm2(rxSig);
    end
end
```

Display the EVM measured using the two approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the EVM object resets after the first frame so that the calculated EVM values more accurately reflect the current SNR.

```
stairs(snrdB(:),[rmsEVM1(:) rmsEVM2(:)])
xlabel('SNR (dB)')
ylabel('EVM (%)')
legend('No Reset', 'Periodic Reset')
```

### Measure EVM Across Different Dimensions

Create OFDM modulator and demodulator objects.

```
ofdmmod = comm.OFDMModulator('FFTLength',32,'NumSymbols',4);  
ofdm demod = comm.OFDMDemodulator('FFTLength',32,'NumSymbols',4);
```

Determine the number of subcarriers and symbols in the OFDM signal.

```
ofdmDims = info(ofdmmod);  
numSC = ofdmDims.DataInputSize(1)
```

```

numSC = 21
numSym = ofdmDims.DataInputSize(2)
numSym = 4

```

Generate random symbols and apply QPSK modulation.

```

msg = randi([0 3],numSC,numSym);
modSig = pskmod(msg,4,pi/4);

```

OFDM modulate the QPSK signal. Pass the signal through an AWGN channel. Demodulate the noisy signal.

```

txSig = ofdmmod(modSig);
rxSig = awgn(txSig,10,'measured');
demodSig = ofdmdemod(rxSig);

```

Create an EVM object, where the result is averaged over the subcarriers. Measure the EVM. There are four entries corresponding to each of the 4 OFDM symbols.

```

evm = comm.EVM('AveragingDimensions',1);
rmsEVM = evm(demodSig,modSig)

```

```

rmsEVM = 1×4

```

```

    27.4354    23.6279    22.6772    23.1699

```

Overwrite the EVM object, where the result is averaged over the OFDM symbols. Measure the EVM. There are 21 entries corresponding to each of the 21 subcarriers.

```

evm = comm.EVM('AveragingDimensions',2);
rmsEVM = evm(demodSig,modSig)

```

```

rmsEVM = 21×1

```

```

    28.8225
    17.8536
    18.6809
    20.8872
    22.3532
    24.7197
    30.1954
    33.4899
    36.2847

```

```
21.4230
   :
```

Measure the EVM and average over both the subcarriers and the OFDM symbols.

```
evm = comm.EVM('AveragingDimensions',[1 2]);
rmsEVM = evm(demodSig,modSig)

rmsEVM = 24.2986
```

### Plot Time-Varying EVM for OFDM Signal

Calculate and plot the EVM of an OFDM signal. The signal consists of two packets separated by an interval.

Create System objects to:

- OFDM modulate a signal
- Introduce phase noise
- Plot time-varying signals

```
ofdmmod = comm.OFDMModulator('FFTLength',256,'NumSymbols',2);

pnoise = comm.PhaseNoise('Level',-60,'FrequencyOffset',20,'SampleRate',1000);

tscope = dsp.TimeScope('YLabel','EVM (%)','YLimits',[0 40], ...
    'SampleRate',1000,'TimeSpan',1.2, ...
    'ShowGrid',true);
```

Create an EVM object. To generate a time-varying estimate of the EVM, set the AveragingDimensions property to 2.

```
evm = comm.EVM('MaximumEVMOutputPort',false, ...
    'ReferenceSignalSource','Input port', ...
    'AveragingDimensions',2);
```

Determine the input data dimensions of the OFDM modulator.

```
modDims = info(ofdmmod)

modDims =
```

struct with fields:

```
DataInputSize: [245 2]  
OutputSize: [544 1]
```

Create QPSK-modulated random data for the first packet. Apply OFDM modulation.

```
data = randi([0 3],modDims.DataInputSize);  
qpskSig = pskmod(data,4,pi/4);  
txSig1 = ofdmmod(qpskSig);
```

Create a second data packet.

```
data = randi([0 3],modDims.DataInputSize);  
qpskSig = pskmod(data,4,pi/4);  
txSig2 = ofdmmod(qpskSig);
```

Concatenate the two packets and include an interval in which nothing is transmitted.

```
txSig = [txSig1; zeros(112,1); txSig2];
```

Apply I/Q amplitude and phase imbalance to the transmitted signal.

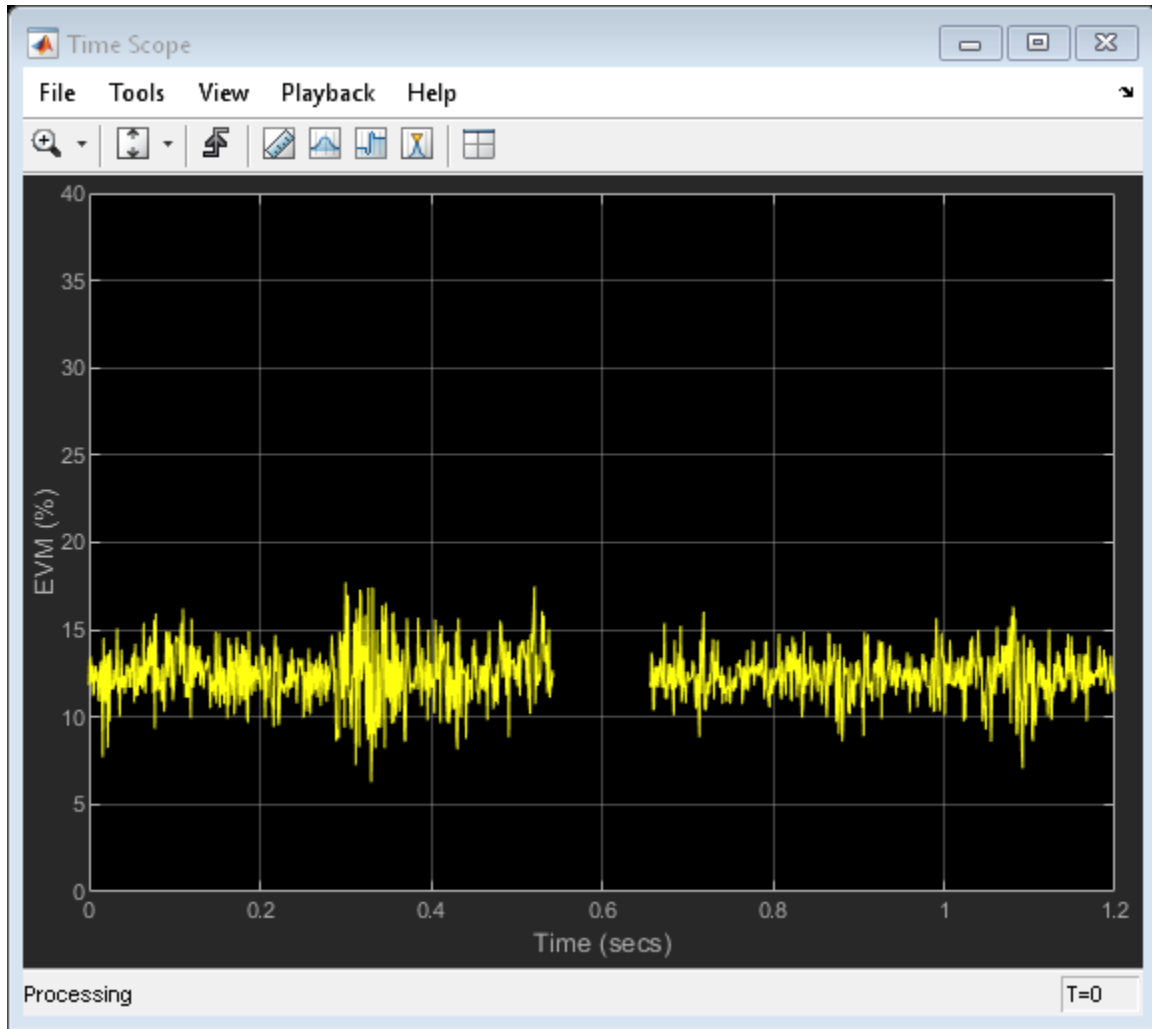

```
rxSigIQimb = iqimbal(txSig,2,5);
```

Apply phase noise.

```
rxSig = pnoise(rxSigIQimb);
```

Measure the EVM of the received signal, and plot its time-varying EVM.

```
e = evm(txSig,rxSig);  
tscope(e)
```

## Algorithms

Both the EVM block and the EVM object provide three normalization methods. You can normalize measurements according to the average power of the reference signal, average

constellation power, or peak constellation power. Different industry standards follow one of these normalization methods.

The block or object calculates the RMS EVM value differently for each normalization method.

EVM Normalization Method	Algorithm
Reference signal	$EVM_{RMS} = \sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{\frac{1}{N} \sum_{k=1}^N (I_k^2 + Q_k^2)}} * 100$
Average power	$EVM_{RMS}(\%) = 100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{avg}}}$
Peak power	$EVM_{RMS}(\%) = 100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{max}}}$

Where:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- $I_k$  = In-phase measurement of the  $k$ th symbol in the burst
- $Q_k$  = Quadrature phase measurement of the  $k$ th symbol in the burst
- $N$  = Input vector length
- $P_{avg}$  = The value for **Average constellation power**
- $P_{max}$  = The value for **Peak constellation power**
- $I_k$  and  $Q_k$  represent ideal (reference) values.  $\tilde{I}_k$  and  $\tilde{Q}_k$  represent measured (received) symbols.

The max EVM is the maximum EVM value in a frame or  $EVM_{max} = \max_{k \in [1, \dots, N]} \{EVM_k\}$ , where  $k$  is the  $k$ th symbol in a burst of length  $N$ .

The definition for  $EVM_k$  varies depending upon which normalization method you select for computing measurements. The block or object supports these algorithms.

EVM Normalization	Algorithm
Reference signal	$EVM_k = \sqrt{\frac{e_k}{\frac{1}{N} \sum_{k=1}^N (I_k^2 + Q_k^2)}} * 100$
Average power	$EVM_k = 100 \sqrt{\frac{e_k}{P_{avg}}}$
Peak power	$EVM_k = 100 \sqrt{\frac{e_k}{P_{max}}}$

The block or object computes the  $X$ -percentile EVM by creating a histogram of all the incoming  $EVM_k$  values. The output provides the EVM value below which  $X\%$  of the EVM values fall.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2012a**

## reset

**System object:** comm.EVM

**Package:** comm

Reset states of EVM measurement object

## Syntax

reset(H)

## Description

reset(H) resets the states of the EVM object, H.

# step

**System object:** comm.EVM

**Package:** comm

Measure error vector magnitude

## Syntax

```
RMSEVM = step(EVM,REFSYM,RXSYM)
```

```
RMSEVM = step(EVM,RXSYM)
```

```
[ ____,MAXEVM] = step( ____ )
```

```
[ ____,XEVM] = step( ____ )
```

```
[ ____,NUMSYM] = step( ____ )
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`RMSEVM = step(EVM,REFSYM,RXSYM)` returns the measured root-mean-square EVM, `RMSEVM`, of the received signal `RXSYM`, based on reference signal `REFSYM`. EVM values are measured as a percentage.

`REFSYM` and `RXSYM` inputs are complex column vectors of equal dimensions and data type. The data type can be double, single, signed integer, or signed fixed point with power-of-two slope and zero bias. All outputs of the object are of data type double. To set the interval over which the EVM is measured, use the `MeasurementIntervalSource` and `MeasurementInterval` properties.

`RMSEVM = step(EVM,RXSYM)` returns the measured EVM of received signal `RXSYM` based on a reference signal specified in the `ReceivedConstellation` property.

---

[ \_\_\_\_, MAXEVM] = step( \_\_\_\_ ) returns the maximum EVM, MAXEVM, given either of the two previous syntaxes.

To return the maximum EVM value, set the `MaximumEVMOutputPort` property to `true`. To set the interval over which the maximum EVM is measured, use the `MeasurementIntervalSource` and `MeasurementInterval` properties.

[ \_\_\_\_, XEVM] = step( \_\_\_\_ ) returns the X-percentile EVM, XEVM.

To return the X-percentile EVM, set the `XPercentileEVMOutputPort` property to `true`. XEVM is the EVM below which X% of the measurements fall, where X is set by the `XPercentileValue` property. XEVM is measured using all the input frames since the last reset.

[ \_\_\_\_, NUMSYM] = step( \_\_\_\_ ) returns the number of symbols, NUMSYM, used to calculate the X-percentile EVM.

To return NUMSYM, set the `SymbolCountOutputPort` property to `true`. NUMSYM is measured using all the input frames since the last reset.

---

**Note** EVM specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.EyeDiagram

**Package:** comm

Display eye diagram of time-domain signals

### Description

The eye diagram System object displays multiple traces of a modulated signal to produce an eye diagram. You can use the object to reveal the modulation characteristics of the signal, such as the effects of pulse shaping or channel distortions. The eye diagram can measure signal characteristics and plot horizontal and vertical bathtub curves when the jitter and noise comply with the dual-Dirac model [1].

To display the eye diagram of an input signal:

- 1 Create a `comm.EyeDiagram` object and set the properties of the object.
- 2 Call `step` to display the eye diagram of the signal.

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`ed = comm.EyeDiagram` returns an eye diagram object, `ed`, using the default properties.

`ed = comm.EyeDiagram(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

**Example:**

```
ed = comm.EyeDiagram('DisplayMode','2D color histogram', ...  
                    'OversamplingMethod','Input interpolation');
```

## Properties

### **Name — Caption to display on the eye diagram window**

'Eye Diagram' (default) | character vector

Name displayed on the eye diagram window, specified as a character vector. Tunable.

### **SampleRate — Input signal sample rate (Hz)**

1 (default) | positive scalar

Sample rate of the input signal in Hz, specified as a positive real scalar.

### **SamplesPerSymbol — Number of samples per symbol**

8 (default) | positive integer scalar

Number of samples per symbol, specified as a positive integer scalar. Tunable.

### **SampleOffset — Number of samples to omit before plotting the first point**

0 (default) | nonnegative integer scalar

Number of samples to omit before plotting the first point, specified as a nonnegative integer scalar. To avoid irregular behavior, specify the offset to be less than the product of `SamplesPerSymbol` and `SamplePerTrace`.

### **SymbolsPerTrace — Number of symbols per trace**

2 (default) | positive integer scalar

Number of symbols per trace, specified as a positive integer scalar. To obtain eye measurements and visualize bathtub curves, use the default value of 2. Tunable.

### **TracesToDisplay — Number of traces to display**

40 (default) | positive integer scalar

Number of traces to display, specified as a positive integer scalar. This property is available when the `DisplayMode` property is specified as 'Line plot'. Tunable.

### **DisplayMode — Eye diagram display mode**

'Line plot' (default) | '2D color histogram'

Eye diagram display mode, specified as 'Line plot' or '2D color histogram'. Tunable.

- Specify 'Line plot' to overlay traces by plotting one line for each of the last `TracesToDisplay` traces.
- Specify '2D color histogram' to display a color gradient that shows how often the input matches different time and amplitude values.

### **EnableMeasurements — Enable eye diagram measurements**

false (default) | true

Enable eye diagram measurements, specified as a logical scalar. Tunable.

### **ShowBathtub — Enable visualization of bathtub curves**

'None' (default) | 'Horizontal' | 'Vertical' | 'Both'

Enable visualization of bathtub curves, specified as 'None', 'Horizontal', 'Vertical', or 'Both'. This property is available when `EnableMeasurements` is true. Tunable.

### **OverlayHistogram — Histogram overlay**

'None' (default) | 'Jitter' | 'Noise'

Histogram overlay, specified as 'None', 'Jitter', or 'Noise'.

- To overlay a horizontal histogram on the eye diagram, set this property to 'Jitter'.
- To overlay a vertical histogram on the eye diagram, set this property to 'Noise'.

This property is available when `DisplayMode` is '2D color histogram' and `EnableMeasurements` is true. Tunable.

### **DecisionBoundary — Amplitude level threshold**

0 (default) | scalar

Amplitude level threshold in V, specified as a scalar. This property separates the different signaling regions for horizontal (jitter) histograms, and is available when `EnableMeasurements` is true. This property is tunable, but the jitter histograms reset when the property changes.

For non-return-to-zero (NRZ) signals, set `DecisionBoundary` to 0. For return-to-zero (RZ) signals, set `DecisionBoundary` to half the maximum amplitude.

### **EyeLevelBoundaries — Time range for calculating eye levels**

[40 60] (default) | vector

Time range for calculating eye levels, specified as a two-element vector. These values are expressed as a percentage of the symbol duration. This property is available when `EnableMeasurements` is `true`. Tunable.

### **RiseFallThresholds — Amplitude levels of the rise and fall transitions**

[10 90] (default) | vector

Amplitude levels of the rise and fall transitions, specified as a two-element vector. These values are expressed as a percentage of the eye amplitude. This property is available when `EnableMeasurements` is `true`. This property is tunable but the crossing histograms of the rise and fall thresholds reset when it is changed.

### **Hysteresis — Amplitude tolerance of the horizontal crossings**

0 (default) | scalar

Amplitude tolerance of the horizontal crossings in  $V$ , specified as a scalar. Increase hysteresis to provide more tolerance to spurious crossings due to noise. This property is available when `EnableMeasurements` is `true`. This property is tunable, but the jitter and the rise and fall histograms reset when the property changes.

### **BERThreshold — BER used for eye measurements**

1e-12 (default) | nonnegative scalar from 0 to 0.5

BER used for eye measurements, specified as a nonnegative scalar from 0 to 0.5. The value is used to make measurements of random jitter, total jitter, horizontal eye openings, and vertical eye openings. This property is available when `EnableMeasurements` is `true`. Tunable.

### **BathtubBER — BER values used to calculate openings of bathtub curves**

[0.5 10.^-(1:12)] | vector

BER values used to calculate openings of bathtub curves, specified as a vector whose elements range from 0 to 0.5. Horizontal and vertical eye openings are calculated for each of the values specified by this property. This property is available when `EnableMeasurements` is `true` and `ShowBathtub` is `'Both'`, `'Horizontal'`, or `'Vertical'`. Tunable.

### **MeasurementDelay — Duration of initial data discarded from measurements**

0 (default) | nonnegative scalar

Duration of initial data discarded from measurements in seconds, specified as a nonnegative scalar. This property is available when `EnableMeasurements` is `true`.

### **OversamplingMethod — Oversampling method**

'None' (default) | 'Input interpolation' | 'Histogram interpolation'

Oversampling method, specified as 'None', 'Input interpolation', or 'Histogram interpolation'. This property is available when `DisplayMode` is '2D color histogram'. Tunable.

To plot eye diagrams as quickly as possible, set `OversamplingMethod` to 'None'. The drawback to not oversampling is that the plots look pixelated when the number of samples per trace is small.

To create smoother, less-pixelated plots using a small number of samples per trace, set `OversamplingMethod` to 'Input interpolation' or 'Histogram interpolation'. Input interpolation is the faster interpolation method and produces good results when the signal-to-noise ratio (SNR) is high. With a lower SNR, this oversampling method is not recommended because it introduces a bias to the centers of the histogram ranges. Histogram interpolation is not as fast as the other techniques, but it provides good results even when the SNR is low.

### **ColorScale — Color scale of the histogram**

'Linear' (default) | 'Logarithmic'

Color scale of the histogram, specified as 'Linear' or 'Logarithmic'. Change this property if certain areas of the histogram include a disproportionate number of points. Use the 'Logarithmic' option for eye diagrams having sharp peaks, where the signal repetitively matches specific time and amplitude values. This property is available when `DisplayMode` is '2D color histogram'. Tunable.

### **ColorFading — Color fading**

false (default) | true

Color fading, specified as a logical scalar. To fade the points in the display as the interval of time after they are first plotted increases, set this property to `true`. This animation resembles an oscilloscope. This property is available when `DisplayMode` is 'Line plot'. Tunable.

### **ShowImaginaryEye — Show imaginary signal component**

false (default) | true

Show imaginary signal component, specified as a logical scalar. To view the imaginary or quadrature component of the input signal, set this property to `true`. This property is available when `EnableMeasurements` is `false`. Tunable.

**YLimits — Y-axis limits**

[-1.1 1.1] (default) | two-element vector

Y-axis limits of the eye diagram in V, specified as a two-element vector. The first element corresponds to  $y_{min}$  and the second to  $y_{max}$ . The second element must be greater than the first. Tunable.

**ShowGrid — Enable grid display**

false (default) | true

Enable grid display on eye diagram, specified as a logical scalar. To display a grid on the eye diagram, set this property to true. Tunable.

**Position — Scope window position**

vector

Scope window position in pixels, specified as a four-element vector of the form [left bottom width height]. Tunable.

**Methods**

hide	Hide scope window
horizontalBathtub	Horizontal bathtub curve
jitterHistogram	Jitter histogram
measurements	Measure eye diagram parameters
noiseHistogram	Noise histogram
reset	Reset states of eye diagram object
show	Make scope window visible
step	Plot eye diagram of input signal
verticalBathtub	Vertical bathtub curve

**Common to All System Objects**

release	Allow System object property value changes
---------	--

## Examples

### Eye Diagram of Filtered QPSK Signal

Specify the sample rate and the number of output samples per symbol parameters.

```
fs = 1000;  
sps = 4;
```

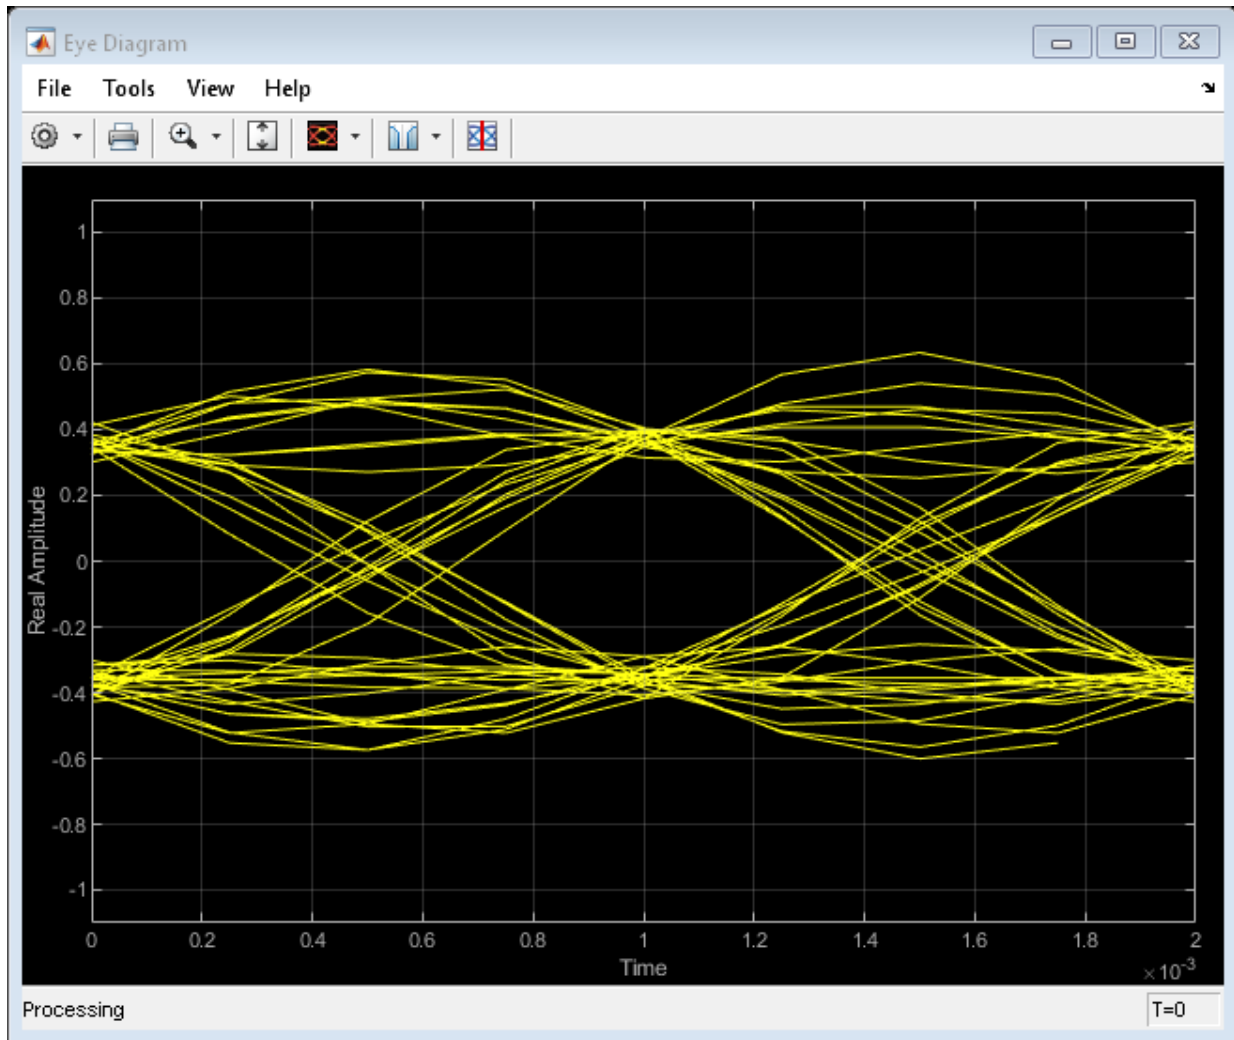

Create transmit filter and eye diagram objects.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);  
ed = comm.EyeDiagram('SampleRate',fs*sps,'SamplesPerSymbol',sps);
```

Generate random symbols and apply QPSK modulation. Then filter the modulated signal and display the eye diagram.

```
data = randi([0 3],1000,1);  
modSig = pskmod(data,4,pi/4);
```

```
txSig = txfilter(modSig);  
ed(txSig)
```

### Effect of Interpolation on 2D Histogram Eye Diagrams

Show the effects of different interpolation methods on 2-D histograms for different signal-to-noise ratio (SNR) conditions.

Create GMSK modulator and eye diagram System objects. Specify that the eye diagram displays using a 2-D color histogram and plots the real and imaginary signals.

```
gmsk = comm.GMSKModulator('PulseLength',3);  
ed = comm.EyeDiagram('DisplayMode','2D color histogram', ...  
    'ShowImaginaryEye',true,'YLimits',[-2 2]);
```

Generate bipolar data and apply GMSK modulation.

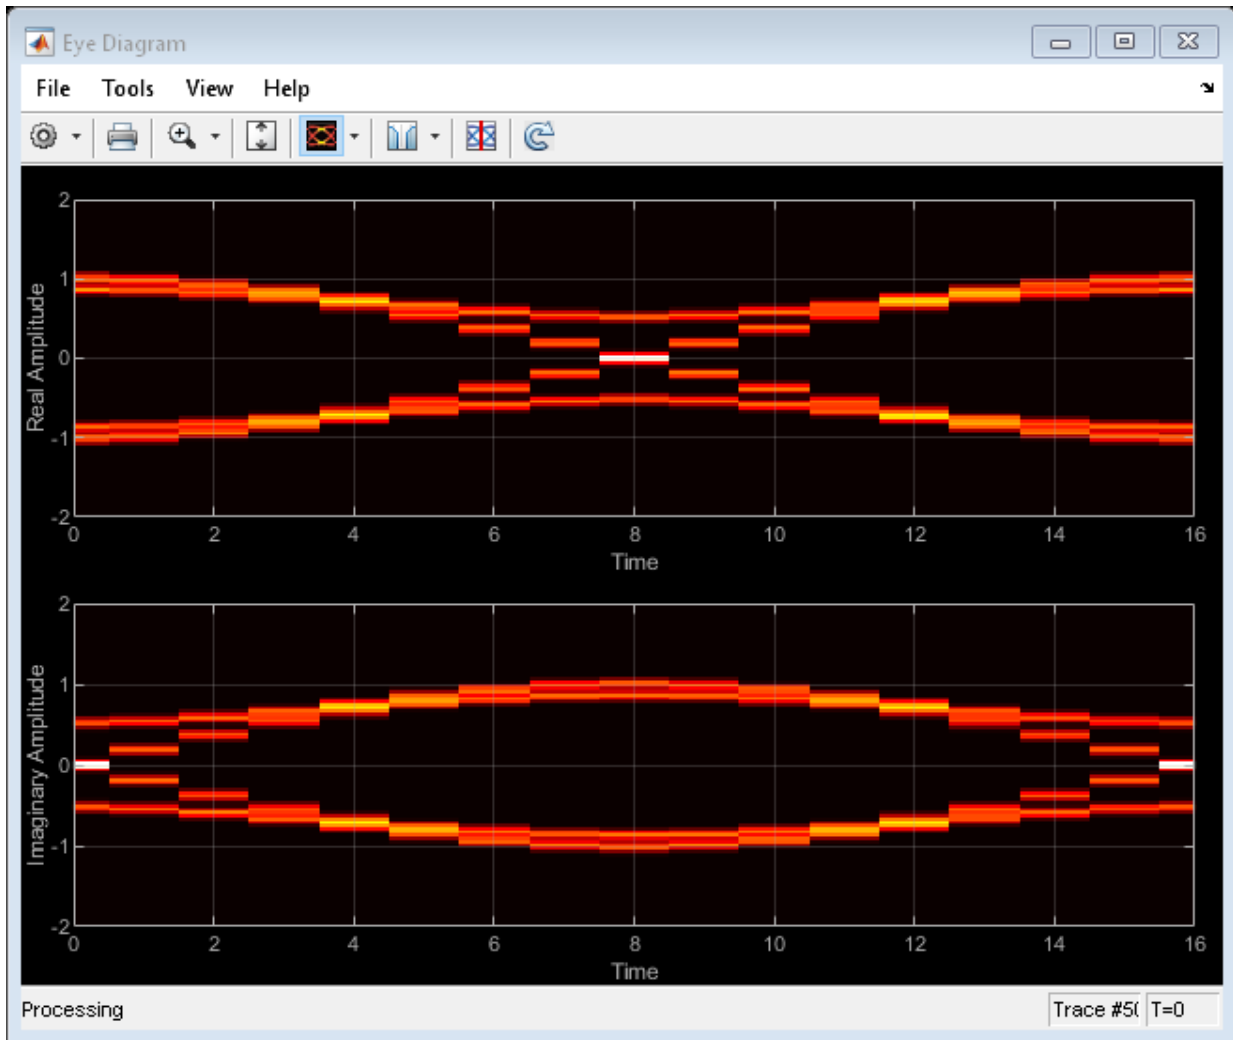

```
d = 2*randi([0 1],1e4,1)-1;  
x = gmsk(d);
```

*%Pass the signal through an AWGN channel having a 25 dB SNR and with a fixed seed for*

```
randStream = RandStream('mt19937ar','Seed',5489);  
y = awgn(x,25,'measured',randStream);
```

Display the eye diagram.

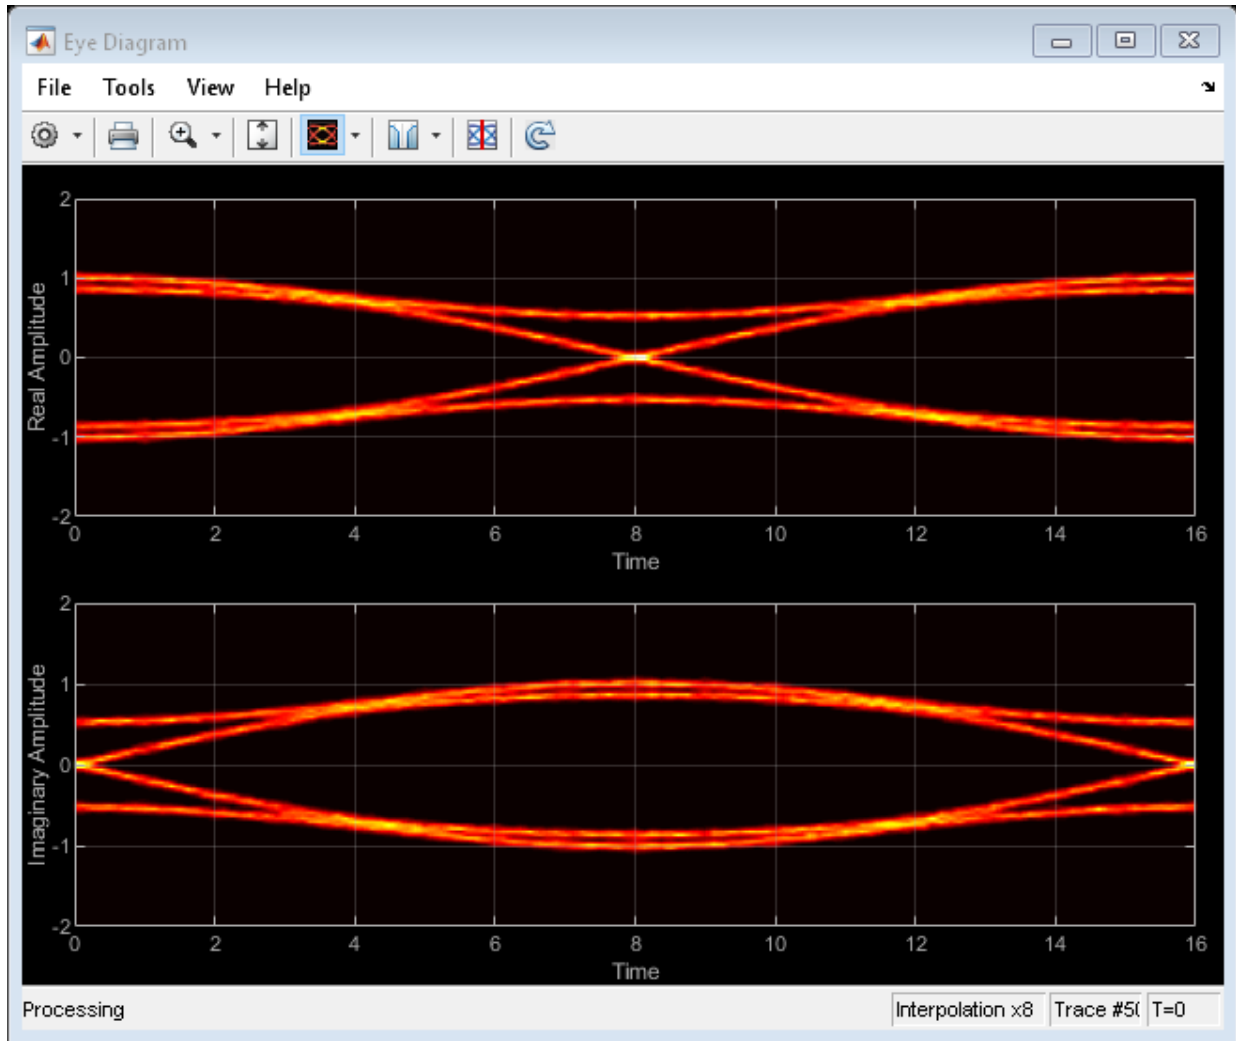

```
ed(y)
```

For a small number of samples per trace (16), the lack of interpolation causes piecewise-continuous behavior.

To compensate for the piecewise-continuous behavior, set the `OversamplingMethod` property to `'Input interpolation'`. Reset the object and display the eye diagram.

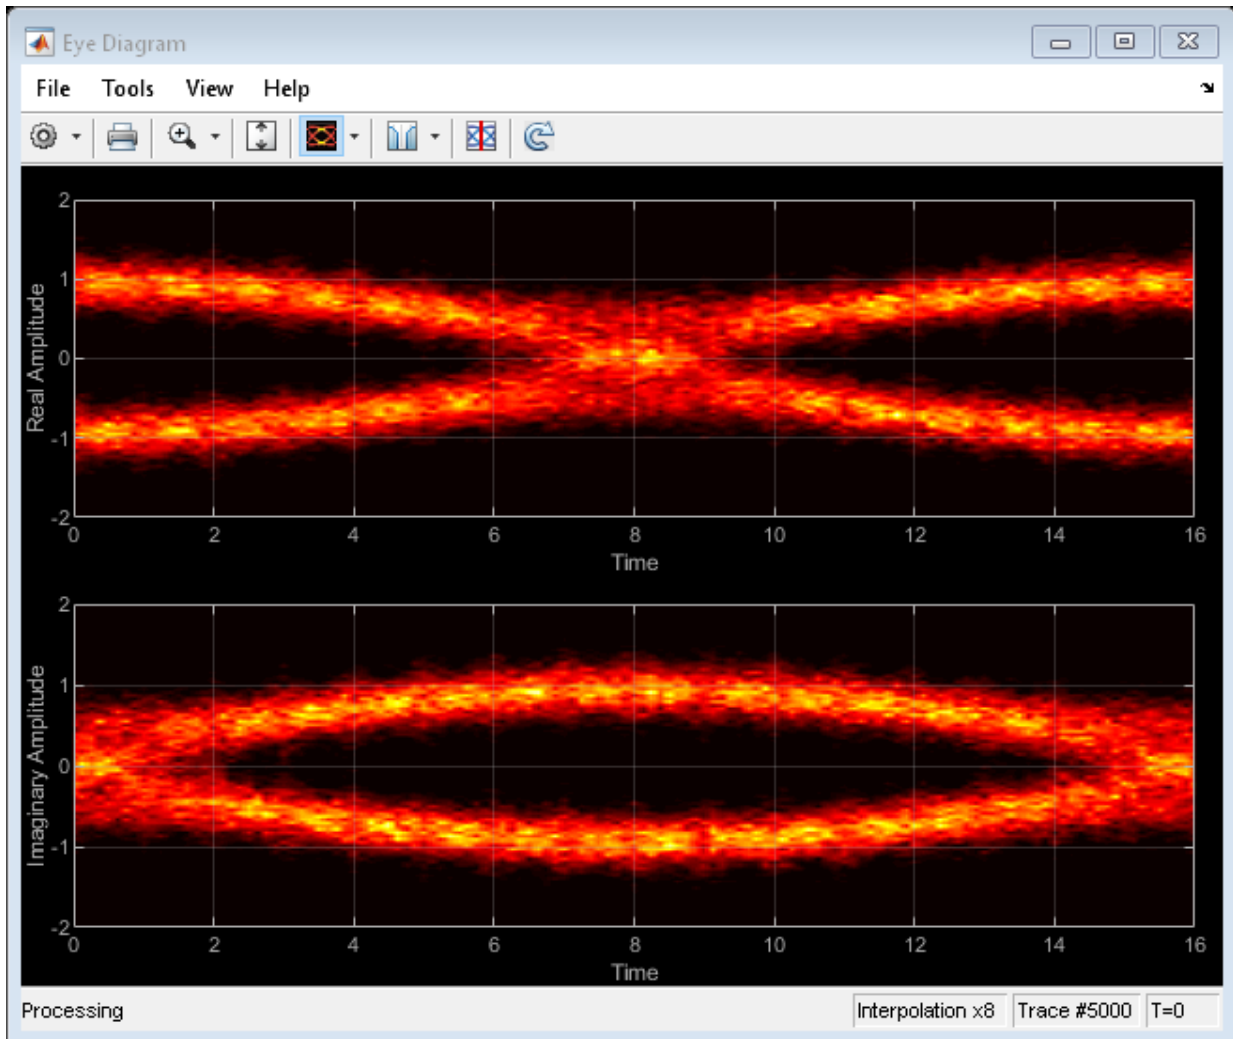

```
ed.OversamplingMethod = 'Input interpolation';  
reset(ed)  
ed(y)
```

The interpolation smooths the eye diagram.

Now pass the GMSK-modulated signal through an AWGN channel having a 10 dB SNR. Display the eye diagram.

```
y = awgn(x,10,'measured',randStream);  
reset(ed)  
ed(y)
```

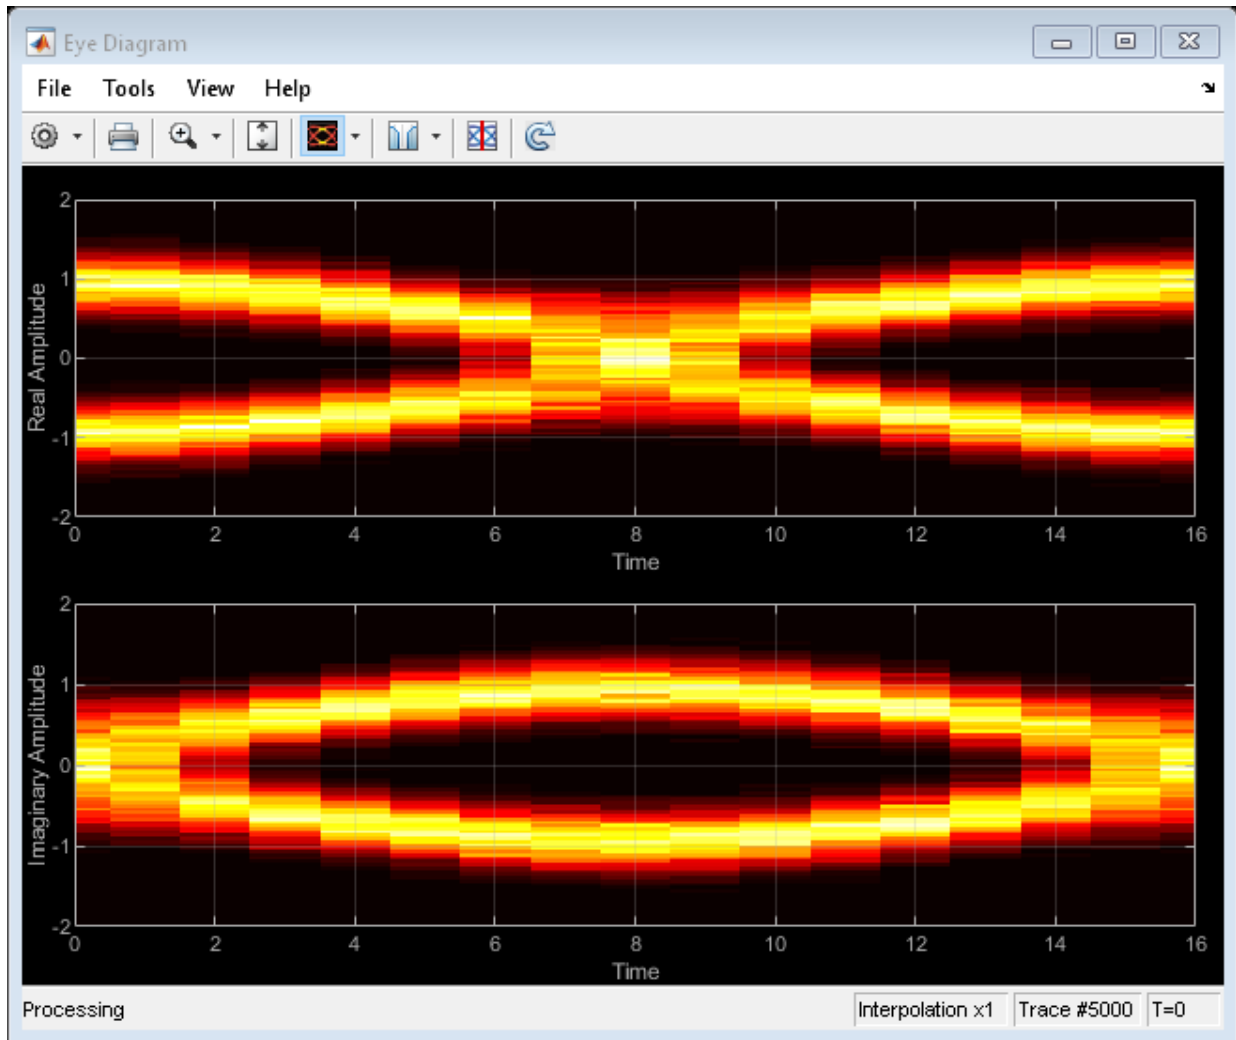

The vertical striping is the result of input interpolation, which has limited accuracy in low-SNR conditions.

Set the `OversamplingMethod` property to `'Histogram interpolation'`. Plot the eye diagram.

```
ed.OversamplingMethod = 'Histogram interpolation';  
reset(ed)  
ed(y)
```

The eye diagram plot now renders accurately because the histogram interpolation method works for all SNR values. This method results in increased execution time.

### Eye Diagram Jitter Measurements and Bathtub Curve Plots

Visualize the eye diagram of a dual-dirac input signal. Compute eye measurements, and visualize horizontal and vertical bathtub curves. Overlay the horizontal (jitter) histogram.

Specify the sample rate, the samples per symbol, and the number of traces.

```
fs = 10000;  
sps = 200;  
numTraces = 2000;
```

Create an eye diagram object having these properties:

- 2-D color histogram display
- Logarithmic color scale
- Jitter histogram overlay
- Horizontal and vertical bathtub curves
- Y-axis limits of [-1.3 1.3]
- Increased window height

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'SampleOffset',sps/2, ...  
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...  
    'EnableMeasurements',true,'OverlayHistogram','Jitter', ...  
    'ShowBathtub','Both','YLimits',[-1.3 1.3]);  
ed.Position = ed.Position + [0 0 0 120];
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);  
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...  
    'DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

```
symbols = src.generate(numTraces*2);
```

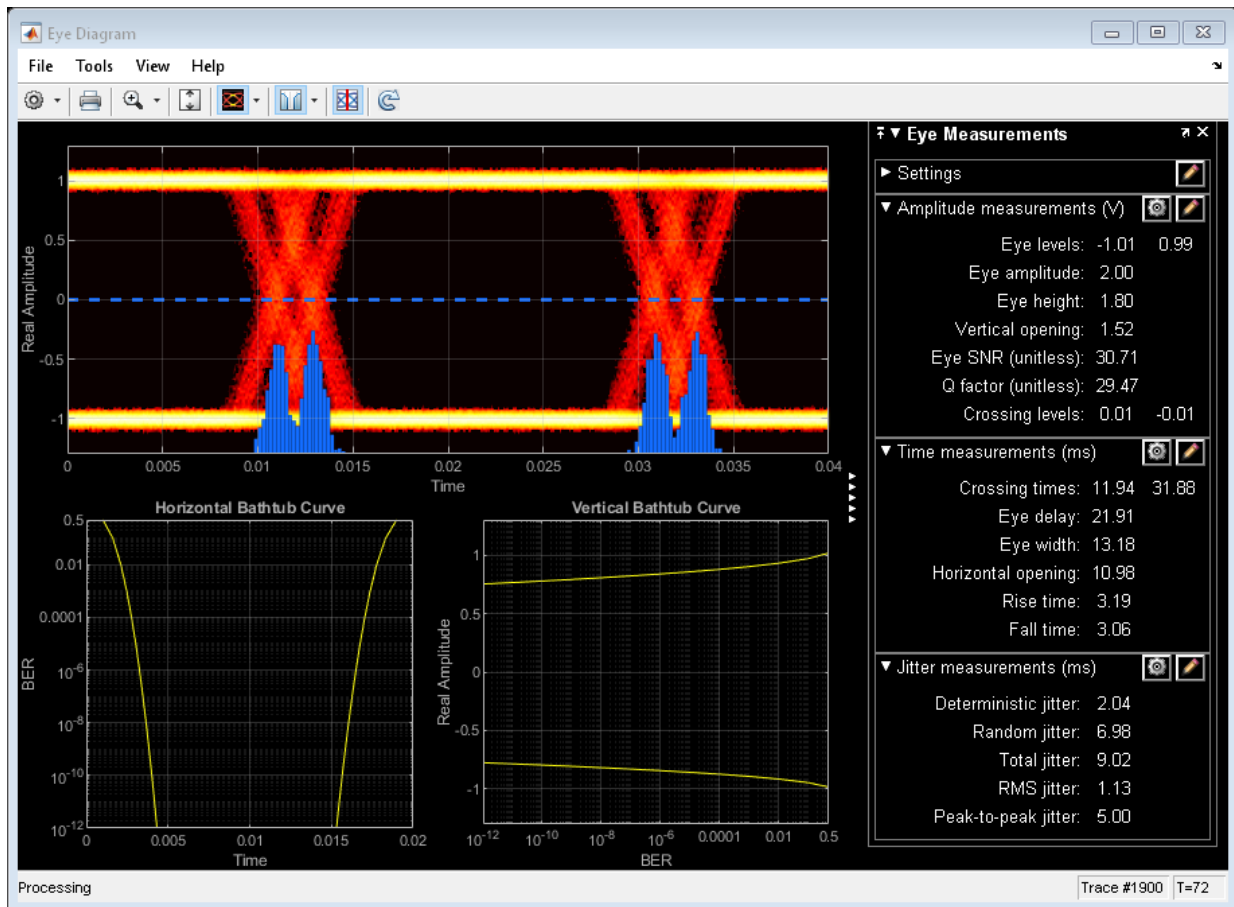

Process the data in packets of 40e3 symbols, add noise, and display the eye diagram.

```
for idx = 1:(numTraces-1)/100  
    x = symbols(1+(idx-1)*100*2*sps:idx*100*2*sps); % Read 40,000 symbols  
    y = awgn(x,30); % Add noise
```

```

ed(y);
end
% Display eye diagram

```

## Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;  
sps = 200;  
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'SampleOffset',sps/2, ...  
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...  
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

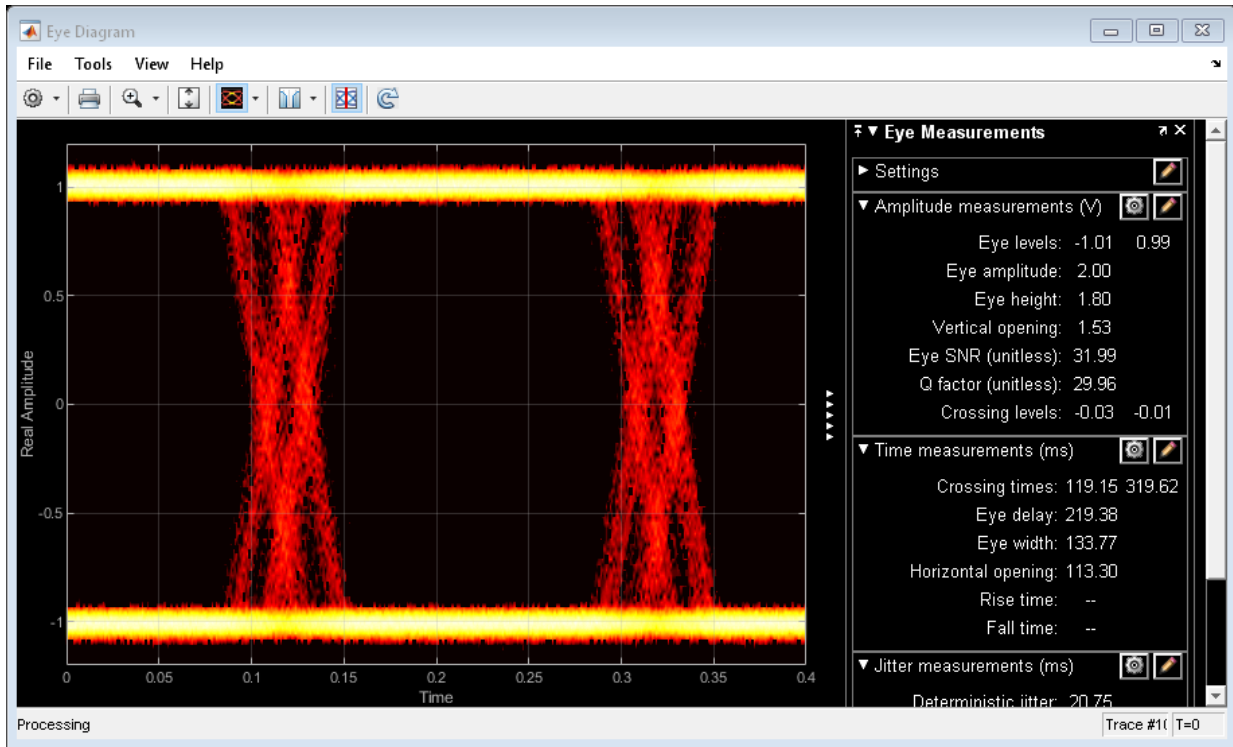

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);  
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...  
    'DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);  
y = awgn(x,30,'measured',randStream);  
ed(y)
```

Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```
jbins = jitterHistogram(ed);
plot(jbins)
```

Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);  
plot(nbins)
```

### Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;  
sps = 200;  
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'SampleOffset',sps/2, ...  
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...  
    'EnableMeasurements',true,'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);  
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...  
    'DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

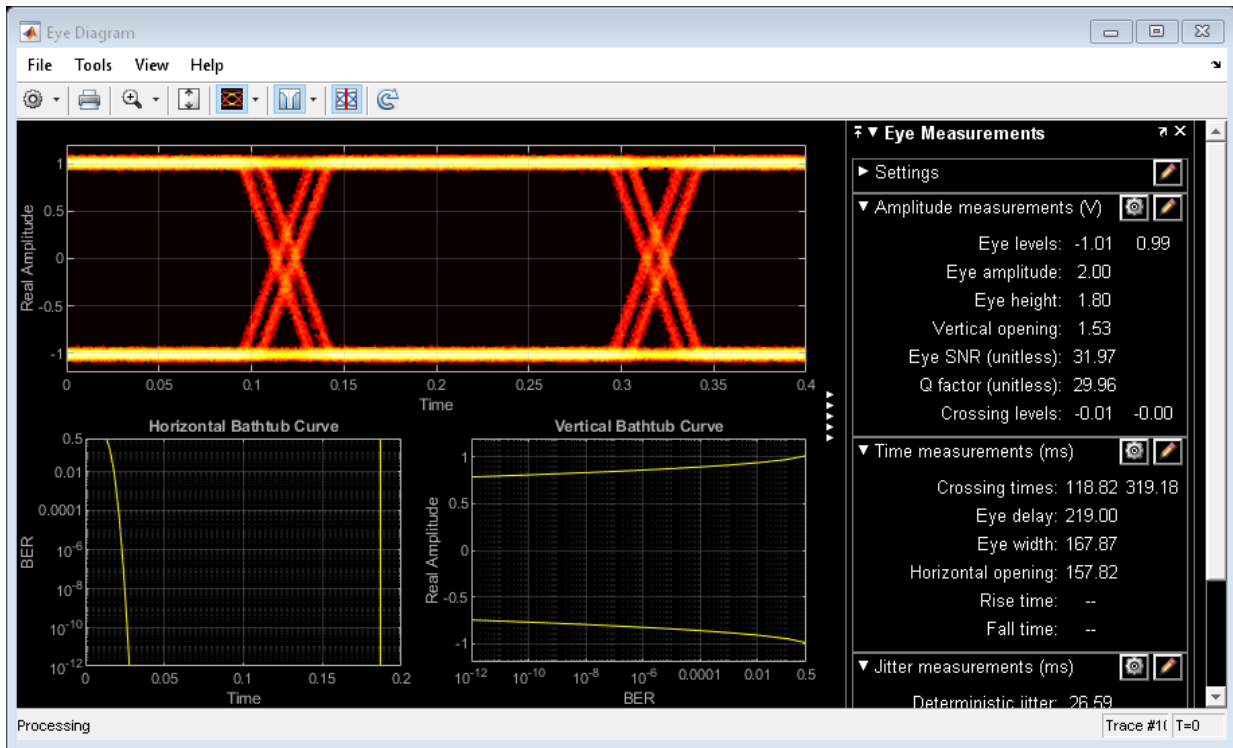

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);  
y = awgn(x,30,'measured',randStream);
```

Display the eye diagram.

```
ed(y)
```

Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold],[hb.BER],'b',[hb.RightThreshold],[hb.BER],'b')
grid
```

## LowerThreshold

**Rise and Fall Time of NRZ Signal**

Create a combined jitter object having random jitter with a  $2e-4$  standard deviation.

```
jtr = commsrc.combinedjitter('RandomJitter', 'on', 'RandomStd', 2e-4);
```

Generate an NRZ signal having random jitter and 3 ms rise and fall times.

```
genNRZ = commsrc.pattern('Jitter', jtr, 'RiseTime', 3e-3, 'FallTime', 3e-3);
x = generate(genNRZ, 2000);
```

Pass the signal through an AWGN channel with fixed seed for repeatable results.

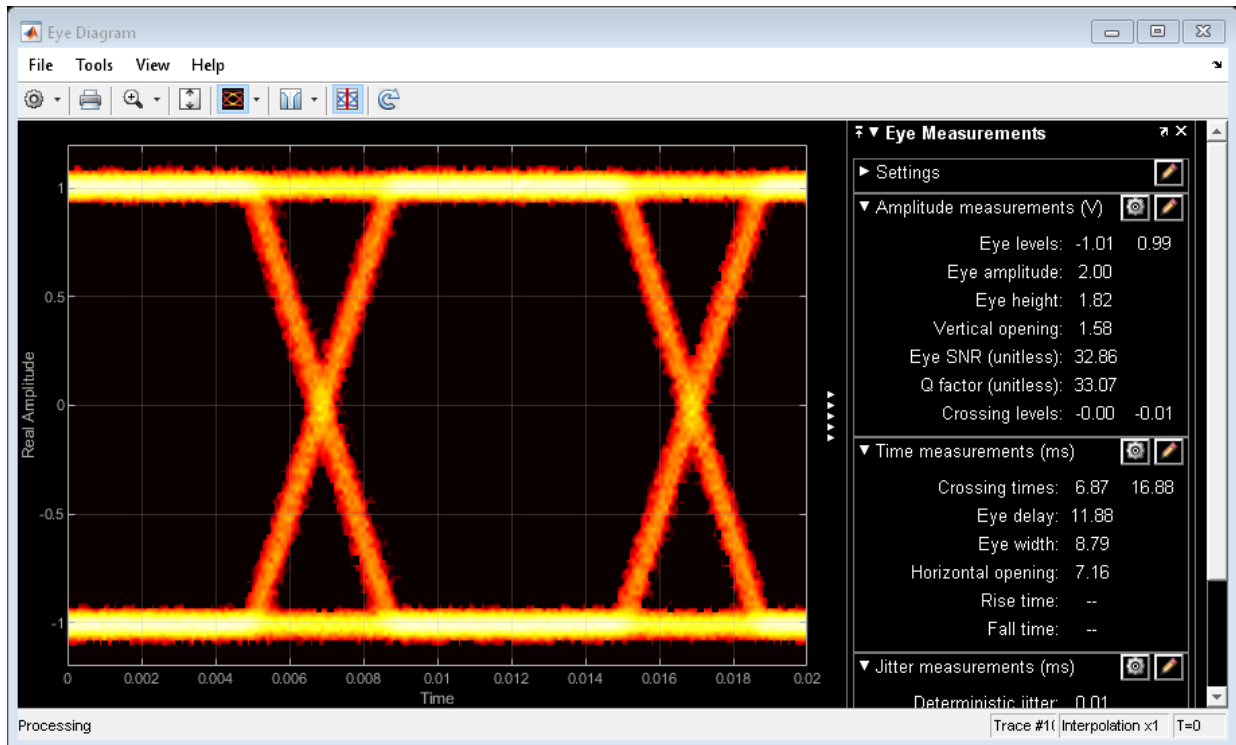

```
randStream = RandStream('mt19937a','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Create an eye diagram object. Enable the measurements.

```
ed = comm.EyeDiagram('SamplesPerSymbol',genNRZ.SamplesPerSymbol, ...
    'SampleRate',genNRZ.SamplingFrequency,'SampleOffset',genNRZ.SamplesPerSymbol/2, ...
    'EnableMeasurements',true,'DisplayMode','2D color histogram', ...
    'OversamplingMethod','Input interpolation','ColorScale','Logarithmic','YLimits',[-1
```

To compute the rise and fall times, determine the rise and fall thresholds from the eye level and eye amplitude measurements. Plot the eye diagram to calculate these parameters.

```
ed(y)
```

Pass the signal through the eye diagram object again to measure the rise and fall times.

```
ed(y)
hide(ed)
```

Display the data by using the `measurements` method.

```
eyestats = measurements(ed);
riseTime = eyestats.RiseTime
fallTime = eyestats.FallTime
```

```
riseTime =
    0.0030
```

```
fallTime =
    0.0030
```

The measured values match the 3 ms specification.

## Measurements

To open the measurements panel, click on the **Eye Measurements** button or select Tools > Measurements > Eye Measurements from the toolbar menu.

---

### Note

- For amplitude measurements, at least one bin per vertical histogram must reach 10 hits before the measurement is taken, ensuring higher accuracy.
- For time measurements, at least one bin per horizontal histogram must reach 10 hits before the measurement is taken.
- When an eye crossing time measurement falls within the  $[-0.5/F_s, 0)$  seconds interval, the time measurement wraps to the end of the eye diagram, i.e., the measurement wraps by  $2 \cdot T_s$  seconds (where  $T_s$  is the symbol time). For a complex signal case, the analyze method issues a warning if the crossing time measurement of the in-phase branch wraps while that of the quadrature branch does not (or vice versa). To avoid

the time-wrapping or a warning, add a half-symbol duration delay to the current value in the `MeasurementDelay` property of the eye diagram object. This additional delay repositions the eye in the approximate center of the scope.

---

### Eye Levels — Amplitude level used to represent data bits

Eye level is the amplitude level used to represent data bits. For the displayed NRZ signal, the levels are -1 V and +1 V. The eye levels are calculated by averaging the 2-D histogram within the eye level boundaries.

### Eye Amplitude — Distance between eye levels

Eye amplitude is the distance in V between the mean value of two eye levels.

### Eye Height – Statistical minimum distance between eye levels

Eye height is the distance between  $\mu - 3\sigma$  of the upper eye level and  $\mu + 3\sigma$  of the lower eye level.  $\mu$  is the mean of the eye level and  $\sigma$  is the standard deviation.

### Vertical Opening — Distance between BER threshold points

The vertical opening is the distance between the two points that correspond to the BER threshold. For example, for a BER threshold of  $10^{-12}$ , these points correspond to the  $7\sigma$  distance from each eye level.

### Eye SNR — Signal-to-noise ratio

The eye SNR is the ratio of the eye level difference to the difference of the vertical standard deviations corresponding to each eye level:

$$\text{SNR} = \frac{L_1 - L_0}{\sigma_1 - \sigma_0},$$

where  $L_1$  and  $L_0$  represent the means of the upper and lower eye levels and  $\sigma_1$  and  $\sigma_0$  represent their standard deviations.

### Q Factor — Quality factor

The Q factor is calculated using the same formula as the Eye SNR. However, the standard deviations of the vertical histograms are replaced with those computed with the dual-Dirac analysis.

### Crossing Levels — Amplitude levels for eye crossings

The crossing levels are the amplitude levels at which the eye crossings occur.

### **Crossing Times — Times for which crossings occur**

The crossing times are the times at which the crossings occur. The times are computed as the mean values of the horizontal (jitter) histograms.

### Eye Delay – Mean time between eye crossings

Eye delay is the midpoint between the two crossing times.

**Eye Width — Statistical minimum time between eye crossings**

Eye width is the horizontal distance between  $\mu + 3\sigma$  of the left crossing time and  $\mu - 3\sigma$  of the right crossing time.  $\mu$  is the mean of the jitter histogram and  $\sigma$  is the standard deviation.

### Horizontal Opening – Time between BER threshold points

The horizontal opening is the distance between the two points that correspond to the BER threshold. For example, for a  $10^{-12}$  BER, these two points correspond to the  $7\sigma$  distance from each crossing time.

**Rise Time — Time to transition from low to high**

Rise time is the mean time between the low and high thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.

### Fall Time – Time to transition from high to low

Fall time is the mean time between the high and low thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.

### **Deterministic Jitter — Deterministic deviation from ideal signal timing**

The deterministic jitter (DJ) is the distance between the two peaks of the dual-Dirac histograms. The probability density function (PDF) of DJ is composed of two delta functions.

### Random Jitter — Random deviation from ideal signal timing

The random jitter (RJ) is the Gaussian unbounded jitter component. The random component of jitter is modeled as a zero-mean Gaussian random variable with a specified standard-deviation,  $\sigma$ . The random jitter is computed as:

$$RJ = (Q_L + Q_R)\sigma,$$

where

$$Q = \sqrt{2} \operatorname{erfc}^{-1} \left( 2 \frac{BER}{\rho} \right).$$

BER is the specified BER threshold.  $\rho$  is the amplitude of the left and right Dirac function, which is determined from the bin counts of the jitter histograms.

**Total Jitter — Deviation from ideal signal timing**

Total jitter (TJ) is the sum of the deterministic and random jitter, such that  $TJ = DJ + RJ$ .

The total jitter PDF is the convolution of the DJ PDF and the RJ PDF.

**RMS Jitter — Standard deviation of jitter**

RMS jitter is the standard deviation of the jitter calculated in the horizontal (jitter) histogram at the decision boundary.

**Peak-to-Peak Jitter — Distance between extreme data points of histogram**

Peak-to-peak jitter is the maximum horizontal distance between the left and right nonzero values in the horizontal histogram of each crossing time.

## Programmatic Configuration

You can programmatically configure the scope properties with callbacks or within scripts by using a scope configuration object as describe in “Control Scope Blocks Programmatically” (Simulink).

- [1] Stephens, Ransom. "Jitter Analysis: The Dual-Dirac Model, RJ/DJ, and Q-Scale." Agilent Technologies Whitepaper. December 2004.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Horizontal bathtub curve

## Syntax

```
s = horizontalBathtub(ed)
```

## Description

`s = horizontalBathtub(ed)` returns a structure array, `s`, for eye diagram object `ed`. Each structure in `s` contains a BER level and the corresponding left and right thresholds between jitter and horizontal eye opening.

---

**Note** This method is available when both of these conditions apply:

- `EnableMeasurements` is `true`
  - `ShowBathtub` is `'Horizontal'` or `'Both'`
- 

## Examples

### Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;  
sps = 200;  
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'SampleOffset',sps/2, ...  
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...  
    'EnableMeasurements',true,'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);  
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...  
    'DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

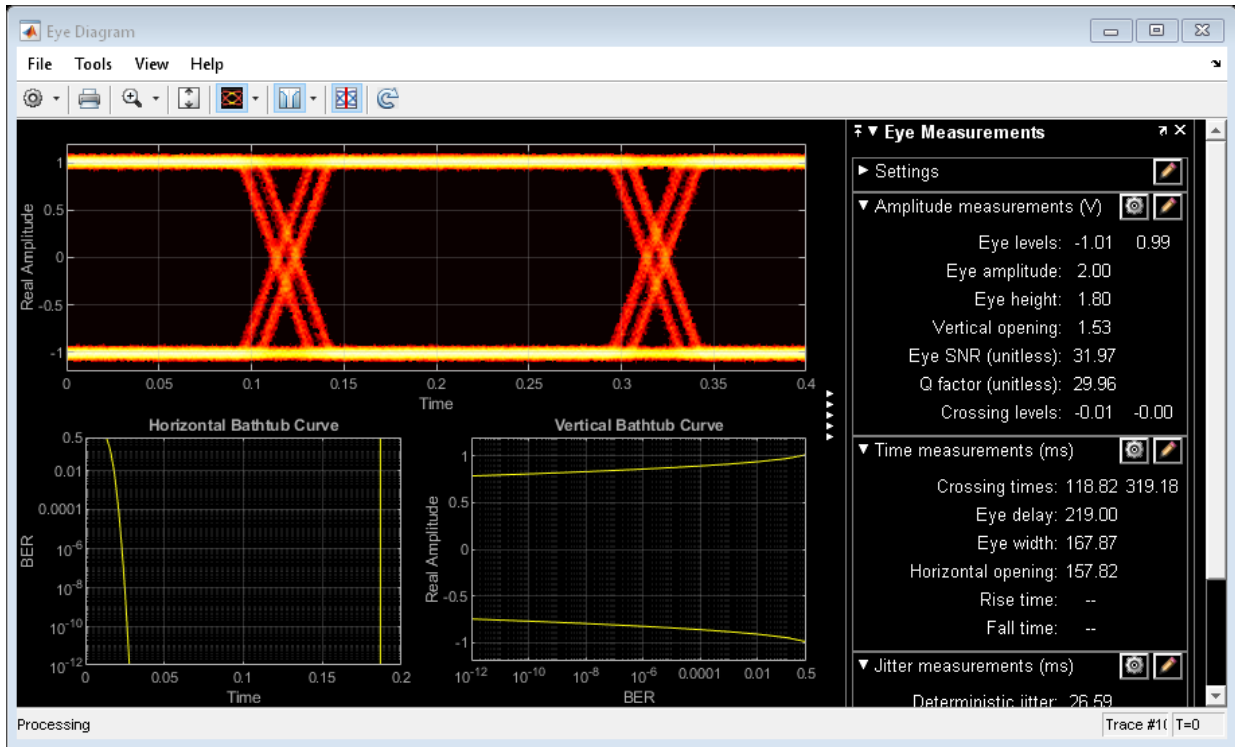

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);  
y = awgn(x,30,'measured',randStream);
```

Display the eye diagram.

```
ed(y)
```

Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold],[hb.BER], 'b', [hb.RightThreshold],[hb.BER], 'b')
grid
```

hb =

1x13 struct array with fields:

Measure eye diagram parameters

## Syntax

`m = measurements(ed)`

## Description

`m = measurements(ed)` returns the amplitude, time, and jitter measurements calculated by eye diagram object `ed`.

---

**Note** This method is available when `EnableMeasurements` is true.

---

## Examples

### Rise and Fall Time of NRZ Signal

Create a combined jitter object having random jitter with a  $2e-4$  standard deviation.

```
jtr = commsrc.combinedjitter('RandomJitter','on','RandomStd',2e-4);
```

Generate an NRZ signal having random jitter and 3 ms rise and fall times.

```
genNRZ = commsrc.pattern('Jitter',jtr,'RiseTime',3e-3,'FallTime',3e-3);  
x = generate(genNRZ,2000);
```

Pass the signal through an AWGN channel with fixed seed for repeatable results.

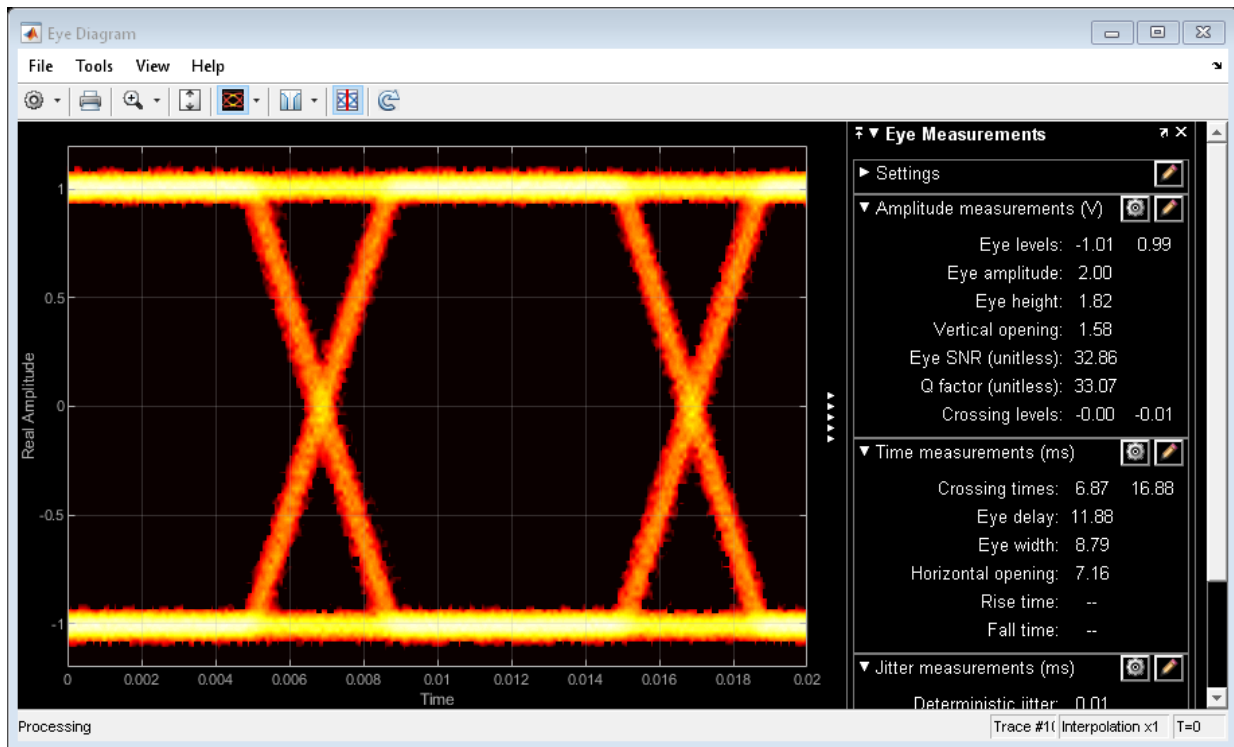

```
randStream = RandStream('mt19937ar','Seed',5489);  
y = awgn(x,30,'measured',randStream);
```

Create an eye diagram object. Enable the measurements.

```
ed = comm.EyeDiagram('SamplesPerSymbol',genNRZ.SamplesPerSymbol, ...
    'SampleRate',genNRZ.SamplingFrequency,'SampleOffset',genNRZ.SamplesPerSymbol/2, ...
    'EnableMeasurements',true,'DisplayMode','2D_color_histogram', ...
    'OversamplingMethod','Input_interpolation','ColorScale','Logarithmic','YLimits',[-1,1])
```

To compute the rise and fall times, determine the rise and fall thresholds from the eye level and eye amplitude measurements. Plot the eye diagram to calculate these parameters.

```
ed(y)
```

Pass the signal through the eye diagram object again to measure the rise and fall times.

```
ed(y)
hide(ed)
```

Display the data by using the measurements method.

```
eyestats = measurements(ed);  
riseTime = eyestats.RiseTime  
fallTime = eyestats.FallTime
```

```
riseTime =  
    0.0030
```

```
fallTime =  
    0.0030
```

The measured values match the 3 ms specification.

---

## step

**System object:** comm.EyeDiagram

**Package:** comm

Plot eye diagram of input signal

## Syntax

`step(ed,x)`

`ed(x)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`step(ed,x)` plots the eye diagram of input signal `x` using `comm.EyeDiagram` object `ed`.

`ed(x)` is equivalent to the first syntax.

---

**Note** `ed` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Examples

### Eye Diagram of Filtered QPSK Signal

Specify the sample rate and the number of output samples per symbol parameters.

```
fs = 1000;  
sps = 4;
```

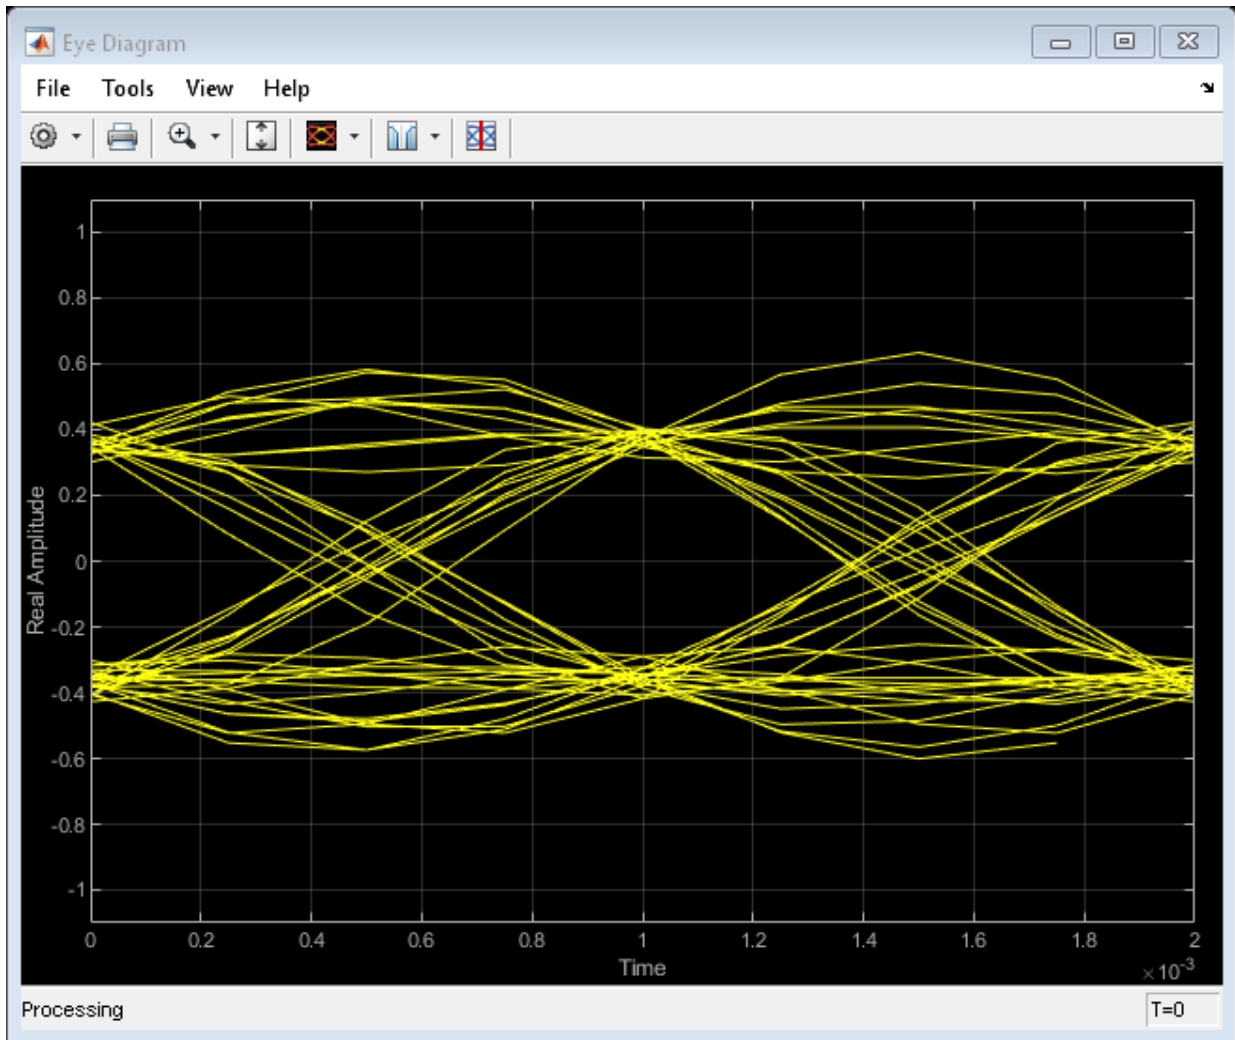

Create transmit filter and eye diagram objects.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);  
ed = comm.EyeDiagram('SampleRate',fs*sps,'SamplesPerSymbol',sps);
```

Generate random symbols and apply QPSK modulation. Then filter the modulated signal and display the eye diagram.

```
data = randi([0 3],1000,1);  
modSig = pskmod(data,4,pi/4);
```

```
txSig = txfilter(modSig);  
ed(txSig)
```

**Introduced in R2016b**

# verticalBathtub

**System object:** comm.EyeDiagram

**Package:** comm

Vertical bathtub curve

## Syntax

```
s = verticalBathtub(ed)
```

## Description

`s = verticalBathtub(ed)` returns a structure array, `s`, for eye diagram object `ed`. Each structure in `s` contains a BER level and the corresponding upper and lower thresholds between noise and vertical eye opening.

---

**Note** This method is available when both of these conditions apply:

- `EnableMeasurements` is `true`
  - `ShowBathtub` is `'Vertical'` or `'Both'`
- 

## Examples

### Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;  
sps = 200;  
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'SampleOffset',sps/2, ...  
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...  
    'EnableMeasurements',true,'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);  
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...  
    'DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

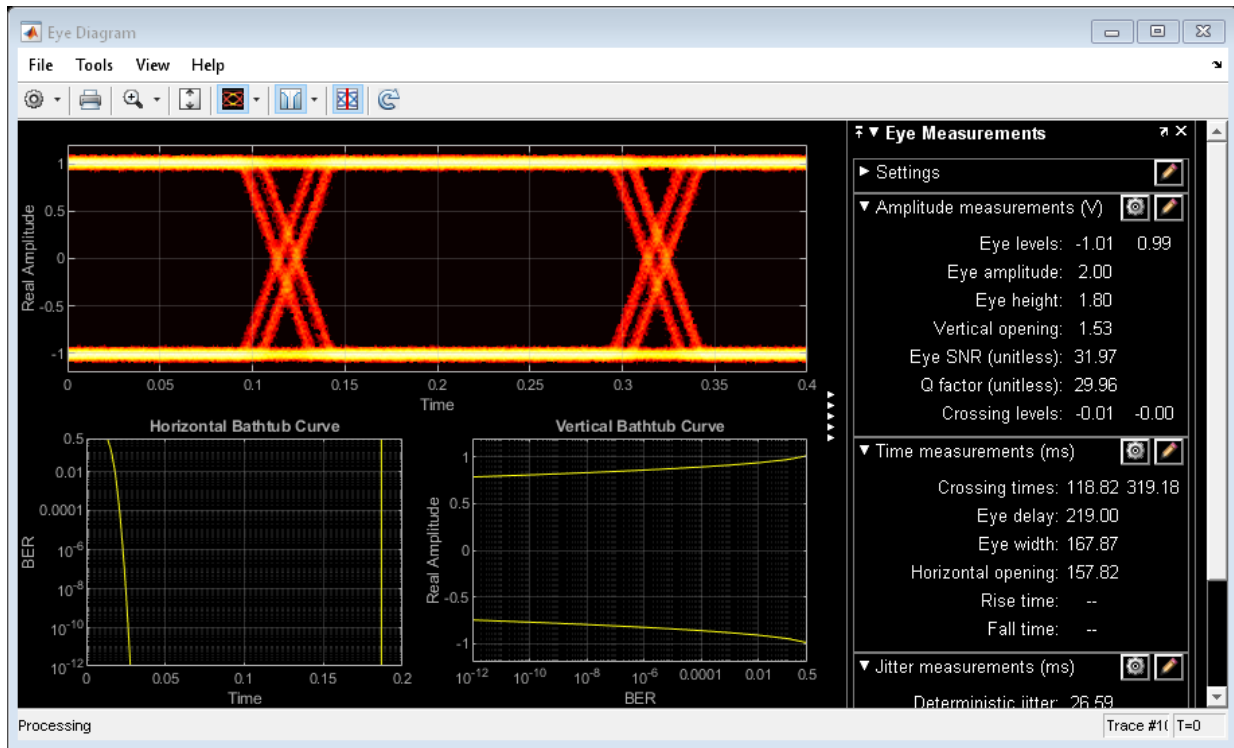

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);  
y = awgn(x,30,'measured',randStream);
```

Display the eye diagram.

```
ed(y)
```

Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold],[hb.BER], 'b', [hb.RightThreshold],[hb.BER], 'b')

Introduced in R2016b

# comm.FMBroadcastDemodulator

**Package:** comm

Demodulate broadcast FM signal

## Description

The `comm.FMBroadcastDemodulator` System object demodulates a complex baseband FM signal and filters the signal with a de-emphasis filter to produce an audio signal. If the `Stereo` property is set to `true`, the object performs stereo decoding. If the `RBDS` property is set to `true`, the object also demodulates the RDS/RBDS waveform. For more details, see “Algorithms” on page 4-777.

To demodulate a complex baseband FM signal:

- 1 Define and set up the `comm.FMBroadcastDemodulator` object. See “Construction” on page 4-771.
- 2 Call `step` to demodulate the complex baseband FM signal according to the properties of `comm.FMBroadcastDemodulator`.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`fmbDemod = comm.FMBroadcastDemodulator` creates a demodulator System object, `fmbDemod`, that frequency demodulates an input signal.

`fmbDemod = comm.FMBroadcastDemodulator(Name,Value)` creates an FM demodulator object, `fmbDemod`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`fmbDemod = comm.FMBroadcastDemodulator(MOD)` creates an FM demodulator object, `fmbDemod`, whose properties are determined by the corresponding FM modulator object, `MOD`.

### Properties

#### **SampleRate**

Input signal sample rate (Hz)

Specify the sample rate of the input signal in Hz as a positive real scalar. The default value is  $240e3$ . This property is nontunable.

#### **FrequencyDeviation**

Peak deviation of the output signal frequency (Hz)

Specify the frequency deviation of the FM demodulator in Hz as a positive real scalar. The default value is  $75e3$ . System bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe. This property is nontunable.

#### **FilterTimeConstant**

Time constant of the de-emphasis filter (s)

Specify the de-emphasis lowpass filter time constant as a positive real scalar. The default value is  $7.5e-05$ . FM broadcast standards specify a value of 75  $\mu$ s in the United States and 50  $\mu$ s in Europe. This property is nontunable.

#### **AudioSampleRate**

Audio sample rate of the output signal (Hz)

Specify the output audio sample rate as a positive real scalar. The default value is **48000**. This property is nontunable.

#### **PlaySound**

Flag to enable or disable audio playback

To playback the output signal on the default audio device, set this property to `true`. The default is `false`. This property is nontunable.

### **BufferSize**

Buffer size of the audio device

Specify the size of the buffer (in samples) that the object uses to communicate with an audio device as a positive scalar integer. The default is `4096`. This property is available only when `PlaySound` is `true`. This property is nontunable.

### **Stereo**

Flag to enable or disable stereo audio

Set this property to `true` to demodulate a stereophonic audio signal. Set to `false` if the input signal is monophonic. The default is `false`. This property is nontunable.

### **RBDS**

Flag to demodulate RDS/RBDS waveform

If `RBDS` is set to `true`, the second output of the `step` method is the baseband RDS/RBDS waveform. The default value is `false`. This property is nontunable.

### **RBDSamplesPerSymbol**

Oversampling factor of RDS/RBDS output

Specify the number of samples of the RDS/RBDS output as a positive integer. The RDS/RBDS sample rate is given by  $\text{RBDSamplesPerSymbol} \times 1187.5$  Hz. According to the RDS/RBDS standard, the sample rate of each bit is 1187.5 Hz.

This property applies only when you set `RBDS` to `true`.

The default is 10.

### **RBDSCostasLoop**

Option to recover phase of RDS/RBDS signal

Specify whether a Costas loop is used to recover the phase of the RDS/RBDS signal. Set this option to `true` for radio stations that do not lock the 57 kHz RDS/RBDS signal in phase with the third harmonic of the 19 kHz pilot tone.

This property applies only when you set `RBDS` to `true`.

The default value is `false`.

## Methods

`info` Filter information about FM broadcast demodulator  
`reset` Reset states of the FM broadcast demodulator object  
`step` Apply FM broadcast demodulation

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### FM Broadcast a Streaming Audio Signal

Modulate and demodulate a streaming audio signal with the FM broadcast modulator and demodulator objects. Play the audio signal using a default audio device.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create an audio file reader System object™ and read the file `guitartune.wav`.

```
audio = dsp.AudioFileReader('guitartune.wav', 'SamplesPerFrame', 4410);
```

Create FM broadcast modulator and demodulator objects. Set the `AudioSampleRate` property to match the sample rate of the input signal. Set the `SampleRate` property of the demodulator to match the specified sample rate of the modulator. Set the `PlaySound` property of the demodulator to `true` to enable audio playback.

```
fmbMod = comm.FMBroadcastModulator('AudioSampleRate', audio.SampleRate, ...  
    'SampleRate', 240e3);  
fmbDemod = comm.FMBroadcastDemodulator( ...
```

```
'AudioSampleRate',audio.SampleRate, ...
'SampleRate',240e3,'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal and playback the audio input.

```
while ~isDone(audio)
    audioData = audio();
    modData = fmbMod(audioData);
    demodData = fmbDemod(modData);
end
```

## FM Modulate and Demodulate an RBDS Waveform

Generate a basic RBDS waveform, FM modulate it with an audio signal, and then demodulate it.

**Note:** This example runs only in R2017a or later.

Create a RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by  $1187.5 \times 10$ . Set the audio sample rate to  $1187.5 \times 40$ .

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;
```

```
afr = dsp.AudioFileReader('rbds_capture_47500.wav','SamplesPerFrame',rbdsFrameLen*afrRate);
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',groupsPerFrame,'SamplesPerSymbol',sps);
```

```
fmMod = comm.FMBroadcastModulator('AudioSampleRate',afr.SampleRate,'SampleRate',outRate,
'Stereo',true,'RBDS',true,'RBDSsamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator('SampleRate',outRate,...
'Stereo',true,'RBDS',true,'PlaySound',true);
scope = dsp.TimeScope('SampleRate',outRate,'YLimits',10^-2*[-1 1]);
```

Get the current audio input. Generate RBDS information at the same configured rate as audio. FM modulate the stereo audio with RBDS information. Add additive white Gaussian

noise. FM demodulate the audio and RBDS waveforms. View the waveforms in a time scope.

```
for idx = 1:7
    input = afr();
    rbdsWave = rbds();
    yFM = fmMod([input input], rbdsWave);
    rcv = awgn(yFM, 40);
    [audioRcv, rbdsRcv] = fmDemod(rcv);
    scope(rbdsRcv);
end
```

## Algorithms

The FM Broadcast demodulator includes the functionality of the baseband FM demodulator, de-emphasis filtering, and the ability to receive stereophonic signals. The

algorithms which govern basic FM modulation and demodulation are covered in `comm.FMDemodulator`.

## Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s,$$

where  $\tau_s$  is the filter time constant. The time constant is 50  $\mu$ s in Europe and 75  $\mu$ s in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s}.$$

For an audio sample rate of 44.1 kHz, the de-emphasis filter has the following response.

## Stereo and RDS/RBDS FM — Multiplex Signal

The FM broadcast demodulator supports stereophonic and monophonic operations. To support stereo transmission, the left (L) and right (R) channel information (L+R) is assigned to the mono portion of the spectrum (0 to 15 kHz). The (L-R) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals.

Here is the spectrum of the multiplex baseband signal,  $m(t)$ .

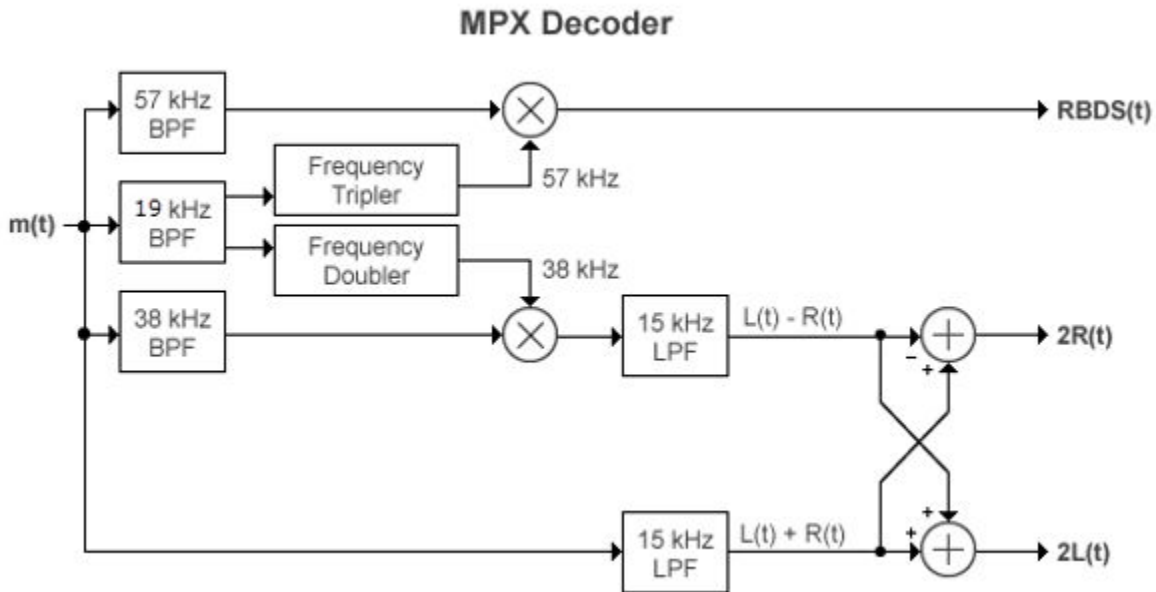

$m(t)$  is given by

$$m(t) = C_0[L(t) + R(t)] + C_1\cos(2\pi \times 19\text{kHz} \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38\text{kHz} \times t) + C_2\text{RBDS}(t)\cos(2\pi \times 57\text{kHz} \times t),$$

where  $C_0$ ,  $C_1$ , and  $C_2$  are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the  $(L(t) \pm R(t))$  signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

The demodulator applies  $m(t)$  to three bandpass filters with center frequencies at 19, 38, and 57 kHz, and to a lowpass filter with a 3-dB cutoff frequency of 15 kHz. The 19 kHz bandpass filter extracts the pilot tone from the modulated signal. The recovered pilot tone is doubled and tripled in frequency to produce the 38 kHz and 57 kHz signals, which demodulate the  $(L - R)$  and RDS/RBDS signals, respectively. To generate a scaled version of the left and right channels that produce the stereo sound, the  $(L + R)$  and  $(L - R)$  signals are added and subtracted. The RDS/RBDS signal is recovered by mixing with the 57 kHz signal.

Here is the block diagram of the FM broadcast demodulator.

## Limitations

The input length must be an integer multiple of the `AudioDecimationFactor` property. If `RBDS` is set to `true`, the input length in addition must be an integer multiple of `RBDSDecimationFactor`. For more information on these two properties, see the `info` method.

Filter information about FM broadcast demodulator

## Syntax

`S = info(fmbDemod)`

## Description

`S = info(fmbDemod)` returns a structure, `S`, containing this information for the `comm.FMBroadcastDemodulator` System object, `fmbDemod`:

Field	Description
AudioDecimationFactor	Decimation factor of the audio demodulator filter.
AudioInterpolationFactor	Interpolation factor of the audio demodulator filter.
RBDSDecimationFactor	Decimation factor of the RDS/RBDS demodulator filter.
RBDSInterpolationFactor	Interpolation factor of the RDS/RBDS demodulator filter.

**Note** When `RBDS` is `true`, the demodulator input sequence length must be a multiple of `AudioDecimationFactor` and `RBDSDecimationFactor`.

When `RBDS` is `false`, the demodulator input sequence length must be a multiple of `AudioDecimationFactor`.

**Introduced in R2015a**

# reset

**System object:** `comm.FMBroadcastDemodulator`

**Package:** `comm`

Reset states of the FM broadcast demodulator object

## Syntax

```
reset(fmbDemod)
```

## Description

`reset(fmbDemod)` resets the states of the `comm.FMBroadcastDemodulator` object, `fmbDemod`.

This method resets the windowed suffix from the last symbol in the previously processed frame.

**Introduced in R2015a**

---

## step

**System object:** comm.FMBroadcastDemodulator

**Package:** comm

Apply FM broadcast demodulation

## Syntax

```
audioSig = step(fmbDemod,X)
[audioSig,rbdsSig] = step(fmbDemod,X)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`audioSig = step(fmbDemod,X)` demodulates the complex baseband FM signal, `X`, and filters this signal with a de-emphasis filter to produce an audio signal, `audioSig`. If the `Stereo` property is set to `true`, stereo decoding is also performed. The output, `audioSig`, is a real vector with length equal to  $(\text{AudioSampleRate}/\text{SampleRate}) \times \text{length}(X)$ .

`[audioSig,rbdsSig] = step(fmbDemod,X)` also demodulates the baseband RBDS signal, `rbdsSig`. The `step` method outputs the RBDS signal only if the `RBDS` property is set to `true`. The output, `rbdsSig`, is a real vector with length equal to  $(\text{RBDSSamplesPerSymbol} \times 1187.5/\text{SampleRate}) \times \text{length}(X)$ .

---

**Note** `fmbDemod` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Introduced in R2015a**

# comm.FMBroadcastModulator

**Package:** comm

Modulate broadcast FM signal

## Description

The `comm.FMBroadcastModulator` System object pre-emphasizes an audio signal and modulates it onto a baseband FM signal. If the `Stereo` property is set to `true`, the object modulates the audio input ( $L-R$ ) in the 38 kHz band, in addition to modulating it in the baseband ( $L+R$ ). If the `RBDS` property is set to `true`, the object modulates a baseband RDS/RBDS signal at 57 kHz. For more details, see “Algorithms” on page 4-792.

To FM modulate an audio signal:

- 1 Define and set up the `comm.FMBroadcastModulator` object. See “Construction” on page 4-787.
- 2 Call `step` to apply broadcast FM modulation to an audio signal according to the properties of `comm.FMBroadcastModulator`.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`fmbMod = comm.FMBroadcastModulator` creates a modulator System object, `fmbMod`, that frequency modulates an input signal.

`fmbMod = comm.FMBroadcastModulator(demod)` creates a broadcast FM modulator object whose properties are determined by the corresponding broadcast FM demodulator object, `demod`.

`fmbMod = comm.FMBroadcastModulator(Name,Value)` creates a broadcast FM modulator object with each specified property `Name` set to the specified `Value`. You can

specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### SampleRate

Output signal sample rate (Hz)

Specify the sample rate of the output signal in Hz as a positive real scalar. The default value is `240e3`. This property is nontunable.

### FrequencyDeviation

Peak deviation of the output signal frequency (Hz)

Specify the frequency deviation of the FM modulator in Hz as a positive real scalar. The default value is `75e3`. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe. This property is nontunable.

### FilterTimeConstant

Filter time constant (s)

Specify the pre-emphasis highpass filter time constant as a positive real scalar. FM broadcast standards specify a value of 75  $\mu$ s in the United States and 50  $\mu$ s in Europe. The default value is `7.5e-05`. The property is nontunable.

### AudioSampleRate

Sample rate of the input audio signal (Hz)

Specify the audio sample rate as a positive real scalar. The default value is `48000`. This property is nontunable.

### Stereo

Flag to set stereo operations

Set this property to `true` if the input is a stereophonic audio signal. Set to `false` if the input signal is monophonic. The default is `false`. This property is nontunable.

**RBDS**

Flag to modulate RDS/RBDS waveform

If RBDS is set to true, the `step` method accepts the baseband RDS/RBDS waveform as its second input and the object modulates the signal at 57 kHz. The default value is false. This property is nontunable.

**RBDSamplesPerSymbol**

Oversampling factor of RDS/RBDS input

Specify the number of samples per RDS/RBDS symbol as a positive integer. The RDS/RBDS sample rate is given by  $\text{RBDSamplesPerSymbol} \times 1187.5$  Hz. According to the RDS/RBDS standard, the sample rate of each bit is 1187.5 Hz.

This property applies only when you set RBDS to true.

The default is 10.

**Methods**

`info` Filter information about FM broadcast modulator  
`reset` Reset states of the FM broadcast modulator object  
`step` Apply FM broadcast modulation

**Common to All System Objects**

<code>release</code>	Allow System object property value changes
----------------------	--

**Examples****FM Broadcast a Streaming Audio Signal**

Modulate and demodulate a streaming audio signal with the FM broadcast modulator and demodulator objects. Play the audio signal using a default audio device.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create an audio file reader System object™ and read the file `guitartune.wav`.

```
audio = dsp.AudioFileReader('guitartune.wav','SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the `AudioSampleRate` property to match the sample rate of the input signal. Set the `SampleRate` property of the demodulator to match the specified sample rate of the modulator. Set the `PlaySound` property of the demodulator to `true` to enable audio playback.

```
fmbMod = comm.FMBroadcastModulator('AudioSampleRate',audio.SampleRate, ...  
    'SampleRate',240e3);  
fmbDemod = comm.FMBroadcastDemodulator( ...  
    'AudioSampleRate',audio.SampleRate, ...  
    'SampleRate',240e3,'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal and playback the audio input.

```
while ~isDone(audio)  
    audioData = audio();  
    modData = fmbMod(audioData);  
    demodData = fmbDemod(modData);  
end
```

### FM Modulate and Demodulate an RBDS Waveform

Generate a basic RBDS waveform, FM modulate it with an audio signal, and then demodulate it.

**Note:** This example runs only in R2017a or later.

Create a RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by  $1187.5 \times 10$ . Set the audio sample rate to  $1187.5 \times 40$ .

```
groupLen = 104;  
sps = 10;
```

```

groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;

afr = dsp.AudioFileReader('rbds_capture_47500.wav','SamplesPerFrame',rbdsFrameLen*afrRate);
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',groupsPerFrame,'SamplesPerSymbol',sps);

fmMod = comm.FMBroadcastModulator('AudioSampleRate',afr.SampleRate,'SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'RBDSsamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator('SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'PlaySound',true);
scope = dsp.TimeScope('SampleRate',outRate,'YLimits',10^-2*[-1 1]);

```

Get the current audio input. Generate RBDS information at the same configured rate as audio. FM modulate the stereo audio with RBDS information. Add additive white Gaussian noise. FM demodulate the audio and RBDS waveforms. View the waveforms in a time scope.

```

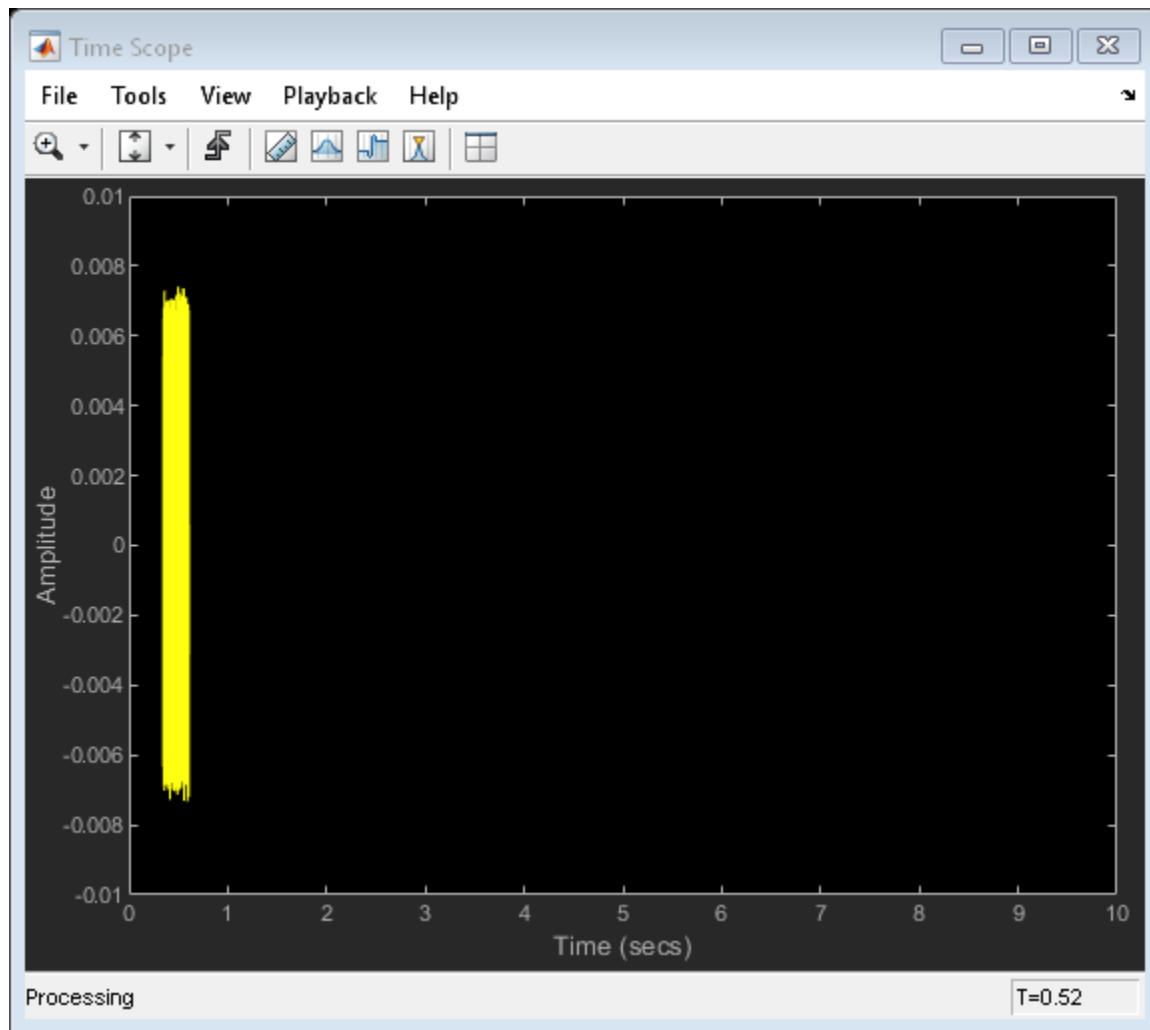

for idx = 1:7
    input = afr();
    rbdsWave = rbds();
    yFM = fmMod([input input], rbdsWave);
    rcv = awgn(yFM, 40);
    [audioRcv, rbdsRcv] = fmDemod(rcv);
    scope(rbdsRcv);
end

```

## Algorithms

The FM Broadcast modulator includes the functionality of the baseband FM modulator, pre-emphasis filtering, and the ability to transmit stereophonic signals. The algorithms

which govern basic FM modulation and demodulation are covered in `comm.FMModulator`.

## Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s,$$

where  $\tau_s$  is the filter time constant. The time constant is 50  $\mu\text{s}$  in Europe and 75  $\mu\text{s}$  in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s}.$$

Irrespective of the audio sampling rate, the signal is converted to a 152 kHz output sampling rate. For an audio sample rate of 44.1 kHz, the pre-emphasis filter has the following response.

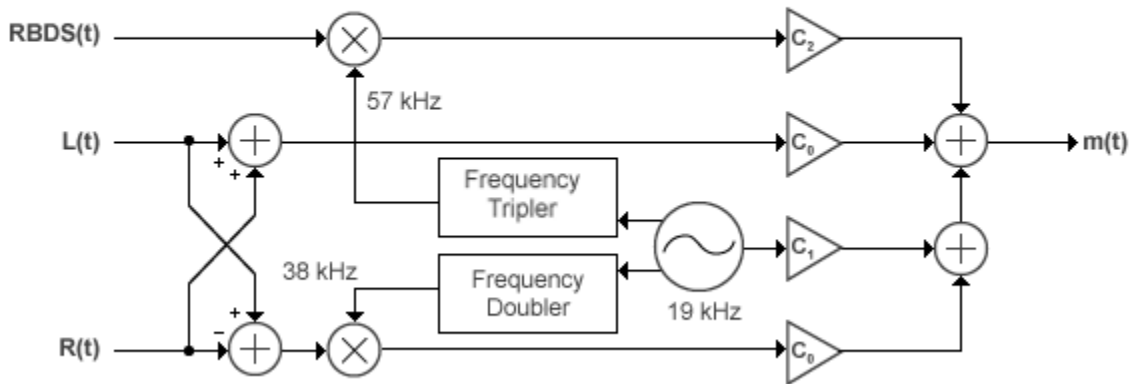

### Stereo and RDS/RBDS FM - Multiplex Signal

The FM broadcast modulator supports stereophonic and monophonic operations. To support stereo transmission, the left (L) and right (R) channel information (L+R) is assigned to the mono portion of the spectrum (0 to 15 kHz). The (L-R) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals. Here is the spectrum of the multiplex baseband signal.

Here is the block diagram of the FM broadcast modulator, which is used to generate the multiplex baseband signal.  $L(t)$  and  $R(t)$  denote the time-domain waveforms from the left and right channels.  $RBDS(t)$  denotes the time-domain waveform of the RDS/RBDS signal.

### MPX Encoder

The multiplex message signal,  $m(t)$  is given by

$$m(t) = C_0[L(t) + R(t)] + C_1\cos(2\pi \times 19\text{kHz} \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38\text{kHz} \times t) + C_2RBDS(t)\cos(2\pi \times 57\text{kHz} \times t),$$

where  $C_0$ ,  $C_1$ , and  $C_2$  are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the  $(L(t) \pm R(t))$  signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

## Limitations

- If RBDS is true, both the audio and RDS/RBDS inputs must satisfy the following equation:

$$\frac{\text{audioLength}}{\text{audioSampleRate}} = \frac{\text{RBDSLength}}{\text{RBDSsampleRate}}$$

- The input length of the audio signal must be an integer multiple of the `AudioDecimationFactor` property. The input length of the RDS/RBDS signal must be an integer multiple of the `RBDSDecimationFactor` property. For more information on these two properties, see the `info` method.

```

## Description

reset(fmbMod) resets the states of the comm.FMBroadcastModulator object, fmbMod.

This method resets the windowed suffix from the last symbol in the previously processed frame.

**Introduced in R2015a**

## step

**System object:** comm.FMBroadcastModulator

**Package:** comm

Apply FM broadcast modulation

## Syntax

```
modSig = step(fmbMod, audioSig)
modSig = step(fmbMod, audioSig, rbdsSig)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

`modSig = step(fmbMod, audioSig)` pre-emphasizes the audio signal, `audioSig`, and modulates it onto a baseband FM signal. The audio signal can be real or complex with a single-precision or a double-precision data type. If the `Stereo` property of `fmbMod` is set to `true`, stereo encoding is performed after pre-emphasis and the audio signal must have at least two channels. If `Stereo` is `false`, the audio signal must be a column vector. The length of the modulated signal, `modSig`, is  $(\text{SampleRate} / \text{AudioSampleRate}) \times \text{length}(\text{audioSig})$ .

`modSig = step(fmbMod, audioSig, rbdsSig)` also modulates a baseband RBDS signal at 57 kHz. You can pass `rbdsSig` as an input only if you set the `RBDS` property to `true`. The length of output vector `modSig` is  $(\text{SampleRate} / \text{AudioSampleRate}) \times \text{length}(\text{audioSig})$ .

---

**Note** `fmbMod` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.FMDemodulator

**Package:** comm

Demodulate using FM method

### Description

The `FMDemodulator` System object demodulates an FM modulated signal.

To FM demodulate a signal:

- 1 Define and set up the `FMDemodulator` object. See “Construction” on page 4-802.
- 2 Call `step` to FM demodulate a signal according to the properties of `comm.FMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.FMDemodulator` creates a demodulator System object, `H`, that frequency demodulates an input signal.

`H = comm.FMDemodulator(mod)` creates an FM demodulator object whose properties are determined by the corresponding FM modulator object, `mod`.

`H = comm.FMDemodulator(Name,Value)` creates an FM demodulator object with each specified property `Name` set to the specified `Value`. `Name` must appear inside single quotes. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### FrequencyDeviation

Peak deviation of the output signal frequency (Hz)

Specify the frequency deviation of the FM demodulator in Hz as a positive real scalar. The default value is  $75e3$ . The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. This property is nontunable.

### SampleRate

Sample rate of input signal (Hz)

Specify the sample rate in Hz as a positive real scalar. The default value is  $240e3$ . The output sample rate is equal to the input sample rate. This property is nontunable.

## Methods

reset      Reset states of the FM demodulator object

## Examples

### FM Modulate and Demodulate a Sinusoidal Signal

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Set the example parameters.

```
fs = 100;           % Sample rate (Hz)
ts = 1/fs;         % Sample period (s)
fd = 25;           % Frequency deviation (Hz)
```

Create a sinusoidal input signal with duration 0.5s and frequency 4 Hz.

```
t = (0:ts:0.5-ts)';  
x = sin(2*pi*4*t);
```

Create an FM modulator System object™.

```
MOD = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
```

FM modulate the input signal and plot its real part. You can see that the frequency of the modulated signal changes with the amplitude of the input signal.

```
y = step(MOD,x);  
plot(t,[x real(y)])
```

Demodulate the FM modulated signal.

```
DEMOM = comm.FMdemodulator('SampleRate',fs,'FrequencyDeviation',fd);  
z = step(DEMOM,y);
```

Plot the input and demodulated signals. The demodulator output signal exactly aligns with the input signal.

```
plot(t,x,'r',t,z,'ks')  
legend('Input Signal','Demod Signal')  
xlabel('Time (s)')  
ylabel('Amplitude')
```

### Create an FM Demodulator from an FM Modulator

Create an FM demodulator System object from an FM modulator object. Modulate and demodulate audio data loaded from a file and compare its spectrum with that of the input data.

Set the example parameters.

```
fd = 50e3;           % Frequency deviation (Hz)
fs = 300e3;         % Sample rate (Hz)
```

Create an FM modulator System object.

```
MOD = comm.FMModulator('FrequencyDeviation', fd, 'SampleRate', fs);
```

Create a companion demodulator object based on the modulator.

```
DEMOM = comm.FMDemodulator(MOD);
```

Verify that the properties are identical in the two System objects.

```
MOD
DEMOM
```

```
MOD =
```

```
comm.FMModulator with properties:
```

```
    SampleRate: 300000
  FrequencyDeviation: 50000
```

```
DEMOM =
```

```
comm.FMDemodulator with properties:
```

```
    SampleRate: 300000
  FrequencyDeviation: 50000
```

Load audio data into structure variable, S.

```
S = load('handel.mat');
data = S.y;
fsamp = S.Fs;
```

Create a spectrum analyzer System object.

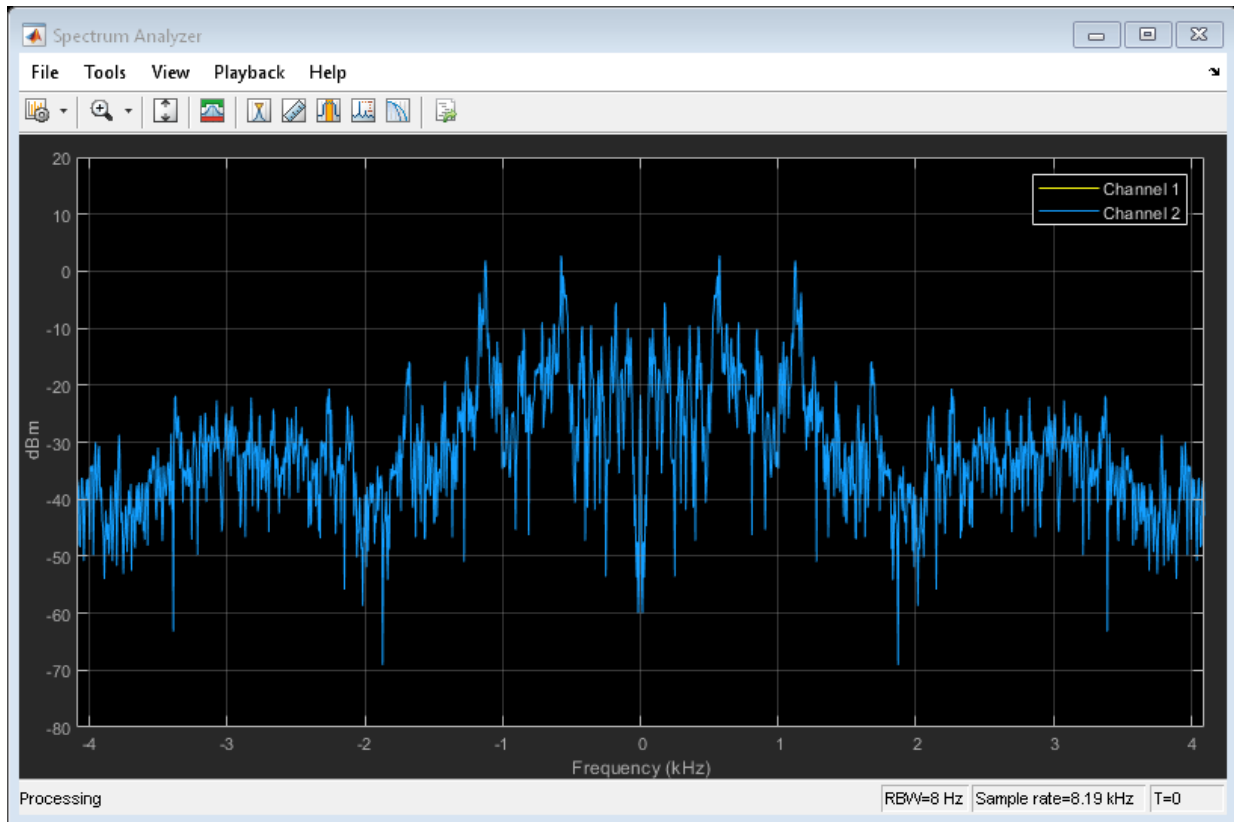

```
SA = dsp.SpectrumAnalyzer('SampleRate',fsamp,'ShowLegend',true);
```

FM modulate and demodulate the audio data.

```
modData = step(MOD,data);  
demodData = step(DEMOD,modData);
```

Verify that the spectrum plot of the input data (Channel 1) is aligned with that of the demodulated data (Channel 2).

```
step(SA,[data demodData])
```

### FM Modulate and Demodulate an Audio File

Playback an audio file after applying FM modulation and demodulation. The example takes advantage of the characteristics of System objects™ to process the data in streaming mode.

Load the audio file, `guitartune.wav`, using an audio file reader object.

```
AUDIO = dsp.AudioFileReader...  
    ('guitartune.wav', 'SamplesPerFrame', 4410);
```

Create an audio device writer object for audio playback.

```
AUDIOPAYER = audioDeviceWriter;
```

Create modulator and demodulator objects having default properties.

```
MOD = comm.FMModulator;  
DEMOM = comm.FMDemodulator;
```

Read audio data, FM modulate, FM demodulate, and playback the demodulated signal, `z`.

```
while ~isDone(AUDIO)  
    x = step(AUDIO);           % Read audio data  
    y = step(MOD,x);          % FM modulate  
    z = step(DEMOM,y);        % FM demodulate  
    step(AUDIOPAYER,z);       % Playback the demodulated signal  
end
```

## Selected Bibliography

- [1] Chakrabarti, I. H., and Hatai, I. "A New High-Performance Digital FM Modulator and Demodulator for Software-Defined Radio and Its FPGA Implementation." *International Journal of Reconfigurable Computing*. Vol. 2011, No. 10.1155/2011, 2011, p. 10.
- [2] Taub, Herbert, and Donald L. Schilling. *Principles of Communication Systems*. New York: McGraw-Hill, 1971, pp. 142-155.

## Algorithms

Represent a frequency modulated passband signal,  $Y(t)$ , as

$$Y(t) = A \cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right),$$

where  $A$  is the carrier amplitude,  $f_c$  is the carrier frequency,  $x(\tau)$  is the baseband input signal, and  $f_\Delta$  is the frequency deviation in Hz. The frequency deviation is the maximum shift from  $f_c$  in one direction, assuming  $|x(t)| \leq 1$ .

A baseband FM signal can be derived from the passband representation by downconverting it by  $f_c$  such that

$$\begin{aligned} y_s(t) &= Y(t)e^{-j2\pi f_c t} = \frac{A}{2} \left[ e^{j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} + e^{-j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} \right] e^{-j2\pi f_c t} \\ &= \frac{A}{2} \left[ e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau) d\tau} \right]. \end{aligned}$$

Removing the component at  $-2f_c$  from  $y_s(t)$  leaves the baseband signal representation,  $y(t)$ , which is expressed as

$$y(t) = \frac{A}{2} e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau}.$$

The expression for  $y(t)$  is rewritten as

$$y(t) = \frac{A}{2} e^{j\phi(t)},$$

where  $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau) d\tau$ , which implies that the input signal is a scaled version of the derivative of the phase,  $\phi(t)$ .

A baseband delay demodulator is used to recover the input signal from  $y(t)$ .

A delayed and conjugated copy of the received signal is subtracted from the signal itself,

$$w(t) = \frac{A^2}{4} e^{j\phi(t)} e^{-j\phi(t-T)} = \frac{A^2}{4} e^{j[\phi(t) - \phi(t-T)]},$$

where  $T$  is the sample period. In discrete terms,  $w_n = w(nT)$ , and

$$w_n = \frac{A^2}{4} e^{j[\phi_n - \phi_{n-1}]},$$

$$v_n = \phi_n - \phi_{n-1}.$$

The signal  $v_n$  is the approximate derivative of  $\phi_n$ , such that  $v_n \approx \dot{\phi}_n$ .

**Introduced in R2015a**

## reset

**System object:** comm.FMDemodulator

**Package:** comm

Reset states of the FM demodulator object

## Syntax

reset(H)

## Description

reset(H) resets the states of the FMDemodulator object, H.

This method resets the windowed suffix from the last symbol in the previously processed frame.

# step

**System object:** comm.FMDemodulator

**Package:** comm

Applies FM baseband demodulation

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  frequency demodulates an input signal,  $X$ , and returns an output signal,  $Y$ . The input  $X$  is real or complex and can be either a scalar or a column vector. Double- and single-precision data types are supported. The output  $Y$  is real and has the same data type and dimensions as  $X$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.FMModulator

**Package:** comm

Modulate using FM method

## Description

The `FMModulator` System object applies FM modulation to an input signal.

To FM modulate a signal:

- 1 Define and set up the `FMModulator` object. See “Construction” on page 4-813.
- 2 Call `step` to apply FM modulation to a signal according to the properties of `comm.FMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.FMModulator` creates a modulator System object, `H`, that frequency modulates an input signal.

`H = comm.FMModulator(demod)` creates an FM modulator object whose properties are determined by the corresponding FM demodulator object, `demod`.

`H = comm.FMModulator(Name,Value)` creates an FM modulator object with each specified property `Name` set to the specified `Value`. `Name` must appear inside single quotes. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### FrequencyDeviation

Peak deviation of the output signal frequency (Hz)

Specify the frequency deviation of the FM modulator in Hz as a positive real scalar. The default value is `75e3`. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. This property is nontunable.

### SampleRate

Sample rate of the input signal (Hz)

Specify the sample rate in Hz as a positive real scalar. The default value is `240e3`. The output sample rate is equal to the input sample rate. This property is nontunable.

## Methods

`reset`      Reset states of the FM modulator object  
`step`        Applies FM baseband modulation

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### FM Modulate a Sinusoidal Signal

Apply baseband modulation to a sine wave input signal and plot its response.

Set the example parameters.

```
fs = 1e3;                    % Sample rate (Hz)
ts = 1/fs;                  % Sample period (s)
fd = 50;                    % Frequency deviation (Hz)
```

Create a sinusoidal input signal with duration 0.5s and frequency 4 Hz.

```
t = (0:ts:0.5-ts)';  
x = sin(2*pi*4*t);
```

Create an FM modulator System object™.

```
MOD = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
```

FM modulate the input signal and plot its real part. You can see that the frequency of the modulated signal changes with the amplitude of the input signal.

```
y = step(MOD,x);  
plot(t,[x real(y)])
```

### Plot Spectrum of FM Modulated Baseband Signal

Apply FM baseband modulation to a white Gaussian noise source and plot its spectrum.

Set the example parameters.

```
fs = 1e3;           % Sample rate (Hz)
ts = 1/fs;         % Sample period (s)
fd = 10;           % Frequency deviation (Hz)
```

Create a white Gaussian noise source having a duration of 5s.

```
t = (0:ts:5-ts)';
x = wgn(length(t),1,0);
```

Create an FM modulator System object? and modulate the input signal.

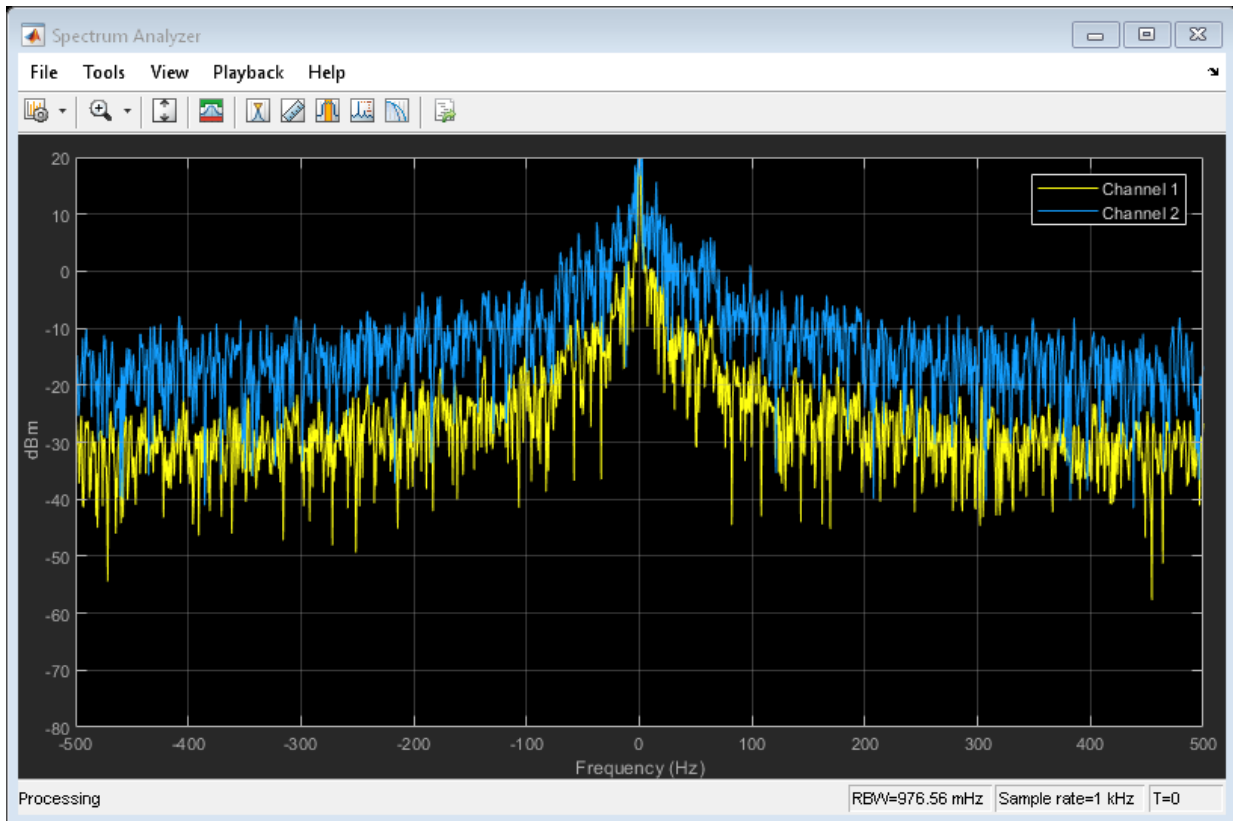

```
MOD1 = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
y = step(MOD1,x);
```

Create another modulator object, MOD2, whose frequency deviation is five times larger and apply FM modulation.

```
MOD2 = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',5*fd);
z = step(MOD2,x);
```

Plot the spectra of the two modulated signals. The larger frequency deviation associated with channel 2 results in a noise level that is 10 dB higher.

```
SA = dsp.SpectrumAnalyzer('SampleRate',fs,'ShowLegend',true);
step(SA,[y z])
```

## Algorithms

Represent a frequency modulated passband signal,  $Y(t)$ , as

$$Y(t) = A \cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right),$$

where  $A$  is the carrier amplitude,  $f_c$  is the carrier frequency,  $x(\tau)$  is the baseband input signal, and  $f_\Delta$  is the frequency deviation in Hz. The frequency deviation is the maximum shift from  $f_c$  in one direction, assuming  $|x(t)| \leq 1$ .

A baseband FM signal can be derived from the passband representation by downconverting it by  $f_c$  such that

$$\begin{aligned} y_s(t) &= Y(t)e^{-j2\pi f_c t} = \frac{A}{2} \left[ e^{j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} + e^{-j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} \right] e^{-j2\pi f_c t} \\ &= \frac{A}{2} \left[ e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau) d\tau} \right]. \end{aligned}$$

Removing the component at  $-2f_c$  from  $y_s(t)$  leaves the baseband signal representation,  $y(t)$ , which is expressed as

$$y(t) = \frac{A}{2} e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau}.$$

The expression for  $y(t)$  is rewritten as

$$y(t) = \frac{A}{2} e^{j\phi(t)},$$

where  $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau) d\tau$ , which implies that the input signal is a scaled version of the derivative of the phase,  $\phi(t)$ .

A baseband delay demodulator is used to recover the input signal from  $y(t)$ .

A delayed and conjugated copy of the received signal is subtracted from the signal itself,

$$w(t) = \frac{A^2}{4} e^{j\phi(t)} e^{-j\phi(t-T)} = \frac{A^2}{4} e^{j[\phi(t) - \phi(t-T)]},$$

where  $T$  is the sample period. In discrete terms,  $w_n = w(nT)$ , and

$$w_n = \frac{A^2}{4} e^{j[\phi_n - \phi_{n-1}]},$$

$$v_n = \phi_n - \phi_{n-1}.$$

The signal  $v_n$  is the approximate derivative of  $\phi_n$ , such that  $v_n \approx \dot{\phi}_n$ .

## comm.FSKDemodulator

**Package:** comm

Demodulate using M-ary FSK method

### Description

The `FSKDemodulator` object demodulates a signal that was modulated using the M-ary frequency shift keying method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals.

To demodulate a signal that was modulated using frequency shift keying:

- 1 Define and set up your FSK demodulator object. See “Construction” on page 4-822.
- 2 Call `step` to demodulate a signal according to the properties of `FSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.FSKDemodulator` creates a demodulator System object, `H`. This object demodulates an M-ary frequency shift keying (M-FSK) signal using a noncoherent energy detector.

`H = comm.FSKDemodulator(Name,Value)` creates an M-FSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.FSKDemodulator(M,FREQSEP,RS,Name,Value)` creates an M-FSK demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, the

FrequencySeparation property set to `FREQSEP`, the SymbolRate property set to `RS`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of frequencies in modulated signal

Specify the number of frequencies in the modulated signal as a numeric, positive, integer scalar value that is a power of two. The default is 8.

### BitOutput

Output data as bits

Specify whether the output is groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector of length equal to `N/SamplesPerSymbol` on page 4-0 .  $N$  is the length of the input data vector to the `step` method. The elements of the output vector are integers between 0 and `ModulationOrder` on page 4-0 -1. When you set this property to `true`, the `step` method outputs a column vector of length equal to  $\log_2(\text{ModulationOrder}) \times (N/\text{SamplesPerSymbol})$ . The property's elements are bit representations of integers between 0 and `ModulationOrder`-1.

### SymbolMapping

Symbol encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder}$  on page 4-0 ) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses Gray-coded ordering.

When you set this property to `Binary`, the object uses natural binary-coded ordering.

For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer  $M-1$ . In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

### FrequencySeparation

Frequency separation between successive tones

Specify the frequency separation between successive symbols in the modulated signal in Hertz as a positive, real scalar value. The default is 6 Hz.

### SamplesPerSymbol

Number of samples per input symbol

Specify the number of samples per input symbol as a positive, integer scalar value. The default is 17.

### SymbolRate

Symbol duration

Specify the symbol rate in symbols per second as a positive, double-precision, real scalar value. The default is 100. To avoid output signal aliasing, specify an output sampling rate,  $F_s = \text{SamplesPerSymbol} \times \text{SymbolRate}$ , which is greater than  $\text{ModulationOrder} \times \text{FrequencySeparation}$ . The symbol duration remain the same, regardless of whether the input is bits or integers.

### OutputDataType

Data type of output

Specify the output data type as one of `logical` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `double`. The default is `double`. The `logical` type is valid only when you set the `BitOutput` property to false and the `ModulationOrder` property to two. When you set the `BitOutput` property to true, the output data requires a type of `logical` | `double`.

## Methods

## Examples

### FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz.

Set the modulation order and frequency separation parameters.

```
M = 8;
freqSep = 100;
```

Create FSK modulator and demodulator System objects™ with modulation order 8 and 100 Hz frequency separation.

```
fskMod = comm.FSKModulator(M, freqSep);
fskDemod = comm.FSKDemodulator(M, freqSep);
```

Create an additive white Gaussian noise channel, where the noise is specified as a signal-to-noise ratio.

```
ch = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', -2);
```

Create an error rate calculator object.

```
err = comm.ErrorRate;
```

Transmit one hundred 50-symbol frames using 8-FSK in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1], 50, 1);
    modSignal = step(fskMod, data);
    noisySignal = step(ch, modSignal);
    receivedData = step(fskDemod, noisySignal);
    errorStats = step(err, data, receivedData);
end
```

Display the error statistics.

```
es = 'Error rate = %4.2e\nNumber of errors = %d\nNumber of symbols = %d\n';  
fprintf(es,errorStats)
```

```
Error rate = 1.40e-02  
Number of errors = 70  
Number of symbols = 5000
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-FSK Demodulator Baseband block reference page. The object properties correspond to the block parameters, except:

- The **Symbol set ordering** parameter corresponds to the SymbolMapping on page 4-0 property.
- The SymbolRate on page 4-0 property replaces the block sample rate capability.

Demodulate using M-ary FSK method

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates input data,  $X$ , with the FSK demodulator System object,  $H$ , and returns  $Y$ .  $X$  must be a double or single precision data type column vector of length equal to an integer multiple of the number of samples per symbol that you specify in the `SamplesPerSymbol` property. Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.FSKModulator

**Package:** comm

Modulate using M-ary FSK method

## Description

The `FSKModulator` object modulates using the M-ary frequency shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using frequency shift keying:

- 1 Define and set up your FSK modulator object. See “Construction” on page 4-829.
- 2 Call `step` to modulate a signal according to the properties of `comm.FSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.FSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the M-ary frequency shift keying (M-FSK) method.

`H = comm.FSKModulator(Name,Value)` creates an M-FSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.FSKModulator(M,FREQSEP,RS,Name,Value)` creates an M-FSK modulator object, `H`. This object has the `ModulationOrder` property set to `M`, the `FrequencySeparation` property set to `FREQSEP`, the `SymbolRate` property set to `RS`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of frequencies in modulated signal

Specify the number of frequencies in the modulated signal as a numeric positive integer scalar value that is a power of two. The default is 8.

### BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input requires a numeric (except single precision data type) column vector of integer values between 0 and `ModulationOrder` on page 4-0 -1. In this case, the input vector can also be of data type `logical` if `ModulationOrder` equals 2.

When you set this property to `true`, the `step` method input requires a double-precision or `logical` data type column vector of bit values. The length of this vector is an integer multiple of `log2(ModulationOrder)`. This vector contains bit representations of integers between 0 and `ModulationOrder-1`.

### SymbolMapping

Symbol encoding

Specify how the object maps an integer or group of `log2(ModulationOrder` on page 4-0 ) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses Gray-coded ordering.

When you set this property to `Binary`, the object uses natural binary-coded ordering. For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer `M-1`. In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

### FrequencySeparation

Frequency separation between successive tones

Specify the frequency separation between successive tones in the modulated signal in Hertz as a positive, real scalar value. The default is 6 Hz. To avoid output signal aliasing, specify an output sampling rate,  $F_s = \text{SamplesPerSymbol} \times \text{SymbolRate}$ , which is greater than  $\text{ModulationOrder} \times \text{FrequencySeparation}$ .

### ContinuousPhase

Phase continuity

Specify if the phase of the output modulated signal is continuous or discontinuous. The default is `true`.

When you set this property to `true`, the modulated signal maintains continuous phase even when its frequency changes.

When you set this property to `false`, the modulated signal comprises portions of  $\text{ModulationOrder}$  sinusoids of different frequencies. In this case, a change in the input value can cause a discontinuous change in the phase of the modulated signal.

### SamplesPerSymbol

Number of samples per output symbol

Specify the number of output samples that the object produces for each integer or binary word in the input as a positive, integer scalar value. The default is 17.

### SymbolRate

Symbol duration

Specify the symbol rate in symbols per second as a positive, double-precision, real scalar. The default is 100. To avoid output signal aliasing, specify an output sampling rate,  $F_s = \text{SamplesPerSymbol} \times \text{SymbolRate}$ , which is greater than  $\text{ModulationOrder} \times \text{FrequencySeparation}$ . The symbol duration remain the same, regardless of whether the input is bits or integers.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

## Methods

release	Allow System object property value changes

## Examples

### FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz.

Set the modulation order and frequency separation parameters.

```
M = 8;  
freqSep = 100;
```

Create FSK modulator and demodulator System objects™ with modulation order 8 and 100 Hz frequency separation.

```
fskMod = comm.FSKModulator(M, freqSep);  
fskDemod = comm.FSKDemodulator(M, freqSep);
```

Create an additive white Gaussian noise channel, where the noise is specified as a signal-to-noise ratio.

```
ch = comm.AWGNChannel('NoiseMethod', ...  
    'Signal to noise ratio (SNR)', 'SNR', -2);
```

Create an error rate calculator object.

```
err = comm.ErrorRate;
```

Transmit one hundred 50-symbol frames using 8-FSK in an AWGN channel.

```
for counter = 1:100  
    data = randi([0 M-1], 50, 1);
```

```

    modSignal = step(fskMod,data);
    noisySignal = step(ch,modSignal);
    receivedData = step(fskDemod,noisySignal);
    errorStats = step(err,data,receivedData);
end

```

Display the error statistics.

```

es = 'Error rate = %4.2e\nNumber of errors = %d\nNumber of symbols = %d\n';
fprintf(es,errorStats)

```

```

Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000

```

## Visualize FSK Modulated Symbol Mapping

Visualize symbol mapping of an FSK modulated signal with a spectrogram.

Specify 20 samples for each symbol. 0 maps to -50 kHz (negative phase slope) and 1 maps to +50 kHz (positive phase slope).

```

mod = comm.FSKModulator;
mod.ModulationOrder = 2;
mod.FrequencySeparation = 100000;
mod.SamplesPerSymbol = 20;
mod.SymbolMapping = 'Gray';
mod.SymbolRate = 1e4

```

```

mod =
    comm.FSKModulator with properties:

```

```

    ModulationOrder: 2
        BitInput: false
        SymbolMapping: 'Gray'
    FrequencySeparation: 100000
        ContinuousPhase: true
    SamplesPerSymbol: 20
        SymbolRate: 10000
    OutputDataType: 'double'

```

```
x = mod([0 1 0 1 0 1]');
figure; subplot(1,2,1); plot(unwrap(angle(x)),0:length(x)-1);
grid on; xlabel('Phase'); ylabel('Samples')
subplot(1,2,2);
spectrogram(x,20,0,[],mod.SymbolRate*mod.SamplesPerSymbol,'centered')
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-FSK Modulator Baseband block reference page. The object properties correspond to the block parameters, except:

- The **Symbol set ordering** parameter corresponds to the SymbolMapping on page 4-0 property.
- The SymbolRate on page 4-0 property takes the place of the block sample rate capability.

## Extended Capabilities

**Introduced in R2012a**

## **reset**

**System object:** comm.FSKModulator

**Package:** comm

Reset states of M-FSK modulator object

## **Syntax**

reset(H)

## **Description**

reset(H) resets the states of the FSKModulator object, H.

---

## step

**System object:** comm.FSKModulator

**Package:** comm

Modulate using M-ary FSK method

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  modulates input data,  $X$ , with the FSK modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be an integer or bit- valued column vector with numeric or logical data types. The length of output vector,  $Y$ , is equal to the number of input samples times the number of samples per symbol you specify in the `SamplesPerSymbol` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.GeneralQAMDemodulator

**Package:** comm

Demodulate using arbitrary QAM constellation

### Description

The `GeneralQAMDemodulator` object demodulates a signal that was modulated using quadrature amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using quadrature amplitude modulation:

- 1 Define and set up your QAM demodulator object. See “Construction” on page 4-838.
- 2 Call `step` to demodulate a signal according to the properties of `comm.GeneralQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.GeneralQAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using a general quadrature amplitude modulation (QAM) method.

`H = comm.GeneralQAMDemodulator(Name,Value)` creates a general QAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.GeneralQAMDemodulator(CONST, Name, Value)` creates a general QAM demodulator object, `H`. This object has the `Constellation` property set to `CONST`, and the other specified properties set to the specified values.

## Properties

### Constellation

Signal constellation

Specify the constellation points as a real or complex, double-precision data type vector. The default is  $\exp(2 \times \pi \times 1i \times (0:7)/8)$ . The length of the vector determines the modulation order.

When you set the `BitOutput` on page 4-0 property to `false`, the `step` method outputs a vector with integer values. These integers are between 0 and  $M-1$ , where  $M$  is the length of this property vector. The length of the output vector equals the length of the input signal.

When you set the `BitOutput` property to `true`, the output signal contains bits. For bit outputs, the size of the signal constellation requires an integer power of two and the output length is an integer multiple of the number of bits per symbol.

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`.

When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to  $\log_2(M)$  times the number of demodulated symbols, where  $M$  is the length of the signal constellation specified in the `Constellation` on page 4-0 property. The length  $M$  determines the modulation order.

When you set this property to `false`, the `step` method outputs a column vector, of length equal to the input data vector. The vector contains integer symbol values between 0 and  $M-1$ .

### **DecisionMethod**

Demodulation decision method

Specify the decision method the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` on page 4-0 property to `false` the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to `true`.

### **VarianceSource**

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

### **Variance**

Noise variance

Specify the variance of the noise as a nonzero, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield `Inf` or `-Inf`. This result occurs because the LLR algorithm would compute the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, using approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the `VarianceSource` on page 4-0 property to `Property`. This property is tunable.

### **OutputDataType**

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision` .

This property applies only when you set the `BitOutput` on page 4-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision` or `Approximate log-likelihood ratio`. In this case, when you set the `OutputDataType` on page 4-0 property to `Full`

precision, the output data type is the same as that of the input when the input data has a single or double-precision data type.

When the input data is of a fixed-point type, the output data type works as if you had set the `OutputDataType` property to `Smallest unsigned integer`.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When you set the `BitOutput` property to `true`, and the `DecisionMethod` property to `Hard Decision` the data type `logical` becomes a valid option.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Approximate log-likelihood ratio` you may only set this property to `Full precision` | `Custom`.

If you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio`, the output data has the same type as that of the input. In this case, that value can be only single or double precision.

### **Fixed-Point Properties**

#### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 4-846.

#### **RoundingMethod**

Rounding of fixed-point numeric values

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies when the object is

not in a full precision configuration. This property does not apply when you set `BitOutput` on page 4-0 to true and `DecisionMethod` on page 4-0 to `Log-likelihood ratio`.

### **OverflowAction**

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration. This property does not apply when you set the `BitOutput` on page 4-0 property to true and the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio`.

### **ConstellationDataType**

Data type of signal constellation

Specify the constellation fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property does not apply when you set the `BitOutput` on page 4-0 property to true and the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio`.

### **CustomConstellationDataType**

Fixed-point data type of signal constellation

Specify the constellation fixed-point type as an `unscaled numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([], 16)`. This property applies when you set the `ConstellationDataType` on page 4-0 property to `Custom`.

### **Accumulator1DataType**

Data type of accumulator 1

Specify the accumulator 1 fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false. This property does not apply when you set the `BitOutput` on page 4-0 property to true and the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio`.

### **CustomAccumulator1DataType**

Fixed-point data type of accumulator 1

Specify the accumulator 1 fixed-point type as a scaled `numericType` object with a Signedness of Auto. The default is `numericType([], 32, 30)`. This property applies when you set the `Accumulator1DataType` on page 4-0 property to Custom.

### **ProductInputDataType**

Data type of product

Specify the product input fixed-point data type as one of Same as accumulator 1 | Custom. The default is Same as accumulator 1. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false, the `BitOutput` on page 4-0 property to true and the `DecisionMethod` on page 4-0 property to Log-likelihood ratio.

### **CustomProductInputDataType**

Fixed-point data type of product

Specify the product input fixed-point type as a scaled `numericType` object with a Signedness of Auto. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false and the `ProductInputDataType` on page 4-0 property to Custom.

### **ProductOutputDataType**

Data type of product output

Specify the product output fixed-point data type as one of Full precision | Custom. The default is Full precision . This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false, the `BitOutput` on page 4-0 property to true and the `DecisionMethod` on page 4-0 property to Log-likelihood ratio.

### **CustomProductOutputDataType**

Fixed-point data type of product output

Specify the product output fixed-point type as a scaled `numericType` object with a Signedness of Auto. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false and the `ProductOutputDataType` on page 4-0 property to Custom.

### **Accumulator2DataType**

Data type of accumulator 2

Specify the accumulator 2 fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false, the `BitOutput` on page 4-0 property to true and the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio`.

### **CustomAccumulator2DataType**

Fixed-point data type accumulator 2

Specify the accumulator 2 fixed-point data type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false and the `Accumulator2DataType` on page 4-0 property to `Custom`.

### **Accumulator3DataType**

Data type of accumulator 3

Specify the accumulator 3 fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false, the `BitOutput` on page 4-0 property to true and the `DecisionMethod` on page 4-0 property to `Approximate log-likelihood ratio`.

### **CustomAccumulator3DataType**

Fixed-point data type of accumulator 3

Specify the accumulator 3 fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false and the `Accumulator3DataType` on page 4-0 property to `Custom`.

### **NoiseScalingInputDataType**

Data type of noise-scaling input

Specify the noise-scaling input fixed-point data type as one of `Same as accumulator 3` | `Custom`. The default is `Same as accumulator 3`. This property applies when you set

the `FullPrecisionOverride` on page 4-0 property to false, the `BitOutput` on page 4-0 property to true and the `DecisionMethod` on page 4-0 property to `Approximate log-likelihood ratio`.

### **CustomNoiseScalingInputDataType**

Fixed-point data type of noise-scaling input

Specify the noise-scaling input fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false and the `NoiseScalingInputDataType` on page 4-0 property to `Custom`.

### **InverseVarianceDataType**

Data type of inverse noise variance

Specify the inverse noise variance fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on page 4-0 property to true, the `DecisionMethod` on page 4-0 property to `Approximate log-likelihood ratio`, and the `VarianceSource` on page 4-0 property to `Property`.

### **CustomInverseVarianceDataType**

Fixed-point data type of inverse noise variance

Specify the inverse noise variance fixed-point type as a `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16, 8)`. This property applies when you set the `InverseVarianceDataType` on page 4-0 property to `Custom`.

### **CustomOutputDataType**

Data type of output

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false and the `OutputDataType` on page 4-0 property to `Custom`.

## Methods

step Demodulate using arbitrary QAM constellation

Common to All System Objects

## Examples

Modulate and demodulate data using an arbitrary three-point constellation.

```
% Setup a three point constellation
c = [1 1i -1];
hQAMMod = comm.GeneralQAMModulator(c);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 15, 'SignalPower', 0.89);
hQAMDemod = comm.GeneralQAMDemodulator(c);

%Create an error rate calculator
hError = comm.ErrorRate;
for counter = 1:100
    % Transmit a 50-symbol frame
    data = randi([0 2], 50, 1);
    modSignal = step(hQAMMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hQAMDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

## More About

### Full Precision for Fixed-Point System Objects

FullPrecisionOverride is a convenience property that, when you set to true, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### Objects

`comm.GeneralQAMModulator` | `comm.RectangularQAMDemodulator`

**Introduced in R2012a**

# step

**System object:** `comm.GeneralQAMDemodulator`

**Package:** `comm`

Demodulate using arbitrary QAM constellation

## Syntax

`Y = step(H,X)`

`Y = step(H,X,VAR)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` demodulates the input data, `X`, with the general QAM demodulator System object, `H`, and returns `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. When you set the `BitOutput` property to true and the `DecisionMethod` property to 'Log-likelihood ratio' the input data type must be single or double precision. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to true, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to 'Input port'.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.GeneralQAMModulator

**Package:** comm

Modulate using arbitrary QAM constellation

### Description

The `GeneralQAMModulator` object modulates using quadrature amplitude modulation. The output is a baseband representation of the modulated signal.

To modulate a signal using quadrature amplitude modulation:

- 1 Define and set up your QAM modulator object. See “Construction” on page 4-850.
- 2 Call `step` to modulate a signal according to the properties of `comm.GeneralQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.GeneralQAMModulator` creates a modulator System object, `H`. This object modulates the input signal using a general quadrature amplitude modulation (QAM) method.

`H = comm.GeneralQAMModulator(Name,Value)` creates a QAM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.GeneralQAMModulator(CONST,Name,Value)` creates a General QAM modulator object, `H`. This object has the `Constellation` property set to `CONST`, and the other specified properties set to the specified values.

## Properties

### Constellation

Signal constellation

Specify the constellation points as a vector of real or complex double-precision data type. The default is  $\exp(2 \times \pi \times 1i \times (0:7)/8)$ . The length of the vector determines the modulation order. The `step` method inputs requires integers between 0 and  $M-1$ , where  $M$  indicates the length of this property vector. The object maps an input integer  $m$  to the  $(m+1)^{\text{st}}$  value in the Constellation vector.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

### Fixed-Point Properties

#### CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([ ], 16)`. This property applies when you set the `OutputDataType` on page 4-0 property to `Custom`.

## Methods

`step` Modulate using arbitrary QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes

### Examples

Modulate data using an arbitrary 3-point constellation. Then, visualize the data in a scatter plot

```
hQAMMod = comm.GeneralQAMModulator;  
% Setup a three point constellation  
hQAMMod.Constellation = [1 1i -1];  
data = randi([0 2],100,1);  
modData = step(hQAMMod, data);  
scatterplot(modData)
```

### Algorithms

# comm.GeneralQAMTCMDemodulator

**Package:** comm

Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

## Description

The `GeneralQAMTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using an arbitrary signal constellation.

To demodulate a signal that was modulated using a trellis-coded, general quadrature amplitude modulator:

- 1 Define and set up your general QAM TCM modulator object. See “Construction” on page 4-855.
- 2 Call `step` to demodulate a signal according to the properties of `comm.GeneralQAMTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.GeneralQAMTCMDemodulator` creates a trellis-coded, general quadrature amplitude (QAM TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to an arbitrary QAM constellation.

`H = comm.GeneralQAMTCMDemodulator(Name,Value)` creates a general QAM TCM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.GeneralQAMTCMDemodulator(TRELLIS,Name,Value)` creates a general QAM TCM demodulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the value that results from `poly2trellis([1 3], [1 0 0; 0 5 2])`.

### TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

### TracebackDepth

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The Traceback depth parameter influences the decoding accuracy and

delay. The decoding delay indicates the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` on page 4-0 property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth×K` zero bits for a rate  $K/N$  convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

### **ResetInputPort**

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous`.

### **Constellation**

Signal constellation

Specify a double- or single-precision complex vector. This vector lists the points in the signal constellation that were used to map the convolutionally encoded data. The constellation must be specified in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to  $2^N$  for a rate  $K/N$  convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed as  $\exp(2 \times \pi \times j \times [0 \ 4 \ 2 \ 6 \ 1 \ 5 \ 3 \ 7]/8)$ .

### **OutputDataType**

Data type of output

Specify output data type as one of `logical` | `double`. The default is `double`.

## Methods

reset Reset states of the general QAM TCM demodulator object

step Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Modulate and Demodulate Data Using QAM TCM

Modulate and demodulate noisy data using QAM TCM modulation with an arbitrary 4-point constellation. Estimate the resultant BER.

Define a trellis structure with two input symbols and four output symbols using a [171 133] generator polynomial. Define an arbitrary four-point constellation.

```
qamTrellis = poly2trellis(7,[171 133]);  
refConst = exp(pi*1i*[1 2 3 6]/4);
```

Create a QAM TCM modulator and demodulator System object™ pair using qamTrellis and refConst.

```
hMod = comm.GeneralQAMTCModulator(qamTrellis,'Constellation', refConst);  
hDemod = comm.GeneralQAMTCMDemodulator(qamTrellis,'Constellation',refConst);
```

Create an AWGN channel object in which the noise is set by using a signal-to-noise ratio.

```
hAWGN = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...  
    'SNR',4);
```

Create an error rate calculator with delay (in bits) equal to the product of TracebackDepth and the number of bits per symbol

```
hError = comm.ErrorRate(...  
    'ReceiveDelay', hDemod.TracebackDepth*log2(qamTrellis.numInputSymbols));
```

Generate random binary data and apply QAM TCM modulation. Pass the signal through an AWGN channel and demodulate. Collect the error statistics.

```
for counter = 1:10
    % Generate binary data
    data = randi([0 1],500,1);
    % Modulate
    modSignal = step(hMod,data);
    % Pass through an AWGN channel
    noisySignal = step(hAWGN,modSignal);
    % Demodulate
    receivedData = step(hDemod,noisySignal);
    % Calculate the error statistics
    errorStats = step(hError,data,receivedData);
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 1.16e-02
Number of errors = 58
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General TCM Decoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Reset states of the general QAM TCM demodulator object

## Syntax

reset(H)

## Description

reset(H) resets the states of the GeneralQAMTCMDemodulator object, H.

# step

**System object:** `comm.GeneralQAMTCMDemodulator`

**Package:** `comm`

Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

## Syntax

`Y = step(H,X)`

`Y = step(H,X,R)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` demodulates the general QAM modulated input data, `X`, and uses the Viterbi algorithm to decode the resulting demodulated convolutionally encoded bits. `X` must be a complex double or single precision column vector. The `step` method outputs a demodulated binary column data vector, `Y`. When the convolutional encoder represents a rate  $K/N$  code, the length of the output vector equals  $K \times L$ , where  $L$  is the length of the input vector, `X`.

`Y = step(H,X,R)` resets the decoder states of the general QAM TCM demodulator System object to the all-zeros state when you input a non-zero reset signal, `R`. `R` must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.GeneralQAMTCMModulator

**Package:** comm

Convolutionally encode binary data and map using arbitrary QAM constellation

### Description

The `GeneralQAMTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal. The object then maps the result to an arbitrary signal constellation. The `SignalConstellation` property lists the signal constellation points in set-partitioned order.

To modulate a signal using a trellis-coded, general quadrature amplitude modulator:

- 1 Define and set up your general QAM TCM modulator object. See “Construction” on page 4-864.
- 2 Call `step` to modulate a signal according to the properties of `comm.GeneralQAMTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.GeneralQAMTCMModulator` creates a trellis-coded, general quadrature amplitude (QAM TCM) modulator System object, `H`. This object convolutionally encodes a binary input signal and maps the result using QAM modulation with a signal constellation specified in the `Constellation` property.

`H = comm.GeneralQAMTCMModulator(Name,Value)` creates a general QAM TCM modulator System object, `H`, with each specified property set to the specified value. You

can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

`H = comm.GeneralQAMTCMModulator(TRELLIS,Name,Value)` creates a general QAM TCM modulator System object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

### TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate  $K/N$  code, the `step` method outputs the vector with length  $y = N \times (L + S)/K$ , where  $S = \text{constraintLength}-1$ . In the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i)-1)$ .  $L$  represents the length of the input to the `step` method.

### ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous`.

### Constellation

Signal constellation

Specify a double- or single-precision complex vector that lists the points in the signal constellation that were used to map the convolutionally encoded data. You must specify the constellation in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to  $2^N$  for a rate  $K/N$  convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed

$\exp(2 \times \pi \times j \times [0 \ 4 \ 2 \ 6 \ 1 \ 5 \ 3 \ 7]/8)$ .

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

## Methods

$Y = \text{step}(H,X,R)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  convolutionally encodes and modulates the input data,  $X$ , and returns the encoded and modulated data,  $Y$ .  $X$  must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector,  $X$ , must be  $K \times L$ , for some positive integer  $L$ . The `step` method outputs a complex column vector,  $Y$ , of length  $L$ .

$Y = \text{step}(H,X,R)$  resets the encoder of the general QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal,  $R$ .  $R$  must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to true.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# comm.GMSKDemodulator

**Package:** comm

Demodulate using GMSK method and the Viterbi algorithm

## Description

The `GMSKDemodulator` object uses a Viterbi algorithm to demodulate a signal that was modulated using the Gaussian minimum shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using Gaussian minimum shift keying:

- 1 Define and set up your GMSK demodulator object. See “Construction” on page 4-822.
- 2 Call `step` to demodulate a signal according to the properties of `GMSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.GMSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input Gaussian minimum shift keying (GMSK) modulated data using the Viterbi algorithm.

`H = comm.GMSKDemodulator(Name,Value)` creates a GMSK demodulator object, `H`. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### BitOutput

Output data as bits

Specify whether the output is groups of bits or integer values. The default is `false`.

When you set the `BitOutput` on page 4-0 property to `false`, the `step` method outputs a column vector of length equal to `N/SamplesPerSymbol` on page 4-0 .  $N$  is the length of the input signal, which is the number of input baseband modulated symbols. The elements of the output vector are  $-1$  or  $1$ .

When you set the `BitOutput` property to `true`, the `step` method outputs a binary column vector of length equal to `N/SamplesPerSymbol` with bit values of  $0$  or  $1$ .

### BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of bandwidth and symbol time for the Gaussian pulse shape as a real, positive scalar. The default `0.3`.

### PulseLength

Pulse length

Specify the length of the Gaussian pulse shape in symbol intervals as a real positive integer. The default `4`.

### SymbolPrehistory

Symbol prehistory

Specify the data symbols used by the modulator prior to the first call to the `step` method. The default is `1`. This property requires a scalar or vector with elements equal to  $-1$  or  $1$ . If the value is a vector, its length must be one less than the value you set in the `PulseLength` on page 4-0 property.

### InitialPhaseOffset

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar value. The default is 0.

### **SamplesPerSymbol**

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar value. The default is 8.

### **TracebackDepth**

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar value. The value of this property is also the output delay, and the number of zero symbols that precede the first meaningful demodulated symbol in the output. The default is 16.

### **OutputDataType**

Data type of output

Specify the output data type as one of `int8` | `int16` | `int32` | `double`, when you set the `BitOutput` on page 4-0 property to `false`.

When you set the `BitOutput` property to `true`, specify the output data type as one of `logical` | `double`. The default is `double`.

## **Methods**

- `reset`    Reset states of the GMSK demodulator object
- `step`     Demodulate using GMSK method and the Viterbi algorithm

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## Examples

### Demodulate a GMSK signal with bit inputs and phase offset

```
% Create a GMSK modulator, an AWGN channel, and a GMSK demodulator. Use a phase offset
hMod = comm.GMSKModulator('BitInput', true, 'InitialPhaseOffset', pi/4);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.GMSKDemodulator('BitOutput', true, ...
    'InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1], 300, 1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.000133
Number of errors = 4
```

### Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput', true, 'PulseLength', 1, 'SamplesPerSymbol', 1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5, 1);
y = gmsk(x)
```

```
y = 5x1 complex
```

```
1.0000 + 0.0000i
-0.0000 - 1.0000i
-1.0000 + 0.0000i
0.0000 + 1.0000i
1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5x1
```

```
0
-1.5708
-3.1416
-4.7124
-6.2832
```

A sequence of zeros causes the phase to shift by  $-\pi/2$  between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
```

```
y = 5x1 complex
```

```
1.0000 + 0.0000i
-0.0000 + 1.0000i
-1.0000 - 0.0000i
0.0000 - 1.0000i
1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5x1
        0
        1.5708
        3.1416
        4.7124
        6.2832
```

A sequence of ones causes the phase to shift by  $+\pi/2$  between samples.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [GMSK Demodulator Baseband block reference page](#). The object properties correspond to the block parameters. For GMSK the phase shift per symbol is  $\pi/2$ , which is a modulation index of 0.5.

# comm.GMSKModulator

**Package:** comm

Modulate using GMSK method

## Description

The `GMSKModulator` object modulates using the Gaussian minimum shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using Gaussian minimum shift keying:

- 1 Define and set up your GMSK modulator object. See “Construction” on page 4-881.
- 2 Call `step` to modulate a signal according to the properties of `comm.GMSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.GMSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the Gaussian minimum shift keying (GMSK) modulation method.

`H = comm.GMSKModulator(Name,Value)` creates a GMSK modulator object, `H`. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### **BitInput**

Assume input is bits

Specify whether the input is bits or integers. The default is `false`.

When you set the `BitInput` on page 4-0 property to `false`, the `step` method input requires a double-precision or signed integer data type column vector with values of `-1` or `1`.

When you set the `BitInput` property to `true`, `step` method input requires a double-precision or logical data type column vector of `0`s and `1`s.

### **BandwidthTimeProduct**

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of the bandwidth and symbol time for the Gaussian pulse shape as a real, positive scalar value. The default is `0.3`.

### **PulseLength**

Pulse length

Specify the length of the Gaussian pulse shape in symbol intervals as a real, positive integer. The default is `4`.

### **SymbolPrehistory**

Symbol prehistory

Specify the data symbols the modulator uses prior to the first call to the `step` method in reverse chronological order. The default is `1`. This property requires a scalar or vector with elements equal to `-1` or `1`. If the value is a vector, then its length must be one less than the value in the `PulseLength` on page 4-0 property.

### **InitialPhaseOffset**

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar value. The default is 0.

### SamplesPerSymbol

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar value. The default is 8. The upsampling factor is the number of output samples that the `step` method produces for each input sample.

### OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

## Methods

`reset`      Reset states of the GMSK modulator object  
`step`        Modulate using GMSK method

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

### Modulate a GMSK signal with bit inputs and phase offset

```
% Create a GMSK modulator, an AWGN channel, and a GMSK demodulator. Use a phase offset
hMod = comm.GMSKModulator('BitInput', true, 'InitialPhaseOffset', pi/4);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.GMSKDemodulator('BitOutput', true, ...
    'InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
```

```
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1],300,1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
```

```
Error rate = 0.000133
Number of errors = 4
```

### Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
```

*y = 5×1 complex*

```
1.0000 + 0.0000i
-0.0000 - 1.0000i
-1.0000 + 0.0000i
0.0000 + 1.0000i
1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5x1

    0
-1.5708
-3.1416
-4.7124
-6.2832
```

A sequence of zeros causes the phase to shift by  $-\pi/2$  between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
```

```
y = 5x1 complex
```

```
1.0000 + 0.0000i
-0.0000 + 1.0000i
-1.0000 - 0.0000i
0.0000 - 1.0000i
1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5x1

    0
 1.5708
 3.1416
 4.7124
 6.2832
```

A sequence of ones causes the phase to shift by  $+\pi/2$  between samples.

### Algorithms

This object implements the algorithm, inputs, and outputs described on the [GMSK Modulator Baseband](#) block reference page. The object properties correspond to the block parameters. For GMSK the phase shift per symbol is  $\pi/2$ , which is a modulation index of 0.5.

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

#### See Also

`comm.CPMDemodulator` | `comm.CPModulator` | `comm.GMSKDemodulator`

**Introduced in R2012a**

## reset

**System object:** comm.GMSKModulator

**Package:** comm

Reset states of the GMSK modulator object

## Syntax

reset(H)

## Description

reset(H) resets the states of the GMSKModulator object, H.

# step

**System object:** comm.GMSKModulator

**Package:** comm

Modulate using GMSK method

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  modulates input data,  $X$ , with the GMSK modulator object,  $H$ . It returns the baseband modulated output in  $Y$ . Depending on the `BitInput` property value, input  $X$  can be a double precision, signed integer, or logical column vector. The length of vector  $Y$  is equal to the number of input samples times the number of samples per symbol that you specify in the `SamplesPerSymbol` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.GMSKTimingSynchronizer

**Package:** comm

Recover symbol timing phase using fourth-order nonlinearity method

## Description

The `GMSKTimingSynchronizer` object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This block implements a general non-data-aided feedback method. This timing synchronization is a non-data-aided feedback method that is independent of carrier phase recovery, but requires prior compensation for the carrier frequency offset. You can use this block for systems that use Gaussian minimum shift keying (GMSK) modulation.

To recover the symbol timing phase of the input signal:

- 1 Define and set up your GMSK timing synchronizer object. See “Construction” on page 4-889.
- 2 Call `step` to recover the symbol timing phase of the input signal according to the properties of `comm.GMSKTimingSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.GMSKTimingSynchronizer` creates a timing phase synchronizer System object, `H`. This object recovers the symbol timing phase of the GMSK input signal using a fourth-order nonlinearity method.

`H = comm.GMSKTimingSynchronizer(Name,Value)` creates a GMSK timing synchronizer object, `H`, with each specified property set to the specified value. You can

specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

### Properties

#### **SamplesPerSymbol**

Number of samples representing each symbol

Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar value greater than 1. The default is 4.

#### **ErrorUpdateGain**

Error update step size

Specify the step size for updating successive timing phase estimates as a positive real scalar value. Typically, this number is less than  $1/\text{SamplesPerSymbol}$  on page 4-0 , which corresponds to a slowly varying timing phase. The default is 0.05. This property is tunable.

#### **ResetInputPort**

Enable synchronization reset input

Set this property to `true` to enable resetting the timing phase recovery process based on an input argument value. The default is `false`.

When you set this property to `true`, you must specify a reset input value to the `step` method.

When you specify a nonzero value as the reset input, the object restarts the timing phase recovery process. When you set this property to `false`, the object does not restart.

#### **ResetCondition**

Condition for timing phase recovery reset

Specify the conditions to reset the timing phase recovery process as one of `Never` | `Every` frame. The default is `Never`.

When you set this property to `Never`, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to `Every frame`, the timing phase recovery restarts at the start of each frame of data. In this case, the restart occurs at each `step` method call. This property applies when you set the `ResetInputPort` on page 4-0 property to `false`.

## Methods

`reset` Reset states of GMSK timing phase synchronizer object

`step` Recover symbol timing phase using fourth-order nonlinearity method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Recover Timing Phase of GMSK Signal

Create GMSK modulator, variable fractional delay, and GMSK timing synchronizer System objects.

```
gmskMod = comm.GMSKModulator('BitInput', true, ...
    'SamplesPerSymbol', 14);
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
gmskTimingSync = comm.GMSKTimingSynchronizer('SamplesPerSymbol', 14, ...
    'ErrorUpdateGain', 0.05);
```

Main processing loop:

```
phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1); % Generate data
    modData = gmskMod(data); % Modulate data

    % Apply timing offset error
    impairedData = varDelay(modData,timingOffset*14);
```

```
% Perform timing phase recovery  
[~,phase] = gmskTimingSync(impairedData);  
phEst(i) = phase(1)/14;  
end
```

Plot the results.

```
plot(1:50,[0.2*ones(50,1) phEst])  
legend( 'Original','Estimated')  
title('Original and Estimated timing phases')
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the **Modulation type** parameter set to GMSK.
- The **Reset** parameter corresponds to the ResetInputPort on page 4-0 and ResetCondition on page 4-0 properties.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

reset(H)

## **Description**

reset(H) resets the states for the GMSKTimingSynchronizer object H.

---

## step

**System object:** comm.GMSKTimingSynchronizer

**Package:** comm

Recover symbol timing phase using fourth-order nonlinearity method

## Syntax

[Y, PHASE] = step(H, X)

[Y, PHASE] = step(H, X, R)

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

[Y, PHASE] = step(H, X) performs timing phase recovery and returns the time-synchronized signal, Y, and the estimated timing phase, PHASE, for input signal X. X must be a double or single precision complex column vector.

[Y, PHASE] = step(H, X, R) restarts the timing phase recovery process when you input a reset signal, R, that is non-zero. R must be a logical or double scalar. This syntax applies when you set the `ResetInputPort` property to true.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.GoldSequence

**Package:** comm

Generate Gold sequence

## Description

The `GoldSequence` object generates a Gold sequence. Gold sequences form a large class of sequences that have good periodic cross-correlation properties.

To generate a Gold sequence:

- 1 Define and set up your Gold sequence object. See “Construction” on page 4-897.
- 2 Call `step` to generate the Gold sequence according to the properties of `comm.GoldSequence`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

## Construction

`H = comm.GoldSequence` creates a Gold sequence generator System object, `H`. This object generates a pseudo-random Gold sequence.

`H = comm.GoldSequence(Name, Value)` creates a Gold sequence generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### FirstPolynomial

Generator polynomial for first preferred PN sequence

Specify the polynomial that determines the feedback connections for the shift register of the first preferred PN sequence generator. The default is ' $z^6 + z + 1$ '. You can specify the polynomial as a character vector. You can also specify the generator polynomial as a numeric, binary vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal 1, and the length of this vector requires a value of  $n+1$ , where  $n$  is the degree of the generator polynomial. Lastly, you can specify the generator polynomial as a numeric vector containing the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0. For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial,  $g(z) = z^8 + z^2 + 1$ . The degree of the first generator polynomial must equal the degree of the second generator polynomial specified in the `SecondPolynomial` on page 4-0 property.

### **FirstInitialConditions**

Initial conditions for first PN sequence generator

Specify the initial conditions for the shift register of the first preferred PN sequence generator. The default is `[0 0 0 0 0 1]`. The initial conditions require a numeric, binary scalar, or a numeric, binary vector with length equal to the degree of the first generator polynomial specified in the `FirstPolynomial` on page 4-0 property. If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. If you set this property to a scalar, the initial conditions of all shift register cells are the specified scalar value.

### **SecondPolynomial**

Generator polynomial for second preferred PN sequence

Specify the polynomial that determines the feedback connections for the shift register of the second preferred PN sequence generator. The default is ' $z^6 + z^5 + z^2 + z + 1$ '. You can specify the polynomial as a character vector. You can also specify the generator polynomial as a binary, numeric vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal 1 and the length of this vector requires a value of  $n+1$ , where  $n$  is the degree of the generator polynomial. Lastly, you can specify the generator polynomial as a numeric vector containing the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0. For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial,  $g(z) = z^8 + z^2 + 1$ . The degree of the second generator polynomial must equal the degree of the first generator polynomial specified in the `FirstPolynomial` on page 4-0 property.

## SecondInitialConditionsSource

Source of initial conditions for second PN sequence

Specify the source of the initial conditions that determines the start of the second PN sequence as one of `Property` | `Input port`. The default is `Property`. When you set this property to `Property`, you can specify the initial conditions as a scalar or binary vector using the `SecondInitialConditions` property. When you set this property to `Input port`, you specify the initial conditions as an input to the `step` method. The object accepts a binary scalar or a binary vector input. The length of the input must equal the degree of the generator polynomial that the `SecondPolynomial` on page 4-0 property specifies.

## SecondInitialConditions

Initial conditions for second PN sequence generator

Specify the initial conditions for the shift register of the second preferred PN sequence generator as a numeric, binary scalar, or as a numeric, binary vector. The length must equal the degree of the second generator polynomial. You set the second generator polynomial in the `SecondPolynomial` on page 4-0 property.

When you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The default is `[0 0 0 0 0 1]`.

When you set this property to a scalar, the initial conditions of all shift register cells are the specified scalar value.

## Index

Index of output sequence of interest

Specify the index of the output sequence of interest from the set of available sequences as a scalar integer. The default is `0`. The scalar integer must be in the range  $[-2, 2^n - 2]$ , where  $n$  is the degree of the generator polynomials you specify in the `FirstPolynomial` on page 4-0 and `SecondPolynomial` on page 4-0 properties.

The index values `-2` and `-1` correspond to the first and second preferred PN sequences as generated by the `FirstPolynomial` and `SecondPolynomial`, respectively.

The set  $G(u, v)$  of available Gold sequences is defined by  $G(u, v) = \{u, v, (u \text{ xor } T^v), (u \text{ xor } T^{2v}), \dots, (u \text{ xor } T^{(N-1)v})\}$ . In this case,  $T$  represents the operator that shifts vectors

cyclically to the left by one place, and  $u, v$  represent the two preferred PN sequences. Also,  $G(u,v)$  contains  $N+2$  Gold sequences of period  $N$ . You select the desired sequence from this set using the `Index` on page 4-0 `property`.

### **Shift**

Sequence offset from initial time

Specify the offset of the Gold sequence from its starting point as a numeric, integer scalar value that can be positive or negative. The default is 0. The Gold sequence has a period of  $N = 2^n - 1$ , where  $n$  is the degree of the generator polynomials specified in the `FirstPolynomial` on page 4-0 and `SecondPolynomial` on page 4-0 `properties`. The shift value is wrapped with respect to the sequence period.

### **VariableSizeOutput**

Enable variable-size outputs

Set this property to true to enable an additional input to the `step` method. The default is false. When you set this property to true, the enabled input specifies the output size of the Gold sequence used for the step. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to false, the `SamplesPerFrame` property specifies the number of output samples.

### **MaximumOutputSize**

Maximum output size

Specify the maximum output size of the Gold sequence as a positive integer 2-element row vector. The second element of the vector must be 1. The default is [10 1].

This property applies when you set the `VariableSizeOutput` property to true.

### **SamplesPerFrame**

Number of output samples per frame

Specify the number of Gold sequence samples that the `step` method outputs as a numeric, integer scalar value. The default is 1. If you set this property to a value of  $M$ , then the `step` method outputs  $M$  samples of a Gold sequence with a period of  $N = 2^n - 1$ .

The value of  $n$  represents the degree of the generator polynomials that you specify in the `FirstPolynomial` on page 4-0 and `SecondPolynomial` on page 4-0 properties.

### ResetInputPort

Enable generator reset input

Set this property to `true` to enable an additional reset input to the `step` method. The default is `false`. This input resets the states of the two shift registers of the Gold sequence generator to the initial conditions specified in the `FirstInitialConditions` on page 4-0 and `SecondInitialConditions` on page 4-0 properties.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `logical` | `Smallest unsigned integer`. The default is `double`.

You must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` mode.

## Methods

`reset`      Reset states of Gold sequence generator object  
`step`        Generate a Gold sequence

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Generate Gold Sequence Samples

Generate 10 samples of a Gold sequence having period  $2^5 - 1$ .

```
goldseq = comm.GoldSequence('FirstPolynomial','x^5+x^2+1',...
    'SecondPolynomial','x^5+x^4+x^3+x^2+1',...
    'FirstInitialConditions',[0 0 0 0 1],...
    'SecondInitialConditions',[0 0 0 0 1],...
    'Index',4,'SamplesPerFrame',10);
x = goldseq()

x = 10x1

     1
     1
     1
     0
     0
     0
     0
     0
     0
     1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Gold Sequence Generator block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

**System object:** comm.GoldSequence

**Package:** comm

Reset states of Gold sequence generator object

## **Syntax**

reset(H)

## **Description**

reset(H) resets the states of the GoldSequence object, H.

## step

**System object:** comm.GoldSequence

**Package:** comm

Generate a Gold sequence

## Syntax

`Y = step(H)`

`Y = step(H,RESET)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

`Y = step(H)` outputs a frame of the Gold sequence in column vector `Y`. Specify the frame length with the `SamplesPerFrame` property. The object uses two PN sequence generators to generate a preferred pair of sequences with period  $N = 2^n - 1$ . Then the object XORs these sequences to produce the output Gold sequence. The value in `n` is the degree of the generator polynomials that you specify in the `FirstPolynomial` and `SecondPolynomial` properties.

`Y = step(H,RESET)` uses `RESET` as the reset signal when you set the `ResetInputPort` property to true. The data type of the `RESET` input must be double precision or logical. `RESET` can be a scalar value or a column vector with length equal to the number of samples per frame specified in the `SamplesPerFrame` property. When the `RESET` input is a non-zero scalar, the object resets to the initial conditions that you specify in the `FirstInitialConditions` and `SecondInitialConditions` properties. It then generates a new output frame. A column vector `RESET` input allows multiple resets within an output frame. A non-zero value at the `i`th element of the vector causes a reset at the `i`th output sample time.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.gpu.AWGNChannel

**Package:** comm

Add white Gaussian noise to input signal with GPU

## Description

The GPU `AWGNChannel` object adds white Gaussian noise to an input signal using a graphics processing unit (GPU).

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

To add white Gaussian noise to an input signal:

- 1 Define and set up your additive white Gaussian noise channel object. See “Construction” on page 4-908.
- 2 Call `step` to add white Gaussian noise to the input signal according to the properties of `comm.gpu.AWGNChannel`. The behavior of `step` is specific to each object in the toolbox.

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.AWGNChannel` creates a GPU-based additive white Gaussian noise (AWGN) channel System object, `H`. This object adds white Gaussian noise to a real or complex input signal.

`H = comm.gpu.AWGNChannel(Name,Value)` creates a GPU-based AWGN channel object, `H`, with the specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

## Properties

### NoiseMethod

Method to specify noise level

Select the method to specify the noise level as one of `Signal to noise ratio (Eb/No)` | `Signal to noise ratio (Es/No)` | `Signal to noise ratio (SNR)` | `Variance`. The default is `Signal to noise ratio (Eb/No)`.

**EbNo**

Energy per bit to noise power spectral density ratio (Eb/No)

Specify the Eb/No ratio in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (Eb/No)`. The default is 10. This property is tunable.

**EsNo**

Energy per symbol to noise power spectral density ratio (Es/No)

Specify the Es/No ratio in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (Es/No)`. The default is 10. This property is tunable.

**SNR**

Signal to noise ratio (SNR)

Specify the SNR value in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (SNR)`. The default is 10. This property is tunable.

**BitsPerSymbol**

Number of bits in one symbol

Specify the number of bits in each input symbol. You can set this property to a numeric, positive, integer scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (Eb/No)`. The default is 1 bit.

**SignalPower**

Input signal power in Watts

Specify the mean square power of the input signal in Watts. Set this property to a numeric, positive, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to`

noise ratio (Eb/No), Signal to noise ratio (Es/No) or Signal to noise ratio (SNR). The default is 1 Watt. The object assumes a nominal impedance of 1 Ohm. This property is tunable.

### **SamplesPerSymbol**

Number of samples per symbol

Specify the number of samples per symbol. Set this property to a numeric, positive, integer scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Signal to noise ratio (Eb/No) or Signal to noise ratio (Es/No). The default is 1 sample.

### **VarianceSource**

Source of noise variance

Specify the source of the noise variance as one of Property | Input port. The default is Property. Set VarianceSource to Input port to specify the noise variance value via an input to the step method. Set VarianceSource to Property to specify the noise variance value using the Variance property. This property applies when you set the NoiseMethod property to Variance.

### **Variance**

Noise variance

Specify the variance of the white Gaussian noise. You can set this property to a numeric, positive, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Variance and the VarianceSource property to Property. The default is 1. This property is tunable.

### **RandomStream**

Source of random number stream

Specify the source of random number stream. The only valid setting for this property is Global stream. The object generates the normally distributed random numbers from the current global random number stream.

### **Seed**

Initial seed of mt19937ar random number stream

The GPU version of the AWGN Channel System object does not use this property.

## Methods

step      Add white Gaussian noise to input signal

Common to All System Objects	
release	Allow System object property value changes

## Algorithm

This object uses the same algorithm as the `comm.AWGNChannel` System object. See the Algorithms section of the `comm.AWGNChannel` help page for more details. The object properties correspond to the related block parameters, except that:

- This object uses `parallel.gpu.RandStream` to provide an interface for controlling the properties of one or more random number streams that the GPU uses. Usage is the same as `RandStream` with the following restrictions:
  - Only the `combRecursive` (MRG32K3A) generator is supported.
  - Only the `Inversion` normal transform is supported.
  - Setting the `substream` property is not allowed.

Enter `help parallel.gpu.RandStream` at the MATLAB command line for more information.

## Examples

### GPU AWGN Channel

Specify the modulation order and generate PSK-modulated random data.

```
M = 8;
modData = pskmod(randi([0 M-1],1000,1),M,pi/M);
```

Create an AWGN channel object that uses a GPU. Pass the modulated data through the channel.

```
gpuChannel = comm.gpu.AWGNChannel('EbNo',15,'BitsPerSymbol', ...  
                                log2(M));  
channelOutput = gpuChannel(modData);
```

Visualize the noiseless and noisy data in scatter plots.

```
scatterplot(modData)  
scatterplot(channelOutput)
```

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

`comm.AWGNChannel`

**Introduced in R2012a**

---

## step

**System object:** `comm.gpu.AWGNChannel`

**Package:** `comm`

Add white Gaussian noise to input signal

## Syntax

`Y = step(H,X)`

`Y = step(H,X,VAR)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` adds white Gaussian noise to input `X` and returns the result in `Y`. The input `X` can be a double or single precision data type scalar, vector, or matrix with real or complex values. The dimensions of input `X` determine single or multichannel processing. For an `M`-by-`N` matrix input, `M` represents the number of time samples per channel and `N` represents the number of channels. `M` and `N` can be equal to 1. The object adds frames of length `M` of Gaussian noise to each of the `N` channels independently.

`Y = step(H,X,VAR)` uses input `VAR` as the variance of the white Gaussian noise. This applies when you set the `NoiseMethod` property to `Variance` and the `VarianceSource` property to `InputPort`. Input `VAR` can be a positive scalar or row vector with a length equal to the number of channels. `VAR` must be of the same data type as input `X`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.gpu.BlockDeinterleaver

**Package:** comm

Restore original ordering of block interleaved sequence with GPU

## Description

The `BlockDeinterleaver` System object restores the original ordering of a sequence that was interleaved using the block interleaver System object.

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To deinterleave the input vector:

- 1 Define and set up your block deinterleaver object. See “Construction” on page 4-918.
- 2 Call `step` to rearrange the elements of the input vector according to the properties of `comm.gpu.BlockDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.BlockDeinterleaver` creates a GPU-based block deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the `BlockInterleaver` System object

`H = comm.gpu.BlockDeinterleaver(Name,Value)` creates a GPU-based block deinterleaver object, `H`, with the specified property name set to the specified value.

`H = comm.gpu.BlockDeinterleaver(PERMVEC)` creates a GPU-based block deinterleaver object, `H`, with the `PermutationVector` property set to `PERMVEC`.

## Properties

### PermutationVector

Permutation vector

Specify the mapping used to permute the input symbols as a column vector of integers. The default is `[5;4;3;2;1]`. The mapping is a vector where the number of elements is equal to the length, `N`, of the input to the `step` method. Each element must be an integer between 1 and `N`, with no repeated values.

## Methods

`step` Deinterleave input sequence

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Algorithm

This object uses the same algorithm as the `comm.BlockDeinterleaver` System object. See Algorithms on the `comm.BlockDeinterleaver` help page for details.

## Examples

### Block Interleaving and Deinterleaving with GPU

Create interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver([3 4 1 2]');
deinterleaver = comm.gpu.BlockDeinterleaver([3 4 1 2]');
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(7,4,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deIntData]
```

```
ans =
```

```

     6     1     6
     7     7     7
     1     6     1
     7     7     7
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans =
```

```

     1
```

Generate a random vector of unique integers as a permutation vector.

```
permVec = randperm(7)';
```

Specify permVec as the permutation vector for the interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver(permVec);  
deinterleaver = comm.gpu.BlockDeinterleaver(permVec);
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,7,1);  
intData = interleaver(data);  
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans =
```

```
1
```

## Extended Capabilities

### GPU Arrays

Deinterleave input sequence

## Syntax

`Y = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a block interleaver. The `step` method forms the output, `Y`, based on the mapping specified by the `PermutationVector` property as `Output(PermutationVector(k))=Input(k)`, for `k = 1:N`, where `N` is the length of the permutation vector. The input `X` must be a column vector of the same length, `N`. The data type of `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.gpu.BlockInterleaver

**Package:** comm

Create block interleaved sequence with GPU

## Description

The GPU `BlockInterleaver` object permutes the symbols in the input signal using a graphics processing unit (GPU).

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To interleave the input signal:

- 1 Define and set up your block interleaver object. See “Construction” on page 4-924.
- 2 Call `step` to reorder the input symbols according to the properties of `comm.gpu.BlockInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a

function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.gpu.BlockInterleaver` creates a GPU-based block interleaver System object, `H`. This object permutes the symbols in the input signal based on a permutation vector.

`H = comm.gpu.BlockInterleaver(Name,Value)` creates a GPU-based block interleaver object, `H`, with the specified property `Name` set to the specified `Value`.

`H = comm.gpu.BlockInterleaver(PERMVEC)` creates a GPU-based block deinterleaver object, `H`, with the `PermutationVector` property set to `PERMVEC`.

### Properties

#### PermutationVector

Permutation vector

Specify the mapping used to permute the input symbols as a column vector of integers. The default is `[5;4;3;2;1]`. The mapping is a vector where the number of elements is equal to the length, `N`, of the input to the `step` method. Each element must be an integer between 1 and `N`, with no repeated values.

# comm.gpu.ConvolutionalEncoder

**Package:** comm.gpu

Convolutionally encode binary data with GPU

## Description

The GPU `ConvolutionalEncoder` object encodes a sequence of binary input vectors to produce a sequence of binary output vectors.

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To convolutionally encode a binary signal:

- 1 Define and set up your convolutional encoder object. See “Construction” on page 4-930.
- 2 Call `step` to encode a sequence of binary input vectors to produce a sequence of binary output vectors according to the properties of `comm.gpu.ConvolutionalEncoder`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.ConvolutionalEncoder` creates a System object, `H`, that convolutionally encodes binary data.

`H = comm.gpu.ConvolutionalEncoder(Name,Value)` creates a convolutional encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.gpu.ConvolutionalEncoder(TRELLIS,Name,Value)` creates a convolutional encoder object, `H`. This object has the `TrellisStructure` on page 4-0 property set to `TRELLIS`, and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. The default is the result of `poly2trellis(7, [171 133])`. Use the `istrellis` function to check if a structure is a valid trellis structure.

### TerminationMethod

Termination method of encoded frame

Specify how the encoded frame is terminated as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently and resets its states to the all-zeros state.

When you set this property to **Terminated**, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to the all-zeros state at the end of the vector. For a rate  $K/N$  code, the `step` method outputs a vector with length  $N \times (L + S)/K$ , where  $S = \text{constraintLength}-1$ . In the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i)-1)$ .  $L$  is the length of the input to the `step` method.

### **ResetInputPort**

Enable encoder reset input

You cannot reset this encoder object using an input port. The only valid property setting is `false`.

### **DelayedResetAction**

Delay output reset

You cannot reset this encoder object using an input port. The only valid property setting is `false`.

### **InitialStateInputPort**

You cannot set the initial state of this encoder object. The only valid property setting is `false`.

### **FinalStateOutputPort**

You cannot output the final state of this encoder object. The only valid property setting is `false`.

### **PuncturePatternSource**

Source of puncture pattern

Specify the source of the puncture pattern as one of `None` | `Property`. The default is `None`. When you set this property to `None` the object does not apply puncturing. When you set this property to `Property`, the object punctures the code. This puncturing is based on the puncture pattern vector that you specify in the `PuncturePattern` on page 4-0 property. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous` or `Truncated`.

### PuncturePattern

Puncture pattern vector

Specify the puncture pattern that the object uses to puncture the encoded data as a column vector. The default is [1; 1; 0; 1; 0; 1]. The vector contains 1s and 0s, where 0 indicates a punctured, or excluded, bit. This property applies when you set the TerminationMethod on page 4-0 property to Continuous or Truncated and the PuncturePatternSource on page 4-0 property to Property.

### NumFrames

Number of independent frames present in the input and output data vectors.

Specify the number of independent frames contained in a single data input/output vector. The default value of this property is 1. The objects segments the input vector into NumFrames segments and encodes them independently. The output contains NumFrames encoded segments. This property is applicable when you set the TerminationMethod on page 4-0 to Terminated or Truncated.

## Methods

release	Allow System object property value changes

## Examples

### 8-PSK-Modulation With Convolutional Encoding

Transmit a Convolutionally Encoded, 8-PSK-Modulated Bit Stream Through an AWGN Channel.

Create a GPU-based Convolutional Encoder System object.

```
hConEnc = comm.gpu.ConvolutionalEncoder;
```

Create a GPU-based PSK Modulator System object that accepts a bit input signal.

```
hMod = comm.gpu.PSKModulator('BitInput',true);
```

Create a GPU-based AWGN Channel System object with a signal-to-noise ratio of seven.

```
hChan = comm.gpu.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)',...
    'SNR',7);
```

Create a GPU-based PSK Demodulator System object that outputs a column vector of bit values.

```
hDemod = comm.gpu.PSKDemodulator('BitOutput',true);
```

Create a GPU-based Viterbi Decoder System object that accepts an input vector of hard decision values, which are zeros or ones.

```
hDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
```

Create an Error Rate System object that ignores 3 data samples before making comparisons. The received data lags behind the transmitted data by 34 samples.

```
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);
```

Run the simulation by using the step method to process data.

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = step(hConEnc, gpuArray(data));
    modSignal = step(hMod, encodedData);
    receivedSignal = step(hChan, modSignal);
    demodSignal = step(hDemod, receivedSignal);
    receivedBits = step(hDec, demodSignal);
    errors = step(hError, data, gather(receivedBits));
end
```

Display the errors.

`disp(errors)`

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Encoder block reference page. The object properties correspond to the block parameters.

### Extended Capabilities

#### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

Reset states of the convolutional encoder object

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the GPU `ConvolutionalEncoder` object, `H`.

# step

**System object:** `comm.gpu.ConvolutionalEncoder`

**Package:** `comm.gpu`

Convolutionally encode binary data

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  encodes the binary data,  $X$ , using the convolutional encoding that you specify in the `TrellisStructure` property. It returns the encoded data,  $Y$ . Both  $X$  and  $Y$  are column vectors of data type `single`, `double`, or `logical`. When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector equals  $K \times L$ , for a positive integer,  $L$ . The `step` method sets the length of the output vector,  $Y$ , to  $L \times N$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.gpu.ConvolutionalInterleaver

**Package:** comm

Permute input symbols using shift registers with GPU

## Description

The GPU `ConvolutionalInterleaver` object permutes the symbols in the input signal using a graphics processing unit (GPU). Internally, this class uses a set of shift registers.

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To convolutionally interleave binary data:

- 1 Define and set up your convolutional interleaver object. See “Construction” on page 4-938.
- 2 Call `step` to convolutionally interleave according to the properties of `comm.gpu.ConvolutionalInterleaver`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.ConvolutionalInterleaver` creates a GPU-based convolutional interleaver System object, `H`. This object permutes the symbols in the input signal using a set of shift registers.

`H = comm.gpu.ConvolutionalInterleaver(Name,Value)` creates a GPU-based convolutional interleaver System object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.gpu.ConvolutionalInterleaver(M,B,IC)` creates a GPU-based convolutional interleaver System object `H`, with the `NumRegisters` property set to `M`, the `RegisterLengthStep` property set to `B`, and the `InitialConditions` property set to `IC`. `M`, `B`, and `IC` are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments.

## Properties

### **NumRegisters**

Number of internal shift registers

Specify the number of internal shift registers as a scalar, positive integer. The default is 6.

### **RegisterLengthStep**

Number of additional symbols that fit in each successive shift register

Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2. The first register holds zero symbols.

### **InitialConditions**

Initial conditions of shift registers

Specify the values that are initially stored in each shift register as a numeric scalar or vector. You do not need to specify a value for the first shift register, which has zero delay. The default is 0. The value of the first element of this property is unimportant because the first shift register has zero delay. If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the NumRegisters on page 4-0 property, then the  $i$ -th shift register stores the  $i$ -th element of the specified vector.

## Methods

reset     Reset states of the convolutional interleaver object  
 step     Permute input symbols using shift registers

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Convolutional Interleaving and Deinterleaving with GPU

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans =  
  
    0     0     0  
    1     0     0  
    2     2     0  
    3     0     0  
    4     4     0  
    5     0     0  
    6     6     0  
    7     1     1  
    8     8     2  
    9     3     3  
   10    10     4  
   11     5     5  
   12    12     6  
   13     7     7  
   14    14     8  
   15     9     9  
   16    16    10  
   17    11    11  
   18    18    12  
   19    13    13  
   20    20    14
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep  
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
```

```
intrlvDelay =
```

```
    6
```

```
numSymErrors =
```

0

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Interleaver block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

`comm.ConvolutionalInterleaver` | `comm.gpu.ConvolutionalDeinterleaver`

**Introduced in R2012a**

## **reset**

**System object:** `comm.gpu.ConvolutionalInterleaver`

**Package:** `comm`

Reset states of the convolutional interleaver object

## **Syntax**

`reset(H)`

## **Description**

`reset(H)` resets the states of the GPU `ConvolutionalInterleaver` object, `H`.

## step

**System object:** `comm.gpu.ConvolutionalInterleaver`

**Package:** `comm`

Permute input symbols using shift registers

## Syntax

`Y = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The input `X` must be a column vector. The data type can be of type `double`, `single`, `uint32`, `int32`, or `logical`. `Y` has the same data type as `X`. The convolutional interleaver object uses a set of  $N$  shift registers, where  $N$  is the value specified by the `NumRegisters` property. The object sets the delay value of the  $k^{\text{th}}$  shift register to the product of  $(k-1)$  and the `RegisterLengthStep` property value. With each new input symbol, a commutator switches to a new register and the new symbol shifts in while the oldest symbol in that register shifts out. When the commutator reaches the  $N^{\text{th}}$  register and the next new input occurs, it returns to the first register.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.gpu.ConvolutionalDeinterleaver

**Package:** comm

Restore ordering of symbols using shift registers with GPU

## Description

The GPU `ConvolutionalDeinterleaver` object recovers a signal that was interleaved using the GPU-based convolutional interleaver object. The parameters in the two blocks should have the same values.

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To recover convolutionally interleaved binary data:

- 1 Define and set up your convolutional deinterleaver object. See “Construction” on page 4-946.
- 2 Call `step` to convolutionally deinterleave according to the properties of `comm.gpu.ConvolutionalDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.ConvolutionalDeinterleaver` creates a GPU-based convolutional deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using a convolutional interleaver.

`H = comm.gpu.ConvolutionalDeinterleaver(Name,Value)` creates a GPU-based convolutional deinterleaver System object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.gpu.ConvolutionalDeinterleaver(M,B,IC)` creates a convolutional deinterleaver System object `H`, with the `NumRegisters` property set to `M`, the `RegisterLengthStep` property set to `B`, and the `InitialConditions` property set to `IC`. `M`, `B`, and `IC` are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments.

## Properties

### **NumRegisters**

Number of internal shift registers

Specify the number of internal shift registers as a scalar, positive integer. The default is 6.

### **RegisterLengthStep**

Number of additional symbols that fit in each successive shift register

Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2. The first register holds zero symbols.

### **InitialConditions**

Initial conditions of shift registers

Specify the values that are initially stored in each shift register (except the first shift register, which has zero delay) as a numeric scalar or vector. The default is 0. If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the `NumRegisters` on page 4-0 property, then the  $i$ -th shift register stores the  $i$ -th element of the specified vector. The value of the first element of this property is unimportant, since the first shift register has zero delay.

## Methods

`step`     Permute input symbols using shift registers  
`reset`    Reset states of the convolutional deinterleaver object

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Convolutional Interleaving and Deinterleaving with GPU

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans =  
    0     0     0  
    1     0     0  
    2     2     0  
    3     0     0  
    4     4     0  
    5     0     0  
    6     6     0  
    7     1     1  
    8     8     2  
    9     3     3  
   10    10     4  
   11     5     5  
   12    12     6  
   13     7     7  
   14    14     8  
   15     9     9  
   16    16    10  
   17    11    11  
   18    18    12  
   19    13    13  
   20    20    14
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep  
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
```

```
intrlvDelay =
```

```
    6
```

```
numSymErrors =
```

## Description

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

The `comm.gpu.LDPCDecoder` System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 4-961.

To decode an LDPC-encoded signal:

- 1** Create the `comm.gpu.LDPCDecoder` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

### Syntax

```
gpu_ldpcdecoder = comm.gpu.LDPCDecoder  
gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)  
gpu_ldpcdecoder = comm.gpu.LDPCDecoder( ____,Name,Value)
```

### Description

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder` creates a GPU-based binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates a GPU-based LDPC decoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder( ____,Name,Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCDecoder('DecisionMethod','Soft decision')` configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type `double`. Enclose each property name in quotes.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

**ParityCheckMatrix — Parity-check matrix**

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse  $(N - K)$ -by- $N$  binary-valued matrix.  $N$  is the length of the received signal and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ . The last  $(N - K)$  columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf(2)`.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R, 'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

**OutputValue — Output value format**

`'Information part'` (default) | `'Whole codeword'`

Output value format, specified as one of these values:

- `'Information part'` — The object outputs a  $K$ -by-1 column vector containing only the information-part of the received log-likelihood ratio vector.  $K$  is the length of the uncoded message.
- `'Whole codeword'` — The object outputs an  $N$ -by-1 column vector containing the whole log-likelihood ratio vector.  $N$  is the length of the received signal.

$N$  and  $K$  must align with the dimension of the  $(N-K)$ -by- $K$  parity-check matrix.

Data Types: `char`

**DecisionMethod — Decision method**

`'Hard decision'` (default) | `'Soft decision'`

Decision method used for decoding, specified as one of these values:

- `'Hard decision'` — The object outputs decoded data of data type `logical`.
- `'Soft decision'` — The object outputs log-likelihood ratios of data type `double`.

Data Types: `char`

### **IterationTerminationCondition — Condition for iteration termination**

`'Maximum iteration count'` (default) | `'Parity check satisfied'`

Condition for iteration termination, specified as one of these values:

- `'Maximum iteration count'` — Decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.
- `'Parity check satisfied'` — Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.

Data Types: `char`

### **MaximumIterationCount — Maximum number of decoding iterations**

`50` (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: `double`

### **NumIterationsOutputPort — Output number of iterations performed**

`false` (default) | `true`

Output number of iterations executed, specified as `false` or `true`. To output the number of iterations executed, set this property to `true`.

Data Types: `logical`

### **FinalParityChecksOutputPort — Output final parity checks**

`false` (default) | `true`

Output final parity checks, specified as `false` or `true`. To output the final calculated parity checks, set this property to `true`.

Data Types: `logical`

## Usage

## Syntax

```
y = gpu_ldpcdecoder(x)
[y,numiter] = gpu_ldpcdecoder(x)
[y,parity] = gpu_ldpcdecoder(x)
[y,numiter,parity] = gpu_ldpcdecoder(x)
```

## Description

`y = gpu_ldpcdecoder(x)` decodes input data using an LDPC code based on the default parity-check matrix.

`[y,numiter] = gpu_ldpcdecoder(x)` returns the decoded data, `y`, and number of iterations performed, `numiter`. To use this syntax, set the `NumIterationsOutputPort` property to `true`.

`[y,parity] = gpu_ldpcdecoder(x)` returns the decoded data, `y`, and final parity checks, `parity`. To use this syntax, set the `FinalParityChecksOutputPort` property to `true`.

`[y,numiter,parity] = gpu_ldpcdecoder(x)` returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the `NumIterationsOutputPort` and `FinalParityChecksOutputPort` properties to `true`.

## Input Arguments

### **x** — Log-likelihood ratios

column vector

Log-likelihood ratios, specified as an  $N$ -by-1 column vector containing the soft-decision output from demodulation.  $N$  is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be 0 if the log-likelihood ratio is positive. The first  $K$  elements correspond to the information-part of the input message.

Data Types: `double`

### Output Arguments

#### **y — Decoded data**

column vector

Decoded data, returned as a column vector. The `DecisionMethod` property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the `OutputValue` property is set to `'Information part'`, the output includes only the information-part of the received log-likelihood ratio vector.
- If the `OutputValue` property is set to `'Whole codeword'`, the output includes the whole log-likelihood ratio vector.

Data Types: `double` | `logical`

#### **numiter — Number of executed decoding iterations**

positive integer

Number of executed decoding iterations, returned as a positive integer.

#### **Dependencies**

To enable this output, set the `NumIterationsOutputPort` property to `true`.

#### **parity — Final parity checks**

column vector

Final parity checks after decoding the input LDPC code, returned as an  $(N-K)$ -by-1 column vector.  $N$  is the number of bits in the LDPC codeword before modulation.  $K$  is the length of the uncoded message.

#### **Dependencies**

To enable this output, set the `FinalParityChecksOutputPort` property to `true`.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

## Examples

### LDPC Encode and Decode QPSK-Modulated Signal Using GPU

Using a `comm.gpu.LDPCDecoder` System Object™ to decode the signal, transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. After adding AWGN, demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals. For more information, see “Simulation Acceleration Using GPUs”.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCEncoder;
gpuLdpcDecoder = comm.gpu.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
```

```
data = logical(randi([0 1],32400,1));
% Transmit and receiver uncoded signal data
mod_uncSig = pskMod(data);
rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
demod_uncSig = pskuDemod(rx_uncSig);
numErrUnc = biterr(data,demod_uncSig);
ttlErrUnc = ttlErrUnc + numErrUnc;
% Transmit and receive LDPC coded signal data
encData = ldpcEncoder(data);
modSig = pskMod(encData);
rxSig = awgn(modSig,snr(ii),'measured');
demodSig = pskDemod(rxSig);
rxBits = gpuldpcDecoder(demodSig);
numErr = biterr(data,rxBits);
ttlErr = ttlErr + numErr;
end
ttlBits = numFrames*length(rxBits);
uncErrRate(ii) = ttlErrUnc/ttlBits;
errRate(ii) = ttlErr/ttlBits;
end
```

Plot the error statistics for uncoded and LDPC-coded data.

```
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded','LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')
```

## Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

### Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager.

For transmitted LDPC-encoded codeword  $c = c_0, c_1, \dots, c_{n-1}$ , the input to the LDPC decoder is the log-likelihood ratio (LLR) value

$$L(c_i) = \log \left( \frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)} \right).$$

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left( \prod_{i' \in V_j \setminus i} \tanh \left( \frac{1}{2} L(q_{i'j}) \right) \right),$$

$$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \setminus j} L(r_{ji'}), \text{ initialized as } L(q_{ij}) = L(c_i) \text{ before the first iteration, and}$$

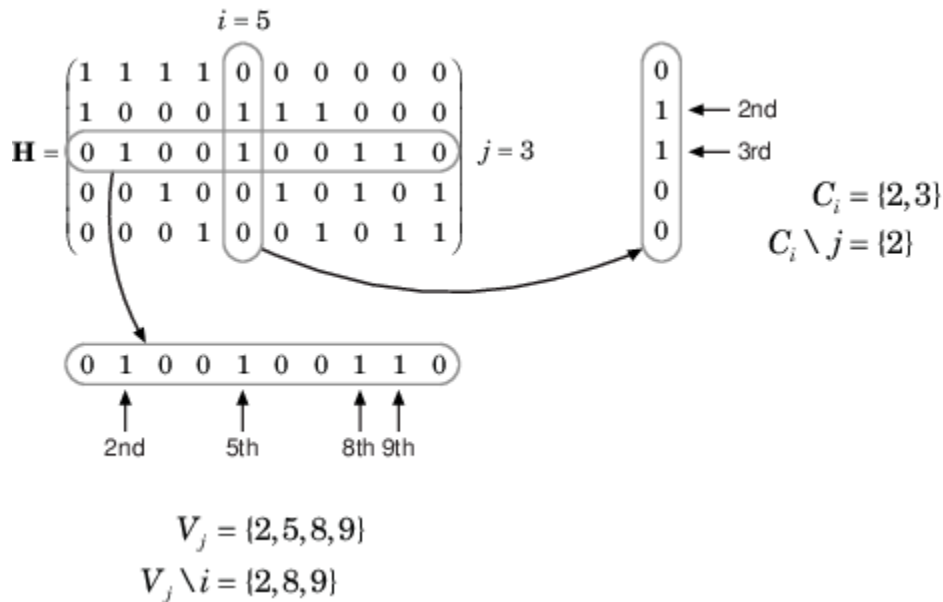

$$L(Q_i) = L(c_i) + \sum_{j' \in C_i} L(r_{ji'}).$$

At the end of each iteration,  $L(Q_i)$  contains the updated estimate of the LLR value for transmitted bit  $c_i$ . The value  $L(Q_i)$  is the soft-decision output for  $c_i$ . If  $L(Q_i) < 0$ , the hard-decision output for  $c_i$  is 1. Otherwise, the hard-decision output for  $c_i$  is 0.

If configured to stop when all parity checks are satisfied, the algorithm verifies the parity-check equation ( $Hc' = 0$ ) at the end of each iteration. When all parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets  $C_i \setminus j$  and  $V_j \setminus i$  are based on the parity-check matrix (PCM). Index sets  $C_i$  and  $V_j$  correspond to all nonzero elements in column  $i$  and row  $j$  of the PCM, respectively.

This figure highlights the computation of these index sets in a given PCM for  $i = 5$  and  $j = 3$ .

To avoid infinite numbers in the algorithm equations,  $\operatorname{atanh}(1)$  and  $\operatorname{atanh}(-1)$  are set to 19.07 and -19.07, respectively. Due to finite precision, MATLAB returns 1 for  $\operatorname{tanh}(19.07)$  and -1 for  $\operatorname{tanh}(-19.07)$ .

# comm.gpu.PSKDemodulator

**Package:** comm

Demodulate using M-ary PSK method with GPU

## Description

The GPU `PSKDemodulator` object demodulates an input signal using the M-ary phase shift keying (M-PSK) method.

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To demodulate a signal that was modulated using phase shift keying:

- 1 Define and set up your PSK demodulator object. See “Construction” on page 4-966.
- 2 Call `step` to demodulate the signal according to the properties of `comm.gpu.PSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a

function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.PSKDemodulator` returns a GPU-based demodulator System object, `H`. This object demodulates the input signal using the M-ary phase shift keying (M-PSK) method.

`H = comm.gpu.PSKDemodulator(Name,Value)` creates a GPU-based M-PSK demodulator object, `H`, with the specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`

`H = comm.gpu.PSKDemodulator(M,PHASE,Name,Value)` creates a GPU-based M-PSK demodulator object, `H`, with the `ModulationOrder` property set to `M`, the `PhaseOffset` property set to `PHASE` and other specified property names set to the specified values. `M` and `PHASE` are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

## Properties

### **ModulationOrder**

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar. The default is 8.

### **PhaseOffset**

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar. The default is  $\pi/8$ .

### **BitOutput**

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. When you set this property to true, the step method outputs a column vector of bit values with length equal to  $\log_2(\text{ModulationOrder})$  times the number of demodulated symbols. When you set this property to false, the step method outputs a column vector, with a length equal to the input data vector that contains integer symbol values between 0 and  $\text{ModulationOrder}-1$ . The default is false.

### **SymbolMapping**

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder})$  bits to the corresponding symbol as `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer  $m$  ( $0 \leq m \leq \text{ModulationOrder}-1$ ) maps to the complex value. This value is represented as  $\exp(j * \text{PhaseOffset} + j * 2 * \pi * m / \text{ModulationOrder})$ . When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping` property.

### **CustomSymbolMapping**

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:7`. This property must be a row or column vector of size `ModulationOrder` with unique integer values in the range  $[0, \text{ModulationOrder}-1]$ . The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of  $0 + \text{PhaseOffset}$ , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of  $-\pi / \text{ModulationOrder} + \text{PhaseOffset}$ . This property applies when you set the `SymbolMapping` property to `Custom`.

### **DecisionMethod**

Demodulation decision method

Specify the decision method that the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set `DecisionMethod` to false, the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to true.

### **VarianceSource**

Source of noise variance

Specify the source of the noise variance as one of `Property | Input port`. The default is `Property`. This property applies when you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

### Variance

Specify the variance of the noise as a positive, real scalar. The default is `1`. If this value is very small (i.e., SNR is very high), then log-likelihood ratio (LLR) computations may yield `Inf` or `-Inf`. This occurs because the LLR algorithm computes the exponential value of very large or very small numbers using finite precision arithmetic. In such cases, use approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, and the `VarianceSource` property to `Property`. This property is tunable.

### OutputDataType

Data type of output

When you set this property to `Full precision`, the output signal inherits its data type from the input signal.

## Methods

<code>constellation</code>	Calculate or plot ideal signal constellation
<code>step</code>	Demodulate using M-ary PSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Algorithm

The `GPU PSK Demodulator System` object uses the same algorithm as the `comm.PSKDemodulator System` object. See `Decoding Algorithm` for details.

## Examples

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Then demodulate, decode, and count errors.

### 16-PSK Modulation and Demodulation

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel.

Create a GPU-based PSK Modulator System object.

```
hMod = comm.gpu.PSKModulator(16, 'PhaseOffset',pi/16);
```

Create a GPU-based AWGN Channel System object with a signal-to-noise ratio of 15.

```
hAWGN = comm.gpu.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 15);
```

Create a GPU-based PSK Demodulator System object.

```
hDemod = comm.gpu.PSKDemodulator(16, 'PhaseOffset',pi/16);
```

Create an error rate calculator System object.

```
hError = comm.ErrorRate;
```

Transmit a frame of data containing 50 symbols.

```
for counter = 1:100
    data = gpuArray.randi([0 hMod.ModulationOrder-1], 50, 1);
```

Run the simulation by using the step method to process data.

```
modSignal = step(hMod, data);
noisySignal = step(hAWGN, modSignal);
receivedData = step(hDemod, noisySignal);
errorStats = step(hError, gather(data), gather(receivedData));
end
```

Compute the error rate results.

```
fprintf('Error rate = %f\nNumber of errors = %d\n',...
       errorStats(1), errorStats(2))
```

### GPU PSK Demodulator

Create GPU PSK modulator and demodulator pair.

```
gpuMod = comm.gpu.PSKModulator;
gpuDemod = comm.gpu.PSKDemodulator;
```

Generate random data symbols. Modulate the data.

```
txData = randi([0 7],1000,1);
txSig = gpuMod(txData);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,20);
```

Demodulate the received signal.

```
rxData = gpuDemod(rxSig);
```

Determine the number of symbol errors.

```
numSymErrors = symerr(txData,rxData)
```

```
numSymErrors =
```

```
736
```

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

## **See Also**

**Introduced in R2012a**

## constellation

Calculate or plot ideal signal constellation

### Syntax

```
y = constellation(h)  
constellation(h)
```

### Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

### Examples

#### Calculate Ideal Signal Constellation for `comm.gpu.PSKDemodulator`

Create a `comm.gpu.PSKDemodulator` System object, and then calculate its ideal signal constellation.

Create a `comm.gpu.PSKDemodulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKDemodulator
```

Calculate and display the ideal signal constellation by calling the `constellation` method.

```
a = constellation(h)
```

## **Plot Ideal Signal Constellation for comm.gpu.PSKDemodulator**

Create a `comm.gpu.PSKDemodulator` System object, and then plot the ideal signal constellation.

Create a `comm.gpu.PSKDemodulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKDemodulator
```

Plot the ideal signal constellation by calling the `constellation` method.

```
constellation(h)
```

## step

Demodulate using M-ary PSK method

### Syntax

$Y = \text{step}(H,X)$   
 $Y = \text{step}(H,X,VAR)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates data,  $X$ , with the GPU PSK Demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a scalar or a column vector with double- or single-precision data type. Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

$Y = \text{step}(H,X,VAR)$  uses soft decision demodulation and noise variance  $VAR$ . This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to `Input port`. The data type of input  $VAR$  must be double or single precision.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.gpu.PSKModulator

**Package:** comm

Modulate using M-ary PSK method with GPU

### Description

The GPU `PSKModulator` object modulates a signal using the M-ary phase shift keying method implemented on a graphics processing unit (GPU). The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. This object accepts a scalar-valued or column vector input signal.

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To modulate a signal using phase shift keying:

- 1 Define and set up your PSK modulator object. See “Construction” on page 4-977.
- 2 Call `step` to modulate the signal according to the properties of `comm.gpu.PSKModulator`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.PSKModulator` returns a GPU-based demodulator System object, `H`. This object modulates the input signal using the M-ary phase shift keying (M-PSK) method with soft decision using the approximate log-likelihood ratio algorithm.

`H = comm.gpu.PSKModulator(Name, Value)` creates a GPU-based M-PSK modulator object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`

`H = comm.gpu.PSKModulator(M, PHASE, Name, Value)` creates a GPU-based M-PSK modulator object, `H`, with the `ModulationOrder` property set to `M`, the `PhaseOffset` property set to `PHASE` and other specified property `Names` set to the specified `Values`. `M` and `PHASE` are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

## Properties

### **ModulationOrder**

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar. The default is 8.

### **PhaseOffset**

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar. The default is  $\pi/8$ .

### **BitInput**

Assume bit inputs

Specify whether the input is bits or integers. The default is false. When you set this property to true, the step method input must be a column vector of bit values whose length is an integer multiple of  $\log_2(\text{ModulationOrder})$ . This vector contains bit representations of integers between 0 and  $\text{ModulationOrder}-1$ . The input data type can be numeric or logical. When you set the BitInput property to false, the step method input must be a column vector of integer symbol values between 0 and  $\text{ModulationOrder}-1$ . The data type of the input must be numeric.

### **SymbolMapping**

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder})$  bits to the corresponding symbol as one of **Binary** | **Gray** | **Custom**. The default is **Gray**. When you set this property to **Gray**, the object uses a Gray-encoded signal constellation. When you set this property to **Binary**, the integer  $m$  ( $0 \leq m \leq \text{ModulationOrder}-1$ ) maps to the complex value  $\exp(j*\text{PhaseOffset} + j*2*\pi*m/\text{ModulationOrder})$ . When you set this property to **Custom**, the object uses the signal constellation defined in the **CustomSymbolMapping** property.

### **CustomSymbolMapping**

Custom constellation encoding

Specify a custom constellation symbol mapping vector. This property must be a row or column vector of size **ModulationOrder** with unique integer values in the range  $[0, \text{ModulationOrder}-1]$ . The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of  $0 + \text{PhaseOffset}$ , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of  $-\pi/\text{ModulationOrder} + \text{PhaseOffset}$ . This property applies when you set the **SymbolMapping** property to **Custom**. The default is  $0:7$ .

### **OutputDataType**

Data type of output

Specify the output data type as one of **double** | **single**. The default is **double**.

## Methods

constellation	Calculate or plot ideal signal constellation
step	Modulate using M-ary PSK method with GPU

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Algorithm

The GPU PSK Modulator System object supports floating-point and integer input data types. This object uses the same algorithm as the `comm.PSKModulator` System object. See the Algorithms section of the `comm.PSKModulator` help page for details.

## Examples

### GPU PSK Modulator

Create binary data for 100, 4-bit symbols

```
data = randi([0 1],400,1);
```

Create a 16-PSK modulator System object with bits as inputs and Gray-coded signal constellation. Change the phase offset to  $\pi/16$ .

```
gpuMod = comm.gpu.PSKModulator(16,'BitInput',true);
gpuMod.PhaseOffset = pi/16;
```

Modulate and plot the data

```
modData = gpuMod(data);
scatterplot(modData)
```

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

# constellation

Calculate or plot ideal signal constellation

## Syntax

```
y = constellation(h)  
constellation(h)
```

## Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

## Examples

### Calculate Ideal Signal Constellation for `comm.gpu.PSKModulator`

Create a `comm.gpu.PSKModulator` System object, and then calculate its ideal signal constellation.

Create a `comm.gpu.PSKModulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKModulator
```

Calculate and display the ideal signal constellation by calling the `constellation` method.

```
a = constellation(h)
```

## **Plot Ideal Signal Constellation for comm.gpu.PSKModulator**

Create a `comm.gpu.PSKModulator` System object, and then plot the ideal signal constellation.

Create a `comm.gpu.PSKModulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKModulator
```

Plot the ideal signal constellation by calling the `constellation` method.

```
constellation(h)
```

# step

Modulate using M-ary PSK method with GPU

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  modulates the input data,  $X$ , using the GPU-based PSK modulator System object,  $H$ . The object returns the baseband modulated output  $Y$ . Depending upon the value of the `BitInput` property, input  $X$  can be an integer or bit-valued column vector with numeric or logical data types.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.gpu.TurboDecoder

**Package:** comm.gpu

Decode input signal using parallel concatenation decoding with GPU

## Description

The GPU Turbo Decoder System object decodes the input signal using a parallel concatenated decoding scheme. This scheme uses the *a-posteriori* probability (APP) decoder as the constituent decoder. Both constituent decoders use the same trellis structure and algorithm.

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To decode an input signal using a turbo decoding scheme:

- 1 Define and set up your turbo decoder object. See “Construction” on page 4-986.
- 2 Call `step` to decode a binary signal according to the properties of `comm.gpu.TurboDecoder`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.TurboDecoder` creates a GPU-based turbo decoder System object, `H`. This object uses the *a-posteriori* probability (APP) constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.

`H = comm.gpu.TurboDecoder(Name, Value)` creates a GPU-based turbo decoder object, `H`, with the specified property name set to the specified value. `Name` must appear inside single quotes ( ' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

`H = comm.gpu.TurboDecoder(TRELLIS, INTERLVRINDICES, NUMITER)` creates a GPU-based turbo decoder object, `H`. In this object, the `TrellisStructure` property is set to `TRELLIS`, the `InterleaverIndices` property set to `INTERLVRINDICES`, and the `NumIterations` property set to `NUMITER`.

## Properties

### TrellisStructure

Trellis structure of constituent convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. The default is the result of `poly2trellis(4, [13 15], 13)`. Use the `istrellis` function to check if a structure is a valid trellis structure.

### InterleaverIndicesSource

Source of interleaver indices

Specify the source of the interleaver indices. The only valid setting for this property is `Property`.

## InterleaverIndices

Interleaver indices

Specify the mapping used to permute the input bits at the encoder as a column vector of integers. The default is `(64:-1:1)'`. This mapping is a vector with the number of elements equal to the length,  $L$ , of the output of the step method. Each element must be an integer between 1 and  $L$ , with no repeated values.

## Algorithm

Decoding algorithm

Specify the decoding algorithm. This object implements true *a posteriori* probability decoding. The only valid setting is `True APP`.

## NumScalingBits

Number of scaling bits

The GPU version of the Turbo Decoder does not use this property.

## NumIterations

Number of decoding iterations

Specify the number of decoding iterations used for each call to the `step` method. The default is 6. The object iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the step method is the hard-decision output of the final LLR update.

## NumFrames

Number of independent frames present in the input and output data vectors.

Specify the number of independent frames that a single data input/output vector contains. The default value of this property is 1. This object segments the input vector into `NumFrames` segments and decodes the segments independently. The output contains `NumFrames` decoded segments.

## Methods

- reset   Reset states of the turbo decoder object
- step    Decode input signal using parallel concatenated decoding scheme

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Transmit and decode using turbo coding

Transmit turbo-encoded blocks of data over a BPSK-modulated AWGN channel. Then, decode using an iterative turbo decoder and display errors.

Define a noise variable, establish a frame length of 256, and use the random stream property so that the results are repeatable.

```
noiseVar = 4; frmLen = 256;  
s = RandStream('mt19937ar', 'Seed', 11);  
intrlvrIndices = randperm(s, frmLen);
```

Create a Turbo Encoder System object. The trellis structure for the constituent convolutional code is `poly2trellis(4, [13 15 17], 13)`. The `InterleaverIndices` property specifies the mapping the object uses to permute the input bits at the encoder as a column vector of integers.

```
turboEnc = comm.TurboEncoder('TrellisStructure', poly2trellis(4, ...  
    [13 15 17], 13), 'InterleaverIndices', intrlvrIndices);
```

Create a BPSK Modulator System object.

```
bpsk = comm.BPSKModulator;
```

Create an AWGN Channel System object.

```
channel = comm.AWGNChannel('NoiseMethod', 'Variance', 'Variance', ...  
    noiseVar);
```

Create a GPU-Based Turbo Decoder System object. The trellis structure for the constituent convolutional code is `poly2trellis(4, [13 15 17], 13)`. The `InterleaverIndices` property specifies the mapping the object uses to permute the input bits at the encoder as a column vector of integers.

```
turboDec = comm.gpu.TurboDecoder('TrellisStructure', poly2trellis(4, ...
    [13 15 17], 13), 'InterleaverIndices', intrlvrIndices, ...
    'NumIterations', 4);
```

Create an Error Rate System object.

```
errorRate = comm.ErrorRate;
```

Run the simulation.

```
for frmIdx = 1:8
    data = randi(s, [0 1], frmLen, 1);
    encodedData = turboEnc(data);
    modSignal = bpsk(encodedData);
    receivedSignal = channel(modSignal);
```

Convert the received signal to log-likelihood ratios for decoding.

```
receivedBits = turboDec(-2/(noiseVar/2))*real(receivedSignal);
```

Compare original the data to the received data and then calculate the error rate results.

```
errorStats = errorRate(data, receivedBits);
end
fprintf('Error rate = %f\nNumber of errors = %d\nTotal bits = %d\n', ...
    errorStats(1), errorStats(2), errorStats(3))
```

## Algorithms

This object implements the inputs and outputs described on the Turbo Decoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

## reset

**System object:** comm.gpu.TurboDecoder

**Package:** comm.gpu

Reset states of the turbo decoder object

## Syntax

reset(H)

## Description

reset(H) resets the states of the GPU TurboDecoder object, H.

# step

**System object:** `comm.gpu.TurboDecoder`

**Package:** `comm.gpu`

Decode input signal using parallel concatenated decoding scheme

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  decodes the input data,  $X$ , using the parallel concatenated convolutional coding scheme. You specify this scheme using the `TrellisStructure` and `InterleaverIndices` properties. It returns the binary decoded data,  $Y$ . Both  $X$  and  $Y$  are column vectors of double-precision data type. When the constituent convolutional code represents a rate  $1/N$  code, the `step` method sets the length of the output vector,  $Y$ , to  $(M-2*N_{\text{Tails}})/(2*N-1)$ .  $M$  represents the input vector length and  $N_{\text{Tails}}$  is given by  $\log_2(\text{TrellisStructure.numStates})*N$ . The output length,  $L$ , is the same as the length of the interleaver indices.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.gpu.ViterbiDecoder

**Package:** comm

Decode convolutionally encoded data using Viterbi algorithm with GPU

### Description

The GPU `ViterbiDecoder` System object decodes input symbols to produce binary output symbols using a graphics processing unit (GPU). This object processes variable-size signals; however, variable-size signals cannot be applied for erasure inputs.

---

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To decode input symbols and produce binary output symbols:

- 1 Define and set up your Viterbi decoder object. See “Construction” on page 4-995.
- 2 Call `step` to decode input symbols according to the properties of `comm.gpu.ViterbiDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.gpu.ViterbiDecoder` creates a Viterbi decoder System object, `H`. This object uses the Viterbi algorithm to decode convolutionally encoded input data.

`H = comm.gpu.ViterbiDecoder(Name,Value)` creates a Viterbi decoder object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.gpu.ViterbiDecoder(TRELLIS,Name,Value)` creates a Viterbi decoder object, `H`, with the `TrellisStructure` property set to `TRELLIS`, and other specified property `Names` set to the specified `Values`.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. This object supports rate 1/2, 1/3 and 1/4 trellises from simple feedforward encoders. The default value is the result of `poly2trellis(7, [171 133])`.

### InputFormat

Input format

Specify the format of the input to the decoder as one of `Unquantized` | `Hard` | `Soft`. The default is `Unquantized`.

When you set this property to `Unquantized`, the input must be a real vector of double or single precision unquantized soft values. The object considers negative numbers to be ones and positive numbers to be zeros. When you set this property to `Hard`, the input

must be a vector of hard decision values, which are zeros or ones. The data type of the inputs can be double precision or single precision. When you set this property to `Soft`, the input must be a vector of quantized soft values represented as integers between 0 and  $2^{\text{SoftInputWordLength}}-1$ . The data type of the inputs can be double precision or single precision.

### **SoftInputWordLength**

Soft input word length

Specify the number of bits used to represent each quantized soft input value as a positive, integer scalar. This property applies when you set the `InputFormat` property to `Soft`. The default is 4 bits.

### **InvalidQuantizedInputAction**

Action when input values are out of range

The only valid setting is `Ignore` which ignores out of range inputs.

### **TracebackDepth**

Traceback depth

Specify the number of trellis branches used to construct each traceback path as a positive, integer scalar less than or equal to 256. The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay. When you set the `TerminationMethod` property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols, or `TracebackDepth` zero bits for a rate  $1/N$  convolutional code. When you set the `TerminationMethod` property to `Truncated` or `Terminated`, there is no output delay and `TracebackDepth` must be less than or equal to the number of symbols in each input. If the code rate is  $1/2$ , a typical traceback depth value is about five times the constraint length of the code. The default is 34.

### **TerminationMethod**

Termination method of encoded frame

Specify `TerminationMethod` as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`. In `Continuous` mode, the object saves its internal state metric at the end of each frame for use with the next frame. The object treats each traceback path

independently. Select `Continuous` mode when the input signal contains only one symbol. In `Truncated` mode, the object treats each frame independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state. In `Terminated` mode, the object treats each frame independently, and the traceback path always starts and ends in the all-zeros state.

### **ResetInputPort**

Enable decoder reset input

Set this property to true to enable an additional step method input. When the reset input is a non-zero value, the object resets the internal states of the decoder to initial conditions. This property applies when you set the `TerminationMethod` property to `Continuous`. The default is false.

### **DelayedResetAction**

Delay output reset

Delaying the output reset is not supported. The only valid setting is false.

### **PuncturePatternSource**

Source of puncture pattern

Specify the source of the puncture pattern as one of `None` | `Property`. The default is `None`. When you set this property to `None` the object assumes no puncturing. Set this property to `Property` to decode punctured codewords based on a puncture pattern vector specified via the `PuncturePattern` property.

### **PuncturePattern**

Puncture pattern vector

Specify puncture pattern used to puncture the encoded data. The default is `[1; 1; 0; 1; 0; 1]`. The puncture pattern is a column vector of ones and zeros, where the zeros indicate where to insert dummy bits. The puncture pattern must match the puncture pattern used by the encoder. This property applies when you set the `PuncturePatternSource` property to `Property`.

### **ErasuresInputPort**

Enable erasures input

Erasures are not supported. The only valid setting is false.

### **OutputDataType**

Data type of output

The only valid setting is `Full precision` which makes the output data type match the input data type.

### **NumFrames**

Number of independent frames present in the input and output data vectors.

Specify the number of independent frames contained in a single data input/output vector. The input vector will be segmented into `NumFrames` segments and decoded independently. The output will contain `NumFrames` decoded segments. The default value of this property is `1`. This property is applies when you set the `TerminationMethod` is set to `Terminated` or `Truncated`.

## **Methods**

- `info`    Display information about GPU-based Viterbi Decoder object
- `reset`    Reset states of the GPU-based Viterbi Decoder modulator object
- `step`    Decode convolutionally encoded data using Viterbi algorithm

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## **Examples**

Transmit a convolutionally encoded 8-DPSK-modulated bit stream through an AWGN channel. Then, demodulate, decode using a Viterbi decoder, and count errors.

```
hConEnc = comm.ConvolutionalEncoder;  
hMod = comm.DPSKModulator('BitInput',true);  
hChan = comm.gpu.AWGNChannel('NoiseMethod', ...  
    'Signal to noise ratio (SNR)', 'SNR',10);  
hDemod = comm.DPSKDemodulator('BitOutput',true);
```

```

hDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
% Delay in bits is TracebackDepth times the number of
% bits per symbol
    delay = hDec.TracebackDepth*...
            log2(hDec.TrellisStructure.numInputSymbols);
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay',delay);
    for counter = 1:20
        data = randi([0 1],30,1);
        encodedData = step(hConEnc, data);
        modSignal = step(hMod, encodedData);
        receivedSignal = step(hChan, modSignal);
        demodSignal = step(hDemod, receivedSignal);
        receivedBits = step(hDec, demodSignal);
        errorStats = step(hError, data, receivedBits);
    end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))

```

comm.ViterbiDecoder

**Introduced in R2012a**

## info

**System object:** comm.gpu.ViterbiDecoder

**Package:** comm

Display information about GPU-based Viterbi Decoder object

## Syntax

```
S = info(OBJ)
```

## Description

`S = info(OBJ)` returns a structure, `S`, containing characteristic information for the System object, `OBJ`. If `OBJ` has no characteristic information, `S` is empty. If `OBJ` has characteristic information, the fields of `S` vary depending on `OBJ`. For object specific details, refer to the help on the `infoImpl` method of that object.

# reset

**System object:** `comm.gpu.ViterbiDecoder`

**Package:** `comm`

Reset states of the GPU-based Viterbi Decoder modulator object

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the GPU-based `ViterbiDecoder` object, `H`.

---

## step

**System object:** `comm.gpu.ViterbiDecoder`

**Package:** `comm`

Decode convolutionally encoded data using Viterbi algorithm

## Syntax

`Y = step(H,X)`

`Y = step(H,X,R)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` decodes encoded data, `X`, using the Viterbi algorithm and returns `Y`. `X`, must be a column vector with data type and values that depend on how you set the `InputFormat` property. If the convolutional code uses an alphabet of  $2^N$  possible symbols, the length of the input vector, `X`, must be  $L*N$  for some positive integer `L`. Similarly, if the decoded data uses an alphabet of  $2^K$  possible output symbols, the length of the output vector, `Y`, is  $L*K$ .

`Y = step(H,X,R)` resets the internal states of the decoder when you input a non-zero reset signal, `R`. `R` must be a double precision, single precision or logical scalar. This syntax applies when you set the `TerminationMethod` property to `Continuous` and the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# gsmDownlinkConfig

Create GSM downlink TDMA frame configuration object

## Description

The `gsmDownlinkConfig` object is a GSM downlink TDMA frame configuration object. Use `gsmDownlinkConfig` objects to create GSM downlink waveforms.

## Creation

## Syntax

```
cfggsmdl = gsmDownlinkConfig
cfggsmdl = gsmDownlinkConfig(sps)
cfggsmdl = gsmDownlinkConfig( ____,Name,Value)
```

## Description

`cfggsmdl = gsmDownlinkConfig` creates a GSM downlink TDMA frame configuration object.

`cfggsmdl = gsmDownlinkConfig(sps)` sets the `SamplesPerSymbol` property to `sps`.

`cfggsmdl = gsmDownlinkConfig( ____,Name,Value)` sets one or more name-value pair arguments using any of the previous syntaxes. For example, `'RiseTime',4` sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

## Properties

### **SamplesPerSymbol** — Samples per symbol

16 (default) | positive integer multiple of 4

Samples per symbol, specified as a positive integer multiple of 4.

Data Types: double

### **BurstType — Burst types**

[ "NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB" ] (default) | string row vector with 8 elements | "NB" | "FB" | "SB" | "Dummy" | "Off"

Burst types for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is "NB", "FB", "SB", "Dummy", or "Off" — Each element specifies the burst type for the corresponding time slot.
- "NB" — Transmit data using a normal burst for every time slot.
- "FB" — Transmit data using a frequency correction burst for every time slot.
- "SB" — Transmit data using a time synchronization burst for every time slot.
- "Dummy" — Transmit data using a dummy burst for every time slot.
- "Off" — All eight time slots contain no data.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 4-1024.

---

**Note** The `BurstType` property is an enumeration. To perform code generation, see “Code Generation” on page 4-1053 and the “MEX Generation for GSM Downlink Waveform” on page 4-1016 example.

---

Example: [ "NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off" ] configures the frame to use normal bursts in time slots 0, 3, and 5, use access bursts in time slots 1, 2, and 6, and transmit no data in time slots 4 and 7.

### **TSC — Training sequence code**

[ 0 1 2 3 4 5 6 7 ] (default) | eight-element row vector | integer in the range [0, 7]

Training sequence code (TSC) for normal bursts in time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] — Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] — Specifies the TSC value for every normal burst time slot.

For more information, see “Training Sequence Code (TSC)” on page 4-1026.

Example: [5 7 0 0 0 0 0 0] configures the frame to use training sequence 5 in time slot 0, training sequence 7 in time slot 1, and training sequence 0 in time slots 2 through 7.

### Dependencies

To enable this property for a time slot, set the corresponding element of `BurstType` to "NB".

Data Types: double

### Attenuation — Power attenuation

[0 0 0 0 0 0 0 0] (default) | eight-element row vector | nonnegative integer

Power attenuation in dB for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers — Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer — Specifies the power attenuation value for every time slot.

Example: [0 0 0 0 0 0 0 3] configures the frame to apply 0 dB attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7.

Data Types: double

### RiseTime — Burst rise time

2 (default) | positive scalar

Burst rise time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 4-1024.

Data Types: double

### RiseDelay — Burst rise delay

0 (default) | positive scalar

Burst rise delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down

duration ( $\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay}$ ) must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 4-1024.

When the burst rise delay is 0, the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude  $\text{RiseDelay}$  symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude  $\text{RiseDelay}$  symbols before the start of the useful part.

Data Types: double

### **FallTime — Burst fall time**

2 (default) | positive scalar

Burst fall time in symbols, specified as a positive scalar in the range  $[1/\text{SamplesPerSymbol}, 29]$ , where the increment resolution is  $1/\text{SamplesPerSymbol}$ . The total ramp-up and ramp-down duration ( $\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay}$ ) must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 4-1024.

Data Types: double

### **FallDelay — Burst fall delay**

0 (default) | positive scalar

Burst fall delay in symbols, specified as a positive scalar in the range  $[-10, 10]$ , where the increment resolution is  $1/\text{SamplesPerSymbol}$ . The total ramp-up and ramp-down duration ( $\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay}$ ) must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 4-1024.

When the burst fall delay is 0, the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude  $\text{FallDelay}$  symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude  $\text{FallDelay}$  symbols before the end of the useful part.

Data Types: double

## Examples

### Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig

cfggsmdl =
  gsmDownlinkConfig with properties:
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
  SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
  Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
  BandwidthTimeProduct: 0.3000
  BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
  BurstLengthInSamples: 2500
  FrameLengthInSamples: 20000

Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### Create GSM Downlink Waveform with Specified Samples per Symbol

Create a GSM downlink TDMA frame configuration object that specifies 8 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms separates each time slot. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object, specifying 8 samples per symbols.

```
sps = 8;
cfggsmdl = gsmDownlinkConfig(sps)

cfggsmdl =
  gsmDownlinkConfig with properties:

      BurstType: [NB      NB      NB      NB      NB      NB      NB      NB]
SamplesPerSymbol: 8
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 2.1667e+06
BandwidthTimeProduct: 0.3000
BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
BurstLengthInSamples: 1250
FrameLengthInSamples: 10000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
```

```
xlabel('Time (ms)')  
ylabel('Amplitude')  
subplot(2,1,2)  
plot(t,unwrap(angle(waveform)))  
grid on  
title('GSM Downlink Waveform - Phase')  
xlabel('Time (ms)')  
ylabel('Phase (rad)')
```

### Create GSM Downlink Waveform with Specified Attenuation

Create two GSM downlink TDMA frame configuration objects. Specify default settings for the first `gsmDownlinkConfig` object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig

cfggsmdl =
  gsmDownlinkConfig with properties:

      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Create another GSM downlink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmdl2 = gsmDownlinkConfig('Attenuation',[1 0 3 4 5 6 4 2])

cfggsmdl2 =
  gsmDownlinkConfig with properties:

      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [1 0 3 4 5 6 4 2]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the `gsmFrame` function. GSM TDMA frames have are eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms separates each time slot. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmdl);
waveform2 = gsmFrame(cfggsmdl2);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### MEX Generation for GSM Downlink Waveform

Generate and run a GSM waveform MEX function from the helper function `createDownlinkWaveform`. The `createDownlinkWaveform` helper function creates a GSM downlink waveform.

### Write MATLAB Function

Open `createDownlinkWaveform.m` to see the code. The `createDownlinkWaveform` helper function generates a GSM downlink waveform by using the `gsmDownlinkConfig` object and the `gsmInfo` and `gsmFrame` functions.

## Generate GSM Waveform

Use the `createDownlinkWaveform` helper function to create a GSM waveform containing two TDMA frames, and then plot the waveform.

```
[x,t] = createDownlinkWaveform(2);  
  
figure  
subplot(2,1,1);  
plot(t,abs(x));  
grid on;  
title('GSM Downlink Waveform - Amplitude');  
xlabel('Time (ms)');  
ylabel('Amplitude')  
subplot(2,1,2);  
plot(t,unwrap(angle(x)));  
grid on;  
title('GSM Downlink Waveform - Phase');  
xlabel('Time (ms)');  
ylabel('Phase (rad)')
```

### Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, `codegen` names the generated MEX function `createDownlinkWaveform_mex`. Generate a MEX function from the `createDownlinkWaveform` helper function, and then run the MEX function to create two TDMA frames.

```
codegen createDownlinkWaveform -args 3
```

## Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the `generateDownlinkFrame` helper function or `createDownlinkWaveform_mex` function.

```
[x,t] = createDownlinkWaveform_mex(2);  
  
figure  
subplot(2,1,1);  
plot(t,abs(x));  
grid on;  
title('MEX - GSM Downlink Waveform - Amplitude');  
xlabel('Time (ms)');  
ylabel('Amplitude')  
subplot(2,1,2);  
plot(t,unwrap(angle(x)));  
grid on;  
title('MEX - GSM Downlink Waveform - Phase');  
xlabel('Time (ms)');  
ylabel('Phase (rad)')
```

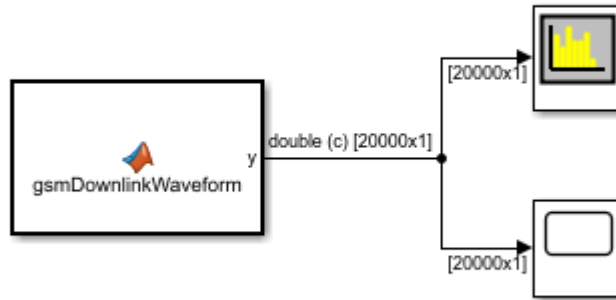

### **GSM Downlink Waveform Generation in Simulink**

Model a GSM® waveform generator in Simulink® by using the MATLAB Function block and Communications Toolbox™ functions.

### **GSM Downlink Waveform Generation**

The MATLAB Function block contains the `gsmDownlinkWaveform` function code. The code in the MATLAB Function block creates a GSM waveform by using the `gsmDownlinkConfig` object and the `gsmFrame` function.

## GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The `gsmDownlinkConfig` object specifies 16 samples per symbol and the time slot configuration for the GSM downlink TDMA frame shown in this table.

Timeslot	Burst Type	Attenuation
0	Normal burst	0 dB
1	FrequencyCorrection burst	0 dB
2	Normal burst	3 dB
3	Synchronization burst	0 dB
4	No data	0 dB
5	Normal burst	6 dB
6	Dummy burst	0 dB
7	Normal burst	3 dB

The output waveform has 16 samples for each GMSK symbol. The `gsmFrame` function generates the samples of the waveform.

### Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the `gsmDownlinkWaveform` function code is set to the GSM symbol rate of  $1625e3/6$  symbols per second. Display the current `gsmDownlinkConfig` object settings by using the `gsmInfo` function.

```
wfInfo =  
  
    struct with fields:  
  
        SymbolRate: 2.7083e+05  
        SampleRate: 4.3333e+06  
        BandwidthTimeProduct: 0.3000  
        BurstLengthInSymbols: 156.2500  
        NumBurstsPerFrame: 8  
        BurstLengthInSamples: 2500  
        FrameLengthInSamples: 20000
```

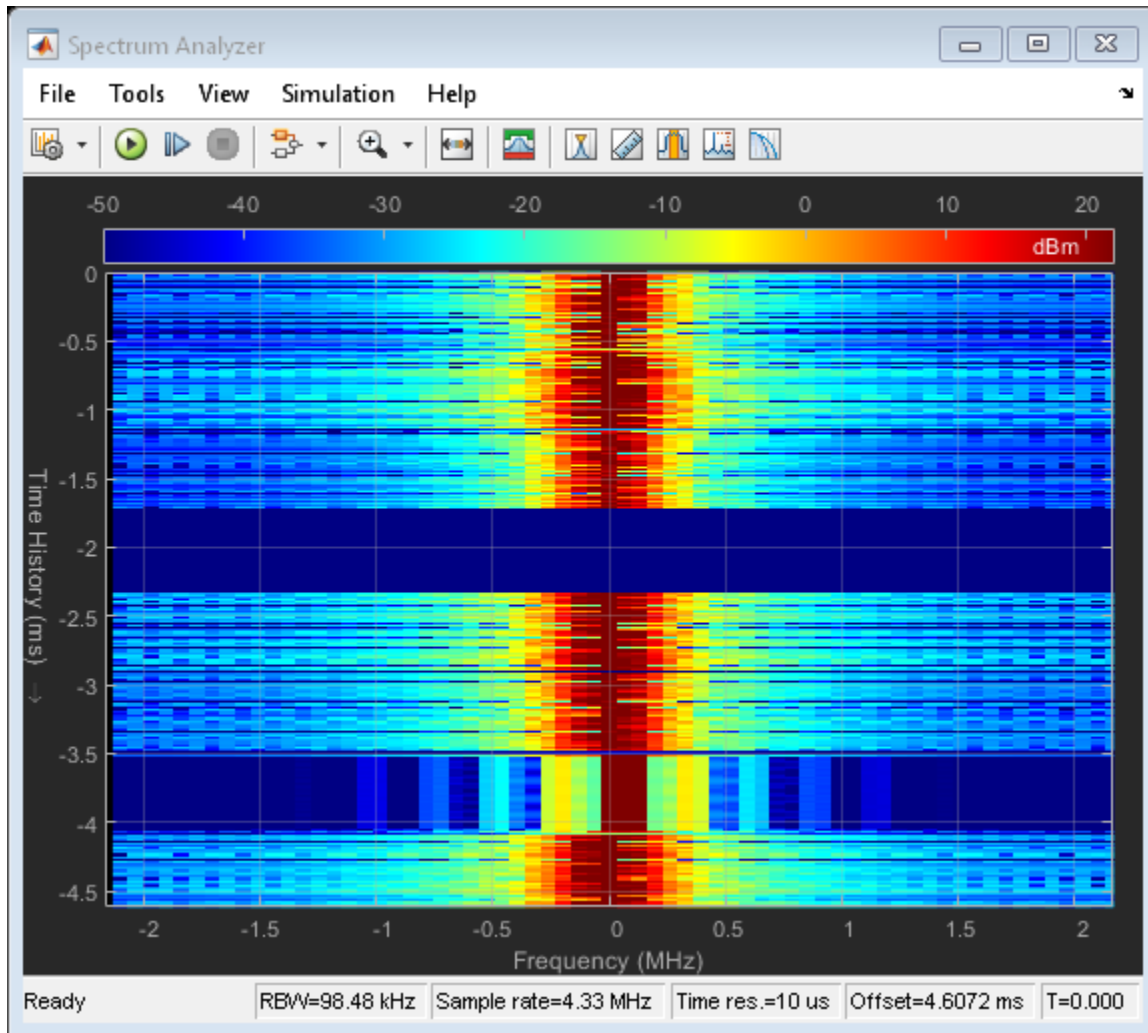

The model sample time of the MATLAB Function block is set to `wfInfo.FrameLengthInSamples/wfInfo.SampleRate`. To view the **Sample time** parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting **Block Parameters (Subsystem)**.

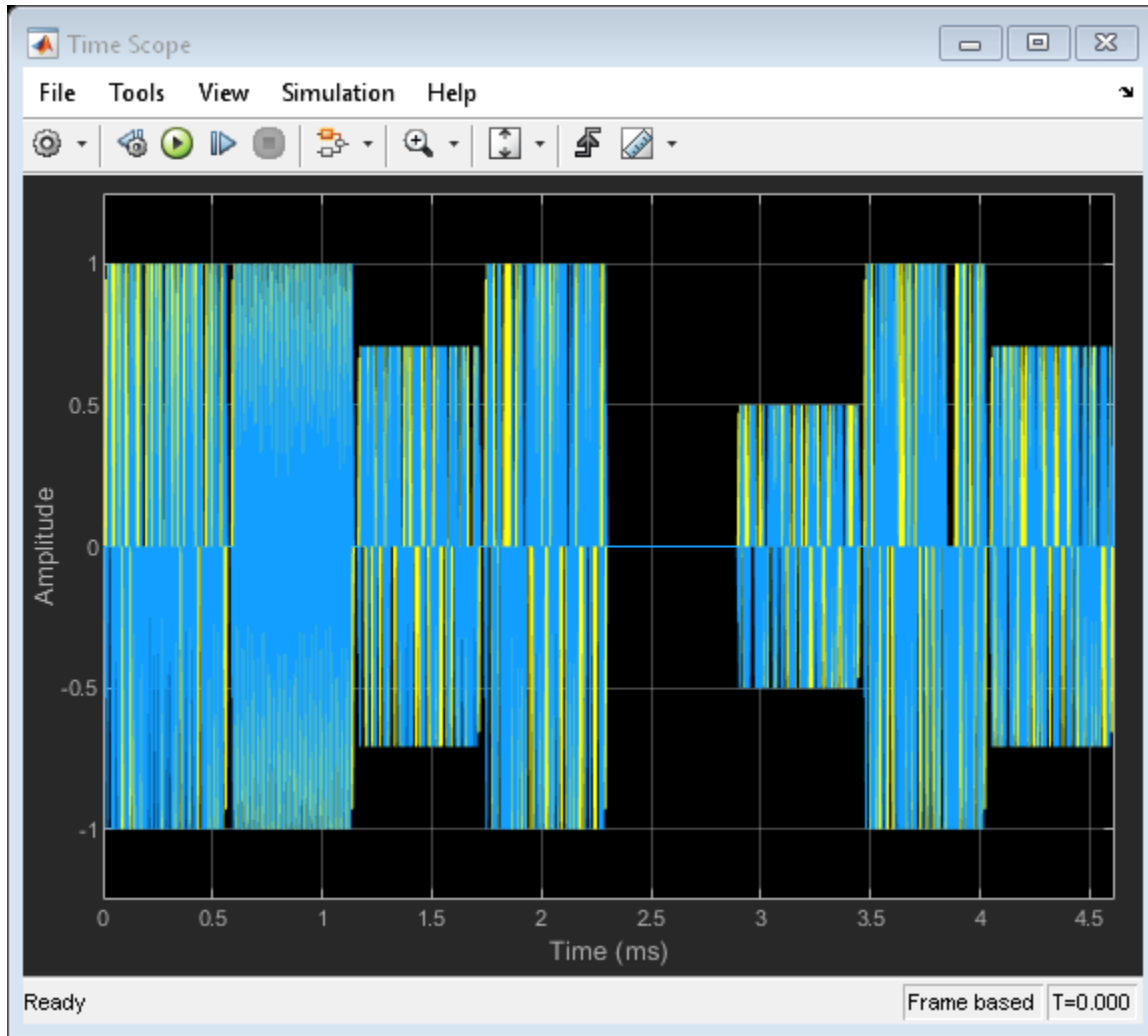

Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The `PreLoadFcn` and `InitFcn` callback functions configure the MATLAB Function block by creating a `gsmDownlinkConfig` object and `wfInfo` structure. To view the callback functions, on the **Modeling** tab, in the **Setup** section, select **Model Settings > Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` or `InitFcn` callback function in the **Model callbacks** pane.

### Results

Display the time domain signal and the spectrogram by running the simulation.

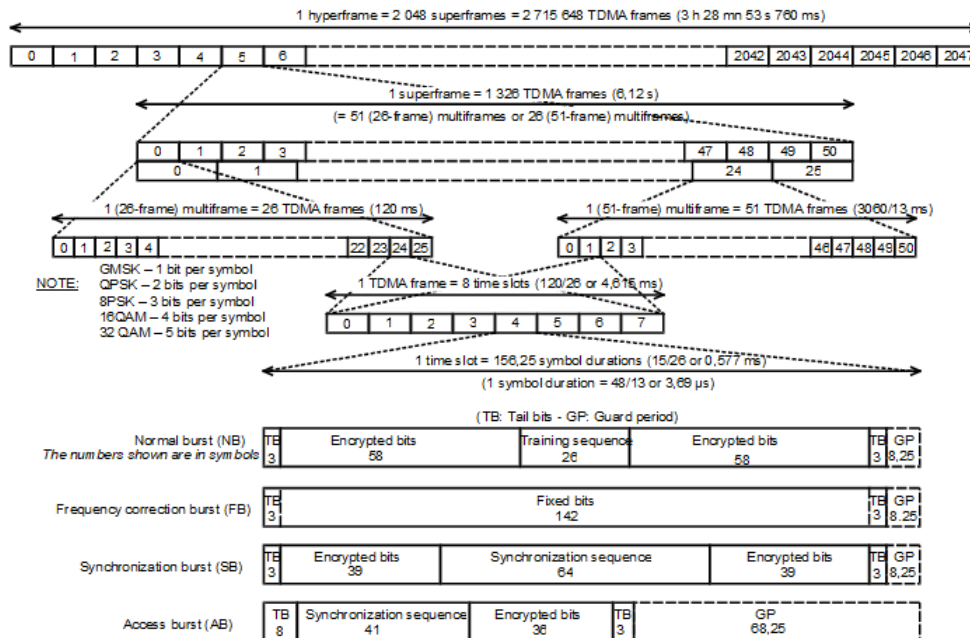

## More About

### GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in

Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of  $15/26$  ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147

Burst Type	Description	Link Direction	Useful Duration
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

*Useful duration*, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through B<sub>N0</sub> and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing 1/2 bit difference between the useful and active parts of the burst.

For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

### Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

<b>Training Sequence Code (TSC)</b>	<b>Training Sequence Bits (BN61, BN62, ..., BN86)</b>
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,0,1,1,1)
2	(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,0,1,1,1,0)
3	(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,0,1,0,0,0,1,1,1,1,0)
4	(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,0,1,1,0,1,0,1,1,0,1,1)
5	(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,0,1,0,0,1,1,1,0,1,1,0,1,0)
6	(1,0,1,0,0,1,1,1,1,0,1,1,0,0,0,0,1,0,1,0,0,1,1,1,1,1,1,1,1,1)
7	(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,0,1,1,1,1,1,0,0)

For more information, see Section 5.2.3 in 3GPP TS 45.002.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `SamplesPerSymbol`, `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties must be set when creating the object, and their settings are static in the generated code.
- The `BurstType` [property must be set using the enumeration type instead of the string representation. Use these `gsmDownlinkBurstType` enumerations: `gsmDownlinkBurstType.NB`, `gsmDownlinkBurstType.FB`, `gsmDownlinkBurstType.SB`, `gsmDownlinkBurstType.Dummy`, and `gsmUplinkBurstType.Off`. For example, this code assigns a frequency correction burst in time slot 2 and 5.

```
cfg = gsmDownlinkConfig
```

```
cfg =
```

```
gsmDownlinkConfig with properties:
```

```
    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
           TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0
```

```
cfg.BurstType([2 5] +1) = gsmDownlinkBurstType.FB
```

```
cfg =
```

```
gsmDownlinkConfig with properties:
```

```
    BurstType: [NB    NB    FB    NB    NB    FB    NB    NB]
SamplesPerSymbol: 16
           TSC: [0 1 2 3 4 5 6 7]
```

```
Attenuation: [0 0 0 0 0 0 0 0]
RiseTime: 2
RiseDelay: 0
FallTime: 2
FallDelay: 0

# gsmUplinkConfig

Create GSM uplink TDMA frame configuration object

## Description

The `gsmUplinkConfig` object is a GSM uplink TDMA frame configuration object. Use `gsmUplinkConfig` objects to create GSM uplink waveforms.

## Creation

## Syntax

```
cfggsmul = gsmUplinkConfig
cfggsmul = gsmUplinkConfig(sps)
cfggsmul = gsmUplinkConfig( ____, Name, Value)
```

## Description

`cfggsmul = gsmUplinkConfig` creates a GSM uplink TDMA frame configuration object.

`cfggsmul = gsmUplinkConfig(sps)` sets the `SamplesPerSymbol` property to `sps`.

`cfggsmul = gsmUplinkConfig( ____, Name, Value)` sets one or more name-value pair arguments using any of the previous syntaxes. For example, `'RiseTime', 4` sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

## Properties

### **SamplesPerSymbol** — Samples per symbol

16 (default) | positive integer multiple of 4

Samples per symbol, specified as a positive integer multiple of 4.

Data Types: double

### **BurstType — Burst types**

[ "NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB" ] (default) | string row vector with 8 elements | "NB" | "AB" | "Off"

Burst types for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is "NB", "AB", or "Off" — Each element specifies the burst type for the corresponding time slot.
- "NB" — Transmit data using a normal burst for every time slot.
- "AB" — Transmit data using an access burst for every time slot.
- "Off" — All eight time slots contain no data.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 4-1049

---

**Note** The `BurstType` property is an enumeration. To perform code generation, see “Code Generation” on page 4-1053 and the “MEX Generation for GSM Uplink Waveform” on page 4-1041 example.

---

Example: [ "NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off" ] configures the frame to use normal bursts in time slots 0, 3, and 5, use access bursts in time slots 1, 2, and 6, and transmit no data in time slots 4 and 7.

### **TSC — Training sequence code**

[ 0 1 2 3 4 5 6 7 ] (default) | eight-element row vector | integer in the range [0, 7]

Training sequence code (TSC) for normal bursts in time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] — Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] — Specifies the TSC value for every normal burst time slot.

For more information, see “Training Sequence Code (TSC)” on page 4-1051.

Example: [ 5 7 0 0 0 0 0 0 ] configures the frame to use training sequence 5 in time slot 0, training sequence 7 in time slot 1, and training sequence 0 in time slots 2 through 7.

### Dependencies

To enable this property for a time slot, set the corresponding element of `BurstType` to "NB".

Data Types: double

### Attenuation — Power attenuation

[0 0 0 0 0 0 0 0] (default) | eight-element row vector | nonnegative integer

Power attenuation in dB for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers — Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer — Specifies the power attenuation value for every time slot.

Example: [0 0 0 0 0 0 0 3] configures the frame to apply 0 dB of attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7.

Data Types: double

### RiseTime — Burst rise time

2 (default) | positive scalar

Burst rise time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration ( $\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay}$ ) must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 4-1049.

Data Types: double

### RiseDelay — Burst rise delay

0 (default) | positive scalar

Burst rise delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration ( $\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay}$ ) must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of

the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 4-1049.

When the burst rise delay is 0, the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude `RiseDelay` symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude `RiseDelay` symbols before the start of the useful part.

Data Types: double

#### **FallTime – Burst fall time**

2 (default) | positive scalar

Burst fall time in symbols, specified as a positive scalar in the range  $[1/\text{SamplesPerSymbol}, 29]$ , where the increment resolution is  $1/\text{SamplesPerSymbol}$ . The total ramp-up and ramp-down duration (`RiseTime - RiseDelay + FallTime + FallDelay`) must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 4-1049.

Data Types: double

#### **FallDelay – Burst fall delay**

0 (default) | positive scalar

Burst fall delay in symbols, specified as a positive scalar in the range  $[-10, 10]$ , where the increment resolution is  $1/\text{SamplesPerSymbol}$ . The total ramp-up and ramp-down duration (`RiseTime - RiseDelay + FallTime + FallDelay`) must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 4-1049.

When the burst fall delay is 0, the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude `FallDelay` symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude `FallDelay` symbols before the end of the useful part.

Data Types: double

## Examples

### Create GSM Uplink Waveform

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig

cfggsmul =
  gsmUplinkConfig with properties:
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
      SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
      Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
      BandwidthTimeProduct: 0.3000
      BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
      BurstLengthInSamples: 2500
      FrameLengthInSamples: 20000

Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### Create GSM Uplink Waveform with Specified Samples per Symbol

Create a GSM uplink TDMA frame configuration object that specifies 4 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms separates each time slot. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 4 samples per symbols.

```
sps = 4;
cfggsmul = gsmUplinkConfig(sps)
```

```

cfggsmul =
  gsmUplinkConfig with properties:

      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 4
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0

```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```

wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 1.0833e+06
BandwidthTimeProduct: 0.3000
BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
BurstLengthInSamples: 625
FrameLengthInSamples: 5000

```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```

waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)

```

```
plot(t,unwrap(angle(waveform)))  
grid on  
title('GSM Uplink Waveform - Phase')  
xlabel('Time (ms)')  
ylabel('Phase (rad)')
```

### Create GSM Uplink Waveform with Specified Attenuation

Create two GSM uplink TDMA frame configuration objects. Specify default settings for the first `gsmUplinkConfig` object and adjust the signal power per time slot for the

second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
cfggsmul =
  gsmUplinkConfig with properties:
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Create another GSM uplink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmul2 = gsmUplinkConfig('Attenuation',[1 2 3 4 5 4 3 2])
cfggsmul2 =
  gsmUplinkConfig with properties:
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [1 2 3 4 5 4 3 2]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `RS`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
```

```
        SampleRate: 4.3333e+06
BandwidthTimeProduct: 0.3000
BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
BurstLengthInSamples: 2500
FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the `gsmFrame` function. GSM TDMA frames are eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmul);
waveform2 = gsmFrame(cfggsmul2);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### MEX Generation for GSM Uplink Waveform

Generate and run a GSM waveform MEX function from the helper function `createUplinkWaveform`. The `createUplinkWaveform` helper function creates a GSM uplink waveform.

### Write MATLAB Function

Open `createUplinkWaveform.m` to see the code. The `createUplinkWaveform` helper function generates a GSM uplink waveform by using the `gsmUplinkConfig` object and the `gsmInfo` and `gsmFrame` functions.

### Generate GSM Waveform

Use the `createUplinkWaveform` helper function to create a GSM waveform containing three TDMA frames, and then plot the waveform.

```
[x,t] = createUplinkWaveform(3);  
  
figure  
subplot(2,1,1);  
plot(t,abs(x));  
grid on;  
title('GSM Uplink Waveform - Amplitude');  
xlabel('Time (ms)');  
ylabel('Amplitude')  
subplot(2,1,2);  
plot(t,unwrap(angle(x)));  
grid on;  
title('GSM Uplink Waveform - Phase');  
xlabel('Time (ms)');  
ylabel('Phase (rad)')
```

### Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, `codegen` names the generated MEX function `createUplinkWaveform_mex`. Generate a MEX function from the `createUplinkWaveform` helper function, and then run the MEX function to create three TDMA frames.

```
codegen createUplinkWaveform -args 3
```

### Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the `generateUplinkFrame` helper function or `createUplinkWaveform_mex` function.

```
[x,t] = createUplinkWaveform_mex(3);

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Uplink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```

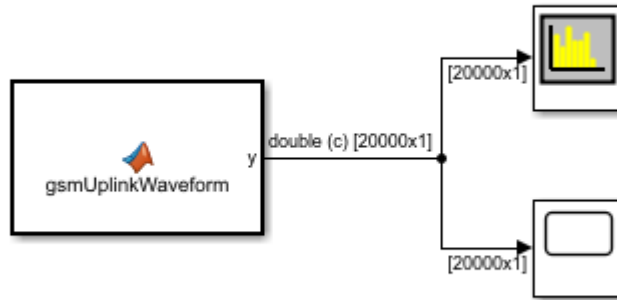

### **GSM Uplink Waveform Generation in Simulink**

Model a GSM® waveform generator in Simulink® by using the MATLAB Function block and Communications Toolbox™ functions.

#### **GSM Uplink Waveform Generation**

The MATLAB Function block contains the `gsmUplinkWaveform` function code. The code in the MATLAB Function block creates a GSM waveform by using the `gsmUplinkConfig` object and the `gsmFrame` function.

### GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The `gsmUplinkConfig` object specifies 16 samples per symbol and the time slot configuration for the GSM uplink TDMA frame shown in this table.

Timeslot	Burst Type	Attenuation
0	Normal burst	0 dB
1	Access burst	0 dB
2	Normal burst	3 dB
3	Normal burst	0 dB
4	No data	0 dB
5	Normal burst	6 dB
6	Normal burst	0 dB
7	Normal burst	3 dB

The output waveform has 16 samples for each GMSK symbol. The `gsmFrame` function generates the samples of the waveform.

#### Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the `gsmUplinkWaveform` function code is set to the GSM symbol rate of  $1625e3/6$  symbols per second. Display the current `gsmUplinkConfig` object settings by using the `gsmInfo` function.

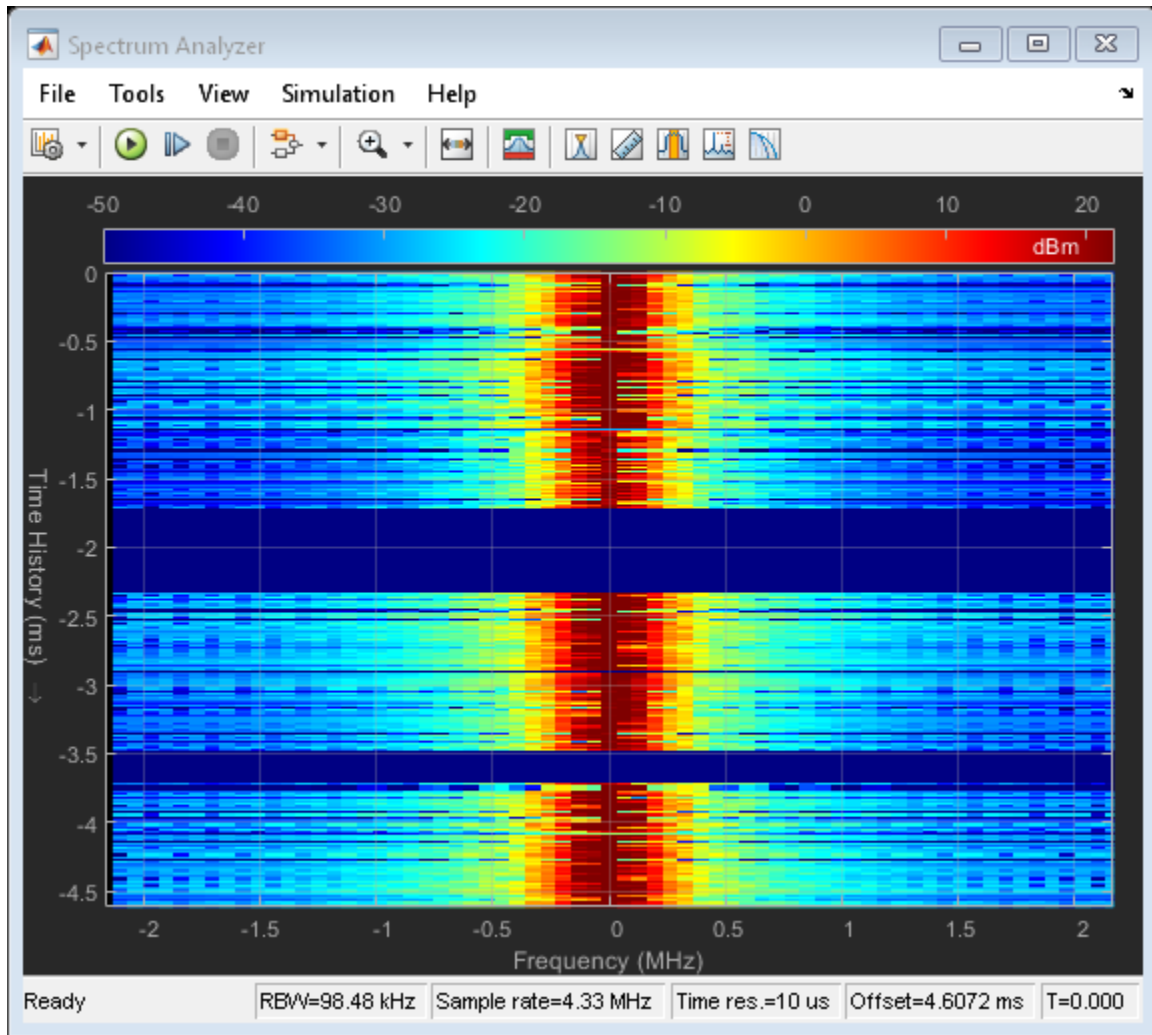

```
wfInfo =  
  
    struct with fields:  
  
        SymbolRate: 2.7083e+05  
        SampleRate: 4.3333e+06  
        BandwidthTimeProduct: 0.3000  
        BurstLengthInSymbols: 156.2500  
        NumBurstsPerFrame: 8  
        BurstLengthInSamples: 2500  
        FrameLengthInSamples: 20000
```

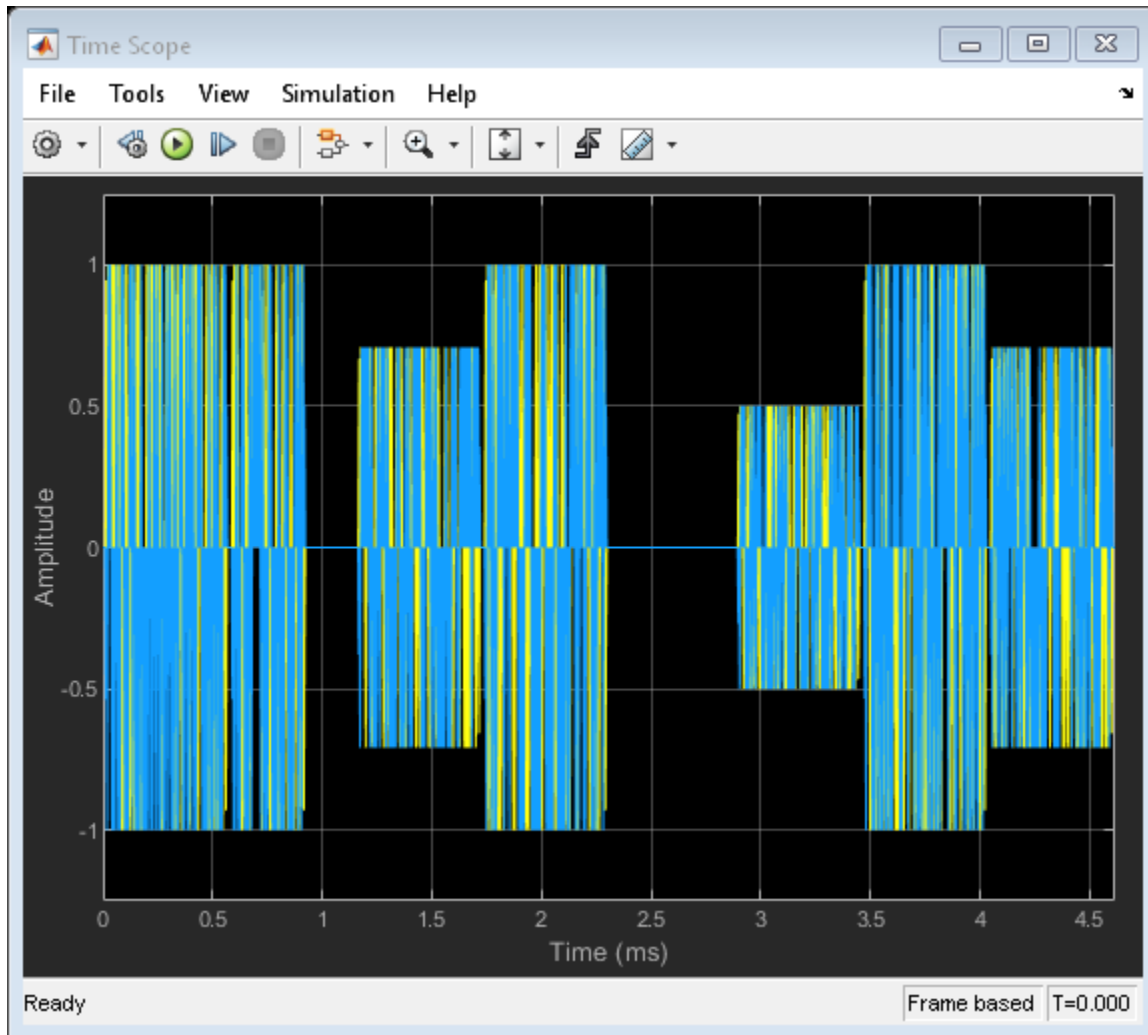

The model sample time of the MATLAB Function block is set to `wfInfo.FrameLengthInSamples/wfInfo.SampleRate`. To view the **Sample time** parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting **Block Parameters (Subsystem)**.

Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The `PreLoadFcn` and `InitFcn` callback functions configure the MATLAB Function block by creating a `gsmUplinkConfig` object and `wfInfo` structure. To view the callback functions, on the **Modeling** tab, in the **Setup** section, select **Model Settings > Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` or `InitFcn` callback function in the **Model callbacks** pane.

## Results

Displays the time domain signal and the spectrogram by running the simulation.

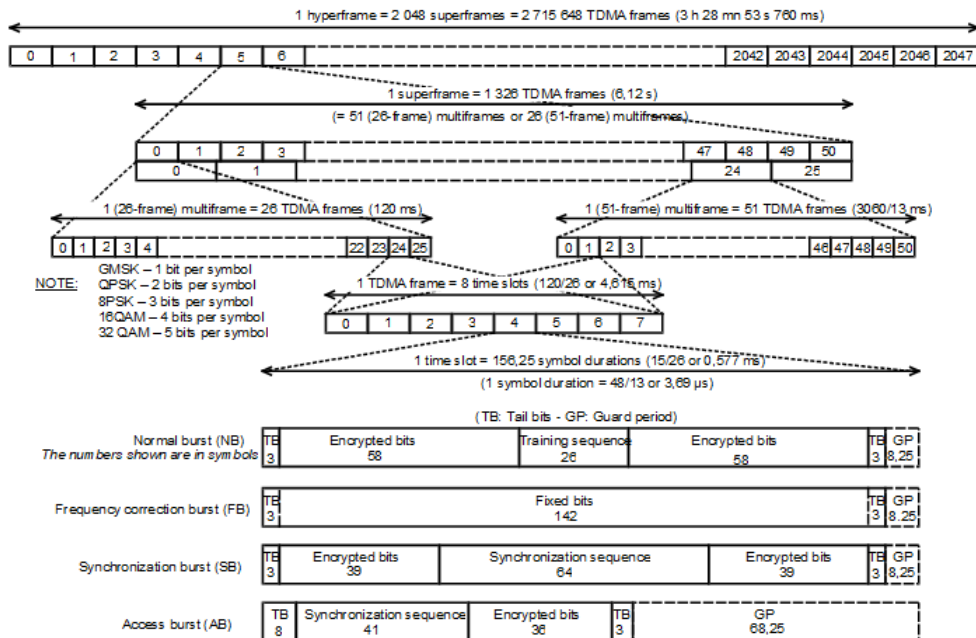

## More About

### GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in

Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of 15/26 ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

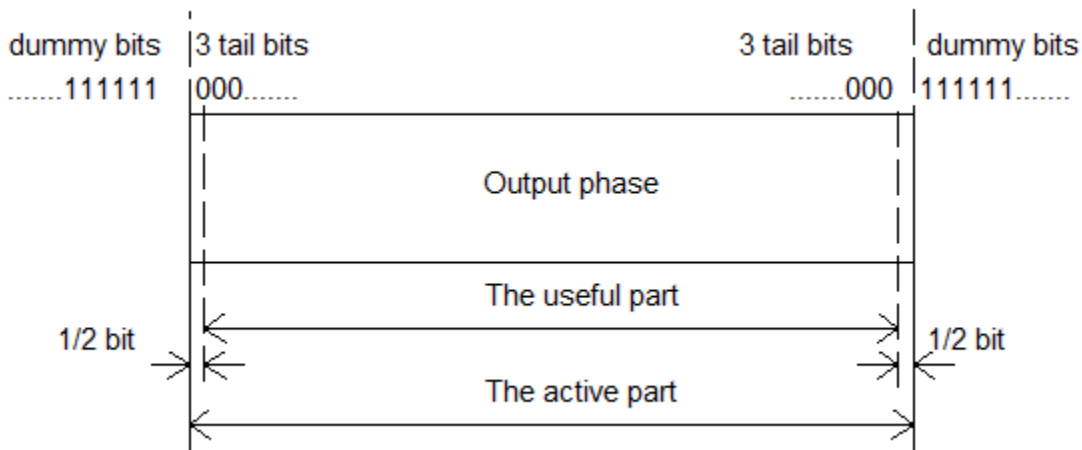

This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147

Burst Type	Description	Link Direction	Useful Duration
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

*Useful duration*, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BNO and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing  $\frac{1}{2}$  bit difference between the useful and active parts of the burst.

For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

## Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

<b>Training Sequence Code (TSC)</b>	<b>Training Sequence Bits (BN61, BN62, ..., BN86)</b>
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,0,1,1,1)
2	(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,0,1,1,1,0)
3	(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,0,1,0,0,0,1,1,1,1,0)
4	(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,0,1,1,0,1,0,1,0,1,1)
5	(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,0,1,0,0,1,1,1,0,1,0)
6	(1,0,1,0,0,1,1,1,1,0,1,1,0,0,0,0,1,0,1,0,0,1,1,1,1,1,1)
7	(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,0,1,1,1,0,0)

For more information, see Section 5.2.3 in 3GPP TS 45.002.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `SamplesPerSymbol`, `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties must be set when creating the object, and their settings are static in the generated code.
- The `BurstType` property must be set using the enumeration type instead of the string representation. Use these `gsmDownlinkBurstType` enumerations: `gsmDownlinkBurstType.NB`, `gsmDownlinkBurstType.AB`, and `gsmUplinkBurstType.Off`. For example, this code assigns an access burst in time slot 2 and 5.

```
cfg = gsmUplinkConfig
```

```
cfg =
```

```
gsmUplinkConfig with properties:
```

```

    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
           TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0

```

```
cfg.BurstType([2 5] +1) = gsmUplinkBurstType.AB
```

```
cfg =
```

```
gsmUplinkConfig with properties:
```

```

    BurstType: [NB    NB    AB    NB    NB    AB    NB    NB]
SamplesPerSymbol: 16
           TSC: [0 1 2 3 4 5 6 7]

# comm.HadamardCode

**Package:** comm

Generate Hadamard code

## Description

The HadamardCode object generates a Hadamard code from a Hadamard matrix, whose rows form an orthogonal set of codes. You can use orthogonal codes for spreading in communication systems in which the receiver is perfectly synchronized with the transmitter. In these systems, the despreading operation is ideal, because the codes decorrelate completely.

To generate a Hadamard code:

- 1 Define and set up your Hadamard code object. See “Construction” on page 4-1055.
- 2 Call `step` to generate a Hadamard according to the properties of `comm.HadamardCode`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

## Construction

`H = comm.HadamardCode` creates a Hadamard code generator System object, `H`. This object generates Hadamard codes from a set of orthogonal codes.

`H = comm.HadamardCode(Name, Value)` creates a Hadamard code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

# Properties

## Length

Length of generated code

Specify the length of the generated code as a numeric, integer scalar value with a power of two. The default is 64.

## Index

Row index of Hadamard matrix

Specify the row index of the Hadamard matrix as a numeric, integer scalar value in the range  $[0, 1, \dots, N-1]$ .  $N$  is the value of the `Length` on page 4-0 property. The default is 60. An  $N \times N$  Hadamard matrix, denoted as  $P(N)$ , is defined recursively as follows:  $P(1) = [1]$   $P(2N) = [P(N) P(N); P(N) -P(N)]$  The  $N \times N$  Hadamard matrix has the property that  $P(N) \times P(N)' = N \times \text{eye}(N)$ . The `step` method outputs code samples from the row of the Hadamard matrix that you specify in this property.

When you set this property to an integer  $k$ , the output code has exactly  $k$  zero crossings, for  $k = 0, 1, \dots, N-1$ .

## SamplesPerFrame

Number of output samples per frame

Specify the number of Hadamard code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is 1.

When you set this property to a value of  $M$ , the `step` method outputs  $M$  samples of a Hadamard code of length  $N$ .  $N$  equals the length of the code that you specify in the `Length` on page 4-0 property.

## OutputDataType

Data type of output

Specify the output data type as one of `double` | `int8`. The default is `double`.

## Methods

reset     Reset states of Hadamard code generator object  
 step     Generate Hadamard code

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Hadamard Code Sequence

Generate 10 samples of a Hadamard code sequence having a length of 128.

```
hadamard = comm.HadamardCode('Length',128,'SamplesPerFrame',10)
```

```
hadamard =  
comm.HadamardCode with properties:
```

```
    Length: 128  
    Index: 60  
SamplesPerFrame: 10  
OutputDataType: 'double'
```

```
seq = hadamard()
```

```
seq = 10×1
```

```
    1  
    1  
    1  
    1  
   -1  
   -1  
   -1  
   -1  
   -1  
   -1  
   -1
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Hadamard Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

## reset

**System object:** comm.HadamardCode

**Package:** comm

Reset states of Hadamard code generator object

## Syntax

reset(H)

## Description

reset(H) resets the states of the HadamardCode object, H.

# step

**System object:** comm.HadamardCode

**Package:** comm

Generate Hadamard code

## Syntax

$Y = \text{step}(H)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj})$  and  $y = \text{obj}()$  perform equivalent operations.

---

$Y = \text{step}(H)$  outputs a frame of the Hadamard code in column vector  $Y$ . Specify the frame length with the `SamplesPerFrame` property. The Hadamard code corresponds to one of the rows of an  $N \times N$  Hadamard matrix, where  $N$  is a nonnegative power of 2, which you specify in the `Length` property. Use the `Index` property to choose the row of the Hadamard matrix. The `step` method outputs the code in a bi-polar format with 0 and 1 mapped to 1 and -1, respectively.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.HDLCRCDetector

**Package:** comm

Detect errors in input data using CRC

## Description

This HDL-optimized cyclic redundancy code (CRC) detector System object computes a checksum on the input data and compares the result against the input checksum. Instead of frame processing, the HDLCRCDetector System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To compute and compare checksums:

- 1 Create the comm.HDLCRCDetector object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

### Syntax

```
CRCDet = comm.HDLCRCDetector  
CRCDet = comm.HDLCRCDetector(Name,Value)  
CRCDet = comm.HDLCRCDetector(poly,Name,Value)
```

### Description

CRCDet = comm.HDLCRCDetector creates an HDL-optimized CRC detector System object, CRCDet, that detects errors in the input data according to a specified generator polynomial.

`CRCDet = comm.HDLCRCDetector(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
CRCDet = comm.HDLCRCDetector('Polynomial',[1 0 0 0 1 0 0 0 0], ...  
'FinalXORValue',[1 1 0 0 0 0 0 0]);
```

specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.

`CRCDet = comm.HDLCRCDetector(poly, Name, Value)` creates an HDL-optimized CRC detector System object, `CRCDet`, with the `Polynomial` property set to `poly`, and the other specified property names set to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### **Polynomial — Generator polynomial**

`[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]` (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

### **InitialState — Initial conditions of shift register**

`0` (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

### **DirectMethod — Method of calculating checksum**

`false` (default) | `true`

Method of calculating checksum, specified as a logical scalar. When this property is `true`, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see “Cyclic Redundancy Check Codes”.

#### **ReflectInput — Input byte order**

`false` (default) | `true`

Input byte order, specified as a logical scalar. When this property is `true`, the object flips the input data on a bitwise basis before it enters the shift register.

#### **ReflectCRCChecksum — Checksum byte order**

`false` (default) | `true`

Checksum byte order, specified as a logical scalar. When this property is `true`, the object flips the output CRC checksum around its center.

#### **FinalXORValue — Checksum mask**

`0` (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

## Usage

## Syntax

```
[Y,startOut,endOut,validOut,err] = CRCn(X,startIn,endIn,validIn)
```

## Description

`[Y,startOut,endOut,validOut,err] = CRCn(X,startIn,endIn,validIn)` computes CRC checksums for an input message `X` based on the control signals and compares the computed checksum with input checksum. If the two checksums are not equal, the output `err` is set to `1 true`).

## Input Arguments

### **X — Input message and appended checksum**

binary column vector | scalar integer

Input message and appended checksum, specified as a binary vector or a scalar integer representing several bits. For example, vector input `[0,0,0,1,0,0,1,1]` is equivalent to `uint8` input 19.

If the input is a vector, the data type can be double or logical. If the input is a scalar, the data type can be unsigned integer or unsigned fixed-point with 0 fractional bits (`fi([],0,N,0)`).

X can be part or all of the message to be checked.

The length of X must be less than or equal to the CRC length, and the CRC length must be divisible by the length of X.

The CRC length is the order of the polynomial that you specify in the `Polynomial` property.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `logical` | `unsigned fi`

### **startIn — Start of input message**

logical scalar

Start of the input message, specified as a logical scalar.

### **endIn — End of input message**

logical scalar

End of the input message, specified as a logical scalar.

### **validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object computes the CRC checksum for input X.

## Output Arguments

### **Y — Message with checksum removed**

binary column vector | scalar integer

Message with checksum removed, returned as a scalar integer or binary column vector with the same width and data type as input *X*.

### **startOut — Start of input message**

logical scalar

Start of the input message, returned as a logical scalar.

### **endOut — End of input message**

logical scalar

End of the input message, returned as a logical scalar.

### **validOut — Validity of input data**

logical scalar

Validity of input data, returned as a logical scalar. When `validOut` is 1 (`true`), the output data *Y* is valid.

### **err — Checksum mismatch**

logical scalar

Checksum mismatch, returned as a logical scalar. `err` is 1 (`true`) when the input checksum does not match the calculated checksum.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Common to All System Objects**

`step`      Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics  
reset Reset internal states of System object

## Examples

### CRC Encode and Decode for HDL

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32-bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;  
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);  
endIn = logical([0 1 0 0 0 0 0 0 0 0 0 0]);  
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the HDLCRCGenerator System object™ while it is processing the input message. The random data is not encoded because the input valid signal is 0 for steps 3 to 10.

```
randIn = randi([0, 1],16,numSteps-2);  
dataIn = [msg randIn];
```

Write a function that creates and calls each System object™. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

**Note:** This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,startOut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn,
```

```

%HDLCRC16Gen
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcg16;
if isempty(crcg16)
    crcg16 = comm.HDLCRCGenerator()
end
[dataOut,startOut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end

function [dataOut,startOut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcd16;
if isempty(crcd16)
    crcd16 = comm.HDLCRCDetector()
end
[dataOut,startOut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end

```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```

for i = 1:numSteps
    [dataOutGen(:,i),startOutGen(i),endOutGen(i),validOutGen(i)] = ...
        HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
end

```

```

crcg16 =

```

```

    comm.HDLCRCGenerator with properties:

```

```

        Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
        InitialState: 0
        DirectMethod: false
        ReflectInput: false
        ReflectCRCChecksum: false
        FinalXORValue: 0
    
```

Add noise by flipping a bit in the message.

```

dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
    
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the `err` flag is set with the last word of the output.

```

for i = 1:numSteps
[dataOut(:,i),startOut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(dataOutNoise(:,i)),startOutGen(i),endOutGen(i),validOutGen(i))
end
    
```

```

crcd16 =
    
```

```

comm.HDLCRCDetector with properties:
    
```

```

        Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
        InitialState: 0
        DirectMethod: false
        ReflectInput: false
        ReflectCRCChecksum: false
        FinalXORValue: 0
    
```

Use the **Logic Analyzer** to view the input and output signals.

```

channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    'validOutGen','startOutGen','endOutGen',...
    {'dataOutGen','Radix','Hexadecimal'},...
    {'dataOutNoise','Radix','Hexadecimal'},...
    'validOut','startOut','endOut','err',...
    {'dataOut','Radix','Hexadecimal'}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels))
    
```

```
        'BackgroundColor', 'Black', 'DisplayChannelHeight', 8);  
  
for ii = 1:length(channels)  
    if iscell(channels{ii})  
        % Display data signals as hexadecimal integers  
        c = channels{ii};  
        modifyDisplayChannel(la, ii, 'Name', c{1}, c{2}, c{3})  
        % Convert binary column vector to integer  
        dat2 = uint16(bi2de(eval(c{1}')));  
        chanData{ii} = squeeze(dat2);  
    else  
        modifyDisplayChannel(la, ii, 'Name', channels{ii})  
        chanData{ii} = squeeze(eval(channels{ii}));  
    end  
end  
la(chanData{:})
```

## Algorithms

### Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. The input frames are contiguous, and the output frames show space between them because the detector block removes the checksum word.

This waveform diagram shows continuous input data. Non-continuous data is also supported.

## Initial Delay

The HDLCRCDetector System object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

$$\text{initialDelay} = 3 * (\text{CRCLength}/\text{inputDataWidth}) + 2$$

**Package:** comm

Generate CRC code bits and append to input data

## Description

This HDL-optimized cyclic redundancy code (CRC) generator System object generates cyclic redundancy code (CRC) bits. Instead of frame processing, the `HDLCRCGenerator` System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To generate cyclic redundancy code bits:

- 1 Create the `comm.HDLCRCGenerator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

### Syntax

```
CRCGen = comm.HDLCRCGenerator  
CRCGen = comm.HDLCRCGenerator(Name,Value)  
CRCGen = comm.HDLCRCGenerator(poly,Name,Value)
```

### Description

`CRCGen = comm.HDLCRCGenerator` creates an HDL-optimized CRC generator System object, `CRCGen`. This object generates CRC bits according to a specified generator polynomial and appends them to the input data.

`CRCGen = comm.HDLCRCGenerator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
CRCGen = comm.HDLCRCGenerator('Polynomial',[1 0 0 0 1 0 0 0 0], ...  
'FinalXORValue',[1 1 0 0 0 0 0 0]);
```

specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.

`CRCGen = comm.HDLCRCGenerator(poly,Name,Value)` sets the `Polynomial` property to `poly`, and the other specified property names to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects* (MATLAB).

### **Polynomial — Generator polynomial**

`[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]` (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

### **InitialState — Initial conditions of shift register**

`0` (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

### **DirectMethod — Method of calculating checksum**

`false` (default) | `true`

Method of calculating checksum, specified as a logical scalar. When this property is `true`, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see “Cyclic Redundancy Check Codes”.

**ReflectInput — Input byte order**

false (default) | true

Input byte order, specified as a logical scalar. When this property is true, the object flips the input data on a bitwise basis before it enters the shift register.

**ReflectCRCChecksum — Checksum byte order**

false (default) | true

Checksum byte order, specified as a logical scalar. When this property is true, the object flips the output CRC checksum around its center.

**FinalXORValue — Checksum mask**

0 (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the Polynomial property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

## Usage

## Syntax

[Y,startOut,endOut,validOut] = CRCn(X,startIn,endIn, validIn)

## Description

[Y,startOut,endOut,validOut] = CRCn(X,startIn,endIn, validIn)  
generates CRC checksums for input message X based on control signals and appends the checksums to X.

### Input Arguments

#### **X — Input message**

binary column vector | scalar integer

Input message, specified as a binary vector or a scalar integer representing several bits. For example, vector input `[0,0,0,1,0,0,1,1]` is equivalent to `uint8` input 19.

If the input is a vector, the data type can be double or logical. If the input is a scalar, the data type can be unsigned integer or unsigned fixed-point with 0 fractional bits (`fi([],0,N,0)`).

X can be part or all of the message to be encoded.

The length of X must be less than or equal to the CRC length, and the CRC length must be divisible by the length of X.

The CRC length is the order of the polynomial that you specify in the `Polynomial` property.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `logical` | `unsigned fi`

#### **startIn — Start of input message**

logical scalar

Start of the input message, specified as a logical scalar.

#### **endIn — End of input message**

logical scalar

End of the input message, specified as a logical scalar.

#### **validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object computes the CRC checksum for input X.

### Output Arguments

#### **Y — Output message with appended checksum**

binary column vector | scalar integer

Output message, consisting of X with appended checksum, returned as a scalar integer or binary column vector with the same width and data type as input X.

**startOut — Start of input message**

logical scalar

Start of the input message, returned as a logical scalar.

**endOut — End of input message**

logical scalar

End of the input message, returned as a logical scalar.

**validOut — Validity of input data**

logical scalar

Validity of input data, returned as a logical scalar. When `validOut` is 1 (`true`), the output data Y is valid.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### CRC Encode and Decode for HDL

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32-bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;  
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);  
endIn = logical([0 1 0 0 0 0 0 0 0 0 0 0]);  
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the HDLCRCGenerator System object™ while it is processing the input message. The random data is not encoded because the input valid signal is 0 for steps 3 to 10.

```
randIn = randi([0, 1],16,numSteps-2);  
dataIn = [msg randIn];
```

Write a function that creates and calls each System object™. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

**Note:** This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,startOut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)  
%HDLCRC16Gen  
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)  
% dataIn is a binary column vector.  
% startIn, endIn, and validIn are logical scalar values.  
% You can generate HDL code from this function.  
  
persistent crcg16;  
if isempty(crcg16)  
    crcg16 = comm.HDLCRCGenerator()
```

```

end
[dataOut,startOut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end

function [dataOut,startOut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn,validOut)
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcd16;
if isempty(crcd16)
    crcd16 = comm.HDLCRCDetector()
end
[dataOut,startOut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end

```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```

for i = 1:numSteps
[dataOutGen(:,i),startOutGen(i),endOutGen(i),validOutGen(i)] = ...
    HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
end

```

```

crcg16 =

```

```

comm.HDLCRCGenerator with properties:

```

```

    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0

```

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the err flag is set with the last word of the output.

```
for i = 1:numSteps
[dataOut(:,i),startOut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(dataOutNoise(:,i)),startOutGen(i),endOutGen(i),validOutGen(i))
end
```

```
crcd16 =
```

```
comm.HDLCRCDetector with properties:
```

```
    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0
```

Use the **Logic Analyzer** to view the input and output signals.

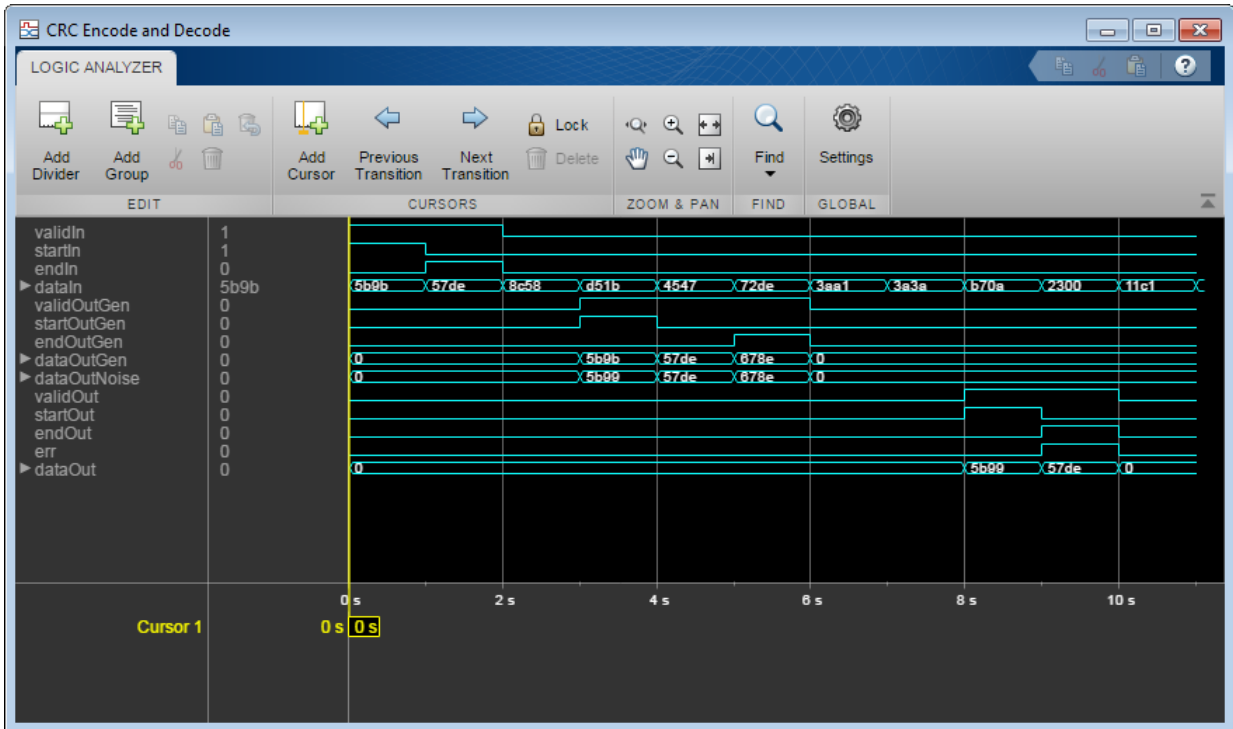

```
channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    'validOutGen','startOutGen','endOutGen',...
    {'dataOutGen','Radix','Hexadecimal'},...
    {'dataOutNoise','Radix','Hexadecimal'},...
    'validOut','startOut','endOut','err',...
    {'dataOut','Radix','Hexadecimal'}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels)
    'BackgroundColor','Black','DisplayChannelHeight',8);

for ii = 1:length(channels)
if iscell(channels{ii})
    % Display data signals as hexadecimal integers
    c = channels{ii};
    modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
    % Convert binary column vector to integer
    dat2 = uint16(bi2de(eval(c{1})));
    chanData{ii} = squeeze(dat2);
end
end
```

```

else
    modifyDisplayChannel(la,ii,'Name',channels{ii})
    chanData{ii} = squeeze(eval(channels{ii}));
end
end
la(chanData{:})

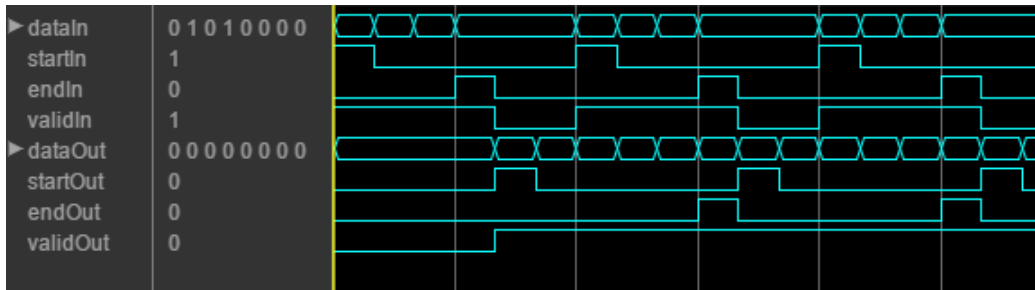

```

## Algorithms

### Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. There must be enough space between the input frames to insert the checksum word.

This waveform diagram shows continuous input data. Non-continuous data is also supported. The output valid signal matches the input valid pattern.

### Initial Delay

The HDLCRCGeneratorSystem object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

$$\text{initialDelay} = (\text{CRCLength}/\text{inputDataWidth}) + 2$$

## comm.HDLRSDecoder

**Package:** comm

Decode message using Reed-Solomon decoder

### Description

The HDL-optimized HDLRSDecoder System object recovers a message vector from a Reed-Solomon (RS) codeword vector. For proper decoding, the code and polynomial property values for this object must match those values in the corresponding encoder.

To recover a message vector from a Reed-Solomon codeword vector:

- 1 Create the `comm.HDLRSDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

### Troubleshooting

- Each input frame must contain more than  $(N-K)*2$  symbols and fewer than or exactly  $N$  symbols. The object infers a shortened code when the number of valid data samples between `startIn` and `endIn` is less than  $N$ . A shortened code still requires  $N$  cycles to perform the Chien search. If the input message is less than  $N$  symbols, leave a guard interval of at least  $N - \text{size}$  inactive cycles before starting the next frame, where `size` is the message length.
- The decoder can operate on up to four messages at a time. If the object receives the start of a fifth message before completely decoding the first message, the object drops data samples from the first message. To avoid this issue, increase the number of inactive cycles between input messages.
- The generator polynomial is not specified explicitly. However, it is defined by the codeword length, the message length, and the  $B$  value for the starting exponent of the roots. To get the value of  $B$  from a generator polynomial, use the `genpoly2b` function.

## Creation

## Syntax

```
RSDec = comm.HDLRSDecoder  
RSDec = comm.HDLRSDecoder(Name,Value)  
RSDec = comm.HDLRSDecoder(N,K,Name,Value)
```

## Description

`RSDec = comm.HDLRSDecoder` creates an HDL-optimized RS decoder System object, `RSDec`, that performs Reed-Solomon decoding.

`RSDec = comm.HDLRSDecoder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
comm.HDLRSDecoder('BSource','Property','B',2)
```

sets a starting power of 2 for the roots of the primitive polynomial.

`RSDec = comm.HDLRSDecoder(N,K,Name,Value)` sets the `CodewordLength` property to `N`, the `MessageLength` property to `K`, and other specified property names to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

### **B** — Starting power for roots of primitive polynomial

1 (default) | positive integer

Starting power for roots of the primitive polynomial, specified as a positive integer.

### Dependencies

The object uses this value when you set `BSource` to `'Property'`.

### **BSource — Source of starting power for roots of primitive polynomial**

`'Auto'` (default) | `'Property'`

Source of the starting power for roots of the primitive polynomial, specified as either `'Property'` or `'Auto'`. When you select `'Auto'`, the object uses  $B = 1$ .

### **CodewordLength — Number of symbols, N, in RS codeword**

7 (default) | positive integer

Number of symbols,  $N$ , in the RS codeword, specified as a positive integer. This value is rounded up to  $2^M - 1$ .  $M$  is the degree of the primitive polynomial, as specified by the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties. The difference of `CodewordLength` - `MessageLength` must be an even integer.

If the value of this property is less than  $2^M - 1$ , the object assumes a shortened RS code.

If you set `PrimitivePolynomialSource` to `'Auto'`, then `CodewordLength` must be in the range  $3 < \text{CodewordLength} \leq 2^{16} - 1$ .

If you set `PrimitivePolynomialSource` to `'Property'`, then `CodewordLength` must be in the range  $3 \leq \text{CodewordLength} \leq 2^M - 1$ .  $M$  must be in the range  $3 \leq M \leq 16$ .

### **MessageLength — Message length, K**

3 (default) | positive integer

Message length,  $K$ , specified as a positive integer. The difference of `CodewordLength` - `MessageLength` must be an even integer.

### **NumErrorsOutputPort — Enable number of errors output argument**

`false` (default) | `true`

When you set this property to `true`, the object returns the number of corrected errors. The number of corrected errors is not valid when `errOut` is `true`, since there were more errors than could be corrected.

### **PrimitivePolynomialSource — Source of primitive polynomial**

`'Auto'` (default) | `'Property'`

Source of the primitive polynomial, specified as either `'Property'` or `'Auto'`.

- When you set this property to 'Auto', the object uses a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength}+1))$ , which is the result of `flipLr(de2bi(primpoly(M)))`.
- When you set this property to 'Property', you must specify a polynomial using the `PrimitivePolynomial` property.

### **PrimitivePolynomial — Primitive polynomial**

[1 0 1 1] (default) | binary row vector

Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over  $\text{gf}(2)$  of degree  $M$ , in descending order of powers. The polynomial defines the finite field  $\text{gf}(2^M)$  corresponding to the integers that form messages and codewords.

#### **Dependencies**

The object uses this value when you set `PrimitivePolynomialSource` to 'Property'.

## **Usage**

## **Syntax**

```
[Y,startOut,endOut,validOut,errOut] = RSDec(X,startIn,endIn,validIn)
[Y,startOut,endOut,validOut,errOut,numErrors] = RSDec(X,startIn,
endIn,validIn)
```

## **Description**

`[Y,startOut,endOut,validOut,errOut] = RSDec(X,startIn,endIn,validIn)` decodes one encoded message symbol,  $X$ , and returns the decoded symbol  $Y$ . The `start` and `end` signals indicate the message frame boundaries. If `errOut` is 1 (true), then the object detected uncorrectable errors in the input frame.

`[Y,startOut,endOut,validOut,errOut,numErrors] = RSDec(X,startIn,endIn,validIn)` decodes the input data, and also returns the number of errors detected and corrected. To use this syntax, set the `NumErrorsOutputPort` property to true. If `errOut` is 1 (true), then the object detected uncorrectable errors in the output frame, and `numErrors` is invalid.

### Input Arguments

#### **X — Input message data or parity symbols**

integer

Input message data and parity symbols, one symbol at a time, specified as an unsigned integer or `fi()` with any binary point scaling.

`double` type is allowed for simulation but not supported for HDL code generation.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

#### **startIn — Start of input data frame**

logical scalar

Start of input data frame, specified as a logical scalar.

Data Types: `logical`

#### **endIn — End of input data frame**

logical scalar

End of input data frame, specified as a logical scalar.

Data Types: `logical`

#### **validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

### Output Arguments

#### **Y — Message data symbols**

integer

Message data symbols, returned one symbol at a time, as an integer with the same data type as the input message, `X`.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

**startOut — Start of output data frame**

logical scalar

Start of output data frame, returned as a logical scalar.

Data Types: logical

**endOut — End of output data frame**

logical scalar

End of output data frame, returned as a logical scalar.

Data Types: logical

**validOut — Validity of output data**

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: logical

**errOut — Uncorrectable error in output data frame**

logical scalar

Uncorrectable error in output data frame, returned as a logical scalar. This signal is 1 (**true**) when the message frame contains uncorrectable errors. In this case, the output data symbols are corrupted. This value is valid when **endOut** is 1 (**true**).

Data Types: logical

**numErrors — Number of errors detected and corrected**

integer

Number of errors detected and corrected, returned as an integer. This value is valid when **endOut** is 1 (**true**) and **errOut** is 0 (**false**).

Data Types: uint8

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

## Examples

### Reed-Solomon Coding and Error Detection for HDL

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;  
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a HDLRSDecoder System object™ with an RS(255,239) code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. B is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

**Note:** This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace myObject(x) with step(myObject,x).

```
function [dataOut,startOut,endOut,validOut] = HDLRSDec80216(dataIn,startIn,endIn,validIn)  
%HDLRSDec80216  
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)  
% dataIn is a uint8 scalar, representing 8 bits of binary data.  
% startIn, endIn, and validIn are logical scalar values.  
% You can generate HDL code from this function.  
  
persistent rsEnc80216;  
if isempty(rsEnc80216)  
    rsEnc80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
```

```

end
[dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end

```

Call the function to encode the message.

```

for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),startOut(ii),endOut(ii),validOut(ii)] = ...
        HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end

```

```
rsEnc80216 =
```

```

comm.HDLRSEncoder with properties:
    CodewordLength: 255
    MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    PuncturePatternSource: 'None'
    BSource: 'Property'
    B: 0

```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to  $(N - K)/2$  errors in each  $N$  symbols. So, in this example, the error correction capability is  $(255 - 239)/2=8$  symbols.

```

numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
    idx = loc(i)+vi;
    symbol = encOut(idx);
    encOut(idx) = randi([0 255],'uint8');
    fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end

```

```

Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82

```

```
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88
```

Write a function that creates and calls a HDLRSDecoder System object™. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```
function [dataOut,startOut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn,errIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent rsDec80216;
if isempty(rsDec80216)
    rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
end
end
[dataOut,startOut,endOut,validOut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
    [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
        HDLRSDec80216(encOut(ii),startOut(ii),endOut(ii),validOut(ii));
end
```

```
rsDec80216 =

comm.HDLRSDecoder with properties:

    CodewordLength: 255
    MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    BSource: 'Property'
    B: 0
```

```
NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
    for jj = 1:messageLength
        if dataIn(jj)~=decOut(jj)
            fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj))
        end
    end
end
end
```

All 188 message symbols were correctly decoded.

Integer-Output RS Decoder HDL Optimized

**Introduced in R2012b**

# comm.HDLRSEncoder

**Package:** comm

Encode message using Reed-Solomon encoder

## Description

The HDL-optimized HDLRSEncoder System object creates a Reed-Solomon (RS) code with message and codeword lengths that you specify.

To encode a message using a Reed-Solomon code:

- 1 Create the `comm.HDLRSEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
RSEnc = comm.HDLRSEncoder  
RSEnc = comm.HDLRSEncoder(Name,Value)  
RSEnc = comm.HDLRSEncoder(N,K,Name,Value)
```

## Description

`RSEnc = comm.HDLRSEncoder` creates an HDL-optimized block encoder System object, `RSEnc`, that performs Reed-Solomon encoding in a streaming fashion for HDL.

`RSEnc = comm.HDLRSEncoder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
comm.HDLRSEncoder('BSource','Property','B',2)
```

sets a starting power of 2 for the roots of the primitive polynomial.

`RSEnc = comm.HDLRSEncoder(N,K,Name,Value)` sets the `CodewordLength` property to `N`, the `MessageLength` property to `K`, and other specified property names to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### **B — Starting power for roots of primitive polynomial**

1 (default) | positive integer

Starting power for roots of the primitive polynomial, specified as a positive integer.

#### **Dependencies**

The object uses this value when you set `BSource` to `'Property'`.

### **BSource — Source of starting power for roots of primitive polynomial**

`'Auto'` (default) | `'Property'`

Source of the starting power for roots of the primitive polynomial, specified as either `'Property'` or `'Auto'`. When you select `'Auto'`, the object uses `B = 1`.

### **CodewordLength — Number of symbols, N, in RS codeword**

7 (default) | positive integer

Number of symbols,  $N$ , in the RS codeword, specified as a positive integer. This value is rounded up to  $2^M-1$ .  $M$  is the degree of the primitive polynomial, as specified by the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties. The difference of `CodewordLength` - `MessageLength` must be an even integer.

If the value of this property is less than  $2^M-1$ , the object assumes a shortened RS code.

If you set `PrimitivePolynomialSource` to 'Auto', then `CodewordLength` must be in the range  $3 < \text{CodewordLength} \leq 2^{16} - 1$ .

If you set `PrimitivePolynomialSource` to 'Property', then `CodewordLength` must be in the range  $3 \leq \text{CodewordLength} \leq 2^M - 1$ .  $M$  must be in the range  $3 \leq M \leq 16$ .

### **MessageLength — Message length, K**

3 (default) | positive integer

Message length,  $K$ , specified as a positive integer. The difference of `CodewordLength` - `MessageLength` must be an even integer.

### **PrimitivePolynomialSource — Source of primitive polynomial**

'Auto' (default) | 'Property'

Source of the primitive polynomial, specified as either 'Property' or 'Auto'.

- When you set this property to 'Auto', the object uses a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength} + 1))$ , which is the result of `flipLr(de2bi(primpoly(M)))`.
- When you set this property to 'Property', you must specify a polynomial using the `PrimitivePolynomial` property.

### **PrimitivePolynomial — Primitive polynomial**

[1 0 1 1] (default) | binary row vector

Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over  $\text{gf}(2)$  of degree  $M$ , in descending order of powers. The polynomial defines the finite field  $\text{gf}(2^M)$  corresponding to the integers that form messages and codewords.

### **Dependencies**

The object uses this value when you set `PrimitivePolynomialSource` to 'Property'.

### **PuncturePatternSource — Source of puncture pattern**

'None' (default) | 'Property'

Source of the puncture pattern, specified as 'None' or 'Property'. If you set this property to 'None', then the object does not apply puncturing to the code. If you set this property to 'Property', then the object punctures the code based on a puncture pattern vector specified in the `PuncturePattern` property.

### **PuncturePattern — Pattern used to puncture encoded data**

[ones(2,1); zeros(2,1)] (default) | binary column vector

Pattern used to puncture the encoded data, specified as a double-precision, binary column vector with a length of `CodewordLength - MessageLength`. The default is [ones(2,1); zeros(2,1)]. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

#### **Dependencies**

This property applies when you set the `PuncturePatternSource` property to 'Property'.

## **Usage**

## **Syntax**

[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn)

## **Description**

[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn) encodes one input message symbol, X, and returns one symbol of encoded data, Y. The `start` and `end` signals indicate the message frame boundaries. The object returns associated parity symbols at the end of each message frame.

## **Input Arguments**

### **X — Input message symbol**

integer

Input message data, one symbol at a time, specified as an unsigned integer or `fi()` with any binary point scaling. The word length of each symbol must be `ceil(log2(CodewordLength+1))`.

`double` type is allowed for simulation but not supported for HDL code generation.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

**startIn — Start of input data frame**

logical scalar

Start of input data frame, specified as a logical scalar.

Data Types: `logical`**endIn — End of input data frame**

logical scalar

End of input data frame, specified as a logical scalar.

Data Types: `logical`**validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`**Output Arguments****Y — Output message data and parity symbols**

integer

Message data and parity symbols, returned one symbol at a time, as an integer with the same data type as the input message, X.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`**startOut — Start of output data frame**

logical scalar

Start of output data frame, returned as a logical scalar.

Data Types: `logical`**endOut — End of output data frame**

logical scalar

End of output data frame, returned as a logical scalar.

Data Types: `logical`

### **validOut — Validity of output data**

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Common to All System Objects**

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## **Examples**

### **Reed-Solomon Coding and Error Detection for HDL**

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;  
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a `HDLRSEncoder` System object™ with an RS(255,239) code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. `B` is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

**Note:** This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,startOut,endOut,validOut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)
%HDLRSEnc80216
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent rsEnc80216;
if isempty(rsEnc80216)
    rsEnc80216 = comm.HDLRSEncoder(255,239,'BSource','Property','B',0)
end
end
[dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to encode the message.

```
for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),startOut(ii),endOut(ii),validOut(ii)] = ...
        HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end
```

rsEnc80216 =

comm.HDLRSEncoder with properties:

```
    CodewordLength: 255
    MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    PuncturePatternSource: 'None'
    BSource: 'Property'
    B: 0
```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to  $(N - K)/2$  errors in each  $N$  symbols. So, in this example, the error correction capability is  $(255 - 239)/2=8$  symbols.

```
numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
    idx = loc(i)+vi;
    symbol = encOut(idx);
    encOut(idx) = randi([0 255],'uint8');
    fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end
```

```
Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88
```

Write a function that creates and calls a HDLRSDecoder System object™. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```
function [dataOut,startOut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn,err)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

    persistent rsDec80216;
    if isempty(rsDec80216)
        rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
    end
    [dataOut,startOut,endOut,validOut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
    [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
        HDLRSDec80216(encOut(ii),startOut(ii),endOut(ii),validOut(ii));
end
```

```
rsDec80216 =
```

```
comm.HDLRSDecoder with properties:
```

```
    CodewordLength: 255
    MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    BSource: 'Property'
    B: 0
    NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
    for jj = 1:messageLength
        if dataIn(jj)~=decOut(jj)
            fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj))
        end
    end
end
```

```
All 188 message symbols were correctly decoded.
```

# comm.HelicalDeinterleaver

**Package:** comm

Restore ordering of symbols using helical array

## Description

The `HelicalDeinterleaver` object permutes the symbols in the input signal by placing them in a row-by-row array and then selecting groups helically to send to the output port.

To helically deinterleave input symbols:

- 1 Define and set up your helical deinterleaver object. See “Construction” on page 4-1105.
- 2 Call `step` to deinterleave input symbols according to the properties of `comm.HelicalDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.HelicalDeinterleaver` creates a helical deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the helical interleaver System object.

`H = comm.HelicalDeinterleaver(Name,Value)` creates a helical deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### NumColumns

Number of columns in helical array

Specify the number of columns in the helical array as a positive integer scalar value. The default is 6.

### GroupSize

Size of each group of input symbols

Specify the size of each group of input symbols as a positive integer scalar value. The default is 4.

### StepSize

Helical array step size

Specify number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires a positive integer scalar value. The default is 1.

### InitialConditions

Initial conditions of helical array

Specify the value that is initially stored in the helical array as a numeric scalar value. The default is 0.

## Methods

- reset     Reset states of the helical deinterleaver object
- step     Restore ordering of symbols using a helical array

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);

for k = 1:10
    data = randi(7,6,1);
    intData = interleaver(data);
    deIntData = deinterleaver(intData);

    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deIntData);
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlvDelay = finddelay(dataIn,dataOut)

intlvDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlvDelay),dataOut(1+intlvDelay:end))

ans = logical
     1
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Helical Deinterleaver block reference page. The object properties correspond to the block parameters.

## Syntax

reset(H)

## Description

reset(H) resets the states of the HelicalDeinterleaver object, H.

# step

**System object:** `comm.HelicalDeinterleaver`

**Package:** `comm`

Restore ordering of symbols using a helical array

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  restores the original ordering of the sequence,  $X$ , that was interleaved using a helical interleaver and returns  $Y$ . The input  $X$  must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects).  $Y$  has the same data type as  $X$ . The helical deinterleaver object uses an array for its computations. If you set the `NumColumns` property of the object to  $C$ , then the array has  $C$  columns and unlimited rows. If you set the `GroupSize` property to  $N$ , then the object accepts an input of length  $C \times N$  and inserts it into the next  $N$  rows of the array. The object also places the value of the `InitialConditions` property into certain positions in the top few rows of the array. This accommodates the helical pattern and also preserves the vector indices of symbols that pass through the `HelicalInterleaver` and `HelicalDeinterleaver` objects. The output consists of consecutive groups of  $N$  symbols. The object selects the  $k$ -th output group in the array from column  $k \bmod C$ . This selection is of type helical because of the reduction modulo  $C$  and because the first symbol in the  $k$ -th group is in row  $1 + (k-1) \times s$ , where  $s$  is the value for the `StepSize` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.HelicalInterleaver

**Package:** comm

Permute input symbols using helical array

### Description

The `HelicalInterleaver` object permutes the symbols in the input signal by placing them in an array in a helical arrangement and then sending rows of the array to the output port.

To helically interleave input symbols:

- 1 Define and set up your helical interleaver object. See “Construction” on page 4-1112.
- 2 Call `step` to interleave input symbols according to the properties of `comm.HelicalInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.HelicalInterleaver` creates a helical interleaver System object, `H`. This object permutes the input symbols in the input signal by placing them in an array in a helical arrangement.

`H = comm.HelicalInterleaver(Name,Value)` creates a helical interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### NumColumns

Number of columns in helical array

Specify the number of columns in the helical array as a positive integer scalar value. The default is 6.

### GroupSize

Size of each group of input symbols

Specify the size of each group of input symbols as a positive integer scalar value. The default is 4.

### StepSize

Helical array step size

Specify the number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires as a positive integer scalar value . The default is 1.

### InitialConditions

Initial conditions of helical array

Specify the value that is initially stored in the helical array as a numeric scalar value. The default is 0.

## Methods

## Examples

### Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...  
    'InitialConditions',-1);  
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...  
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);  
  
for k = 1:10  
    data = randi(7,6,1);  
    intData = interleaver(data);  
    deIntData = deinterleaver(intData);  
  
    dataIn = cat(1,dataIn,data);  
    dataOut = cat(1,dataOut,deIntData);  
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlvDelay = finddelay(dataIn,dataOut)  
  
intlvDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlvDelay),dataOut(1+intlvDelay:end))  
  
ans = logical  
     1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Helical Interleaver block reference page. The object properties correspond to the block parameters.

Reset states of the helical interleaver object

## **Syntax**

`reset(H)`

## **Description**

`reset(H)` resets the states of the `HelicalInterleaver` object, `H`.

## step

**System object:** comm.HelicalInterleaver

**Package:** comm

Permute input symbols using a helical array

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  permutes input sequence,  $X$ , and returns interleaved sequence,  $Y$ . The input  $X$  must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects).  $Y$  has the same data type as  $X$ . The helical interleaver object places the elements of  $X$  in an array in a helical fashion. If you set the `NumColumns` property of the object to  $C$ , then the array has  $C$  columns and unlimited rows. If you set the `GroupSize` property to  $N$ , then the object accepts an input of length  $C \times N$  and partitions the input into consecutive groups of  $N$  symbols. The object places the  $k$ -th group in the array along column  $k \bmod C$ . This placement is of type helical because of the reduction modulo  $C$  and because the first symbol in the  $k$ -th group is in the row  $1+(k-1) \times s$ , where  $s$  is the value for the `StepSize` property. Positions in the array that do not contain input symbols have default contents specified by the `InitialConditions` property. The object outputs  $C \times N$  symbols from the array by reading the next  $N$  rows sequentially.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.IntegerToBit

**Package:** comm

(To be removed) Convert vector of integers to vector of bits

---

**Note** will be removed in a future release. Use `de2bi` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `IntegerToBit` object maps each integer (or fixed-point value) in the input vector to a group of bits in the output vector.

To map integers to bits:

- 1 Define and set up your integer to bit object. See “Construction” on page 4-1119.
- 2 Call `step` to map integers in the input vector to groups of bits in the output vector according to the properties of `comm.IntegerToBit`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.IntegerToBit` creates an integer-to-bit converter System object, `H`. This object maps a vector of integer-valued or fixed-point inputs to a vector of bits.

`H = comm.IntegerToBit(Name,Value)` creates an integer-to-bit converter object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.IntegerToBit(NUMBITS, Name, Value)` creates an integer-to-bit converter object, `H`. This object has the `BitsPerInteger` property set to `NUMBITS` and the other specified properties set to the specified values.

## Properties

### **BitsPerInteger**

Number of bits per integer

Specify the number of bits the System object uses to represent each input integer. You must set this property to a scalar integer between 1 and 32. The default is 3.

### **MSBFirst**

Output bit words with first bit as most significant bit

Set this property to `true` to indicate that the first bit of the output bit words is the most significant bit (MSB). The default is `true`. Set this property to `false` to indicate that the first bit of the output bit words is the least significant bit (LSB).

### **SignedIntegerInput**

Assume inputs are signed integers

Set this property to `true` if the integer inputs are signed. The default is `false`. Set this property to `false` if the integer inputs are unsigned. If the `SignedIntegerInput` on page 4-0 property is `false`, the input values must be between 0 and  $(2^N)-1$ . In this case,  $N$  is the value you specified in the `BitsPerInteger` on page 4-0 property. When you set this property to `true`, the input values must be between  $-(2^{(N-1)})$  and  $(2^{(N-1)})-1$ .

### **OutputDataType**

Data type of output

Specify output data type as one of `Full precision | Smallest unsigned integer | Same as input | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical`. The default is `Full precision`.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When you set this property to `Full precision`, the object determines the output data type based on the input data type. If the input data type is double- or single-precision, the output data has the same data type as the input data. Otherwise, the output data type is determined in the same way as when you set this property to `Smallest unsigned integer`.

When you set this property to `Same as input`, and the input data type is numeric or fixed-point integer (fi object), the output data has the same data type as the input data.

## Methods

`step` (To be removed) Convert vector of integers to vector of bits

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

### Convert random integers to 4-bit words

```
hIntToBit = comm.IntegerToBit(4);
intData = randi([0 2^hIntToBit.BitsPerInteger-1],3,1);
bitData = step(hIntToBit,intData)
```

```
bitData = 12×1
```

```
1
1
0
1
1
1
1
0
```

```
0
0
⋮
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Integer to Bit Converter block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

**comm.IntegerToBit will be removed in a future release. Use de2bi instead.**

*Not recommended starting in R2019b*

Data types as supported by comm.IntegerToBit are not inherently supported by functions. This code shows decimal to binary conversion for various data types using this function.

### Examples Using de2bi for Various Data Types

```
function compde2bi

% Number of integers
n = randi([1 100]);

% Default
h1 = comm.IntegerToBit;
bpi = h1.BitsPerInteger;
x = randi([0,2^bpi-1],n,1);
y1 = h1(x);
y2 = reshape(de2bi(x,bpi,'left-msb'),[],1);
isequal(y1,y2)

% Right MSB, logical input
h2 = comm.IntegerToBit( ...
    'BitsPerInteger',5, ...
    'MSBFirst',false);
bpi = h2.BitsPerInteger;
x = randi([0,2^bpi-1],n,1);
y1 = h2(x);
y2 = reshape(de2bi(x,bpi,'right-msb'),[],1);
isequal(y1,y2)
```

```
% Right MSB, signed input, single input
h3 = comm.IntegerToBit( ...
    'BitsPerInteger',8, ...
    'MSBFirst',false, ...
    'SignedIntegerInput',true);
bpi = h3.BitsPerInteger;
N = 2^bpi;
x = randi([-N/2,N/2-1],n,1);
y1 = h3(x);
y2 = reshape(de2bi(x+(x<0)*N,bpi,'right-msb'),[],1);
isequal(y1,y2)
end
```

## See Also

**Introduced in R2012a**

# step

**System object:** `comm.IntegerToBit`

**Package:** `comm`

(To be removed) Convert vector of integers to vector of bits

---

**Note** `comm.IntegerToBit` will be removed in a future release. Use `de2bi` instead.

---

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  converts integer input,  $X$ , to corresponding bits,  $Y$ . The input must be scalar or a column vector and the data type can be numeric or fixed-point (fi objects). The output is a column vector with length equal to  $\text{length}(X) \times N$ , where  $N$  is the value of the `BitsPerInteger` property. If any input value is outside the range of  $N$ , the object issues an error. If the `SignedIntegerInput` property is `false`, the input values must be between 0 and  $(2^N)-1$ . If you set the `SignedIntegerInput` property to `true`, the input values must be between  $-(2^{(N-1)})$  and  $(2^{(N-1)})-1$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.IntegrateAndDumpFilter

**Package:** comm

Integrate discrete-time signal with periodic resets

### Description

The `IntegrateAndDumpFilter` object creates a cumulative sum of the discrete-time input signal, while resetting the sum to zero according to a fixed schedule. When the simulation begins, the object discards the number of samples specified in the `Offset` property. After this initial period, the object sums the input signal along columns and resets the sum to zero every  $N_{\text{input}}$  samples, set by the integration period property. The reset occurs after the object produces output at that time step.

To integrate discrete-time signals with periodic resets:

- 1 Define and set up your integrate and dump filter object. See “Construction” on page 4-1126.
- 2 Call `step` to integrate discrete-time signals according to the properties of `comm.IntegrateAndDumpFilter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

### Construction

`H = comm.IntegrateAndDumpFilter` creates an integrate and dump filter System object, `H`. this object integrates over a number of samples in an integration period, and then resets at the end of that period.

`H = comm.IntegrateAndDumpFilter(Name, Value)` creates an integrate and dump filter object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.IntegrateAndDumpFilter(PERIOD, Name, Value)` creates an integrate and dump filter object, `H`. This object has the `IntegrationPeriod` property set to `PERIOD` and the other specified properties set to the specified values.

## Properties

### IntegrationPeriod

Integration period

Specify the integration period, in samples, as a positive, integer scalar value greater than 1. The integration period defines the length of the sample blocks that the object integrates between resets. The default is 8.

### Offset

Number of offset samples

Specify a nonnegative, integer vector or scalar specifying the number of input samples that the object discards from each column of input data at the beginning of data processing. Discarding begins when you call the `step` method for the first time. The default is 0.

When you set the `Offset` on page 4-0 property to a nonzero value, the object outputs one or more zeros during the initial period while discarding input samples.

When you specify this property as a vector of length  $L$ , the  $i$ -th element of the vector corresponds to the offset for the  $i$ -th column of the input data matrix, which has  $L$  columns.

When you specify this property as a scalar value, the object applies the same offset to each column of the input data matrix. The offset creates a transient effect, rather than a persistent delay.

### DecimateOutput

Decimate output

Specify whether the `step` method returns intermediate cumulative sum results or decimates intermediate results. The default is `true`.

When you set this property to `true`, the `step` method returns one output sample, consisting of the final integration value, for each block of `IntegrationPeriod` on page 4-0 input samples. If the inputs are  $(K \times \text{IntegrationPeriod}) \times L$  matrices, then the outputs are  $K \times L$  matrices.

When you set this property to `false`, the `step` method returns `IntegrationPeriod` output samples, comprising the intermediate cumulative sum values, for each block of `IntegrationPeriod` input samples. In this case, inputs and outputs have the same dimensions.

### **Fixed-Point Properties**

#### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 4-1131.

#### **RoundingMethod**

Rounding of fixed-point numeric values

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

#### **OverflowAction**

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

## AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Custom`. The default is `Full precision`. When you set this property to `Full precision` the object automatically calculates the accumulator output word and fraction lengths. Set this property to `Custom` to specify the accumulator data type using the `CustomAccumulatorDataType` on page 4-0 property. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false.

## CustomAccumulatorDataType

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false and the `AccumulatorDataType` on page 4-0 property to `Custom`.

## OutputDataType

Data type of output

Specify the output fixed-point type as one of `Same as accumulator` | `Same as input` | `Custom`. The default is `Same as accumulator`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false.

## CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to false and the `OutputDataType` on page 4-0 property to `Custom`.

## Methods

`step` Integrate discrete-time signal with periodic resets

**Common to All System Objects**

release	Allow System object property value changes
---------	--

## Examples

### Pass Noisy Pulses Through Integrate and Dump Filter

Create an integrate and dump filter having an integration period of 20 samples.

```
intdump = comm.IntegrateAndDumpFilter(20);
```

Generate binary data.

```
d = randi([0 1],50,1);
```

Upsample the data, and pass it through an AWGN channel.

```
x = upsample(d,20);  
y = awgn(x,25,'measured');
```

Pass the noisy data through the filter.

```
z = intdump(y);
```

Plot the original and filtered data. The integrate and dump filter removes most of the noise effects.

```
stairs([d z])  
legend('Original Data','Filtered Data')  
xlabel('Samples')  
ylabel('Amplitude')  
grid
```

## More About

### Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum

or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Integrate and Dump block reference page. The object properties correspond to the block parameters, except:

The **Output intermediate values** parameter corresponds to the `DecimateOutput` on page 4-0 property.

## Extended Capabilities

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2012a**

---

## step

**System object:** comm.IntegrateAndDumpFilter

**Package:** comm

Integrate discrete-time signal with periodic resets

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  periodically integrates blocks of  $N$  samples from the input data,  $X$ , and returns the result in  $Y$ .  $N$  is the number of samples that you specify in the `IntegrationPeriod` property.  $X$  is a column vector or a matrix and the data type is double, single or fixed-point (fi objects).  $X$  must have  $K*N$  rows for some positive integer  $K$ , with one or more columns. The object treats each column as an independent channel with integration occurring along every column. The dimensions of output  $Y$  depend on the value you set for the `DecimateOutput` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.KasamiSequence

**Package:** comm

Generate Kasami sequence

## Description

The `KasamiSequence` object generates a sequence from the set of Kasami sequences. The Kasami sequences are a set of sequences that have good cross-correlation properties.

To generate a Kasami sequence:

- 1 Define and set up your Kasami sequence object. See “Construction” on page 4-1135.
- 2 Call `step` to generate a Kasami sequence according to the properties of `comm.KasamiSequence`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

## Construction

`H = comm.KasamiSequence` creates a `KasamiSequence` System object, `H`. This object generates a Kasami sequence.

`H = comm.KasamiSequence(Name, Value)` creates a Kasami sequence generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### Polynomial

Generator polynomial

Specify the polynomial that determines the shift register's feedback connections. The default is ' $z^6 + z + 1$ '.

You can specify the generator polynomial as a character vector or as a binary numeric vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal 1. Specify the length of this vector as  $n+1$ , where  $n$  is the degree of the generator polynomial and must be even.

Lastly, you can specify the generator polynomial as a vector containing the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0. For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial,  $g(z) = z^8 + z^2 + 1$ .

### InitialConditions

Initial conditions of shift register

Specify the initial values of the shift register as a binary numeric scalar or as binary numeric vector. The default is `[0 0 0 0 0 1]`. Set the vector length equal to the degree of the generator polynomial.

When you set this property to a vector value, each element of the vector corresponds to the initial value of the corresponding cell in the shift register.

When you set this property to a scalar value, that value specifies the initial conditions of all the cells of the shift register. The scalar, or at least one element of the specified vector, requires a nonzero value for the object to generate a nonzero sequence.

### Index

Sequence index

Specify the index to select a Kasami sequence of interest from the set of possible sequences. The default is 0. Kasami sequences have a period equal to  $N = 2^n - 1$ , where  $n$  indicates a nonnegative, even integer equal to the degree of the generator polynomial that you specify in the `Polynomial` on page 4-0 property.

There are two classes of Kasami sequences: those obtained from a small set and those obtained from a large set. You choose a Kasami sequence from the small set by setting this property to a numeric, scalar, integer value in the range  $[0 \dots 2^{n/2}-2]$ . You choose a sequence from the large set by setting this property to a numeric  $1 \times 2$  integer vector  $[k \ m]$  for  $k$  in  $[-2, \dots, 2^n-2]$ , and  $m$  in  $[-1, \dots, 2^{n/2}-2]$ .

### **Shift**

Sequence offset from initial time

Specify the offset of the Kasami sequence from its starting point as a numeric, integer scalar value that can be positive or negative. The default is 0. The Kasami sequence has a period of  $N = 2^n - 1$ , where  $n$  is the degree of the generator polynomial that you specify in the `Polynomial` on page 4-0 property. The shift value is wrapped with respect to the sequence period.

### **VariableSizeOutput**

Enable variable-size outputs

Set this property to true to enable an additional input to the step method. The default is false. When you set this property to true, the enabled input specifies the output size of the Kasami sequence used for the step. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to false, the `SamplesPerFrame` property specifies the number of output samples.

### **MaximumOutputSize**

Maximum output size

Specify the maximum output size of the Kasami sequence as a positive integer 2-element row vector. The second element of the vector must be 1. The default is `[10 1]`.

This property applies when you set the `VariableSizeOutput` property to true.

### **SamplesPerFrame**

Number of output samples per frame

Specify the number of Kasami sequence samples that the step method outputs as a numeric, positive, integer scalar value. The default value is 1.

When you set this property to a value of  $M$ , then the `step` method outputs  $M$  samples of a Kasami sequence that has a period of  $N = 2^n - 1$ . The value  $n$  equals the degree of the generator polynomial that you specify in the `Polynomial` on page 4-0 property.

### ResetInputPort

Enable generator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. The additional input resets the states of the Kasami sequence generator to the initial conditions that you specify in the `InitialConditions` on page 4-0 property.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `logical`. The default is `double`.

## Methods

`reset`     Reset states of Kasami sequence generator object  
`step`     Generate a Kasami sequence

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Spread BPSK Data with a Kasami Sequence

Spread BPSK data with a Kasami sequence of length 255 by using the Kasami sequence System object.

Generate binary data and apply BPSK modulation.

```
data = randi([0 1],10,1);  
modData = pskmod(data,2);
```

Create a Kasami sequence object of length 255 using generator polynomial  $x^8 + x^7 + x^4 + 1$ .

```
kasamiSequence = comm.KasamiSequence('Polynomial',[8 7 4 0], ...
    'InitialConditions',[0 0 0 0 0 0 0 1], 'SamplesPerFrame',255);
```

Generate the Kasami sequence and convert it to bipolar form.

```
kasSeq = kasamiSequence();
kasSeq = 2*kasSeq - 1;
```

Apply a gain of  $1/\sqrt{255}$  to ensure that the spreading operation does not increase the overall signal power.

```
kasSeq = kasSeq/sqrt(255);
```

Spread the BPSK data using the Kasami sequence.

```
spreadData = modData*kasSeq';
spreadData = spreadData(:);
```

Verify that the spread data sequence is 255 times longer than the input data sequence.

```
spreadingFactor = length(spreadData)/length(data)
spreadingFactor = 255
```

Verify that the spreading operation did not increase the signal power.

```
spreadSigPwr = sum(abs(spreadData).^2)/length(data)
spreadSigPwr = 1.0000
```

Change the generator polynomial of the Kasami sequence generator to  $x^8 + x^3 + 1$  after first releasing the object. Use the character representation of the polynomial.

```
release(kasamiSequence)
kasamiSequence.Polynomial = 'x^8 + x^3 + 1';
```

Generate a new sequence and convert it to bipolar form.

```
kasSeq = kasamiSequence();
kasSeq = 2*kasSeq - 1;
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Kasami Sequence Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## reset

**System object:** comm.KasamiSequence

**Package:** comm

Reset states of Kasami sequence generator object

## Syntax

reset(H)

## Description

reset(H) resets the states of the KasamiSequence object, H.

# step

**System object:** comm.KasamiSequence

**Package:** comm

Generate a Kasami sequence

## Syntax

$Y = \text{step}(H)$

$Y = \text{step}(H, \text{RESET})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj})$  and  $y = \text{obj}()$  perform equivalent operations.

---

$Y = \text{step}(H)$  outputs a frame of the Kasami sequence in column vector  $Y$ . Specify the frame length with the `SamplesPerFrame` property. The Kasami sequence has a period of  $N = 2^n - 1$ , where  $n$  is the degree of the generator polynomial that you specify in the `Polynomial` property.

$Y = \text{step}(H, \text{RESET})$  uses `RESET` as the reset signal when you set the `ResetInputPort` property to `true`. The data type of the `RESET` input must be double precision or logical. `RESET` can be a scalar value or a column vector with a length equal to the number of samples per frame that you specify in the `SamplesPerFrame` property. When the `RESET` input is a non-zero scalar, the object resets to the initial conditions that you specify in the `InitialConditions` property. It then generates a new output frame. A column vector `RESET` input allows multiple resets within an output frame. A non-zero value at the  $i$ -th element of the vector causes a reset at the  $i$ -th output sample time.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.LDPCDecoder

**Package:** comm

Decode binary low-density parity-check (LDPC) code

### Description

The `comm.LDPCDecoder` System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 4-1152.

To decode an LDPC-encoded signal:

- 1 Create the `comm.LDPCDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

### Creation

### Syntax

```
ldpcdecoder = comm.LDPCDecoder  
ldpcdecoder = comm.LDPCDecoder(parity)  
ldpcdecoder = comm.LDPCDecoder( ___, Name, Value)
```

### Description

`ldpcdecoder = comm.LDPCDecoder` creates a binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.

`ldpcdecoder = comm.LDPCDecoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates an LDPC decoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`ldpcdecoder = comm.LDPCDecoder( ___, Name, Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCDecoder('DecisionMethod','Soft decision')` configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type `double`. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects* (MATLAB).

### ParityCheckMatrix — Parity-check matrix

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse  $(N - K)$ -by- $N$  binary-valued matrix.  $N$  is the length of the received signal and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ . The last  $(N - K)$  columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf(2)`.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R,'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of

`dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

### **OutputValue — Output value format**

`'Information part'` (default) | `'Whole codeword'`

Output value format, specified as one of these values:

- `'Information part'` — The object outputs a  $K$ -by-1 column vector containing only the information-part of the received log-likelihood ratio vector.  $K$  is the length of the uncoded message.
- `'Whole codeword'` — The object outputs an  $N$ -by-1 column vector containing the whole log-likelihood ratio vector.  $N$  is the length of the received signal.

$N$  and  $K$  must align with the dimension of the  $(N-K)$ -by- $K$  parity-check matrix.

Data Types: `char`

### **DecisionMethod — Decision method**

`'Hard decision'` (default) | `'Soft decision'`

Decision method used for decoding, specified as one of these values:

- `'Hard decision'` — The object outputs decoded data of data type `logical`.
- `'Soft decision'` — The object outputs log-likelihood ratios of data type `double`.

Data Types: `char`

### **IterationTerminationCondition — Condition for iteration termination**

`'Maximum iteration count'` (default) | `'Parity check satisfied'`

Condition for iteration termination, specified as one of these values:

- `'Maximum iteration count'` — Decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.
- `'Parity check satisfied'` — Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.

Data Types: `char`

**MaximumIterationCount — Maximum number of decoding iterations**

50 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: double

**NumIterationsOutputPort — Output number of iterations executed**

false (default) | true

Output number of iterations performed, specified as `false` or `true`. To output the number of iterations executed, set this property to `true`.

Data Types: logical

**FinalParityChecksOutputPort — Output final parity checks**

false (default) | true

Output final parity checks, specified as `false` or `true`. To output the final calculated parity checks, set this property to `true`.

Data Types: logical

## Usage

## Syntax

```
y = ldpcdecoder(x)
[y,numiter] = ldpcdecoder(x)
[y,parity] = ldpcdecoder(x)
[y,numiter,parity] = ldpcdecoder(x)
```

## Description

`y = ldpcdecoder(x)` decodes input data using an LDPC code based on the default parity-check matrix.

`[y,numiter] = ldpcdecoder(x)` returns the decoded data, `y`, and number of iterations performed, `numiter`. To use this syntax, set the `NumIterationsOutputPort` property to `true`.

`[y,parity] = ldpcdecoder(x)` returns the decoded data, `y`, and final parity checks, `parity`. To use this syntax, set the `FinalParityChecksOutputPort` property to `true`.

`[y,numiter,parity] = ldpcdecoder(x)` returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the `NumIterationsOutputPort` and `FinalParityChecksOutputPort` properties to `true`.

### Input Arguments

#### **x — Log-likelihood ratios**

column vector

Log-likelihood ratios, specified as an  $N$ -by-1 column vector containing the soft-decision output from demodulation.  $N$  is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be 0 if the log-likelihood ratio is positive. The first  $K$  elements correspond to the information-part of the input message.

Data Types: `double`

### Output Arguments

#### **y — Decoded data**

column vector

Decoded data, returned as a column vector. The `DecisionMethod` property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the `OutputValue` property is set to `'Information part'`, the output includes only the information-part of the received log-likelihood ratio vector.
- If the `OutputValue` property is set to `'Whole codeword'`, the output includes the whole log-likelihood ratio vector.

Data Types: `double` | `logical`

#### **numiter — Number of executed decoding iterations**

positive integer

Number of executed decoding iterations, returned as a positive integer.

**Dependencies**

To enable this output, set the `NumIterationsOutputPort` property to `true`.

**parity — Final parity checks**

column vector

Final parity checks after decoding the input LDPC code, returned as an  $(N-K)$ -by-1 column vector.  $N$  is the number of bits in the LDPC codeword before modulation.  $K$  is the length of the uncoded message.

**Dependencies**

To enable this output, set the `FinalParityChecksOutputPort` property to `true`.

**Object Functions**

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

**Common to All System Objects**

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

**Examples****LDPC Encode and Decode QPSK-Modulated Signal**

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals.

Define simulation variables. Create `System` objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```

M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPC Encoder;
ldpcDecoder = comm.LDPC Decoder;
pskMod = comm.PSK Modulator(M, 'BitInput', true);
pskDemod = comm.PSK Demodulator(M, 'BitOutput', true, ...
    'DecisionMethod', 'Approximate log-likelihood ratio');
pskuDemod = comm.PSK Demodulator(M, 'BitOutput', true, ...
    'DecisionMethod', 'Hard decision');
errRate = zeros(1, length(snr));
uncErrRate = zeros(1, length(snr));

```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```

for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
        data = logical(randi([0 1], 32400, 1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig, snr(ii), 'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data, demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig, snr(ii), 'measured');
        demodSig = pskDemod(rxSig);
        rxBits = ldpcDecoder(demodSig);
        numErr = biterr(data, rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end

```

Plot the error statistics for uncoded and LDPC-coded data.

```
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded', 'LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')
```

## Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

## Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager.

For transmitted LDPC-encoded codeword  $c = c_0, c_1, \dots, c_{n-1}$ , the input to the LDPC decoder is the log-likelihood ratio (LLR) value

$$L(c_i) = \log \left( \frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)} \right).$$

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left( \prod_{i' \in V_j \setminus i} \tanh \left( \frac{1}{2} L(q_{i'j}) \right) \right),$$

$$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \setminus j} L(r_{ji'}), \text{ initialized as } L(q_{ij}) = L(c_i) \text{ before the first iteration, and}$$

$$L(Q_i) = L(c_i) + \sum_{j' \in C_i} L(r_{ji'}).$$

At the end of each iteration,  $L(Q_i)$  contains the updated estimate of the LLR value for transmitted bit  $c_i$ . The value  $L(Q_i)$  is the soft-decision output for  $c_i$ . If  $L(Q_i) < 0$ , the hard-decision output for  $c_i$  is 1. Otherwise, the hard-decision output for  $c_i$  is 0.

If configured to stop when all parity checks are satisfied, the algorithm verifies the parity-check equation ( $Hc' = 0$ ) at the end of each iteration. When all parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets  $C_i \setminus j$  and  $V_j \setminus i$  are based on the parity-check matrix (PCM). Index sets  $C_i$  and  $V_j$  correspond to all nonzero elements in column  $i$  and row  $j$  of the PCM, respectively.

This figure highlights the computation of these index sets in a given PCM for  $i = 5$  and  $j = 3$ .

To avoid infinite numbers in the algorithm equations,  $\operatorname{atanh}(1)$  and  $\operatorname{atanh}(-1)$  are set to 19.07 and -19.07, respectively. Due to finite precision, MATLAB returns 1 for  $\tanh(19.07)$  and -1 for  $\tanh(-19.07)$ .

**Introduced in R2012a**

# comm.LDPCEncoder

**Package:** comm

Encode binary low-density parity-check (LDPC) code

## Description

The `comm.LDPCEncoder` System object applies LDPC coding to a binary input message. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

To encode a binary LDPC code:

- 1 Create the `comm.LDPCEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

### Syntax

```
ldpcencoder = comm.LDPCEncoder  
ldpcencoder = comm.LDPCEncoder(parity)  
ldpcencoder = comm.LDPCEncoder( ____,Name,Value)
```

### Description

`ldpcencoder = comm.LDPCEncoder` creates a binary LDPC encoder System object. This object performs LDPC encoding based on the default parity-check matrix.

`ldpcencoder = comm.LDPCEncoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates an LDPC encoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`ldpcencoder = comm.LDPCDecoder( ___, Name, Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCDecoder('ParityCheckMatrix', sparse(I(:,1), I(:,2), 1))` configures an LDPC encoder System object to encode data using the parity matrix `sparse(I(:,1), I(:,2), 1)`. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

### **ParityCheckMatrix — Parity-check matrix**

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse  $(N - K)$ -by- $N$  binary-valued matrix.  $N$  is the length of the output codeword vector, and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ . The last  $(N - K)$  columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2,  $gf(2)$ .

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1), I(:,2), 1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

---

### **Note**

- When the last  $(N - K)$  columns of the parity-check matrix form a triangular matrix, forward or backward substitution is performed to solve the parity-check equation.

- When the last  $(N - K)$  columns of the parity-check matrix do not form a triangular matrix, a matrix inversion is performed to solve the parity-check equation. If a large matrix needs to be inverted, initializations or updates take more time.
- 

Example: `dvbs2ldpc(R, 'indices')` configures the index matrix for the DVB-S.2 standard, where  $R$  is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

## Usage

## Syntax

```
codeword = ldpcencoder(message)
```

## Description

`codeword = ldpcencoder(message)` codes the input message using an LDPC code based on a parity-check matrix. The LDPC codeword output is a solution to the parity-check equation.

## Input Arguments

### **message** — Input message

binary column vector

Input message, specified as a  $K$ -by-1 column vector containing binary-valued elements.  $K$  is the length of the uncoded message.

Data Types: `double` | `logical`

### Output Arguments

#### **codeword — LDPC codeword**

column vector

LDPC codeword, returned as an  $N$ -by-1 column vector.  $N$  is the number of bits in the LDPC codeword. The output signal inherits its data type from the input signal. The LDPC codeword output is a solution to the parity-check equation. The input message comprises the first  $K$  bits of the LDPC codeword output, and the parity check comprises the remaining  $(N - K)$  bits.

Data Types: `double` | `logical`

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

### Examples

#### **LDPC Encode and Decode QPSK-Modulated Signal**

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```

M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCDecoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));

```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```

for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = ldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end

```

Plot the error statistics for uncoded and LDPC-coded data.

```
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded', 'LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')
```

# comm.LTEMIMOChannel

**Package:** comm

(To be removed) Filter input signal through LTE MIMO multipath fading channel

---

**Note** `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

---

## Description

The `comm.LTEMIMOChannel` System object filters an input signal through an LTE multiple-input multiple-output (MIMO) multipath fading channel.

A specialization of the `comm.MIMOChannel` System object, the `comm.LTEMIMOChannel` System objects offers pre-set configurations for use with LTE link level simulations. In addition to the `comm.MIMOChannel` System object, the `comm.LTEMIMOChannel` System object also corrects the correlation matrix to be positive semi-definite, after rounding to 4-digit precision. This System object models Rayleigh fading for each of its links.

To filter an input signal using an LTE MIMO multipath fading channel:

- 1 Define and set up your LTE MIMO multipath fading channel object. See “Construction” on page 4-1163.
- 2 Call `step` to filter the input signal using an LTE MIMO multipath fading channel according to the properties of `comm.LTEMIMOChannel`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.LTEMIMOChannel` creates a 3GPP Long Term Evolution (LTE) Release 10 specified multiple-input multiple-output (MIMO) multipath fading channel System object, `H`. This object filters a real or complex input signal through the multipath LTE MIMO channel to obtain the channel impaired signal.

`H = comm.LTEMIMOChannel(Name, Value)` creates an LTE MIMO multipath fading channel object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### SampleRate

Input signal sample rate (Hertz)

Specify the sample rate of the input signal in hertz as a double-precision, real, positive scalar. The default value of this property is 30.72 MHz, as defined in the LTE specification.

### Profile

Channel propagation profile

Specify the propagation conditions of the LTE multipath fading channel as one of EPA 5Hz | EVA 5Hz | EVA 70Hz | ETU 70Hz | ETU 300Hz, which are supported in the LTE specification Release 10. The default value of this property is EPA 5Hz.

This property defines the delay profile of the channel to be one of EPA, EVA, and ETU. This property also defines the maximum Doppler shift of the channel to be 5 Hz, 70 Hz, or 300 Hz. The Doppler spectrum always has a Jakes shape in the LTE specification. The EPA profile has seven paths. The EVA and ETU profiles have nine paths.

The following tables list the delay and relative power per path associated with each profile.

**Extended Pedestrian A Model (EPA)**

<b>Excess tap delay [ns]</b>	<b>Relative power [db]</b>
0	0.0
30	-1.0
70	-2.0
90	-3.0
110	-8.0
190	-17.2
410	-20.8

**Extended Vehicular A Model (EVA)**

<b>Excess tap delay [ns]</b>	<b>Relative power [db]</b>
0	0.0
30	-1.5
150	-1.4
310	-3.6
370	-0.6
710	-9.1
1090	-7.0
1730	-12.0
2510	-16.9

**Extended Typical Urban Model (ETU)**

<b>Excess tap delay [ns]</b>	<b>Relative power [db]</b>
0	-1.0
50	-1.0
120	-1.0
200	0.0
230	0.0

Excess tap delay [ns]	Relative power [db]
500	0.0
1600	-3.0
2300	-5.0
5000	-7.0

### AntennaConfiguration

Antenna configuration

Specify the antenna configuration of the LTE MIMO channel as one of 1x2 | 2x2 | 4x2 | 4x4. These configurations are supported in the LTE specification Release 10. The default value of this property is 2x2.

The property value is in the format of  $N_t$ -by- $N_r$ .  $N_t$  represents the number of transmit antennas and  $N_r$  represents the number of receive antennas.

### CorrelationLevel

Spatial correlation strength

Specify the spatial correlation strength of the LTE MIMO channel as one of Low | Medium | High. The default value of this property is Low. When you set this property to Low, the MIMO channel is spatially uncorrelated.

The transmit and receive spatial correlation matrices are defined from this property according to the LTE specification Release 10. See the Algorithms section for more information.

### AntennaSelection

Antenna selection

Specify the antenna selection scheme as one of Off | Tx | Rx | Tx and Rx, where Tx represents transmit antennas and Rx represents receive antennas. When you select Tx and/or Rx, additional input(s) are required to specify which antennas are selected for signal transmission. The default value of this property is Off.

### RandomStream

Source of random number stream

Specify the source of random number stream as one of `Global stream | mt19937ar` with `seed`. The default value of this property is `Global stream`. When you set this property to `Global stream`, the current global random number stream is used for normally distributed random number generation. In this case, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar` with `seed`, the object uses the `mt19937ar` algorithm for normally distributed random number generation. In this case, the `reset` method resets the filters and reinitializes the random number stream to the value of the `Seed` property.

### **Seed**

Initial seed of `mt19937ar` random number stream

Specify the initial seed of an `mt19937ar` random number generator algorithm as a double-precision, real, nonnegative integer scalar. The default value of this property is `73`. This property applies when you set the `RandomStream` property to `mt19937ar` with `seed`. The `Seed` reinitializes the `mt19937ar` random number stream in the `reset` method.

### **NormalizePathGains**

Normalize path gains (logical)

Set this property to `true` to normalize the fading processes so that the total power of the path gains, averaged over time, is  $0$  dB. The default value of this property is `true`. When you set this property to `false`, there is no normalization for path gains.

### **NormalizeChannelOutputs**

Normalize channel outputs (logical)

Set this property to `true` to normalize the channel outputs by the number of receive antennas. The default value of this property is `true`. When you set this property to `false`, there is no normalization for channel outputs.

### **PathGainsOutputPort**

Enable path gain output (logical)

Set this property to `true` to output the channel path gains of the underlying fading process. The default value of this property is `false`.

## Methods

reset (To be removed) Reset states of the LTEMIMOChannel object

step (To be removed) Filter input signal through LTE MIMO multipath fading channel

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Configure MIMO Channel Object Using LTE MIMO Channel Object

Configure an equivalent MIMOChannel System Object using the LTEMIMOChannel System Object. Then, verify that the channel output and the path gain output from the two objects are the same.

Create a PSK Modulator System object™ to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],2e3,1));
```

Split modulated data into two spatial streams.

```
channelInput = reshape(modData,[2 1e3]).';
```

Create an LTEMIMOChannel System object with a 2-by-2 antenna configuration and a medium correlation level.

```
lteChan = comm.LTEMIMOChannel(...
    'Profile',          'EVA 5Hz',...
    'AntennaConfiguration', '2x2',...
    'CorrelationLevel',  'Medium',...
    'AntennaSelection',  'Off',...
    'RandomStream',     'mt19937ar with seed',...
    'Seed',             99,...
    'PathGainsOutputPort', true);
```

Warning: COMM.LTEMIMOCHANNEL will be removed in a future release. Use COMM.MIMOCHANNEL

Filter the modulated data using the LTEMIMOChannel System object, lteChan.

```
[LTEChanOut,LTEPathGains] = lteChan(channelInput);
```

Create an equivalent MIMOChannel System object, `mimoChannel`, using the properties of the LTEMIMOChannel System object, `lteChan`.

The `KFactor`, `DirectPathDopplerShift` and `DirectPathInitialPhase` properties only exist for the MIMOChannel System object. All other MIMOChannel System object properties also exist for the LTEMIMOChannel System object; however, some properties are hidden and read-only.

```
mimoChannel = comm.MIMOChannel( ...  
    'SampleRate',lteChan.SampleRate, ...  
    'PathDelays',lteChan.PathDelays, ...  
    'AveragePathGains',lteChan.AveragePathGains, ...  
    'NormalizePathGains',lteChan.NormalizePathGains, ...  
    'FadingDistribution',lteChan.FadingDistribution, ...  
    'MaximumDopplerShift',lteChan.MaximumDopplerShift, ...  
    'DopplerSpectrum',lteChan.DopplerSpectrum, ...  
    'SpatialCorrelationSpecification', ...  
        lteChan.SpatialCorrelationSpecification, ...  
    'SpatialCorrelationMatrix',lteChan.SpatialCorrelationMatrix, ...  
    'AntennaSelection',lteChan.AntennaSelection, ...  
    'NormalizeChannelOutputs',lteChan.NormalizeChannelOutputs, ...  
    'RandomStream',lteChan.RandomStream, ...  
    'Seed',lteChan.Seed, ...  
    'PathGainsOutputPort',lteChan.PathGainsOutputPort);
```

Filter the modulated data using the equivalent `mimoChannel` object.

```
[MIMOChanOut, MIMOPathGains] = mimoChannel(channelInput);
```

Verify that the channel output and the path gain output from the two objects are the same.

```
sameChOutput = isequal(LTEChanOut,MIMOChanOut)  
  
sameChOutput = logical  
    1  
  
samePathGains = isequal(LTEPathGains,MIMOPathGains)  
  
samePathGains = logical  
    1
```

You can repeat the preceding process with `AntennaConfiguration` set to 4x2 or 4x4 and `CorrelationLevel` set to Medium or High for `lteChan`.

## Algorithms

This System object is a specialized implementation of the `comm.MIMOChannel` System object. For additional algorithm information, see the `comm.MIMOChannel` System object help page.

### Spatial Correlation Matrices

The following table defines the transmitter eNodeB correlation matrix.

	One Antenna	Two Antennas	Four Antennas
eNodeB Correlation	$R_{eNB} = 1$	$R_{eNB} = \begin{pmatrix} 1 & \alpha \\ \alpha^* & 1 \end{pmatrix}$	$R_{eNB} = \begin{pmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{pmatrix}$

The following table defines the receiver UE correlation matrix.

	One Antenna	Two Antennas	Four Antennas
UE Correlation	$R_{UE} = 1$	$R_{UE} = \begin{pmatrix} 1 & \beta \\ \beta^* & 1 \end{pmatrix}$	$R_{UE} =$ $\begin{pmatrix} 1 & \beta^{1/9} & \beta^{4/9} & \beta \\ \beta^{1/9*} & 1 & \beta^{1/9} & \beta^{4/9} \\ \beta^{4/9*} & \beta^{1/9*} & 1 & \beta^{1/9} \\ \beta^* & \beta^{4/9*} & \beta^{1/9*} & 1 \end{pmatrix}$

The following table describes the  $R_{\text{spat}}$  channel spatial correlation matrix between the transmitter and receiver antennas.

Tx-by-Rx Configuration	Correlation Matrix
1-by-2	$R_{\text{spat}} = R_{UE} = \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$
2-by-2	$R_{\text{spat}} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha \\ \alpha^* & 1 \end{bmatrix} \otimes \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$ $= \begin{bmatrix} 1 & \beta & \alpha & \alpha\beta \\ \beta^* & 1 & \alpha\beta^* & \alpha \\ \alpha^* & \alpha^*\beta & 1 & \beta \\ \alpha^*\beta^* & \alpha^* & \beta^* & 1 \end{bmatrix}$

Tx-by-Rx Configuration	Correlation Matrix
4-by-2	$R_{spat} = R_{eNB} \otimes R_{UE}$ $= \begin{bmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{bmatrix} \otimes \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$
4-by-4	$R_{spat} = R_{eNB} \otimes R_{UE}$ $= \begin{bmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{bmatrix} \otimes \begin{bmatrix} 1 & \beta^{1/9} & \beta^{4/9} & \beta \\ \beta^{1/9*} & 1 & \beta^{1/9} & \beta^{4/9} \\ \beta^{4/9*} & \beta^{1/9*} & 1 & \beta^{1/9} \\ \beta^* & \beta^{4/9*} & \beta^{1/9*} & 1 \end{bmatrix}$

### Spatial Correlation Correction

Low Correlation		Medium Correlation		High Correlation	
$\alpha$	$\beta$	$\alpha$	$\beta$	$\alpha$	$\beta$

Low Correlation		Medium Correlation		High Correlation	
0	0	0.3	0.9	0.9	0.9

To insure the correlation matrix is positive semi-definite after round-off to 4 digit precision, this System object uses the following equation:

$$R_{high} = [R_{spatial} + aI_n]/(1 + a)$$

Where

$\alpha$  represents the scaling factor such that the smallest value is used to obtain a positive semi-definite result.

For the 4-by-2 high correlation case,  $\alpha=0.00010$ .

For the 4-by-4 high correlation case,  $\alpha=0.00012$ .

The object uses the same method to adjust the 4-by-4 medium correlation matrix to insure the correlation matrix is positive semi-definite after rounding to 4 digit precision with  $\alpha = 0.00012$ .

### **See Also**

comm.MIMOChannel

**Introduced in R2012a**

# reset

**System object:** `comm.LTEMIMOChannel`

**Package:** `comm`

(To be removed) Reset states of the `LTEMIMOChannel` object

---

**Note** `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

---

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the `LTEMIMOChannel` object, `H`.

If you set the `RandomStream` property of `H` to `Global` stream, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar` with `seed`, the `reset` method not only resets the filters but also reinitializes the random number stream to the value of the `Seed` property.

## step

**System object:** `comm.LTEMIMOChannel`

**Package:** `comm`

(To be removed) Filter input signal through LTE MIMO multipath fading channel

---

**Note** `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

---

## Syntax

`Y = step(H,X)`

`[Y,PATHGAINS] = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` filters input signal `X` through an LTE MIMO multipath fading channel and returns the result in `Y`. The input `X` can be a double- or single-precision data type scalar, vector, or 2-D matrix with real or complex values. `X` is of size  $N_s$ -by- $N_t$ .  $N_s$  represents the number of samples and  $N_t$  represents the number of transmit antennas that must match the `AntennaConfiguration` property setting of `H`. `Y` is the output signal of size  $N_s$ -by- $N_r$ .  $N_r$  represents the number of receive antennas that is specified by the `AntennaConfiguration` property of `H`. `Y` contains complex values with same precision as input signal.

`[Y,PATHGAINS] = step(H,X)` returns the LTE MIMO channel path gains of the underlying fading process in `PATHGAINS`. This applies when you set the `PathGainsOutputPort` property to `true`. `PATHGAINS` is of size  $N_s$ -by- $N_p$ -by- $N_t$ -by- $N_r$ .  $N_p$

represents the number of discrete paths of the channel implicitly defined by the Profile property of H. PATHGAINS contains complex values with same precision as input signal.

---

**Note** obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

# comm.MatrixDeinterleaver

**Package:** comm

(To be removed) Deinterleave input symbols using permutation matrix

## Compatibility

comm.MatrixDeinterleaver will be removed in a future release. Use `matdeintrlv` instead. For more information, see “Compatibility Considerations” on page 4-1179.

## Description

The `MatrixDeinterleaver` object performs block deinterleaving by filling a matrix with the input symbols column by column and then sending the matrix contents to the output port row by row. The `number of rows` and `number of columns` properties set the dimensions of the matrix that the object uses internally for computations.

To deinterleave input symbols using a permutation vector:

- 1 Define and set up your matrix deinterleaver object. See “Construction” on page 4-1178.
- 2 Call `step` to deinterleave the input signal according to the properties of `comm.MatrixDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.MatrixDeinterleaver` creates a matrix deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the matrix interleaver object.

`H = comm.MatrixDeinterleaver(Name, Value)` creates a matrix deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.MatrixDeinterleaver(N, M)` creates a matrix deinterleaver object, `H`. This object has the `NumRows` property set to `N`, the `NumColumns` property set to `M`.

## Properties

### NumRows

Number of rows of permutation matrix

Specify the number of permutation matrix rows as a scalar, positive integer. The default is 3.

### NumColumns

Number of columns of permutation matrix

Specify the number of permutation matrix columns as a scalar, positive integer. The default is 4.

## Methods

`step` (To be removed) Deinterleave input symbols using permutation matrix

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Matrix Interleaving and Deinterleaving

Create matrix interleaver and deinterleaver objects.

```
interleaver = comm.MatrixInterleaver('NumRows',2,'NumColumns', 5);
```

Warning: COMM.MATRIXINTERLEAVER will be removed in a future release. Use MATINTRLV inst

```
deinterleaver = comm.MatrixDeinterleaver('NumRows',2,'NumColumns', 5);
```

Warning: COMM.MATRIXDEINTERLEAVER will be removed in a future release. Use MATDEINTRLV

Generate random data, interleave, and then deinterleave the data.

```
data = randi(7,10,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical
     1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Deinterleaver block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

### **comm.MatrixDeinterleaver will be removed**

*Not recommended starting in R2019b*

`comm.MatrixDeinterleaver` will be removed in a future release. Use `matdeintrlv` instead.

## Extended Capabilities

### C/C++ Code Generation

# comm.MatrixInterleaver

**Package:** comm

(To be removed) Permute input symbols using permutation matrix

## Compatibility

comm.MatrixInterleaver will be removed in a future release. Use `matintrlv` instead. For more information, see “Compatibility Considerations” on page 4-1185.

## Description

The `MatrixInterleaver` object performs block interleaving by filling a matrix with the input symbols row by row and then outputs the matrix contents column-by-column.

To perform block interleaving using a permutation matrix:

- 1 Define and set up your matrix interleaver object. See “Construction” on page 4-1183.
- 2 Call `step` to interleave the input symbols according to the properties of `comm.MatrixInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.MatrixInterleaver` creates a matrix interleaver System object, `H`. This object permutes the input by filling a permutation matrix with the input symbols row by row. The object then outputs the matrix contents column by column.

`H = comm.MatrixInterleaver(Name, Value)` creates a matrix interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.MatrixInterleaver(N, M)` creates a matrix interleaver object, `H`. This object has the `NumRows` property set to `N`, the `NumColumns` property set to `M`.

## Properties

### **NumRows**

Number of rows of permutation matrix

Specify the number of permutation matrix rows as a scalar, positive integer. The default is 3.

# comm.MatrixHelicalScanDeinterleaver

**Package:** comm

(To be removed) Deinterleave input symbols by filling a matrix along diagonals

## Compatibility

comm.MatrixHelicalScanDeinterleaver will be removed in a future release. Use `helscandeintrlv` instead. For more information, see “Compatibility Considerations” on page 4-1192.

## Description

The `MatrixHelicalScanDeinterleaver` object performs block deinterleaving by filling a matrix with the input symbols helically and then outputs the matrix contents row by row. The number of rows and number of columns properties represent the dimensions of the matrix that the object uses internally for computations.

To deinterleave the input symbols by filling a matrix with the input symbols helically and then outputting the matrix contents row-by-row:

- 1 Define and set up your matrix helical scan deinterleaver object. See “Construction” on page 4-1190.
- 2 Call `step` to deinterleave the input signal according to the properties of `comm.MatrixHelicalScanDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.MatrixHelicalScanDeinterleaver` creates a matrix helical scan deinterleaver object, `H`. This object restores the original ordering of a sequence that was interleaved using the matrix helical scan interleaver System object.

`H = comm.MatrixHelicalScanDeinterleaver(Name,Value)` creates a matrix helical scan deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### **NumRows**

Number of rows of permutation matrix

Specify the number of rows in the permutation matrix as a scalar, positive integer. The default is 64.

### **NumColumns**

Number of columns of permutation matrix

Specify the number of columns in the permutation matrix as a scalar, positive integer. The default is 64.

### **StepSize**

Slope of diagonals

Specify slope as a scalar integer between 0 and the value you specify in the `NumRows` on page 4-0 property. The default is 1. The slope value indicates the amount by which the row index increases as the column index increases by 1. When you set the value of this property to 0, the object does not interleave and the output matches the input.

## Methods

step (To be removed) Deinterleave input symbols by filling a matrix along diagonals

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Matrix Helical Scan Interleaving and Deinterleaving

Create matrix helical scan interleaver and deinterleaver objects.

```
interleaver = comm.MatrixHelicalScanInterleaver('NumRows',4,'NumColumns', 4);
```

Warning: COMM.MATRIXHELICALSCANINTERLEAVER will be removed in a future release. Use HELICALSCANINTERLEAVER instead.

```
deinterleaver = comm.MatrixHelicalScanDeinterleaver('NumRows',4,'NumColumns',4);
```

Warning: COMM.MATRIXHELICALSCANDEINTERLEAVER will be removed in a future release. Use HELICALSCANDEINTERLEAVER instead.

Generate random symbols. Pass the data through the interleaver, and then pass that data through the deinterleaver.

```
data = randi(7,16,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intData deIntData]
```

```
ans = 16×3
```

```

6     6     6
7     1     7
1     2     1
7     1     7
5     5     5
1     7     1
```

```
2     6     2
4     7     4
7     7     7
7     4     7
:
```

Confirm that the original and deinterleaved sequences are identical.

```
isequal(data,deIntData)
```

```
ans = logical
      1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Helical Scan Deinterleaver block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

### **comm.MatrixHelicalScanDeinterleaver will be removed**

*Not recommended starting in R2019b*

comm.MatrixHelicalScanDeinterleaver will be removed in a future release. Use `helscandeintrlv` instead.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

(To be removed) Deinterleave input symbols by filling a matrix along diagonals

## Compatibility

`step` will be removed in a future release. Use `helscandeintrlv` instead.

## Syntax

`Y = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` restores the original ordering of the sequence, `X`. The object fills a permutation matrix with the input symbols in a helical fashion and output the contents row by row, and returns `Y`. The input `X` must be a `NumRows × NumColumns` long column vector and the data type can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.MatrixHelicalScanInterleaver

**Package:** comm

(To be removed) Permute input symbols by selecting matrix elements along diagonals

### Compatibility

comm.MatrixHelicalScanInterleaver will be removed in a future release. Use `helscanintrlv` instead. For more information, see “Compatibility Considerations” on page 4-1199.

### Description

The `MatrixHelicalScanInterleaver` object performs block interleaving by filling a matrix with the input symbols row by row and then outputs the matrix contents helically. The number of rows and number of columns properties are the dimensions of the matrix that the object uses internally for computations.

To interleave the input signal by filling a matrix row-by-row with the input symbols and then outputting the matrix contents helically:

- 1 Define and set up your matrix helical scan interleaver object. See “Construction” on page 4-1197.
- 2 Call `step` to interleave the input signal according to the properties of `comm.MatrixHelicalScanInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.MatrixHelicalScanInterleaver` creates a matrix helical scan interleaver object, `H`. This object permutes the input by filling a permutation matrix with the input symbols row by row and then outputs the matrix contents helically.

`H = comm.MatrixHelicalScanInterleaver(Name, Value)` creates a matrix helical scan interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### NumRows

Number of rows of permutation matrix

Specify the number of rows in the permutation matrix as a scalar, positive integer. The default is 64.

### NumColumns

Number of columns of permutation matrix

Specify the number of columns in the permutation matrix as a scalar, positive integer. The default is 64.

### StepSize

Slope of diagonals

Specify slope as a scalar integer between 0 and the value you specify in the `NumRows` on page 4-0 property. The slope value represents the amount by which the row index increases as the column index increases by 1. When you set the value of this property to 0, the object does not interleave and the output matches the input. The default is 1.

## Methods

step (To be removed) Permute input symbols by selecting matrix elements along diagonals

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Matrix Helical Scan Interleaving and Deinterleaving

Create matrix helical scan interleaver and deinterleaver objects.

```
interleaver = comm.MatrixHelicalScanInterleaver('NumRows',4,'NumColumns',4);
```

Warning: COMM.MATRIXHELICALSCANINTERLEAVER will be removed in a future release. Use HELICALSCANINTERLEAVER instead.

```
deinterleaver = comm.MatrixHelicalScanDeinterleaver('NumRows',4,'NumColumns',4);
```

Warning: COMM.MATRIXHELICALSCANDEINTERLEAVER will be removed in a future release. Use HELICALSCANDEINTERLEAVER instead.

Generate random symbols. Pass the data through the interleaver, and then pass that data through the deinterleaver.

```
data = randi(7,16,1);  
intData = interleaver(data);  
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intData deIntData]
```

```
ans = 16×3
```

```
6     6     6  
7     1     7  
1     2     1  
7     1     7  
5     5     5
```

```

1     7     1
2     6     2
4     7     4
7     7     7
7     4     7
:

```

Confirm that the original and deinterleaved sequences are identical.

```
isequal(data,deIntData)
```

```
ans = logical
      1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Helical Scan Deinterleaver block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

### **comm.MatrixHelicalScanInterleaver will be removed**

*Not recommended starting in R2019b*

comm.MatrixHelicalScanInterleaver will be removed in a future release. Use `helscanintrlv` instead.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2012a**

---

## step

**System object:** comm.MatrixHelicalScanInterleaver

**Package:** comm

(To be removed) Permute input symbols by selecting matrix elements along diagonals

## Compatibility

step will be removed in a future release. Use helscanintrlv instead.

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  permutes input sequence,  $X$ , and returns interleaved sequence,  $Y$ . The input  $X$  must be a  $\text{NumRows} \times \text{NumColumns}$  long column vector and the data type can be numeric, logical, or fixed-point (fi objects).  $Y$  has the same data type as  $X$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.MemorylessNonlinearity

**Package:** comm

Apply memoryless nonlinearity to input signal

## Description

The `MemorylessNonlinearity` object applies a memoryless nonlinearity to a complex, baseband signal. You can use the object to model radio frequency (RF) impairments to a signal at the receiver.

To apply memoryless nonlinearity to the input signal:

- 1 Define and set up your memoryless nonlinearity object. See “Construction” on page 4-1203.
- 2 Call `step` to apply memoryless nonlinearity according to the properties of `comm.MemorylessNonlinearity`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.MemorylessNonlinearity` creates a memoryless nonlinearity System object, `H`. This object models receiver radio frequency (RF) impairments.

`H = comm.MemorylessNonlinearity(Name,Value)` creates a memoryless nonlinearity object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### Method

Method used to model nonlinearity

Specify the nonlinearity method as one of `Cubic polynomial` | `Hyperbolic tangent` | `Saleh model` | `Ghorbani model` | `Rapp model` | `'Look up table'`. The default is `Cubic polynomial`. This property is non-tunable.

### InputScaling

Scale factor applied to input signal

Specify the scale factor in decibels. The object applies this factor to the input signal as a real scalar value of double- or single-precision data type. The default is 0. This property applies when you set the `Method` on page 4-0 property to `Saleh model` or `Ghorbani model`. This property is tunable.

### LinearGain

Linear gain applied to output signal

Specify the linear gain (in decibels) that the object applies to the output signal as a real scalar value of double- or single-precision data type. The default is 0. This property applies when you set the `Method` on page 4-0 property to `Cubic polynomial`, `Hyperbolic tangent`, or `Rapp model`. This property is tunable.

### IIP3

Third-order input intercept point

Specify the third-order input intercept point (in decibels relative to a milliwatt) as a real scalar value of double- or single-precision data type. The default is 30. This property applies when you set the `Method` on page 4-0 property to `Cubic polynomial` or `Hyperbolic tangent`. This property is tunable.

### AMPMConversion

AM/PM conversion factor

Specify the AM/PM conversion factor (in degrees per decibel) as a real scalar value of double- or single-precision data type. The default is 10. This property applies when you

set the `Method` on page 4-0 property to `Cubic polynomial` or `Hyperbolic tangent`. This property is tunable.

### **AMAMPParameters**

AM/AM conversion parameters

Specify the AM/AM conversion parameters that the object uses to compute the amplitude gain for an input signal as a real vector of double- or single-precision data type. The default is [2.1587 1.1517] for the Saleh model and [8.1081 1.5413 6.5202 -0.0718] for the Ghorbani model.

This property applies when you set the `Method` on page 4-0 property to `Saleh model` or `Ghorbani model`.

When you set the `Method` property to `Saleh model`, this property is a two-element vector that specifies alpha and beta values. Otherwise, this property is a four-element vector that specifies x1, x2, x3, and x4 values. This property is tunable.

### **AMPMPParameters**

AM/PM conversion parameters

Specify the AM/PM conversion parameters used to compute the phase change for an input signal as a real vector of double- or single-precision data type. The default is [4.0033 9.1040] for the Saleh model and [4.6645 2.0965 10.88 -0.003] for the Ghorbani model.

This property applies when you set the `Method` on page 4-0 property to `Saleh model` or `Ghorbani model`.

When you set the `Method` property to `Saleh model`, this property is a two-element vector that specifies alpha and beta values. Otherwise, this property is a four-element vector that specifies y1, y2, y3, and y4 values. This property is tunable.

### **PowerLowerLimit**

Lower input power limit

Minimum input power in decibels relative to a milliwatt, specified as a scalar, for which AM/PM conversion scales linearly with input power value. The default is 10. Below this value, the phase shift resulting from AM/PM conversion is zero. This property applies

when you set the `Method` on page 4-0 property to `Cubic polynomial` or `Hyperbolic tangent`. This property is tunable.

### **PowerUpperLimit**

Upper input power limit

Specify the maximum input power (in decibels relative to a milliwatt) for which AM/PM conversion scales linearly with input power value. The default is `inf`. Above this value, the phase shift resulting from AM/PM conversion is constant. You must set the `PowerUpperLimit` on page 4-0 property to a real scalar value, which is greater than the `PowerLowerLimit` on page 4-0 property and of double- or single-precision data type. This property applies when you set the `Method` on page 4-0 property to `Cubic polynomial` or `Hyperbolic tangent`. This property is tunable.

### **OutputScaling**

Scale factor applied to output signal

Specify the scale factor (in decibels) that the object applies to the output signal as a real scalar value of double- or single-precision data type. The default is `0`. This property applies when you set the `Method` on page 4-0 property to `Saleh model` or `Ghorbani model`. This property is tunable.

### **Smoothness**

Smoothness factor

Specify the smoothness factor as a real scalar value of double- or single-precision data type. The default is `0.5`. This property applies when you set the `Method` on page 4-0 property to `Rapp model`. This property is tunable.

### **OutputSaturationLevel**

Output saturation level

Specify the output saturation level as a real scalar value of double- or single-precision data type. This property applies when you set the `Method` on page 4-0 property to `Rapp model`. The default is `1`. This property is tunable.

### **Table**

Amplifier characteristics lookup table

Amplifier characteristics lookup table, specified as a  $[P_{in}, P_{out}, \Phi]$ -by- $N$  matrix of measured power amplifier (PA) characteristics. The  $N$  rows of the matrix contain measured values of the PA input signal,  $P_{in}$ , The PA output signal,  $P_{out}$ , and the output phase shift,  $\Phi$ . The signal levels ( $P_{in}$  and  $P_{out}$ ) must be in dBm, and the phase shift ( $\Phi$ ) must be in degrees. This System object uses the measured PA characteristics defined by this property to compute the AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) nonlinear impairment characteristics. The System object distorts the input signal by the computed AM/AM (in dBm/dBm) and AM/PM (in deg/dBm). The default PA characteristics matrix is [-25, 5.16, -0.25; -20, 10.11, -0.47; -15, 15.11, -0.68; -10, 20.05, -0.89; -5, 24.79, -1.22; 0, 27.64, 5.59; 5, 28.49, 12.03]. This property applies when you set the Method property to 'Lookup table'. This property is tunable.

## Methods

step Apply memoryless nonlinearity to input signal

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Apply Saleh Model Nonlinearity to 16-QAM Signal

Generate 16-QAM modulated data with an average power of 10 mW and pass the data through a nonlinear power amplifier.

```
M = 16;
data = randi([0 M-1]', 1000, 1);
avgPow = 1e-2;
minD = avgPow*2/MinD(avgPow, M);
```

Create Memoryless Nonlinearity System object using the Saleh model.

```
saleh = comm.MemorylessNonlinearity('Method', 'Saleh model');
```

Generate modulated symbols and pass them through the nonlinearity model.

```
modData = (minD/2).*qammod(data,M);  
y = saleh(modData);
```

Plot the resultant scatter plot.

```
scatterplot(y)
```

```
function minD = avgPow2MinD(avgPow, M)  
% Average power to minimum distance  
nBits = log2(M);  
if (mod(nBits,2)==0)  
    % Square QAM  
    sf = (M - 1)/6;  
else  
    % Cross QAM
```

```

        if (nBits > 4)
            sf = ((31 * M / 32) - 1) / 6;
        else
            sf = ((5 * M / 4) - 1) / 6;
        end
    end
    minD = sqrt(avgPow/sf);
end

```

### Nonlinear Amplifier Gain Compression

Plot the gain compression of a nonlinear amplifier for a 16-QAM signal.

Specify the modulation order and samples per symbol parameters.

```

M = 16;
sps = 4;

```

To model a nonlinear amplifier, create a memoryless nonlinearity object having a 30 dB third order intercept point. Create a raised cosine transmit filter.

```

amplifier = comm.MemorylessNonlinearity('IIP3',30);

txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6, ...
    'OutputSamplesPerSymbol',sps, ...
    'Gain',sqrt(sps));

```

Specify the input power in dBm. Convert the input power to W and initialize the gain vector.

```

pindBm = -5:25;
pin = 10.^((pindBm-30)/10);
gain = zeros(length(pindBm),1);

```

Execute the main processing loop, which includes these steps:

- Generating random data symbols
- Modulating the data and adjusting the average power
- Filtering the modulated signal

- Amplifying the signal
- Measuring the gain

```
for k = 1:length(pin)
    data = randi([0 M-1],1000,1);
    modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin(k));
    filtSig = txfilter(modSig);
    ampSig = amplifier(filtSig);
    gain(k) = 10*log10(var(ampSig)/var(filtSig));
end
```

Plot the amplifier gain as a function of the input signal power.

```
arrayplot = dsp.ArrayPlot('PlotType','Line','XLabel','Power In (dBm)', ...
    'XOffset',-5,'YLimits',[-5 5]);
arrayplot(gain)
```

The 1 dB gain compression point occurs for an input power of 18.5 dBm. To increase the point at which a 1 dB compression is observed, increase the third order intercept point, `amplifier.IIP3`.

### Distort 16QAM Signal with Custom Power Amplifier Nonlinearities

Apply nonlinear power amplifier (PA) characteristics to a 16-QAM signal by setting the `Method` property to `Lookup table`.

Define parameters for the modulation order, samples per symbol, input power, and create random data.

```
M = 16; % Modulation order
sps = 4; % Samples per symbol
pindBm = -2; % Input power
pin = 10.^((pindBm-30)/10); % power in Watts
data = randi([0 M-1],1000,1);
refdata = 0:M-1;
refconst = qammod(refdata,M,'UnitAveragePower',true);
```

Create a memoryless nonlinearity System object, a transmit filter System object, and a constellation diagram System objects. The default lookup table values are used for the memoryless nonlinearity System object.

```
amplifier = comm.MemorylessNonlinearity('Method','Lookup table');
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6,'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
constellation = comm.ConstellationDiagram('SamplesPerSymbol',4,'ReferenceConstellation',
    'Title','Amplified/Distorted Signal');
```

Modulate the random data. Filter and apply the nonlinear amplifier characteristics to the modulation symbols.

```
modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin);
filtSig = txfilter(modSig);
ampSig = amplifier(filtSig);
```

Compute input and output signal levels and the phase shift.

```
poutdBm = (20*log10(abs(ampSig)))+30;
simulated_pindBm = (20*log10(abs(filtSig)))+30;
phase = angle(ampSig.*conj(filtSig))*180/pi;
```

Plot AM/AM characteristics, AM/PM characteristics, and the constellation results.

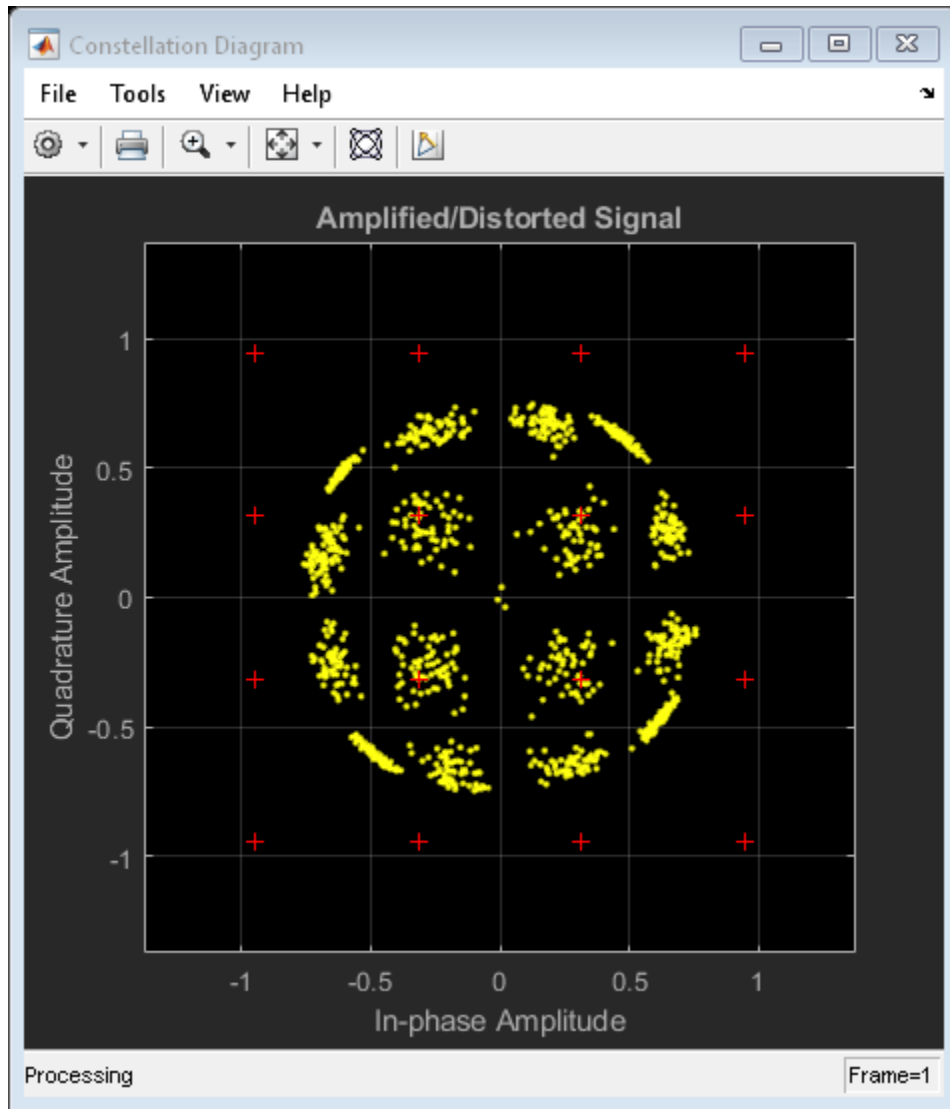

```
figure
set(gcf,'units','normalized','position',[.25 1/3 .5 1/3])
subplot(1,2,1)
plot(simulated_pindBm,poutdBm, '.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,2), '.', 'Markersize',15);
xlabel('Input Power (dBm)')
ylabel('Output Power (dBm)');
grid on;
title('AM/AM Characteristic');
Legend={'Simulated Results','Measurement'};
legend (Legend,'Location','north');

subplot(1,2,2)
plot(simulated_pindBm,phase, '.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,3), '.', 'Markersize',15);
legend (Legend,'Location','north');
xlabel('Input Power (dBm)');
ylabel('Output Phase Shift (deg.)');
grid on; title('AM/PM Characteristic');
```

Constellation compression, due to the nonlinear amplifier characteristics, is evident compared to the reference constellation.

```
constellation(ampSig)
```

## Distort 16QAM Signal with Measured Power Amplifier Nonlinearities

Apply nonlinear power amplifier (PA) characteristics to a 16-QAM signal by setting the Method property to Lookup table.

Define parameters for the modulation order, samples per symbol, input power, and create random data.

```
M = 16; % Modulation order
sps = 4; % Samples per symbol
pindBm = -8; % Input power
pin = 10.^((pindBm-30)/10); % power in Watts
data = randi([0 M-1],1000,1);
refdata = 0:M-1;
refconst = qammod(refdata,M,'UnitAveragePower',true);
paChar = pa_performance_characteristics();
```

Create a memoryless nonlinearity System object, a transmit filter System object, and a constellation diagram System object. The default lookup table values are used for the memoryless nonlinearity System object.

```
amplifier = comm.MemorylessNonlinearity('Method','Lookup table','Table',paChar);
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6,'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
constellation = comm.ConstellationDiagram('SamplesPerSymbol',4, ...
    'Title','Amplified/Distorted Signal','NumInputPorts',2, ...
    'ReferenceConstellation',refconst,'ShowLegend',true, ...
    'ChannelNames',{'Amplified signal','Filtered signal'});
```

Modulate the random data. Filter and apply the nonlinear amplifier characteristics to the modulation symbols.

```
modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin);
filtSig = txfilter(modSig);
ampSig = amplifier(filtSig);
```

Compute input and output signal levels and the phase shift.

```
poutdBm = (20*log10(abs(ampSig)))+30;
simulated_pindBm = (20*log10(abs(filtSig)))+30;
phase = angle(ampSig.*conj(filtSig))*180/pi;
```

Plot AM/AM characteristics, AM/PM characteristics, and the constellation results.

```
figure
set(gcf,'units','normalized','position',[.25 1/3 .5 1/3])
```

```

subplot(1,2,1)
plot(simulated_pindBm,poutdBm, '.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,2),'.','Markersize',15);
xlabel('Input Power (dBm)')
ylabel('Output Power (dBm)');
grid on;
title('AM/AM Characteristic');
Legend={'Simulated Results','Measurement'};
legend (Legend,'Location','south');

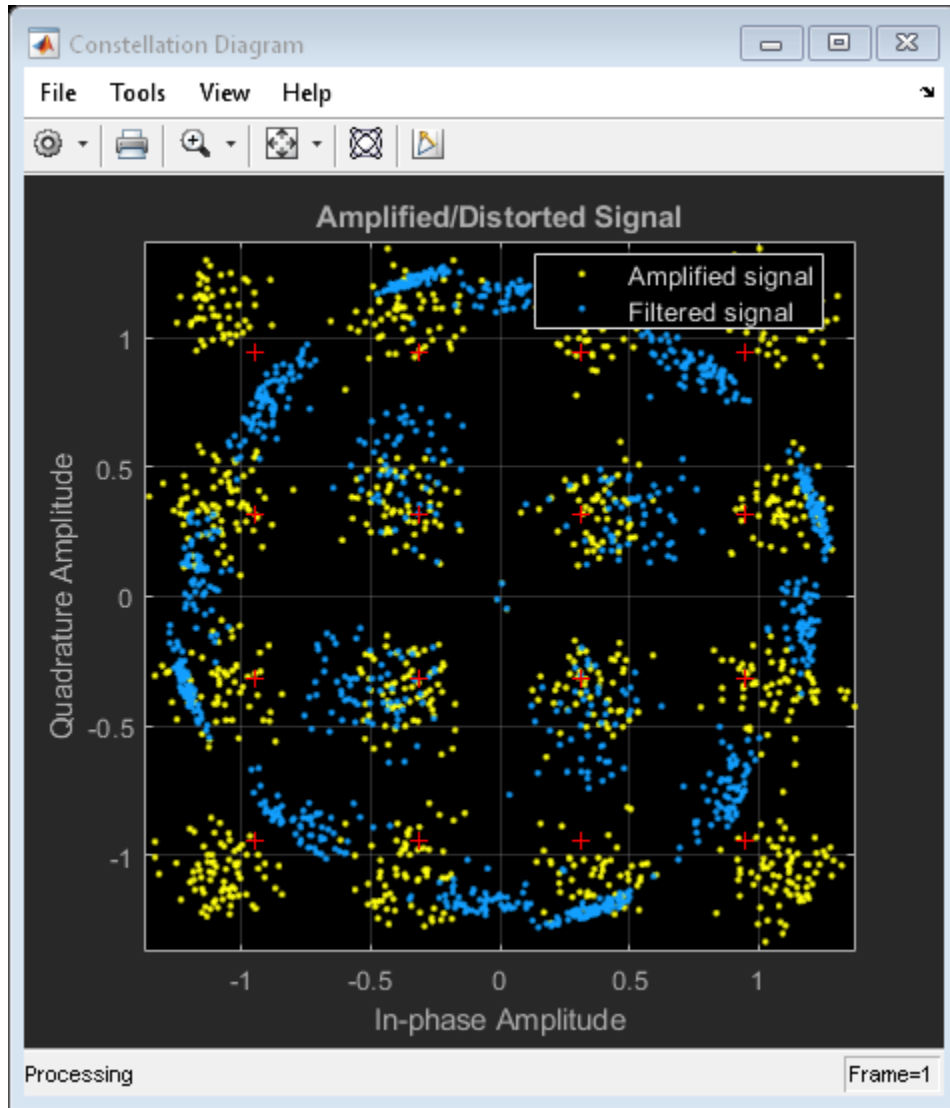

subplot(1,2,2)
plot(simulated_pindBm,phase, '.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,3),'.','Markersize',15);
legend (Legend,'Location','south');
xlabel('Input Power (dBm)');
ylabel('Output Phase Shift (deg.)');
grid on; title('AM/PM Characteristic');

```

For the purpose of constellation comparison, normalize the amplified signal and the filtered signal. The nonlinear amplifier characteristics cause compression of the amplified signal constellation compared to the filtered constellation.

```
filtSig = filtSig/mean(abs(filtSig)); % Normalized filtered signal  
ampSig = ampSig/mean(abs(ampSig)); % Normalized amplified signal  
constellation(filtSig,ampSig)
```

```
function paChar = pa_performance_characteristics()
```

The `pa_performance_characteristics` helper function provides the amplifier performance characteristics. The data is extracted from figure 4 of Hammi, Oualid, et al. "Power amplifiers' model assessment and memory effects intensity quantification using

memoryless post-compensation technique." IEEE Transactions on Microwave Theory and Techniques 56.12 (2008): 3170-3179.

The operating specification for the LDMOS-based Doherty Amplifier are:

- Frequency: 2110MHz
- Peak Power: 300w
- Small Signal Gain: 61dB

Each row in HAV08\_Table specifies Pin (dBm), Gain(dB), Phase shift (Degree).

```
HAV08_Table = ...

**System object:** comm.MemorylessNonlinearity

**Package:** comm

Apply memoryless nonlinearity to input signal

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  applies memoryless nonlinearity to the input,  $X$ , using the nonlinearity method you specify in the `Method` property, and returns the result in  $Y$ . The input  $X$  must be a complex scalar or column vector of data type double or single precision. The output,  $Y$ , is of the same data type as the input,  $X$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.MER

**Package:** comm

Measure modulation error ratio

## Description

The `comm.MER` (modulation error ratio) object measures the signal-to-noise ratio (SNR) in digital modulation applications. You can use MER measurements to determine system performance in communications applications. For example, determining whether a DVB-T system conforms to applicable radio transmission standards requires accurate MER measurements. The block measures all outputs in dB.

To measure modulation error ratio:

- 1 Define and set up your MER object. See “Construction” on page 4-1222.
- 2 Call `step` to measure the modulation error ratio according to the properties of `comm.MER`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`MER = comm.MER` creates a modulation error ratio (MER) System object, `MER`. This object measures the signal-to-noise ratio (SNR) in digital modulation applications.

`MER = comm.MER(Name,Value)` creates an MER object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

**Example:** `MER = comm.MER('ReferenceSignalSource','Estimated from reference constellation')` creates an object, `MER`, that measures the MER of a received signal by using a reference constellation.

## Properties

### ReferenceSignalSource

Reference signal source

Reference signal source, specified as either `'Input port'` (default) or `'Estimated from reference constellation'`. To provide an explicit reference signal against which the input signal is measured, set this property to `'Input port'`. To measure the MER of the input signal against a reference constellation, set this property to `'Estimated from reference constellation'`.

### ReferenceConstellation

Reference constellation

Reference constellation, specified as a vector. This property is available when the `ReferenceSignalSource` property is `'Estimated from reference constellation'`.

The default is `[0.7071 - 0.7071i; -0.7071 - 0.7071i; -0.7071 + 0.7071i; 0.7071 + 0.7071i]`, which corresponds to a standard QPSK constellation. You can derive constellation points by using modulation functions or objects. For example, to derive the reference constellation for a 16-QAM signal, you can use `qammod(0:15,16)`.

### MeasurementIntervalSource

Measurement interval source

Measurement interval source, specified as one of the following: `'Input length'` (default), `'Entire history'`, `'Custom'`, or `'Custom with periodic reset'`. This property affects the RMS and maximum MER outputs only.

- To calculate MER using only the current samples, set this property to `'Input length'`.
- To calculate MER for all samples, set this property to `'Entire history'`.

- To calculate MER over an interval you specify and to use a sliding window, set this property to `'Custom'`.
- To calculate MER over an interval you specify and to reset the object each time the measurement interval is filled, set this property to `'Custom with periodic reset'`.

### **MeasurementInterval**

Measurement interval

Measurement interval over which the MER is calculated, specified in samples as a real positive integer. This property is available when `MeasurementIntervalSource` is `'Custom'` or `'Custom with periodic reset'`. The default is `100`.

### **AveragingDimensions**

Averaging dimensions

Averaging dimensions, specified as a positive integer or row vector of positive integers. This property determines the dimensions over which the averaging is performed. For example, to average across the rows, set this property to `2`. The default is `1`.

The object supports variable-size inputs over the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must remain constant between step calls. For example, if the input has size `[4 3 2]` and `AveragingDimensions` is `[1 3]`, the output size is `[1 3 1]`, and the second dimension must remain fixed at `3`.

### **MinimumMEROutputPort**

Minimum MER measurement output port

Minimum MER measurement output port, specified as a logical scalar. To create an output port for minimum MER measurements, set this property to `true`. The default is `false`.

### **XPercentileMEROutputPort**

X-percentile MER measurement output port

X-percentile MER measurement output port, specified as a logical scalar. To create an output port for X-percentile MER measurements, set this property to `true`. The X-

percentile MER measurements persist until you reset the object. These measurements are calculated by using all of the input frames since the last reset. The default is `false`.

### **XPercentileValue**

X-percentile value

X-percentile value above which X% of the MER measurements fall, specified as a real scalar from 0 to 100. This property applies when `XPercentileMEROutputPort` is `true`. The default is 95.

### **SymbolCountOutputPort**

Symbol count output port

Symbol count output port, specified as a logical scalar. To output the number of accumulated symbols used to calculate the X-percentile MER measurements, set this property to `true`. This property is available when `XPercentileMEROutputPort` property is `true`. The default is `false`.

## **Methods**

`reset`      Reset states of MER measurement object  
`step`        Measure modulation error ratio

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## **Examples**

### **Measure MER of Noisy 16-QAM Modulated Signal**

Create an MER object which outputs minimum MER, 90-percentile MER, and the number of symbols.

```
mer = comm.MER('MinimumMEROutputPort',true, ...  
             'XPercentileMEROutputPort',true,'XPercentileValue',90,...  
             'SymbolCountOutputPort',true);
```

Generate random data. Apply 16-QAM modulation having unit average power. Pass the signal through an AWGN channel.

```
data = randi([0 15],1000,1);  
refsym = qammod(data,16,'UnitAveragePower',true);  
rxsym = awgn(refsym,20);
```

Determine the RMS, minimum, and 90th percentile MER values.

```
[MERdB,MinMER,PercentileMER,NumSym] = mer(refsym,rxsym)
```

```
MERdB = 20.1071
```

```
MinMER = 11.4248
```

```
PercentileMER = 16.5850
```

```
NumSym = 1000
```

### Measure MER Using Reference Constellation

Generate random data symbols, and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);  
txSig = pskmod(d,8,pi/8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,30);
```

Create an MER object. Measure the MER using the transmitted signal as the reference.

```
mer = comm.MER;  
mer1 = mer(txSig,rxSig);
```

Release the MER object. Set the object to use a reference constellation for making MER measurements.

```

release(mer)
mer.ReferenceSignalSource = 'Estimated from reference constellation';
mer.ReferenceConstellation = pskmod(0:7,8,pi/8);

```

Measure the MER using only the received signal as an input. Verify that it matches the result obtained with a reference signal.

```

mer2 = mer(rxSig);
[mer1 mer2]

ans = 1x2

    30.0271    30.0271

```

### Measure MER Using Custom Measurement Interval

Measure the MER of a noisy 8-PSK signal using two types of custom measurement intervals. Display the results.

Set the number of frames, M, and the number of subframes per frame, K.

```

M = 2;
K = 5;

```

Set the number of symbols in a subframe. Calculate the corresponding frame length.

```

sfLen = 100;
frmLen = K*sfLen

frmLen = 500

```

Create an MER object. Configure the object to use a custom measurement interval equal to the frame length.

```

mer1 = comm.MER('MeasurementIntervalSource','Custom', ...
    'MeasurementInterval',frmLen);

```

Configure the object to measure MER using an 8-PSK reference constellation.

```

mer1.ReferenceSignalSource = 'Estimated from reference constellation';
mer1.ReferenceConstellation = pskmod(0:7,8,pi/8);

```

Create an MER object, and configure it use a 500-symbol measurement interval with a periodic reset. Configure the object to measure MER using an 8-PSK reference constellation.

```
mer2 = comm.MER('MeasurementIntervalSource','Custom with periodic reset', ...  
    'MeasurementInterval',frmLen);  
mer2.ReferenceSignalSource = 'Estimated from reference constellation';  
mer2.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Initialize the MER and signal-to-noise arrays.

```
merNoReset = zeros(K,M);  
merReset = zeros(K,M);  
snrdB = zeros(K,M);
```

Measure the MER for a noisy 8-PSK signal using both objects. The SNR is increases by 1 dB from subframe to subframe. For `merNoReset`, the 500 most recent symbols are used to compute the estimate. In this case, a sliding window is used so that an entire data frame is used as the basis for the estimate. For `merReset`, the symbols are cleared each time a new frame is encountered.

```
for m = 1:M  
    for k = 1:K  
        data = randi([0 7],sfLen,1);  
        txSig = pskmod(data,8,pi/8);  
        snrdB(k,m) = k+(m-1)*K+7;  
        rxSig = awgn(txSig,snrdB(k,m));  
        merNoReset(k,m) = mer1(rxSig);  
        merReset(k,m) = mer2(rxSig);  
    end  
end
```

Display the MER measured using the two approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the MER object resets after the first frame so that the calculated MER values more accurately reflect the current SNR.

```
stairs(snrdB(:),[merNoReset(:) merReset(:)])  
xlabel('SNR (dB)')  
ylabel('MER (%)')  
legend('No Reset', 'Periodic Reset')
```

### Measure MER Across Different Dimensions

Create OFDM modulator and demodulator objects.

```
ofdmmod = comm.OFDMModulator('FFTLength',32,'NumSymbols',4);
ofdmdemod = comm.OFDMDemodulator('FFTLength',32,'NumSymbols',4);
```

Determine the number of subcarriers and symbols in the OFDM signal.

```
ofdmDims = info(ofdmmod);
numSC = ofdmDims.DataInputSize(1)
```

```
numSC = 21
```

```
numSym = ofdmDims.DataInputSize(2)
```

```
numSym = 4
```

Generate random symbols and apply QPSK modulation.

```
msg = randi([0 3],numSC,numSym);
```

```
modSig = pskmod(msg,4,pi/4);
```

OFDM modulate the QPSK signal. Pass the signal through an AWGN channel. Demodulate the noisy signal.

```
txSig = ofdmmod(modSig);
```

```
rxSig = awgn(txSig,10,'measured');
```

```
demodSig = ofdmdemod(rxSig);
```

Create an MER object, where the result is averaged over the subcarriers. Measure the MER. There are four entries corresponding to each of the 4 OFDM symbols.

```
mer = comm.MER('AveragingDimensions',1);
```

```
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 1×4
```

```
11.2338 12.5315 12.8882 12.7015
```

Overwrite the MER object, where the result is averaged over the OFDM symbols. Measure the MER. There are 21 entries corresponding to each of the 21 subcarriers.

```
mer = comm.MER('AveragingDimensions',2);
```

```
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 21×1
```

```
10.8054
```

```
14.9655
```

```
14.5721
```

```
13.6024
```

```
13.0132
```

```
12.1391
```

```
10.4012
```

```
9.5017
```

```
8.8055
```

```
13.3824
⋮
```

Measure the MER and average over both the subcarriers and the OFDM symbols.

```
mer = comm.MER('AveragingDimensions',[1 2]);
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 12.2884
```

## Algorithms

MER is a measure of the SNR in a modulated signal calculated in dB. The MER over  $N$  symbols is

$$\text{MER} = 10 \cdot \log_{10} \left( \frac{\sum_{n=1}^N (I_k^2 + Q_k^2)}{\sum_{n=1}^N (e_k)} \right) \text{dB},$$

The MER for the  $k$ th symbol is

$$\text{MER}_k = 10 * \log_{10} \left( \frac{\frac{1}{N} \sum_{n=1}^N (I_k^2 + Q_k^2)}{e_k} \right) \text{dB}.$$

The minimum MER represents the minimum MER value in a burst, or

$$\text{MER}_{\min} = \min_{k \in [1, \dots, N]} \{ \text{MER}_k \},$$

where:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- $I_k$  = In-phase measurement of the  $k$ th symbol in the burst

- $Q_k$  = Quadrature phase measurement of the  $k$ th symbol in the burst
- $I_k$  and  $Q_k$  represent ideal (reference) values.  $\tilde{I}_k$  and  $\tilde{Q}_k$  represent measured (received) symbols.

The block computes the  $X$ -percentile MER by creating a histogram of all the incoming  $MER_k$  values. The output provides the MER value above which  $X\%$  of the MER values fall.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2012a**

## reset

**System object:** comm.MER

**Package:** comm

Reset states of MER measurement object

## Syntax

reset(H)

## Description

reset(H) resets the states of the MER object, H.

## step

**System object:** comm.MER

**Package:** comm

Measure modulation error ratio

## Syntax

```
MERDB= step(MER,REFSYM,RXSYM)
MERDB = step(MER,RXSYM)
[ ___,MINMER] = step( ___ )
[ ___,XMER] = step( ___ )
[ ___,NUMSYM] = step( ___ )
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`MERDB= step(MER,REFSYM,RXSYM)` returns the measured MER, `MERDB`, of the received signal `RXSYM`, based on reference signal `REFSYM`. MER values are measured in dB.

`REFSYM`. `REFSYM` and `RXSYM` inputs are complex column vectors of equal dimensions and data type. The data type can be double, single, signed integer, or signed fixed point with power-of-two slope and zero bias. All outputs of the object are of data type double. To set the interval over which the MER is measured, use the `MeasurementIntervalSource` and `MeasurementInterval` properties.

`MERDB = step(MER,RXSYM)` returns the measured MER of received signal `RXSYM` based on a reference signal specified in the `ReceivedConstellation` property.

`[ ___,MINMER] = step( ___ )` returns the minimum MER, `MINMER`, given either of the two previous syntaxes.

---

To return minimum MER, set the `MinimumMEROutputPort` property to `true`. To set the interval over which `MINMER` is measured, use the `MeasurementIntervalSource` and `MeasurementInterval` properties.

[ \_\_\_\_, `XMER`] = `step`( \_\_\_\_) returns the  $X$ -percentile MER, `XMER`.

To return the  $X$ -percentile MER, set the `XPercentileMEROutputPort` property to `true`. `XMER` is the MER above which  $X\%$  of the measurements fall, where  $X$  is set by the `XPercentileValue` property. `XMER` is measured using all the input frames since the last reset.

[ \_\_\_\_, `NUMSYM`] = `step`( \_\_\_\_) returns the number of symbols, `NUMSYM`, used to calculate the  $X$ -percentile MER.

To return `NUMSYM`, set the `SymbolCountOutputPort` to `true`. `NUMSYM` is measured using all the input frames since the last reset.

---

**Note** MER specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.MIMOChannel

**Package:** comm

Filter input signal through MIMO multipath fading channel

### Description

A comm.MIMOChannel object filters an input signal through a multiple-input/multiple-output (MIMO) multipath fading channel. This object models both Rayleigh and Rician fading and employs the Kronecker model for modeling the spatial correlation between the links. For processing details, see the Algorithms on page 4-1268 section.

To filter an input signal through a MIMO multipath fading channel:

- 1 Create the comm.MIMOChannel object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

### Creation

### Syntax

```
mimochan = comm.MIMOChannel  
mimochan = comm.MIMOChannel(Name,Value)
```

### Description

mimochan = comm.MIMOChannel creates a multiple-input multiple-output (MIMO) frequency-selective or frequency-flat fading channel System object. This object filters a real or complex input signal through the multipath MIMO channel to obtain the channel-impaired signal.

`mimochan = comm.MIMOChannel(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.MIMOChannel('SampleRate', 2)`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

### **SampleRate** — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

Data Types: double

### **PathDelays** — Discrete path delay

0 (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When you set `PathDelays` to a scalar, the MIMO channel is frequency flat.
- When you set `PathDelays` to a vector, the MIMO channel is frequency selective.

Data Types: double

### **AveragePathGains** — Average path gains (dB)

0 (default) | scalar | row vector

Average path gains in decibels, specified as a scalar or row vector. `AveragePathGains` must have the same size as `PathDelays`.

Data Types: double

### **NormalizePathGains** — Normalize path gains

true (default) | false

Normalize path gains, specified as `true` or `false`.

- When you set this property to `true`, the fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- When you set this property to `false`, there is no normalization on path gains.

The average powers of the path gains are specified by the `AveragePathGains` property.

Data Types: `logical`

### **FadingDistribution — Fading distribution**

'Rayleigh' (default) | 'Rician'

Fading distribution to use for the channel, specified as 'Rayleigh' or 'Rician'.

Data Types: `char`

### **KFactor — K-factor of Rician fading channel**

3 (default) | positive scalar | row vector

K-factor of a Rician fading channel, specified as a positive scalar or a 1-by- $N_p$  vector of positive-valued elements.  $N_p$  equals number of path delays specified by the `PathDelays` property.

- If you set `KFactor` to a scalar, the first discrete path is a Rician fading process with a Rician K-factor of `KFactor`. Any remaining discrete paths are independent Rayleigh fading processes.
- If you set `KFactor` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to a zero-valued element of the `KFactor` vector is a Rayleigh fading process.

### **Dependencies**

This property applies when `FadingDistribution` is `Rician`.

Data Types: `double`

### **DirectPathDopplerShift — Doppler shifts for line-of-sight components (Hz)**

0 (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the Rician fading channel in hertz, specified as a scalar or row vector. This property must have the same size as `KFactor`.

- If you set `DirectPathDopplerShift` to a scalar, it represents the line-of-sight component Doppler shift of the first discrete path that is a Rician fading process.
- If you set `DirectPathDopplerShift` to a row vector, the discrete path that is a Rician fading process has its line-of-sight component Doppler shift specified by the elements of `DirectPathDopplerShift` that correspond to positive elements in the `KFactor` vector.

### Dependencies

This property applies when `FadingDistribution` is `Rician`.

Data Types: `double`

### **DirectPathInitialPhase — Initial phases for line-of-sight components (Radians)**

`0` (default) | scalar | row vector

Initial phases for the line-of-sight components of the Rician fading channel in radians, specified as a scalar or row vector. This property must have the same size as `KFactor`.

- If you set `DirectPathInitialPhase` to a scalar, it represents the line-of-sight component initial phase of the first discrete path that is a Rician fading process.
- If you set `DirectPathInitialPhase` to a row vector, the discrete path that is a Rician fading process has its line-of-sight component initial phase specified by the elements of `DirectPathInitialPhase` that correspond to positive elements in the `KFactor` vector.

### Dependencies

This property applies when `FadingDistribution` is `Rician`.

Data Types: `double`

### **MaximumDopplerShift — Maximum Doppler shift for all channel paths (Hz)**

`0.001` (default) | nonnegative scalar

Maximum Doppler shift for all channel paths in hertz, specified as a nonnegative scalar.

The Doppler shift applies to all channel paths. When you set this property to `0`, the channel remains static for the entire input. You can use the `reset` object function to generate a new channel realization.

MaximumDopplerShift must be smaller than  $(\text{SampleRate}/10)/f_c$  for each path, where  $f_c$  represents the cutoff frequency factor of the path. For more information on the cutoff frequency, see Cutoff Frequency Factor on page 4-1268.

Data Types: double

### DopplerSpectrum — Doppler spectrum shape for all channel paths

doppler('Jakes') (default) | doppler('Flat') | doppler('Rounded', ...) |  
doppler('Bell', ...) | doppler('Asymmetric Jakes', ...) |  
doppler('Restricted Jakes', ...) | doppler('Gaussian', ...) |  
doppler('BiGaussian', ...)

Doppler spectrum shape for all channel paths, specified as a single Doppler spectrum structure returned from the `doppler` function or a 1-by- $N_p$  cell array of such structures. The default value of this property is the Jakes Doppler spectrum (`doppler('Jakes')`).

- If you assign a single call to `doppler`, all paths have the same specified Doppler spectrum.
- If you assign a 1-by- $N_p$  cell array of calls to `doppler` using any of the specified syntaxes, each path has the Doppler spectrum specified by the corresponding Doppler spectrum structure in the array. In this case,  $N_p$  equals the value of the `PathDelays` property.

The maximum Doppler shift value necessary to specify the Doppler spectrum/spectra is given by the `MaximumDopplerShift` property.

### Dependencies

This property applies when `MaximumDopplerShift` is greater than zero.

If you assign the `FadingTechnique` property to 'Sum of sinusoids', you must set `DopplerSpectrum` to `doppler('Jakes')`.

### SpatialCorrelationSpecification — Spatial correlation specification

'Separate Tx Rx' (default) | 'None' | 'Combined'

Spatial correlation specification, specified as 'Separate Tx Rx', 'None', or 'Combined'.

- Choose 'Spatial Tx Rx' to separately specify the transmit and receive spatial correlation matrices from which the number of transmit antenna ( $N_T$ ) and number of receive antennas ( $N_R$ ) are derived.

- Choose 'None' to specify the number of transmit and receive antennas.
- Choose 'Combined' to specify a single correlation matrix for the whole channel, from which the product of  $N_T$  and  $N_R$  is derived.

Data Types: char

### **NumTransmitAntennas — Number of transmit antennas**

2 (default) | positive integer

Number of transmit antennas, specified as a positive integer.

#### **Dependencies**

This property applies when SpatialCorrelationSpecification is 'None' or 'Combined'.

Data Types: double

### **NumReceiveAntennas — Number of receive antennas**

2 (default) | positive integer

Number of receive antennas, specified as a positive integer.

#### **Dependencies**

This property applies when SpatialCorrelationSpecification is 'None' or 'Combined'.

Data Types: double

### **TransmitCorrelationMatrix — Spatial correlation of transmitter**

[1 0; 0 1] (default) | matrix | 3-D array

Specify the spatial correlation of the transmitter as an  $N_T$ -by- $N_T$  matrix or  $N_T$ -by- $N_T$ -by- $N_P$  array.  $N_T$  is the number of transmit antennas, and  $N_P$  equals the value of the PathDelays property.

- If PathDelays is a scalar, the channel is frequency-flat, and TransmitCorrelationMatrix is an  $N_T$ -by- $N_T$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If PathDelays is a vector, the channel is frequency selective, and you can specify TransmitCorrelationMatrix as a matrix. Each path has the same transmit spatial correlation matrix.
- Alternatively, you can specify TransmitCorrelationMatrix as an  $N_T$ -by- $N_T$ -by- $N_P$  array, where each path can have its own different transmit spatial correlation matrix.

### Dependencies

This property applies when you set the `SpatialCorrelationSpecification` property to 'Separate Tx Rx'.

Data Types: double

Complex Number Support: Yes

### ReceiveCorrelationMatrix — Spatial correlation of receiver

[1 0; 0 1] (default) | matrix | 3-D array

Specify the spatial correlation of the receiver as an  $N_R$ -by- $N_R$  matrix or  $N_R$ -by- $N_R$ -by- $N_P$  array.  $N_R$  is the number of receive antennas, and  $N_P$  equals the value of the `PathDelays` property.

- If `PathDelays` is a scalar, the channel is frequency flat, and `ReceiveCorrelationMatrix` is an  $N_R$ -by- $N_R$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If `PathDelays` is a vector, the channel is frequency selective, and you can specify `ReceiveCorrelationMatrix` as a matrix. Each path has the same receive spatial correlation matrix.
- Alternatively, you can specify `ReceiveCorrelationMatrix` as an  $N_R$ -by- $N_R$ -by- $N_P$  array, where each path can have its own different receive spatial correlation matrix.

### Dependencies

This property applies when you set the `SpatialCorrelationSpecification` property to 'Separate Tx Rx'.

Data Types: double

Complex Number Support: Yes

### SpatialCorrelationMatrix — Combined spatial correlation matrix

[1 0 0 0; 0 1 0 0; 0 0 1 0; 0 0 0 1] (default) | matrix | 3-D array

Combined spatial correlation matrix, specified as an  $N_{TR}$ -by- $N_{TR}$  matrix or  $N_{TR}$ -by- $N_{TR}$ -by- $N_P$  array, where  $N_{TR} = (N_T \times N_R)$ , and  $N_P$  equals the value of the `PathDelays` property.

- If `PathDelays` is a scalar, the channel is frequency flat, and `SpatialCorrelationMatrix` is an  $N_{TR}$ -by- $N_{TR}$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.

- If PathDelays is a vector, the channel is frequency selective, and you can specify SpatialCorrelationMatrix as a matrix. Each path has the same spatial correlation matrix.
- Alternatively, you can specify SpatialCorrelationMatrix as an  $N_{TR}$ -by- $N_{TR}$ -by- $N_P$  array, where each path can have its own different combined spatial correlation matrix.

### Dependencies

This property applies when you set the SpatialCorrelationSpecification property to 'Combined'.

Data Types: double

### AntennaSelection — Antenna selection scheme

'Off' (default) | 'Tx' | 'Rx' | 'Tx and Rx'

Antenna selection scheme, specified as 'Off', 'Tx', 'Rx', or 'Tx and Rx'.

Tx represents transmit antennas and Rx represents receive antennas. When you configure any antenna selection other than the default setting, the object requires one or more inputs to specify which antennas are selected for signal transmission. For more information, see Antenna Selection on page 4-1269.

Data Types: char

### NormalizeChannelOutputs — Normalize channel outputs

true (default) | false

Normalize channel outputs, specified as true or false.

- When you set this property to true, channel outputs are normalized by the number of receive antennas.
- When you set this property to false, channel outputs are not normalized.

Data Types: logical

### FadingTechnique — Channel model fading technique

'Filtered Gaussian noise' (default) | 'Sum of sinusoids'

Channel model fading technique, specified as 'Filtered Gaussian noise' or 'Sum of sinusoids'.

Data Types: char

### **NumSinusoids — Number of sinusoids used**

48 (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

#### **Dependencies**

This property applies when FadingTechnique is 'Sum of sinusoids'.

Data Types: double

### **InitialTimeSource — Source to control start time of fading process**

'Property' (default) | 'Input port'

Source to control the start time of the fading process, specified as 'Property' or 'Input port'.

- 'Property' -- Use the InitialTime property to set the initial time offset.
- 'Input port' -- Specify the start time of the fading process by using the initialtime input to the object. The input value can change in consecutive calls to the object.

#### **Dependencies**

This property applies when FadingTechnique is 'Sum of sinusoids'.

### **InitialTime — Initial time offset**

0 (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

When InitialTime is not a multiple of 1/SampleRate, it is rounded up to the nearest sample position.

#### **Dependencies**

This property applies when the FadingTechnique property is set to 'Sum of sinusoids' and the InitialTimeSource property is set to 'Property'.

Data Types: double

### **RandomStream — Source of random number stream**

'Global stream' (default) | 'mt19937ar with seed'

Source of the random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- 'Global stream' -- The current global random number stream is used for normally distributed random number generation. In this case, the `reset` object function resets the filters only.
- 'mt19937ar with seed' -- The mt19937ar algorithm is used for normally distributed random number generation. In this case, the `reset` object function resets the filters and also reinitializes the random number stream to the value of the `Seed` property.

Data Types: char

### **Seed — Initial seed of mt19937ar random number stream**

73 (default) | nonnegative integer

Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. When the `reset` object function is called, the mt19937ar random number stream is reinitialized to the `Seed` value.

### **Dependencies**

This property applies when you set the `RandomStream` property to 'mt19937ar with seed'.

Data Types: double

### **PathGainsOutputPort — Option to output path gains**

false (default) | true

Option to output path gains, specified as `false` or `true`. Set this property to `true` to output the channel path gains of the underlying fading process.

Data Types: logical

### **Visualization — Channel visualization**

'Off' (default) | 'Impulse response' | 'Frequency response' | 'Impulse and frequency responses' | 'Doppler spectrum'

Channel visualization preference, specified as 'Off', 'Impulse response', 'Frequency response', 'Impulse and frequency responses', or 'Doppler spectrum'. When visualization is on, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see Channel Visualization.

### **Dependencies**

Visualization applies only when the FadingTechnique property is set to 'Filtered Gaussian noise'.

### **AntennaPairsToDisplay — Transmit-receive antenna pair to display**

[1 1] (default) | row vector

Transmit-receive antenna pair to display, specified as a 1-by-2 vector, where the first element corresponds to the desired transmit antenna and the second element corresponds to the desired receive antenna. At this time, only a single pair can be displayed.

### **Dependencies**

This property applies when Visualization is not Off.

### **PathsForDopplerDisplay — Path for which the Doppler spectrum is displayed**

1 (default) | positive integer

Path for which the Doppler spectrum is displayed, specified as a positive integer from 1 to  $N_p$ , where  $N_p$  equals the value of the PathDelays property.

### **Dependencies**

This property applies when Visualization is set to 'Doppler spectrum'.

### **SamplesToDisplay — Percentage of samples to display**

25% (default) | 10% | 50% | 100%

Percentage of samples to display, specified as 10%, 25%, 50%, or 100%. Increasing the percentage improves display accuracy at the expense of simulation speed.

### **Dependencies**

This property applies when Visualization is 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

## Usage

## Syntax

```
outsignal = mimochan(insignal)
outsignal = mimochan(insignal,seltx)
outsignal = mimochan(insignal,selrx)
outsignal = mimochan(insignal,seltx,selrx)
outsignal = mimochan( ____,initialtime)
[outsignal,pathgains] = mimochan( ____ )
```

## Description

`outsignal = mimochan(insignal)` filters the input signal through the MIMO fading channel specified by `mimochan` and returns the result in `outsignal`.

`outsignal = mimochan(insignal,seltx)` turns on the transmit antennas selected by `seltx` for channel processing.

This syntax applies when you set the `AntennaSelection` property of the object to `'Tx'`.

For example, to select the first and third transmit antenna index as active:

```
mimochan = comm.MIMOChannel('AntennaSelection','Tx');
seltx = [1 0 1];
...
outsignal = mimochan(insignal,seltx);
```

`outsignal = mimochan(insignal,selrx)` turns on receive antennas, selected by `selrx` for channel processing.

This syntax applies when you set the `AntennaSelection` property of the object to `'Rx'`.

For example, to select the second receive antenna index as active:

```
mimochan = comm.MIMOChannel('AntennaSelection','Rx');
selrx = [0 1];
...
outsignal = mimochan(insignal,selrx);
```

`outsignal = mimochan(insignal,seltx,selrx)` turns on transmit and receive antennas, selected by `seltx` and `selrx` for channel processing.

This syntax applies when you set the `AntennaSelection` property of the object to 'Tx and Rx'.

For example:

```
mimochan = comm.MIMOChannel('AntennaSelection','Tx and Rx');
seltx = [1 1];
selrx = [0 1];
...
outsignal = mimochan(insignal,selrx);
```

`outsignal = mimochan( ____, initialtime)` specifies a start time for the fading process.

This syntax applies when you set the `FadingTechnique` property of the object to 'Sum of sinusoids' and the `InitialTimeSource` property of the object to 'Input port'. The syntax supports input options from prior syntaxes.

`[outsignal,pathgains] = mimochan( ____, )` also returns the MIMO channel path gains for antenna selection schemes. The syntax supports input options from prior syntaxes.

## Input Arguments

### **insignal** — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, an  $N_S$  element column vector, an  $N_S$ -by- $N_T$  matrix, or an  $N_S$ -by- $N_{ST}$  matrix.

- $N_S$  is the number of samples.
- $N_T$  is the number of transmit antennas.  $N_T$  is determined by the `TransmitCorrelationMatrix` or `NumTransmitAntennas` property values of the object.
- $N_{ST}$  is the number of selected transmit antennas, as determined by the number of elements set to 1 in the vector provided to the `seltx` input.

The number of transmit antennas is determined by the `TransmitCorrelationMatrix` or `NumTransmitAntennas` property values of the object.

Data Types: double | single  
Complex Number Support: Yes

### **selTx — Select active transmit antennas**

binary vector

Select active transmit antennas, specified as a 1-by- $N_T$  binary vector.  $N_T$  represents the number of transmit antennas. Elements set to 1 identify selected antenna indices and 0 identify nonselected antenna indices.

Data Types: double

### **selRx — Select active receive antennas**

binary vector

Select active receive antennas, specified as a 1-by- $N_R$  binary vector.  $N_R$  represents the number of receive antennas. Elements set to 1 identify selected antenna indices and 0 identify nonselected antenna indices.

Data Types: double

### **initialTime — Initial time offset**

0 (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

The initial time offset must be greater than the last frame end time. When `initialTime` is not a multiple of `1/SampleRate`, it is rounded up to the nearest sample position.

Data Types: double

## **Output Arguments**

### **outSignal — Output signal**

matrix

Output data signal, returned as an  $N_S$ -by- $N_R$  or  $N_S$ -by- $N_{SR}$  matrix.

- $N_S$  is the number of samples.
- $N_R$  is the number of receive antennas.  $N_R$  is determined by the `ReceiveCorrelationMatrix` or `NumReceiveAntennas` property values of the object.
- $N_{SR}$  is the number of selected receive antennas, as determined by the number of elements set to 1 in the vector provided to the `selRx` input.

### **pathgains — Output path gains**

4-D array

Output path gains, returned as an  $N_S$ -by- $N_P$ -by- $N_T$ -by- $N_R$  array with NaN values for the unselected transmit-receive antenna pairs.

- $N_S$  is the number of samples.
- $N_P$  equals the value of the PathDelays property.
- $N_T$  is the number of transmit antennas.
- $N_R$  is the number of receive antennas.

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Specific to comm.MIMOChannel**

`info` Characteristic information about the fading channel object

### **Common to All System Objects**

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

---

#### **Note**

- If you set the `RandomStream` property of the object to `'Global stream'`, the `reset` object function resets the filters only.
  - If you set `RandomStream` to `'mt19937ar with seed'`, the `reset` object function resets the filters and also reinitializes the random number stream to the value of the `Seed` property.
-

## Examples

### Pass QPSK Data Through 4-by-2 MIMO Channel

Create a 4-by-2 MIMO channel by using the MIMO channel System object. Pass modulated and spatially encoded data through the channel.

Generate QPSK-modulated data.

```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Create an orthogonal space-time block encoder to encode the modulated data into four spatially separated streams. Encode the data.

```
ostbc = comm.OSTBCEncoder('NumTransmitAntennas',4,'SymbolRate',1/2);
txSig = ostbc(modData);
```

Create a MIMO channel object, using name-value pairs to set the properties. The channel consists of two paths with a maximum Doppler shift of 5 Hz. Set the `SpatialCorrelationSpecification` property to 'None', which requires that you specify the number of transmit and receive antennas. Set the number of transmit antennas to 4 and the number of receive antennas to 2.

```
mimochannel = comm.MIMOChannel(...
    'SampleRate',1000, ...
    'PathDelays',[0 2e-3], ...
    'AveragePathGains',[0 -5], ...
    'MaximumDopplerShift',5, ...
    'SpatialCorrelationSpecification','None', ...
    'NumTransmitAntennas',4, ...
    'NumReceiveAntennas',2);
```

Pass the modulated and encoded data through the MIMO channel.

```
rxSig = mimochannel(txSig);
```

Create a time vector, `t`, to use for plotting the power of the received signal.

```
ts = 1/mimochannel.SampleRate;
t = (0:ts:(size(txSig,1)-1)*ts)';
```

Calculate and plot the power of the signal received by antenna 1.

```
pwrdB = 20*log10(abs(rxSig(:,1)));  
  
plot(t,pwrdB)  
xlabel('Time (s)')  
ylabel('Power (dBW)')
```

### Examine Spatial Correlation Characteristics of 2-by-2 Rayleigh Fading Channel

Without specifying antenna selection, filter PSK-modulated data through a 2-by-2 Rayleigh fading channel and examine the spatial correlation characteristics of the channel realization. Use the `release` object function to unlock the object to set the

AntennaSelection property to 'Tx and Rx' and then confirm the unselected transmit-receive antenna pairs.

### Examine Spatial Correlation Characteristics Without Specifying Antenna Selection

Create a PSK modulator System object™ to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],1e5,1));
```

Split the modulated data into two spatial streams.

```
channelInput = reshape(modData,[2 5e4]).';
```

Create a 2-by-2 MIMO channel System object with two discrete paths. Each path has different transmit and receive correlation matrices, specified by the TransmitCorrelationMatrix and ReceiveCorrelationMatrix properties.

```
mimoChan = comm.MIMOChannel('SampleRate',1000, 'PathDelays',[0 1e-3], ...
    'AveragePathGains',[3 5], 'NormalizePathGains',false, 'MaximumDopplerShift',5, ...
    'TransmitCorrelationMatrix',cat(3,eye(2),[1 0.1;0.1 1]), ...
    'ReceiveCorrelationMatrix',cat(3,[1 0.2;0.2 1],eye(2)), ...
    'RandomStream','mt19937ar with seed', 'Seed',33, 'PathGainsOutputPort',true);
```

Filter the modulated data using the MIMO channel object.

```
[~,pathGains] = mimoChan(channelInput);
```

The transmit spatial correlation for the first discrete path at the first receive antenna is specified as an identity matrix in the TransmitCorrelationMatrix property. Confirm that the channel output pathGains exhibits the same statistical characteristics by using the corrcoef function.

```
disp('Tx spatial correlation, first path, first Rx:');
```

```
Tx spatial correlation, first path, first Rx:
```

```
disp(corrcoef(squeeze(pathGains(:,1,:],1))));
```

```
1.0000 + 0.0000i    0.0357 - 0.0253i
0.0357 + 0.0253i    1.0000 + 0.0000i
```

The transmit spatial correlation for the second discrete path at the second receive antenna is specified as `[1 0.1;0.1 1]` in the `TransmitCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics.

```
disp('Tx spatial correlation, second path, second Rx:');
```

```
Tx spatial correlation, second path, second Rx:
```

```
disp(corrcoef(squeeze(pathGains(:,2,:,2))));
```

```
1.0000 + 0.0000i    0.0863 + 0.0009i
0.0863 - 0.0009i    1.0000 + 0.0000i
```

The receive spatial correlation for the first discrete path at the second transmit antenna is specified as `[1 0.2;0.2 1]` in the `ReceiveCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics.

```
disp('Rx spatial correlation, first path, second Tx:');
```

```
Rx spatial correlation, first path, second Tx:
```

```
disp(corrcoef(squeeze(pathGains(:,1,2,:))));
```

```
1.0000 + 0.0000i    0.2236 + 0.0550i
0.2236 - 0.0550i    1.0000 + 0.0000i
```

The receive spatial correlation for the second discrete path at the first transmit antenna is specified as an identity matrix in the `ReceiveCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics.

```
disp('Rx spatial correlation, second path, first Tx:');
```

```
Rx spatial correlation, second path, first Tx:
```

```
disp(corrcoef(squeeze(pathGains(:,2,1,:))));
```

```
1.0000 + 0.0000i   -0.0088 - 0.0489i
-0.0088 + 0.0489i    1.0000 + 0.0000i
```

### **Examine Spatial Correlation Characteristics Specifying Antenna Selection**

Enable transmit and receive antenna selection for the `mimoChan` object. The input frame size is shortened to 100.

```

release(mimoChan);
mimoChan.AntennaSelection = 'Tx and Rx';
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],100,1));

```

Select the first transmit antenna and second receive antenna.

```
[channelOutput,pathGains] = mimoChan(modData,[1 0],[0 1]);
```

Confirm that the path gains that MATLAB® returns have NaN values for the unselected transmit-receive antenna pairs.

```
disp('Return 1 if the path gains for the second transmit antenna are NaN:');
```

Return 1 if the path gains for the second transmit antenna are NaN:

```
disp(isequal(isnan(squeeze(pathGains(:,:,2,:))), ones(100,2,2)));
```

0

```
disp('Return 1 if the path gains for the first receive antenna are NaN:');
```

Return 1 if the path gains for the first receive antenna are NaN:

```
disp(isequal(isnan(squeeze(pathGains(:,:,,1))), ones(100,2,2)));
```

0

## Display Impulse and Frequency Responses of Frequency Selective Channel

Create a frequency selective MIMO channel and display its impulse and frequency responses.

Set the sample rate to 10 MHz and specify path delays and gains using the extended vehicular A (EVA) channel parameters. Set the maximum Doppler shift to 70 Hz.

```

fs = 10e6; % Hz
pathDelays = [0 30 150 310 370 710 1090 1730 2510]*1e-9; % sec
avgPathGains = [0 -1.5 -1.4 -3.6 -0.6 -9.1 -7 -12 -16.9]; % dB
fD = 70; % Hz

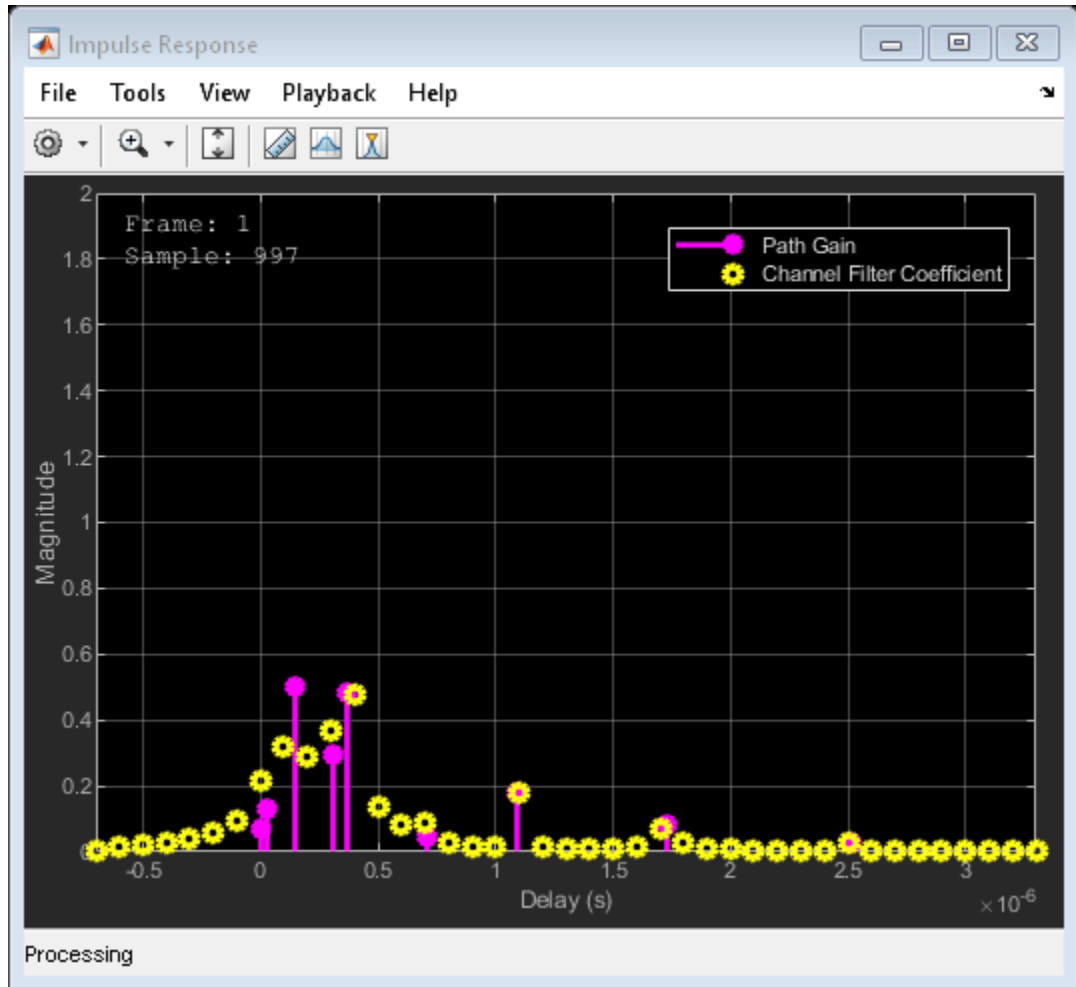

```

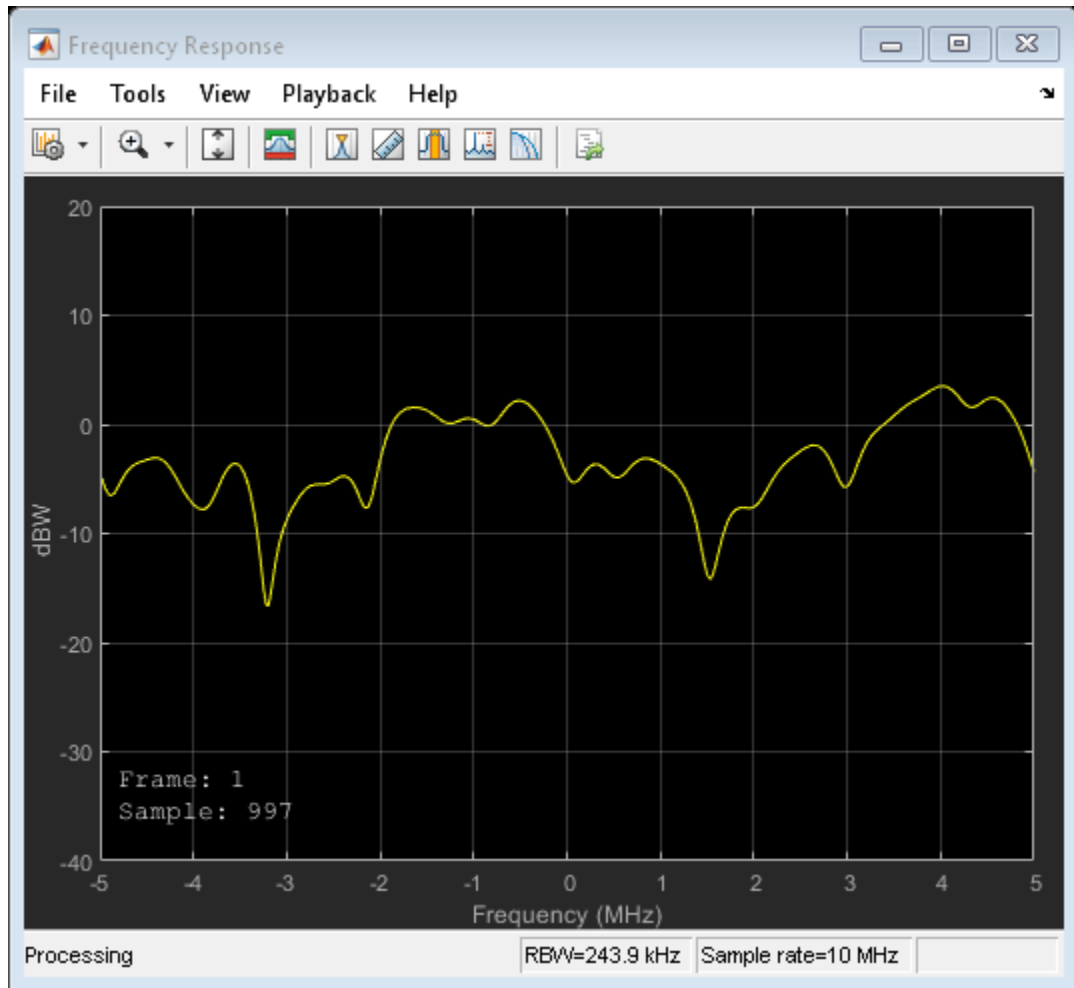

Create a 2x2 MIMO channel System object with the previously defined parameters and set the Visualization property to Impulse and frequency responses using name-value pairs. By default, the antenna pair corresponding to transmit antenna 1 and receive antenna 1 will be displayed.

```
mimoChan = comm.MIMOChannel('SampleRate',fs, ...  
    'PathDelays',pathDelays, ...  
    'AveragePathGains',avgPathGains, ...  
    'MaximumDopplerShift',fD, ...  
    'Visualization','Impulse and frequency responses');
```

Generate random binary data and pass it through the MIMO channel. The impulse response plot allows you to easily identify the individual paths and their corresponding filter coefficients. The frequency selective nature of the EVA channel is shown by the frequency response plot.

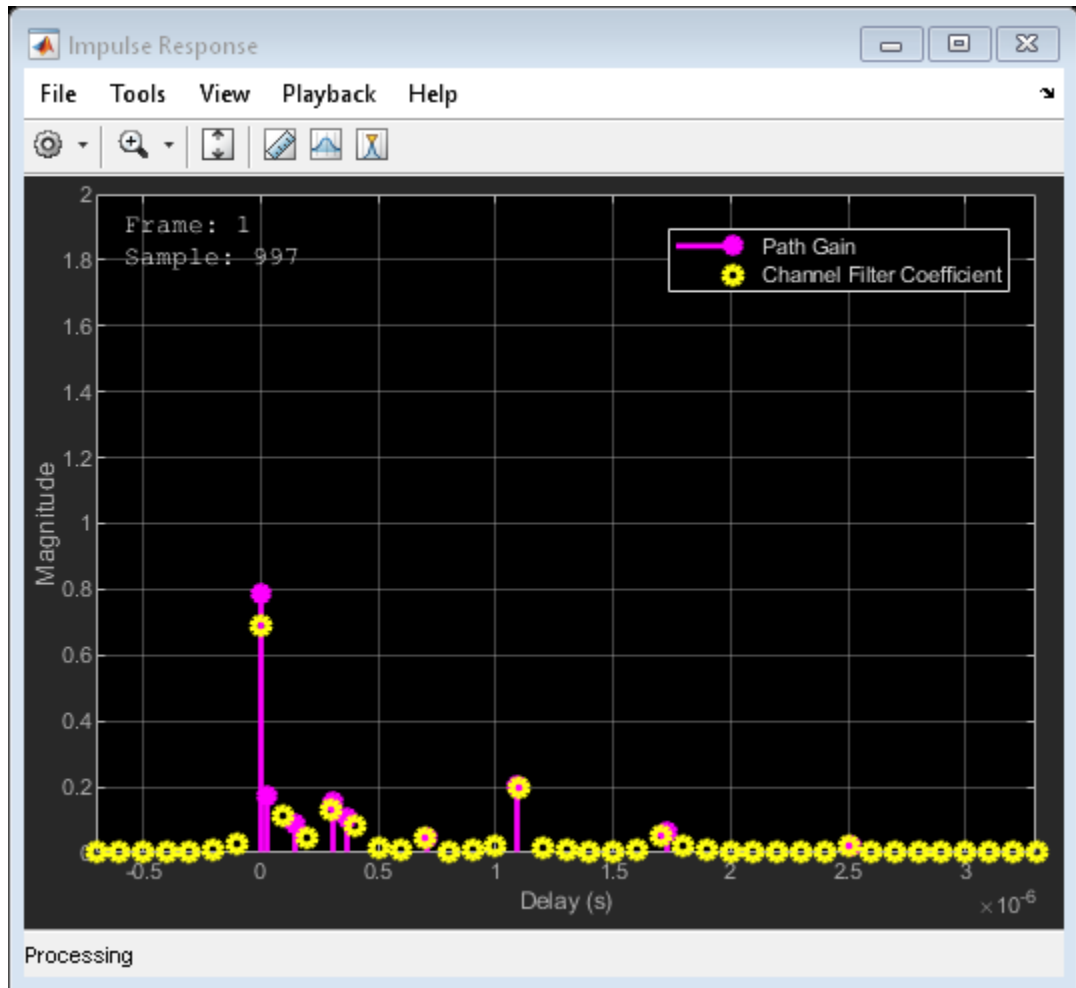

```
x = randi([0 1],1000,2);  
y = mimoChan(x);
```

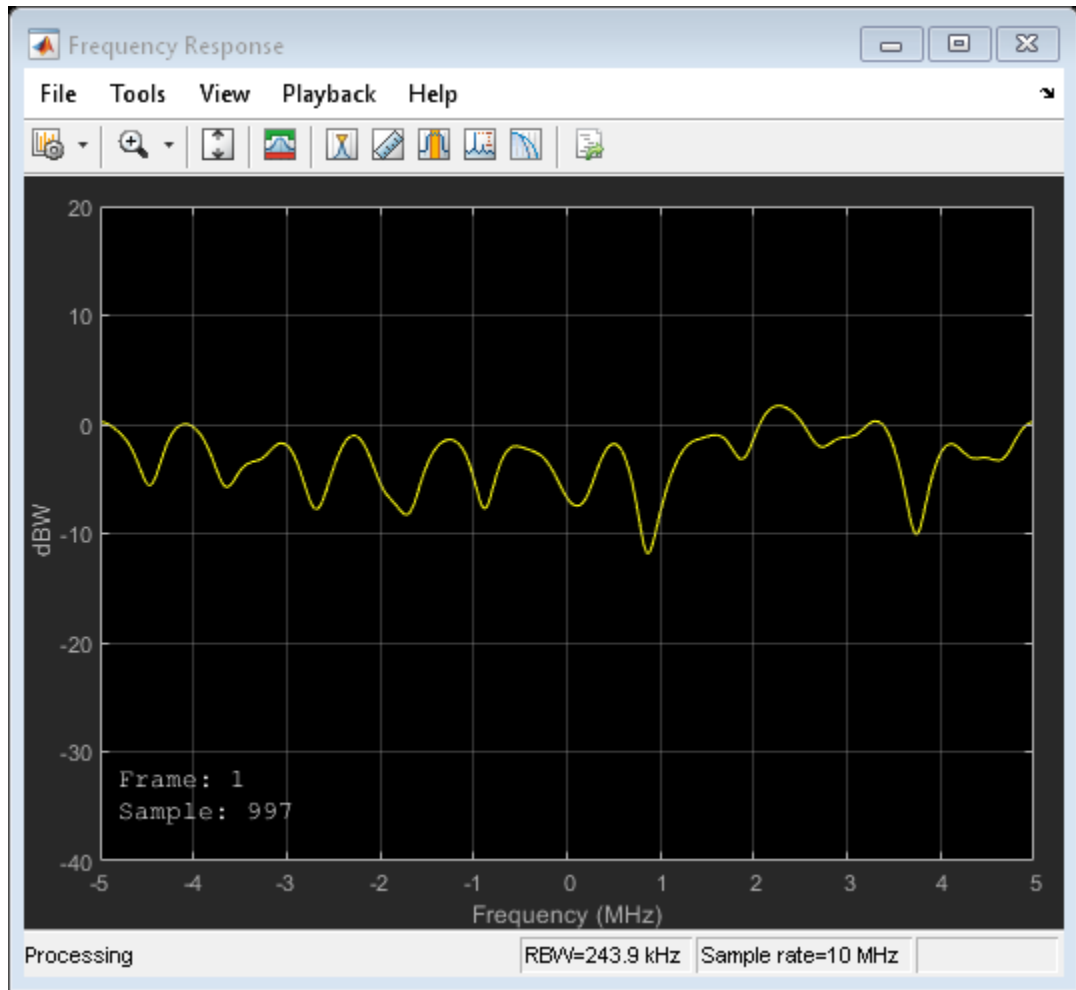

Release `mimoChan` and set the `AntennaPairsToDisplay` property to `[2 1]` to view the antenna pair corresponding to transmit antenna 2 and receive antenna 1. It is necessary to release the object as the property is non-tunable.

```
release(mimoChan)
mimoChan.AntennaPairsToDisplay = [2 1];
y = mimoChan(x);
```

### Display Doppler for 2x2 MIMO Channel

Create and visualize the Doppler spectra of a MIMO channel having two paths.

Construct a cell array of Doppler structures to be used in creating the channel. The Doppler spectrum of the first path is set to have a bell shape while the second path is set to be flat.

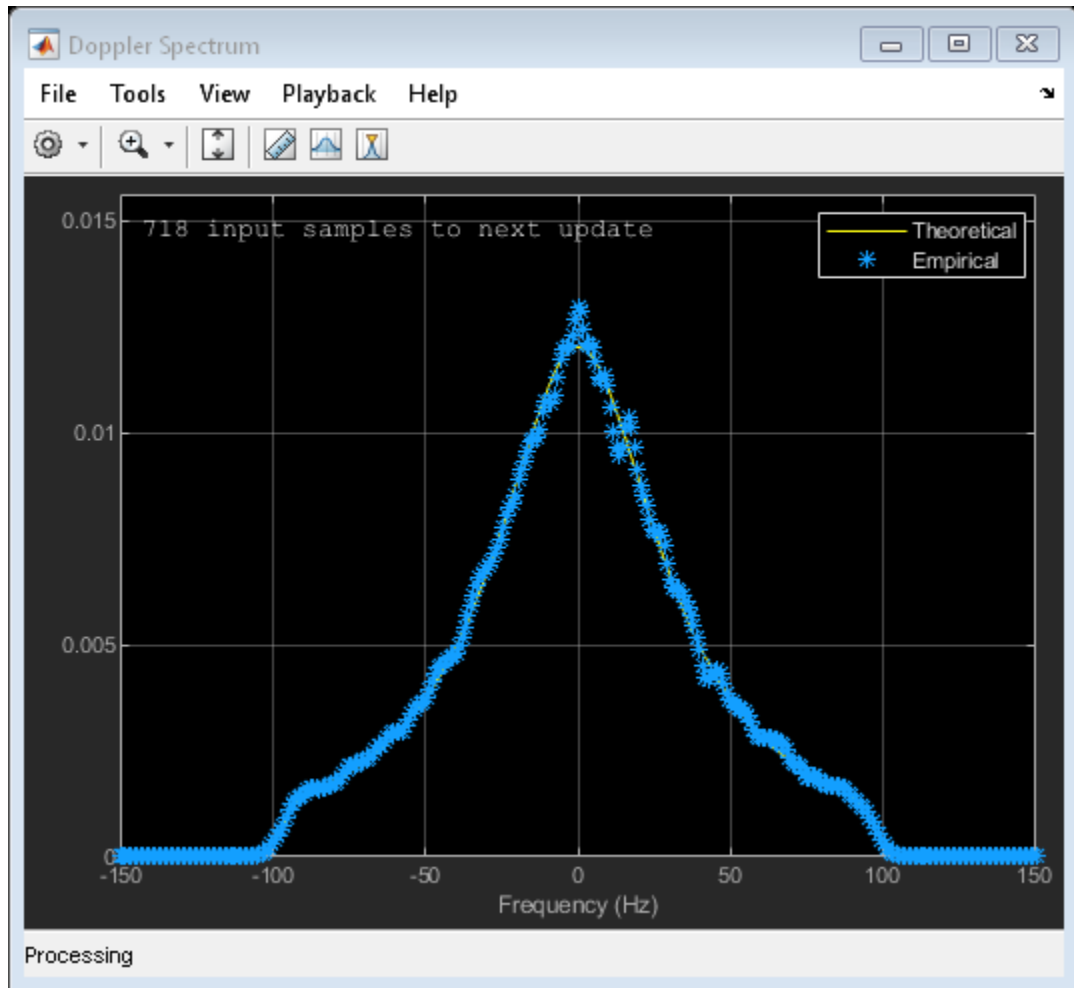

```
dp{1} = doppler('Bell');  
dp{2} = doppler('Flat');
```

Create a default 2x2 MIMO channel with two paths and a 100 Hz maximum Doppler shift using name-value pairs. Set the `Visualization` property to `Doppler spectrum` and set `PathsForDopplerDisplay` to 1. The Doppler spectrum of the first path will be displayed.

```
mimoChan = comm.MIMOChannel('SampleRate',1000, ...  
    'PathDelays',[0 0.002], ...  
    'AveragePathGains',[0 -3], ...  
    'MaximumDopplerShift',100, ...  
    'DopplerSpectrum',dp, ...  
    'Visualization','Doppler spectrum', ...  
    'PathsForDopplerDisplay',1);
```

Pass random data through the MIMO channel to generate the Doppler spectrum of the first path. Since the Doppler spectrum plot only updates when its buffer is filled, the `mimoChan` function is invoked multiple times to improve the accuracy of the estimate. Observe that the spectrum has a bell shape and that its minimum and maximum frequencies fall within the limits set by `MaximumDopplerShift`.

```
for k = 1:25  
    x = randi([0 1],10000,2);  
    y = mimoChan(x);  
end
```

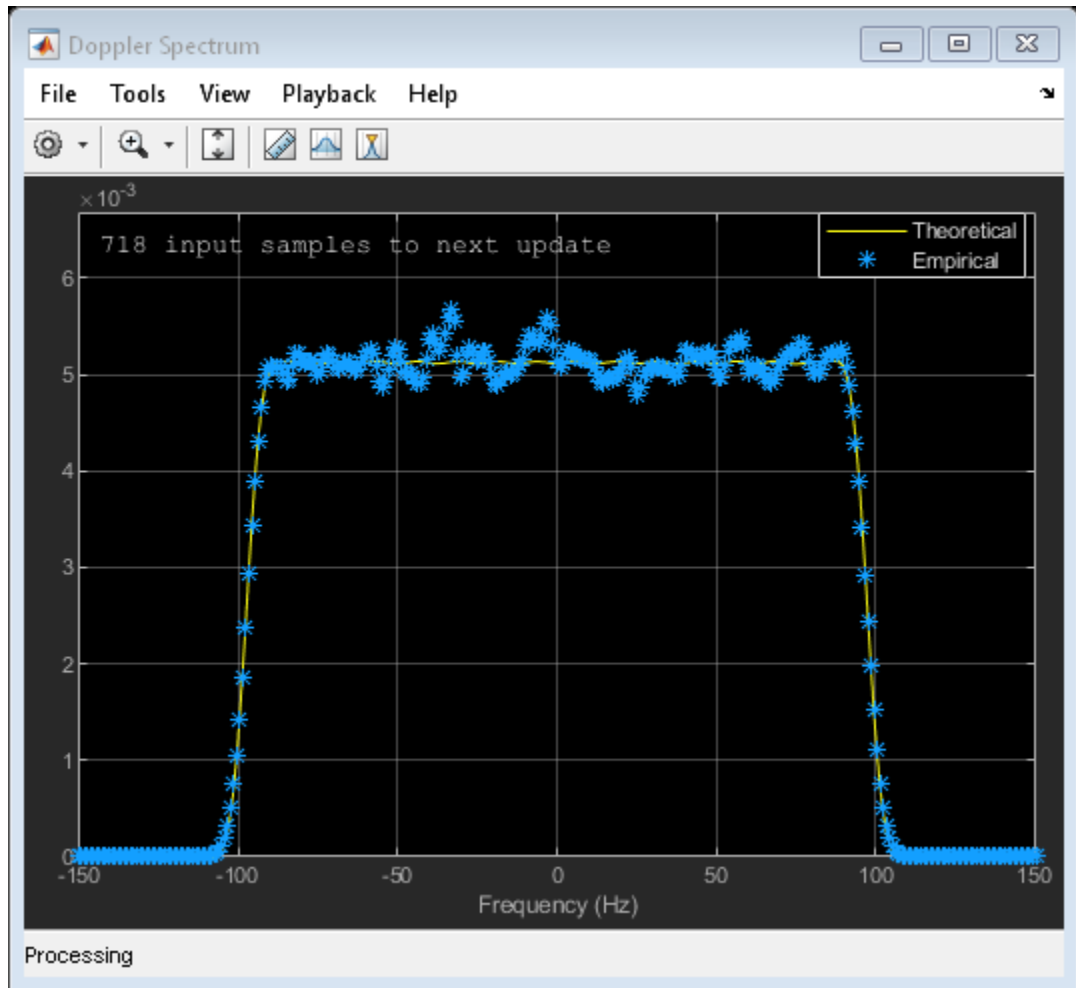

Release `mimoChan` and set the `PathsForDopplerDisplay` property to 2. It is necessary to release the object as the property is non-tunable. Call the function multiple times to display the Doppler spectrum of the second path. Observe that the spectrum is flat.

```
release(mimoChan)
mimoChan.PathsForDopplerDisplay = 2;
for k = 1:25
    x = randi([0 1],10000,2);
```

```
y = mimoChan(x);  
end
```

### Model MIMO Channel Using Sum-of-Sinusoids Technique

Create a MIMO channel object and pass data through it using the sum-of-sinusoids technique. The example demonstrates how the channel state is maintained in cases in which data is discontinuously transmitted.

Define the overall simulation time and three time segments for which data will be transmitted. In this case, the channel is simulated for 1 s with a 1000 Hz sampling rate. One 1000-sample, continuous data sequence is transmitted at time 0. Three 100-sample data packets are transmitted at time 0.1 s, 0.4 s, and 0.7 s.

```
t0 = 0:0.001:0.999; % Transmission 0
t1 = 0.1:0.001:0.199; % Transmission 1
t2 = 0.4:0.001:0.499; % Transmission 2
t3 = 0.7:0.001:0.799; % Transmission 3
```

Generate random binary data corresponding to the previously defined time intervals.

```
d0 = randi([0 1],1000,2); % 1000 samples
d1 = randi([0 1],100,2); % 100 samples
d2 = randi([0 1],100,2); % 100 samples
d3 = randi([0 1],100,2); % 100 samples
```

Create a flat fading 2x2 MIMO channel System object with the Sum of sinusoids fading technique. So that results can be repeated, specify a seed using a name-value pair. As the `InitialTime` property is not specified, the fading channel will be simulated from time 0. Enable the path gains output port.

```
mimoChan1 = comm.MIMOChannel('SampleRate',1000, ...
    'MaximumDopplerShift',5, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'PathGainsOutputPort',true);
```

Create a clone of the MIMO channel System object. Set the `InitialTimeSource` property to `Input port` so that the fading channel offset time can be specified as an input argument to the `mimoChan` function.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
```

Pass random binary data through the first channel object, `mimoChan1`. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.

```
[~,pg0] = mimoChan1(d0);
```

Pass random data through the second channel object, `mimoChan2`, where the initial time offsets are provided as input arguments.

```
[~,pg1] = mimoChan2(d1,0.1);
[~,pg2] = mimoChan2(d2,0.4);
[~,pg3] = mimoChan2(d3,0.7);
```

Compare the number of samples processed by the two channels using the `info` method. You can see that 1000 samples were processed by `mimoChan1` while only 300 were processed by `mimoChan2`.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1×2
```

```
1000    300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```
pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));
```

Plot the path gains for the continuous and discontinuous cases. Observe that the gains for the three segments perfectly match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data as the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
```

```
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
```

### Calculate Execution Time Advantage Using Sum of Sinusoids

Demonstrate the advantage of using the sum of sinusoids fading technique when simulating a channel with burst data.

Set the simulation parameters such that the sampling rate is 100 kHz, the total simulation time is 100 seconds, and the duty cycle for the burst data is 25%.

```
fs = 1e5;           % Hz
tsim = 100;        % seconds
dutyCycle = 0.25;
```

Create a flat fading 2x2 MIMO channel object using the default Filtered Gaussian noise technique.

```
fgn = comm.MIMOChannel('SampleRate',fs);
```

Create a similar MIMO channel object using the Sum of sinusoids technique where the fading process start times are given as an input argument.

```
sos = comm.MIMOChannel('SampleRate',fs, ...
    'FadingTechnique','Sum of sinusoids', ...
    'NumSinusoids',48, ...
    'InitialTimeSource','Input port');
```

Run a continuous sequence of random bits through the filtered Gaussian noise MIMO channel object. Use the tic/toc stopwatch timer functions to measure the execution time of the function call.

```
tic
y = fgn(randi([0 1],fs*tsim,2));
tFGN = toc;
```

To transmit a data burst each second, pass random bits through the sum of sinusoids MIMO channel object by calling the sos function inside of a for loop. Use the tic/toc stopwatch timer to measure the execution time.

```
tic
for k = 1:tsim
    z = sos(randi([0 1],fs*dutyCycle,2),0.5+(k-1));
end
tSOS = toc;
```

Compare the ratio of the sum of sinusoids execution time to the filtered Gaussian noise execution time. The ratio is less than one, which indicates that the sum of sinusoids technique is faster.

```
tSOS/tFGN
```

```
ans = 0.2691
```

## Algorithms

The fading processing per link is described in Methodology for Simulating Multipath Fading Channels and assumes the same parameters for all ( $N_T \times N_R$ ) links of the MIMO channel. Each link comprises all multipaths for that link.

### The Kronecker Model

The Kronecker model assumes that the spatial correlations at the transmit and receive sides are separable. Equivalently, the direction of departure (DoD) and directions of arrival (DoA) spectra are assumed to be separable. The full correlation matrix is:

$$R_H = E[R_t \otimes R_r]$$

- The  $\otimes$  symbol represents the Kronecker product.
- $R_t$  represents the correlation matrix at the transmit side:  $R_t = E[H^H H]$ , of size  $N_T$ -by- $N_T$ .
- $R_r$  represents the correlation matrix at the receive side:  $R_r = E[HH^H]$ , of size  $N_R$ -by- $N_R$ .

You can obtain a realization of the MIMO channel matrix as:

$$H = R_r^{\frac{1}{2}} A R_t^{\frac{1}{2}}$$

$A$  is an  $N_R$ -by- $N_T$  matrix of independent identically distributed complex Gaussian variables with zero mean and unit variance.

### Cutoff Frequency Factor

The following information explains how the cutoff frequency factor,  $f_c$ , is determined for different Doppler spectrum types:

- For any Doppler spectrum type other than Gaussian and BiGaussian,  $f_c$  equals 1.
- For a doppler( 'Gaussian' ) spectrum type,  $f_c$  equals `NormalizedStandardDeviation*sqrt(2*log(2))`.

- For a doppler( 'BiGaussian' ) spectrum type:
  - If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \cdot \sqrt{2 \cdot \log(2)}$ .
  - If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(2) \cdot \sqrt{2 \cdot \log(2)}$ .
  - If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \cdot \sqrt{2 \cdot \log(2)}$ .
  - In all other cases,  $f_c$  equals 1.

## Antenna Selection

When the object is in antenna selection mode, it uses the following algorithms to process an input signal:

- All random path gains are always generated and keep evolving for each link, whether or not a given link is selected. The path gain values output for the non-selected links are populated with NaN.
- The spatial correlation only applies to the selected transmit and/or receive antennas, and the correlation coefficients are the corresponding entries in the transmit, receive, or combined correlation matrices. In other words, the spatial correlation matrix for the selected transmit or receive antennas is a submatrix of the transmit, receive, or combined spatial correlation matrix property value.
- For signal paths associated with nonactive antennas, a signal with zero power is transmitted to the channel filter.
- Channel output normalization happens over the number of selected receive antennas.

# info

**Package:** comm

Characteristic information about the fading channel object

## Syntax

```
infostruct = info(obj)
```

## Description

`infostruct = info(obj)` returns a structure containing characteristic information for the System object.

## Examples

### Get comm.MIMOChannel Info

Use the `info` object function to get information from a `comm.MIMOChannel` object.

Create a MIMO channel object and some data to pass through the channel.

```
mimo = comm.MIMOChannel('SampleRate',1000);  
data = randi([0 1],600,2);
```

Check the MIMO channel object information

```
info(mimo)
```

```
ans = struct with fields:  
    ChannelFilterDelay: 0  
    ChannelFilterCoefficients: 1  
    NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
mimo(data);  
info(mimo)  
  
ans = struct with fields:  
    ChannelFilterDelay: 0  
    ChannelFilterCoefficients: 1  
    NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a two second path delay. Recheck the object information.

```
release(mimo)  
mimo.PathDelays = 2;  
info(mimo)  
  
ans = struct with fields:  
    ChannelFilterDelay: 0  
    ChannelFilterCoefficients: [1x2001 double]  
    NumSamplesProcessed: 0
```

### Model MIMO Channel Using Sum-of-Sinusoids Technique

Create a MIMO channel object and pass data through it using the sum-of-sinusoids technique. The example demonstrates how the channel state is maintained in cases in which data is discontinuously transmitted.

Define the overall simulation time and three time segments for which data will be transmitted. In this case, the channel is simulated for 1 s with a 1000 Hz sampling rate. One 1000-sample, continuous data sequence is transmitted at time 0. Three 100-sample data packets are transmitted at time 0.1 s, 0.4 s, and 0.7 s.

```
t0 = 0:0.001:0.999;    % Transmission 0  
t1 = 0.1:0.001:0.199; % Transmission 1  
t2 = 0.4:0.001:0.499; % Transmission 2  
t3 = 0.7:0.001:0.799; % Transmission 3
```

Generate random binary data corresponding to the previously defined time intervals.

```

d0 = randi([0 1],1000,2); % 1000 samples
d1 = randi([0 1],100,2); % 100 samples
d2 = randi([0 1],100,2); % 100 samples
d3 = randi([0 1],100,2); % 100 samples

```

Create a flat fading 2x2 MIMO channel System object with the `Sum of sinusoids` fading technique. So that results can be repeated, specify a seed using a name-value pair. As the `InitialTime` property is not specified, the fading channel will be simulated from time 0. Enable the path gains output port.

```

mimoChan1 = comm.MIMOChannel('SampleRate',1000, ...
    'MaximumDopplerShift',5, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'PathGainsOutputPort',true);

```

Create a clone of the MIMO channel System object. Set the `InitialTimeSource` property to `Input port` so that the fading channel offset time can be specified as an input argument to the `mimoChan` function.

```

mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';

```

Pass random binary data through the first channel object, `mimoChan1`. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.

```

[~,pg0] = mimoChan1(d0);

```

Pass random data through the second channel object, `mimoChan2`, where the initial time offsets are provided as input arguments.

```

[~,pg1] = mimoChan2(d1,0.1);
[~,pg2] = mimoChan2(d2,0.4);
[~,pg3] = mimoChan2(d3,0.7);

```

Compare the number of samples processed by the two channels using the `info` method. You can see that 1000 samples were processed by `mimoChan1` while only 300 were processed by `mimoChan2`.

```

G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]

```

```
ans = 1×2  
  
      1000      300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```
pathGain0 = 20*log10(abs(pg0(:,1,1,1)));  
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));  
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));  
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));
```

Plot the path gains for the continuous and discontinuous cases. Observe that the gains for the three segments perfectly match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data as the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')  
hold on  
plot(t1,pathGain1,'b')  
plot(t2,pathGain2,'b')  
plot(t3,pathGain3,'b')  
grid  
xlabel('Time (sec)')  
ylabel('Path Gain (dB)')  
legend('Continuous','Discontinuous','location','nw')
```

## Input Arguments

**obj** — System object to get information from

System object

System object to get information from.

# Output Arguments

### **infostruct** — Structure containing object information

struct

Structure containing these fields with information about the System object.

### **ChannelFilterDelay** — Channel filter delay

positive integer

Channel filter delay in samples, returned as a positive integer.

### **ChannelFilterCoefficients** — Channel filter coefficients

matrix

Channel filter coefficients, returned as a matrix. The coefficient matrix is used to convert path gains to channel filter tap gains for each sample and each pair of transmit and receive antennas.

### **NumSamplesProcessed** — Number of samples processed by the channel object

positive integer

Number of samples processed by the channel object since the last reset, returned as a positive integer.

### **LastFrameTime** — Last frame ending time

positive scalar

Last frame ending time in seconds, returned as a positive scalar. Use this value to confirm the simulation time.

### **Dependencies**

This property applies when `FadingTechnique` is 'Sum of sinusoids' and `InitialTimeSource` is 'Input port'.

## comm.MLSEEqualizer

**Package:** comm

Equalize using maximum likelihood sequence estimation

### Description

The `MLSEEqualizer` object uses the Viterbi algorithm to equalize a linearly modulated signal through a dispersive channel. The object processes input frames and outputs the maximum likelihood sequence estimate (MLSE) of the signal. This processing uses an estimate of the channel modeled as a finite impulse response (FIR) filter.

To equalize a linearly modulated signal and output the maximum likelihood sequence estimate:

- 1 Define and set up your maximum likelihood sequence estimate equalizer object. See “Construction” on page 4-1278.
- 2 Call `step` to equalize a linearly modulated signal and output the maximum likelihood sequence estimate according to the properties of `comm.MLSEEqualizer`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.MLSEEqualizer` creates a maximum likelihood sequence estimation equalizer (MLSEE) System object, `H`. This object uses the Viterbi algorithm and a channel estimate to equalize a linearly modulated signal that has been transmitted through a dispersive channel.

`H = comm.MLSEEqualizer(Name, Value)` creates an MLSEE object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.MLSEEqualizer(CHANNEL, Name, Value)` creates an MLSEE object, `H`. This object has the `Channel` property set to `CHANNEL`, and the other specified properties set to the specified values.

## Properties

### ChannelSource

Source of channel coefficients

Specify the source of the channel coefficients as one of `Input port | Property`. The default is `Property`.

### Channel

Channel coefficients

Specify the channel as a numeric, column vector containing the coefficients of an FIR filter. The default is `[1;0.7;0.5;0.3]`. The length of this vector determines the memory length of the channel. This must be an integer multiple of the samples per symbol, that you specify in the `SamplesPerSymbol` on page 4-0 property. This property applies when you set the `ChannelSource` on page 4-0 property to `Property`.

### Constellation

Input signal constellation

Specify the constellation of the input modulated signal as a complex vector. The default is `[1+1i -1+1i -1-1i 1-1i]`.

### TracebackDepth

Traceback depth of Viterbi algorithm

Specify the number of trellis branches (the number of symbols), the Viterbi algorithm uses to construct each traceback path. The default is 21. The traceback depth influences the decoding accuracy and delay. The decoding delay represents the number of zero

symbols that precede the first decoded symbol in the output. When you set the `TerminationMethod` on page 4-0 property to `Continuous`, the decoding delay equals the number of zero symbols of this property. When you set the `TerminationMethod` property to `Truncated`, there is no output delay.

### **TerminationMethod**

Termination method of Viterbi algorithm

Specify the termination method of the Viterbi algorithm as one of `Continuous` | `Truncated`. The default is `Truncated`. When you set this property to `Continuous`, the object initializes the Viterbi algorithm metrics of all the states to 0 in the first call to the `step` method. Then, the object saves its internal state metric at the end of each frame, for use with the next frame. When you set this property to `Truncated`, the object resets at every frame. The Viterbi algorithm processes each frame of data independently, resetting the state metric at the end of each frame. The traceback path always starts at the state with the minimum metric. The initialization of the state metrics depends on whether you specify a preamble or postamble. If you set the `PreambleSource` on page 4-0 property to `None`, the object initializes the metrics of all the states to 0 at the beginning of each data frame. If you set the `PreambleSource` property to `Property`, the object uses the preamble that you specify at the `Preamble` on page 4-0 property, to initialize the state metrics at the beginning of each data frame. When you specify a preamble, the traceback path ends at one of the states represented by that preamble. If you set the `PostambleSource` on page 4-0 property to `None`, the traceback path starts at the state with the smallest metric. If you set the `PostambleSource` property to `Property`, the traceback path begins at the state represented by the postamble that you specify at the `Postamble` on page 4-0 property. If the postamble does not decode to a unique state, the decoder identifies the smallest of all possible decoded states that are represented by the postamble. The decoder then begins traceback decoding at that state. When you set this property to `Truncated`, the `step` method input data signal must contain at least `TracebackDepth` on page 4-0 symbols, not including an optional preamble.

### **ResetInputPort**

Enable equalizer reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this input is a nonzero, double-precision or logical scalar value, the object resets the states of the equalizer. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous`.

## PreambleSource

Source of preamble

Specify the source of the preamble that is expected to precede the input signal. Choose from `None` | `Property`. The default is `None`. Set this property to `Property` to specify a preamble using the `Preamble` on page 4-0 property. This property applies when you set the `TerminationMethod` on page 4-0 property to `Truncated`.

## Preamble

Preamble that precedes input signals

Specify a preamble that is expected to precede the data in the input signal as an integer row vector. The default is `[0 3 2 1]`. The values of the preamble should be between `0` and `M-1`, where `M` is the length of the signal constellation that you specify in the `Constellation` on page 4-0 property. An integer value of `k-1` in the vector corresponds to the `k`-th entry in the vector stored in the `Constellation` property. This property applies when you set the `TerminationMethod` on page 4-0 property to `Truncated` and the `PreambleSource` on page 4-0 property to `Property`.

## PostambleSource

Source of postamble

Specify the source of the postamble that is expected to follow the input signal. Choose from `None` | `Property`. The default is `None`. Set this property to `Property` to specify a postamble in the `Postamble` on page 4-0 property. This property applies when you set the `TerminationMethod` on page 4-0 property to `Truncated`.

## Postamble

Postamble that follows input signals

Specify a postamble that is expected to follow the data in the input signal as an integer row vector. The default is `[0 2 3 1]`. The values of the postamble should be between `0` and `M-1`. In this case, `M` indicates the length of the `Constellation` on page 4-0 property. An integer value of `k-1` in the vector corresponds to the `k`-th entry in the vector specified in the `Constellation` property. This property applies when you set the `TerminationMethod` on page 4-0 property to `Truncated` and the `PostambleSource` on page 4-0 property to `Property`. The default is `[0 2 3 1]`.

### SamplesPerSymbol

Number of samples per symbol

Specify the number of samples per symbol in the input signal as an integer scalar value. The default is 1.

## Methods

reset    Reset states of MLSEE object

step    Equalize using maximum likelihood sequence estimation

Common to All System Objects	
release	Allow System object property value changes

## Examples

### MLSE Equalize QPSK Signal Through Dispersive Channel

This example shows how to use an MLSE equalizer to remove the effects of a frequency-selective channel.

Specify static channel coefficients.

```
chCoeffs = [.986; .845; .237; .12345+.31i];
```

Create an MLSE equalizer object. Create an error rate calculator object.

```
mlse = comm.MLSEEqualizer('TracebackDepth',10,...  
    'Channel',chCoeffs,'Constellation',pskmod(0:3,4,pi/4));  
errorRate = comm.ErrorRate;
```

The main processing loop includes these steps:

- Data generation
- QPSK modulation

- Channel filtering
- Signal equalization
- QPSK demodulation
- Error computation

```

for n = 1:50
    data= randi([0 3],100,1);
    modSignal = pskmod(data,4,pi/4,'gray');

    % Introduce channel distortion.
    chanOutput = filter(chCoeffs,1,modSignal);

    % Equalize the channel output and demodulate.
    eqSignal = mlse(chanOutput);
    demodData = pskdemod(eqSignal,4,pi/4,'gray');

    % Compute BER.
    errorStats = errorRate(data,demodData);
end

```

Display the bit error rate and the number of errors.

```

ber = errorStats(1)
numErrors = errorStats(2)

```

```
ber =
```

```
0
```

```
numErrors =
```

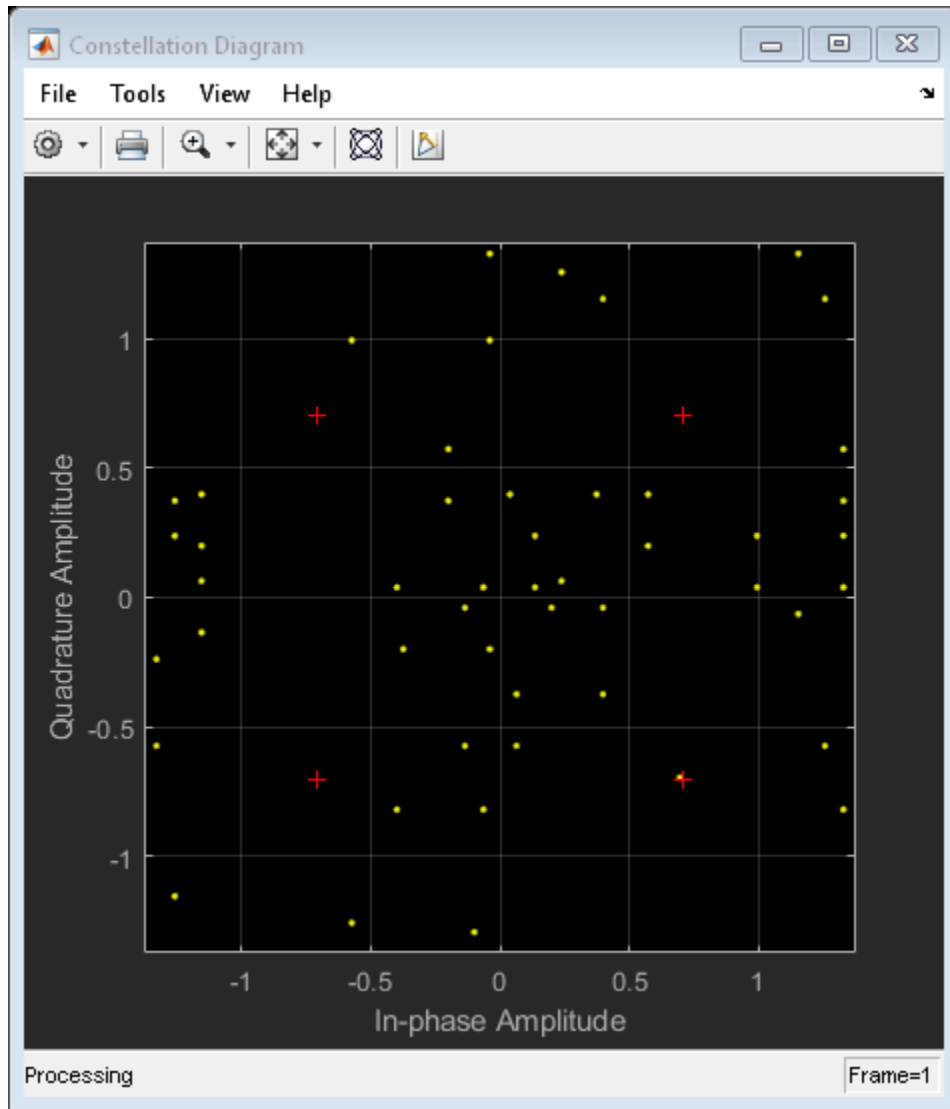

```
0
```

Plot the signal constellation prior to equalization.

```

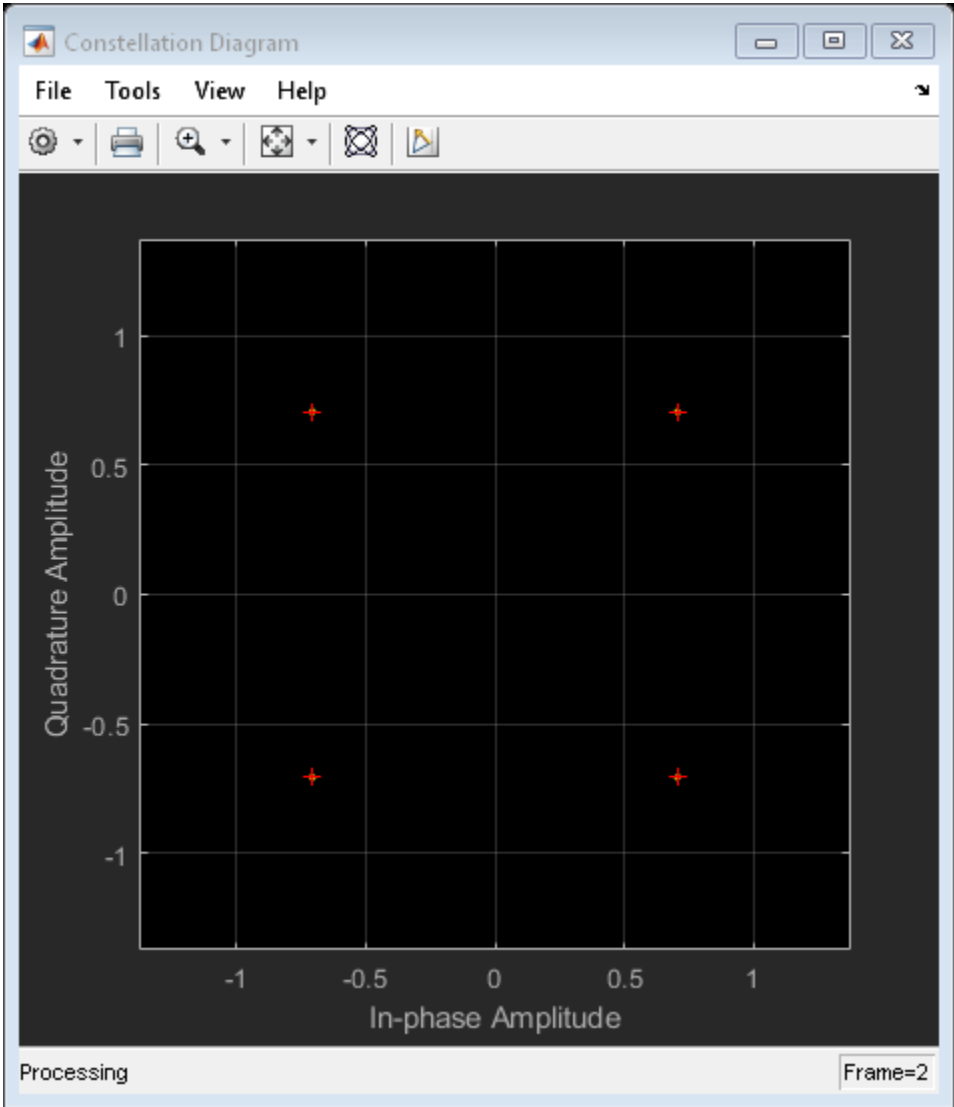

constDiagram = comm.ConstellationDiagram;
constDiagram(chanOutput)

```

Plot the signal constellation after equalization.

```
constDiagram(eqSignal)
```

The equalized symbols align perfectly with the QPSK reference constellation.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MLSE Equalizer block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## reset

**System object:** comm.MLSEEqualizer

**Package:** comm

Reset states of MLSEE object

## Syntax

reset(H)

## Description

reset(H) resets the states of the MLSEEqualizer object, H.

# step

**System object:** comm.MLSEEqualizer

**Package:** comm

Equalize using maximum likelihood sequence estimation

## Syntax

```
Y = step(H,X)
Y = step(H,X,CHANNEL)
Y = step(H,X,RESET)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` equalizes the linearly modulated data input, `X`, using the Viterbi algorithm. The `step` method outputs `Y`, the maximum likelihood sequence estimate of the signal. Input `X` must be a column vector of data type `double` or `single`.

`Y = step(H,X,CHANNEL)` uses `CHANNEL` as the channel coefficients when you set the `ChannelSource` property to `'Input port'`. The channel coefficients input, `CHANNEL`, must be a numeric, column vector containing the coefficients of an FIR filter in descending order of powers of `z`. The length of this vector is the channel memory, which must be an integer multiple of the samples per input symbol specified in the `SamplesPerSymbol` property.

`Y = step(H,X,RESET)` uses `RESET` as the reset signal when you set the `TerminationMethod` property to `'Continuous'` and the `ResetInputPort` property to `true`. The object resets when `RESET` has a non-zero value. `RESET` must be a double precision or logical scalar. You can combine optional input arguments when you set their

enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties. For example, `Y = step(H,X,CHANNEL,RESET)`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.MSKDemodulator

**Package:** comm

Demodulate using MSK method and the Viterbi algorithm

### Description

The `comm.MSKDemodulator` object demodulates a signal that was modulated using the minimum shift keying method. The object expects the input signal to be a baseband representation of a coherent modulated signal with no precoding. The initial phase offset property sets the initial phase of the modulated waveform.

To demodulate a signal that was modulated using minimum shift keying:

- 1 Define and set up your MSK demodulator object. See “Construction” on page 4-1290.
- 2 Call `step` to demodulate the signal according to the properties of `comm.MSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.MSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input minimum shift keying (MSK) modulated data using the Viterbi algorithm.

`H = comm.MSKDemodulator(Name,Value)` creates an MSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector with a length equal to `N/SamplesPerSymbol` on page 4-0 .  $N$  represents the length of the input signal, which is the number of input baseband modulated symbols. The elements of the output vector are `-1` or `1`.

When you set the `BitOutput` on page 4-0 property to `true`, the `step` method outputs a binary column vector with a length equal to `N/SamplesPerSymbol`. The vector elements are bit values of `0` or `1`.

### InitialPhaseOffset

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar value. The default is `0`.

### SamplesPerSymbol

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar value. The default is `8`.

### TracebackDepth

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar value. The default is `16`. The value of this property is also the output delay. This value indicates number of zero symbols that precede the first meaningful demodulated symbol in the output.

## OutputDataType

Data type of output

Specify the output data type as one of `int8` | `int16` | `int32` | `double`, when you set the `BitOutput` on page 4-0 property to `false`. The default is `double`.

When you set the `BitOutput` property to `true`, specify the output data type as one of `logical` | `double`.

## Methods

`reset`    Reset states of the MSK demodulator object  
`step`     Demodulate using MSK method and the Viterbi algorithm

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Demodulate an MSK signal with bit inputs and phase offset

```
% Create an MSK modulator, an AWGN channel, and an MSK demodulator. Use a  
% phase offset of pi/4.
```

```
hMod = comm.MSKModulator('BitInput', true, ...  
                        'InitialPhaseOffset', pi/4);  
hAWGN = comm.AWGNChannel('NoiseMethod', ...  
                        'Signal to noise ratio (SNR)', 'SNR', 0);  
hDemod = comm.MSKDemodulator('BitOutput', true, ...  
                            'InitialPhaseOffset', pi/4);
```

```
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
```

```
hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);  
for counter = 1:100  
    % Transmit 100 3-bit words  
    data = randi([0 1], 300, 1);  
    modSignal = step(hMod, data);  
    noisySignal = step(hAWGN, modSignal);  
    receivedData = step(hDemod, noisySignal);
```

```

    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))

```

```

Error rate = 0.000000
Number of errors = 0

```

### Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```

x = zeros(5,1);
y = gmsk(x)

```

*y = 5×1 complex*

```

    1.0000 + 0.0000i
   -0.0000 - 1.0000i
   -1.0000 + 0.0000i
    0.0000 + 1.0000i
    1.0000 - 0.0000i

```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

*theta = 5×1*

```

    0
   -1.5708
   -3.1416

```

```
-4.7124  
-6.2832
```

A sequence of zeros causes the phase to shift by  $-\pi/2$  between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)  
x = ones(5,1);  
y = gmsk(x)
```

*y = 5×1 complex*

```
1.0000 + 0.0000i  
-0.0000 + 1.0000i  
-1.0000 - 0.0000i  
0.0000 - 1.0000i  
1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

*theta = 5×1*

```
0  
1.5708  
3.1416  
4.7124  
6.2832
```

A sequence of ones causes the phase to shift by  $+\pi/2$  between samples.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For MSK the phase shift per symbol is  $\pi/2$ , which is a modulation index of 0.5.

Demodulate using MSK method and the Viterbi algorithm

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates input data,  $X$ , with the MSK demodulator System object,  $H$ , and returns  $Y$ .  $X$  must be a double or single precision column vector with a length equal to an integer multiple of the number of samples per symbol you specify in the `SamplesPerSymbol` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.MSKModulator

**Package:** comm

Modulate using MSK method

### Description

The `MSKModulator` object modulates using the minimum shift keying method. The output is a baseband representation of the modulated signal. The `initialPhaseOffset` property sets the initial phase of the output waveform, measured in radians.

To modulate a signal using minimum shift keying:

- 1 Define and set up your MSK modulator object. See “Construction” on page 4-1298.
- 2 Call `step` to modulate the signal according to the properties of `comm.MSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.MSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the minimum shift keying (MSK) modulation method.

`H = comm.MSKModulator(Name,Value)` creates an MSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`.

When you set the `BitInput` on page 4-0 property to `false`, the `step` method input must be a column vector with a double-precision or signed integer data type and of values equal to `-1` or `1`.

When you set the `BitInput` property to `true`, the `step` method input requires double-precision or logical data type column vector of `0s` and `1s`.

### InitialPhaseOffset

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar value. The default is `0`.

### SamplesPerSymbol

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar value. The default is `8`. The upsampling factor indicates the number of output samples that the `step` method produces for each input sample.

### OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

## Methods

reset      Reset states of the MSK modulator object  
step        Modulate using MSK method

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Modulate an MSK signal with bit inputs and phase offset

```
% Create an MSK modulator, an AWGN channel, and an MSK demodulator. Use a
% phase offset of pi/4.
hMod = comm.MSKModulator('BitInput', true, ...
    'InitialPhaseOffset', pi/4);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.MSKDemodulator('BitOutput', true, ...
    'InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1], 300, 1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))

Error rate = 0.000000
Number of errors = 0
```

## Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
```

```
y = 5×1 complex
```

```
1.0000 + 0.0000i
-0.0000 - 1.0000i
-1.0000 + 0.0000i
0.0000 + 1.0000i
1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1
```

```
0
-1.5708
-3.1416
-4.7124
-6.2832
```

A sequence of zeros causes the phase to shift by  $-\pi/2$  between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
```

```
y = 5x1 complex
```

```
1.0000 + 0.0000i  
-0.0000 + 1.0000i  
-1.0000 - 0.0000i  
0.0000 - 1.0000i  
1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5x1
```

```
0  
1.5708  
3.1416  
4.7124  
6.2832
```

A sequence of ones causes the phase to shift by  $+\pi/2$  between samples.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the [MSK Demodulator Baseband](#) block reference page. The object properties correspond to the block parameters. For MSK the phase shift per symbol is  $\pi/2$ , which is a modulation index of 0.5.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

# step

**System object:** comm.MSKModulator

**Package:** comm

Modulate using MSK method

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  modulates input data,  $X$ , with the MSK modulator object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be a double precision, signed integer, or logical column vector. The length of output vector,  $Y$ , is equal to the number of input samples times the number of samples per symbol you specify in the `SamplesPerSymbol` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.MSKTimingSynchronizer

**Package:** comm

Recover symbol timing phase using fourth-order nonlinearity method

### Description

The `MSKTimingSynchronizer` object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This object implements a general non-data-aided feedback method that is independent of carrier phase recovery. This method requires prior compensation for the carrier frequency offset. This object is suitable for systems that use baseband minimum shift keying (MSK) modulation.

To recover the symbol timing phase of the input signal:

- 1 Define and set up your MSK timing synchronizer object. See “Construction” on page 4-1306.
- 2 Call `step` to recover the symbol timing phase of the input signal according to the properties of `comm.MSKTimingSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.MSKTimingSynchronizer` creates a timing phase synchronizer System object, `H`. This object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method.

`H = comm.MSKTimingSynchronizer(Name,Value)` creates an MSK timing synchronizer object, `H`, with each specified property set to the specified value. You can

specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### **SamplesPerSymbol**

Number of samples representing each symbol

Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar greater than 1. The default is 4.

### **ErrorUpdateGain**

Error update step size

Specify the step size for updating successive timing phase estimates as a positive, real scalar value. The default is 0.05. Typically, this number is less than  $1/\text{SamplesPerSymbol}$  on page 4-0, which corresponds to a slowly varying timing phase. This property is tunable.

### **ResetInputPort**

Enable synchronization reset input

Set this property to `true` to enable resetting the timing phase recovery process based on an input argument value. The default is `false`.

When you set this property to `true`, you must specify a reset input value to the `step` method.

When the reset input is a nonzero value, the object restarts the timing phase recovery process. When you set this property to `false`, the object does not restart.

### **ResetCondition**

Condition for timing phase recovery reset

Specify the conditions to reset the timing phase recovery process as one of `Never` | `Every` frame. The default is `Never`.

When you set this property to `Never`, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to `Every frame`, the timing phase recovery restarts at the start of each frame of data. Thus, each time the object calls the `step` method. This property applies when you set the `ResetInputPort` on page 4-0 property to `false`.

## Methods

`reset` Reset states of MSK timing phase synchronizer object

`step` Recover symbol timing phase using fourth-order nonlinearity method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Recover Timing Phase of MSK Signal

Create MSK modulator, variable fractional delay, and MSK timing synchronizer System objects.

```
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',14);
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
mskTimingSync = comm.MSKTimingSynchronizer('SamplesPerSymbol',14,'ErrorUpdateGain',0.01);
```

Main processing loop.

```
phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1);    % Generate data
    modData = mskMod(data);      % Modulate data

    % Apply timing offset error.
    impairedData = varDelay(modData,timingOffset*14);
    % Perform timing phase recovery.
    [~,phase] = mskTimingSync(impairedData);
```

```
    phEst(i) = phase(1)/14;  
end
```

Plot the results.

```
plot(1:50,[0.2*ones(50,1) phEst]);  
legend('Original','Estimated')  
title('Original and Estimated timing phases');
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the **Modulation type** parameter set to MSK.
- The **Reset** parameter corresponds to the ResetInputPort on page 4-0 and ResetCondition on page 4-0 properties.

## comm.MultimultiplexedDeinterleaver

**Package:** comm

Deinterleave input symbols using set of shift registers with specified delays

### Description

The `MultiplexedDeinterleaver` object restores the original ordering of a sequence that was interleaved using the General Multiplexed Interleaver object.

To deinterleave the input symbols:

- 1 Define and set up your multiplexed deinterleaver object. See “Construction” on page 4-1314.
- 2 Call `step` to restore the original ordering of the input sequence according to the properties of `comm.MultimultiplexedDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.MultimultiplexedDeinterleaver` creates a multiplexed deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the multiplexed interleaver System object.

`H = comm.MultimultiplexedDeinterleaver(Name,Value)` creates a multiplexed deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### Delay

Interleaver delay

Specify the lengths of the shift registers as an integer column vector. The default is [2;0;1;3;10].

### InitialConditions

Initial conditions of shift registers

Specify the initial values in each shift register as a numeric scalar value or a column vector. The default is 0. When you set this property to a column vector, the vector length must equal the value of the Delay on page 4-0 property. This vector contains initial conditions, where the  $i$ -th initial condition is stored in the  $i$ th shift register.

## Methods

---------	--

## Examples

### Multiplexed Interleaving and Deinterleaving

Create interleaver and deinterleaver objects.

```
interleaver = comm.MultplexedInterleaver('Delay',[1; 0; 2; 1]);
deinterleaver = comm.MultplexedDeinterleaver('Delay',[1; 0; 2; 1]);
```

Generate a random data sequence. Pass the data sequence through the interleaver and deinterleaver.

```
[dataIn,dataOut] = deal([]);           % Initialize data arrays

for k = 1:50
    data = randi([0 7],20,1);          % Generate data sequence
    intData = interleaver(data);      % Interleave sequence
    deIntData = deinterleaver(intData); % Deinterleave sequence

    dataIn = cat(1,dataIn,data);      % Save original data
    dataOut = cat(1,dataOut,deIntData); % Save deinterleaved data
end
```

Determine the delay through the interleaver and deinterleaver.

```
intlvrDelay = finddelay(dataIn,dataOut)

intlvrDelay = 8
```

After accounting for the delay, confirm that the original and deinterleaved sequences are identical.

```
isequal(dataIn(1:end-intlvrDelay),dataOut(intlvrDelay+1:end))

ans = logical
     1
```

## step

**System object:** comm.MultplexedDeinterleaver

**Package:** comm

Deinterleave input symbols using a set of shift registers with specified delays

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  restores the original ordering of the sequence,  $X$ , that was interleaved using a multiplexed interleaver and returns  $Y$ . The input  $X$  must be a column vector. The data type for  $X$  can be numeric, logical, or fixed-point (fi objects).  $Y$  has the same data type as  $X$ . The multiplexed deinterleaver object uses  $N$  shift registers, where  $N$  is the number of elements in the vector specified by the `Delay` property. When a new input symbol enters the deinterleaver, a commutator switches to a new register. The new symbol shifts in while the oldest symbol in that register is shifted out. When the commutator reaches the  $N$ th register, upon the next new input, it returns to the first register. The multiplexed deinterleaver associated with a multiplexed interleaver has the same number of registers as the interleaver. The delay in a particular deinterleaver register depends on the largest interleaver delay minus the interleaver delay for the given register.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.MultplexedInterleaver

**Package:** comm

Permute input symbols using set of shift registers with specified delays

## Description

The `MultiplexedInterleaver` object permutes the symbols in the input signal. Internally, the object uses a set of shift registers, each with its own delay value.

To permute the symbols in the input signal:

- 1 Define and set up your multiplexed interleaver object. See “Construction” on page 4-1321.
- 2 Call `step` to interleave the input signal according to the properties of `comm.MultplexedInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.MultplexedInterleaver` creates a multiplexed interleaver System object, `H`. This object permutes the symbols in the input signal using a set of shift registers with specified delays.

`H = comm.MultplexedInterleaver(Name,Value)` creates a multiplexed interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

# comm.OQPSKDemodulator

**Package:** comm

Demodulation using OQPSK method

## Description

The `comm.OQPSKDemodulator` object applies pulse shape filtering to the input waveform and demodulates it using the offset quadrature phase shift keying (OQPSK) method. For more information, see “Pulse Shaping Filter” on page 4-1337. The input is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 4-1336.

To demodulate a signal that is OQPSK modulated:

- 1 Create the `comm.OQPSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
oqpskdemod = comm.OQPSKDemodulator
oqpskdemod = comm.OQPSKDemodulator(mod)
oqpskdemod = comm.OQPSKDemodulator(Name,Value)
oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)
```

## Description

`oqpskdemod = comm.OQPSKDemodulator` creates a demodulator System object. This object can jointly match-filter and decimate a waveform, and demodulate it using the offset quadrature phase shift keying (OQPSK) method.

`oqpskdemod = comm.OQPSKDemodulator(mod)` creates a demodulator System object with symmetric configuration to the OQPSK modulator object, `mod`.

`oqpskdemod = comm.OQPSKDemodulator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.OQPSKDemodulator('BitOutput',true)`

`oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)` sets the `PhaseOffset` property of the created object to `phase` and sets any other specified `Name, Value` pairs.

Example: `comm.OQPSKDemodulator(0.5*pi,'SamplesPerSymbol',2)`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see `System Design in MATLAB Using System Objects (MATLAB)`.

### PhaseOffset — Phase of zeroth point of signal constellation

0 (default) | scalar

Phase of zeroth point of the signal constellation in radians, specified as a scalar.

Example: `'PhaseOffset',0` aligns the OQPSK signal constellation points on the axes,  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: double

### BitOutput — Option to output data as bits

false (default) | true

Option to output data as bits, specified as `false` or `true`.

- When you set this property to `false`, the object outputs a column vector of integer values with a length equal to the number of demodulated symbols. The output values are integer representations of two bits and range from 0 to 3.
- When you set this property to `true`, the object outputs a binary column vector of bit values. The output vector length is twice as long as the number of input symbols.

Data Types: `logical`

**SymbolMapping — Signal constellation bit mapping**

'Gray' (default) | 'Binary' | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as 'Gray', 'Binary', or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr><td>1</td><td>0</td></tr> <tr><td>3</td><td>2</td></tr> </table>	1	0	3	2	<table border="1"> <tr><td>01</td><td>00</td></tr> <tr><td>11</td><td>10</td></tr> </table>	01	00	11	10	The signal constellation mapping is Gray-encoded.

de2bi(c)	de2bi(d)										

Data Types: char | double

### **PulseShape — Filtering pulse shape**

'Half sine' (default) | 'Normal raised cosine' | 'Root raised cosine' | 'Custom'

Filtering pulse shape, specified as 'Half sine', 'Normal raised cosine' | 'Root raised cosine', or 'Custom'.

Data Types: char

### **RolloffFactor — Raised cosine filter rolloff factor**

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1.

#### **Dependencies**

This property applies when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

### **FilterSpanInSymbols — Filter length**

10 (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to FilterSpanInSymbols symbols.

#### **Dependencies**

This property applies when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

### **FilterNumerator — Filter numerator**

[0.7071 0.7071] (default) | row vector

Filter numerator, specified as a row vector.

#### **Dependencies**

This property applies when PulseShape is 'Custom'.

Data Types: double

### **SamplesPerSymbol — Number of samples per symbol**

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

### **OutputDataType — Data type assigned to output**

'double' (default) | 'single' | 'uint8'

Data type assigned to output, specified as 'double', 'single', or 'uint8'.

Data Types: char

## Usage

## Syntax

```
outsignal = oqpskdemod(waveform)
```

## Description

`outsignal = oqpskdemod(waveform)` returns the demodulated output signal. The object produces one output symbol for each input pulse.

## Input Arguments

### **waveform — Received waveform**

scalar | column vector

Received waveform, specified as a complex scalar or column vector.

Data Types: double

Complex Number Support: Yes

## Output Arguments

### **outsignal** — Demodulated signal

integer vector | bit vector

Demodulated signal, returned as an  $N_S$ -element integer vector or bit vector, where  $N_S$  is the number of samples.

The received waveform is pulse shaped according to the configuration properties `PulseShape` and `SamplesPerSymbol`. The setting of the `BitOutput` property determines the interpretation of the received waveform.

Data Types: `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the `ReceiveDelay` property to 2.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300
    txData = randi([0 1],100,1);
    modSig = oqpskmod(txData);
    rxSig = channel(modSig);
    rxData = oqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 3.3336e-05
```

```
numErrors = errorStats(2)
```

```
numErrors = 1
```

```
numBits = errorStats(3)
```

```
numBits = 29998
```

### **OQPSK Signal with Root Raised Cosine Filtering**

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

## System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```
sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data

modulator = comm.OQPSKModulator('BitInput',true,'SamplesPerSymbol',sps,'PulseShape','R
demodulator = comm.OQPSKDemodulator(modulator);
```

## Waveform transmission and reception

Use the `modulator` object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform, snr);
```

Use the `demodulator` object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))

ber = 0
```

## Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Create an OQPSK modulated signal and add noise to the signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);

impairedSig = awgn(oqpskSig,15);
```

### Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align I and Q. Apply matched filtering to the received OQPSK signal.

```
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end)));

halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps, halfSinePulse, 'DecimationOffset', sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping,'OutputType','llr');
```

## More About

### Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

Pulse Shape	Input/Output Data (*)	End-to-End Delay Incurred by any an OQPSK Modulator-Demodulator Object Pair (in samples)
'Half sine' or 'Custom'	Integer	1
	Bit	2
'Normal raised cosine' or 'Root raised cosine'	Integer	FilterSpanInSymbols
	Bit	2*FilterSpanInSymbols
(*) Set the data type property (BitInput for modulation or BitOutput for demodulation) to false for integer data and true for bit data.		

## Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

**Package:** comm

Modulation using OQPSK method

## Description

The `comm.OQPSKModulator` object modulates the input signal using the offset quadrature phase shift keying (OQPSK) method and applies pulse shape filtering to the output waveform. For more information, see “Pulse Shaping Filter” on page 4-1349. The output is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 4-1348.

To modulate a signal using offset quadrature phase shift keying:

- 1 Create the `comm.OQPSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

## Syntax

```
oqpskmod = comm.OQPSKModulator
oqpskmod = comm.OQPSKModulator(demod)
oqpskmod = comm.OQPSKModulator(Name,Value)
oqpskmod = comm.OQPSKModulator(phase,Name,Value)
```

### Description

`oqpskmod = comm.OQPSKModulator` creates a modulator System object. This object applies offset quadrature phase shift keying (OQPSK) modulation and pulse shape filtering to the input signal.

`oqpskmod = comm.OQPSKModulator(demod)` creates a modulator System object with symmetric configuration to the OQPSK demodulator object, `demod`.

`oqpskmod = comm.OQPSKModulator(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.OQPSKModulator('BitInput', true)`

`oqpskmod = comm.OQPSKModulator(phase, Name, Value)` sets the `PhaseOffset` property of the created object to `phase` and sets any other specified `Name, Value` pairs.

Example: `comm.OQPSKModulator(0.5*pi, 'SymbolMapping', 'Binary')`

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

#### **PhaseOffset — Phase of zeroth point of signal constellation**

0 (default) | scalar

Phase of zeroth point of the signal constellation in radians, specified as a scalar.

Example: `'PhaseOffset', 0` aligns the OQPSK signal constellation points on the axes,  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: double

#### **BitInput — Option to provide input in bits**

false (default) | true

Option to provide input in bits, specified as `false` or `true`.

- When this property is set to `false`, the input values must be integer representations of two-bit input segments and range from 0 to 3.
- When this property is set to `true`, the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: `logical`

### SymbolMapping – Signal constellation bit mapping

'Gray' (default) | 'Binary' | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as 'Gray', 'Binary', or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr> <td>1</td> <td>0</td> </tr> <tr> <td>3</td> <td>2</td> </tr> </table>	1	0	3	2	<table border="1"> <tr> <td>01</td> <td>00</td> </tr> <tr> <td>11</td> <td>10</td> </tr> </table>	01	00	11	10	The signal constellation mapping is Gray-encoded.

de2bi(c)	de2bi(d)										

Data Types: `char` | `double`

### **PulseShape — Filtering pulse shape**

'Half sine' (default) | 'Normal raised cosine' | 'Root raised cosine' | 'Custom'

Filtering pulse shape, specified as 'Half sine', 'Normal raised cosine', 'Root raised cosine', or 'Custom'.

Data Types: char

### **RolloffFactor — Raised cosine filter rolloff factor**

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1.

### **Dependencies**

This property applies when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

### **FilterSpanInSymbols — Filter length**

10 (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to FilterSpanInSymbols symbols.

### **Dependencies**

This property applies when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

### **FilterNumerator — Filter numerator**

[0.7071 0.7071] (default) | row vector

Filter numerator, specified as a row vector.

### **Dependencies**

This property applies when PulseShape is 'Custom'.

Data Types: double

**SamplesPerSymbol — Number of samples per symbol**

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

**OutputDataType — Data type assigned to output**

'double' (default) | 'single'

Data type assigned to output, specified as 'double' or 'single'.

Data Types: char

## Usage

## Syntax

```
waveform = oqpskmod(insignal)
```

## Description

`waveform = oqpskmod(insignal)` returns baseband-modulated output. The output waveform is pulse shaped according to the configuration properties `PulseShape` and `SamplesPerSymbol`.

## Input Arguments

**insignal — Input signal**

integer column vector | bit column vector

Input signal, specified as an  $N_S$ -element column vector of integers or bits, where  $N_S$  is the number of samples.

The setting of the `BitInput` property determines the interpretation of the input vector.

Data Types: double

### Output Arguments

#### **waveform** — Output waveform

vector

Output waveform, returned as a vector. The output waveform is pulse-shaped according to the configuration properties `PulseShape` and `SamplesPerSymbol`.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

- `step` Run System object algorithm
- `release` Release resources and allow changes to System object property values and input characteristics
- `reset` Reset internal states of System object

### Examples

#### **OQPSK Signal in AWGN**

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);  
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);  
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the `ReceiveDelay` property to 2.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```

for counter = 1:300
    txData = randi([0 1],100,1);
    modSig = oqpskmod(txData);
    rxSig = channel(modSig);
    rxData = oqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end

```

Display the error statistics.

```

ber = errorStats(1)

ber = 3.3336e-05

numErrors = errorStats(2)

numErrors = 1

numBits = errorStats(3)

numBits = 29998

```

### Create OQPSK Modulator Using Demodulator

Use an OQPSK demodulator object to initialize an OQPSK modulator object while creating it.

Create an OQPSK demodulator, assigning it a phase offset of  $\frac{1}{2}\pi$ .

```

phase = 0.5*pi;
oqpskdemod = comm.OQPSKDemodulator(phase)

oqpskdemod =
    comm.OQPSKDemodulator with properties:

```

```
Modulation
  PhaseOffset: 1.5708
  SymbolMapping: 'Gray'
  BitOutput: false

Filtering
  PulseShape: 'Half sine'
  SamplesPerSymbol: 4

  OutputDataType: 'double'
```

Use the demodulator object to initialize an OQPSK modulator while creating it.

```
oqpskmod = comm.OQPSKModulator(oqpskdemod)
```

```
oqpskmod =
comm.OQPSKModulator with properties:
```

```
Modulation
  PhaseOffset: 1.5708
  SymbolMapping: 'Gray'
  BitInput: false

Filtering
  PulseShape: 'Half sine'
  SamplesPerSymbol: 4

  OutputDataType: 'double'
```

### **OQPSK Signal with Root Raised Cosine Filtering**

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

#### **System initialization**

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```

sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data

modulator = comm.OQPSKModulator('BitInput',true,'SamplesPerSymbol',sps,'PulseShape','R
demodulator = comm.OQPSKDemodulator(modulator);

```

### Waveform transmission and reception

Use the `modulator` object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform, snr);
```

Use the `demodulator` object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))

ber = 0
```

### Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Create an OQPSK modulated signal and add noise to the signal.

```

sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);

impairedSig = awgn(oqpskSig,15);

```

### Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align I and Q. Apply matched filtering to the received OQPSK signal.

```
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end-sps/2)));

halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps, halfSinePulse, 'DecimationOffset', sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK, 4, oqpskModSymbolMapping, 'OutputType', 'llr');
```

## More About

### Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

Pulse Shape	Input/Output Data (*)	End-to-End Delay Incurred by any an OQPSK Modulator-Demodulator Object Pair (in samples)

**Introduced in R2012a**

# comm.OSTBCCCombiner

**Package:** comm

Combine inputs using orthogonal space-time block code

## Description

The `OSTBCCCombiner` object combines the input signal (from all of the receive antennas) and the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC. The input channel estimate does not need to be constant and can vary at each call to the `step` method. The combining algorithm uses only the estimate for the first symbol period per codeword block. A symbol demodulator or decoder would follow the Combiner object in a MIMO communications system.

To combine input signals and extract the soft information of the symbols encoded by an OSTBC:

- 1 Define and set up your OSTBC combiner object. See “Construction” on page 4-1351.
- 2 Call `step` to Combine inputs using an orthogonal space-time block code according to the properties of `comm.OSTBCCCombiner`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.OSTBCCCombiner` creates an orthogonal space-time block code (OSTBC) combiner System object, `H`. This object combines the input signal (from all of the receive antennas) with the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC.

`H = comm.OSTBCCombiner(Name, Value)` creates an OSTBC Combiner object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.OSTBCCombiner(N, M, Name, Value)` creates an OSTBC Combiner object, `H`. This object has the `NumTransmitAntennas` property set to `N`, the `NumReceiveAntennas` property set to `N`, and the other specified properties set to the specified values.

## Properties

### **NumTransmitAntennas**

Number of transmit antennas

Specify the number of antennas at the transmitter as 2 | 3 | 4. The default is 2.

### **SymbolRate**

Symbol rate of code

Specify the symbol rate of the code as 3/4 | 1/2. The default is 3/4. This property applies when the `NumTransmitAntennas` on page 4-0 property is greater than 2. For 2 transmit antennas, the symbol rate defaults to 1.

### **NumReceiveAntennas**

Number of receive antennas

Specify the number of antennas at the receiver as a double-precision, real, scalar integer value from 1 to 8. The default is 1.

### **Fixed-Point Properties**

#### **RoundingMethod**

Rounding of fixed-point numeric values

Specify the rounding method as `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`.

**OverflowAction**

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property specifies the action to be taken in case of overflow. Such overflow occurs if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

**ProductDataType**

Data type of product

Specify the product data type as one of `Full precision` | `Custom`. The default is `Full precision`.

**CustomProductDataType**

Fixed-point data type of product

Specify the product fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `ProductDataType` property to `Custom`.

**AccumulatorDataType**

Data type of accumulator

Specify the accumulator data type as `Full precision` | `Same as product` | `Custom`. The default is `Full precision`.

**CustomAccumulatorDataType**

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `AccumulatorDataType` property to `Custom`.

**EnergyProductDataType**

Data type of energy product

Specify the complex energy product data type as one of `Full precision` | `Same as product` | `Custom`. The default is `Full precision`. This property sets the data type of the complex product in the denominator to calculate the total energy in the MIMO channel.

### **CustomEnergyProductDataType**

Fixed-point data type of energy product

Specify the energy product fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `EnergyProductDataType` property to `Custom`.

### **EnergyAccumulatorDataType**

Data type of energy accumulator

Specify the energy accumulator data type as one of `Full precision` | `Same as energy product` | `Same as accumulator` | `Custom`. The default is `Full precision`. This property sets the data type of the summation in the denominator to calculate the total energy in the MIMO channel.

### **CustomEnergyAccumulatorDataType**

Fixed-point data type of energy accumulator

Specify the energy accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `EnergyAccumulatorDataType` property to `Custom`.

### **DivisionDataType**

Data type of division

Specify the division data type as one of `Same as accumulator` | `Custom`. The default is `Same as accumulator`. This property sets the data type at the output of the division operation. The setting normalizes diversity combining by the total energy in the MIMO channel.

### **CustomDivisionDataType**

Fixed-point data type of division

Specify the division fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `DivisionDataType` property to `Custom`.

## Methods

`step` Combine inputs using orthogonal space-time block code

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Encode with OSTBC and Calculate Errors

Determine the bit error rate for a QSPK signal employing OSTBC encoding when transmitted through a 4x2 MIMO channel. Perfect channel estimation is assumed to be used by the OSTBC combiner.

Define the system parameters.

```
numTx = 4;           % Number of transmit antennas
numRx = 2;           % Number of receive antennas
Rs = 1e6;            % Sampling rate (Hz)
tau = [0 2e-6];      % Path delays (sec)
pdb = [0 -10];       % Average path gains (dB)
maxDopp = 30;        % Maximum Doppler shift (Hz)
numBits = 12000;     % Number of bits
SNR = 6;             % Signal-to-noise ratio (dB)
```

Set the random number generator to its default state to ensure repeatable results.

```
rng default
```

Create a QPSK modulator System object™. Set the `BitInput` property to `true` and the `SymbolMapping` property to `Gray`.

```
hMod = comm.QPSKModulator(...  
    'BitInput', true, ...  
    'SymbolMapping', 'Gray');
```

Create a corresponding QPSK demodulator System object. Set the `SymbolMapping` property to `Gray` and the `BitOutput` property to `true`.

```
hDemod = comm.QPSKDemodulator(...  
    'SymbolMapping', 'Gray', ...  
    'BitOutput', true);
```

Create an OSTBC encoder and combiner pair, where the number of antennas is specified in the system parameters.

```
hOSTBCEnc = comm.OSTBCEncoder(...  
    'NumTransmitAntennas', numTx);  
  
hOSTBCComb = comm.OSTBCCombiner(...  
    'NumTransmitAntennas', numTx, ...  
    'NumReceiveAntennas', numRx);
```

Create a flat 4x2 MIMO Channel System object, where the channel characteristics are set using name-value pairs. The path gains are made available to serve as a perfect channel estimate for the OSTBC combiner.

```
hChan = comm.MIMOChannel(...  
    'SampleRate', Rs, ...  
    'PathDelays', tau, ...  
    'AveragePathGains', pdb, ...  
    'MaximumDopplerShift', maxDopp, ...  
    'SpatialCorrelationSpecification', 'None', ...  
    'NumTransmitAntennas', numTx, ...  
    'NumReceiveAntennas', numRx, ...  
    'PathGainsOutputPort', true);
```

Create an AWGN channel System object in which the noise method is specified as a signal-to-noise ratio.

```
hAWGN = comm.AWGNChannel(...  
    'NoiseMethod', 'Signal to noise ratio (SNR)', ...  
    'SNR', SNR, ...  
    'SignalPower', 1);
```

Generate a random sequence of bits.

```
data = randi([0 1],numBits,1);
```

Apply QPSK modulation.

```
modData = step(hMod,data);
```

Encode the modulated data using the OSTBC encoder object.

```
encData = step(hOSTBCEnc,modData);
```

Transmit the encoded data through the MIMO channel and add white noise by using the `step` functions of the MIMO and AWGN channel objects, respectively.

```
[chanOut,pathGains] = step(hChan,encData);
rxSignal = step(hAWGN,chanOut);
```

Sum the `pathGains` array along the number of paths (2nd dimension) to form the channel estimate. Apply the `squeeze` function to make its dimensions conform with those of `rxSignal`.

```
chEst = squeeze(sum(pathGains,2));
```

Combine the received MIMO signal and its channel estimate using the `step` function of the OSTBC combiner object. Demodulate the combined signal.

```
combinedData = step(hOSTBCComb,rxSignal,chEst);
receivedData = step(hDemod,combinedData);
```

Compute the number of bit errors and the bit error rate.

```
[numErrors,ber] = biterr(data,receivedData)
```

```
numErrors = 11
```

```
ber = 9.1667e-04
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Combiner block reference page. The object properties correspond to the block parameters.

### **See Also**

`comm.OSTBCEncoder`

**Introduced in R2012a**

## step

**System object:** comm.OSTBCCCombiner

**Package:** comm

Combine inputs using orthogonal space-time block code

## Syntax

$Y = \text{step}(H, X, \text{CEST})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X, \text{CEST})$  combines the received data,  $X$ , and the channel estimate,  $\text{CEST}$ , to extract the symbols encoded by an OSTBC. Both  $X$  and  $\text{CEST}$  are complex-valued and of the same data type, which can be double, single, or signed fixed point with power-of-two slope and zero bias. When the step method input  $X$  has double or single precision, the output,  $Y$ , has the same data type as the input. The input channel estimate can remain constant or can vary during each codeword block transmission. The combining algorithm uses the estimate only for the first symbol period per codeword block.

The time domain length,  $T/\text{SymbolRate}$ , must be a multiple of the codeword block length.  $T$  is the output symbol sequence length in the time domain. Specifically, when you set the `NumTransmitAntennas` property to 2,  $T/\text{SymbolRate}$  must be a multiple of two. When you set the `NumTransmitAntennas` property greater than 2,  $T/\text{SymbolRate}$  must be a multiple of four. For an input of  $T/\text{SymbolRate}$  rows by `NumReceiveAntennas` columns, the input channel estimate,  $\text{CEST}$ , must be a matrix of size  $T/\text{SymbolRate}$  by `NumTransmitAntennas` by `NumReceiveAntennas`. In this case, the extracted symbol data,  $Y$ , is a column vector with  $T$  elements. Input matrix size can be  $F$  by  $T/\text{SymbolRate}$  by `NumReceiveAntennas`, where  $F$  is an optional dimension (typically frequency domain)

over which the combining calculation is independent. In this case, the input channel estimate, `CEST`, must be a matrix of size  $F$  by  $T/\text{SymbolRate}$  by `NumTransmitAntennas` by `NumReceiveAntennas`. The extracted symbol data,  $Y$ , is an  $F$  rows by  $T$  columns matrix.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.OSTBCEncoder

**Package:** comm

Encode input using orthogonal space-time block code

## Description

The OSTBCEncoder object encodes an input symbol sequence using orthogonal space-time block code (OSTBC). The block maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

To encode an input symbol sequence using an orthogonal space-time block code:

- 1 Define and set up your OSTBC encoder object. See “Construction” on page 4-1361.
- 2 Call `step` to encode an input symbol sequence according to the properties of `comm.OSTBCEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.OSTBCEncoder` creates an orthogonal space-time block code (OSTBC) encoder System object, `H`. This object maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

`H = comm.OSTBCEncoder(Name,Value)` creates an OSTBC encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.OSTBCEncoder(N,Name,Value)` creates an OSTBC encoder object, `H`. This object has the `NumTransmitAntennas` property set to `N`, and the other specified properties set to the specified values.

## Properties

### **NumTransmitAntennas**

Number of transmit antennas

Specify the number of antennas at the transmitter as 2 | 3 | 4. The default is 2.

### **SymbolRate**

Symbol rate of code

Specify the symbol rate of the code as one of 3/4 | 1/2. The default is 3/4. This property applies when you set the NumTransmitAntennas on page 4-0 property to greater than 2. For 2 transmit antennas, the symbol rate defaults to 1.

### **Fixed-Point Properties**

#### **OverflowAction**

Action when fixed-point numeric values overflow

Specify the overflow action as one of Wrap | Saturate. The default is Wrap. This property specifies the action to be taken in the case of an overflow. Such overflow occurs when the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

## Methods

step Encode input using orthogonal space-time block code

## Examples

## Encode BPSK Modulated Data with OSTBC

Generate random binary data, modulate using the BPSK modulation scheme, and encode the modulated data using OSTBC.

Generate an 8-by-1 vector of random binary data.

```
data = randi([0 1],8,1);
```

Create BPSK Modulator System object and modulated the data using the `step` function.

```
bpskMod = comm.BPSKModulator;
modData = bpskMod(data);
```

Create an OSTBC Encoder and encode the modulated signal. As the default number of transmit antennas is 2, you can see that `encData` is an 8-by-2 vector.

```
ostbcEnc = comm.OSTBCEncoder;
encData = ostbcEnc(modData)
```

```
encData = 8×2 complex
```

```
-1.0000 + 0.0000i  -1.0000 + 0.0000i
 1.0000 + 0.0000i  -1.0000 - 0.0000i
 1.0000 + 0.0000i  -1.0000 + 0.0000i
 1.0000 + 0.0000i   1.0000 + 0.0000i
-1.0000 + 0.0000i   1.0000 + 0.0000i
-1.0000 + 0.0000i  -1.0000 - 0.0000i
 1.0000 + 0.0000i  -1.0000 + 0.0000i
 1.0000 + 0.0000i   1.0000 + 0.0000i
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Encoder block reference page. The object properties correspond to the block parameters.

When this object processes variable-size signals:

- If the input signal is a column vector, the first dimension can change, but the second dimension must remain fixed at 1.

- If the input signal is a matrix, both dimensions can change.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**System object:** comm.OSTBCEncoder

**Package:** comm

Encode input using orthogonal space-time block code

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  encodes the input data,  $X$ , using OSTBC encoder object,  $H$ . The input is a complex-valued column vector or matrix of data type `double`, `single`, or signed fixed-point with power-of-two slope and zero bias. The `step` method output,  $Y$ , is the same data type as the input data. The time domain length,  $T$ , of  $X$  must be a multiple of the number of symbols in each codeword matrix. Specifically, when you set the `NumTransmitAntennas` property is 2 or the `SymbolRate` property is  $1/2$ ,  $T$  must be a multiple of two and when the `SymbolRate` property to  $3/4$ ,  $T$  must be a multiple of three. For a time or spatial domain input of  $T$  rows by one column, the encoded output data,  $Y$ , is a  $(T/\text{SymbolRate})$ -by-`NumTransmitAntennas` matrix. The input matrix size can be  $F$  rows by  $T$  columns, where  $F$  is the additional dimension (typically the frequency domain) over which the encoding calculation is independent. In this case, the output is an  $F$ -by- $(T/\text{SymbolRate})$ -by-`NumTransmitAntennas` matrix.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.OVSFCode

**Package:** comm

Generate OVSF code

## Description

The `OVSFCode` object generates an orthogonal variable spreading factor (OVSF) code from a set of orthogonal codes. OVSF codes were first introduced for 3G communication systems. They are primarily used to preserve orthogonality between different channels in a communication system.

To generate an OVSF code:

- 1 Define and set up your OVSF code object. See “Construction” on page 4-1367.
- 2 Call `step` to generate an OVSF code according to the properties of `comm.OVSFCode`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.OVSFCode` creates an orthogonal variable spreading factor (OVSF) code generator System object, `H`. This object generates an OVSF code.

`H = comm.OVSFCode(Name, Value)` creates an OVSF code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### SpreadingFactor

Length of generated code

Specify the length of the generated code as an integer scalar value with a power of two. The default is 64.

### Index

Index of code of interest

Specify the index of the desired code from the available set of codes that have the spreading factor specified in the `SpreadingFactor` on page 4-0 property. This property must be an integer scalar in the range 0 to `SpreadingFactor-1`. The default is 60.

OVSF codes are defined as the rows of an  $n$ -by- $n$  matrix,  $C_n$ , where  $n$  is the value specified in the `SpreadingFactor` property.

You can define the matrix  $C_n$  recursively as follows:

First, define  $C_1 = [1]$ .

Next, assume that  $C_n$  is defined and let  $C_n(k)$  denote the  $k$ -th row of  $C_n$ .

Then,  $C_{2n} = [C_n(0) \ C_n(0); C_n(0) \ -C_n(0); \dots ; C_n(n-1) \ C_n(n-1); C_n(n-1) \ -C_n(n-1)]$ .

$C_n$  is only defined for values of  $n$  that are a power of 2. Set this property to a value of  $k$  to choose the  $k$ -th row of the  $C$  matrix as the code of interest.

### SamplesPerFrame

Number of output samples per frame

Specify the number of OVSF code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is 1. If you set this property to a value of  $M$ , then the `step` method outputs  $M$  samples of an OVSF code of length  $N$ .  $N$  is the length of the OVSF code that you specify in the `SpreadingFactor` on page 4-0 property.

### OutputDataType

Data type of output

Specify output data type as one of `double` | `int8`. The default is `double`.

## Methods

reset      Reset states of OVSF code generator object  
 step        Generate OVSF code

Common to All System Objects	
release	Allow System object property value changes

## Examples

Generate 10 samples of an OVSF code with a spreading factor of 64.

```
hOVSF = comm.OVSFCode('SamplesPerFrame', 10, 'SpreadingFactor', 64);
seq = step(hOVSF)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OVSF Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

## See Also

## **Description**

reset(H) resets the states of the OVSFCode object, H.

---

## step

**System object:** comm.OVSFCode

**Package:** comm

Generate OVSF code

## Syntax

$Y = \text{step}(H)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H)$  outputs a frame of the OVSF code in column vector  $Y$ . Specify the frame length with the `SamplesPerFrame` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.PAMDemodulator

**Package:** comm

(Not recommended) Demodulate using M-ary PAM method

---

**Note** `comm.PAMDemodulator` is not recommended. Use `pamdemod` instead.

---

### Description

The `PAMDemodulator` object demodulates a signal that was modulated using M-ary pulse amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using M-ary pulse amplitude modulation:

- 1 Define and set up your PAM demodulator object. See “Construction” on page 4-1372.
- 2 Call `step` to demodulate the signal according to the properties of `comm.PAMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.PAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

`H = comm.PAMDemodulator(Name,Value)` creates an M-PAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.PAMDemodulator(M,Name,Value)` creates an M-PAM demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4. When you set the `BitOutput` on page 4-0 property to `false`, this value must be even. When you set the `BitOutput` property to `true`, this value requires an integer power of two.

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`.

When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to  $\log_2(\text{ModulationOrder on page 4-0})$  times the number of demodulated symbols.

When you set this property to `false`, the `step` method outputs a column vector, with length equal to the input data vector. This value contains integer symbol values between 0 and `ModulationOrder-1`.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder on page 4-0})$  bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses a Gray-encoded signal constellation.

When you set this property to `Binary`, the integer  $m$ , between  $0 \leq m \leq (\text{ModulationOrder}-1)$  maps to the complex value  $2^{m-\text{ModulationOrder}+1}$ .

### **NormalizationMethod**

Constellation normalization method

Specify the method used to normalize the signal constellation as one of `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

### **MinimumDistance**

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Minimum distance between symbols`.

### **AveragePower**

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Average power`.

### **PeakPower**

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Peak power`.

### **OutputDataType**

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

When you set this property to `Full precision`, and the input data type is `single` or `double` precision, the output data has the same data type that of the input.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` on page 4-0 property to `Smallest unsigned integer`.

When you set the `BitOutput` on page 4-0 property to `true`, then logical data type becomes a valid option.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 4-1378.

### **DenormalizationFactorDataType**

Data type of denormalization factor

Specify the denormalization factor data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`.

### **CustomDenormalizationFactorDataType**

Fixed-point data type of denormalization factor

Specify the denormalization factor fixed-point type as an `unscaled numeric type` object with a signedness of `Auto`. The default is `numeric type([], 16)`. This property applies when you set the `DenormalizationFactorDataType` on page 4-0 property to `Custom`.

### **ProductDataType**

Data type of product

Specify the product data type as one of `Full precision` | `Custom`. The default is `Full precision`. When you set this property to `Full precision` the object calculates the full-precision product word and fraction lengths. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to `false`.

### **CustomProductDataType**

Fixed-point data type of product

Specify the product fixed-point type as an `unscaled numerictype` object with a signedness of `Auto`. The default is `numerictype([],32)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to `false` and the `ProductDataType` on page 4-0 property to `Custom`.

### **ProductRoundingMethod**

Rounding of fixed-point numeric value of product

Specify the product rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies when the object is not in a full precision configuration

### **ProductOverflowAction**

Action when fixed-point numeric value of product overflows

Specify the product overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration.

### **SumDataType**

Data type of sum

Specify the sum data type as one of `Full precision` | `Same as product` | `Custom`. The default is `Full precision`. When you set this property to `Full precision`, the object calculates the full-precision sum word and fraction lengths. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to `false`

## CustomSumDataType

Fixed-point data type of sum

Specify the sum fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([],32)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to `false` and the `SumDataType` on page 4-0 property to `Custom`.

## Methods

`constellation` (Not recommended) Calculate or plot ideal signal constellation  
`step` (Not recommended) Demodulate using M-ary PAM method

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

Modulate and demodulate a signal using 16-PAM modulation.

```
hMod = comm.PAMModulator(16);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', ...
    'SNR',20, 'SignalPower', 85);
hDemod = comm.PAMDemodulator(16);
%Create an error rate calculator
hError = comm.ErrorRate;
for counter = 1:100
    % Transmit a 50-symbol frame
    data = randi([0 hMod.ModulationOrder-1],50,1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

## Compatibility Considerations

### **comm.PAMDemodulator is not recommended**

`comm.PAMDemodulator` is not recommended. Use `pamdemod` instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.

%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pamdemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdemodObj(complex(y)); % Demodulate.

%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pamdemod(y,M); % Demodulate.
```

## More About

### **Full Precision for Fixed-Point System Objects**

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## step

**System object:** comm.PAMDemodulator

**Package:** comm

(Not recommended) Demodulate using M-ary PAM method

---

**Note** comm.PAMDemodulator is not recommended. Use pamdemod instead.

---

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates data,  $X$ , with the M-PAM demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a scalar or column vector. The data type of the input can be double or single precision, signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.PAMModulator

**Package:** comm

(Not recommended) Modulate using M-ary PAM method

---

**Note** `comm.PAMModulator` is not recommended. Use `pammod` instead.

---

### Description

The `PAMModulator` object modulates using M-ary pulse amplitude modulation. The output is a baseband representation of the modulated signal. The M-ary number parameter, `M`, represents the number of points in the signal constellation and requires an even integer.

To modulate a signal using M-ary pulse amplitude modulation:

- 1 Define and set up your PAM modulator object. See “Construction” on page 4-1384.
- 2 Call `step` to modulate the signal according to the properties of `comm.PAMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.PAMModulator` creates a modulator System object, `H`. This object modulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

`H = comm.PAMModulator(Name,Value)` creates an M-PAM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.PAMModulator(M,Name,Value)` creates an M-PAM modulator object, `H`. This object has the `ModulationOrder` property set to `M` and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4. When you set the `BitInput` on page 4-0 property to `false`, `ModulationOrder` must be even. When you set the `BitInput` property to `true`, `ModulationOrder` must be an integer power of two.

### BitInput

Assume bit inputs

Specify whether the input is in bits or integers. The default is `false`.

When you set this property to `true`, the `step` method input requires a column vector of bit values whose length is an integer multiple of  $\log_2(\text{ModulationOrder on page 4-0})$ . This vector contains bit representations of integers between 0 and `ModulationOrder-1`.

When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between 0 and `ModulationOrder-1`.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder on page 4-0})$  input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses a Gray-encoded signal constellation.

When you set this property to `Binary`, the input integer  $m$ , between  $0 \leq m \leq \text{ModulationOrder}-1$ ) maps to the complex value  $2^m - \text{ModulationOrder} + 1$ .

### **NormalizationMethod**

Constellation normalization method

Specify the method used to normalize the signal constellation as one of `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

### **MinimumDistance**

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Minimum distance between symbols`.

### **AveragePower**

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Average power`.

### **PeakPower**

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Peak power`.

### **OutputDataType**

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

### **Fixed-Point Properties**

#### **CustomOutputDataType**

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([],16)`. This property applies when you set the `OutputDataType` on page 4-0 property to `Custom`.

## Methods

`constellation` (Not recommended) Calculate or plot ideal signal constellation  
`step` (Not recommended) Modulate using M-ary PAM method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

Modulate data using 16-PAM modulation, and visualize the data in a scatter plot.

```
% Create binary data for 100, 4-bit symbols
data = randi([0 1],400,1);
% Create a 16-PAM modulator System object with bits as inputs and
% Gray-coded signal constellation
hModulator = comm.PAMModulator(16,'BitInput',true);
% Modulate and plot the data
modData = step(hModulator, data);
constellation(hModulator)
```

## Compatibility Considerations

### **comm.PAMModulator is not recommended**

`comm.PAMModulator` is not recommended. Use `pammod` instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.

%% Using PAM modulation and demodulation system objects
```

```
pammodObj = comm.PAMModulator(M);
pamdemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdemodObj(complex(y)); % Demodulate.

%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pamdemod(y,M); % Demodulate.
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  modulates input data,  $X$ , with the M-PAM modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.PhaseFrequencyOffset

**Package:** comm

Apply phase and frequency offsets to input signal

## Description

The `PhaseFrequencyOffset` object applies phase and frequency offsets to an incoming signal.

To apply phase and frequency offsets to the input signal:

- 1 Define and set up your phase frequency offset object. See “Construction” on page 4-1393.
- 2 Call `step` to apply phase and frequency offsets to the input signal according to the properties of `comm.PhaseFrequencyOffset`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.PhaseFrequencyOffset` creates a phase and frequency offset System object, `H`. This object applies phase and frequency offsets to an input signal.

`H = comm.PhaseFrequencyOffset(Name,Value)` creates a phase and frequency offset object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### PhaseOffset

Phase offset

Specify the phase offset in degrees. The default is 0. If the `step` method input is an  $M$ -by- $N$  matrix, the `PhaseOffset` on page 4-0 property can be set to a numeric scalar, an  $M$ -by-1, or 1-by- $N$  numeric vector, or an  $M$ -by- $N$  numeric matrix.

When you set the `PhaseOffset` property to a scalar value, the object applies the constant specified phase offset to each column of the input matrix.

When you set this property to an  $M$ -by-1 vector, the object applies time varying phase offsets, specified in the vector of this property, to each column of the input to the `step` method.

When you set this property to a 1-by- $N$  vector, the object applies the  $i$ -th constant phase offset of this property to the  $i$ -th column of the input to the `step` method.

When you set this property to an  $M$ -by- $N$  matrix, the object applies the  $i$ -th time varying phase offsets, specified in the  $i$ -th column of this property, to the  $i$ -th column of the input to the `step` method. This property is tunable.

### FrequencyOffsetSource

Source of frequency offset

Specify the source of the frequency offset as one of `Property | Input port`. The default is `Property`. If you set this property to `Property`, you can specify the frequency offset using the `FrequencyOffset` on page 4-0 property. If you set this property to `Input port`, you specify the frequency offset as a step method input.

### FrequencyOffset

Frequency offset

Specify the frequency offset in Hertz. The default is 0. If the `step` method input is an  $M$ -by- $N$  matrix, then the `FrequencyOffset` on page 4-0 property is a numeric scalar, an  $M$ -by-1, or 1-by- $N$  numeric vector, or an  $M$ -by- $N$  numeric matrix.

This property applies when you set the `FrequencyOffsetSource` on page 4-0 property to `Property`.

When you set this property to a scalar value, the object applies the constant specified frequency offset to each column of the input to the `step` method.

When you set this property to an  $M$ -by-1 vector, the object applies time-varying frequency offsets. These offsets are specified in the property, to each column of the input to the `step` method.

When you set this property to a 1-by- $N$  vector, the object applies the  $i$ -th constant frequency offset in this property to the  $i$ -th column of the input to the `step` method.

When you set this property to an  $M$ -by- $N$  matrix, the object applies the  $i$ -th time varying frequency offset. This offset is specified in the  $i$ -th column of this property and to the  $i$ -th column of input to the `step` method. This property is tunable.

## SampleRate

Sample rate

Specify the sample rate of the input samples in seconds as a double-precision, real, positive scalar value. The default is 1.

$\text{SampleRate} = \text{Input Vector Size} / \text{Simulink Sample Time}$

## Methods

`step` Apply phase and frequency offsets to input signal

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Introduce Phase Offset to 16-QAM Signal

Introduce a phase offset to a 16-QAM signal and view its effect on the constellation.

Create a phase frequency offset System object™. Set the phase offset to 30 degrees.

```
pfo = comm.PhaseFrequencyOffset('PhaseOffset',30);
```

Generate random symbols and apply 16-QAM modulation.

```
M = 16;  
data = (0:M-1)';  
modData = qammod(data,M);
```

Plot the 16-QAM constellation.

```
scatterplot(modData);  
title('Original Constellation')  
xlim([-5 5])  
ylim([-5 5])
```

Introduce a phase offset using `pfo` and plot the offset constellation. Note that it has been shifted 30 degrees.

```
impairedData = pfo(modData);  
scatterplot(impairedData);  
title('Constellation after phase offset')  
xlim([-5 5])  
ylim([-5 5])
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Phase/Frequency Offset block reference page. The object properties correspond to the block parameters, except:

The object provides a `SampleRate` on page 4-0 property, which you must specify. The block senses the sample time of the signal and therefore does not have a corresponding parameter.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### See Also

`comm.MemorylessNonlinearity` | `comm.PhaseNoise` | `comm.ThermalNoise`

**Introduced in R2012a**

# step

**System object:** `comm.PhaseFrequencyOffset`

**Package:** `comm`

Apply phase and frequency offsets to input signal

## Syntax

`Y = step(H,X)`

`Y = step(H,X,FRQ)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` applies phase and frequency offsets to input `X`, and returns `Y`. The input `X` is a double or single precision matrix `X`, of dimensions `MxN`. `M` is the number of time samples in the input signals and `N` is number of channels. Both `M` and `N` can be equal to 1. The object adds phase and frequency offsets independently to each column of `X`. The data type and dimensions of `X` and `Y` are the same.

`Y = step(H,X,FRQ)` uses `FRQ` as the frequency offset that the object applies to input `X` when you set the `FrequencyOffsetSource` property to 'Input port'. When the `X` input is an `MxN` matrix, the value for `FRQ` can be a numeric scalar, an `Mx1` or `1xN` numeric vector, or an `MxN` numeric matrix. When the `FRQ` input is a scalar, the object applies a constant frequency offset, `FRQ`, to each column of `X`. When the `FRQ` input is an `Mx1` vector, the object applies time varying frequency offsets, which are specified in the `FRQ` vector, to each column of `X`. When the `FRQ` input is a `1xN` vector, the object applies the `ith` constant frequency offset in `FRQ` to the `ith` column of `X`. When the `FRQ` input is an `MxN` matrix, the object applies the `ith` time varying frequency offsets, specified in the `ith` column of `FRQ`, to the `ith` column of `X`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.PhaseNoise

**Package:** comm

Apply phase noise to baseband signal

### Description

The `comm.PhaseNoise` System object adds phase noise to a complex signal. This object emulates impairments introduced by the local oscillator of a wireless communication transmitter or receiver. The object generates filtered phase noise according to the specified spectral mask and adds it to the input signal. For a description of the phase noise modeling, see “Algorithms” on page 4-1409.

To add phase noise using a `comm.PhaseNoise` object:

- 1 Create the `comm.PhaseNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

### Creation

### Syntax

```
phznoise = comm.PhaseNoise  
phznoise = comm.PhaseNoise(Name,Value)  
phznoise = comm.PhaseNoise(level,offset,samplerate)
```

### Description

`phznoise = comm.PhaseNoise` creates a phase noise System object with default property values.

`phznoise = comm.PhaseNoise(Name, Value)` creates a phase noise object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`phznoise = comm.PhaseNoise(level, offset, samplerate)` creates a phase noise object with the phase noise level, frequency offset, and sample rate properties specified as value-only arguments. When specifying a value-only argument, you must specify all preceding value-only arguments.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects* (MATLAB).

### **Level — Phase noise level**

`[-60 -80]` (default) | vector of negative scalars

Phase noise level in decibels relative to carrier per hertz (dBc/Hz), specified as a vector of negative scalars. The `Level` and `FrequencyOffset` properties must have the same length.

Data Types: `double`

### **FrequencyOffset — Frequency offset**

`[20 200]` (default) | vector of positive increasing values

Frequency offset in Hz, specified as a vector of positive increasing values. The `Level` and `FrequencyOffset` properties must have the same length.

Data Types: `double`

### **SampleRate — Sample rate**

`1024` (default) | positive scalar

Sample rate in samples per second, specified as a positive scalar. To avoid aliasing, the sample rate must be greater than twice the largest value specified by `FrequencyOffset`.

Data Types: double

### **RandomStream — Source of random stream**

'Global stream' (default) | 'mt19937ar with seed'

Source of the random stream, specified as 'Global stream' or 'mt19937ar with seed'. If `RandomStream` is set to 'mt19937ar with seed', the mt19937ar algorithm is used for normally distributed random number generation, in which case the `reset` method reinitializes the random number stream to the value of the `Seed` property.

Data Types: char | string

### **Seed — Initial seed**

2137 (default) | positive scalar less than  $2^{32}$

Initial seed for `RandomStream`, specified as a positive scalar less than  $2^{32}$ .

### **Dependencies**

To enable this property, set `RandomStream` to 'mt19937ar with seed'.

Data Types: double

## **Usage**

## **Syntax**

```
out = phznoise(in)
```

## **Description**

`out = phznoise(in)` adds phase noise, specified by the `phznoise` System object, to the input signal. The result is returned in `out`.

## **Input Arguments**

### **in — Input signal**

complex column vector

Input signal, specified as an  $N_S$ -by-1 vector of complex values.  $N_S$  is the number of samples.

Data Types: double

Complex Number Support: Yes

## Output Arguments

### **out** — Output signal

column vector

Output signal, returned as an  $N_S$ -by-1 vector of complex values.  $N_S$  equals the number of samples in the input signal.

Data Types: double

Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Specific to comm.PhaseNoise**

`visualize` Visualize spectrum mask of phase noise

### **Common to All System Objects**

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Phase Noise Effects on 16-QAM Signal

Add a phase noise vector and frequency offset vector to a 16-QAM signal. Then plot the signal.

Create a phase noise System object.

```
pnoise = comm.PhaseNoise('Level',-50,'FrequencyOffset',20);
```

Generate modulated symbols.

```
M = 16; % From 16-QAM  
data = randi([0 M-1],1000,1);  
modData = qammod(data,M);
```

Use `pnoise` to apply phase noise. Plot the impaired data.

```
y = pnoise(modData);  
scatterplot(y)
```

### Phase Noise Effects on Signal Spectrum

Create a sine wave generator having a carrier frequency of 100 Hz, a sample rate of 1000 Hz, and a frame size of 10,000 samples.

```
sinewave = dsp.SineWave('Frequency',100,'SampleRate',1000, ...
    'SamplesPerFrame',1e4,'ComplexOutput',true);
```

Create a phase noise object. Specify the phase noise level to be  $-40$  dBc/Hz for a 100 Hz offset and  $-70$  dBc/Hz for a 200 Hz offset.

```
pnoise = comm.PhaseNoise('Level',[-40 -70],'FrequencyOffset',[100 200], ...  
    'SampleRate',1000);
```

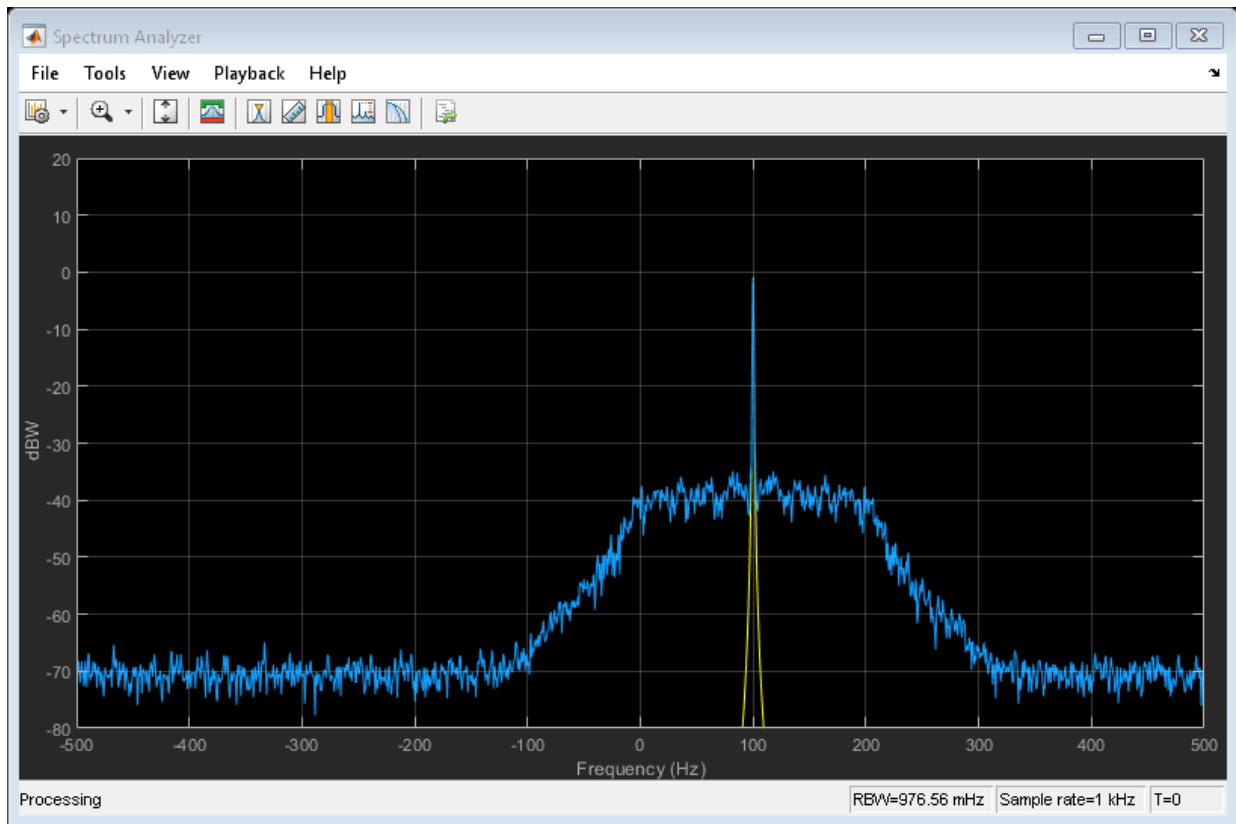

Create a spectrum analyzer.

```
spectrum = dsp.SpectrumAnalyzer('NumInputPorts',2,'SampleRate',1000, ...  
    'SpectralAverages',10,'PowerUnits','dBW');
```

Generate a sine wave and add phase noise to it. Plot the spectrum of the sine wave and the noisy signal.

```
x = sinewave();  
y = pnoise(x);
```

```
spectrum(x,y)
```

The phase noise is  $-40$  dBW within  $\pm 100$  Hz of the carrier. The phase noise is  $-70$  dB below the carrier for offsets greater than 200 Hz.

## Algorithms

The output signal,  $y_k$ , is related to input sequence  $x_k$  by  $y_k = x_k e^{j\varphi_k}$ , where  $\varphi_k$  is the phase noise. The phase noise is filtered Gaussian noise such that  $\varphi_k = f(n_k)$ , where  $n_k$  is the noise sequence and  $f$  represents a filtering operation.

To model the phase noise, define the power spectrum density (PSD) mask characteristic by specifying scalar or vector values for the frequency offset and phase noise level.

- For a scalar frequency offset and phase noise level specification, an IIR digital filter computes the spectrum mask. The spectrum mask has a  $1/f$  characteristic that passes through the specified point.
- For a vector frequency offset and phase noise level specification, an FIR filter computes the spectrum mask. The spectrum mask is interpolated across  $\log_{10}(f)$ . It is flat from DC to the lowest frequency offset, and from the highest frequency offset to half the sample rate.

### IIR Digital Filter

For the IIR digital filter, the numerator coefficient is

$$\lambda = \sqrt{2\pi f_{offset} 10^{L/10}},$$

where  $f_{\text{offset}}$  is the frequency offset in Hz and  $L$  is the phase noise level in dBc/Hz. The denominator coefficients,  $\gamma_i$ , are recursively determined as

$$\gamma_i = (i - 2.5) \frac{\gamma_{i-1}}{i - 1},$$

where  $\gamma_1 = 1$ ,  $i = \{1, 2, \dots, N_t\}$ , and  $N_t$  is the number of filter coefficients.  $N_t$  is a power of 2, from  $2^7$  to  $2^{19}$ . The value of  $N_t$  grows as the phase noise offset decreases towards 0 Hz.

### FIR Filter

For the FIR filter, the phase noise level is determined through  $\log_{10}(f)$  interpolation for frequency offsets over the range  $[df, f_s / 2]$ , where  $df$  is the frequency resolution and  $f_s$  is the sample rate. The phase noise is flat from 0 Hz to the smallest frequency offset, and from the largest frequency offset to  $f_s / 2$ . The frequency resolution is equal to  $\frac{f_s}{2} \left( \frac{1}{N_t} \right)$ , where  $N_t$  is the number of coefficients, and is a power of 2 less than or equal to  $2^{16}$ . If  $N_t < 2^8$ , a time domain FIR filter is used. Otherwise, a frequency domain FIR filter is used.

The algorithm increases  $N_t$  until these conditions are met:

- The frequency resolution is less than the minimum value of the frequency offset vector.
- The frequency resolution is less than the minimum difference between two consecutive frequencies in the frequency offset vector.
- The maximum number of FIR filter taps is  $2^{16}$ .

# comm.PNSequence

**Package:** comm

Generate a pseudo-noise (PN) sequence

## Description

The PNSequence object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR). This block implements LFSR using a simple shift register generator (SSRG, or Fibonacci) configuration. You can use a pseudonoise sequence in a pseudorandom scrambler and descrambler. You can also use one in a direct-sequence spread-spectrum system.

To generate a PN sequence:

- 1 Define and set up your PN sequence object. See “Construction” on page 4-1415.
- 2 Call `step` to generate a PN sequence according to the properties of `comm.PNSequence`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

## Construction

`H = comm.PNSequence` creates a pseudo-noise (PN) sequence generator System object, `H`. This object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR).

`H = comm.PNSequence(Name, Value)` creates a PN sequence generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### Polynomial

Generator polynomial

Specify the polynomial that determines the shift register's feedback connections. The default is ' $z^6 + z + 1$ '. You can specify the generator polynomial as a character vector or as a numeric, binary vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal 1, and the length of this vector must be  $n+1$ . The value  $n$  indicates the degree of the generator polynomial. Lastly, you can specify the generator polynomial as a numeric vector containing the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0. For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial,  $g(z) = z^8 + z^2 + 1$ . The PN sequence has a period of  $N = 2^n - 1$  (applies only to maximal length sequences).

### InitialConditionsSource

Source of initial conditions

Specify the source of the initial conditions that determines the start of the PN sequence as one of `Property | Input port`. The default is `Property`. When you set this property to `Property`, the initial conditions can be specified as a scalar or binary vector using the `InitialConditions` on page 4-0 property. When you set this property to `Input port`, you specify the initial conditions as an input to the `step` method. The object accepts a binary scalar or a binary vector input. The length of the input must equal the degree of the generator polynomial that the `Polynomial` property specifies.

### InitialConditions

Initial conditions of shift register

Specify the initial values of the shift register as a binary, numeric scalar or a binary, numeric vector. The default is `[0 0 0 0 0 1]`. Set the vector length equal to the degree of the generator polynomial. If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. If you set this property to a scalar, the initial conditions of all the cells of the shift register are the specified scalar value. The scalar, or at least one element of the specified vector, must be nonzero for the object to generate a nonzero sequence.

## MaskSource

Source of mask to shift PN sequence

Specify the source of the mask that determines the shift of the PN sequence as one of `Property` | `Input port`. The default is `Property`. When you set this property to `Property`, the mask can be specified as a scalar or binary vector using the `Mask` property. When you set this property to `Input port`, the mask, which is an input to the `step` method, can only be specified as a binary vector. This vector must have a length equal to the degree of the generator polynomial specified in the `Polynomial` property.

## Mask

Mask to shift PN sequence

Specify the mask that determines how the PN sequence is shifted from its starting point as a numeric, integer scalar or as a binary vector. The default is `0`.

When you set this property to an integer scalar, the value is the length of the shift. A scalar shift can be positive or negative. When the PN sequence has a period of  $N = 2^n - 1$ , where  $n$  is the degree of the generator polynomial that you specify in the `Polynomial` property, the object wraps shift values that are negative or greater than  $N$ .

When you set this property to a binary vector, its length must equal the degree of the generator polynomial specified in the `Polynomial` property. The mask vector that represents  $m(z) = z^D$  modulo  $g(z)$ , where  $g(z)$  is the generator polynomial, and the mask vector corresponds to a shift of  $D$ . For example, for a generator polynomial of degree of 4, the mask vector corresponding to  $D = 2$  is `[0 1 0 0]`, which represents the polynomial  $m(z) = z^2$ .

You can calculate the mask vector using the `shift2mask` function. This property applies when you set the `MaskSource` property to `Property`.

## VariableSizeOutput

Enable variable-size outputs

Set this property to true to enable an additional input to the `step` method. The default is false. When you set this property to true, the enabled input specifies the output size of the PN sequence used for the step. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to `false`, the `SamplesPerFrame` property specifies the number of output samples.

### **MaximumOutputSize**

Maximum output size

Specify the maximum output size of the PN sequence as a positive integer 2-element row vector. The second element of the vector must be 1. The default is `[10 1]`.

This property applies when you set the `VariableSizeOutput` property to `true`.

### **SamplesPerFrame**

Number of samples output per frame

Number of samples output per frame by the PN sequence object, specified as positive integer. The default is 1. If you set this property to a value of  $M$ , then the object outputs  $M$  samples of a PN sequence that has a period of  $N = 2^n - 1$ . The value  $n$  represents the degree of the generator polynomial that you specify in the `Polynomial` property. If you set the `BitPackedOutput` property to `false`, the samples are bits from the PN sequence. If you set the `BitPackedOutput` property to `true`, then the output corresponds to `SamplesPerFrame` groups of bit-packed samples.

### **ResetInputPort**

Enable generator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. This input resets the states of the PN sequence generator to the initial conditions specified in the `InitialConditions` property.

### **BitPackedOutput**

Option to output bit-packed words

Option to output bit-packed words, specified as `false` or `true`. Set this property to `true` to enable bit-packed outputs. The first bit from the left in the bit-packed word is considered the most significant bit. The default is `false`.

When `BitPackedOutput` is `true`, the object outputs a column vector of length  $M$ , which contains integer representations of bit words of length  $P$ .  $M$  is the number of samples per

frame specified in the `SamplesPerFrame` property.  $P$  is the size of the bit-packed words specified in the `NumPackedBits` property.

### **NumPackedBits**

Number of bits per bit-packed word

Specify the number of bits to pack into each output data word as a numeric, integer scalar value from 1 to 32. The default is 8.

#### **Dependencies**

This property applies when you set the `BitPackedOutput` property to `true`.

### **SignedOutput**

Output signed bit-packed words

Set this property to `true` to obtain signed, bit-packed, output words. The default is `false`. In this case, a 1 in the most significant bit (sign bit) indicates a negative value. The property indicates negative numbers in a two's complement format.

#### **Dependencies**

This property applies when you set the `BitPackedOutput` property to `true`.

### **OutputDataType**

Data type of output

Specify the output data type as one of these:

- When `BitPackedOutput` property is `false`, `OutputDataType` can be `'double'`, `'logical'`, or `'Smallest unsigned integer'`.
- When `BitPackedOutput` property is `true`, `OutputDataType` can be `'double'` or `'Smallest integer'`.

The default is `double`.

---

**Note** You must have a Fixed-Point Designer user license to use this property in `'Smallest unsigned integer'` or `'Smallest integer'` mode.

---

### Dependencies

The valid settings for output data type depends on the setting of BitPackedOutput.

## Methods

reset      Reset states of PN sequence generator object  
step        Generate a pseudo-noise (PN) sequence

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Generate Maximal Length PN Sequences

Generate a 14-sample frame of a maximal length PN sequence given generator polynomial,  $x^3 + x^2 + 1$ .

Generate PN sequence data by using the `comm.PNSequence` object. The sequence repeats itself as it contains 14 samples while the maximal sequence length is only 7 samples ( $2^3 - 1$ ).

```
pnSequence = comm.PNSequence('Polynomial',[3 2 0], ...  
    'SamplesPerFrame',14,'InitialConditions',[0 0 1]);  
x1 = pnSequence();  
[x1(1:7) x1(8:14)]
```

```
ans = 7x2
```

```
1     1  
0     0  
0     0  
1     1  
1     1  
1     1  
0     0
```

Create another maximal length sequence based on the generator polynomial,  $x^4 + x + 1$ . As it is a fourth order polynomial, the sequence repeats itself after 15 samples ( $2^4 - 1$ ).

```
pnSequence2 = comm.PNSequence('Polynomial','x^4+x+1', ...
    'InitialConditions',[0 0 0 1],'SamplesPerFrame',30);
x2 = pnSequence2();
[x2(1:15) x2(16:30)]
```

```
ans = 15x2
```

```
    1     1
    0     0
    0     0
    0     0
    1     1
    0     0
    0     0
    1     1
    1     1
    0     0
    :
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the PN Sequence Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

Reset states of PN sequence generator object

## Syntax

reset(H)

## Description

reset(H) resets the states of the PNSequence object, H.

## step

**System object:** comm.PNSequence

**Package:** comm

Generate a pseudo-noise (PN) sequence

## Syntax

```
y = step(pnseqObj)
y = step(pnseqObj,initCond)
y = step(pnseqObj,mask)
y = step(pnseqObj,outputSize)
y = step(pnseqObj,reset)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

`y = step(pnseqObj)` outputs a frame of the PN sequence in column vector `y`. Specify the frame length with the `SamplesPerFrame` property. The PN sequence has a period of  $N = 2^n - 1$ , where  $n$  is the degree of the generator polynomial that you specify in the `Polynomial` property.

`y = step(pnseqObj,initCond)` uses `initCond` as the initial conditions value when you set the `InitialConditionsSource` property to 'Input port'. `initCond` must be a numeric scalar or numeric, binary vector with length equal to the degree of the generator polynomial specified in the `Polynomial` property.

`y = step(pnseqObj,mask)` uses `mask` as the shift value when you set the `MaskSource` property to 'Input port'. `mask` must be a numeric, binary vector with length equal to the degree of the generator polynomial specified in the `Polynomial` property. Refer to the `Mask` property help for details of the mask calculation.

`y = step(pnseqObj, outputSize)` uses `outputSize` as the output size for the current step when you set the `VariableSizeOutput` property to true. The `outputSize` input must be a non-negative integer scalar or 2-element row vector. The scalar or the first element of the row vector must be less than or equal to the first element of `MaximumOutputSize` property value. The second element of the `outputSize` row vector input must be 1.

`y = step(pnseqObj, reset)` uses `reset` as the reset signal when you set the `ResetInputPort` property to true. The data type of the `reset` input must be double precision or logical. `reset` can be a scalar value or a column vector with length equal to the number of samples per frame specified in the `SamplesPerFrame` property. When the `reset` input is a non zero scalar, the object resets to the initial conditions that you specify in the `InitialConditions` property and then generates a new output frame. A column vector `reset` input allows multiple resets within an output frame. A non-zero value at the *i*th element of the vector will cause a reset at the *i*th output sample time.

You can combine optional input arguments when you set their enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties. For example, `y = step(pnseqObj, mask, reset)`. You cannot combine `reset` and `initCond` in the same object `step` call.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.PreambleDetector

**Package:** comm

Detect preamble in data

### Description

The `comm.PreambleDetector` System object detects a preamble in an input data sequence. A preamble is a set of symbols or bits used in packet-based communication systems to indicate the start of a packet. The preamble detector object finds the location corresponding to the end of the preamble.

To detect a preamble in an input data sequence:

- 1 Create a `comm.PreambleDetector` object and set the properties of the object.
- 2 Call `step` to detect the presence of a preamble.

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`prbdet = comm.PreambleDetector` creates a preamble detector object, `prbdet`, using the default properties.

`prbdet = comm.PreambleDetector(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

`prbdet = comm.PreambleDetector(prb, Name, Value)` specifies the preamble, `prb` in addition to those properties specified by using `Name, Value` pairs.

**Example:**

```
prbdet = comm.PreambleDetector('Input', 'Bit', 'Detections', 'First');
```

## Properties

### Input — Type of input data

'Symbol' (default) | 'Bit'

Type of input data, specified as 'Symbol' or 'Bit'. For binary inputs, set this parameter to 'Bit'. For all other inputs, set this parameter to 'Symbol'. Symbol data can be of data type `single` or `double` while bit data can, in addition, support the `Boolean`, `int8`, and `uint8` data types.

### Preamble — Preamble sequence

[1+1i; 1-1i] (default) | column vector

Preamble sequence, specified as a real or complex column vector. The object uses this sequence to detect the presence of the preamble in the input data. If `Input` is 'Bit', the preamble must be a binary sequence. If `Input` is 'Symbol', the preamble can be any real or complex sequence.

Data Types: `double` | `single` | `logical` | `int8` | `uint8`

### Threshold — Detection threshold

3 (default) | nonnegative scalar

Detection threshold, specified as a nonnegative scalar. When the computed detection metric is greater than or equal to `Threshold`, the preamble is detected. This property is available when `Input` is set to 'Symbol'. Tunable.

### Detections — Number of preambles to detect

'All' (default) | 'First'

Number of preambles to detect, specified as 'All' or 'First'.

- 'All' — Detects all the preambles in the input data sequence.
- 'First' — Detect only the first preamble in the input data sequence.

## Methods

<code>reset</code>	Reset states of preamble detector object
<code>step</code>	Detect preamble in data

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Detect Preamble from Binary Data Sequence

Specify a six-bit preamble.

```
prb = [1 0 0 1 0 1]';
```

Create a preamble detector object using preamble `prb` and taking bit inputs.

```
prbdet = comm.PreambleDetector(prb, 'Input', 'Bit');
```

Generate a binary data sequence containing two preambles and using random bits to represent the data fields.

```
pkt = [prb; randi([0 1],10,1); prb; randi([0 1],10,1)];
```

Locate the indices of the two preambles. The indices correspond to the end of the preambles.

```
idx = prbdet(pkt)
```

```
idx = 2×1
```

```
    6  
   22
```

The detector correctly identified indices 6 and 22 as the end of the two preambles inserted in the sequence.

### Detect Preamble in Noisy QPSK Signal

Create a preamble and apply QPSK modulation.

```
p1 = [0 1 2 3 3 2 1 0]';
p = [p1; p1];
prb = pskmod(p,4,pi/4, 'gray');
```

Create a `comm.PreambleDetector` object using preamble `prb`.

```
prbdet = comm.PreambleDetector(prb)

prbdet =
  comm.PreambleDetector with properties:
    Input: 'Symbol'
    Preamble: [16x1 double]
    Threshold: 3
    Detections: 'All'
```

Generate a sequence of random symbols. The first sequence represents the last 20 symbols from a previous packet. The second sequence represents the symbols from the current packet.

```
d1 = randi([0 3],20,1);
d2 = randi([0 3],100,1);
```

Modulate the two sequences.

```
x1 = pskmod(d1,4,pi/4, 'gray');
x2 = pskmod(d2,4,pi/4, 'gray');
```

Create a sequence of modulated symbols consisting of the remnant of the previous packet, the preamble, and the current packet.

```
y = [x1; prb; x2];
```

Add white Gaussian noise.

```
z = awgn(y,10);
```

Determine the preamble index and the detection metric.

```
[idx, detmet] = prbdet(z);
```

Calculate the number of elements in `idx`. Because the number of elements is greater than one, the detection threshold is too low.

```
numel(idx)
```

```
ans = 80
```

Display the five largest detection metrics.

```
detmetSort = sort(detmet, 'descend');  
detmetSort(1:5)
```

```
ans = 5×1
```

```
16.3115  
13.6900  
10.5698  
9.1920  
8.9706
```

Increase the threshold and determine the preamble index.

```
prbdet.Threshold = 15;  
idx = prbdet(z)
```

```
idx = 36
```

The result of 36 corresponds to the sum of the preamble length (16) and the remaining samples in the previous packet (20). This indicates that the preamble has been successfully detected.

## Algorithms

### Bit Inputs

When the input data is composed of bits, the preamble detector uses an exact pattern match.

### Symbol Inputs

When the input data is composed of symbols, the preamble detector uses a cross-correlation algorithm. A finite impulse response (FIR) filter, in which the coefficients are specified from the preamble, computes the cross-correlation between the input data and the preamble. When a sequence of input samples match the preamble, the filter output reaches its peak. The index of the peak corresponds to the end of the preamble sequence

in the input data. See Discrete FIR Filter for further information on the FIR filter algorithm.

The cross-correlation values that are greater than or equal to the specified threshold are reported as peaks.

- If the detection threshold is too low, the algorithm will detect false peaks, or, in the extreme case, detect as many detected peaks as there are input samples.
- If the detection threshold is too high, the algorithm will miss detecting peaks, or, in the extreme case, detect no peaks.

Consequently, the selection of the detection threshold is critical.

**Package:** comm

Reset states of preamble detector object

## **Syntax**

reset(prbdet)

## **Description**

reset(prbdet) resets the states of the PreambleDetector object, prbdet.

**Introduced in R2016b**

# step

**System object:** comm.PreambleDetector

**Package:** comm

Detect preamble in data

## Syntax

```
idx = step(prbdet,x)
[idx,detmet] = step(prbdet,x)
idx = prbdet(x)
[idx,detmet] = prbdet(x)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`idx = step(prbdet,x)` returns the location of the end of the preamble in data sequence `x`, using preamble detector `prbdet`. The index is of data type `double`.

`[idx,detmet] = step(prbdet,x)` also returns the detection metric, `detmet`. This syntax is available when the Input property is 'Symbol'. `detmet` has the same dimensions and data type as `x`.

The output, `detmet`, is determined by one of these algorithms:

- If either the preamble or input data is complex, the detection metric is the absolute value of the cross-correlation of the preamble and the input signal.
- If both the preamble and input data are real, the detection metric is the cross-correlation of the preamble and the input signal.

`idx = prbdet(x)` is equivalent to the first syntax.

`[idx,detmet] = prbdet(x)` is equivalent to the second syntax.

---

**Note** `prbdet` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Introduced in R2016b**

# comm.PSKCoarseFrequencyEstimator

**Package:** comm

(To be removed) Estimate frequency offset for PSK signal

---

**Note** will be removed in a future release. Use `comm.CoarseFrequencyCompensator` instead.

---

## Description

The `PSKCoarseFrequencyEstimator` System object estimates frequency offset for a PSK signal.

To estimate frequency offset for a PSK signal:

- 1 Define and set up your PSK coarse frequency estimator object. See “Construction” on page 4-1435.
- 2 Call `step` to estimate frequency offset for a PSK signal according to the properties of `comm.PSKCoarseFrequencyEstimator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.PSKCoarseFrequencyEstimator` creates a PSK coarse frequency offset estimator object, `H`. This object uses an open-loop technique to estimate the carrier frequency offset in a received PSK signal.

`H = comm.PSKCoarseFrequencyEstimator(Name,Value)` creates a PSK coarse frequency offset estimator object, `H`, with the specified property `Name` set to the specified

Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### **ModulationOrder**

Modulation order the object uses

Specify the modulation order of the PSK signal as a positive, real scalar of data type double. This value must be a positive power of 2. The default is 4.

### **Algorithm**

Estimation algorithm to object uses

Specify the estimation algorithm as one of FFT-based or Correlation-based. The default is FFT-based.

### **FrequencyResolution**

Desired frequency resolution (Hz)

Specify the desired frequency resolution for offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length used to perform spectral analysis, and must be less than or equal to half the SampleRate on page 4-0 property. This property applies only if the Algorithm property is FFT-based. The default is 0.001.

### **MaximumOffset**

Maximum measurable frequency offset (Hz)

Specify the maximum measurable frequency offset as a positive, real scalar of data type double. The default is 0.05.

The value of this property must be less than  $\text{SampleRate on page 4-0} / \text{ModulationOrder on page 4-0}$ . It is recommended that  $\text{MaximumOffset on page 4-0}$  be less than or equal to  $\text{SampleRate on page 4-0} / (4 * \text{ModulationOrder on page 4-0})$ . This property is active only if the Algorithm property is Correlation-based.

## SampleRate

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1.

## Methods

`reset` (To be removed) Reset states of the PSKCoarseFrequencyEstimator object

`step` (To be removed) Estimate frequency offset for PSK signal

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Correct For a Frequency Offset in a QPSK Signal

Estimate and correct for a -250 Hz frequency offset in a QPSK signal using the PSK Coarse Frequency Estimator System object?

Create a square root raised cosine transmit filter System object.

```
txfilter = comm.RaisedCosineTransmitFilter;
```

Create a phase frequency offset object, where the `FrequencyOffset` property is set to -250 Hz and `SampleRate` is set to 4000 Hz using name-value pairs.

```
pfo = comm.PhaseFrequencyOffset(...
    'FrequencyOffset', -250, ...
    'SampleRate', 4000);
```

Create a PSK coarse frequency estimator System object with a sample rate of 4 kHz and a frequency resolution of 1 Hz.

```
frequencyEst = comm.PSKCoarseFrequencyEstimator(...  
    'SampleRate',4000, ...  
    'FrequencyResolution',1);
```

Create a second phase frequency offset object to correct the offset. Set the `FrequencyOffsetSource` property to `Input port` so that the frequency correction estimate is an input argument.

```
pfoCorrect = comm.PhaseFrequencyOffset(...  
    'FrequencyOffsetSource','Input port', ...  
    'SampleRate',4000);
```

Generate a QPSK signal, filter the signal, apply the frequency offset, and pass the signal through the AWGN channel.

```
modData = pskmod(randi([0 3],4096,1),4,pi/4);    % Generate QPSK signal  
txFiltData = txfilter(modData);                % Apply Tx filter  
offsetData = pfo(txFiltData);                  % Apply frequency offset  
noisyData = awgn(offsetData,25);               % Pass through AWGN channel
```

Estimate the frequency offset by using `frequencyEst`. Observe that the estimate is close to the -250 Hz target.

```
estFreqOffset = frequencyEst(noisyData)
```

```
estFreqOffset =  
  
    -250
```

Correct for the frequency offset using `pfoCorrect` and the inverse of the estimated frequency offset.

```
compensatedData = pfoCorrect(noisyData,-estFreqOffset);
```

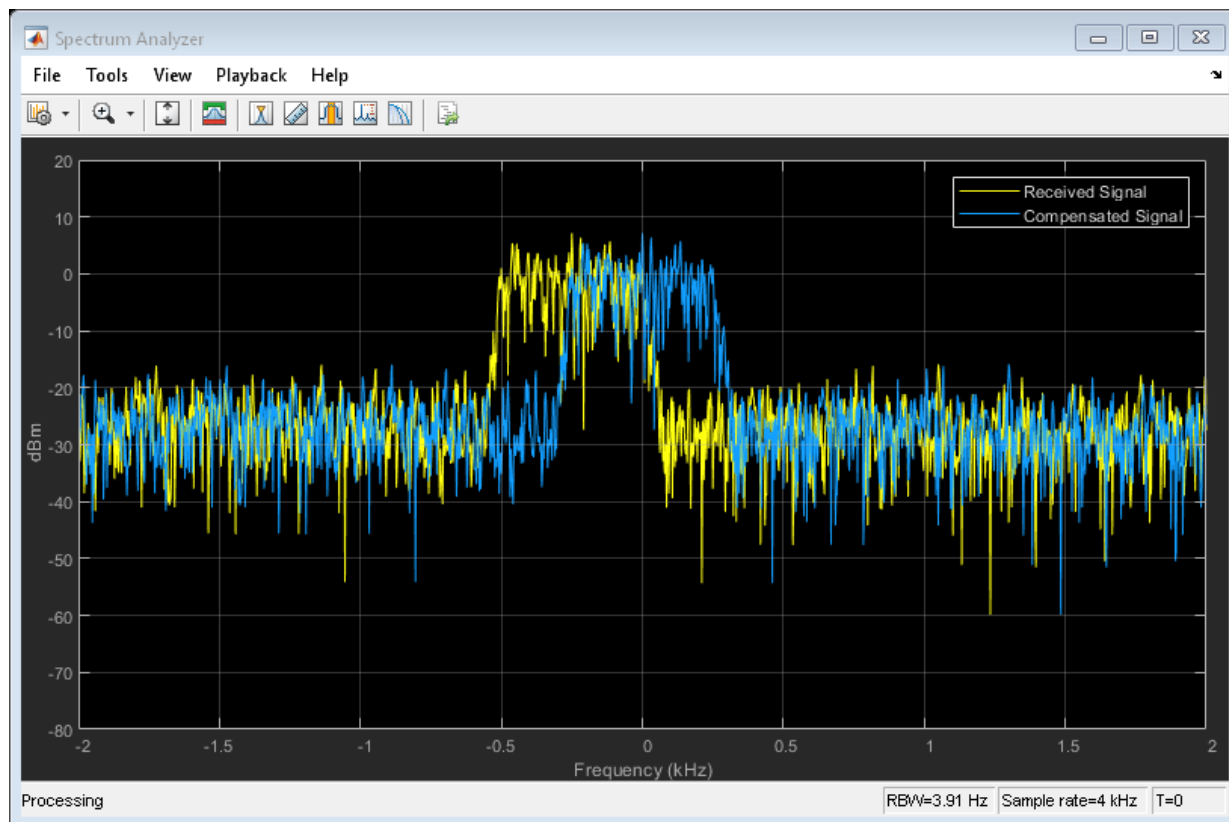

Create a spectrum analyzer object to view the frequency response of the signals.

```
spectrum = dsp.SpectrumAnalyzer('SampleRate',4000, 'ShowLegend',true, ...  
    'ChannelNames',{'Received Signal' 'Compensated Signal'});
```

Plot the frequency response of the received signal, which is shifted 250 Hz to the left, and of the compensated signal using the spectrum analyzer. The compensated signal is now properly centered.

```
spectrum([noisyData compensatedData]);
```

## Compatibility Considerations

### **comm.PSKCoarseFrequencyEstimator will be removed**

*Not recommended starting in R2019a*

comm.PSKCoarseFrequencyEstimator will be removed. Use comm.CoarseFrequencyCompensator instead.

(To be removed) Estimate frequency offset for PSK signal

---

**Note** will be removed in a future release. Use `comm.CoarseFrequencyCompensator` instead.

---

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  estimates the carrier frequency offset of the input  $X$  and returns the result in  $Y$ .  $X$  must be a complex column vector of data type `double`. The `step` method outputs the estimate  $Y$  as a scalar of type `double`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.PSKDemodulator

**Package:** comm

Demodulate using M-ary PSK method

## Description

The `PSKDemodulator` object demodulates an input signal using the M-ary phase shift keying (M-PSK) method.

To demodulate a signal that was modulated using phase shift keying:

- 1 Define and set up your PSK demodulator object. See “Construction” on page 4-1443.
- 2 Call `step` to demodulate the signal according to the properties of `comm.PSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.PSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the M-ary phase shift keying (M-PSK) method.

`H = comm.PSKDemodulator(Name, Value)` creates an M-PSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PSKDemodulator(M, PHASE, Name, Value)` creates an M-PSK demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, the `PhaseOffset` property set to `PHASE`, and the other specified properties set to the specified values. `M` and `PHASE` are value-only arguments. To specify a value-only argument, you must also

specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8.

### PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar value. The default is  $\pi/8$ .

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`. When you set this property to `true`, the `step` method outputs a column vector of bit values. The length of this vector equals  $\log_2(\text{ModulationOrder on page 4-0})$  times the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector with a length equal to the input data vector. This vector contains integer symbol values between 0 and  $\text{ModulationOrder}-1$ .

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder on page 4-0})$  bits to the corresponding symbol. Choose from `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer  $m$ , between  $0 \leq m \leq \text{ModulationOrder}-1$  maps to the complex value  $\exp(j \times \text{PhaseOffset on page 4-0} + j \times 2 \times \pi \times m / \text{ModulationOrder})$ . When you set this property to `Custom`, the object

uses the signal constellation defined in the `CustomSymbolMapping` on page 4-0 property.

### **CustomSymbolMapping**

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:7`. This property requires a row or column vector with a size of `ModulationOrder` on page 4-0 . This vector must have unique integer values in the range `[0, ModulationOrder-1]`. The values must be of data type `double`. The first element of this vector corresponds to the constellation point at an angle of  $\theta + \text{PhaseOffset}$  on page 4-0 , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of  $-\pi/\text{ModulationOrder} + \text{PhaseOffset}$ . This property applies when you set the `SymbolMapping` on page 4-0 property to `Custom`.

### **DecisionMethod**

Demodulation decision method

Specify the decision method the object uses as `Hard decision | Log-likelihood ratio | Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` on page 4-0 property to `false`, the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to `true`.

### **VarianceSource**

Source of noise variance

Specify the source of the noise variance as one of `Property | Input port`. The default is `Property`. This property applies when you set the `BitOutput` on page 4-0 property to `true` and the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

### **Variance**

Noise variance

Specify the variance of the noise as a positive, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield `Inf` or `-Inf`. This result occurs because the LLR algorithm computes the exponential

of very large or very small numbers using finite-precision arithmetic. In such cases, use approximate LLR instead because the algorithm for that option does not compute exponentials. This property applies when you set the `BitOutput` on page 4-0 property to `true`, the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio`, or `Approximate log-likelihood ratio`, and the `VarianceSource` on page 4-0 property to `Property`. This property is tunable.

### **OutputDataType**

Data type of output

Specify the output data type as `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`. This property applies when you set the `BitOutput` on page 4-0 property to `false`. It also applies when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`. In this second case, when the `OutputDataType` on page 4-0 property is set to `Full precision`, the input data type is single- or double-precision, the output data has the same data type as the input. . When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` property to `Smallest unsigned integer`.

When you set `BitOutput` to `true` and the `DecisionMethod` property to `Hard Decision`, then logical data type becomes a valid option. If you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, the output data has the same data type as the input. In this case, the data type must be single- or double-precision.

### **Fixed-Point Properties**

#### **DerotateFactorDataType**

Data type of derotate factor

Specify the derotate factor data type as `Same word length as input` | `Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on page 4-0 property to `false`. It also applies when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`. The object uses the derotate factor in the computations only when the `ModulationOrder` on page 4-0 property is 2, 4, or 8. The `step` method input must also have a fixed-point type, and the `PhaseOffset` on page 4-0 property must have a nontrivial value. For `ModulationOrder` = 2, the phase offset is trivial if that value is a

multiple of  $\pi/2$ . For `ModulationOrder = 4`, the phase offset is trivial if that value is an even multiple of  $\pi/4$ . For `ModulationOrder = 8`, there are no trivial phase offsets.

### CustomDerotateFactorDataType

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([],16)`. This property applies when you set the `DerotateFactorDataType` on page 4-0 property to `Custom`. The word length must be a value between 2 and 128.

## Examples

### 16-PSK with Custom Symbol Mapping

Create 16-PSK modulator and demodulator System objects™ in which custom symbol mapping is used. Estimate the BER in an AWGN channel and compare the performance with that of a theoretical Gray-coded PSK system.

Create a custom symbol mapping for the 16-PSK modulation scheme. The 16 integer symbols must have values which fall between 0 and 15.

```
custMap = [0 2 4 6 8 10 12 14 15 13 11 9 7 5 3 1];
```

Create a 16-PSK modulator and demodulator pair having custom symbol mapping defined by the array, `custMap`.

```
pskModulator = comm.PSKModulator(16,'BitInput',true, ...
    'SymbolMapping','Custom', ...
```

```
'CustomSymbolMapping', custMap);
pskDemodulator = comm.PSKDemodulator(16, 'BitOutput', true, ...
    'SymbolMapping', 'Custom', ...
    'CustomSymbolMapping', custMap);
```

Display the modulator constellation.

```
constellation(pskModulator)
```

Create an AWGN channel System object for use with 16-ary data.

```
awgnChannel = comm.AWGNChannel('BitsPerSymbol', log2(16));
```

Create an error rate object to track the BER statistics.

```
errorRate = comm.ErrorRate;
```

Initialize the simulation vectors. The Eb/No is varied from 6 to 18 dB in 1 dB steps.

```
ebnoVec = 6:18;
ber = zeros(size(ebnoVec));
```

Estimate the BER by modulating binary data, passing it through an AWGN channel, demodulating the received signal, and collecting the error statistics.

```
for k = 1:length(ebnoVec)

    % Reset the error counter for each Eb/No value
    reset(errorRate)
    % Reset the array used to collect the error statistics
    errVec = [0 0 0];
    % Set the channel Eb/No
    awgnChannel.EbNo = ebnoVec(k);

    while errVec(2) < 200 && errVec(3) < 1e7
        % Generate a 1000-symbol frame
        data = randi([0 1],4000,1);
        % Modulate the binary data
        modData = pskModulator(data);
        % Pass the modulated data through the AWGN channel
        rxSig = awgnChannel(modData);
        % Demodulate the received signal
        rxData = pskDemodulator(rxSig);
        % Collect the error statistics
        errVec = errorRate(data,rxData);
    end

    % Save the BER data
    ber(k) = errVec(1);
end
```

Generate theoretical BER data for an AWGN channel using `berawgn`.

```
berTheory = berawgn(ebnoVec, 'psk', 16, 'nondiff');
```

Plot the simulated and theoretical results. Because the simulated results rely on 16-PSK modulation that does not use Gray codes, the performance is not as good as that predicted by theory.

```
figure
semilogy(ebnoVec,[ber; berTheory])
```

```
xlabel('Eb/No (dB)')
ylabel('BER')
grid
legend('Simulation','Theory','location','ne')
```

# step

**System object:** comm.PSKDemodulator

**Package:** comm

Demodulate using M-ary PSK method

## Syntax

$Y = \text{step}(H, X)$

$Y = \text{step}(H, X, \text{VAR})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  demodulates data,  $X$ , with the PSK demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a scalar or a column vector with double or single precision data type. If the value of the `ModulationOrder` property is less than or equal to 8 and you set `BitOutput` to `false`, or when you set the `DecisionMethod` property to `Hard Decision` and `BitOutput` to `true`, the object accepts an input with a signed integer data type or signed fixed point (fi objects). Depending on the `BitOutput` property value, output  $Y$ , can be integer or bit valued.

$Y = \text{step}(H, X, \text{VAR})$  uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to `Input port`. The data type of input `VAR` must be double or single precision.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.PSKModulator

**Package:** comm

Modulate using M-ary PSK method

### Description

The `PSKModulator` object modulates using the M-ary phase shift keying method. The output is a baseband representation of the modulated signal. The M-ary number parameter, `M`, is the number of points in the signal constellation.

To modulate a signal using phase shift keying:

- 1 Define and set up your PSK modulator object. See “Construction” on page 4-1466.
- 2 Call `step` to modulate the signal according to the properties of `comm.PSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.PSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the M-ary phase shift keying (M-PSK) method.

`H = comm.PSKModulator(Name,Value)` creates an M-PSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.PSKModulator(M,PHASE,Name,Value)` creates an M-PSK modulator object, `H`. This object has the `ModulationOrder` property set to `M`, the `PhaseOffset` property set to `PHASE`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8.

### PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar value. The default is  $\pi/8$ .

### BitInput

Assume bit inputs

Specify whether the input is bits or integers. When you set this property to `true`, the `step` method input must be a column vector of bit values. This vector must have a length that is an integer multiple of  $\log_2(\text{ModulationOrder on page 4-0})$ . This vector contains bit representations of integers between 0 and  $\text{ModulationOrder}-1$ . When you set the `BitInput on page 4-0` property to `false`, the `step` method input must be a column vector of numeric data type integer symbol values. These values must be between 0 and  $\text{ModulationOrder}-1$ . The default is `false`.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder on page 4-0})$  input bits to the corresponding symbol as one of `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer  $m$ , between  $0 \leq m \leq \text{ModulationOrder}-1$  maps to the complex value  $\exp(j \times \text{PhaseOffset on page 4-0} + j \times 2 \times \pi \times m / \text{ModulationOrder})$ . When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping on page 4-0` property.

### CustomSymbolMapping

Custom constellation encoding

Specify a custom constellation symbol mapping vector. This property requires a row or column vector of size `ModulationOrder` on page 4-0 and must have unique integer values in the range  $[0, \text{ModulationOrder}-1]$ . The values must be of data type `double`. The first element of this vector corresponds to the constellation point at an angle of  $\theta + \text{PhaseOffset}$  on page 4-0, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of  $-\pi / \text{ModulationOrder} + \text{PhaseOffset}$ . This property applies when you set the `SymbolMapping` on page 4-0 property to `Custom`. The default is `0:7`.

### OutputDataType

Data type of output

Specify the output data type as `double` | `single` | `Custom`. The default is `double`.

### Fixed-Point Properties

#### CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([ ], 16)`. This property applies when you set the `OutputDataType` on page 4-0 property to `Custom`.

## Methods

<code>constellation</code>	Calculate or plot ideal signal constellation
<code>step</code>	Modulate using M-ary PSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Add White Gaussian Noise to 8-PSK Signal

Modulate an 8-PSK signal, add white Gaussian noise, and plot the signal to observe the effects of noise.

Create a PSK modulator System object™. The default modulation order for the PSK modulator object is 8.

```
pskModulator = comm.PSKModulator;
```

Modulate the signal.

```
modData = pskModulator(randi([0 7],2000,1));
```

Add white Gaussian noise to the modulated signal by passing the signal through an AWGN channel.

```
channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',3);
```

Transmit the signal through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the noiseless and noisy data using scatter plots to observe the effects of noise.

```
scatterplot(modData)
```

```
scatterplot(channelOutput)
```

Change the EbNo property to 10 dB to increase the noise.

```
channel.EbNo = 10;
```

Pass the modulated data through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the channel output. You can see the effects of increased noise.

```
scatterplot(channelOutput)
```

## Algorithms

The block outputs a baseband signal by mapping input bits or integers to complex symbols according to the following:

$$s_n(t) = \exp\left(j\pi\left(\frac{2n+1}{M}\right)\right); \quad n \in \{0, 1, \dots, M-1\}.$$

This applies when a natural binary ordering is used. Another common mapping is Gray coding, which has the advantage that only one bit changes between adjacent constellation

points. This results in better bit error rate performance. For 8-PSK modulation with Gray coding, the mapping between the input and output symbols is shown.

<b>Input</b>	<b>Output</b>
0	0 (000)
1	1 (001)
2	3 (011)
3	2 (010)
4	6 (110)
5	7 (111)
6	5 (101)
7	4 (100)

The corresponding constellation diagram follows.

When the input signal is composed of bits, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of  $\log_2(M)$  bits.

constellation(demod)
```

---

# step

**System object:** comm.PSKModulator

**Package:** comm

Modulate using M-ary PSK method

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  modulates input data,  $X$ , with the PSK modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.PSKTCMDemodulator

**Package:** comm

Demodulate convolutionally encoded data mapped to M-ary PSK signal constellation

### Description

The `PSKTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a PSK signal constellation.

To demodulate a signal that was modulated using trellis-coded modulation:

- 1 Define and set up your PSK TCM demodulator object. See “Construction” on page 4-1480.
- 2 Call `step` to demodulate the signal according to the properties of `comm.PSKTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.PSKTCMDemodulator` creates a trellis-coded, M-ary phase shift, keying (PSK TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to an M-PSK constellation.

`H = comm.PSKTCMDemodulator(Name,Value)` creates a PSK TCM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.PSKTCMDemodulator(TRELLIS,Name,Value)` creates a PSK TCM demodulator System object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

## Properties

### **TrellisStructure**

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether the trellis structure is valid. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

### **TerminationMethod**

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

### **TracebackDepth**

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The traceback depth influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` on page 4-0 property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth×K` zero bits for a rate  $K/N$  convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

### **ResetInputPort**

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous`.

### **ModulationOrder**

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be 4, 8, or 16. The default is 8. The `ModulationOrder` on page 4-0 property value must equal the number of possible input symbols to the convolutional decoder of the PSK TCM demodulator object. The `ModulationOrder` property must equal  $2^N$  for a rate  $K/N$  convolutional code.

### **OutputDataType**

Data type of output

Specify output data type as `logical` | `double`. The default is `double`.

## **Methods**

`reset` Reset states of the PSK TCM demodulator object

`step` Demodulate convolutionally encoded data mapped to M-ary PSK constellation

**Common to All System Objects**

release	Allow System object property value changes

## Examples

### Demodulate Noisy PSK QAM Data

Modulate and demodulate data using 8-PSK TCM modulation in an AWGN channel. Estimate the resulting error rate.

Define a trellis structure with four input symbols and eight output symbols.

```
t = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create modulator and demodulator System objects™ using trellis, `t`, having modulation order 8.

```
hMod = comm.PSKTCModulator(t,'ModulationOrder',8);
hDemod = comm.PSKTCMDemodulator(t,'ModulationOrder',8, ...
    'TracebackDepth',16);
```

Create an AWGN channel object.

```
hAWGN = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',7);
```

Create an error rate calculator with delay in bits equal to `TracebackDepth` times the number of bits per symbol.

```
hError = comm.ErrorRate('ReceiveDelay',...
    hDemod.TracebackDepth*log2(t.numInputSymbols));
```

Generate random binary data and modulate with 8-PSK TCM. Pass the modulated signal through the AWGN channel and demodulate. Calculate the error statistics.

```
for counter = 1:10
    % Transmit frames of 250 2-bit symbols
    data = randi([0 1],500,1);
    % Modulate
    modSignal = step(hMod,data);
    % Pass through AWGN channel
```

```
noisySignal = step(hAWGN,modSignal);  
% Demodulate  
receivedData = step(hDemod,noisySignal);  
% Calculate error statistics  
errorStats = step(hError,data,receivedData);  
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...  
    errorStats(1),errorStats(2))
```

```
Error rate = 2.17e-02  
Number of errors = 108
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## comm.PSKTCMModulator

**Package:** comm

Convolutionally encode binary data and map using M-ary PSK signal constellation

### Description

The `PSKTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and then mapping the result to a PSK signal constellation.

To modulate a signal using trellis-coded modulation:

- 1 Define and set up your PSK TCM modulator object. See “Construction” on page 4-1488.
- 2 Call `step` to modulate the signal according to the properties of `comm.PSKTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.PSKTCMModulator` creates a trellis-coded M-ary phase shift keying (PSK TCM) modulator System object, `H`. This object convolutionally encodes a binary input signal and maps the result to an M-PSK constellation.

`H = comm.PSKTCMModulator(Name,Value)` creates a PSK TCM encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.PSKTCMModulator(TRELLIS,Name,Value)` creates a PSK TCM encoder object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a trellis structure is valid. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

### TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. However, for each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate  $K/N$  code, the `step` method outputs the vector with a length given by  $y = N \times (L + S)/K$ , where  $S = \text{constraintLength}-1$  (or, in the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i)-1)$ ).  $L$  indicates the length of the input to the `step` method.

### ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the

encoder reset to initial conditions. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous`.

### **ModulationOrder**

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to 4, 8, or 16. The default is 8. The value of the `ModulationOrder` on page 4-0 property must equal the number of possible output symbols from the convolutional encoder of the PSK TCM modulator. Thus, the value for the `ModulationOrder` property must equal  $2^N$  for a rate  $K/N$  convolutional code.

### **OutputDataType**

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

## **Methods**

`reset` Reset states of the PSK TCM modulator object

`step` Convolutionally encode binary data and map using M-ary PSK constellation

<b>Common to All System Objects</b>	
<code>release</code>	Allow System object property value changes

## **Examples**

### **Modulate Data Using 8-PSK TCM Modulation**

Modulate random data using 8-PSK TCM modulation and display the constellation diagram.

Create binary data.

```
data = randi([0 1],1000,1);
```

Define a trellis structure with four input symbols and eight output symbols.

```
t = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create an 8-PSK TCM modulator object using the trellis structure variable, t.

```
hMod = comm.PSKTCMModulator(t,'ModulationOrder',8);
```

Modulate and plot the data.

```
modData = step(hMod,data);  
scatterplot(modData);
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

`Y = step(H,X,R)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` convolutionally encodes and modulates the input binary data column vector, `X`, and returns the encoded and modulated data, `Y`. `X` must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector, `X`, must be  $K \times L$ , for some positive integer  $L$ . The `step` method outputs a complex column vector, `Y`, of length  $L$ .

`Y = step(H,X,R)` resets the encoder of the PSK TCM modulator object to the all-zeros state when you input a reset signal, `R`, that is non-zero. `R` must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## comm.QAMCoarseFrequencyEstimator

**Package:** comm

(To be removed) Estimate frequency offset for QAM signal

---

**Note** comm.QAMCoarseFrequencyEstimator will be removed in a future release. Use comm.CoarseFrequencyCompensator instead.

---

### Description

The QAMCoarseFrequencyEstimator System object estimates frequency offset for a QAM signal.

To estimate frequency offset for a QAM signal:

- 1 Define and set up your QAM Coarse Frequency Estimator object. See “Construction” on page 4-1496.
- 2 Call `step` to estimate frequency offset for a QAM signal according to the properties of `comm.QAMCoarseFrequencyEstimator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.QAMCoarseFrequencyEstimator` creates a rectangular QAM coarse frequency offset estimator object, `H`. This object uses an open-loop, FFT-based technique to estimate the carrier frequency offset in a received rectangular QAM signal.

`H = comm.QAMCoarseFrequencyEstimator(Name,Value)` creates a rectangular QAM coarse frequency offset estimator object, `H`, with the specified property `Name` set to

the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### FrequencyResolution

Desired frequency resolution (Hz)

Specify the desired frequency resolution for offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length that the object uses to perform spectral analysis. The value for this property must be less than or equal to half the SampleRate on page 4-0 property. The default is 0.001.

### SampleRate

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1.

## Examples

### Correct Frequency Offset in 16-QAM Signal

Estimate and correct for a -250 Hz frequency offset in a 16-QAM signal using the QAM Coarse Frequency Estimator System object?.

Create a rectangular QAM modulator System object using name-value pairs to set the modulation order to 16 and the constellation to have an average power of 1 W.

```
qamModulator = comm.RectangularQAMModulator('ModulationOrder',16, ...  
      'NormalizationMethod','Average power', ...  
      'AveragePower',1);
```

Create a square root raised cosine transmit filter System object.

```
txfilter = comm.RaisedCosineTransmitFilter;
```

Create a phase frequency offset object, where the FrequencyOffset property is set to -250 Hz and SampleRate is set to 4000 Hz using name-value pairs.

```
pfo = comm.PhaseFrequencyOffset(...  
      'FrequencyOffset',-250, ...  
      'SampleRate',4000);
```

Create a QAM coarse frequency estimator System object with a sample rate of 4 kHz and a frequency resolution of 1 Hz.

```
frequencyEst = comm.QAMCoarseFrequencyEstimator(...  
      'SampleRate',4000, ...  
      'FrequencyResolution',1);
```

Create a second phase frequency offset object to correct the offset. Set the FrequencyOffsetSource property to Input port so that the frequency correction estimate is an input argument.

```
pfoCorrect = comm.PhaseFrequencyOffset(...  
      'FrequencyOffsetSource','Input port', ...  
      'SampleRate',4000);
```

Create a spectrum analyzer object to view the frequency response of the signals.

```
spectrum = dsp.SpectrumAnalyzer('SampleRate',4000);
```

Generate a 16-QAM signal, filter the signal, apply the frequency offset, and pass the signal through the AWGN channel.

```
modData = qamModulator(randi([0 15],4096,1)); % Generate QAM signal  
txFiltData = txfilter(modData); % Apply Tx filter  
offsetData = pfo(txFiltData); % Apply frequency offset  
noisyData = awgn(offsetData,25,'measured'); % Pass through AWGN channel
```

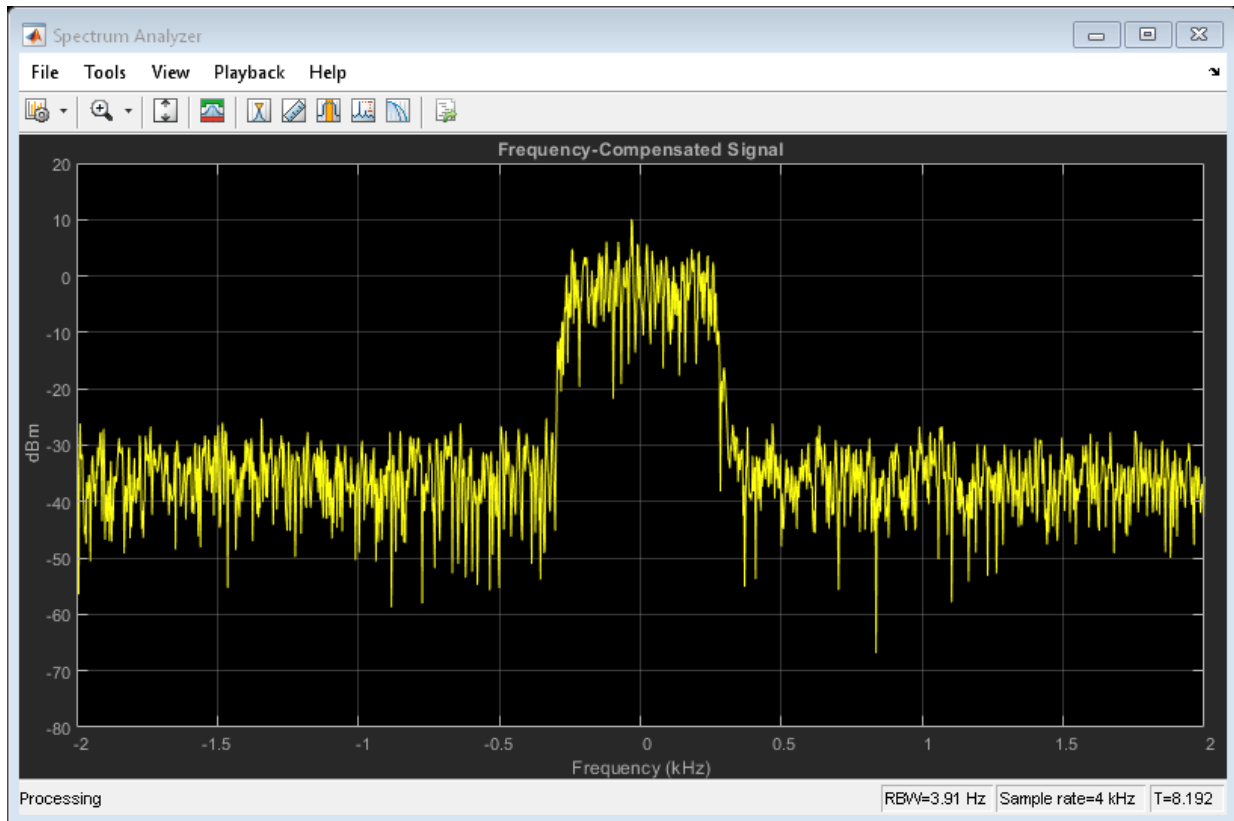

-250

Correct for the frequency offset using `pfoCorrect` and the inverse of the estimated frequency offset.

```
compensatedData = pfoCorrect(noisyData, -estFreqOffset);
```

Plot the frequency response of the compensated signal using the spectrum analyzer. The signal is now properly centered.

```
spectrum.Title = 'Frequency-Compensated Signal';  
spectrum(compensatedData);
```

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  estimates the carrier frequency offset of the input  $X$  and returns the result in  $Y$ .  $X$  must be a complex column vector of data type `double`. The `step` method outputs the estimate  $Y$  as a scalar of type `double`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.QPSKDemodulator

**Package:** comm

Demodulate using QPSK method

## Description

The `QPSKDemodulator` object demodulates a signal that was modulated using the quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using quadrature phase shift keying:

- 1 Define and set up your QPSK demodulator object. See “Construction” on page 4-1505.
- 2 Call `step` to demodulate the signal according to the properties of `comm.QPSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.QPSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the quadrature phase shift keying (QPSK) method.

`H = comm.QPSKDemodulator(Name,Value)` creates a QPSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.QPSKDemodulator(PHASE, Name, Value)` creates a QPSK demodulator object, `H`. This object has the `PhaseOffset` property set to `PHASE`, and the other specified properties set to the specified values.

## Properties

### PhaseOffset

Phase of zeroth point in constellation

Specify the phase offset of the zeroth point in the constellation, in radians, as a real scalar value. The default is  $\pi/4$ .

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values.

When you set this property to `true`, the `step` method outputs a column vector of bit values with length equal to twice the number of demodulated symbols.

When you set this property to `false`, the `step` method outputs a column vector with length equal to the input data vector. This vector contains integer symbol values between 0 and 3. The default is `false`.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of 2 bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses a Gray-encoded signal constellation.

When you set this property to `Binary`, the integer  $m$ , between  $0 \leq m \leq 3$  maps to the complex value  $\exp(j \times \text{PhaseOffset}) + j \times 2\pi \times m/4$ .

### DecisionMethod

Demodulation decision method

Specify the decision method the object uses as `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`.

When you set the `BitOutput` on page 4-0 property to `false`, the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to `true`.

### **VarianceSource**

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the `BitOutput` on page 4-0 property to `true` and the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

### **Variance**

Noise variance

Specify the variance of the noise as a positive, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield `Inf` or `-Inf`. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, use approximate LLR is because that option's algorithm does not compute exponentials.

This property applies when you set the `BitOutput` on page 4-0 property to `true`, the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, and the `VarianceSource` on page 4-0 property to `Property`. This property is tunable.

### **OutputDataType**

Data type of output

Specify the output data type as `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

This property applies when you set the `BitOutput` on page 4-0 property to `false`. The property also applies when you set the `BitOutput` property to `true` and the

`DecisionMethod` on page 4-0 property to `Hard` decision. In this second case, when the `OutputDataType` on page 4-0 property is set to `Full` precision, and the input data type is single or double precision, the output data has the same as that of the input.

When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` property to `Smallest unsigned integer`.

When you set `BitOutput` to `true` and the `DecisionMethod` property to `Hard Decision`, then `logical` data type becomes a valid option.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, the output data type is the same as that of the input. In this case, that data type can only be single or double precision.

### **Fixed-Point Properties**

#### **DerotateFactorDataType**

Data type of derotate factor

Specify derotate factor data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`.

This property applies when you set the `BitOutput` on page 4-0 property to `false`. The property also applies when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard` decision. The object uses the derotate factor in the computations only when the step method input is a fixed-point type and the `PhaseOffset` on page 4-0 property has a value that is not an even multiple of  $\pi/4$ .

#### **CustomDerotateFactorDataType**

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an `unscaled numeric type` object with a signedness of `Auto`. The default is `numeric type ([ ], 16)`. This property applies when you set the `DerotateFactorDataType` on page 4-0 property to `Custom`.

## Methods

constellation      Calculate or plot ideal signal constellation  
 step                Demodulate using QPSK method

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Plot QPSK Reference Constellation

Create a QPSK modulator.

```
mod = comm.QPSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 4×1 complex
```

```
 0.7071 + 0.7071i  

-0.7071 + 0.7071i  

-0.7071 - 0.7071i  

 0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

Create a PSK demodulator having 0 phase offset.

```
demod = comm.QPSKDemodulator('PhaseOffset',0);
```

Plot its reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```

### BER Estimate of QPSK Signal

Create a QPSK modulator and demodulator pair that operate on bits.

```
qpskModulator = comm.QPSKModulator('BitInput',true);  
qpskDemodulator = comm.QPSKDemodulator('BitOutput',true);
```

Create an AWGN channel object and an error rate counter.

```
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);  
errorRate = comm.ErrorRate;
```

Generate random binary data and apply QPSK modulation.

```
data = randi([0 1],1000,1);  
txSig = qpskModulator(data);
```

Pass the signal through the AWGN channel and demodulate it.

```
rxSig = channel(txSig);  
rxData = qpskDemodulator(rxSig);
```

Calculate the error statistics. Display the BER.

```
errorStats = errorRate(data,rxData);  
  
errorStats(1)  
  
ans = 0.0100
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the QPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

constellation(demod)
```

---

## step

**System object:** comm.QPSKDemodulator

**Package:** comm

Demodulate using QPSK method

## Syntax

$Y = \text{step}(H,X)$

$Y = \text{step}(H,X,VAR)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates input data,  $X$ , with the QPSK demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a scalar or a column vector with double or single precision data type. When you set the `BitOutput` property to `false`, or when you set the `DecisionMethod` property to `Hard decision` and the `BitOutput` property to `true`, the data type of the input can also be signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

$Y = \text{step}(H,X,VAR)$  uses soft decision demodulation and noise variance  $VAR$ . This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to `Input port`. The data type of input  $VAR$  must be double or single precision.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.QPSKModulator

**Package:** comm

Modulate using QPSK method

## Description

The `QPSKModulator` object modulates using the quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using quadrature phase shift keying:

- 1 Define and set up your QPSK modulator object. See “Construction” on page 4-1519.
- 2 Call `step` to modulate the signal according to the properties of `comm.QPSKModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.QPSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the quadrature phase shift keying (QPSK) method.

`H = comm.QPSKModulator(Name,Value)` creates a QPSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.QPSKModulator(PHASE,Name,Value)` creates a QPSK modulator object, `H`. This object has the `PhaseOffset` property set to `PHASE` and the other specified properties set to the specified values.

## Properties

### PhaseOffset

Phase of zeroth point in constellation

Specify the phase offset of the zeroth point in the constellation, in radians, as a real scalar value. The default is  $\pi/4$ .

### BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `true`, the `step` method input must be a column vector of bit values. This vector must have a length that is an integer multiple of 2. This vector contains bit representations of integers between 0 and 3. When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between 0 and 3.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or a group of two input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer  $m$ , between  $0 \leq m \leq 3$ , maps to the complex value  $\exp(j \times \text{PhaseOffset on page 4-0} + j \times 2 \times \pi \times m/4)$ .

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

### Fixed-Point Properties

#### CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `OutputDataType` on page 4-0 property to `Custom`.

## Methods

<code>constellation</code>	Calculate or plot ideal signal constellation
<code>step</code>	Modulate using QPSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Plot QPSK Reference Constellation

Create a QPSK modulator.

```
mod = comm.QPSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 4×1 complex
```

```
    0.7071 + 0.7071i
   -0.7071 + 0.7071i
   -0.7071 - 0.7071i
    0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

Create a PSK demodulator having 0 phase offset.

```
demod = comm.QPSKDemodulator('PhaseOffset',0);
```

Plot its reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```

### Phase Noise on QPSK Signal

Create a QPSK modulator object and a phase noise object.

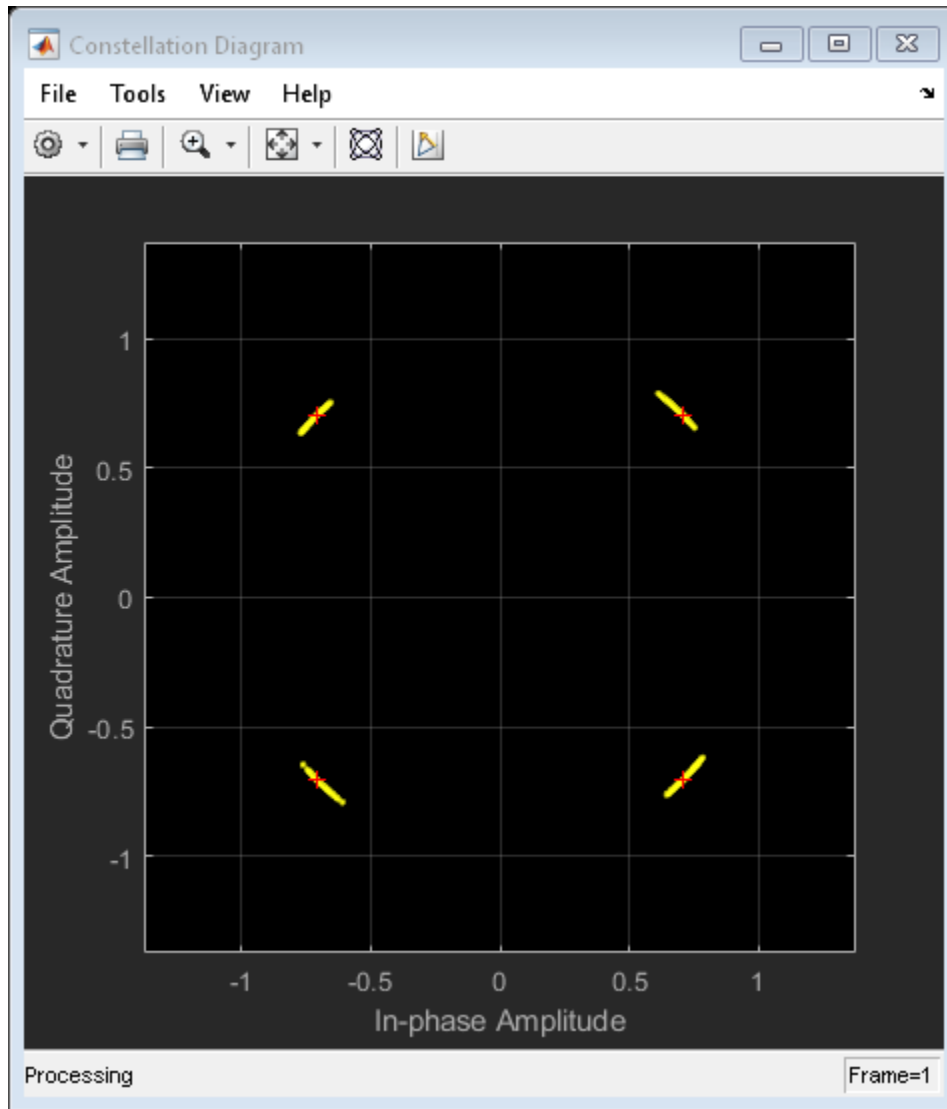

```
qpskModulator = comm.QPSKModulator;
phNoise = comm.PhaseNoise('Level', -55, 'FrequencyOffset', 20, 'SampleRate', 1000);
```

Generate random QPSK data. Pass the signal through the phase noise object.

```
d = randi([0 3], 1000, 1);
x = qpskModulator(d);
y = phNoise(x);
```

Display the constellation diagram of the QPSK signal. The phase noise has introduced a rotational distortion on the constellation diagram.

```
constDiagram = comm.ConstellationDiagram;  
constDiagram(y)
```

Modulate using QPSK method

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  modulates input data,  $X$ , with the QPSK modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.RaisedCosineReceiveFilter

**Package:** comm

Apply pulse shaping by decimating signal using raised cosine filter

## Description

The Raised Cosine Receive Filter System object applies pulse-shaping by decimating an input signal using a raised cosine FIR filter.

To decimate the input signal:

- 1 Define and set up your raised cosine receive filter object. See “Construction” on page 4-1531.
- 2 Call `step` to decimate the input signal according to the properties of `comm.RaisedCosineReceiveFilter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.RaisedCosineReceiveFilter` returns a raised cosine receive filter System object, `H`, which decimates the input signal. The filter uses an efficient polyphase FIR decimation structure and has unit energy.

`H = comm.RaisedCosineReceiveFilter(PropertyName,PropertyValue, ...)` returns a raised cosine receive filter object, `H`, with each specified property set to the specified value.

## Properties

### Shape

Filter shape

Specify the filter shape as one of `Normal` or `Square root`. The default is `Square root`.

### RolloffFactor

Rolloff factor

Specify the rolloff factor as a scalar between 0 and 1. The default is 0.2.

### FilterSpanInSymbols

Filter span in symbols

Specify the number of symbols the filter spans as an integer-valued positive scalar. The default is 10. Because the ideal raised cosine filter has an infinite impulse response, the object truncates the impulse response to the value you specify for this property.

### InputSamplesPerSymbol

Input samples per symbol

Specify the number of input samples that represent a symbol. The default is 8. This property accepts an integer-valued, positive double or single scalar value. The raised cosine filter has  $(\text{FilterSpanInSymbols} \times \text{InputSamplesPerSymbol} + 1)$  taps.

### DecimationFactor

Decimation factor

Specify the factor by which the object reduces the sampling rate of the input signal. The default value is 8. This property accepts a positive integer scalar value between 1 and `InputSamplesPerSymbol`. The value must evenly divide into `InputSamplesPerSymbol`. The number of input rows must be a multiple of the decimation factor. If you set `DecimationFactor` to 1, then the object only applies filtering without downsampling.

## DecimationOffset

Specify the number of filtered samples the System object discards before downsampling. The default is 0. This property accepts an integer valued scalar between 0 and DecimationFactor - 1.

## Gain

Linear filter gain

Specify the linear gain of the filter as a positive numeric scalar. The default is 1. The object designs a raised cosine filter that has unit energy, and then applies the linear gain to obtain final tap values.

## Methods

coeffs	Returns coefficients for filters
reset	Reset internal states of System object
step	Output decimated values of input signal

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### Filter Signal Using Square Root Raised Cosine Receive Filter

Filter the output of a square root raised cosine transmit filter using a matched square root raised cosine receive filter. The input signal has eight samples per symbol.

Create a raised cosine transmit filter and set the OutputSamplesPerSymbol property to 8.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',8);
```

Create a raised cosine receive filter and set the InputSamplesPerSymbol property to 8 and the DecimationFactor property to 8.

```
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',8, ...
    'DecimationFactor',8);
```

Use the `coeffs` function to determine the filter coefficients for both filters.

```
txCoef = coeffs(txfilter);
rxCoef = coeffs(rxfilter);
```

Launch the filter visualization tool and display the magnitude responses of the two filters. Observe that they have identical responses.

```
fvtool(txCoef.Numerator,1,rxCoef.Numerator,1);
legend('Tx Filter','Rx Filter')
```

Generate a random bipolar signal and then interpolate.

```
preTx = 2*randi([0 1],100,1) - 1;  
y = txfilter(preTx);
```

Decimate the signal using the raised cosine receive filter System object.

```
postRx = rxfilter(y);
```

The filter delay is equal to the `FilterSpanInSymbols` property. Adjust for the delay to compare the pre-Tx filter signal with the post-Rx filter signal.

```
delay = txfilter.FilterSpanInSymbols;  
x = (1:(length(preTx)-delay));  
plot(x,preTx(1:end-delay),x,postRx(delay+1:end))  
legend('Pre-Tx Filter','Post-Rx Filter')
```

You can see that the two signals overlap one another since the receive filter is *matched* to the transmit filter.

### Specify Filter Span of Raised Cosine Receive Filter

Decimate a bipolar signal using a square root raised cosine filter whose impulse response is truncated to six symbol durations.

Create a raised cosine transmit filter and set the `FilterSpanInSymbols` property to 6. The object truncates the impulse response to six symbols.

```
txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
```

Generate a random bipolar signal and filter it using `txfilter`.

```
x = 2*randi([0 1],25,1) - 1;  
y = txfilter(x);
```

Create a matched raised cosine receive filter System object.

```
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',6);
```

Launch the filter visualization tool to show the impulse response of the receive filter.

```
fvtool(rxfilter,'Analysis','impulse')
```

Filter the output signal from the transmit filter using the matched receive filter object, `rxfilter`.

```
r = rxfilter(y);
```

Plot the interpolated signal. Because of the filter span, there is a delay of six symbols before data passes through the filter.

```
stem(r)
```

### **Raised Cosine Receive Filter with Unity Passband Gain**

Create a raised cosine receive filter with unity passband gain.

Create a raised cosine receive filter System object™. Obtain the filter coefficients using the `coeffs` function.

```
rxfilter = comm.RaisedCosineReceiveFilter;  
b = coeffs(rxfilter);
```

A filter with unity passband gain has filter coefficients such that the sum of coefficients is 1. Therefore, set the `Gain` property to the inverse of the sum of `b.Numerator`.

```
rxfilter.Gain = 1/sum(b.Numerator);
```

Verify that the sum of the coefficients from the resulting filter equal 1.

```
bNorm = coeffs(rxfilter);  
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the frequency response of the filter. Note that it shows a passband gain of 0 dB, which is unity gain.

```
fvtool(rxfilter)
```

## **Extended Capabilities**

## coeffs

**System object:** comm.RaisedCosineReceiveFilter

**Package:** comm

Returns coefficients for filters

## Syntax

```
S = coeffs(H)
S = coeffs(H, 'Arithmetic', ARITH, ...)
```

## Description

`S = coeffs(H)` Returns the coefficients of filter System object, `H`, in the structure `S`.

`S = coeffs(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object, `H`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of `double`, `single`, or `fixed`. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The `coeffs` method returns the quantized filter coefficients when you set `ARITH` to `single` or `fixed`.

# reset

## Syntax

`reset(Obj)`

## Description

`reset(Obj)` resets the internal states of System object `Obj` to their initial values.

---

## step

**System object:** comm.RaisedCosineReceiveFilter

**Package:** comm

Output decimated values of input signal

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  outputs the decimated values,  $Y$ , of the input signal  $X$ . The System object treats the input matrix  $K_i$ -by- $N$  as  $N$  independent channels. The System object filters each channel over time and generates a  $K_o$ -by- $N$  output matrix.  $K_o = K_i/M$  where  $M$  represents the decimation factor. The System object supports real and complex floating-point inputs.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.RaisedCosineTransmitFilter

**Package:** comm

Apply pulse shaping by interpolating signal using raised cosine filter

### Description

The Raised Cosine Transmit Filter System object applies pulse-shaping by interpolating an input signal using a raised cosine FIR filter.

To interpolate the input signal:

- 1 Define and set up your raised cosine transmit filter object. See “Construction” on page 4-1544.
- 2 Call `step` to interpolate the input signal according to the properties of `comm.RaisedCosineTransmitFilter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.RaisedCosineTransmitFilter` returns a raised cosine transmit filter System object, `H`, which interpolates an input signal using a raised cosine FIR filter. The filter uses an efficient polyphase FIR interpolation structure and has unit energy.

`H = comm.RaisedCosineTransmitFilter(PropertyName,PropertyValue, ...)` returns a raised cosine transmit filter object, `H`, with each specified property set to the specified value.

## Properties

### Shape

Filter shape

Specify the filter shape as one of `Normal` or `Square root`. The default is `Square root`.

### RolloffFactor

Rolloff factor

Specify the rolloff factor as a scalar between 0 and 1. The default is 0.2.

### FilterSpanInSymbols

Filter span in symbols

Specify the number of symbols the filter spans as an integer-valued, positive scalar. The default is 10. Because the ideal raised cosine filter has an infinite impulse response, the object truncates the impulse response to the value you specify for this property.

### OutputSamplesPerSymbol

Output samples per symbol

Specify the number of output samples for each input symbol. The default is 8. This property accepts an integer-valued, positive scalar value. The raised cosine filter has  $(\text{FilterSpanInSymbols} \times \text{OutputSamplesPerSymbol} + 1)$  taps.

### Gain

Linear filter gain

Specify the linear gain of the filter as a positive numeric scalar. The default is 1. The object designs a raised cosine filter that has unit energy, and then applies the linear gain to obtain final tap values.

## Methods

coeffs	Returns coefficients for filters
reset	Reset internal states of System object
step	Output interpolated values of input signal

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Interpolate Signal Using Square Root Raised Cosine Filter

This example shows how to interpolate a signal using the `comm.RaisedCosineTransmitFilter` System object and to display its spectrum.

Create a square root raised square root cosine transmit filter object. You can see that its default settings are such that the filter has a square root shape and that there are 8 samples per symbol.

```
txfilter = comm.RaisedCosineTransmitFilter
```

```
txfilter =
```

```
comm.RaisedCosineTransmitFilter with properties:
```

```
          Shape: 'Square root'  
    RolloffFactor: 0.2000  
  FilterSpanInSymbols: 10  
OutputSamplesPerSymbol: 8  
          Gain: 1
```

Generate random bipolar data.

```
data = 2*randi([0 1],10000,1) - 1;
```

Filter the data by using the RRC filter.

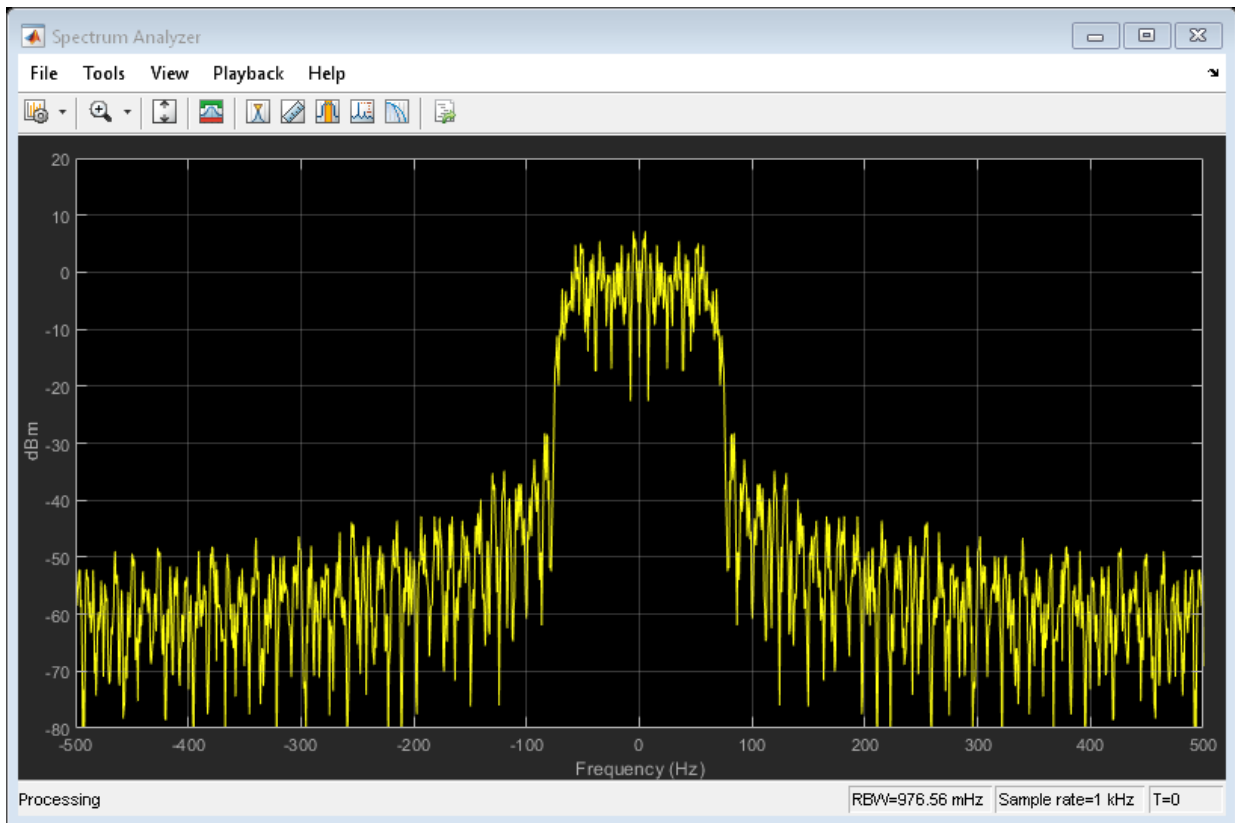

```
filteredData = txfilter(data);
```

To view the spectrum of the filtered signal, create a spectrum analyzer object with a sample rate of 1000 Hz.

```
spectrumAnalyzer = dsp.SpectrumAnalyzer('SampleRate',1000);
```

View the spectrum of the filtered signal using the spectrum analyzer.

```
spectrumAnalyzer(filteredData)
```

### Specify Filter Span of Raised Cosine Transmit Filter

This example shows to create an interpolated signal from a square root raised cosine filter that is truncated to six symbol durations.

Create a raised cosine filter and set the `FilterSpanInSymbols` to 6. The object truncates the impulse response to six symbols.

```
txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
```

Launch the filter visualization tool to show the impulse response.

```
fvtool(txfilter)
```

Generate random bipolar data and pass it through the filter.

```
x = 2*randi([0 1],96,1) - 1;  
y = txfilter(x);
```

Plot the interpolated signal.

```
plot(y)  
grid on
```

### **Raised Cosine Transmit Filter with Unity Passband Gain**

This example shows how to create a raised cosine transmit filter with unity passband gain.

Generate a filter with unit energy. You can obtain the filter coefficients using the `coeffs` function.

```
txfilter = comm.RaisedCosineTransmitFilter;  
b = coeffs(txfilter);
```

Plot the filter response. You can see that its gain is greater than unity (more than 0 dB).

```
fvtool(txfilter)
```

A filter with unity passband gain has filter coefficients that sum to 1. Set the `Gain` property to the inverse of the sum of `b.Numerator`

```
txfilter.Gain = 1/sum(b.Numerator);
```

Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(txfilter);  
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response. Note that it shows a passband gain of 0 dB.

```
fvtool(txfilter)
```

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### **See Also**

`comm.RaisedCosineReceiveFilter` | `rcosdesign`

**Introduced in R2013b**

## coeffs

**System object:** comm.RaisedCosineTransmitFilter

**Package:** comm

Returns coefficients for filters

## Syntax

```
S = coeffs(H)
S = coeffs(H, 'Arithmetic', ARITH, ...)
```

## Description

`S = coeffs(H)` Returns the coefficients of filter System object, H, in the structure S.

`S = coeffs(H, 'Arithmetic', ARITH, ...)` analyzes the filter System object, H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of `double`, `single`, or `fixed`. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The coeffs method returns the quantized filter coefficients when you set ARITH to `single` or `fixed`.

## **reset**

**System object:** comm.RaisedCosineTransmitFilter

**Package:** comm

Reset internal states of System object

## **Syntax**

reset(OBJ)

## **Description**

reset(OBJ) resets the internal states of System object OBJ to their initial values.

---

## step

**System object:** comm.RaisedCosineTransmitFilter

**Package:** comm

Output interpolated values of input signal

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  outputs the interpolated values,  $Y$ , of the input signal  $X$ . The System object treats the input matrix  $K_i$ -by- $N$  as  $N$  independent channels. The object interpolates each channel over the first dimension and then generates a  $K_o$ -by- $N$  output matrix. In the output matrix,  $K_o = K_i * L$ , where  $L$  represents the output samples per symbol. The object supports real and complex floating-point inputs.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.RayleighChannel

**Package:** comm

Filter input signal through a Rayleigh multipath fading channel

### Description

The `RayleighChannel` System object filters an input signal through a Rayleigh fading channel. The fading processing per link is per the Methodology for Simulating Multipath Fading Channels

To filter an input signal using a Rayleigh multipath fading channel:

- 1 Define and set up your Rayleigh channel object. See “Construction” on page 4-1556.
- 2 Call `step` to filter the input signal through a Rayleigh multipath fading channel according to the properties of `comm.RayleighChannel`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.RayleighChannel` creates a frequency-selective or frequency-flat multipath Rayleigh fading channel System object, `H`. This object filters a real or complex input signal through the multipath channel to obtain the channel impaired signal.

`H = comm.RayleighChannel(Name,Value)` creates a multipath Rayleigh fading channel object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### SampleRate

Input signal sample rate (hertz)

Specify the sample rate of the input signal in hertz as a double-precision, real, positive scalar. The default value of this property is 1 Hz.

### PathDelays

Discrete path delay vector (seconds)

Specify the delays of the discrete paths in seconds as a double-precision, real, scalar or row vector. The default value of this property is 0.

When you set `PathDelays` to a scalar, the channel is frequency flat.

When you set `PathDelays` to a vector, the channel is frequency selective.

### AveragePathGains

Average path gain vector (decibels)

Specify the average gains of the discrete paths in decibels as a double-precision, real, scalar or row vector. The default value of this property is 0.

`AveragePathGains` must have the same size as `PathDelays` on page 4-0 .

### NormalizePathGains

Normalize average path gains to 0 dB

Set this property to true to normalize the fading processes such that the total power of the path gains, averaged over time, is 0 dB. The default value of this property is true.

### MaximumDopplerShift

Maximum Doppler shift (hertz)

Specify the maximum Doppler shift for all channel paths in hertz as a double-precision, real, nonnegative scalar. The default value of this property is 0.001 Hz.

The Doppler shift applies to all the paths of the channel. When you set the `MaximumDopplerShift` to 0, the channel remains static for the entire input. You can use the `reset` method to generate a new channel realization.

The `MaximumDopplerShift` must be smaller than  $\text{SampleRate}/10/f_c$  for each path, where  $f_c$  represents the cutoff frequency factor of the path. For most Doppler spectrum types, the value of  $f_c$  is 1. For Gaussian and BiGaussian Doppler spectrum types,  $f_c$  is dependent on the Doppler spectrum structure fields. For more details about how  $f_c$  is defined, see “Cutoff Frequency Factor” on page 4-1575.

### **DopplerSpectrum**

Doppler spectrum object(s)

Specify the Doppler spectrum shape for the path(s) of the channel. This property accepts a single Doppler spectrum structure returned from the `doppler` function or a row cell array of such structures. The maximum Doppler shift value necessary to specify the Doppler spectrum/spectra is given by the `MaximumDopplerShift` on page 4-0 property. This property applies when the `MaximumDopplerShift` on page 4-0 property value is greater than 0. The default value of this property is `doppler('Jakes')`.

If you assign a single Doppler spectrum structure to `DopplerSpectrum`, all paths have the same specified Doppler spectrum. If the `FadingTechnique` property is `Sum of sinusoids`, `DopplerSpectrum` must be `doppler('Jakes')`; otherwise, select from the following:

- `doppler('Jakes')`
- `doppler('Flat')`
- `doppler('Rounded', ...)`
- `doppler('Bell', ...)`
- `doppler('Asymmetric Jakes', ...)`
- `doppler('Restricted Jakes', ...)`
- `doppler('Gaussian', ...)`
- `doppler('BiGaussian', ...)`

If you assign a row cell array of different Doppler spectrum structures (which can be chosen from any of those on the previous list) to `DopplerSpectrum`, each path has the Doppler spectrum specified by the corresponding structure in the cell array. In this case, the length of `DopplerSpectrum` must be equal to the length of `PathDelays`.

To generate C code, specify this property to a single Doppler spectrum structure. The default value of this property is `doppler('Jakes')`.

### **FadingTechnique**

Fading technique used to model the channel

Select between `Filtered Gaussian noise` and `Sum of sinusoids` to specify the way in which the channel is modeled. The default value is `Filtered Gaussian noise`.

### **NumSinusoids**

Number of sinusoids used to model the fading process

The `NumSinuoids` property is a positive integer scalar that specified the number of sinusoids used in modeling the channel and is available only when the `FadingTechnique` property is set to `Sum of sinusoids`. The default value is `48`.

### **InitialTimeSource**

Source to control the start time of the fading process

Specify the initial time source as either `Property` or `Input port`. This property is available when the `FadingTechnique` property is set to `Sum of sinusoids`. When `InitialTimeSource` is set to `Input port`, the start time of the fading process is specified using the `INITIALTIME` input to the `step` function. The input value can change in consecutive calls to the `step` function. The default value is `Property`.

### **InitialTime**

Start time of the fading process (s)

Specify the time offset of the fading process as a real nonnegative scalar in seconds. This property applies when the `FadingTechnique` property is set to `Sum of sinusoids` and the `InitialTimeSource` property is set to `Property`. The default value is `0`.

`InitialTime` must be greater than the last frame end time. When `InitialTime` is not a multiple of `1/SampleRate`, it is rounded up to the nearest sample position.

### **RandomStream**

Source of random number stream

Specify the source of random number stream as one of `Global stream` | `mt19937ar` with `seed`. The default value of this property is `Global stream`.

If you set `RandomStream` to `Global stream`, the current global random number stream is used for normally distributed random number generation. In this case, the `reset` method only resets the filters.

If you set `RandomStream` to `mt19937ar` with `seed`, the `mt19937ar` algorithm is used for normally distributed random number generation. In this case, the `reset` method not only resets the filters but also reinitializes the random number stream to the value of the `Seed` property.

### **Seed**

Initial seed of `mt19937ar` random number stream

Specify the initial seed of a `mt19937ar` random number generator algorithm as a double-precision, real, nonnegative integer scalar. The default value of this property is `73`. This property applies when you set the `RandomStream` property to `mt19937ar` with `seed`. The `Seed` reinitializes the `mt19937ar` random number stream in the `reset` method.

### **PathGainsOutputPort**

Enable path gain output (logical)

Set this property to `true` to output the channel path gains of the underlying fading process. The default value of this property is `false`.

### **Visualization**

Enable channel visualization

Specify the type of channel visualization to display as one of `Off` | `Impulse response` | `Frequency response` | `Impulse and frequency responses` | `Doppler spectrum`. The default value of this property is `Off`.

### **SamplesToDisplay**

Specify percentage of samples to display

You can specify the percentage of samples to display, since displaying fewer samples will result in better performance at the expense of lower accuracy. Specify the property as one of `10%` | `25%` | `50%` | `100%`. This applies when `Visualization` is set to `Impulse`

response, Frequency response, or Impulse and frequency responses. The default value is 25%.

### PathsForDopplerDisplay

Specify path for Doppler display

You can specify an integer scalar which selects the discrete path used in constructing a Doppler spectrum plot. The specified path must be an element of  $\{1, 2, \dots, N_p\}$ , where  $N_p$  is the number of discrete paths per link specified in the object. This property applies when `Visualization` is set to `Doppler spectrum`. The default value is 1.

## Methods

- info    Display information about the `RayleighChannel` object
- reset    Reset states of the `RayleighChannel` object
- step    Filter input signal through multipath Rayleigh fading channel

Common to All System Objects	
release	Allow System object property value changes

## Visualization

### Impulse Response

The impulse response plot displays the path gains, the channel filter coefficients, and the interpolated path gains. The path gains shown in magenta occur at time instances which correspond to the specified `PathDelays` property and may not be aligned with the input sampling time. The channel filter coefficients shown in yellow are used to model the channel. They are interpolated from the actual path gains and are aligned with the input sampling time. In cases in which the path gains are aligned with the sampling time, they will overlap the filter coefficients. Sinc interpolation is used to connect the channel filter coefficients and is shown in blue. These points are used solely for display purposes and not used in subsequent channel filtering. For a flat fading channel (one path), the sinc interpolation curve is not displayed. For all impulse response plots, the frame and sample numbers are shown in the display's upper left corner.

The impulse response plot shares the same toolbar and menus as the System object it was based on, `dsp.ArrayPlot`.

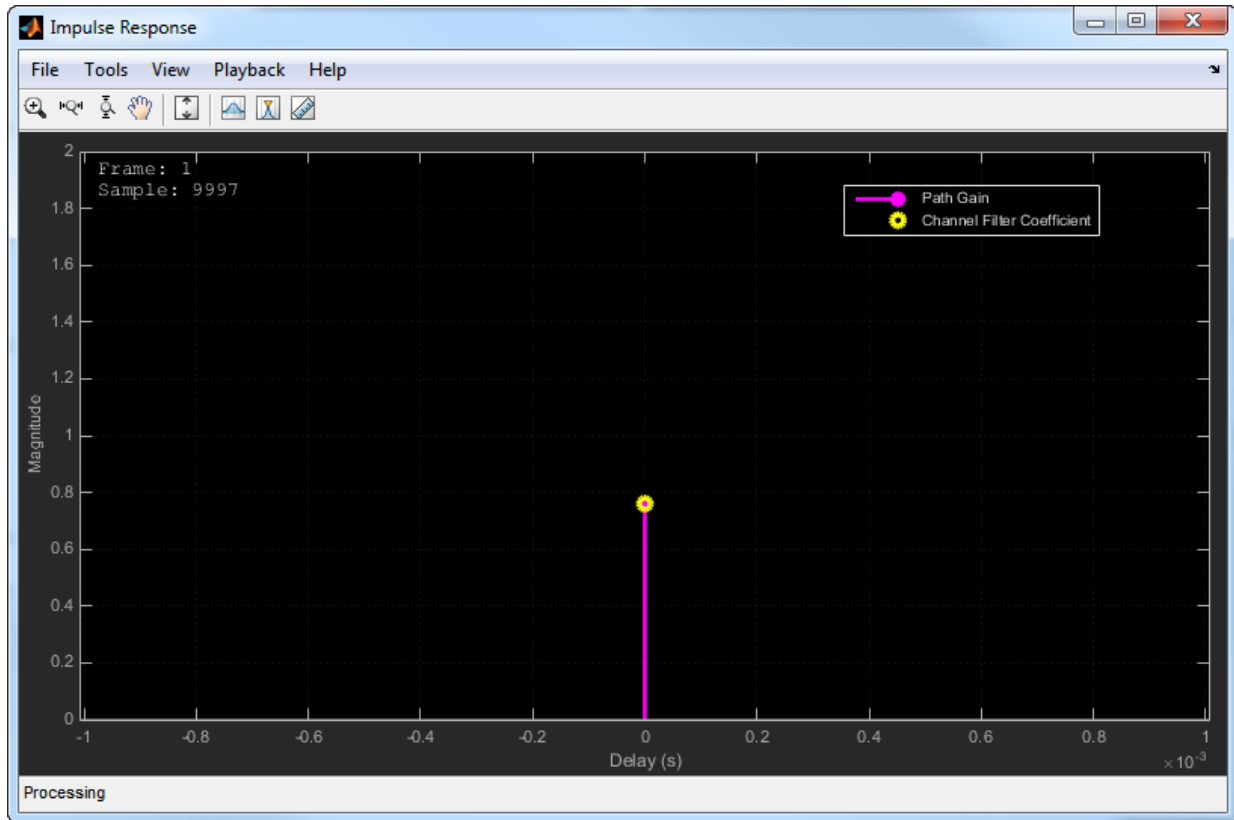

In the figure, the impulse response of a channel is shown for the case in which the path gains are aligned with the sample time. The overlap between the path gains and filter coefficients is evident.

The case in which the specified path gains are not aligned with the `SampleRate` property is shown below. Observe that the path gains and the channel filter coefficients do not overlap and that the filter coefficients are equally distributed.

The impulse response for a frequency flat channel is shown below. You can see that the interpolated path gains are not displayed.

---

### Note

- The displayed and specified path gain locations can differ by as much as 5% of the input sample time.
  - The visualization display speed is controlled by the combination of the `SamplesToDisplay` property and the **Reduce Updates to Improve Performance** menu item. Reducing the percentage of samples to display and the enabling reduced updates will speed up the rendering of the impulse response.
  - After the impulse response plots are manually closed, the `step` call for the Rayleigh channel object will be executed at its normal speed.
  - Code generation is available only when the `Visualization` property is `Off`.
-

## Frequency Response

The frequency response plot displays the Rayleigh channel spectrum by taking a discrete Fourier transform of the channel filter coefficients. The frequency response plot shares the same toolbar and menus as the System object it was based on, `dsp.SpectrumAnalyzer`. The default parameter settings are shown below. These parameters can be changed from their default values by using the **View > Spectrum Settings** menu.

Parameter	Value
Window	Rectangular
WindowLength	Channel filter length
FFTLength	512
PowerUnits	dBW
YLimits	Based on <code>NormalizePathGains</code> and <code>AveragePathGains</code> properties

The frequency response plot for a frequency selective channel is shown.

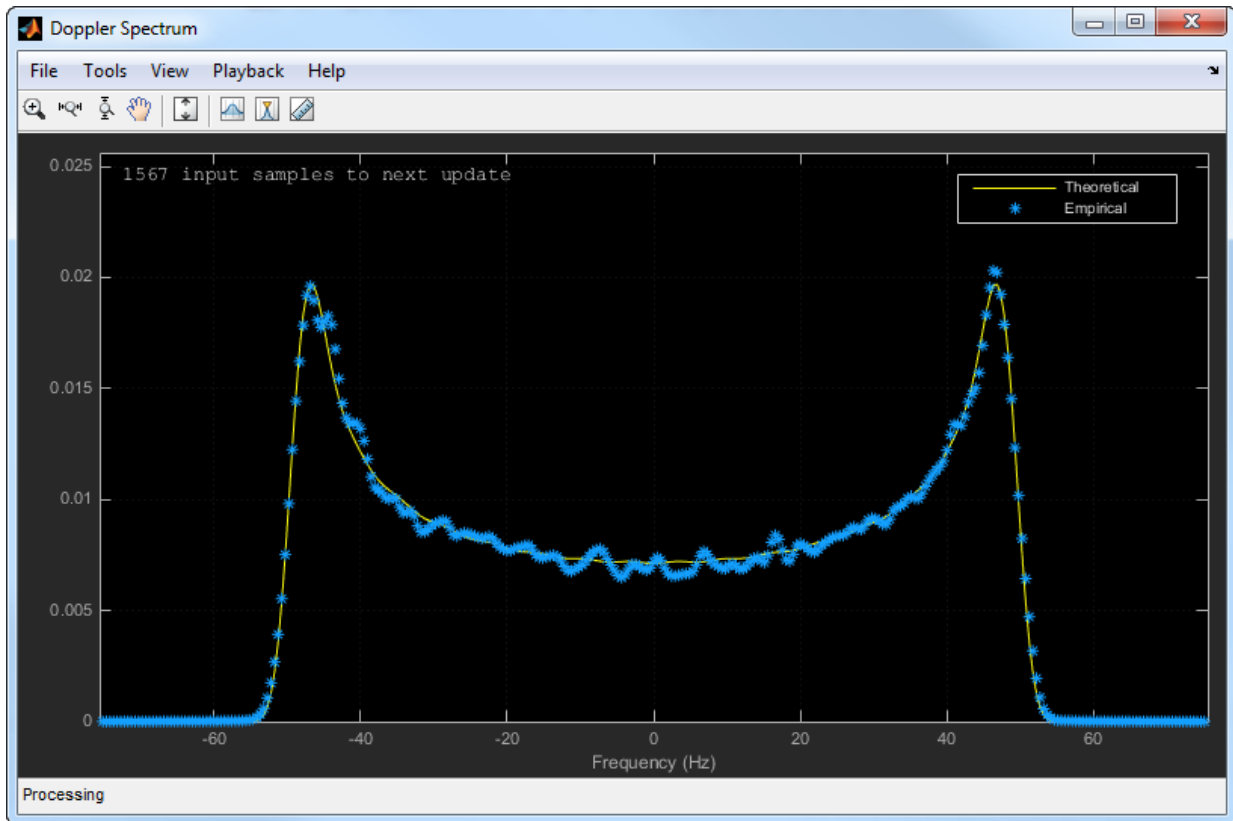

### Note

- The visualization display speed is controlled by the combination of the `SamplesToDisplay` property and the **Reduce Plot Rate to Improve Performance** menu item. Reducing the percentage of samples to display and the enabling reduced updates will speed up the rendering of the frequency response.
  - After the frequency response plots are manually closed, the step call for the Rayleigh channel object will be executed at its normal speed.
  - Code generation is available only when the `Visualization` property is `Off`.
-

## Doppler Spectrum

The Doppler spectrum plot displays both the theoretical Doppler spectrum and the empirically determined data points. The theoretical data is displayed as a yellow line for the case of non-static channels and as a yellow point for static channels, while the empirical data is shown in blue. There is an internal buffer which must be completely filled with filtered Gaussian samples before the empirical plot is updated. The empirical plot is the running mean of the spectrum calculated from each full buffer. For non-static channels, the number of input samples needed before the next update is displayed in the upper left hand corner. The samples needed is a function of the sample rate and the maximum Doppler shift. For static channels, the text `Reset fading channel for next update` is displayed.

---

### Note

- After the Doppler spectrum plots are manually closed, the `step` call for the Rayleigh channel object will be executed at its normal speed.
  - Code generation is available only when the `Visualization` property is `Off`.
- 

## Examples

### Produce the Same Outputs Using Two Different Random Number Generation Methods

The Rayleigh Channel System object™ has two methods for random number generation. You can use the current global stream or the `mt19937ar` algorithm with a specified seed. By interacting with the global stream, the object can produce the same outputs from the two methods.

Create a PSK Modulator System object to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
channelInput = pskModulator(randi([0 pskModulator.ModulationOrder-1],1024,1));
```

Create a Rayleigh channel System object.

```
rayChan = comm.RayleighChannel(...
    'SampleRate',10e3, ...
    'PathDelays',[0 1.5e-4], ...
    'AveragePathGains',[2 3], ...
    'NormalizePathGains',true, ...
    'MaximumDopplerShift',30, ...
    'DopplerSpectrum',{doppler('Gaussian',0.6),doppler('Flat')}, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',22, ...
    'PathGainsOutputPort',true);
```

Filter the modulated data using the Rayleigh channel System object, rayChan.

```
[chanOut1,pathGains1] = rayChan(channelInput);
```

Use global stream for random number generation.

```
release(rayChan);
rayChan.RandomStream = 'Global stream';
```

Set the global stream to have the same seed that was specified above.

```
rng(22)
```

Filter the modulated data using rayChan for the second time.

```
[chanOut2,pathGains2] = rayChan(channelInput);
```

Verify that the channel and path gain outputs are the same for each of the two methods.

```
isequal(chanOut1,chanOut2)
```

```
ans = logical
     1
```

```
isequal(pathGains1,pathGains2)
```

```
ans = logical
     1
```

### Display Impulse and Frequency Responses of a Rayleigh Channel

This example shows how to create a frequency selective Rayleigh channel and display its impulse and frequency responses.

Set the sample rate to 3.84 MHz and specify path delays and gains using ITU pedestrian B channel parameters. Set the maximum Doppler shift to 50 Hz.

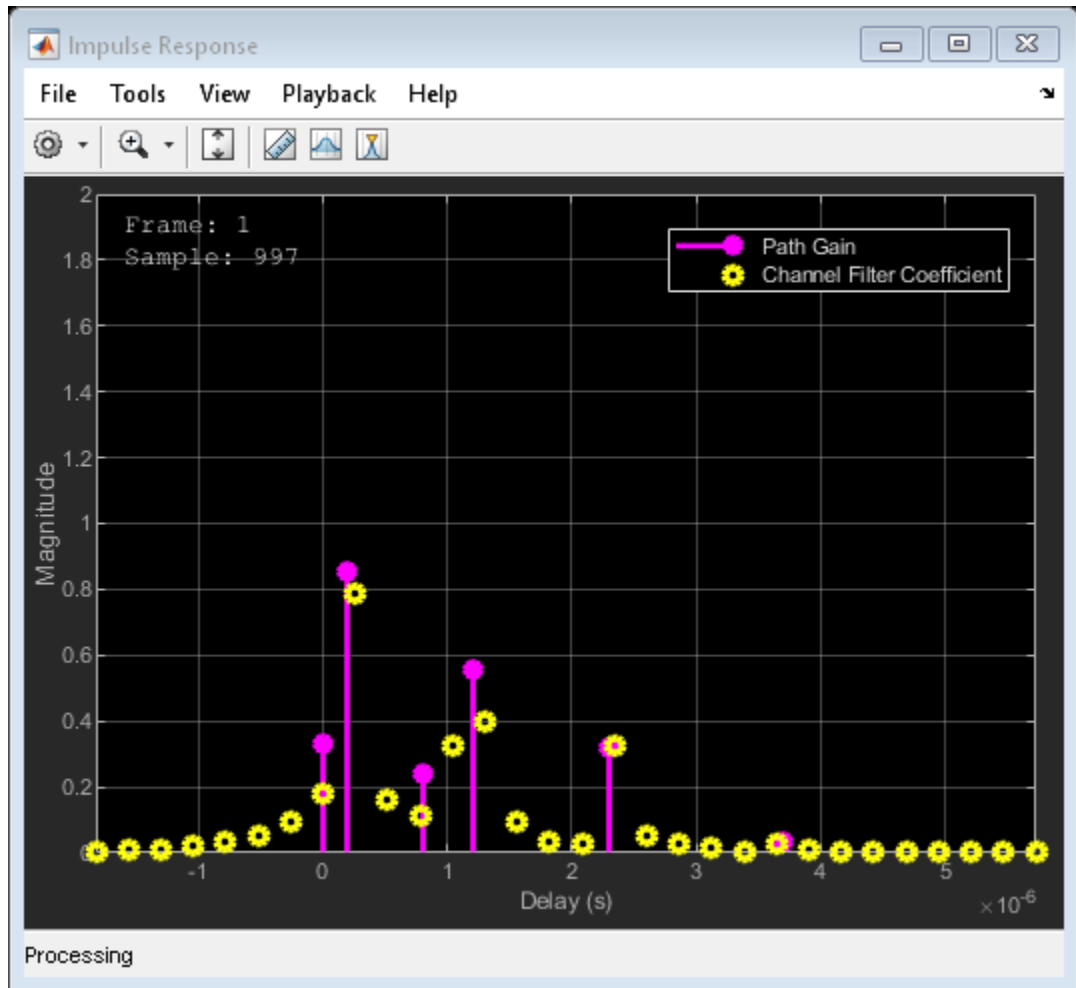

```
fs = 3.84e6; % Hz
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % sec
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB
fD = 50; % Hz
```

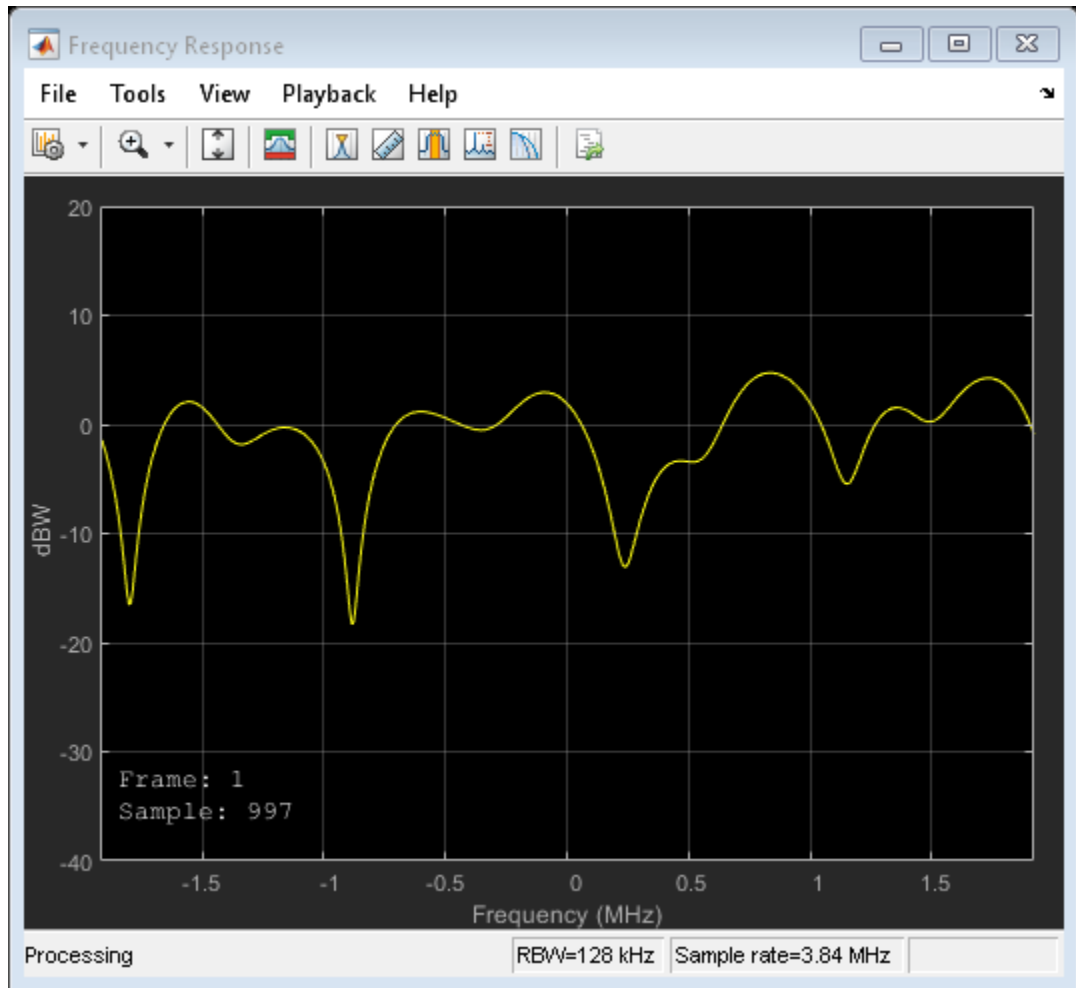

Create a Rayleigh channel System object with the previously defined parameters and set the `Visualization` property to `Impulse and frequency responses` using name-value pairs.

```
rchan = comm.RayleighChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'MaximumDopplerShift',fD, ...
    'Visualization','Impulse and frequency responses');
```

Generate random binary data and pass it through the Rayleigh channel. The impulse response plot allows you to easily identify the individual paths and their corresponding filter coefficients. The frequency selective nature of the pedestrian B channel is shown by the frequency response plot.

```
x = randi([0 1],1000,1);
y = rchan(x);
```

### Generate a Rayleigh Channel Using Sum-of-Sinusoids Technique

This example shows how to generate a Rayleigh channel using the sum-of-sinusoids technique.

Set the channel parameters.

```

fs = 1000;           % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5;             % Maximum Doppler shift (Hz)
numSamples = 1000; % Number of samples

```

Create a Rayleigh channel object using a name-value pair to set the `FadingTechnique` property to `Sum of sinusoids`.

```

rchan = comm.RayleighChannel('SampleRate',fs, ...
'PathDelays',pathDelays,'AveragePathGains',pathPower, ...
'MaximumDopplerShift',fD,'FadingTechnique','Sum of sinusoids')

```

```

rchan =
  comm.RayleighChannel with properties:

```

```

    SampleRate: 1000
    PathDelays: [0 0.0025]
  AveragePathGains: [0 -6]
  NormalizePathGains: true
  MaximumDopplerShift: 5
  DopplerSpectrum: [1x1 struct]

```

Show all properties

Pass an all-ones vector through the Rayleigh channel.

```

y = rchan(ones(numSamples,1));

```

Plot the magnitude of the Rayleigh channel output.

```

t = (0:numSamples-1)/fs;
plot(t,20*log10(abs(y)))
xlabel('Time (s)')
ylabel('Amplitude')

```

## Algorithms

### Cutoff Frequency Factor

The following information explains how the cutoff frequency factor,  $f_c$ , is determined for different Doppler spectrum types:

- For any Doppler spectrum type other than Gaussian and BiGaussian,  $f_c$  equals 1.
- For a doppler( 'Gaussian' ) spectrum type,  $f_c$  equals  $\text{NormalizedStandardDeviation} \cdot \sqrt{2 \cdot \log(2)}$ .
- For a doppler( 'BiGaussian' ) spectrum type:
  - If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \cdot \sqrt{2 \cdot \log(2)}$ .
  - If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(2) \cdot \sqrt{2 \cdot \log(2)}$ .
  - If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \cdot \sqrt{2 \cdot \log(2)}$ .
  - In all other cases,  $f_c$  equals 1.

## info

**System object:** comm.RayleighChannel

**Package:** comm

Display information about the RayleighChannel object

## Syntax

`S = info(OBJ)`

## Description

`S = info(OBJ)` returns a structure, `S`, containing characteristic information for the System object, `OBJ`. If `OBJ` has no characteristic information, `S` is empty. If `OBJ` has characteristic information, the fields of `S` vary depending on `OBJ`. For object specific details, refer to the help on the `infoImpl` method of that object.

## reset

**System object:** `comm.RayleighChannel`

**Package:** `comm`

Reset states of the `RayleighChannel` object

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the `RayleighChannel` object, `H`.

If you set the `RandomStream` property of `H` to `Global stream`, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar` with `seed`, the `reset` method not only resets the filters but also reinitializes the random number stream to the value of the `Seed` property.

## step

**System object:** `comm.RayleighChannel`

**Package:** `comm`

Filter input signal through multipath Rayleigh fading channel

## Syntax

```
Y = step(H,X)
[Y,PATHGAINS] = step(H,X)
___ = step(H,X,INITIALTIME)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` filters input signal `X` through a multipath Rayleigh fading channel and returns the result in `Y`. Both the input `X` and the output signal `Y` are of size  $N_s$ -by-1, where  $N_s$  represents the number of samples. The input `X` can be of double- or single-precision data type with real or complex values. `Y` contains complex values with same precision as input signal.

`[Y,PATHGAINS] = step(H,X)` returns the channel path gains of the underlying Rayleigh fading process in `PATHGAINS`. This syntax applies when you set the `PathGainsOutputPort` property of `H` to `true`. `PATHGAINS` is of size  $N_s$ -by- $N_p$ , where  $N_p$  represents the number of paths, i.e., the length of the `PathDelays` property value of `H`. `PATHGAINS` contains complex values with same precision as input signal.

`___ = step(H,X,INITIALTIME)` passes data through the Rayleigh channel beginning at `INITIALTIME`, where `INITIALTIME` is a nonnegative real scalar measured in seconds. This syntax applies when the `FadingTechnique` property of `H` is set to `Sum of sinusoids`

and the `InitialTimeSource` property of `H` is set to `Input port`. The `INITIALTIME` must be greater than the last frame end time. When `INITIALTIME` is not a multiple of  $1/\text{SampleRate}$ , it is rounded up to the nearest sample position.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.RBDSWaveformGenerator

**Package:** comm

Generate RDS/RBDS waveform

## Description

The `comm.RBDSWaveformGenerator` System object generates configurable standard-compliant baseband RDS/RBDS waveforms in MATLAB. RDS/RBDS waveforms supplement FM radio stations with additional textual information, such as song title, artist name, and station description. The RDS/RBDS signal lies in the 57-kHz band of the baseband FM radio signal.

Use this object to generate a waveform containing RadioText Plus (RT+) information and register a custom encoding implementation for an Open Data Application (ODA). You can also specify the time, data, and the program type. The object supports short, scrolling 8-character text, and longer 32-character or 64-character text.

To generate baseband RDS/RBDS waveforms:

- 1 Create a `comm.RBDSWaveformGenerator` object and set the properties of the object.
- 2 Call `step` to generate the waveform.

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`rbdsngen = comm.RBDSWaveformGenerator` creates an RDS/RBDS waveform generator object, `rbdsngen`, using the default properties.

`rbdsngen = comm.RBDSWaveformGenerator(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

### Example:

```
rbdsngen = comm.RBDSWaveformGenerator('GroupsPerFrame',20,'SamplesPerSymbol',10,...  
                                       'SendRadioTextPlus',true);
```

## Properties

If a property is listed as tunable, then you can change its value even when the object is locked.

### **SamplesPerSymbol** — Number of samples per symbol

10 (default) | positive even integer

Number of samples per symbol (bit), specified as a positive even integer. Half of the samples represent one amplitude level of Manchester coding. The other half of the samples represent the opposite level.

### **GroupsPerFrame** — Number of groups per output frame

10 (default) | scalar integer

Number of groups per output frame, specified as a scalar integer. Each group is 104 symbols (bits) long.

### **RadioText** — Long text conveyed with type 2A groups

'Long text' (default) | character vector

Radio text conveyed with type 2A groups, specified as a character vector that is up to 64 characters long. The object transmits the specified text four characters at a time, using type 2A groups.

Tunable: Yes

### **ProgramServiceName** — Label of the program service

'ShortTxt' (default) | character vector

Label of the program service, specified as a character vector that is up to eight characters long. This information is conveyed as a short text with type 0A groups, two characters at a time.

Tunable: Yes

**ProgramIdentificationCode — Program identification code**`[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]` (default) | 16-bit row vector

Program identification (PI) code, specified as a 16-bit row vector. In North America, the PI code conveys the call letters of the station. Example call letters include 'WABC' and 'KXYZ'.

To generate North American PI codes for a station's call letters, use the `callLettersToPICode` method.

**ProgramType — Program type**`'No program type or undefined'` (default) | character vector

Program type, specified as a character vector containing one of the 31 values allowed by the RDS/RBDS standard. For a list of program types that the RDS/RBDS standard allows in North America, see [1].

Tunable: Yes

**ProgramTypeName — Program type name**`''` (default) | character vector

Program type name, specified as a character vector that is up to eight characters long. This text further characterizes the program type, such as 'Football' for the program type 'Sports'. The object conveys the program type name using type 10A groups. If this property is empty, then no 10A groups are generated.

Tunable: Yes

**SendDateTime — Option to advertise date and time**`false` (default) | `true`

Option to advertise the date and time, specified as either `false` or `true`. When you set this property to `true`, one 4A group is periodically generated every 685 groups (once a minute).

**AlternativeFrequencies — Alternative frequencies**`[]` (default) | numeric row vector

Alternative frequencies, specified as a numeric row vector in MHz. This information is conveyed with type 0A groups. It indicates other transmitters broadcasting the same program in the same or adjacent reception areas. With this information, receivers can switch to a different frequency with better reception.

### **SendRadioTextPlus — Option to send RT+ information**

false (default) | true

Option to transmit RadioText Plus (RT+) information, specified as a scalar logical. When you set this property to `true`, the RT+ ODA information is advertised with type 3A groups. In addition, the RT+ content types, specified in `RadioTextType1`, `RadioTextType2`, and the two RT+ substrings indexed by `RadioTextIndices` are conveyed with the open-format type 11A group.

### **RadioTextType1 — Content type of first RT+ substring**

'Item.Artist' (default) | character vector

Content type of the first RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

### **RadioTextType2 — Content type of second RT+ substring**

'Item.Title' (default) | character vector

Content type of the second RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

### **RadioTextIndices — Start and end indices of RT+ substrings**

[1 2; 3 4] (default) | 2-by-2 matrix of positive integers

Start and end indices of RT+ substrings, specified as a 2-by-2 matrix of positive integers. The first column indexes the beginning of each RT+ substring. The second column indexes the end of each substring.

Tunable: Yes

## Methods

callLettersToPICode	Convert North-American call letters to binary PI code
registerODA	Register a custom encoding implementation for an ODA
reset	Reset states of RBDS waveform generator object
step	Generate RDS/RBDS waveform

## Examples

### Generate a Basic RBDS Waveform

Generate a basic RBDS waveform, FM modulate the waveform with an audio signal, and then demodulate the waveform.

Each frame of the RBDS waveform contains 19 groups, with a group length of 104 bits (symbols) each. Set the number of samples per RBDS symbol to 10. Therefore, the number of samples in each frame of RBDS waveform is  $104 \times 10 \times 19 = 19,760$ . According to the RBDS standard, the bit rate is 1187.5 Hz. So, the RBDS sample rate =  $1187.5 \times$  samples per RBDS symbol. Set the audio frame rate to  $40 \times 1187.5 = 47,500$ .

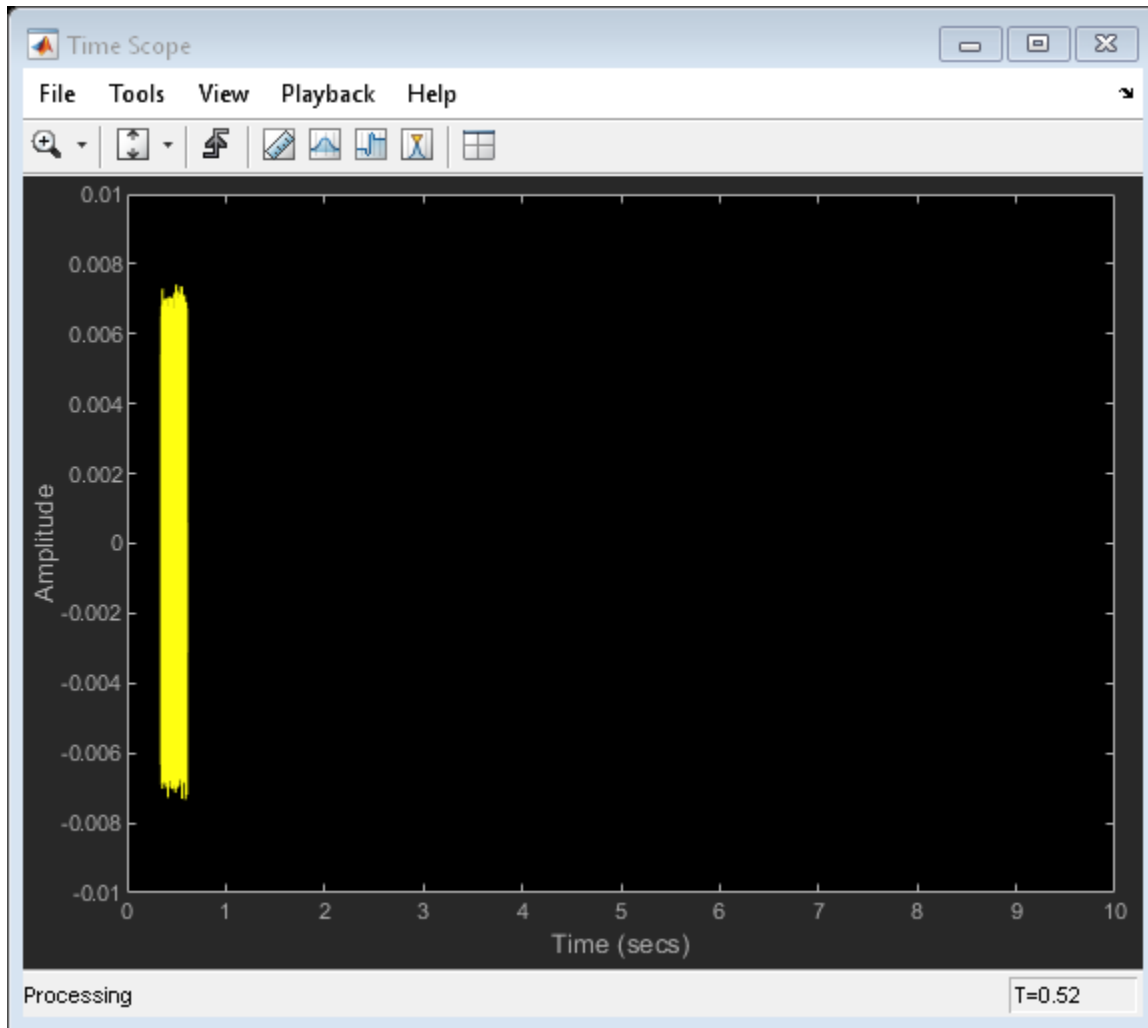

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;

afr = dsp.AudioFileReader('rbds_capture_47500.wav', 'SamplesPerFrame', rbdsFrameLen*afrRate);
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame', groupsPerFrame, 'SamplesPerSymbol', sps);

fmMod = comm.FMBroadcastModulator('AudioSampleRate', afr.SampleRate, 'SampleRate', outRate,
    'Stereo', true, 'RBDS', true, 'RBDSsamplesPerSymbol', sps);
fmDemod = comm.FMBroadcastDemodulator('SampleRate', outRate, ...
    'Stereo', true, 'RBDS', true, 'PlaySound', true);
scope = dsp.TimeScope('SampleRate', outRate, 'YLimits', 10^-2*[-1 1]);
```

Get the audio input and generate the RBDS waveform. FM modulate the stereo audio with the RBDS waveform, add noise, and FM demodulate the audio and RBDS waveforms. View the demodulated RBDS waveform in the time scope.

```
for idx = 1:7
    input = afr(); % get current audio input
    rbdsWave = rbds(); % generate RBDS info at the same configured
    yFM = fmMod([input input], rbdsWave); % FM modulate stereo audio with RBDS info
    rcv = awgn(yFM, 40); % add noise
    [audioRcv, rbdsRcv] = fmDemod(rcv); % FM demodulate the audio and RBDS waveforms
    scope(rbdsRcv);
end
```

### Generate RBDS Waveform with RadioText Plus Information

Create a `comm.RBDSWaveformGenerator` System object™ with 20 groups per frame and 10 samples per symbol. Add the Radio Text plus (RT+) information, such as artist name

and song, title, to the waveform. Indicate the start and end of the RT+ substrings by using the `RadioTextIndices` property.

```
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',20,'SamplesPerSymbol',10,...
    'SendRadioTextPlus', true);
rbds.RadioText = 'MyArtist - MySongTitle';
rbds.RadioTextType1 = 'Item.Artist';
rbds.RadioTextType2 = 'Item.Title';
rbds.RadioTextIndices = [1 8; 12 22];
for idx = 1:10
    rbds.step();
end
```

### Register a Custom Encoding Implementation

Register a custom encoding implementation for an Open Data Application (ODA) by using the `registerODA` method of the `comm.RBDSWaveformGenerator` System object™. Set the ODA ID to 'CD46', which is the ID for the traffic message channel. The allocated group type is 8A.

```
rbds = comm.RBDSWaveformGenerator();
odaID = 'CD46';
allocatedGroupType = '8A';
```

This example uses the following templates as a starting point for custom encoding implementation.

```
mainProcessingFcn = @CustomODAEncodingMain;
fcn3A              = @CustomODAEncoding3A;
registerODA(rbds,odaID,allocatedGroupType,mainProcessingFcn,fcn3A);
s = info(rbds);
s.ODAMap

ans=2×4 struct
    ID
    GroupType
    FunctionMain
    Function3A
```

## Configure RBDS Waveforms with Date and Time Information

Generate RBDS waveform with date and time information, the program type, and alternative frequencies. The `comm.RBDSWaveformGenerator` object uses type 4A groups for date and time information, type 10A groups for the program type information, and type 0A groups for alternative frequencies. View the waveform in a spectrum analyzer.

```
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',1000);
scope = dsp.SpectrumAnalyzer('SampleRate',1187.5*rbds.SamplesPerSymbol,'YLimits',[-140
rbds.SendDateTime = true;           % send type 4A groups
rbds.ProgramType = 'Sports';
rbds.ProgramTypeName = 'Football'; % send type 10A groups
rbds.AlternativeFrequencies = [99.1 102.5]; % info sent in type 0A groups
wave = rbds.step();
scope(wave)
```

## Algorithms

`comm.RBDSWaveformGenerator` generates waveforms according to the RDS/RBDS standard [1]. The RDS/RBDS standard consists of three layers: physical layer, data-link layer, and session and application layer.

### Physical Layer

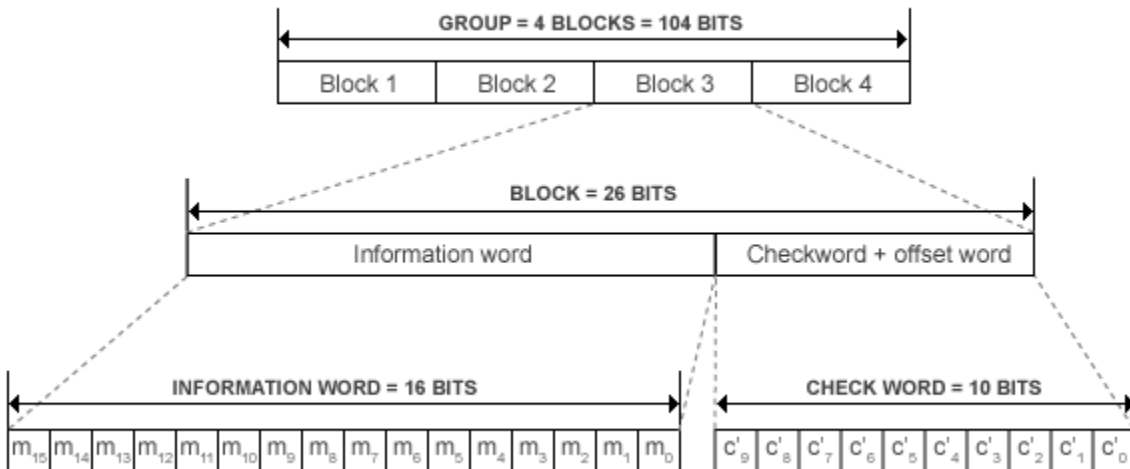

The physical layer (first layer) converts the data-link bits to an analog waveform by conducting differential encoding and biphase symbol encoding (Manchester encoding) and pulse-shaping filtering.

## Data-Link Layer

The data-link layer (second layer) performs (26,16) cyclic encoding shortened from (341,331) encoding [1]. The second layer is responsible for error detection, error correction, and the establishment of group-level synchronization. Each group of RDS/RBDS frames contains four blocks of 26 bits (that is 104 bits) each. Each block contains an information word and a check word. Each information word contains 16 bits, and each check word contains 10 bits.

Here is the baseband coding structure for the RDS/RBDS waveform. For more details, see [1].

For each block, a unique offset word is modulo-2 added to the checkword bits. The added offset word provides a group and block synchronization system in the receiver (decoder). Because the addition of the offset is reversible in the decoder, the normal additive error-correcting and detecting properties of the basic code are unaffected.

## Session and Application Layer

The first block in every group contains a program identification (PI) code. The first four bits of the second block of every group are allocated to a four-bit code. This code specifies

the application of the group. Groups are referred to as types 0-15 according to the binary weighting  $A_3 = 8$ ,  $A_2 = 4$ ,  $A_1 = 2$ ,  $A_0 = 1$ . The fifth bit of the second block,  $B_0$ , defines the version of the application. If  $B_0 = 0$ , the version of the group is A. The PI code in this version is inserted into block 1 only. Example group types include 0A, 1A, 2A, 3A, and 4A.

The Program Type code and Traffic Program Identification (PI) occupy fixed locations in block 2 of every group.

### Group Types

Group Type	Group Type Code/Version					Description
	$A_3$	$A_2$	$A_1$	$A_0$	$B_0$	
0A	0	0	0	0	0	Basic station information. Short, usually scrolling text, up to 8 characters long. Transmitted 2 characters at a time.
2A	0	0	1	0	0	Radio text. Long text, up to 64 characters long. Transmitted 4 characters at a time.
3A	0	0	1	1	0	Specification of used Open Data Applications and their allocation group type. Example: Radio Text Plus information is sent using 11A group.
4A	0	1	0	0	0	Date and time. Optional group that can be transmitted once in every 685 groups (once a minute).
10A	1	0	1	0	0	Program type name. Example: Football for ProgramType = 'Sports'.
11A	1	0	1	1	0	Open Data Applications. Example: RadioText Plus (RT+).

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

In addition, the following limitations apply when you generate code that contains this System object or when you use this object in a MATLAB function block.

- The group type 4A cannot be transmitted in the generated code.
- The `registerODA` method is not supported.
- The `ProgramType` property is not tunable.

**Introduced in R2017a**

## **callLettersToPICode**

**System object:** comm.RBDSWaveformGenerator

**Package:** comm

Convert North-American call letters to binary PI code

### **Syntax**

```
picode = callLettersToPICode(rbdsgen, callLetters)
```

### **Description**

`picode = callLettersToPICode(rbdsgen, callLetters)` returns the 16-bit program identification (PI) code that corresponds to `callLetters`. Acceptable call letter formats are 3-character or 4-character vectors beginning with 'K' or 'W'.

**Introduced in R2017a**

# registerODA

**System object:** comm.RBDSWaveformGenerator

**Package:** comm

Register a custom encoding implementation for an ODA

## Syntax

```
registerODA(rbdsgen,odaID,group,handleMain,handle3A)
```

## Description

`registerODA(rbdsgen,odaID,group,handleMain,handle3A)` associates the Open Data Application (ODA) specified by the hexadecimal ID `odaID`, with the type group groups generated by `rbdsgen`. The four 16-bit information words of these groups are generated by the function handle `handleMain`. The third information word of type 3A groups, which is ODA-specific, is generated by the function handle `handle3A`.

**Introduced in R2017a**

## **reset**

**System object:** comm.RBDSWaveformGenerator

**Package:** comm

Reset states of RBDS waveform generator object

## **Syntax**

```
reset(rbdsgen)
```

## **Description**

`reset(rbdsgen)` resets the states of the `RBDSWaveformGenerator` object, `rbdsgen`.

**Introduced in R2017a**

---

## step

**System object:** comm.RBDSWaveformGenerator

**Package:** comm

Generate RDS/RBDS waveform

## Syntax

`y = step(rbdsgen)`

## Description

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`y = step(rbdsgen)` outputs a frame of the baseband RDS/RBDS waveform in column vector `y`. The waveform contains the number of 104-bit groups, specified in the `GroupsPerFrame` property of the object. Each symbol is oversampled according to the `SamplesPerSymbol` property. Thus, the output length is `SamplesPerSymbol × 104 × GroupsPerFrame` samples. The object uses an internal scheduler to determine the order and frequency of the transmitted group types.

---

**Note** `rbdsgen` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Introduced in R2017a**

# comm.RectangularQAMDemodulator

**Package:** comm

(To be removed) Demodulate using rectangular QAM signal constellation

---

**Note** comm.RectangularQAMDemodulator will be removed in a future release. Use qamdemod instead. For more information, see “Compatibility Considerations”.

---

## Description

The RectangularQAMDemodulator object demodulates a signal that was modulated using quadrature amplitude modulation with a constellation on a rectangular lattice.

To demodulate a signal that was modulated using quadrature amplitude modulation:

- 1 Define and set up your rectangular QAM demodulator object. See “Construction” on page 4-1599.
- 2 Call `step` to demodulate the signal according to the properties of `comm.RectangularQAMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.RectangularQAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the rectangular quadrature amplitude modulation (QAM) method.

`H = comm.RectangularQAMDemodulator(Name,Value)` creates a rectangular QAM demodulator object, `H`, with each specified property set to the specified value. You can

specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

`H = comm.RectangularQAMDemodulator(M,Name,Value)` creates a rectangular QAM demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as scalar value with a positive, integer power of two. The default is 16.

### PhaseOffset

Phase offset of constellation

Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0.

### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. When you set this property to `true` the `step` method outputs a column vector of bit values whose length equals  $\log_2(\text{ModulationOrder})$  times the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector with a length equal to the input data vector. This vector contains integer symbol values between 0 and `ModulationOrder-1`. The default is `false`.

### SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder})$  bits to the corresponding symbol as one of `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-coded signal

constellation. When you set this property to **Binary**, the object uses a natural binary-coded constellation. When you set this property to **Custom**, the object uses the signal constellation defined in the **CustomSymbolMapping** on page 4-0 property.

### **CustomSymbolMapping**

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is **0:15**. This property is a row or column vector with a size of **ModulationOrder** on page 4-0 and with unique integer values in the range **[0, ModulationOrder-1]**. The values must be of data type **double**. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the **SymbolMapping** on page 4-0 property to **Custom**.

### **NormalizationMethod**

Constellation normalization method

Specify the method used to normalize the signal constellation as **Minimum distance between symbols** | **Average power** | **Peak power**. The default is **Minimum distance between symbols**.

### **MinimumDistance**

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is **2**. This property applies when you set the **NormalizationMethod** on page 4-0 property to **Minimum distance between symbols**.

### **AveragePower**

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is **1**. This property applies when you set the **NormalizationMethod** on page 4-0 property to **Average power**.

### **PeakPower**

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Peak power`.

### **DecisionMethod**

Demodulation decision method

Specify the decision method the object uses as `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` on page 4-0 property to `false` the object always performs hard-decision demodulation. This property applies when you set the `BitOutput` property to `true`.

### **VarianceSource**

Source of noise variance

Specify the source of the noise variance as `Property` | `Input port`. The default is `Property`. This property applies when you set the `BitOutput` on page 4-0 property to `true` and the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

### **Variance**

Noise variance

Specify the variance of the noise as a positive, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield `Inf` or `-Inf`. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, using approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the `BitOutput` on page 4-0 property to `true`, the `DecisionMethod` on page 4-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, and the `VarianceSource` on page 4-0 property to `Property`. This property is tunable.

## OutputDataType

Data type of output

Specify the output data type as `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

This property applies only when you set the `BitOutput` on page 4-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`. In this case, when the `OutputDataType` on page 4-0 property is set to `Full precision`, and the input data type is single- or double-precision, the output data has the same data type as the input.

When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` property to `Smallest unsigned integer`.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Hard Decision`, then `logical` data type becomes a valid option.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, the output data type is the same as that of the input. In this case, that data type can only be single- or double-precision.

## Fixed-Point Properties

### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 4-1608.

### **DerotateFactorDataType**

Data type of derotate factor

Specify the derotate factor data type as `Same word length as input` | `Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on page 4-0 property to `false`, or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`. The object uses the derotate factor in the computations only when the step method input is of a fixed-point type and the `PhaseOffset` on page 4-0 property has a value that is not a multiple of  $\pi/2$ .

### **CustomDerotateFactorDataType**

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `DerotateFactorDataType` on page 4-0 property to `Custom`.

### **DenormalizationFactorDataType**

Data type of denormalization factor

Specify the denormalization factor data type as `Same word length as input` | `Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on page 4-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`.

### **CustomDenormalizationFactorDataType**

Fixed-point data type of denormalization factor

Specify the denormalization factor fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `DenormalizationFactorDataType` on page 4-0 property to `Custom`.

### **ProductDataType**

Data type of product

Specify the product data type as `Full precision | Custom`. The default is `Full precision`. This property applies when you set the `BitOutput` on page 4-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`.

### **CustomProductDataType**

Fixed-point data type of product

Specify the product fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([],32)`. This property applies when you set the `ProductDataType` on page 4-0 property to `Custom`.

### **ProductRoundingMethod**

Rounding of fixed-point numeric value of product

Specify the product rounding method as `Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero`. The default is `Floor`. This property applies when the object is not in a full precision configuration, when you set the `BitOutput` on page 4-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`.

### **ProductOverflowAction**

Action when fixed-point numeric value of product overflows

Specify the product overflow action as `Wrap | Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration, when you set the `BitOutput` on page 4-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`.

### **SumDataType**

Data type of sum

Specify the sum data type as `Full precision | Same as product | Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to `false`, when you set the `BitOutput` on page 4-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 4-0 property to `Hard decision`.

## CustomSumDataType

Fixed-point data type of sum

Specify the sum fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32)`. This property applies when you set the `FullPrecisionOverride` on page 4-0 property to `false` or when you set the `SumDataType` on page 4-0 property `Custom`.

## Methods

`constellation` (To be removed) Calculate or plot ideal signal constellation  
`step` (To be removed) Demodulate using rectangular QAM method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Modulate and Demodulate Data Using 16-QAM

This example shows how to modulate and demodulate data using 16-QAM modulation.

Create rectangular QAM modulator and demodulator objects with the modulation order set to 16.

```
hMod = comm.RectangularQAMModulator('ModulationOrder',16);
hDemod = comm.RectangularQAMDemodulator('ModulationOrder',16);
```

Create an AWGN channel object.

```
hAWGN = comm.AWGNChannel('EbNo',2,'BitsPerSymbol',4);
```

To track the number of errors, create an error rate counter object.

```
hError = comm.ErrorRate;
```

Set the random number generator to its default state to ensure repeatability.

```
rng default
```

Generate random data symbols and apply 16-QAM modulation.

```
dataIn = randi([0 15],10000,1);  
txSig = step(hMod,dataIn);
```

Pass the modulated data through the AWGN channel.

```
rxSig = step(hAWGN,txSig);
```

Display the noisy constellation using the scatterplot function.

```
scatterplot(rxSig)
```

Demodulate the received data symbols.

```
dataOut = step(hDemod,rxSig);
```

Using the `step` function of `hError`, calculate the error statistics.

```
errorStats = step(hError,dataIn,dataOut);
```

Display the error statistics, where you can observe that 8 errors were recorded in 10,000 transmitted symbols.

```
fprintf('\nError rate = %f\nNumber of errors = %d\nNumber of symbols = %d\n', ...  
errorStats)
```

```
Error rate = 0.000800  
Number of errors = 8  
Number of symbols = 10000
```

## More About

### Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

**comm.RectangularQAMDemodulator will be removed in a future release. Use qamdemod instead.**

*Not recommended starting in R2018b*

Constellation normalization by PeakPower and AveragePower (other than unit average power) as supported by comm.RectangularQAMModulator and comm.RectangularQAMDemodulator is not inherently provided by functions. This code shows you how to perform peak power and average power normalization using qammod and qamdemod functions.

### Average Power Normalization for Hard Decision

end

```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## See Also

### Functions

genqamdemod | qamdemod

### Objects

comm.GeneralQAMDemodulator

### Introduced in R2012a

# constellation

**System object:** `comm.RectangularQAMDemodulator`

**Package:** `comm`

(To be removed) Calculate or plot ideal signal constellation

---

**Note** `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead.

---

## Syntax

```
y = constellation(h)
constellation(h)
```

## Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

## Examples

### Plot QAM Reference Constellations

Plot QAM reference constellation using the `qammod` and `qamdemod` functions. Show that the `'PlotConstellation,true'` Name,Value pair property works for both `qammod` and `qamdemod` functions. Also show the symbol ordering for Gray and binary code ordering by representing the data in binary format.

Create symbols for a 16-QAM modulator.

```
M = 16; % For 16-QAM
refSym = (0:M-1)';
```

Plot the reference constellation using the `qammod` function.

```
qammod(refSym,M,'PlotConstellation',true);
```

The default symbol order is Gray code ordering. To highlight the Gray symbol mapping, replot the reference constellation using binary input type. When you specify `'InputType','bit'`, the input signal must contain binary values, and the number of rows must be an integer multiple of  $\log_2(M)$ . Tranpose the input vector so that the input symbols map to the column vectors.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'PlotConstellation',true,'InputType','bit');
```

Replot the reference constellation using binary-coded symbol ordering.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'bin','PlotConstellation',true,'InputType','bit');
```

Create symbols for a 64-QAM modulator.

```
M = 64; % For 64-QAM
refSym = (0:M-1);
```

Plot the reference constellation using the `qamdemod` function.

```
qamdemod(refSym,M, 'PlotConstellation', true);
```

# step

**System object:** `comm.RectangularQAMDemodulator`

**Package:** `comm`

(To be removed) Demodulate using rectangular QAM method

---

**Note** `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead.

---

## Syntax

`Y = step(H,X)`

`Y = step(H,X,VAR)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` demodulates the input data, `X`, with the rectangular QAM demodulator System object, `H`, and returns, `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. When `ModulationOrder` is an even power of two and you set the `BitOutput` property to `false` or, when you set the `DecisionMethod` to `Hard decision` and the `BitOutput` property to `true`, the data type of the input can also be signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and

the `VarianceSource` property to `Input` port. The data type of input `VAR` must be double or single precision.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.RectangularQAMModulator

**Package:** comm

(To be removed) Modulate using rectangular QAM signal constellation

---

**Note** `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead. For more information, see “Compatibility Considerations”.

---

### Description

The `RectangularQAMModulator` object modulates using M-ary quadrature amplitude modulation with a constellation on a rectangular lattice. The output is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal.

To modulate a signal using quadrature amplitude modulation:

- 1 Define and set up your rectangular QAM modulator object. See “Construction” on page 4-1628.
- 2 Call `step` to modulate the signal according to the properties of `comm.RectangularQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.RectangularQAMModulator` creates a modulator object, `H`. This object modulates the input using the rectangular quadrature amplitude modulation (QAM) method.

`H = comm.RectangularQAMModulator(Name, Value)` creates a rectangular QAM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.RectangularQAMModulator(M, Name, Value)` creates a rectangular QAM modulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

## Properties

### **ModulationOrder**

Number of points in signal constellation

Specify the number of points in the signal constellation as scalar value that is a positive integer power of two. The default is 16.

### **PhaseOffset**

Phase offset of constellation

Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0.

### **BitInput**

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `true`, the `step` method input requires a column vector of bit values. The length of this vector must be an integer multiple of  $\log_2(\text{ModulationOrder})$  (page 4-0). This vector contains bit representations of integers between 0 and  $\text{ModulationOrder}-1$ . When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between 0 and  $\text{ModulationOrder}-1$ .

### **SymbolMapping**

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder})$  (page 4-0) input bits to the corresponding symbol as `Binary` | `Gray` | `Custom`. The default is

Gray. When you set this property to `Gray`, the System object uses a Gray-coded signal constellation. When you set this property to `Binary`, the object uses a natural binary-coded constellation. When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping` on page 4-0 property.

### **CustomSymbolMapping**

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:15`. This property is a row or column vector with a size of `ModulationOrder` on page 4-0 . This vector has unique integer values in the range `[0, ModulationOrder-1]`. These values must be of data type `double`. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the `SymbolMapping` on page 4-0 property to `Custom`.

### **NormalizationMethod**

Constellation normalization method

Specify the method used to normalize the signal constellation as `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

### **MinimumDistance**

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Minimum distance between symbols`.

### **AveragePower**

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Average power`.

**PeakPower**

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 4-0 property to `Peak` power.

**OutputDataType**

Data type of output

Specify the output data type as `double` | `single` | `Custom`. The default is `double`.

**Fixed-Point Properties****CustomOutputDataType**

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([ ], 16)`. This property applies when you set the `OutputDataType` on page 4-0 property to `Custom`.

**Methods**

`constellation` (To be removed) Calculate or plot ideal signal constellation  
`step` (To be removed) Modulate using rectangular QAM method

**Common to All System Objects**

<code>release</code>	Allow System object property value changes
----------------------	--

**Examples****Modulate Data with 64-QAM**

This example shows how to modulate binary data with a 64-QAM System object and by using the `qammod` function. The `comm.RectangularQAMModulator` System object will

be removed in a future release, use `qammod` instead. The resultant constellation is displayed. For comparison, modulation using the `comm.RectangularQAMModulator` System object is also included.

Generate random binary data. When using binary input data, the signal length must be a multiple of the number of bits per symbol. There are 6 bits/symbol in 64-QAM.

```
bps = 6;  
M = 2^bps; % 64-QAM  
data = randi([0 1],6000,1);
```

Create a 64-QAM modulator object that accepts binary input.

```
rectqamMod = comm.RectangularQAMModulator('ModulationOrder',64,'BitInput',true);
```

Modulate the data using the `qammod` function and using the `rectqamMod` System object. Plot the both sets of modulated data using the `scatterplot` function.

```
dataMod = qammod(data,M,'InputType','bit');  
dataModSO = rectqamMod(data);  
scatterplot(dataMod)
```

```
scatterplot(dataModS0)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

**comm.RectangularQAMModulator will be removed in a future release. Use qammod instead.**

*Not recommended starting in R2018b*

Constellation normalization by PeakPower and AveragePower (other than unit average power) as supported by comm.RectangularQAMModulator and comm.RectangularQAMDemodulator is not inherently provided by functions. This code shows you how to perform peak power and average power normalization using qammod and qamdmod functions.

**Introduced in R2012a**

# constellation

**System object:** comm.RectangularQAMModulator

**Package:** comm

(To be removed) Calculate or plot ideal signal constellation

---

**Note** comm.RectangularQAMModulator will be removed in a future release. Use qammod instead.

---

## Syntax

```
y = constellation(h)
constellation(h)
```

## Description

y = constellation(h) returns the numerical values of the constellation.

constellation(h) generates a constellation plot for the object.

## Examples

### Plot QAM Reference Constellations

Plot QAM reference constellation using the qammod and qamdemod functions. Show that the 'PlotConstellation,true' Name,Value pair property works for both qammod and qamdemod functions. Also show the symbol ordering for Gray and binary code ordering by representing the data in binary format.

Create symbols for a 16-QAM modulator.

```
M = 16; % For 16-QAM
refSym = (0:M-1)';
```

Plot the reference constellation using the `qammod` function.

```
qammod(refSym,M,'PlotConstellation',true);
```

The default symbol order is Gray code ordering. To highlight the Gray symbol mapping, replot the reference constellation using binary input type. When you specify `'InputType','bit'`, the input signal must contain binary values, and the number of rows must be an integer multiple of  $\log_2(M)$ . Tranpose the input vector so that the input symbols map to the column vectors.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'PlotConstellation',true,'InputType','bit');
```

Replot the reference constellation using binary-coded symbol ordering.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'bin','PlotConstellation',true,'InputType','bit');
```

Create symbols for a 64-QAM modulator.

```
M = 64; % For 64-QAM
refSym = (0:M-1);
```

Plot the reference constellation using the `qamdemod` function.

```
qamdemod(refSym,M,'PlotConstellation',true);
```

# step

**System object:** `comm.RectangularQAMModulator`

**Package:** `comm`

(To be removed) Modulate using rectangular QAM method

---

**Note** `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.

---

## Syntax

`Y = step(H,X)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` modulates input data, `X`, with the rectangular QAM modulator object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.RectangularQAMTCMDemodulator

**Package:** comm

Demodulate convolutionally encoded data mapped to rectangular QAM signal constellation

### Description

The `RectangularQAMTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a rectangular QAM signal constellation.

To demodulate convolutionally encoded data mapped to a rectangular QAM signal constellation:

- 1 Define and set up your rectangular QAM TCM demodulator object. See “Construction” on page 4-1654.
- 2 Call `step` to demodulate the signal according to the properties of `comm.RectangularQAMTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.RectangularQAMTCMDemodulator` creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to a rectangular QAM constellation.

`H = comm.RectangularQAMTCMDemodulator(Name,Value)` creates a rectangular, QAM TCM, demodulator object, `H`, with each specified property set to the specified value.

You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

`H = comm.RectangularQAMTCMDemodulator(TRELLIS,Name,Value)` creates a rectangular QAM TCM demodulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a structure is a valid trellis. The default is the result of `poly2trellis([3 1 1], [ 5 2 0 0; 0 0 1 0; 0 0 0 1])`.

### TerminationMethod

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, you should use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

### TracebackDepth

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The Traceback depth parameter influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the TerminationMethod property to `Continuous`, the decoding delay consists of TracebackDepth zero symbols or TracebackDepth $\times$ K zero bits for a rate  $K/N$  convolutional code.

When you set the TerminationMethod property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

### **ResetInputPort**

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the TerminationMethod property to `Continuous`.

### **ModulationOrder**

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be 4, 8, 16, 32, or 64. The default is 16. The ModulationOrder property value must equal the number of possible input symbols to the convolutional decoder of the rectangular QAM TCM demodulator object. The ModulationOrder must equal  $2^N$  for a rate  $K/N$  convolutional code.

### **OutputDataType**

Data type of output

Specify output data type as `logical` | `double`. The default is `double`.

## Methods

- reset Reset states of the rectangular QAM TCM demodulator object
- step Demodulate convolutionally encoded data mapped to rectangular QAM constellation

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Modulate and Demodulate Using Rectangular 16-QAM TCM

Modulate and demodulate data using 16-QAM TCM in an AWGN channel. Estimate the BER.

Create QAM TCM modulator and demodulator System objects™.

```
hMod = comm.RectangularQAMTCModulator;
hDemod = comm.RectangularQAMTCMDemodulator('TracebackDepth',16);
```

Create an AWGN channel object.

```
hAWGN = comm.AWGNChannel('EbNo',5);
```

Determine the delay through the QAM TCM demodulator. The demodulator uses the Viterbi algorithm to decode the TCM signal that was modulated using rectangular QAM. To accurately calculate the bit error rate, the delay through the decoder must be known.

```
bitsPerSymbol = log2(hDemod.TrellisStructure.numInputSymbols);
delay = hDemod.TracebackDepth*bitsPerSymbol;
```

Create an error rate calculator object with the ReceiveDelay property set to delay.

```
hErrorCalc = comm.ErrorRate('ReceiveDelay',delay);
```

Generate binary data and modulate with 16-QAM TCM. Pass the signal through an AWGN channel and demodulate. Calculate the error statistics. The loop runs until either 100 bit errors are encountered or 1e7 total bits are transmitted.

```
% Initialize the error results vector.
errStats = [0 0 0];

while errStats(2) < 100 && errStats(3) < 1e7
    % Transmit frames of 200 3-bit symbols
    txData = randi([0 1],600,1);
    % Modulate
    txSig = step(hMod,txData);
    % Pass through AWGN channel
    rxSig = step(hAWGN,txSig);
    % Demodulate
    rxData = step(hDemod,rxSig);
    % Collect error statistics
    errStats = step(hErrorCalc,txData,rxData);
end
```

Display the error data.

```
fprintf('Error rate = %4.2e\nNumber of errors = %d\n', ...
    errStats(1),errStats(2))
```

```
Error rate = 1.94e-03
Number of errors = 100
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Decoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

**System object:** comm.RectangularQAMTCMDemodulator

**Package:** comm

Demodulate convolutionally encoded data mapped to rectangular QAM constellation

## Syntax

$Y = \text{step}(H,X)$   
 $Y = \text{step}(H,X,R)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj},x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates the rectangular QAM modulated input data,  $X$ , and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits.  $X$  must be a complex, double or single precision column vector. The `step` method outputs a demodulated, binary data column vector,  $Y$ . When the convolutional encoder represents a rate  $K/N$  code, the length of the output vector is  $K*L$ , where  $L$  is the length of the input vector,  $X$ .

$Y = \text{step}(H,X,R)$  resets the decoder to the all-zeros state when you input a reset signal,  $R$  that is non-zero.  $R$  must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to true.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.RectangularQAMTCMModulator

**Package:** comm

Convolutionally encode binary data and map using rectangular QAM signal constellation

## Description

The `RectangularQAMTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a rectangular QAM signal constellation.

To convolutionally encode binary data and map the result using a rectangular QAM constellation:

- 1 Define and set up your rectangular QAM TCM modulator object. See “Construction” on page 4-1663.
- 2 Call `step` to modulate the signal according to the properties of `comm.RectangularQAMTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.RectangularQAMTCMModulator` creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) System object, `H`. This object convolutionally encodes a binary input signal and maps the result to a rectangular QAM constellation.

`H = comm.RectangularQAMTCMModulator(Name,Value)` creates a rectangular QAM TCM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.RectangularQAMTCMModulator(TRELLIS,Name,Value)` creates a rectangular QAM TCM modulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a structure is a valid trellis. The default is the result of `poly2trellis([3 1 1], [ 5 2 0 0; 0 0 1 0; 0 0 0 1])`.

### TerminationMethod

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate  $K/N$  code, the `step` method outputs the vector with a length given by  $y = N \times (L + S)/K$ , where  $S = \text{constraintLength}-1$  (or, in the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i)-1)$ ).  $L$  is the length of the input to the `step` method.

### ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When you set the reset input to the `step` method to a nonzero value, the object

resets the encoder to the all-zeros state. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous`.

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to 4, 8, 16, 32, or 64. The default is 16. The value of the `ModulationOrder` on page 4-0 property must equal the number of possible output symbols from the convolutional encoder of the QAM TCM modulator. Thus, the value for the `ModulationOrder` property must equal  $2^N$  for a rate  $K/N$  convolutional code.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

## Methods

`reset` Reset states of the rectangular QAM TCM modulator object

`step` Convolutionally encode binary data and map using rectangular QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Modulate Data Using Rectangular QAM TCM

Modulate data using rectangular 16-QAM TCM modulation and display the scatter plot.

Generate random binary data. The length of the data vector must be an integer multiple of the number of input streams into the encoder,  $\log_2(8) = 3$ .

```
data = randi([0 1],3000,1);
```

Create a modulator System object™ and use its `step` function to modulate the data.

```
hMod = comm.RectangularQAMTCMModulator;  
modData = step(hMod,data);
```

Plot the modulated data.

```
scatterplot(modData)
```

## Algorithms

Convolutionally encode binary data and map using rectangular QAM constellation

## Syntax

`Y = step(H,X)`

`Y = step(H,X,R)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` convolutionally encodes and modulates the input data numeric or logical column vector `X`, and returns the encoded and modulated data, `Y`. `X` must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector, `X`, must be  $K \times L$ , for some positive integer  $L$ . The `step` method outputs a complex column vector, `Y`, of length  $L$ .

`Y = step(H,X,R)` resets the encoder of the rectangular QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal, `R`. `R` must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.RicianChannel

**Package:** comm

Filter input signal through a Rician fading channel

## Description

The `RicianChannel` System object filters an input signal through a Rician multipath fading channel. The fading processing per link is described in Methodology for Simulating Multipath Fading Channels.

To filter an input signal using a Rician multipath fading channel:

- 1 Define and set up your Rician channel object. See “Construction” on page 4-1671.
- 2 Call `step` to filter the input signal through a Rician multipath fading channel according to the properties of `comm.RicianChannel`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.RicianChannel` creates a frequency-selective or frequency-flat multipath Rician fading channel System object, `H`. This object filters a real or complex input signal through the multipath channel to obtain the channel impaired signal.

`H = comm.RicianChannel(Name,Value)` creates a multipath Rician fading channel object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### SampleRate

Input signal sample rate (hertz)

Specify the sample rate of the input signal in hertz as a double-precision, real, positive scalar. The default value of this property is 1 Hz.

### PathDelays

Discrete path delay vector (seconds)

Specify the delays of the discrete paths in seconds as a double-precision, real, scalar or row vector. The default value of this property is 0.

When you set `PathDelays` to a scalar, the channel is frequency flat.

When you set `PathDelays` to a vector, the channel is frequency selective.

### AveragePathGains

Average path gain vector (decibels)

Specify the average gains of the discrete paths in decibels as a double-precision, real, scalar or row vector. The default value of this property is 0. `AveragePathGains` must have the same size as `PathDelays`.

### NormalizePathGains

Normalize average path gains to 0 dB

When you set this property to true, the object normalizes the fading processes so that the total power of the path gains, averaged over time, is 0dB. The default value of this property is true.

### KFactor

Rician K-factor scalar or vector (linear scale)

Specify the K-factor of a Rician fading channel as a double-precision, real, positive scalar or nonnegative, nonzero row vector of the same length as `PathDelays`. The default value of this property is 3.

If `KFactor` is a scalar, then the first discrete path is a Rician fading process with a Rician K-factor of `KFactor`. The remaining discrete paths are independent Rayleigh fading processes. If `KFactor` is a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process with a Rician K factor specified by that element. The discrete path corresponding to a zero-valued element of the `KFactor` vector is a Rayleigh fading process.

### **DirectPathDopplerShift**

Doppler shift(s) of line-of-sight component(s) (hertz)

Specify the Doppler shifts for the line-of-sight components of a Rician fading channel in hertz as a double-precision, real scalar or row vector. The default value of this property is 0.

`DirectPathDopplerShift` must have the same size as `KFactor`. If `DirectPathDopplerShift` is a scalar, this value represents the line-of-sight component Doppler shift of the first discrete path. This path exhibits a Rician fading process. If `DirectPathDopplerShift` is a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. Its line-of-sight component Doppler shift is specified by the corresponding element of `DirectPathDopplerShift`.

### **DirectPathInitialPhase**

Initial phase(s) of line-of-sight component(s) (radians)

Specify the initial phase(s) of the line-of-sight components of a Rician fading channel in radians as a double-precision, real scalar or row vector. The default value of this property is 0.

`DirectPathInitialPhase` must have the same size as `KFactor`. If `DirectPathInitialPhase` is a scalar, this value represents the line-of-sight component initial phase of the first discrete path. This path exhibits a Rician fading process. If `DirectPathInitialPhase` is a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. Its line-of-sight component initial phase is specified by the corresponding element of `DirectPathInitialPhase`.

### **MaximumDopplerShift**

Maximum Doppler shift (hertz)

Specify the maximum Doppler shift for all channel paths in hertz as a double-precision, real, nonnegative scalar. The default value of this property is 0.001 Hz.

The Doppler shift applies to all the paths of the channel. When you set the `MaximumDopplerShift` to 0, the channel remains static for the entire input. You can use the `reset` method to generate a new channel realization.

The `MaximumDopplerShift` must be smaller than  $\text{SampleRate}/10/f_c$  for each path, where  $f_c$  represents the cutoff frequency factor of the path. For a Doppler spectrum type other than Gaussian and bi-Gaussian,  $f_c$  is 1. For Gaussian and bi-Gaussian Doppler spectrum types,  $f_c$  is dependent on the Doppler spectrum object properties. Refer to the algorithm section of the `comm.MIMOChannel` for more details about how  $f_c$  is defined.

### DopplerSpectrum

Doppler spectrum

Specify the Doppler spectrum shape for the path(s) of the channel. This property accepts a single Doppler spectrum structure returned from the `doppler` function or a row cell array of such structures. The maximum Doppler shift value necessary to specify the Doppler spectrum/spectra is given by the `MaximumDopplerShift` property. This property applies when the `MaximumDopplerShift` property value is greater than 0. The default value of this property is `doppler('Jakes')`.

If you assign a single Doppler spectrum structure to `DopplerSpectrum`, all paths have the same specified Doppler spectrum. If the `FadingTechnique` property is `Sum of sinusoids`, `DopplerSpectrum` must be `doppler('Jakes')`; otherwise, select from the following:

- `doppler('Jakes')`
- `doppler('Flat')`
- `doppler('Rounded', ...)`
- `doppler('Bell', ...)`
- `doppler('Asymmetric Jakes', ...)`
- `doppler('Restricted Jakes', ...)`
- `doppler('Gaussian', ...)`
- `doppler('BiGaussian', ...)`

If you assign a row cell array of different Doppler spectrum structures (which can be chosen from any of those on the previous list) to `DopplerSpectrum`, each path has the Doppler spectrum specified by the corresponding structure in the cell array. In this case, the length of `DopplerSpectrum` must be equal to the length of `PathDelays`.

To generate C code, specify this property to a single Doppler spectrum structure.

### **FadingTechnique**

Fading technique used to model the channel

Select between `Filtered Gaussian noise` and `Sum of sinusoids` to specify the way in which the channel is modeled. The default value is `Filtered Gaussian noise`.

### **NumSinusoids**

Number of sinusoids used to model the fading process

The `NumSinuoids` property is a positive integer scalar that specified the number of sinusoids used in modeling the channel and is available only when the `FadingTechnique` property is set to `Sum of sinusoids`. The default value is 48.

### **InitialTimeSource**

Source to control the start time of the fading process

Specify the initial time source as either `Property` or `Input port`. This property is available when the `FadingTechnique` property is set to `Sum of sinusoids`. When `InitialTimeSource` is set to `Input port`, the start time of the fading process is specified using the `INITIALTIME` input to the `step` function. The input value can change in consecutive calls to the `step` function. The default value is `Property`.

### **InitialTime**

Start time of the fading process (s)

Specify the time offset of the fading process as a real nonnegative scalar in seconds. This property applies when the `FadingTechnique` property is set to `Sum of sinusoids` and the `InitialTimeSource` property is set to `Property`. The default value is 0.

`InitialTime` must be greater than the last frame end time. When `InitialTime` is not a multiple of  $1/\text{SampleRate}$ , it is rounded up to the nearest sample position.

### **RandomStream**

Source of random number stream

Specify the source of random number stream as one of `Global stream` | `mt19937ar` with `seed`. The default value of this property is `Global stream`.

If you set `RandomStream` to `Global stream`, the current global random number stream is used for normally distributed random number generation. In this case, the `reset` method only resets the filters.

If you set `RandomStream` to `mt19937ar` with `seed`, the `mt19937ar` algorithm is used for normally distributed random number generation. In this case, the `reset` method not only resets the filters, but also reinitializes the random number stream to the value of the `Seed` property.

### **Seed**

Initial seed of `mt19937ar` random number stream

Specify the initial seed of an `mt19937ar` random number generator algorithm as a double-precision, real, nonnegative integer scalar. The default value of this property is `73`. This property applies when you set the `RandomStream` property to `mt19937ar` with `seed`. The `Seed` reinitializes the `mt19937ar` random number stream in the `reset` method.

### **PathGainsOutputPort**

Output channel path gains

Set this property to `true` to output the channel path gains of the underlying fading process. The default value of this property is `false`.

### **Visualization**

Enable channel visualization

Specify the type of channel visualization to display as one of `Off` | `Impulse response` | `Frequency response` | `Impulse and frequency responses` | `Doppler spectrum`. The default value of this property is `Off`.

### **SamplesToDisplay**

Specify percentage of samples to display

You can specify the percentage of samples to display, since displaying fewer samples will result in better performance at the expense of lower accuracy. Specify the property as one of `10%` | `25%` | `50%` | `100%`. This applies when `Visualization` is set to `Impulse`

response, Frequency response, or Impulse and frequency responses. The default value is 25%.

### PathsForDopplerDisplay

Specify path for Doppler display

You can specify an integer scalar which selects the discrete path used in constructing a Doppler spectrum plot. The specified path must be an element of  $\{1, 2, \dots, N_p\}$ , where  $N_p$  is the number of discrete paths per link specified in the object. This property applies when `Visualization` is set to `Doppler spectrum`. The default value is 1.

## Methods

- info Characteristic information about Rician Channel
- reset Reset states of the `RicianChannel` object
- step Filter input signal through multipath Rician fading channel

Common to All System Objects	
release	Allow System object property value changes

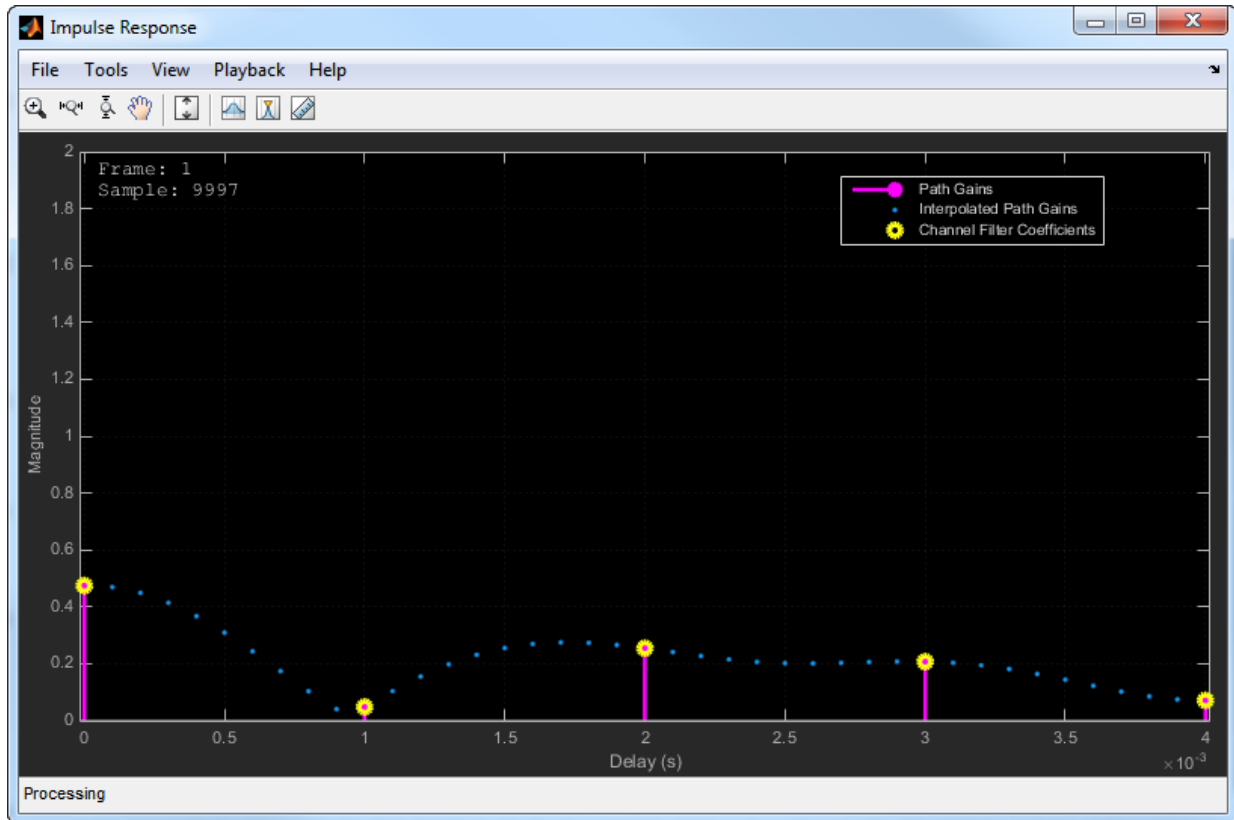

## Visualization

### Impulse Response

The impulse response plot displays the path gains, the channel filter coefficients, and the interpolated path gains. The path gains shown in magenta occur at time instances which correspond to the specified `PathDelays` property and may not be aligned with the input sampling time. The channel filter coefficients shown in yellow are used to model the channel. They are interpolated from the actual path gains and are aligned with the input sampling time. In cases in which the path gains are aligned with the sampling time, they will overlap the filter coefficients. Sinc interpolation is used to connect the channel filter coefficients and is shown in blue. These points are used solely for display purposes and not used in subsequent channel filtering. For a flat fading channel (one path), the sinc interpolation curve is not displayed. For all impulse response plots, the frame and sample numbers are shown in the display's upper left corner.

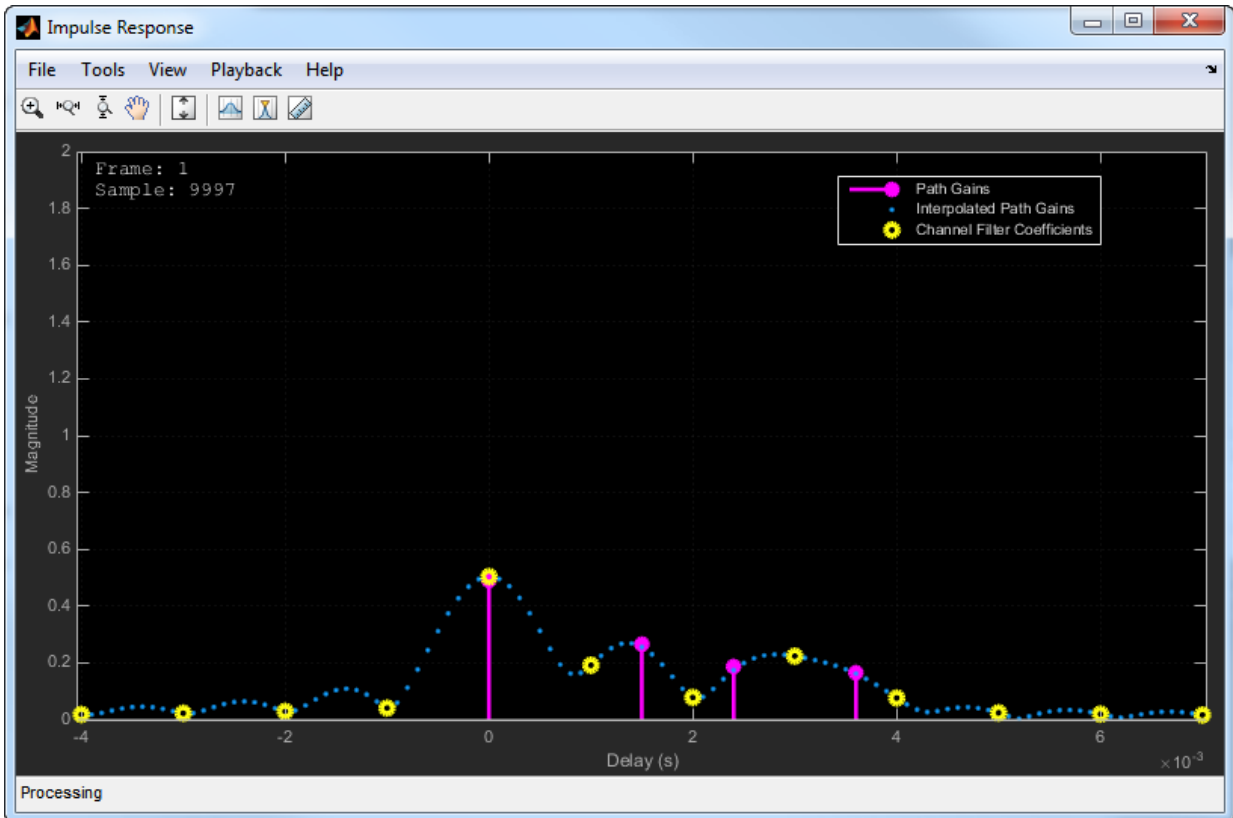

The impulse response plot shares the same toolbar and menus as the System object it was based on, `dsp.ArrayPlot`.

In the figure, the impulse response of a channel is shown for the case in which the path gains are aligned with the sample time. The overlap between the path gains and filter coefficients is evident.

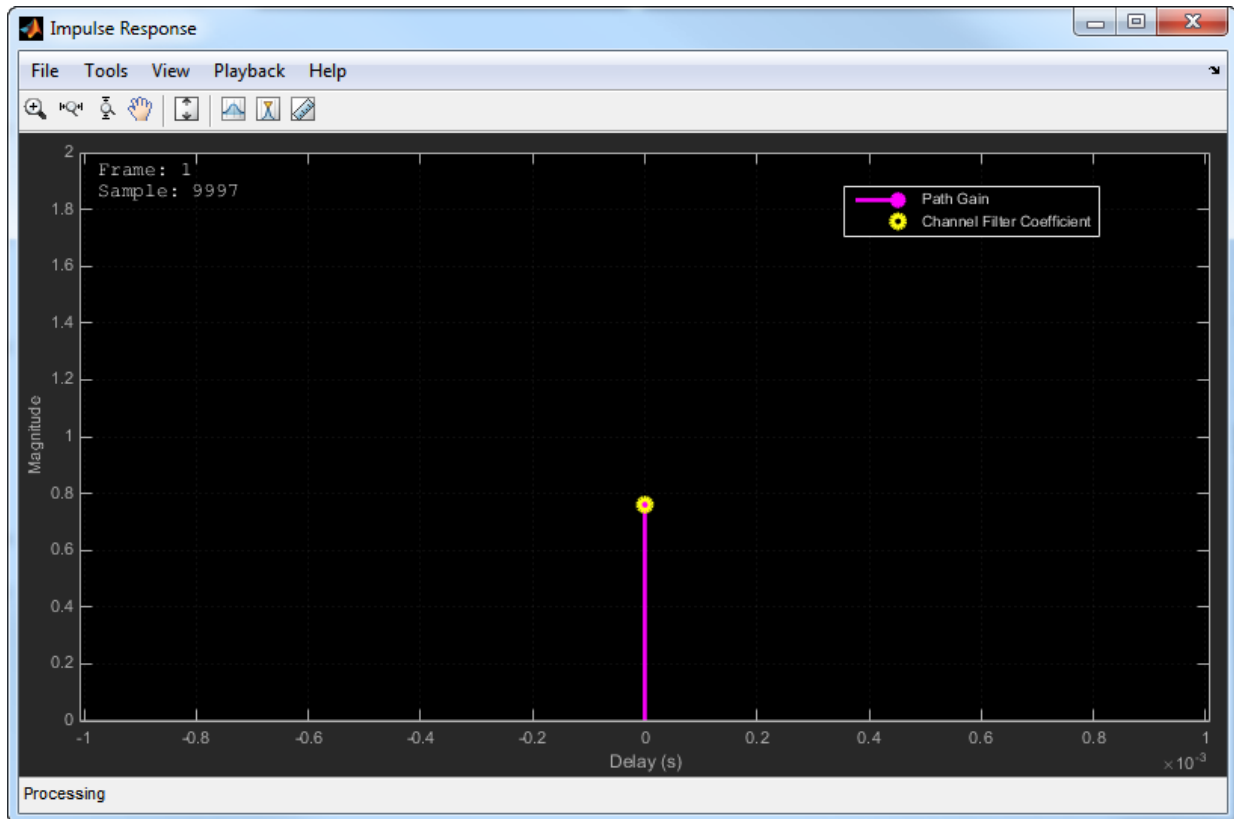

The case in which the specified path gains are not aligned with the `SampleRate` property is shown below. Observe that the path gains and the channel filter coefficients do not overlap and that the filter coefficients are equally distributed.

The impulse response for a frequency flat channel is shown below. You can see that the interpolated path gains are not displayed.

---

### Note

- The displayed and specified path gain locations can differ by as much as 5% of the input sample time.
  - The visualization display speed is controlled by the combination of the `SamplesToDisplay` property and the **Reduce Updates to Improve Performance** menu item. Reducing the percentage of samples to display and the enabling reduced updates will speed up the rendering of the impulse response.
  - After the impulse response plots are manually closed, the `step` call for the Rician channel object will be executed at its normal speed.
  - Code generation is available only when the `Visualization` property is `Off`.
-

## Frequency Response

The frequency response plot displays the Rician channel spectrum by taking a discrete Fourier transform of the channel filter coefficients. The frequency response plot shares the same toolbar and menus as the System object it was based on, `dsp.SpectrumAnalyzer`. The default parameter settings are shown below. These parameters can be changed from their default values by using the **View > Spectrum Settings** menu.

Parameter	Value
Window	Rectangular
WindowLength	Channel filter length
FFTLength	512
PowerUnits	dBW
YLimits	Based on <code>NormalizePathGains</code> and <code>AveragePathGains</code> properties

The frequency response plot for a frequency selective channel is shown.

---

### Note

- The visualization display speed is controlled by the combination of the `SamplesToDisplay` property and the **Reduce Plot Rate to Improve Performance** menu item. Reducing the percentage of samples to display and the enabling reduced updates will speed up the rendering of the frequency response.
  - After the frequency response plots are manually closed, the step call for the Rician channel object will be executed at its normal speed.
  - Code generation is available only when the `Visualization` property is `Off`.
-

## Doppler Spectrum

The Doppler spectrum plot displays both the theoretical Doppler spectrum and the empirically determined data points. The theoretical data is displayed as a yellow line for the case of non-static channels and as a yellow point for static channels, while the empirical data is shown in blue. There is an internal buffer which must be completely filled with filtered Gaussian samples before the empirical plot is updated. The empirical plot is the running mean of the spectrum calculated from each full buffer. For non-static channels, the number of input samples needed before the next update is displayed in the upper left hand corner. The samples needed is a function of the sample rate and the maximum Doppler shift. For static channels, the text `Reset fading channel for next update` is displayed.

---

### Note

- After the Doppler spectrum plots are manually closed, the `step` call for the Rician channel object will be executed at its normal speed.
  - Code generation is available only when the `Visualization` property is `Off`.
- 

## Examples

### Produce Same Rician Channel Output Using Different Random Number Generation Methods

The Rician Channel System object™ has two methods for random number generation. You can use the current global stream or the `mt19937ar` algorithm with a specified seed. By interacting with the global stream, the object can produce the same outputs from the two methods.

Create a PSK Modulator System object to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
channelInput = pskModulator(randi([0 pskModulator.ModulationOrder-1],1024,1));
```

Create a Rician channel System object. Set the RandomStream property to mt19937ar with seed using a name-value pair. Set the random number seed to 73.

```
ricianChan = comm.RicianChannel(...
    'SampleRate',1e6,...
    'PathDelays',[0.0 0.5 1.2]*1e-6,...
    'AveragePathGains',[0.1 0.5 0.2],...
    'KFactor',2.8,...
    'DirectPathDopplerShift',5.0,...
    'DirectPathInitialPhase',0.5,...
    'MaximumDopplerShift',50,...
    'DopplerSpectrum',doppler('Bell', 8),...
    'RandomStream','mt19937ar with seed', ...
    'Seed',73, ...
    'PathGainsOutputPort',true);
```

Filter the modulated data using the Rician channel System object, ricianChan.

```
[RicianChanOut1, RicianPathGains1] = ricianChan(channelInput);
```

Set the object to use the global stream for random number generation.

```
release(ricianChan);
ricianChan.RandomStream = 'Global stream';
```

Set the global stream to use the same seed that was specified for hRicianChan.

```
rng(73)
```

Filter the modulated data using hRicianChan for the case where the channel uses the global random number generator.

```
[RicianChanOut2,RicianPathGains2] = ricianChan(channelInput);
```

Verify that the channel and path gain outputs are the same for both function calls.

```
isequal(RicianChanOut1,RicianChanOut2)
```

```
ans = logical
     1
```

```
isequal(RicianPathGains1,RicianPathGains2)
```

```
ans = logical  
     1
```

### Rician Channel Impulse and Frequency Responses

This example shows how to create a frequency selective Rician channel and display its impulse and frequency responses.

Set the sample rate to 3.84 MHz and specify path delays and gains using ITU pedestrian B channel parameters. Set the Rician K-factor to 10 and the maximum Doppler shift to 50 Hz.

```
fs = 3.84e6; % Hz  
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % sec  
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB  
fD = 50; % Hz
```

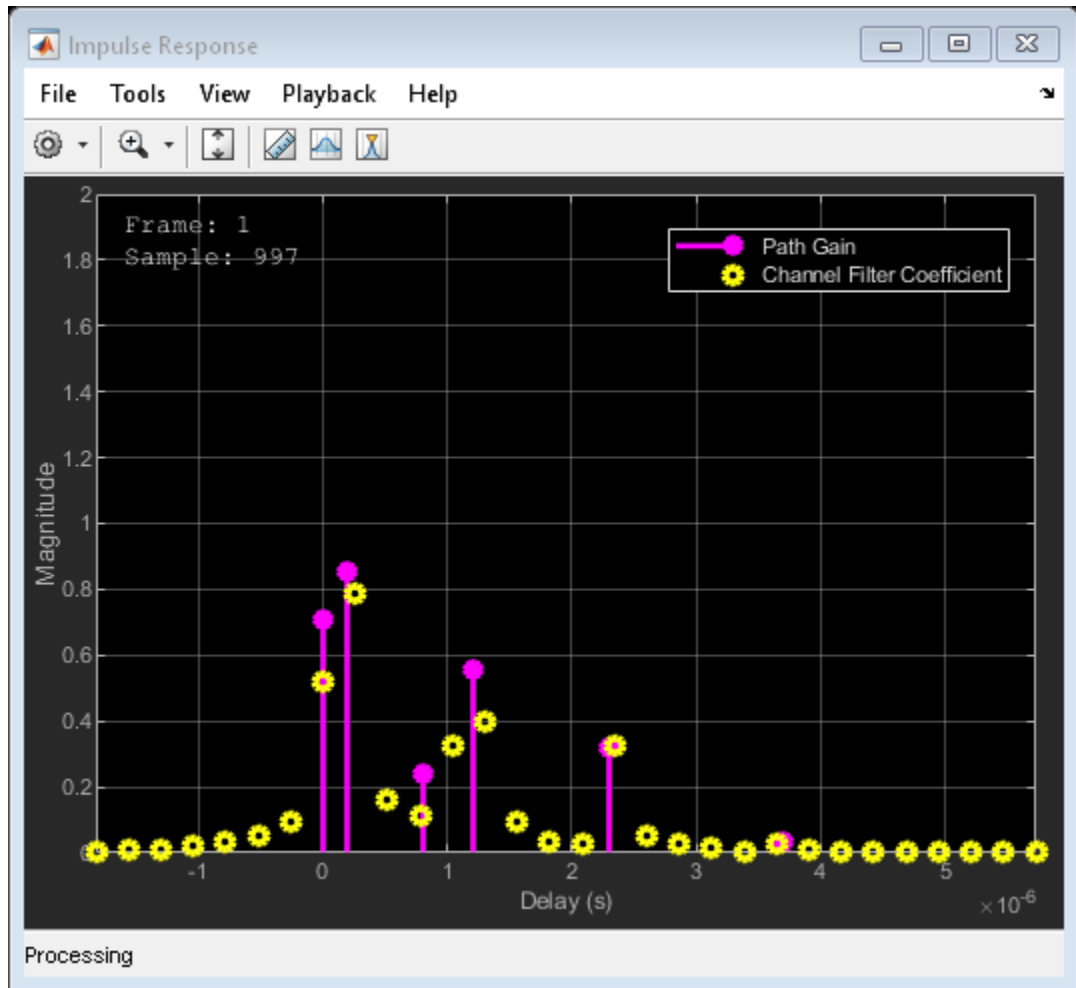

Create a Rician channel System object with the previously defined parameters and set the Visualization property to Impulse and frequency responses using name-value pairs.

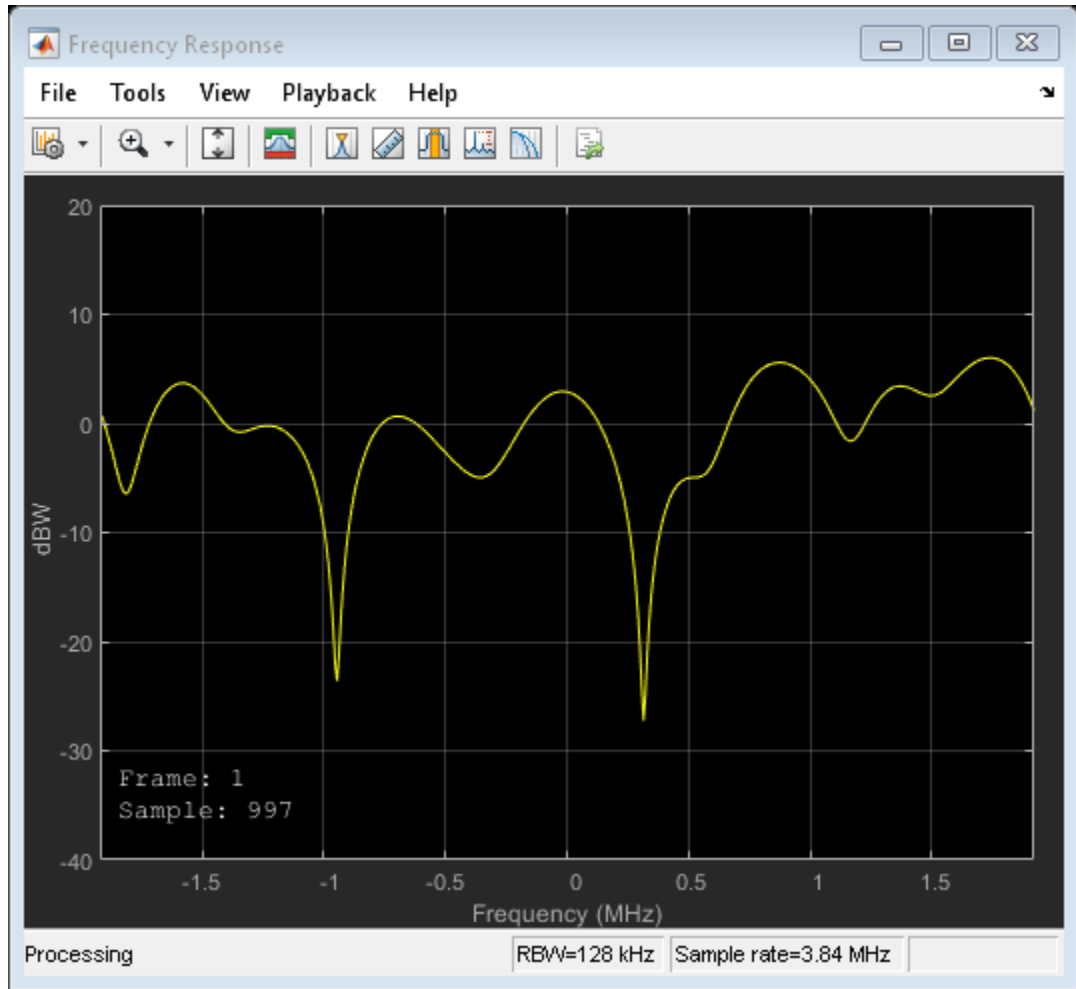

```
ricianChan = comm.RicianChannel('SampleRate',fs, ...  
    'PathDelays',pathDelays, ...  
    'AveragePathGains',avgPathGains, ...  
    'KFactor',10, ...  
    'MaximumDopplerShift',fD, ...  
    'Visualization','Impulse and frequency responses');
```

Generate random binary data and pass it through the Rician channel. The impulse response plot allows you to easily identify the individual paths and their corresponding filter coefficients. The frequency selective nature of the pedestrian B channel is shown by the frequency response plot.

```
x = randi([0 1],1000,1);  
y = ricianChan(x);
```

**Introduced in R2013b**

### info

**System object:** `comm.RicianChannel`

**Package:** `comm`

Characteristic information about Rician Channel

### Syntax

```
S = info(OBJ)
```

### Description

`S = info(OBJ)` returns a structure, `S`, containing characteristic information for the System object, `OBJ`. If `OBJ` has no characteristic information, `S` is empty. If `OBJ` has characteristic information, the fields of `S` vary depending on `OBJ`. For object specific details, refer to the help on the `infoImpl` method of that object.

## reset

**System object:** `comm.RicianChannel`

**Package:** `comm`

Reset states of the `RicianChannel` object

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the `RicianChannel` object, `H`.

If you set the `RandomStream` property of `H` to `Global stream`, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar` with `seed`, the `reset` method not only resets the filters but also reinitializes the random number stream to the value of the `Seed` property.

## step

**System object:** `comm.RicianChannel`

**Package:** `comm`

Filter input signal through multipath Rician fading channel

## Syntax

```
Y = step(H,X)
[Y,PATHGAINS] = step(H,X)
___ = step(H,X,INITIALTIME)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` filters input signal `X` through a multipath Rician fading channel and returns the result in `Y`. Both the input `X` and the output signal `Y` are of size  $N_s$ -by-1, where  $N_s$  represents the number of samples. The input `X` can be of double- or single-precision data type with real or complex values. `Y` contains complex values with same precision as input signal.

`[Y,PATHGAINS] = step(H,X)` returns the channel path gains of the underlying Rician fading process in `PATHGAINS`. This syntax applies when you set the `PathGainsOutputPort` property of `H` to `true`. `PATHGAINS` is of size  $N_s$ -by- $N_p$ , where  $N_p$  represents the number of paths, i.e., the length of the `PathDelays` property value of `H`. `PATHGAINS` contains complex values with same precision as input signal.

`___ = step(H,X,INITIALTIME)` passes data through the Rician channel beginning at `INITIALTIME`, where `INITIALTIME` is a nonnegative real scalar measured in seconds. This syntax applies when the `FadingTechnique` property of `H` is set to `Sum of sinusoids`

and the `InitialTimeSource` property of `H` is set to `Input port`. The `INITIALTIME` must be greater than the last frame end time. When `INITIALTIME` is not a multiple of  $1/\text{SampleRate}$ , it is rounded up to the nearest sample position.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.RSDecoder

**Package:** comm

Decode data using Reed-Solomon decoder

### Description

The `RSDecoder` object recovers a message vector from a Reed-Solomon codeword vector. For proper decoding, the property values for this object should match the property values in the corresponding RS Encoder object.

To decode data using a Reed-Solomon decoding scheme:

- 1 Define and set up your Reed-Solomon decoder object. See “Construction” on page 4-1694.
- 2 Call `step` to decode data according to the properties of `comm.RSDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`dec = comm.RSDecoder` creates a block decoder System object, `dec`. This object performs Reed-Solomon (RS) decoding.

`dec = comm.RSDecoder(N,K)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`dec = comm.RSDecoder(N,K,GP)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, and the `GeneratorPolynomial` property set to `GP`.

`dec = comm.RSDecoder(N,K,GP,S)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and the `ShortMessageLength` property set to `S`.

`dec = comm.RSDecoder(N,K,GP,S,Name,Value)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and each specified property `Name` set to the specified `Value`.

`dec = comm.RSDecoder(Name,Value)` creates an RS decoder object, `dec`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

---

**Note** The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 4-112 on the `comm.BCHDecoder` reference page.

---

### BitInput

Assume that input is bits

Specify whether the input comprises bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input data value must be a numeric, column vector of integers. The `step` method outputs an encoded data output vector. The output result is a column vector of integers. Each symbol that forms the input message and output codewords is an integer between 0 and  $2^M - 1$ . These integers correspond to an element of the finite Galois field  $gf(2^M)$ .  $M$  is the degree of the primitive polynomial that you specify with the `PrimitivePolynomialSource` on page 4-0 and `PrimitivePolynomial` on page 4-0 properties.

When you set this property to `true`, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

### **CodewordLength**

Codeword length

Specify the codeword length of the RS code in symbols as a double-precision, positive, integer scalar value. The default is 7.

For a full-length RS code, the value of this property must be  $2^M-1$ , where  $M$  is an integer such that  $3 \leq M \leq 16$ .

### **MessageLength**

Message length

Specify the message length in symbols as a double-precision positive integer scalar value. The default is 3.

### **ShortMessageLengthSource**

Short message length source

Specify the source of the shortened message as `Auto` or `Property`. When this property is set to `Auto`, the RS code is defined by the `CodewordLength` on page 4-0 , `MessageLength` on page 4-0 , `GeneratorPolynomial` on page 4-0 , and `PrimitivePolynomial` on page 4-0 properties.

When `ShortMessageLengthSource` is set to `Property`, you must specify the `ShortMessageLength` on page 4-0 property, which is used with the other properties to define the RS code. The default is `Auto`.

### **ShortMessageLength**

Shortened message length

Specify the length of the shortened message in symbols as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength` on page 4-0 .

When `ShortMessageLength` < `MessageLength`, the RS code is shortened. The default is 3.

## **GeneratorPolynomialSource**

Source of generator polynomial

Specify the source of the generator polynomial as `Auto` or `Property`. The default is `Auto`.

When you set this property to `Auto`, the object chooses the generator polynomial automatically. The object calculates the generator polynomial based on the value of the `PrimitivePolynomialSource` on page 4-0 property.

When you set this property to `Auto`, the object automatically chooses the generator polynomial. The object calculates the generator polynomial based on the value of the `PrimitivePolynomial` on page 4-0 property.

When you set this property to `Property`, you must specify a generator polynomial using the `GeneratorPolynomial` on page 4-0 property.

## **GeneratorPolynomial**

Generator polynomial

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois field row vector whose entries are in the range from 0 to  $2^M-1$  and represent a generator polynomial in descending order of powers. The length of the generator polynomial must be `CodewordLength-MessageLength+1`. This property applies when you set `GeneratorPolynomialSource` on page 4-0 to `Property`.

The default is the result of `rsgenpoly(7,3,[],[], 'double')`, which corresponds to `[1 3 1 2 3]`.

When you use this object to generate code, you must set the generator polynomial to a double-precision integer row vector.

## **CheckGeneratorPolynomial**

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check. The default is `true`. This check verifies that the specified generator polynomial is valid.

For larger codes, disabling the check accelerates processing time. As a best practice, perform the check at least once before setting this property to `false`. This property applies when you set `GeneratorPolynomialSource` on page 4-0 to `Property`.

### **PrimitivePolynomialSource**

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. The default is `Auto`.

When you set this property to `Auto`, the object uses a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength on page 4-0} + 1))$ .

When you set `PrimitivePolynomialSource` to `Property`, you must specify a polynomial using `PrimitivePolynomial` on page 4-0 .

### **PrimitivePolynomial**

Primitive polynomial

Specify the primitive polynomial that defines the finite field  $\text{gf}(2^M)$  corresponding to the integers that form messages and codewords. The default is the result of `flipplr(de2bi(primpoly(3)))`, which is `[1 0 1 1]` or the polynomial  $x^3 + x + 1$ . Specify this property as a double-precision, binary, row vector that represents a primitive polynomial over  $\text{GF}(2)$  of degree  $M$  in descending order of powers. This property applies when you set `PrimitivePolynomialSource` on page 4-0 to `Property`.

### **PuncturePatternSource**

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. The default is `None`.

If you set this property to `None`, the object does not apply puncturing to the code. If you set it to `Property`, the object punctures the code based on a puncture pattern vector specified in `PuncturePattern` on page 4-0 .

### **PuncturePattern**

Puncture pattern vector

Specify the pattern used to puncture the encoded data as a double-precision, binary column vector of length  $(\text{CodewordLength on page 4-0} - \text{MessageLength on page 4-0})$ .

0 ). The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword. This property applies when you set `PuncturePatternSource` on page 4-0 to `Property`.

### **ErasuresInputPort**

Enable erasures input

Set this property to `true` to specify a vector of erasures as an input to the `step` method. The default is `false`. The erasures input must be a double-precision or logical binary column vector that indicates which symbols of the input codewords to erase.

The length of the erasures vector is explained in “Input and Output Signal Lengths in BCH and RS System Objects” on page 4-112.

When this property is set to `false`, the object assumes no erasures.

### **NumCorrectedErrorsOutputPort**

Enable number of corrected errors output

Set this property to `true` to obtain the number of corrected errors as an output to the `step` method. The default is `true`. A nonnegative value in the  $i$ -th element of the error output vector, denotes the number of corrected errors in the  $i$ -th input codeword. A value of -1 in the  $i$ -th element of the error output vector indicates that a decoding error occurred for that codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the RS code.

### **OutputDataType**

Data type of output

Specify the output data type as `Same as input`, `double`, or `logical`. The default is `Same as input`. This property applies when you set `BitInput` on page 4-0 to `true`.

## **Methods**

`step` Decode data using a Reed-Solomon decoder

### Common to All System Objects

release	Allow System object property value changes
---------	--

## Examples

### Transmit an RS-encoded, 8-DPSK-modulated symbol stream

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.

```
enc = comm.RSEncoder;
mod = comm.DPSKModulator('BitInput',false);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',false);
hDdecec = comm.RSDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
    data = randi([0 7], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedSymbols = step(hDdecec, demodSignal);
    errorStats = step(errorRate, data, receivedSymbols);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.115578
Number of errors = 69
```

### Transmit a Shortened RS-encoded, 256-QAM-modulated Symbol Stream

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where  $N$  is the codeword length,  $K$  is the nominal message length, and  $S$  is the shortened message length. Set the modulation order,  $M$ , and the number of frames,  $L$ .

```
N = 255;
K = 239;
S = 188;
M = 256;
L = 50;
```

Create an AWGN channel System object and an error rate System object.

```
awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (Eb/No)', ...
    'EbNo',15,'BitsPerSymbol',log2(M));
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Create the Reed-Solomon generator polynomial from the DVB-T standard.

```
gp = rsgenpoly(N,K,[],0);
```

Create a Reed-Solomon encoder and decoder pair using the shortened message length,  $S$ , and the DVB-T generator polynomial,  $gp$ .

```
enc = comm.RSEncoder(N,K,gp,S);
dec = comm.RSDecoder(N,K,gp,S);
```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.

```
for counter = 1:L
    data = randi([0 1],S,log2(M));
    encodedData = step(enc,bi2de(data));
    modSignal = qammod(encodedData,M,'UnitAveragePower',true);
    rxSignal = awgnChan(modSignal);
    demodSignal = qamdemod(rxSignal,M,'UnitAveragePower',true);
    rxBits = dec(demodSignal);
    dataOut = de2bi(rxBits);
    errorStats = errorRate(data(:),dataOut(:));
end
```

Display the error rate and number of errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

Error rate = 2.01e-02  
Number of errors = 1509

### **Algorithms**

This object implements the algorithm, inputs, and outputs described in “Algorithms for BCH and RS Errors-only Decoding”.

### **Extended Capabilities**

#### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2012a**

---

## step

**System object:** comm.RSDecoder

**Package:** comm

Decode data using a Reed-Solomon decoder

## Syntax

`[Y,ERR] = step(H,X)`

`Y = step(H,X)`

`Y = step(H,X,ERASURES)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`[Y,ERR] = step(H,X)` decodes the encoded input data, `X`, into the output vector `Y` and returns the number of corrected symbols in output vector `ERR`. The value of the `BitInput` property determines whether `X` is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the `step` function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 4-112. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `true`. A value of `-1` in the  $i$ -th element of the error output vector indicates that a decoding error occurred for that codeword.

`Y = step(H,X)` decodes the encoded data, `X`, into the output vector `Y`. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `false`.

`Y = step(H,X,ERASURES)` uses the binary column input vector, `ERASURES`, to erase the symbols of the input codewords. The elements in `ERASURES` must be of data type `double` or `logical`. Values of `1` in the `ERASURES` vector correspond to erased symbols, and values

of 0 correspond to non-erased symbols. This syntax applies when you set the `ErasuresInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.RSEncoder

**Package:** comm

Encode data using Reed-Solomon encoder

## Description

The `RSEncoder` object creates a Reed-Solomon code with message and codeword lengths you specify.

To encode data using a Reed-Solomon encoding scheme:

- 1 Define and set up your Reed-Solomon encoder object. See “Construction” on page 4-1705.
- 2 Call `step` to encode data according to the properties of `comm.RSEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`enc = comm.RSEncoder` creates a block encoder System object, `enc`. This object performs Reed-Solomon (RS) encoding.

`enc = comm.RSEncoder(N,K)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`enc = comm.RSEncoder(N,K,GP)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, and the `GeneratorPolynomial` property set to `GP`.

`enc = comm.RSEncoder(N,K,GP,S)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the

GeneratorPolynomial property set to GP, and the ShortMessageLength property set to S.

`enc = comm.RSEncoder(N,K,GP,S,Name,Value)` creates an RS encoder object, `enc`, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, the ShortMessageLength property set to S, and each specified property Name set to the specified Value.

`enc = comm.RSEncoder(Name,Value)` creates an RS encoder object, `enc`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

---

**Note** The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 4-112 on the `comm.BCHDecoder` reference page.

---

### BitInput

Assume that input is bits

Specify whether the input comprises bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input data value must be a numeric, column vector of integers. Each symbol that forms the input message and output codewords is an integer between 0 and  $2^M-1$ . These integers correspond to an element of the finite Galois field  $\text{gf}(2^M)$ .  $M$  is the degree of the primitive polynomial that you specify with the `PrimitivePolynomialSource` on page 4-0 and `PrimitivePolynomial` on page 4-0 properties.

When you set this property to `true`, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

### CodewordLength

Codeword length

Specify the codeword length of the RS code as a double-precision positive integer scalar value. The default is 7.

For a full-length RS code, the value of this property must be  $2^M - 1$ , where  $M$  is an integer such that  $3 \leq M \leq 16$ .

### **MessageLength**

Message length

Specify the message length as a double-precision positive integer scalar value. The default is 3.

### **ShortMessageLengthSource**

Short message length source

Specify the source of the shortened message as `Auto` or `Property`. When this property is set to `Auto`, the RS code is defined by the `CodewordLength` on page 4-0, `MessageLength` on page 4-0, `GeneratorPolynomial` on page 4-0, and `PrimitivePolynomial` on page 4-0 properties. When `ShortMessageLengthSource` is set to `Property`, you must specify the `ShortMessageLength` on page 4-0 property, which is used with the other properties to define the RS code. The default is `Auto`.

### **ShortMessageLength**

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength` on page 4-0. When `ShortMessageLength` < `MessageLength`, the RS code is shortened. The default is 3.

### **GeneratorPolynomialSource**

Source of generator polynomial

Specify the source of the generator polynomial as `Auto` or `Property`. The default is `Auto`.

When you set this property to `Auto`, the object chooses the generator polynomial automatically. The object calculates the generator polynomial based on the value of the `PrimitivePolynomial` on page 4-0 property.

When you set `GeneratorPolynomialSource` to `Property`, you must specify a generator polynomial using the `GeneratorPolynomial` on page 4-0 property.

### **GeneratorPolynomial**

Generator polynomial

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois row vector. The Galois row vector entries must be in the range from 0 to  $2^M - 1$ . These entries must represent a generator polynomial in descending order of powers. Each coefficient is an element of the Galois field  $\text{gf}(2^M)$ , represented in integer format. The length of the generator polynomial must be `CodewordLength` on page 4-0 - `MessageLength` on page 4-0 + 1.

The default is the result of `rsgenpoly(7,3,[],[],'double')`, which evaluates to a  $\text{GF}(2^3)$  array with elements `[1 3 1 2 3]`. This property applies when you set `GeneratorPolynomialSource` on page 4-0 to `Property`.

### **CheckGeneratorPolynomial**

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check. The default is `true`. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check speeds up processing. As a best practice, perform the check at least once before setting this property to `false`. This property applies when `GeneratorPolynomialSource` on page 4-0 is set to `Property`.

### **PrimitivePolynomialSource**

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. The default is `Auto`.

When you set this property to `Auto`, the object uses a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength} on page 4-0 + 1)).$

When you set this property to `Property`, you must specify a polynomial using the `PrimitivePolynomial` on page 4-0 property.

## PrimitivePolynomial

Primitive polynomial

Specify the primitive polynomial that defines the finite field  $\text{gf}(2^M)$  corresponding to the integers that form messages and codewords. Specify this property as a double-precision, binary row vector that represents a primitive polynomial over  $\text{gf}(2)$  of degree  $M$  in descending order of powers.

If `CodewordLength` on page 4-0 is less than  $2^M-1$ , the object uses a shortened RS code. The default is the result of `fliplr(de2bi(primpoly(3)))`, which is `[1 0 1 1]` or the polynomial  $x^3 + x + 1$ .

This property applies when you set `PrimitivePolynomialSource` on page 4-0 to `Property`.

## PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. The default is `None`.

If you set this property to `None`, the object does not apply puncturing to the code. If you set this property to `Property`, the object punctures the code based on a puncture pattern vector specified in the `PuncturePattern` on page 4-0 property.

## PuncturePattern

Puncture pattern vector

Specify the pattern used to puncture the encoded data as a double-precision, binary column vector with a length of  $(\text{CodewordLength}$  on page 4-0 -  $\text{MessageLength}$  on page 4-0). The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword. This property applies when you set the `PuncturePatternSource` on page 4-0 property to `Property`.

## OutputDataType

Data type of output

Specify the output data type as `Same as input`, `double`, or `logical`. The default is `Same as input`. This property applies when you set the `BitInput` on page 4-0 property to `true`.

## Methods

`step` Encode data using a Reed-Solomon encoder

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

### Transmit an RS-encoded, 8-DPSK-modulated symbol stream

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.

```
enc = comm.RSEncoder;
mod = comm.DPSKModulator('BitInput',false);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',false);
hDdecec = comm.RSDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
    data = randi([0 7], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedSymbols = step(hDdecec, demodSignal);
    errorStats = step(errorRate, data, receivedSymbols);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.115578
Number of errors = 69
```

### Transmit a Shortened RS-encoded, 256-QAM-modulated Symbol Stream

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where  $N$  is the codeword length,  $K$  is the nominal message length, and  $S$  is the shortened message length. Set the modulation order,  $M$ , and the number of frames,  $L$ .

```
N = 255;
K = 239;
S = 188;
M = 256;
L = 50;
```

Create an AWGN channel System object and an error rate System object.

```
awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (Eb/No)', ...
    'EbNo',15,'BitsPerSymbol',log2(M));
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Create the Reed-Solomon generator polynomial from the DVB-T standard.

```
gp = rsgenpoly(N,K,[],0);
```

Create a Reed-Solomon encoder and decoder pair using the shortened message length,  $S$ , and the DVB-T generator polynomial,  $gp$ .

```
enc = comm.RSEncoder(N,K,gp,S);
dec = comm.RSDecoder(N,K,gp,S);
```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.

```
for counter = 1:L
    data = randi([0 1],S,log2(M));
    encodedData = step(enc,bi2de(data));
    modSignal = qammod(encodedData,M,'UnitAveragePower',true);
    rxSignal = awgnChan(modSignal);
```

```
demodSignal = qamdemod(rxSignal,M,'UnitAveragePower',true);
rxBits = dec(demodSignal);
dataOut = de2bi(rxBits);
errorStats = errorRate(data(:),dataOut(:));
end
```

Display the error rate and number of errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
```

```
Error rate = 2.01e-02
Number of errors = 1509
```

## Algorithms

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.Scrambler

**Package:** comm

Scramble input signal

### Description

The comm.Scrambler object scrambles a scalar or column vector input signal.

This schematic shows the scrambler operation. The adders operate modulo  $N$ , where  $N$  is the value specified by the Calculation base property.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the scrambler.

To scramble an input signal:

- 1 Create the comm.Scrambler object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

## Creation

### Syntax

```
scrambler = comm.Scrambler  
scrambler = comm.Scrambler(base,poly,cond)  
scrambler = comm.Scrambler( ___,Name,Value)
```

### Description

`scrambler = comm.Scrambler` creates a scrambler System object. This object scrambles the input data by using a linear feedback shift register that you specify with the `Polynomial` property.

`scrambler = comm.Scrambler(base,poly,cond)` creates the scrambler object with the `CalculationBase` property set to `base`, the `Polynomial` property set to `poly`, and the `InitialConditions` property set to `cond`.

Example: `comm.Scrambler(8,'1 + z^-2 + z^-3 + z^-5 + z^-7',[0 3 2 2 5 1 7])` sets the calculation base to 8, and the scrambler polynomial and initial conditions as specified.

`scrambler = comm.Scrambler( ___,Name,Value)` sets properties using one or more name-value pairs and either of the previous syntaxes. Enclose each property name in single quotes.

Example: `comm.Scrambler('CalculationBase',2)`

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

### CalculationBase — Range of input data

4 (default) | nonnegative integer

Range of input data used in the scrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from 0 to `CalculationBase - 1`.

Data Types: double

### Polynomial — Connections for linear feedback shift registers

'1 + z<sup>-1</sup> + z<sup>-2</sup> + z<sup>-4</sup>' (default) | character vector | integer vector | binary vector

Connections for linear feedback shift registers in the scrambler, specified as a character vector, integer vector, or binary vector. The `Polynomial` property defines if each switch in the scrambler is on or off. Specify the polynomial as:

- A character vector, such as '1 + z<sup>-6</sup> + z<sup>-8</sup>'. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0 -6 -8], listing the scrambler coefficients in order of descending powers of  $z^{-1}$ , where  $p(z^{-1}) = 1 + p_1z^{-1} + p_2z^{-2} + \dots$
- A binary vector, such as [1 0 0 0 0 0 1 0 1], listing the powers of  $z$  that appear in the polynomial that have a coefficient of 1. In this case, the order of the scramble polynomial is one less than the binary vector length.

Example: '1 + z<sup>-6</sup> + z<sup>-8</sup>', [0 -6 -8], and [1 0 0 0 0 0 1 0 1] all represent this polynomial:

$$p(z^{-1}) = 1 + z^{-6} + z^{-8}$$

Data Types: double | char

### InitialConditionsSource — Initial conditions source

'Property' (default) | 'Input port'

- 'Property' - Specify scrambler initial conditions by using the `InitialConditions` property.
- 'Input port' - Specify scrambler initial conditions by using an additional input argument, `initcond`, when calling the object.

Data Types: char

### InitialConditions — Initial conditions of scrambler registers

[0 1 2 3] (default) | nonnegative integer vector

Initial conditions of scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of `InitialConditions` must equal the order of the `Polynomial` property. The vector element values must be integers from 0 to `CalculationBase - 1`.

### Dependencies

This property is available when `InitialConditionsSource` is set to `'Property'`.

### ResetInputPort — Scrambler state reset port

`false` (default) | `true`

Scrambler state reset port, specified as `false` or `true`. If `ResetInputPort` is `true`, you can reset the scrambler object by using an additional input argument, `reset`, when calling the object.

### Dependencies

This property is available when `InitialConditionsSource` is set to `'Property'`.

## Usage

## Syntax

```
scrambledOut = scrambler(signal)
scrambledOut = scrambler(signal,initcond)
scrambledOut = scrambler(signal,reset)
```

## Description

`scrambledOut = scrambler(signal)` scrambles the input signal. The output is the same data type and length as the input vector.

`scrambledOut = scrambler(signal,initcond)` provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the `InitialConditionsSource` property of the object to `'Input port'`.

`scrambledOut = scrambler(signal, reset)` provides an additional input indicating whether to reset the state of the scrambler.

This syntax applies when you set `InitialConditionsSource` to 'Property' and `ResetInputPort` to `true`.

### Input Arguments

#### **signal** — Input signal

column vector

Input signal, specified as a column vector.

Example: `scrambledOut = scrambler([0 1 1 0 1])`

Data Types: `double` | `logical`

#### **initcond** — Initial register conditions

nonnegative integer column vector

Initial scrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of `initcond` must equal the order of the Polynomial property. The vector element values must be integers from 0 to `CalculationBase - 1`.

Example: `scrambledOut = scrambler(signal, [0 1 1 0])` corresponds to possible initial register states for a scrambler with a polynomial order of 4 and a calculation base of 2 or higher.

Data Types: `double`

#### **reset** — Reset initial state of scrambler

scalar

Reset the initial state of the scrambler when the simulation starts, specified as a scalar. When the value of `reset` is nonzero, the object is reset before it is called.

Example: `scrambledOut = scrambler(signal, 0)` scrambles the input signal without resetting the scrambler states.

Data Types: `double`

## Output Arguments

### **out** — Scrambled output

column vector

Scrambled output, returned as a column vector with the same data type and length as signal.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Scramble and Descramble Data

Scramble and descramble 8-ary data using `comm.Scrambler` and `comm.Descrambler` System objects™ having a calculation base of 8.

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.

```
N = 8;
scrambler = comm.Scrambler(N, '1 + z^-2 + z^-3 + z^-5 + z^-7', ...
    [0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N, [1 0 1 1 0 1 0 1], ...
    [0 3 2 2 5 1 7]);
```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.

```
data = randi([0 N-1],5,1);  
scrData = scrambler(data);  
deScrData = descrambler(scrData);  
[data scrData deScrData]
```

```
ans = 5×3
```

```
    6    7    6  
    7    5    7  
    1    7    1  
    7    0    7  
    5    3    5
```

Verify that the descrambled data matches the original data.

```
isequal(data,deScrData)
```

```
ans = logical  
     1
```

### Scramble and Descramble Data with Changing Initial Conditions

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the `InitialConditionsSource` property to 'Input port' so you can set the initial conditions as an argument to the object.

```
N = 4;  
scrambler = comm.Scrambler(N,'1 + z^-3','InitialConditionsSource','Input port');  
descrambler = comm.Descrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
```

Preallocate memory for the error vector which will be used to store errors output by the `symerr` function.

```
errVec = zeros(10,1);
```

Scramble and descramble random integers while changing the initial conditions, `initCond`, each time the loop executes. Use the `symerr` function to determine if the scrambling and descrambling operations result in symbol errors.

```
for k = 1:10
    initCond = randperm(3)';
    data = randi([0 N-1],5,1);
    scrData = scrambler(data,initCond);
    deScrData = descrambler(scrData,initCond);
    errVec(k) = symerr(data,deScrData);
end
```

Examine `errVec` to verify that the output from the descrambler matches the original data.

`errVec`

`errVec = 10×1`

**Package:** comm

Decode input using sphere decoder

## Description

The Sphere Decoder System object decodes the symbols sent over  $N_T$  antennas using the sphere decoding algorithm.

To decode input symbols using a sphere decoder:

- 1 Define and set up your sphere decoder object. See “Construction” on page 4-1723.
- 2 Call `step` to decode input symbols according to the properties of `comm.SphereDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.SphereDecoder` creates a System object, `H`. This object uses the sphere decoding algorithm to find the maximum-likelihood solution for a set of received symbols over a MIMO channel with  $N_T$  transmit antennas and  $N_R$  receive antennas.

`H = comm.SphereDecoder(Name,Value)` creates a sphere decoder object, `H`, with the specified property name set to the specified value. `Name` must appear inside single quotes ('). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`H = comm.SphereDecoder(CONSTELLATION, BITTABLE)` creates a sphere decoder object, `H`, with the `Constellation` property set to `CONSTELLATION`, and the `BitTable` property set to `BITTABLE`.

## Properties

### Constellation

Signal constellation per transmit antenna

Specify the constellation as a complex column vector containing the constellation points to which the transmitted bits are mapped. The default setting is a QPSK constellation with an average power of 1. The length of the vector must be a power of two. The object assumes that each transmit antenna uses the same constellation.

### BitTable

Bit mapping used for each constellation point.

Specify the bit mapping for the symbols that the `Constellation` property specifies as a numerical matrix. The default is `[0 0; 0 1; 1 0; 1 1]`, which matches the default `Constellation` property value.

The matrix size must be `[ConstellationLength bitsPerSymbol]`. `ConstellationLength` represents the length of the `Constellation` property. `bitsPerSymbol` represents the number of bits that each symbol encodes.

### InitialRadius

Initial search radius of the decoding algorithm.

Specify the initial search radius for the decoding algorithm as either `Infinity` | `ZF Solution`. The default is `Infinity`.

When you set this property to `Infinity`, the object sets the initial search radius to `Inf`.

When you set this property to `ZF Solution`, the object sets the initial search radius to the zero-forcing solution. This calculation uses the pseudo-inverse of the input channel when decoding. Large constellations and/or antenna counts can benefit from the initial reduction in the search radius. In most cases, however, the extra computation of the `ZF Solution` will not provide a benefit.

## DecisionType

Specify the decoding decision method as either `Soft` | `Hard`. The default is `Soft`.

When you set this property to `Soft`, the decoder outputs log-likelihood ratios (LLRs), or soft bits.

When you set this property to `Hard`, the decoder converts the soft LLRs to bits. The hard-decision output logical array follows the mapping of a zero for a negative LLR and one for all other values.

## Methods

`step` Decode received symbols using sphere decoding algorithm

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Decode Using a Sphere Decoder

Modulate a set of bits using 16-QAM constellation. Transmit the signal as two parallel streams over a MIMO channel. Decode using a sphere decoder with perfect channel knowledge.

Specify the modulation order, the number of transmitted bits, the Eb/No ratio, and the symbol mapping.

```
bps = 4; % Bits per symbol
M = 2^bps; % Modulation order
nBits = 1e3*bps;
ebno = 10;
symMap = [11 10 14 15 9 8 12 13 1 0 4 5 3 2 6 7];
```

Generate and display the symbol mapping of the 16-QAM modulator by using the `qammod` function and the custom symbol map.

```
sym = qammod(symMap(1:M)',M,symMap,'UnitAveragePower',true,'PlotConstellation',true);
```

Convert the decimal value of the symbol map to binary bits using the left bit as the most significant bit (msb). The M-by-bps matrix bitTable is used by the sphere decoder.

```
bitTable = de2bi(symMap, bps, 'left-msb');
```

Create a 2x2 MIMO Channel System object with PathGainsOutputPort set to true to use the path gains as a channel estimate. To ensure the repeatability of results, set the object to use the global random number stream.

```
mimo = comm.MIMOChannel( ...
    'PathGainsOutputPort', true, ...
    'RandomStream', 'Global stream');
```

Create an AWGN Channel System object.

```
awgnChan = comm.AWGNChannel('EbNo',ebno,'BitsPerSymbol',bps);
```

Create a Sphere Decoder System object that processes bits using hard-decision decoding. Configure using the custom bit table and symbol map.

```
sphDec = comm.SphereDecoder('Constellation',sym, ...
    'BitTable',bitTable,'DecisionType','Hard');
```

Create an error rate System object.

```
berRate = comm.ErrorRate;
```

Set the global random number generator seed.

```
rng(37)
```

Generate a random data stream.

```
data = randi([0 1],nBits,1);
```

Modulate the data and reshape it into two streams to be used with the 2x2 MIMO channel.

```
modData = qammod(data,M,symMap,'InputType','bit','UnitAveragePower',true);
modData = reshape(modData,[],2);
```

Pass the modulated data through the MIMO fading channel and add AWGN.

```
[fadedSig,pathGains] = mimo(modData);
rxSig = awgnChan(fadedSig);
```

Decode the received signal using pathGains as a perfect channel estimate.

```
decodedData = sphDec(rxSig,squeeze(pathGains));
```

Convert the decoded hard-decision data, which is a logical matrix, into a double column vector to enable the calculation of error statistics. Calculate and display the bit error rate and the number of errors.

```
dataOut = double(decodedData(:));
errorStats = berRate(data,dataOut);
errorStats(1:2)
```

```
ans = 2x1
    0.0380
   152.0000
```

## Algorithm

This object implements a soft-output max-log a posteriori probability (APP) MIMO detector by means of a soft-output Schnorr-Euchner sphere decoder (SESD), implemented as single tree search (STS) tree traversal. The algorithm assumes the same constellation and bit table on all of the transmit antennas. Given as inputs, the received symbol vector and the estimated channel matrix, the algorithm outputs the log-likelihood ratios (LLRs) of the transmitted bits.

The algorithm assumes a MIMO system model with  $N_T$  transmit antennas and  $N_R$  receive antennas where  $N_T$  symbols are simultaneously sent, expressed as:

$$y = Hs + n.$$

where  $y$  is the received symbols,  $H$  is the MIMO channel matrix,  $s$  is the transmitted symbol vector, and  $n$  is the thermal noise.

The MIMO detector seeks the maximum-likelihood (ML) solution,  $\hat{s}_{ML}$ , such that:

$$\hat{s}_{ML} = \underset{s \in O}{\operatorname{argmin}} \|y - Hs\|^2$$

where  $O$  is the complex-valued constellation from which the  $N_T$  elements of  $s$  are chosen.

Soft detection also computes a log-likelihood ratio (LLR) for each bit that serves as a measure of the reliability of the estimate for each bit. The LLR is calculated as using the max-log approximation:

$$L(x_{j,b}) = \min_{\substack{\hat{s} \in x_{j,b}^{(0)} \\ \lambda^{ML}}} \|y - Hs\|^2 - \min_{\substack{\hat{s} \in x_{j,b}^{(1)} \\ \lambda_{j,b}^{ML}}} \|y - Hs\|^2$$

where

- $L(x_{j,b})$  is the LLR estimate for each bit.
- $x_{j,b}$  is each sent bit, the  $b$ th bit of the  $j$ th symbol.
- $x_{j,b}^{(0)}$  and  $x_{j,b}^{(1)}$  are the disjoint sets of vector symbols that have the  $b$ th bit in the label of the  $j$ th scalar symbol equal to 0 and 1, respectively. The two  $\lambda$  symbols denotes the distance calculated as norm squared., specifically:
  - $\lambda^{ML}$  is the distance  $\widehat{s}_{ML}$ .
  - $\lambda_{j,b}^{\overline{ML}}$  is the distance to the counter-hypothesis, which denotes the binary complement of the  $b$ th bit in the binary label of the  $j$ th entry of  $\widehat{s}_{ML}$ , specifically the minimum of the symbol set  $x_{j,b}^{\left(\overline{x_{j,b}^{ML}}\right)}$ , which contains all of the possible vectors for which the  $b$ th bit of the  $j$ th entry is flipped compared to the same entry of  $\widehat{s}_{ML}$ .

Based on whether  $x_{j,b}^{\left(x_{j,b}^{ML}\right)}$  is 0 or 1, the LLR estimate for bit  $x_{j,b}$  is computed as follows:

$$L(x_{j,b}) = \begin{cases} \lambda^{ML} - \lambda_{j,b}^{\overline{ML}}, & x_{j,b}^{ML} = 0 \\ \lambda_{j,b}^{\overline{ML}} - \lambda^{ML}, & x_{j,b}^{ML} = 1 \end{cases}$$

The design of a decoder strives to efficiently find  $\widehat{s}_{ML}$ ,  $\lambda^{ML}$ , and  $\lambda_{j,b}^{\overline{ML}}$ .

This search can be converted into a tree search by means of the sphere decoding algorithms. To this end, the channel matrix is decomposed into  $H = QR$  by means of a  $QR$  decomposition. Left-multiplying  $y$  by  $Q^H$ , the problem can be reformulated as:

$$\lambda^{ML} = \arg \min_{s \in o} \|\bar{y} - Rs\|^2$$

$$\lambda_{j,b}^{\overline{ML}} = \underset{s \in x_{j,b}^{\left(x_{j,b}^{ML}\right)}}{\operatorname{argmin}} \|\bar{y} - Rs\|^2$$

Using this reformulated problem statement, the triangular structure of  $R$  can be exploited to arrange a tree structure such that each of the leaf nodes corresponds to a possible  $s$  vector and the partial distances to the nodes in the tree can be calculated cumulatively adding to the partial distance of the parent node.

In the STS algorithm, the  $\lambda^{ML}$  and  $\lambda_{j,b}^{\overline{ML}}$  metrics are searched concurrently. The goal is to have a list containing the metric  $\lambda^{ML}$ , along with the corresponding bit sequence  $x^{ML}$  and the metrics  $x_{j,b}^{(ML)}$  of all counter-hypotheses. The sub-tree originating from a given node is searched only if the result can lead to an update of either  $\lambda^{ML}$  or  $\lambda_{j,b}^{\overline{ML}}$ .

The STS algorithm flow can be summarized as:

- 1** If when reaching a leaf node, a new ML hypothesis is found ( $d(x) < \lambda^{ML}$ ), all  $\lambda_{j,b}^{\overline{ML}}$  for which  $x_{j,b} = x_{j,b}^{\overline{ML}}$  are set to  $\lambda^{ML}$  which now turns into a valued counter-hypothesis. Then,  $\lambda^{ML}$  is set to the current distance,  $d(x)$ .
- 2** If  $d(x) \geq \lambda^{ML}$ , only the counter-hypotheses have to be checked. For all  $j$  and  $b$  for which ( $d(x) < \lambda_{j,b}^{\overline{ML}}$ ) and  $x_{j,b} = x_{j,b}^{\overline{ML}}$ , the decoder updates  $\lambda_{j,b}^{\overline{ML}}$  to be  $d(x)$ .
- 3** A sub-tree is pruned if the partial distance of the node is bigger than the current  $\lambda_{j,b}^{\overline{ML}}$  which may be affected when traversing the subtree.
- 4** The STS concludes once all of the tree nodes have been visited once or pruned.

## Limitations

- The output LLR values are not scaled by the noise variance. For coded links employing iterative coding (LDPC or turbo) or MIMO OFDM with Viterbi decoding, the output LLR values should be scaled by the channel state information to achieve better performance.

Decode received symbols using sphere decoding algorithm

## Syntax

$Y = \text{step}(H, \text{RXSYMBOLS}, \text{CHAN})$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, \text{RXSYMBOLS}, \text{CHAN})$  decodes the received symbols, `RXSYMBOLS`, using the sphere decoding algorithm. The algorithm can be employed to decode  $N_s$  channel realizations in one call, where in each channel realization,  $N_r$  symbols are received.

The inputs are:

**RXSYMBOLS:** a  $[N_s \ N_r]$  complex double matrix containing the received symbols.

**CHAN:** a  $[N_s \ N_t \ N_r]$  or  $[1 \ N_t \ N_r]$  complex double matrix representing the fading channel coefficients of the flat-fading MIMO channel. For the  $[N_s \ N_t \ N_r]$  case, the object applies each channel matrix to each  $N_r$  symbol set. For the block fading case, i.e., when the size of `CHAN` is  $[1 \ N_t \ N_r]$ , the same channel is applied to all of the received symbols.

The output  $Y$ , which depends on the setting of the `DecisionType` property, is a double matrix containing the Log-Likelihood Ratios (LLRs) of the decoded bits or the bits themselves. For both cases, the size of the output is  $[N_s * \text{bitsPerSymbol} \ N_t]$ , where `bitsPerSymbol` represents the number of bits per transmitted symbol, as determined by the `BitTable` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.SymbolSynchronizer

**Package:** comm

Correct symbol timing clock skew

### Description

The `comm.SymbolSynchronizer` System object corrects symbol timing clock skew between a single-carrier transmitter and receiver for PAM, PSK, QAM, and OQPSK modulation schemes. For more information, see “Symbol Synchronization Overview” on page 4-1755.

---

**Note** The input signal operates on a sample-rate basis and the output signal operates on a symbol-rate basis.

---

To correct symbol timing clock skew:

- 1 Create the `comm.SymbolSynchronizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

### Creation

### Syntax

```
symbolSync = comm.SymbolSynchronizer  
symbolSync = comm.SymbolSynchronizer(Name, Value)
```

## Description

`symbolSync = comm.SymbolSynchronizer` creates a symbol synchronizer System object for correcting the clock skew between a single-carrier transmitter and receiver.

`symbolSync = comm.SymbolSynchronizer(Name, Value)` sets properties using one or more name-value pairs. For example, `comm.SymbolSynchronizer('Modulation', 'OQPSK')` configures the symbol synchronizer System object for an OQPSK-modulated input signal. Enclose each property name in quotes.

`Tunable DampingFactor`, `NormalizedLoopBandwidth`, and `DetectorGain` properties enable you to optimize synchronizer performance in your simulation loop without releasing the object.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

## Name-Value Pair Arguments

### **Modulation** — Modulation type

'PAM/PSK/QAM' (default) | 'OQPSK'

Modulation type, specified as 'PAM/PSK/QAM' or 'OQPSK'.

**Tunable:** No

Data Types: char | string

### **TimingErrorDetector** — Timing error detector method

Zero-Crossing (decision-directed) (default) | Gardner (non-data-aided) | Early-Late (non-data-aided) | Mueller-Muller (decision-directed)

Timing error detector method, specified as Zero-Crossing (decision-directed), Gardner (non-data-aided), Early-Late (non-data-aided), or Mueller-Muller (decision-directed). This property assigns the timing error detection scheme used in the synchronizer. For more information, see “Timing Error Detection (TED)” on page 4-1756.

**Tunable:** No

Data Types: char | string

### **SamplesPerSymbol — Samples per symbol**

2 (default) | integer greater than 1

Samples per symbol, specified as an integer greater than 1.

**Tunable:** No

Data Types: double

### **DampingFactor — Damping factor of loop filter**

1 (default) | positive scalar

Damping factor of the loop filter, specified as a positive scalar. For more information, see “Loop Filter” on page 4-1760.

**Tunable:** Yes

Data Types: double | single

### **NormalizedLoopBandwidth — Normalized bandwidth of loop filter**

0.01 (default) | scalar in the range (0, 1)

Normalized bandwidth of the loop filter, specified as a scalar in the range (0, 1). The loop bandwidth is normalized to the sample rate of the input signal. For more information, see “Loop Filter” on page 4-1760.

---

**Note** To ensure the symbol synchronizer locks, set the NormalizedLoopBandwidth property to a value less than 0.1.

---

**Tunable:** Yes

Data Types: double | single

**DetectorGain — Phase detector gain**

2.7 (default) | positive scalar

Phase detector gain, specified as a positive scalar.

**Tunable:** Yes

Data Types: double | single

## Usage

---

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

---

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Syntax

```
symbols = symbolSync(samples)
```

## Description

`symbols = symbolSync(samples)` corrects symbol timing clock skew between a single-carrier transmitter and receiver based on the input samples and outputs synchronized symbols.

- The input operates on a sample-rate basis and the output signal operates on a symbol-rate basis.
- You can tune the `DampingFactor`, `NormalizedLoopBandwidth`, and `DetectorGain` properties to improve the synchronizer performance.

## Input Arguments

**samples — Input samples**

scalar (default) | column vector

Input samples, specified as a scalar or column vector of a PAM-, PSK-, QAM-, or OQPSK-modulated single-carrier signal.

Data Types: `double` | `single`  
Complex Number Support: Yes

### Output Arguments

#### **symbols** — Synchronized symbols

column vector

Synchronized symbols, returned as a variable-sized column vector. The output symbols inherit the data type from the input samples. For an input with dimensions  $N_{\text{samp}}$ -by-1, this output has dimensions  $N_{\text{sym}}$ -by-1.  $N_{\text{sym}}$  is approximately equal to  $N_{\text{samp}}$  divided by  $N_{\text{sps}}$ , where  $N_{\text{sps}}$  is equal to the `SamplesPerSymbol` property value. If the output exceeds the maximum output size of  $\left\lceil \frac{N_{\text{samp}}}{N_{\text{sps}}} \times 1.1 \right\rceil$ , it is truncated.

#### **timingErr** — Estimated timing error

scalar in the range [0, 1] | column vector of elements in the range [0, 1]

Estimated timing error for each input sample, returned as a scalar in the range [0, 1] or column vector of elements in the range [0, 1]. The estimated timing error is normalized to the input sample rate. `timingErr` has the same data type and size as `input samples`.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `comm.SymbolSynchronizer`

`clone`      Create duplicate System object  
`isLocked`   Determine if System object is in use

### Common to All System Objects

`step`      Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics  
 reset Reset internal states of System object

## Examples

### Correct Symbol Timing Error of QPSK-Modulated Signal

Correct a fixed symbol timing error on a noisy QPSK-modulated signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.

```
M = 4;           % Modulation order for QPSK
nSym = 5000;    % Number of symbols in a packet
sps = 4;       % Samples per symbol
timingErr = 2;  % Samples of timing error
snr = 15;      % Signal-to-noise ratio (dB)
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter( ...
    'InputSamplesPerSymbol',sps,'DecimationFactor',2);
```

Create a symbol synchronizer System object to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer;
```

Generate random M-ary symbols and apply QPSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M,pi/4);
```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a 1/4 symbol through the fixed delay and channel.

```
fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in
```

Filter the modulated signal through a transmit RRC filter by using the `txfilter` object. Apply a signal timing error by using the `fixedDelay` object.

```
txSig = txfilter(modSig);  
delaySig = fixedDelay(txSig);
```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.

```
rxSig = awgn(delaySig,snr,'measured');
```

Filter the modulated signal through a receive RRC filter by using the `rxfilter` object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected QPSK reference constellation.

```
rxSample = rxfilter(rxSig);  
scatterplot(rxSample(1001:end),2)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected QPSK constellation.

```
rxSync = symbolSync(rxSample);  
scatterplot(rxSync(1001:end),2)
```

Demodulate the QPSK signal.

```
recData = pskdemod(rxSync,M,pi/4);
```

Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.

```
sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
    rxfilter.FilterSpanInSymbols/2);
```

Compute the BER, taking into account the system delay.

```
[numErr,ber] = biterr(sysDelay(data),recData)
```

```
numErr = 12
```

```
ber = 0.0012
```

## Correct Symbol Timing Error of BPSK-Modulated Signal

Correct a fixed symbol timing error on a noisy BPSK transmission signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.

```
M = 2;           % Modulation order for BPSK
nSym = 20000;   % Number of symbols in a packet
sps = 4;       % Samples per symbol
timingErr = 2;  % Samples of timing error
snr = 15;      % Signal-to-noise ratio (dB)
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter(...
    'InputSamplesPerSymbol',sps,'DecimationFactor',1);
```

Create a symbol synchronizer System object™ to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer(...
    'SamplesPerSymbol',sps, ...
    'NormalizedLoopBandwidth',0.01, ...
    'DampingFactor',1.0, ...
    'TimingErrorDetector','Early-Late (non-data-aided)');
```

Generate random data symbols and apply BPSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M);
```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a 1/4 symbol through the fixed delay and channel.

```
fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in
```

Filter the modulated signal through a transmit RRC filter by using the `txfilter` object. Apply a signal timing error by using the `fixedDelay` object.

```
txSig = txfilter(modSig);  
delayedSig = fixedDelay(txSig);
```

Pass the delayed signal through an AWGN channel.

```
rxSig = awgn(delayedSig,snr,'measured');
```

Filter the modulated signal through a receive RRC filter by using the `rxfilter` object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected BPSK reference constellation.

```
rxSample = rxfilter(rxSig);  
scatterplot(rxSample(10000:end),2)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected BPSK constellation.

```
rxSync = symbolSync(rxSample);  
scatterplot(rxSync(10000:end),2)
```

Demodulate the BPSK signal.

```
recData = pskdemod(rxSync,M);
```

Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.

```
sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...  
    rxfilter.FilterSpanInSymbols/2);
```

Compute the BER, taking into account the system delay.

```
[numErr1,ber1] = biterr(sysDelay(data),recData)
```

```
numErr1 = 8
```

```
ber1 = 4.0000e-04
```

## Correct Symbol Timing and Doppler Offsets

Correct symbol timing and frequency offset errors by using the `comm.SymbolSynchronizer` and `comm.CarrierSynchronizer` System objects.

### Configuration

Initialize simulation parameters.

```
M = 16;           % Modulation order
nSym = 2000;     % Number of symbols in a packet
sps = 2;         % Samples per symbol
spsFilt = 8;     % Samples per symbol for filters and channel
spsSync = 2;    % Samples per symbol for synchronizers
lenFilt = 10;    % RRC filter length
```

Create a matched pair of root raised cosine (RRC) filter System objects for transmitter and receiver.

```
txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',lenFilt, ...
    'OutputSamplesPerSymbol',spsFilt,'Gain',sqrt(spsFilt));
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',lenFilt, ...
    'InputSamplesPerSymbol',spsFilt,'DecimationFactor',spsFilt/2,'Gain',sqrt(1/spsFilt));
```

Create a phase-frequency offset System object to introduce a 100 Hz Doppler shift.

```
doppler = comm.PhaseFrequencyOffset('FrequencyOffset',100, ...
    'PhaseOffset',45,'SampleRate',1e6);
```

Create a variable delay System object to introduce timing offsets.

```
varDelay = dsp.VariableFractionalDelay;
```

Create carrier and symbol synchronizer System objects to correct for Doppler shift and timing offset, respectively.

```
carrierSync = comm.CarrierSynchronizer('SamplesPerSymbol',spsSync);
symbolSync = comm.SymbolSynchronizer( ...
    'TimingErrorDetector','Early-Late (non-data-aided)', ...
    'SamplesPerSymbol',spsSync);
```

Create constellation diagram System objects to view the results.

```
refConst = qammod(0:M-1,M,'UnitAveragePower',true);
cdReceive = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsFilt,'Title','Received Signal');
cdDoppler = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsSync,'Title','Frequency Corrected Signal');
cdTiming = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsSync,'Title','Frequency and Timing Synchronized Signal');
```

### Main Processing Loop

The main processing loop:

- Generates random symbols and apply QAM modulation.
- Filters the modulated signal.
- Applies frequency and timing offsets.
- Passes the transmitted signal through an AWGN channel.
- Filters the received signal.
- Corrects the Doppler shift.
- Corrects the timing offset.

```
for k = 1:15
    data = randi([0 M-1],nSym,1);
    modSig = qammod(data,M,'UnitAveragePower',true);
    txSig = txfilter(modSig);

    txDoppler = doppler(txSig);
    txDelay = varDelay(txDoppler,k/15);

    rxSig = awgn(txDelay,25);

    rxFiltSig = rxfilter(rxSig);
    rxCorr = carrierSync(rxFiltSig);
    rxData = symbolSync(rxCorr);
end
```

### Visualization

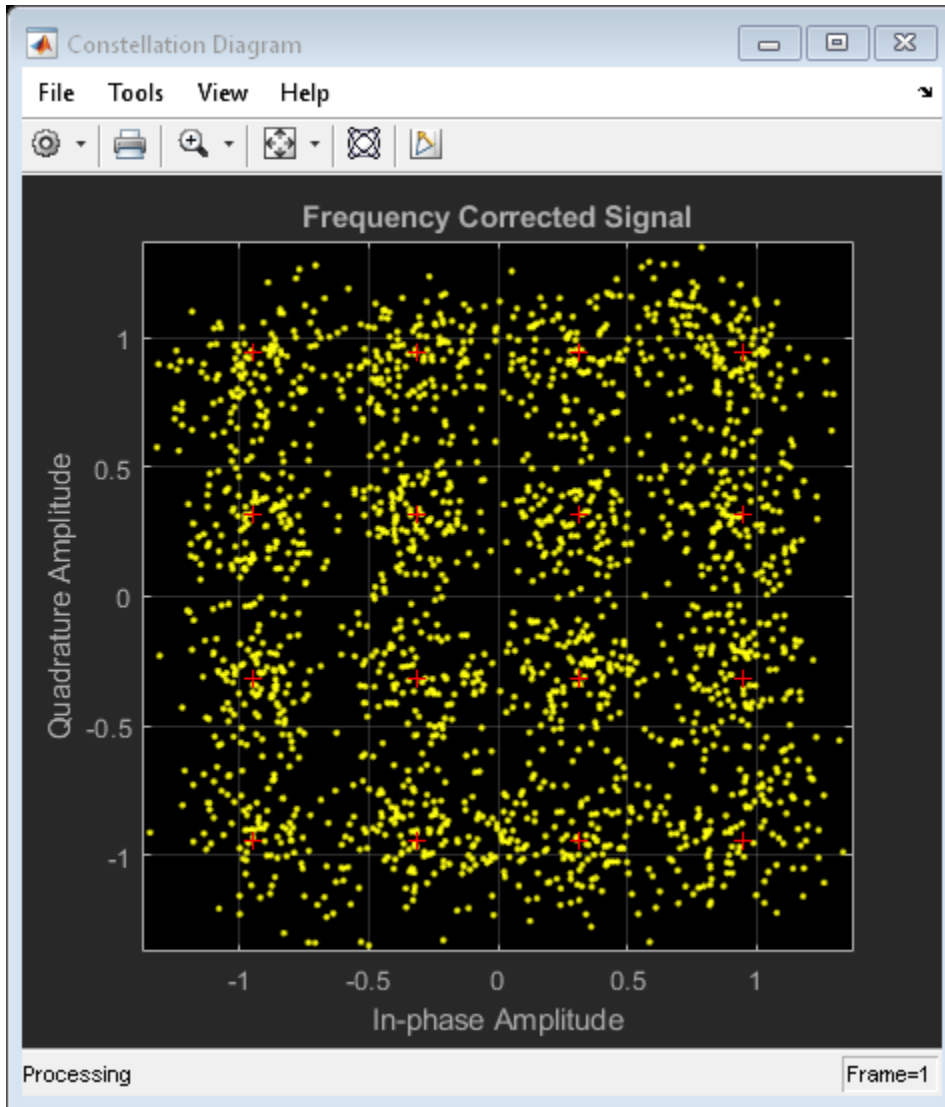

Plot the constellation diagrams of the received signal, frequency corrected signal, and frequency and timing synchronized signal. Specific constellation points cannot be identified in the received signal and can be only partially identified in the frequency

corrected signal. However, the timing and frequency synchronized signal aligns with the expected QAM constellation points.

```
cdReceive(rxSig)
```

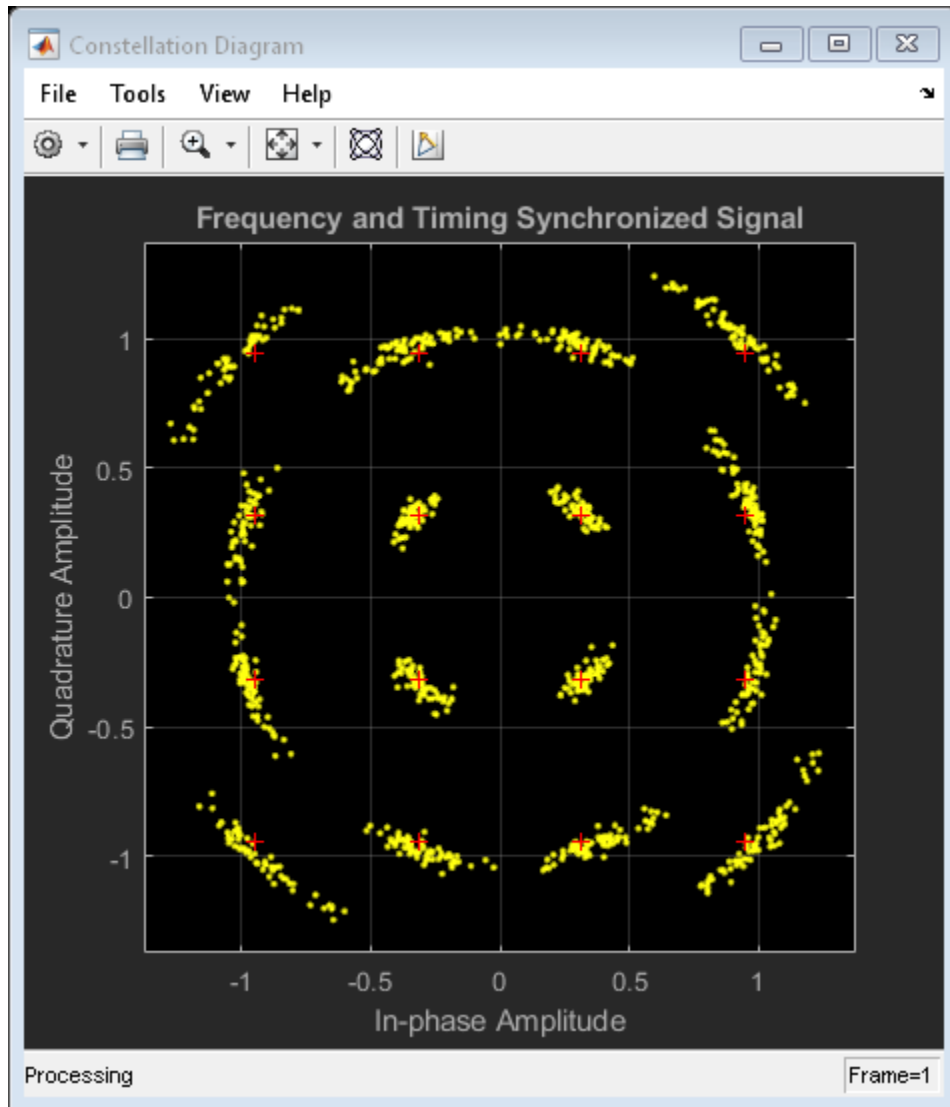

`cdDoppler(rxCorr)`

`cdTiming(rxData)`

### Timing Error for Noisy 8-PSK Signal

Correct a monotonically increasing symbol timing error on a noisy 8-PSK signal. Display the normalized timing error.

Initialize simulation parameters.

```
M = 8;           % Modulation order
nSym = 5000;     % Number of symbol in a packet
sps = 2;        % Samples per symbol
nSamp = sps*nSym; % Number of samples in a packet
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter( ...
    'InputSamplesPerSymbol',sps, ...
    'DecimationFactor',1);
```

Create a variable fractional delay System object™ to introduce a monotonically increasing timing error.

```
varDelay = dsp.VariableFractionalDelay;
```

Create a symbol synchronizer System object to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer(...
    'TimingErrorDetector','Mueller-Muller (decision-directed)', ...
    'SamplesPerSymbol',sps);
```

Generate random 8-ary symbols and apply 8-PSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M,pi/8);
```

Filter the modulated signal through a raised cosine transmit filter and apply a monotonically increasing timing delay.

```
vdelay = (0:1/nSamp:1-1/nSamp)';
txSig = txfilter(modSig);
delaySig = varDelay(txSig,vdelay);
```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.

```
rxSig = awgn(delaySig,15,'measured');
```

Filter the modulated signal through a receive RRC filter. Display the scatter plot. Due to the timing error, the received signal does not align with the expected 8-PSK reference constellation.

```
rxSample = rxfilter(rxSig);  
scatterplot(rxSample,sps)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected 8-PSK constellation.

```
[rxSym,tError] = symbolSync(rxSample);  
scatterplot(rxSym(1001:end))
```

Plot the timing error estimate. Over time, the normalized timing error increases to 1 sample.

```
figure
plot(vdelay,tError)
xlabel('Time (s)')
ylabel('Timing Error (samples)')
```

## More About

### Symbol Synchronization Overview

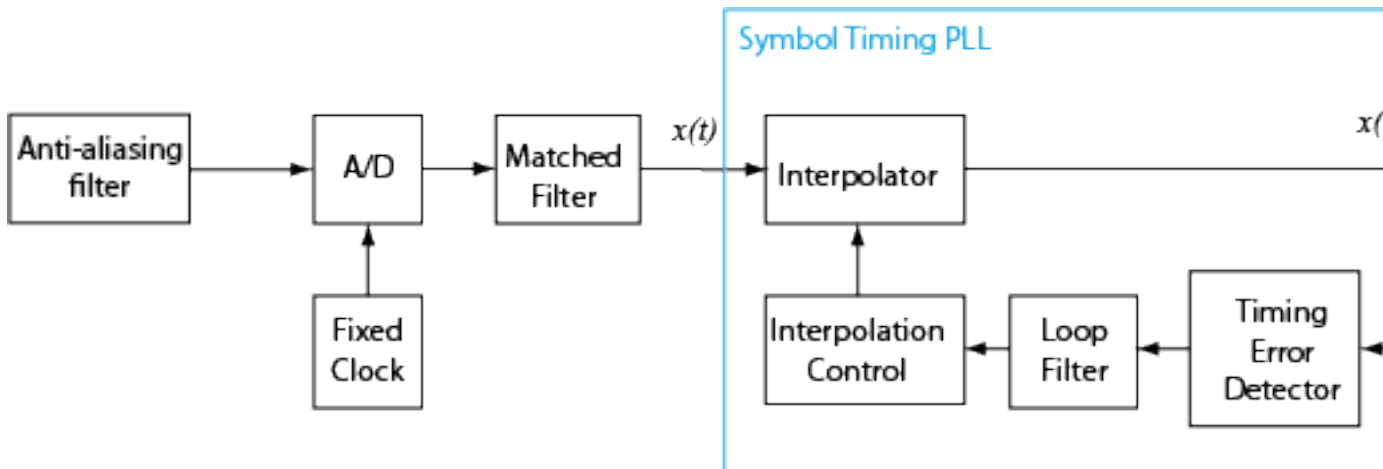

The symbol timing synchronizer algorithm is based on a phased lock loop (PLL) algorithm that consists of four components:

- A timing error detector (TED)
- An interpolator

- An interpolation controller
- A loop filter

For OQPSK modulation, the in-phase and quadrature signal components are first aligned (as in QPSK modulation) using a state buffer to cache the last half symbol of the previous input. After initial alignment, the remaining synchronization process is the same as for QPSK modulation.

This block diagram shows an example of a timing synchronizer. In the figure, the symbol timing PLL operates on  $x(t)$ , the received sample signal after matched filtering. The symbol timing PLL outputs the symbol signal,  $x(kT_s + \hat{\tau})$ , after correcting for the clock skew between the transmitter and receiver.

### Timing Error Detection (TED)

The symbol timing synchronizer supports non-data-aided TED and decision-directed TED methods. This table shows the timing estimate expressions for the TED method options.

TED Method	Expression
Zero-crossing (decision-directed)	$e(k) = x((k - 1/2)T_s + \hat{\tau})[\hat{a}_0(k - 1) - \hat{a}_0(k)] + y((k - 1/2)T_s + \hat{\tau})[\hat{a}_1(k - 1) - \hat{a}_1(k)]$
Gardner (non-data-aided)	$e(k) = x((k - 1/2)T_s + \hat{\tau})[x((k - 1)T_s + \hat{\tau}) - x(kT_s + \hat{\tau})] + y((k - 1/2)T_s + \hat{\tau})[y((k - 1)T_s + \hat{\tau}) - y(kT_s + \hat{\tau})]$
Early-late (non-data-aided)	$e(k) = x(kT_s + \hat{\tau})[x((k + 1/2)T_s + \hat{\tau}) - x((k - 1/2)T_s + \hat{\tau})] + y(kT_s + \hat{\tau})[y((k + 1/2)T_s + \hat{\tau}) - y((k - 1/2)T_s + \hat{\tau})]$
Mueller-Muller (decision-directed)	$e(k) = \hat{a}_0(k - 1)x(kT_s + \hat{\tau}) - \hat{a}_0(k)x((k - 1)T_s + \hat{\tau}) + \hat{a}_1(k - 1)y(kT_s + \hat{\tau}) - \hat{a}_1(k)y((k - 1)T_s + \hat{\tau})$

Non-data-aided TED uses received samples without any knowledge of the transmitted signal or the results of the channel estimation. Non-data-aided TED is used to estimate the timing error for signals with modulation schemes that have constellation points aligned with the in-phase or quadrature axis. Examples of signals suitable for the Gardner or early-late methods include QPSK-modulated signals with a zero phase offset that has points at  $\{1+0i, 0+1i, -1+0i, 0-1i\}$  and BPSK-modulated signals with a zero phase offset.

- Gardner method** — The Gardner method is a non-data-aided feedback method that is independent of carrier phase recovery. It is used for baseband systems and modulated carrier systems. More specifically, this method is used for systems that use a linear modulation type with Nyquist pulses that have an excess bandwidth between approximately 40% and 100%. Examples include systems that use PAM, PSK, QAM, or OQPSK modulation and that shape the signal using raised cosine filters whose rolloff factor is between 0.4 and 1. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth increases (or rolloff factor increases in the case of a raised cosine filter). The Gardner method is similar to the early-late gate method.
- Early-late method** — The early-late method is a non-data-aided feedback method. It is used for systems that use a linear modulation type such as PAM, PSK, QAM, or

OQPSK modulation. For example, systems using a raised cosine filter with Nyquist pulses. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth of the pulse increases (or rolloff factor increases in the case of a raised cosine filter).

The early-late method is similar to the Gardner method. The Gardner method performs better in systems with high SNR values because it has lower self noise than the early-late method.

Decision-directed TED uses the `sign` function to estimate the in-phase and quadrature components of received samples, which result in lower computational complexity than non-data-aided TED.

- **Zero-crossing method** — The zero-crossing method is a decision-directed technique that requires 2 samples per symbol at the input to the synchronizer. It is used in low-SNR conditions for all values of excess bandwidth and in moderate-SNR conditions for moderate excess bandwidth factors in the approximate range [0.4, 0.6].
- **Mueller-Muller method** — The Mueller-Muller method is a decision-directed feedback method that requires prior recovery of the carrier phase. When the input signal has Nyquist pulses (for example, when using a raised cosine filter), the Mueller-Muller method has no self noise. For narrowband signaling in the presence of noise, the performance of the Mueller-Muller method improves as the excess bandwidth factor of the pulse decreases.

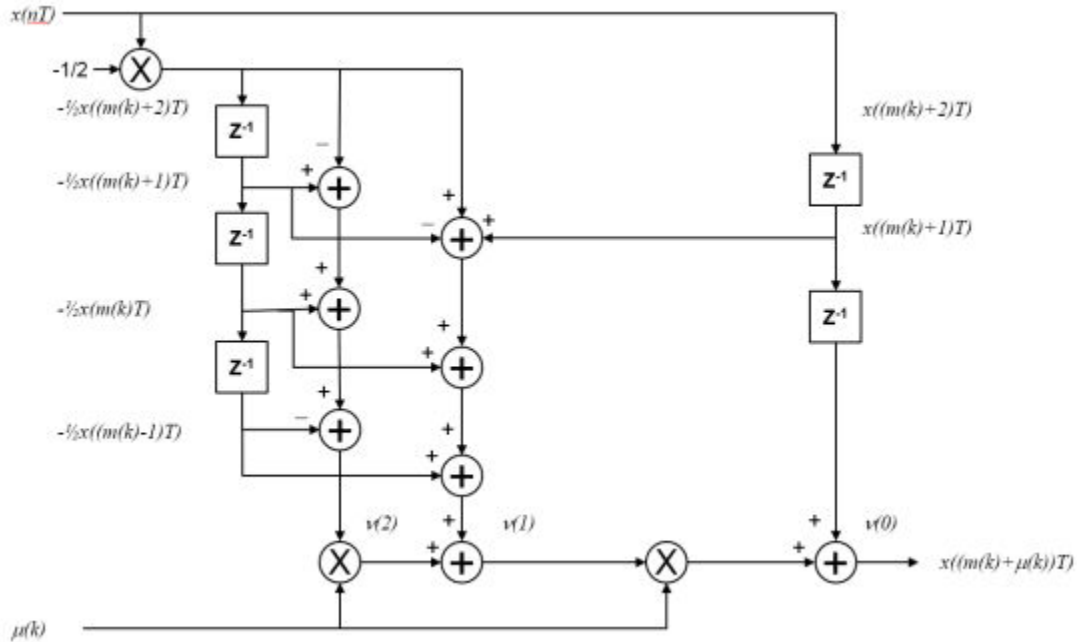

Because the decision-directed methods (zero-crossing and Mueller-Muller) estimate timing error based on the sign of the in-phase and quadrature components of signals passed to the synchronizer, they are not recommended for constellations that have points with either a zero in-phase or a quadrature component.  $x(kT_s + \hat{\tau})$  and  $y(kT_s + \hat{\tau})$  are the in-phase and quadrature components of the input signals to the timing error detector, where  $\hat{\tau}$  is the estimated timing error. The Mueller-Muller method coefficients  $\hat{a}_0(k)$  and  $\hat{a}_1(k)$  are the estimates of  $x(kT_s + \hat{\tau})$  and  $y(kT_s + \hat{\tau})$ . The timing estimates are made by applying the `sign` function to the in-phase and quadrature components and are used for only the decision-directed TED methods.

## Interpolator

The time delay is estimated from the fixed-rate samples of the matched filter, which are asynchronous with the symbol rate. Because the resulting samples are not aligned with the symbol boundaries, an interpolator is used to "move" the samples. Because the time

delay is unknown, the interpolator must be adaptive. Moreover, because the interpolant is a linear combination of the available samples, it can be thought of as the output of a filter.

The interpolator uses a piecewise parabolic interpolator with a Farrow structure and coefficient  $\alpha$  set to  $1/2$  (see Rice, Michael, *Digital Communications: A Discrete-Time Approach*).

## Interpolation Control

Interpolation control provides the interpolator with the basepoint index and fractional interval. The basepoint index is the sample index nearest to the interpolant. The fractional interval is the ratio of the time between the interpolant and its basepoint index and the interpolation interval.

Interpolation is performed for every sample, and a strobe signal is used to determine if the interpolant is output. The synchronizer uses a modulo-1 counter interpolation control to provide the strobe and the fractional interval for use with the interpolator.

## Loop Filter

The synchronizer uses a proportional-plus integrator (PI) loop filter. The proportional gain,  $K_1$ , and the integrator gain,  $K_2$ , are calculated by

$$K_1 = \frac{-4\zeta\theta}{(1 + 2\zeta\theta + \theta^2)K_p}$$

and

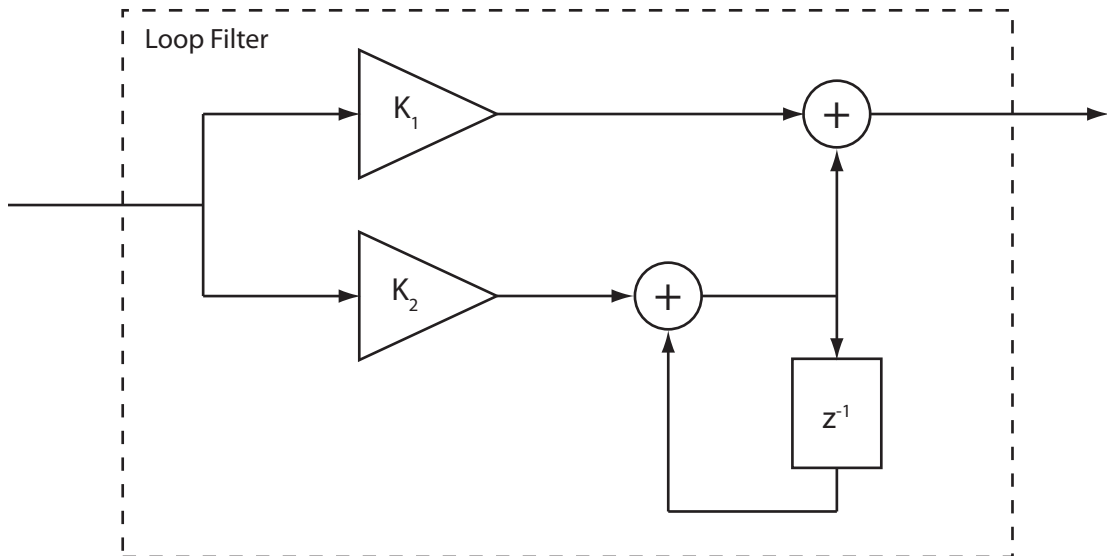

$$K_2 = \frac{-4\theta^2}{(1 + 2\zeta\theta + \theta^2)K_p} .$$

The interim term,  $\theta$ , is given by

$$\theta = \frac{B_n T_s}{\zeta + \frac{1}{4\zeta}} ,$$

where:

- $N$  is the number of samples per symbol.
- $\zeta$  is the damping factor.
- $B_n T_s$  is the normalized loop bandwidth.
- $K_p$  is the detector gain.

**Introduced in R2015a**

# comm.ThermalNoise

**Package:** comm

Add thermal noise to signal

## Description

The `ThermalNoise` object simulates the effects of thermal noise on a complex, baseband signal.

To add thermal noise to a complex, baseband signal:

- 1 Define and set up your thermal noise object. See “Construction” on page 4-1763.
- 2 Call `step` to add thermal noise according to the properties of `comm.ThermalNoise`.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`tn = comm.ThermalNoise` creates a receiver thermal noise System object, `H`. This object adds thermal noise to the complex, baseband input signal.

`tn = comm.ThermalNoise(Name, Value)` creates a receiver thermal noise object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

**NoiseMethod** — Method used to set noise power

'Noise temperature' (default) | 'Noise figure' | 'Noise factor'

Method used to set the noise power, specified as 'Noise temperature', 'Noise figure', or 'Noise factor'.

### **NoiseTemperature — Receiver noise temperature**

290 (default) | nonnegative real scalar

Receiver noise temperature, specified in degrees K as a nonnegative real scalar. This property is available when `NoiseMethod` is equal to 'Noise temperature'. Noise temperature is typically used to characterize satellite receivers because the input noise temperature can vary and is often less than 290 K. Tunable.

### **NoiseFigure — Noise figure**

3.01 (default) | nonnegative real scalar

Noise figure, specified in dB as a nonnegative real scalar. This property is available when `NoiseMethod` is equal to 'Noise figure'. Noise figure describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K. The noise figure is the dB equivalent of the noise factor. Tunable.

### **NoiseFactor — Noise factor**

2 (default) | real scalar  $\geq 1$

Noise factor, specified as a real scalar greater than or equal to 1. This property is available when `NoiseMethod` is equal to 'Noise factor'. Noise factor describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K. The noise factor is the linear equivalent of the noise figure. Tunable.

### **SampleRate — Sample rate**

1 (default) | positive real scalar

Sample rate, specified as in Hz as a positive real scalar. The object computes the variance of the noise added to the input signal as  $kT \times \text{SampleRate}$ . The value  $k$  is Boltzmann's constant and  $T$  is the noise temperature specified explicitly or implicitly via one of the noise methods.

### **Add290KAntennaNoise — Add 290 K antenna noise**

false (default) | true

Add 290 K antenna noise to the input signal, specified as a logical scalar. To add 290 K antenna noise, set this property to `true`. This property is available when `NoiseMethod` is equal to 'Noise factor' or 'Noise figure'.

The total noise applied to the input signal is the sum of the circuit noise and the antenna noise.

## Methods

step            Add receiver thermal noise

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Add Thermal Noise to QPSK Signal

Create a thermal noise object having a noise temperature of 290 K and a sample rate of 5 MHz.

```
thNoise = comm.ThermalNoise('NoiseTemperature',290,'SampleRate',5e6);
```

Generate QPSK-modulated data having an output power of 20 dBm.

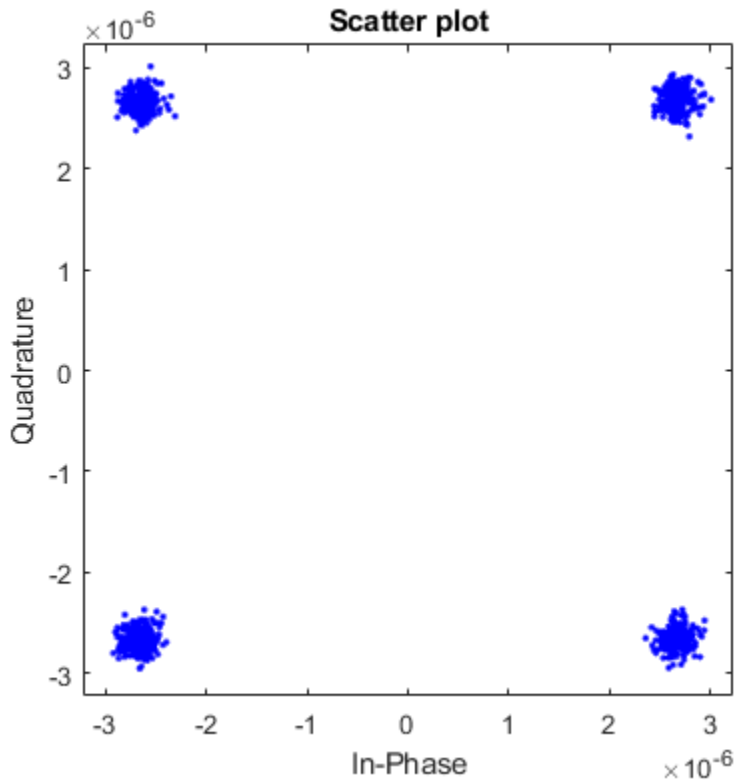

```
data = randi([0 3],1000,1);
modData = 0.3162*pskmod(data,4,pi/4);
```

Attenuate the signal by the free space path loss assuming a 1000 m link distance and a carrier frequency of 2 GHz.

```
fsl = (4*pi*1000*2e9/3e8)^2;
rxData = modData/sqrt(fsl);
```

Add thermal noise to the signal. Plot the noisy constellation.

```
noisyData = thNoise(rxData);
scatterplot(noisyData)
```

### Add Antenna and Receiver Thermal Noise to 16-QAM Signal

Create a thermal noise object having a 5 dB noise figure and a 10 MHz sample rate. Specify that the 290 K antenna noise be included.

```
thermalNoise = comm.ThermalNoise('NoiseMethod','Noise figure', ...  
    'NoiseFigure',5, ...  
    'SampleRate',10e6, ...  
    'Add290KAntennaNoise',true);
```

Generate QPSK-modulated data having a 1 W output power.

```
data = randi([0 15],1000,1);  
modSig = qammod(data,16, 'UnitAveragePower', true);
```

Attenuate the signal by the free space path loss assuming a 1 km link distance and a 5 GHz carrier frequency.

```
fsl = (4*pi*1000*5e9/3e8)^2;  
rxSig = modSig/sqrt(fsl);
```

Add thermal noise to the signal and plot its constellation.

```
noisySig = thermalNoise(rxSig);  
scatterplot(noisySig)
```

Estimate the SNR.

```
mer = comm.MER;  
snrEst1 = mer(rxSig,noisySig)
```

```
snrEst1 = 22.6611
```

Decrease the noise figure to 0 dB, and plot the resultant received signal. Because antenna noise is included, the signal is not completely noiseless.

```
thermalNoise.NoiseFigure = 0;  
noisySig = thermalNoise(rxSig);  
scatterplot(noisySig)
```

Estimate the SNR. The SNR is 5 dB higher than in the first case, which is expected given the 5 dB decrease in the noise figure.

```

snrEst2 = mer(rxSig,noisySig)
snrEst2 = 27.8658
snrEst2 - snrEst1
ans = 5.2047

```

## Algorithms

Wireless receiver performance is often expressed as a noise factor or figure. The noise factor is defined as the ratio of the input signal-to-noise ratio,  $S_i/N_i$  to the output signal-to-noise ratio,  $S_o/N_o$ , such that

$$F = \frac{S_i/N_i}{S_o/N_o} .$$

Given receiver gain  $G$  and receiver noise power  $N_{ckt}$ , the noise factor can be expressed as

$$\begin{aligned} F &= \frac{S_i/N_i}{GS_i/(N_{ckt} + GN_i)} \\ &= \frac{N_{ckt} + GN_i}{GN_i} . \end{aligned}$$

The IEEE defines the noise factor assuming that noise temperature at the input is  $T_0$ , where  $T_0 = 290$  K. The noise factor is then

$$\begin{aligned} F &= \frac{N_{ckt} + GN_i}{GN_i} \\ &= \frac{GkBT_{ckt} + GkBT_0}{GkBT_0} \\ &= \frac{T_{ckt} + T_0}{T_0} . \end{aligned}$$

$T_{ckt}$  is the equivalent input noise temperature of the receiver and is expressed as

$$T_{ckt} = T_0(F - 1) .$$

The overall noise temperature of an antenna and receiver,  $T_{sys}$ , is

$$T_{\text{sys}} = T_{\text{ant}} + T_{\text{ckt}},$$

where  $T_{\text{ant}}$  is the antenna noise temperature.

The noise figure,  $NF$ , is the dB equivalent of the noise factor and can be expressed as

$$NF = 10\log_{10}(F).$$

`comm.AWGNChannel`

**Introduced in R2012a**

---

## step

**System object:** comm.ThermalNoise

**Package:** comm

Add receiver thermal noise

## Syntax

$Y = \text{step}(H, X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  adds thermal noise to the complex, baseband input signal,  $X$ , and outputs the result in  $Y$ . The input signal  $X$  must be a complex, double or single precision data type column vector or scalar.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.TurboDecoder

**Package:** comm

Decode input signal using parallel concatenated decoding scheme

### Description

The Turbo Decoder System object decodes the input signal using a parallel concatenated decoding scheme that employs the *a-posteriori* probability (APP) decoder as the constituent decoder. Both constituent decoders use the same trellis structure and algorithm.

To decode an input signal using a turbo decoding scheme:

- 1 Define and set up your turbo decoder object. See “Construction” on page 4-1772.
- 2 Call `step` to decode a binary signal according to the properties of `comm.TurboDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.TurboDecoder` creates a System object, `H`. This object uses the *a-posteriori* probability (APP) constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.

`H = comm.TurboDecoder(Name, Value)` creates a turbo decoder object, `H`, with the specified property name set to the specified value. `Name` must appear inside single quotes ( ' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

`H = comm.TurboDecoder(TRELLIS, INTERLVRINDICES, NUMITER)` creates a turbo decoder object, `H`, with the `TrellisStructure` property set to `TRELLIS`, the

InterleaverIndices property set to INTERLVRINDICES, and the NumIterations property set to NUMITER.

## Properties

### TrellisStructure

Trellis structure of constituent convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the result of `poly2trellis(4, [13 15], 13)`.

### InterleaverIndicesSource

Source of interleaver indices

Specify the source of the interleaver indices as one of `Property | Input port`. When you set this property to `Input port`, the object uses the interleaver indices specified as an input to the `step` method. When you set this property to `Property`, the object uses the interleaver indices that you specify in the `InterleaverIndices` property. When you set this property to `Input port`, the object processes variable-size signals.

Default: `Property`

### InterleaverIndices

Interleaver indices

Specify the mapping used to permute the input bits at the encoder as a column vector of integers. This mapping is a vector with the number of elements equal to length,  $L$ , of the output of the `step` method. Each element must be an integer between 1 and  $L$ , with no repeated values.

Default: `(64:-1:1)'`.

### Algorithm

Decoding algorithm

Specify the decoding algorithm that the object uses for decoding as one of `True APP | Max* | Max`. When you set this property to `True APP`, the object implements true  $a$ -

*posteriori* probability decoding. When you set this property to any other value, the object uses approximations to increase the speed of the computations.

Default: True APP

### **NumScalingBits**

Number of scaling bits

Specify the number of bits the constituent decoders use to scale the input data to avoid losing precision during the computations. The constituent decoders multiply the input by  $2^{\text{NumScalingBits}}$  and divide the pre-output by the same factor. The `NumScalingBits` property must be a scalar integer between 0 and 8. This property applies when you set the `Algorithm` property to `Max*`.

Default: 3

### **NumIterations**

Number of decoding iterations

Specify the number of decoding iterations used for each call to the `step` method. The object iterates and provide updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the `step` method is the hard-decision output of the final LLR update.

Default: 6

## **Methods**

`step` Decode input signal using parallel concatenated decoding scheme

## **Examples**

## Transmit and Receive Turbo-Encoded Data over a BPSK-Modulated AWGN Channel

Simulate the transmission and reception of BPSK data over an AWGN channel using turbo encoding and decoding.

Set the Eb/No (dB) and frame length parameters. Set the random number generator to its default state to ensure that the results are repeatable.

```
EbNo= -6;
frmLen = 256;
rng default
```

Calculate the noise variance from the Eb/No ratio. Generate random interleaver indices.

```
noiseVar = 10^(-EbNo/10);
intrlvrIndices = randperm(frmLen);
```

Create a turbo encoder and decoder pair using the trellis structure given by `poly2trellis(4,[13 15 17],13)` and `intrlvrIndices`.

```
hTEnc = comm.TurboEncoder('TrellisStructure',poly2trellis(4, ...
    [13 15 17],13),'InterleaverIndices',intrlvrIndices);

hTDec = comm.TurboDecoder('TrellisStructure',poly2trellis(4, ...
    [13 15 17],13),'InterleaverIndices',intrlvrIndices, ...
    'NumIterations',4);
```

Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined by using a log-likelihood ratio method.

```
hMod = comm.BPSKModulator;
hDemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...
    'Variance',noiseVar);
```

Create an AWGN channel object and an error rate object.

```
hChan = comm.AWGNChannel('EbNo',EbNo);
hError = comm.ErrorRate;
```

The main processing loop performs the following steps:

- Generate binary data
- Turbo encode the data

- Modulate the encoded data
- Pass the modulated signal through an AWGN channel
- Demodulate the noisy signal using LLR to output soft bits
- Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite that expected by the turbo decoder, the decoder input must use the inverse of demodulated signal.
- Calculate the error statistics

```
for frmIdx = 1:100
    data = randi([0 1],frmLen,1);
    encodedData = step(hTEnc,data);
    modSignal = step(hMod,encodedData);
    receivedSignal = step(hChan,modSignal);
    demodSignal = step(hDemod,receivedSignal);
    receivedBits = step(hTDec,-demodSignal);
    errorStats = step(hError,data,receivedBits);
end
```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', ...
        errorStats)
```

```
Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600
```

### **Turbo Coding with 16-QAM Modulation in an AWGN Channel**

Simulate an end-to-end communication link employing 16-QAM using turbo codes in an AWGN channel. The packet sizes are randomly selected from a set of {500, 1000, 1500}. Because the packet size varies, provide the interleaver indices to the turbo encoder and decoder objects as an input to their associated object calls.

Set the modulation order and Eb/No (dB) parameters. Set the random number generator to its default state to be able to repeat the results.

```
M = 16;
EbNo= -2;
rng default
```

Calculate the noise variance from the Eb/No ratio and the modulation order.

```
noiseVar = 10^(-EbNo/10)*(1/log2(M));
```

Create a turbo encoder and decoder pair. The interleaver indices are supplied by an input argument to the object when executed.

```
turboEnc = comm.TurboEncoder('InterleaverIndicesSource','Input port');
turboDec = comm.TurboDecoder('InterleaverIndicesSource','Input port','NumIterations',4);
```

Create an AWGN channel object and an error rate object.

```
awgnChan = comm.AWGNChannel('EbNo',EbNo,'BitsPerSymbol',log2(M));
errRate = comm.ErrorRate;
```

The processing loop performs the following steps:

- Select a random packet size and generate interleaver indices
- Generate random binary data
- Turbo encode the data
- Apply 16-QAM modulation, normalize the average signal power.
- Pass the modulated signal through an AWGN channel
- Demodulate the noisy signal by using a log-likelihood ratio method, output soft bits, normalize the average signal power
- Turbo decode the data
- Calculate the error statistics

```
numPkts = 100;
for pktIdx = 1:numPkts
    % Randomly select one of three possible packet sizes
    pktLen = 500*randi([1 3],1,1);

    % Determine the interleaver indices given the packet length
    intrlvrIndices = randperm(pktLen);

    % Generate random binary data
    data = randi([0 1],pktLen,1);

    % Turbo encode the data
    encodedData = turboEnc(data,intrlvrIndices);

    % Modulate the encoded data
```

```
modSignal = qammod(encodedData,M,'InputType','bit','UnitAveragePower',true);

% Pass the signal through the AWGN channel
receivedSignal = awgnChan(modSignal);

% Demodulate the received signal
demodSignal = qamdemod(receivedSignal,M,'OutputType','llr', ...
    'UnitAveragePower',true,'NoiseVariance',noiseVar);

% Turbo decode the demodulated signal. Because the bit mapping from the
% demodulator is opposite that expected by the turbo decoder, the
% decoder input must use the inverse of demodulated signal.
receivedBits = turboDec(-demodSignal,intrLvrIndices);

% Calculate the error statistics
errorStats = errRate(data,receivedBits);
end
```

Display the error statistics.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', ...
    errorStats)
```

```
Bit error rate = 3.51e-04
Number of errors = 33
Total bits = 94000
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Turbo Decoder block reference page. The object properties correspond to the block parameters.

# step

**System object:** `comm.TurboDecoder`

**Package:** `comm`

Decode input signal using parallel concatenated decoding scheme

## Syntax

`Y = step(H,X)`

`Y = step(H, X, INTERLVRINDICES)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` decodes the input data, `X`, using the parallel concatenated convolutional coding scheme that you specify using the `TrellisStructure` and `InterleaverIndices` properties. It returns the binary decoded data, `Y`. Both `X` and `Y` are column vectors of double precision data type. When the constituent convolutional code represents a rate  $1/N$  code, the `step` method sets the length of the output vector, `Y`, to  $(M-2*\text{numTails})/(2*N-1)$ , where `M` represents the input vector length and `numTails` is given by  $\log_2(\text{TrellisStructure.numStates})*N$ . The output length, `L`, is the same as the length of the interleaver indices.

`Y = step(H, X, INTERLVRINDICES)` uses the `INTERLVRINDICES` specified as an input. `INTERLVRINDICES` is a column vector containing integer values from 1 to `L` with no repeated values. The lengths of the `INTERLVRINDICES` input and the `Y` output are the same.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.TurboEncoder

**Package:** comm

Encode input signal using parallel concatenated encoding scheme

### Description

The Turbo Encoder System object encodes a binary input signal using a parallel concatenated coding scheme. This coding scheme uses two identical convolutional encoders and appends the termination bits at the end of the encoded data bits.

To encode an input signal using a turbo coding scheme:

- 1 Define and set up your turbo encoder object. See “Construction” on page 4-1782.
- 2 Call `step` to encode a binary signal according to the properties of `comm.TurboEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.TurboEncoder` creates a System object, `H`, that encodes binary data using a turbo encoder.

`H = comm.TurboEncoder(Name, Value)` creates a turbo encoder object, `H`, with the specified property name set to the specified value. `Name` must appear inside single quotes ( `'` ). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

`H = comm.TurboEncoder(TRELLIS, INTERLVRINDICES)` creates a turbo encoder object, `H`. In this construction, the `TrellisStructure` property is set to `TRELLIS`, and the `InterleaverIndices` property is set to `INTERLVRINDICES`.

## Properties

### TrellisStructure

Trellis structure of constituent convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the result of `poly2trellis(4, [13 15], 13)`.

### InterleaverIndicesSource

Source of interleaver indices

Specify the source of the interleaver indices as one of `Property` | `Input port`. When you set this property to `Input port`, the object uses the interleaver indices specified as an input to the `step` method. When you set this property to `Property`, the object uses the interleaver indices that you specify in the `InterleaverIndices` property. When you set this property to `Input port`, the object processes variable-size signals.

Default: `Property`

### InterleaverIndices

Interleaver indices

Specify the mapping used to permute the input bits at the encoder as a column vector of integers. This mapping is a vector with the number of elements equal to the length of the input for the `step` method. Each element must be an integer between 1 and  $L$ , with no repeated values.

Default: `(64:-1:1)'`.

## Methods

`step` Encode input signal using parallel concatenated coding scheme

## Examples

### Transmit and Receive Turbo-Encoded Data over a BPSK-Modulated AWGN Channel

Simulate the transmission and reception of BPSK data over an AWGN channel using turbo encoding and decoding.

Set the Eb/No (dB) and frame length parameters. Set the random number generator to its default state to ensure that the results are repeatable.

```
EbNo= -6;  
frmLen = 256;  
rng default
```

Calculate the noise variance from the Eb/No ratio. Generate random interleaver indices.

```
noiseVar = 10^(-EbNo/10);  
intrlvrIndices = randperm(frmLen);
```

Create a turbo encoder and decoder pair using the trellis structure given by `poly2trellis(4,[13 15 17],13)` and `intrlvrIndices`.

```
hTEnc = comm.TurboEncoder('TrellisStructure',poly2trellis(4, ...  
    [13 15 17],13), 'InterleaverIndices',intrlvrIndices);  
  
hTDec = comm.TurboDecoder('TrellisStructure',poly2trellis(4, ...  
    [13 15 17],13), 'InterleaverIndices',intrlvrIndices, ...  
    'NumIterations',4);
```

Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined by using a log-likelihood ratio method.

```
hMod = comm.BPSKModulator;  
hDemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...  
    'Variance',noiseVar);
```

Create an AWGN channel object and an error rate object.

```
hChan = comm.AWGNChannel('EbNo',EbNo);  
hError = comm.ErrorRate;
```

The main processing loop performs the following steps:

- Generate binary data
- Turbo encode the data
- Modulate the encoded data
- Pass the modulated signal through an AWGN channel
- Demodulate the noisy signal using LLR to output soft bits
- Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite that expected by the turbo decoder, the decoder input must use the inverse of demodulated signal.
- Calculate the error statistics

```

for frmIdx = 1:100
    data = randi([0 1],frmLen,1);
    encodedData = step(hTEnc,data);
    modSignal = step(hMod,encodedData);
    receivedSignal = step(hChan,modSignal);
    demodSignal = step(hDemod,receivedSignal);
    receivedBits = step(hTDec,-demodSignal);
    errorStats = step(hError,data,receivedBits);
end

```

Display the error data.

```

fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', ...
        errorStats)

```

```

Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600

```

### Turbo Coding with 16-QAM Modulation in an AWGN Channel

Simulate an end-to-end communication link employing 16-QAM using turbo codes in an AWGN channel. The packet sizes are randomly selected from a set of {500, 1000, 1500}. Because the packet size varies, provide the interleaver indices to the turbo encoder and decoder objects as an input to their associated object calls.

Set the modulation order and Eb/No (dB) parameters. Set the random number generator to its default state to be able to repeat the results.

```
M = 16;  
EbNo = -2;  
rng default
```

Calculate the noise variance from the Eb/No ratio and the modulation order.

```
noiseVar = 10^(-EbNo/10)*(1/log2(M));
```

Create a turbo encoder and decoder pair. The interleaver indices are supplied by an input argument to the object when executed.

```
turboEnc = comm.TurboEncoder('InterleaverIndicesSource','Input port');  
turboDec = comm.TurboDecoder('InterleaverIndicesSource','Input port','NumIterations',4);
```

Create an AWGN channel object and an error rate object.

```
awgnChan = comm.AWGNChannel('EbNo',EbNo,'BitsPerSymbol',log2(M));  
errRate = comm.ErrorRate;
```

The processing loop performs the following steps:

- Select a random packet size and generate interleaver indices
- Generate random binary data
- Turbo encode the data
- Apply 16-QAM modulation, normalize the average signal power.
- Pass the modulated signal through an AWGN channel
- Demodulate the noisy signal by using a log-likelihood ratio method, output soft bits, normalize the average signal power
- Turbo decode the data
- Calculate the error statistics

```
numPkts = 100;  
for pktIdx = 1:numPkts  
    % Randomly select one of three possible packet sizes  
    pktLen = 500*randi([1 3],1,1);  
  
    % Determine the interleaver indices given the packet length  
    intrlvrIndices = randperm(pktLen);  
  
    % Generate random binary data  
    data = randi([0 1],pktLen,1);
```

```

% Turbo encode the data
encodedData = turboEnc(data,intrlvIndices);

% Modulate the encoded data
modSignal = qammod(encodedData,M,'InputType','bit','UnitAveragePower',true);

% Pass the signal through the AWGN channel
receivedSignal = awgnChan(modSignal);

% Demodulate the received signal
demodSignal = qamdemod(receivedSignal,M,'OutputType','llr', ...
    'UnitAveragePower',true,'NoiseVariance',noiseVar);

% Turbo decode the demodulated signal. Because the bit mapping from the
% demodulator is opposite that expected by the turbo decoder, the
% decoder input must use the inverse of demodulated signal.
receivedBits = turboDec(-demodSignal,intrlvIndices);

% Calculate the error statistics
errorStats = errRate(data,receivedBits);
end

```

Display the error statistics.

```

fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', ...
    errorStats)

```

```

Bit error rate = 3.51e-04
Number of errors = 33
Total bits = 94000

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Turbo Encoder block reference page. The object properties correspond to the block parameters.

## step

**System object:** `comm.TurboEncoder`

**Package:** `comm`

Encode input signal using parallel concatenated coding scheme

## Syntax

`Y = step(H,X)`

`Y = step(H, X, INTERLVRINDICES)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` encodes the input data, `X`, using the parallel concatenated convolutional coding scheme that you specify using the `TrellisStructure` and `InterleaverIndices` properties. It returns the binary encoded data, `Y`. Both `X` and `Y` are column vectors of numeric, logical, or unsigned fixed point with word length 1 (fi object). When the constituent convolutional encoder represents a rate  $1/N$  code, the `step` method sets the length of the output vector, `Y`, to  $L*(2*N-1)+2*numTails$  where `L` represents the input vector length and `numTails` is given by  $\log_2(\text{TrellisStructure.numStates})*N$ . The tail bits, due to the termination, are appended at the end after the input bits are encoded.

`Y = step(H, X, INTERLVRINDICES)` uses the `INTERLVRINDICES` specified as an input. `INTERLVRINDICES` is a column vector containing integer values from 1 to `L` with no repeated values. The length of the data input `X` and the `INTERLVRINDICES` input must be the same.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# comm.ViterbiDecoder

**Package:** comm

Decode convolutionally encoded data using Viterbi algorithm

## Description

The `ViterbiDecoder` object decodes input symbols to produce binary output symbols. This object can process several symbols at a time for faster performance. This object processes variable-size signals; however, variable-size signals cannot be applied for erasure inputs.

To decode input symbols and produce binary output symbols:

- 1 Define and set up your Viterbi decoder object. See “Construction” on page 4-1791.
- 2 Call `step` to decode input symbols according to the properties of `comm.ViterbiDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.ViterbiDecoder` creates a Viterbi decoder System object, `H`. This object uses the Viterbi algorithm to decode convolutionally encoded input data.

`H = comm.ViterbiDecoder(Name,Value)` creates a Viterbi decoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.ViterbiDecoder(TRELLIS,Name,Value)` creates a Viterbi decoder object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. The default is the result of `poly2trellis(7, [171 133])`. Use the `istrellis` function to verify whether a structure is a valid trellis.

### InputFormat

Input format

Specify the format of the input to the decoder as `Unquantized` | `Hard` | `Soft`. The default is `Unquantized`.

When you set this property to `Unquantized`, the input must be a real vector of double- or single-precision soft values that are unquantized. The object considers negative numbers to be 1s and positive numbers to be 0s.

When you set this property to `Hard`, the input must be a vector of hard decision values, which are 0s or 1s. The data type of the inputs can be double-precision, single-precision, logical, 8-, 16-, and 32-bit signed integers. You can also use 8-, 16-, and 32-bit unsigned integers.

When you set this property to `Soft`, the input requires a vector of quantized soft values

represented as integers between 0 and  $2^{\text{SoftInputWordLength}} - 1$ . The data type of the inputs can be double-precision, single-precision, logical, 8-, 16-, and 32-bit signed integers. You can also use 8-, 16-, and 32-bit unsigned integers. Alternately, you can specify the data type as an unsigned and unscaled fixed point object (`fi`) with a word length equal to the word length that you specify in the `SoftInputWordLength` property. The object considers negative numbers to be 0s and positive numbers to be 1s.

## SoftInputWordLength

Soft input word length

Specify the number of bits to represent each quantized soft input value as a positive, integer scalar value. The default is 4 bits. This property applies when you set the `InputFormat` on page 4-0 property to `Soft`.

## InvalidQuantizedInputAction

Action when input values are out of range

Specify the action the object takes when input values are out of range as `Ignore` | `Error`. The default is `Ignore`. Set this property to `Error` so that the object generates an error when the quantized input values are out of range. This property applies when you set the `InputFormat` on page 4-0 property to `Hard` or `Soft`.

## TracebackDepth

Traceback depth

Specify the number of trellis branches to construct each traceback path as a numeric, integer scalar value. The default is 34. The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay.

When you set the `TerminationMethod` on page 4-0 property to `Continuous`, the decoding delay consists of `TracebackDepth` on page 4-0 zero symbols or `TracebackDepth` ×  $K$  zero bits for a rate  $K/N$  convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, there is no output delay. In this case, `TracebackDepth` must be less than or equal to the number of symbols in each input.

As a general estimate, a typical `TracebackDepth` property value is approximately two to three times  $(k - 1)/(1 - r)$ , where  $k$  is the constraint length of the code and  $r$  is the code rate [1]. For example:

- A rate 1/2 code has a `TracebackDepth` of  $5(k - 1)$ .
- A rate 2/3 code has a `TracebackDepth` of  $7.5(k - 1)$ .
- A rate 3/4 code has a `TracebackDepth` of  $10(k - 1)$ .

- A rate 5/6 code has a `TracebackDepth` of  $15(k - 1)$ .

### **TerminationMethod**

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

In `Continuous` mode, the object saves the internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently.

In `Truncated` mode, the object treats each frame independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state. In `Terminated` mode, the object treats each frame independently, and the traceback path always starts and ends in the all-zeros state.

### **ResetInputPort**

Enable decoder reset input

Set this property to `true` to enable an additional `step` method input. The default is `false`. When the reset input is a nonzero value, the object resets the internal states of the decoder to initial conditions. This property applies when you set the `TerminationMethod` on page 4-0 property to `Continuous`.

### **DelayedResetAction**

Reset on nonzero input via port

Set this property to `true` to delay resetting the object output. The default is `false`. When you set this property to `true`, the reset of the internal states of the decoder occurs after the object computes the decoded data. When you set this property to `false`, the reset of the internal states of the decoder occurs before the object computes the decoded data. This property applies when you set the `ResetInputPort` on page 4-0 property to `true`.

### **PuncturePatternSource**

Source of puncture pattern

Specify the source of the puncture pattern as `None` | `Property`. The default is `None`.

When you set this property to `None`, the object assumes no puncturing. Set this property to `Property` to decode punctured codewords based on a puncture pattern vector specified via the `PuncturePattern` on page 4-0 property.

### **PuncturePattern**

Puncture pattern vector

Specify puncture pattern to puncture the encoded data. The default is `[1; 1; 0; 1; 0; 1]`. The puncture pattern is a column vector of 1s and 0s. The 0s indicate the position to insert dummy bits. The puncture pattern must match the puncture pattern used by the encoder. This property applies when you set the `PuncturePatternSource` on page 4-0 property to `Property`.

### **ErasuresInputPort**

Enable erasures input

Set this property to `true` to specify a vector of erasures as a `step` method input. The default is `false`. The erasures input must be a double-precision or logical, binary, column vector. This vector indicates which symbols of the input codewords to erase. Values of 1 indicate erased bits. The decoder does not update the branch metric for the erasures in the incoming data stream.

The lengths of the `step` method erasure input and the `step` method data input must be the same. When you set this property to `false`, the object assumes no erasures.

### **OutputDataType**

Data type of output

Specify the data type of the output as `Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical`. The default is `Full precision`.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

## Fixed-Point Properties

### StateMetricDataType

Data type of state metric

Specify the state metric data type as `Full precision` | `Custom`. The default is `Full precision`.

When you set this property to `Full precision`, the object sets the state metric fixed-point type to `numericType([], 16)`. This property applies when you set the `InputFormat` on page 4-0 property to `Hard` or `Soft`.

When you set the `InputFormat` property to `Hard`, the `step` method data input must be a column vector. This vector comprises unsigned, fixed point numbers (fi objects) of word length 1 to enable fixed-point Viterbi decoding. Based on this input (either a 0 or a 1), the object calculates the internal branch metrics using an unsigned integer of word length  $L$ . In this case,  $L$  indicates the number of output bits as specified by the trellis structure.

When you set the `InputFormat` property to `Soft`, the `step` method data input must be a column vector. This vector comprises unsigned, fixed point numbers (fi objects) of word length  $N$ .  $N$  indicates the number of soft-decision bits specified in the `SoftInputWordLength` on page 4-0 property.

The `step` method data inputs must be integers in the range 0 to  $2^N-1$ . The object calculates the internal branch metrics using an unsigned integer of word length  $L = (N + Nout - 1)$ . In this case,  $Nout$  represents the number of output bits as specified by the trellis structure.

### CustomStateMetricDataType

Fixed-point data type of state metric

Specify the state metric fixed-point type as an unscaled, `numericType` object with a signedness of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `StateMetricDataType` on page 4-0 property to `Custom`.

## Methods

- reset    Reset states of the Viterbi decoder object
- step    Decode convolutionally encoded data using Viterbi algorithm

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Encode and Decode 8-DPSK Modulated Data

Transmit a convolutionally encoded 8-DPSK modulated bit stream through an AWGN channel. Then, demodulate and decode using a Viterbi decoder.

Create the necessary System objects.

```
hConEnc = comm.ConvolutionalEncoder;
hMod = comm.DPSKModulator('BitInput',true);
hChan = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)',...
    'SNR',10);
hDemod = comm.DPSKDemodulator('BitOutput',true);
hDec = comm.ViterbiDecoder('InputFormat','Hard');
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);
```

Process the data using the following steps:

- 1    Generate random bits
- 2    Convolutionally encode the data
- 3    Apply DPSK modulation
- 4    Pass the modulated signal through AWGN
- 5    Demodulate the noisy signal
- 6    Decode the data using a Viterbi algorithm
- 7    Collect error statistics

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = step(hConEnc, data);
    modSignal = step(hMod, encodedData);
    receivedSignal = step(hChan, modSignal);
    demodSignal = step(hDemod, receivedSignal);
    receivedBits = step(hDec, demodSignal);
    errors = step(hError, data, receivedBits);
end
```

Display the number of errors.

```
errors(2)
```

```
ans = 3
```

### Convolutional Encoding and Viterbi Decoding with a Puncture Pattern Matrix

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical

Define a puncture pattern matrix and reshape it into vector form for use with the Encoder and Decoder objects.

```
pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);
```

Create convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by pPatternVec.

```
ENC = comm.ConvolutionalEncoder(...
    'PuncturePatternSource','Property', ...
    'PuncturePattern',pPatternVec);

DEC = comm.ViterbiDecoder('InputFormat','Hard', ...
    'PuncturePatternSource','Property',...
    'PuncturePattern',pPatternVec);
```

Create an error rate counter with the appropriate receive delay.

```
ERR = comm.ErrorRate('ReceiveDelay',DEC.TracebackDepth);
```

Encode and decode a sequence of random bits.

```
dataIn = randi([0 1],600,1);  
dataEncoded = step(ENC,dataIn);  
dataOut = step(DEC,dataEncoded);
```

Verify that there are no errors in the output data.

```
errStats = step(ERR,dataIn,dataOut);  
errStats(2)  
  
ans = 0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Viterbi Decoder block reference page. The object properties correspond to the block parameters, except:

- The **Decision type** parameter corresponds to the `InputFormat` on page 4-0 property.
- The **Operation mode** parameter corresponds to the `TerminationMethod` on page 4-0 property.

**Introduced in R2012a**

## reset

**System object:** `comm.ViterbiDecoder`

**Package:** `comm`

Reset states of the Viterbi decoder object

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the `ViterbiDecoder` object, `H`.

# step

**System object:** `comm.ViterbiDecoder`

**Package:** `comm`

Decode convolutionally encoded data using Viterbi algorithm

## Syntax

`Y = step(H,X)`

`Y = step(H,X,ERASURES)`

`Y = step(H,X,R)`

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` decodes encoded data, `X`, using the Viterbi algorithm and returns `Y`. `X`, must be a column vector with data type and values that depend on how you set the `InputFormat` property. If the convolutional code uses an alphabet of  $2^N$  possible symbols, the length of the input vector, `X`, must be  $L \times N$  for some positive integer  $L$ . Similarly, if the decoded data uses an alphabet of  $2^K$  possible output symbols, the length of the output vector, `Y`, is  $L \times K$ .

`Y = step(H,X,ERASURES)` uses the binary column input vector, `ERASURES`, to erase the symbols of the input codewords. The elements in `ERASURES` must be of data type `double` or `logical`. Values of `1` in the `ERASURES` vector correspond to erased symbols, and values of `0` correspond to non-erased symbols. The lengths of the `X` and `ERASURES` inputs must be the same. This syntax applies when you set the `ErasuresInputPort` property to `true`.

`Y = step(H,X,R)` resets the internal states of the decoder when you input a non-zero reset signal, `R`. `R` must be a double precision or `logical` scalar. This syntax applies when

you set the `TerminationMethod` property to `Continuous` and the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.WalshCode

**Package:** comm

Generate Walsh code from orthogonal set of codes

### Description

The `WalshCode` object generates a Walsh code from an orthogonal set of codes.

To generate a Walsh code:

- 1 Define and set up your Walsh code object. See “Construction” on page 4-1804.
- 2 Call `step` to encode the input signal according to the properties of `comm.WalshCode`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

### Construction

`H = comm.WalshCode` creates a Walsh code generator System object, `H`. This object generates a Walsh code from a set of orthogonal codes.

`H = comm.WalshCode(Name, Value)` creates a Walsh code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

### Properties

#### Length

Length of generated code

Specify the length of the generated code as a numeric, integer scalar value that is a power of two. The default is 64.

### Index

Index of code of interest

Specify the index of the desired code from the available set of codes as a numeric, integer scalar value in the range  $[0, 1, \dots, N-1]$ .  $N$  is the value of the `Length` on page 4-0 property. The default is 60. The number of zero crossings in the generated code equals the value of the specified index.

### SamplesPerFrame

Number of output samples per frame

Specify the number of Walsh code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is 1. If you set this property to a value of  $M$ , then the `step` method outputs  $M$  samples of a Walsh code of length  $N$ .  $N$  is the length of the code that you specify in the `Length` on page 4-0 property.

### OutputDataType

Data type of output

Specify the output data type as `double` | `int8`. The default is `double`.

## Methods

`reset`    Reset states of Walsh code generator object  
`step`     Generate Walsh code from orthogonal set of codes

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Walsh Code Sequence

Generate 16 samples of a length-64 Walsh code sequence.

```
walsh = comm.WalshCode('SamplesPerFrame',16)
```

```
walsh =  
comm.WalshCode with properties:
```

```
    Length: 64  
    Index: 60  
SamplesPerFrame: 16  
OutputDataType: 'double'
```

```
seq = walsh()
```

```
seq = 16×1
```

```
    1  
   -1  
    1  
   -1  
    1  
   -1  
    1  
   -1  
    1  
   -1  
    1  
   -1  
    ⋮
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Walsh Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Reset states of Walsh code generator object

## **Syntax**

`reset(H)`

## **Description**

`reset(H)` resets the states of the `WalshCode` object, `H`.

---

## step

**System object:** comm.WalshCode

**Package:** comm

Generate Walsh code from orthogonal set of codes

## Syntax

$Y = \text{step}(H)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

$Y = \text{step}(H)$  outputs a frame of the Walsh code in column vector  $Y$ . Specify the frame length with the `SamplesPerFrame` property. The Walsh code corresponds to a row of an  $N \times N$  Hadamard matrix, where  $N$  is a nonnegative power of 2 that you specify in the `Length` property. Use the `Index` property to choose the row of the Hadamard matrix. The output code is in a bi-polar format with 0 and 1 mapped to 1 and -1 respectively.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## comm.WINNER2Channel

**Package:** comm

Filter input signal through WINNER II fading channel

### Download Required

To use `comm.WINNER2Channel`, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons” (MATLAB).

### Description

The `comm.WINNER2Channel` System object filters an input signal through a WINNER II fading channel. The object utilizes the basic model defined and provided by the WINNER II Channel Models [1].

To filter an input signal using a WINNER II fading channel:

- 1 Define and set up your WINNER II channel object. See “Construction” on page 4-1810.
- 2 Call `step` to filter the input signal through a WINNER II fading channel according to the properties of `comm.WINNER2Channel`.

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

### Construction

`chan = comm.WINNER2Channel` creates a WINNER II fading channel System object to model single or multiple links. `chan` generates channel coefficients using the WINNER II spatial channel model (SCM). It also filters a real or complex input signal through the fading channel for each link.

`chan = comm.WINNER2Channel(Name, Value)` creates a WINNER II fading channel object, `chan`, that overrides default values using one or more `Name, Value` pair arguments. You can specify additional name-value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

`chan = comm.WINNER2Channel(cfgModel)` creates a WINNER II fading channel object with the `ModelConfig` property set to `cfgModel`.

`chan = comm.WINNER2Channel(cfgModel, cfgLayout)` creates a WINNER II fading channel object with the `ModelConfig` property set to `cfgModel` and the `LayoutConfig` property set to `cfgLayout`.

## Properties

### ModelConfig

WINNER II model parameter configuration

WINNER II model parameter configuration, specified as a structure containing these fields:

### NumTimeSamples

Number of time samples. The default value is 100.

---

**Note** If the number of samples in the input signal ( $N_S$ ) does not match `NumTimeSamples`, `NumTimeSamples` is updated to match  $N_S$ .

---

### FixedPdpUsed

Set to 'yes' to use predefined path delays and powers for specific scenarios. The default value is 'no'.

### FixedAnglesUsed

Set to 'yes' to use predefined angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios. The default value is 'no'.

### **IntraClusterDsUsed**

Set to 'yes' to divide each of the two strongest clusters per link into three subclusters. The default value is 'yes'.

### **PolarisedArrays**

Set to 'yes' to use dual polarized arrays. The default value is 'yes'.

### **UseManualPropCondition**

Set to 'yes' to use the manually defined propagation conditions (LOS or NLOS) in the `LayoutConfig.PropagConditionVector` field. Set to 'no' to draw propagation conditions from predefined LOS probabilities. The default value is 'yes'.

### **UniformTimeSampling**

Set to 'yes' to sample all links at the same time instants. The default value is 'no'.

### **SampleDensity**

Number of time samples per half wavelength. The default value is  $2e6$ .

### **CenterFrequency**

Center frequency of carrier. The default value  $5.25e9$  Hz.

### **DelaySamplingInterval**

Sampling grid to which the path delays are rounded. The default value of 0 seconds indicates no rounding on path delays.

- `DelaySamplingInterval` specifies the input signal sample time.
- When performing channel filtering, the object uses `DelaySamplingInterval = 0` to obtain the original path delays. Any non-zero value of `DelaySamplingInterval` is ignored, specifically the path delays used are not rounded to be multiples of `DelaySamplingInterval` values that are non-zero.

### **ShadowingModelUsed**

Set to 'yes' to include shadow fading in the model. The default value is 'no'.

**PathLossModelUsed**

Set to 'yes' to include path loss in the model. The default value is 'no'.

**PathLossModel**

Path loss model function name, specified as 'pathloss', which uses the internal pathloss function from the "WINNER II Channel" Add-On to model the path loss. The PathLossModel property is applicable only when PathLossModelUsed is 'yes'. The default value is 'pathloss'.

**PathLossOption**

Path loss option indicating the wall material for the NLOS path loss calculation of scenario A1, specified as one of {'CR\_light', 'CR\_heavy', 'RR\_light', 'RR\_heavy'}. The default value is 'CR\_light'. The PathLossOption property is applicable only when PathLossModelUsed is 'yes'.

See LayoutConfig.ScenarioVector for the scenario number mapping.

**RandomSeed**

Seed for random number generators. To use the global random stream, set RandomSeed to empty, []. The default is [].

**LayoutConfig**

WINNER II layout parameter configuration

WINNER II layout parameter configuration, specified as a structure containing these fields:

**Stations**

Row vector of structures to describe antenna arrays for active stations. The row ordering specifies BS sectors first, followed by the MS. The default assigns two structures, one for BS and one for MS.

**NofSect**

Vector of number of sectors in each BS. The default is 1.

### **Pairing**

A 2-by- $N_L$  matrix, where  $N_L$  specifies the number links to be modeled. The default is [1;2].

### **ScenarioVector**

A 1-by- $N_L$  vector of scenario numbers. The default is 1, which specifies scenario A1.

The scenarios numbers map as {1=A1, 2=A2, 3=B1, 4=B2, 5=B3, 6=B4, 10=C1, 11=C2, 12=C3, 13=C4, 14=D1, 15=D2a}.

For more information, see WINNER II Channel Models [1], Section 2.3.

### **PropagConditionVector**

A 1-by- $N_L$  vector of propagation conditions (LOS = 1 and NLOS = 0) for each link. The default is 1.

### **StreetWidth**

A 1-by- $N_L$  vector of identical values that specify the average width (in meters) of the streets. `StreetWidth` is used for the path loss model of the B1 and B2 scenarios. The default is 20. See `ScenarioVector` for the scenario number mapping. All elements must have the same value. The `StreetWidth` property is applicable only when the `ModelConfig.PathLossModelUsed` property is 'yes'.

### **Dist1**

A 1-by- $N_L$  vector of distances from BS to the last LOS point. `Dist1` is used for the path loss model of the B1 and B2 scenarios. The default value is NaN, which means the distance is randomly determined in path loss function. See `ScenarioVector` for the scenario number mapping. `Dist1` is applicable only when the `ModelConfig.PathLossModelUsed` property is 'yes'.

For more information, see WINNER II Channel Models [1], Figure 4-3.

### **NumFloors**

A 1-by- $N_L$  vector indicating the floor number where the indoor BS or MS is located. The default value is 1. The `NumFloors` property is used for the path loss model of the A2 and B4 scenarios only. See `ScenarioVector` for the scenario number mapping. The

NumFloors property is applicable only when ModelConfig.PathLossModelUsed is 'yes'.

### NumPenetratedFloors

A 1-by- $N_L$  vector indicating the number of penetrated floors between BS and MS. The default value is 0. The NumPenetratedFloors is used for the NLOS path loss model of the A1 scenario. See ScenarioVector for the scenario number mapping. The NumPenetratedFloors property is applicable only when PathLossModelUsed is 'yes'.

For more information, see WINNER II Channel Models [1], Table 4-4.

### NormalizeChannelOutputs

Normalize channel outputs, specified as true or false. Set this property to true to normalize the channel outputs by the number of receive antennas at the mobile station (MS) for each link. The default value is true.

For more information, see “Channel Power” on page 4-1819.

## Methods

release	Allow System object property value changes

## Examples

### WINNER II Channel with Two Mobile Stations

Simulate a system that has two MS connected to one BS. One MS is 8 meters away from the BS; the other is 20 meters away from the BS. Impulse signals are sent through the

two links. The spectrum of the received signals at MS shows frequency selectivity. It also shows the MS that is closer the BS has a larger average received power than the other MS.

Specify random number generator seed for repeatability.

```
rng(100);
```

Initial frame length and sample rate.

```
frmLen = 1024;
```

Configure layout parameters.

```
BSAA = winner2.AntennaArray('UCA', 8, 0.02); % UCA-8 antenna array for BS
MSAA1 = winner2.AntennaArray('ULA', 2, 0.01); % ULA-2 antenna array for MS
MSAA2 = winner2.AntennaArray('ULA', 4, 0.005); % ULA-4 antenna array for MS
MSIdx = [2 3]; BSIdx = {1}; NL = 2; maxRange = 100; rndSeed = 101;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL, ...
    [BSAA,MSAA1,MSAA2],maxRange,rndSeed);
```

Adjust BS and MS positions.

```
cfgLayout.Stations(1).Pos(1:2) = [10, 10];
cfgLayout.Stations(2).Pos(1:2) = [18, 10]; % 8 meters away from BS
cfgLayout.Stations(3).Pos(1:2) = [22, 26]; % 20 meters away from BS
```

NLOS for both links

```
cfgLayout.Pairing = [1 1; 2 3];
cfgLayout.PropagConditionVector = [0 0];
```

Configure model parameters

```
cfgModel = winner2.wimparset;
cfgModel.NumTimeSamples = frmLen; % Frame length
cfgModel.IntraClusterDsUsed = 'no'; % No cluster splitting
cfgModel.SampleDensity = 2e5; % For lower sample rate
cfgModel.PathLossModelUsed = 'yes'; % Turn on path loss
cfgModel.ShadowingModelUsed = 'yes'; % Turn on shadowing
```

Create a WINNER II channel System object.

```
wimChan = comm.WINNER2Channel(cfgModel, cfgLayout);
```

Call the info method of the object to get some system information

```

chanInfo = info(wimChan)

chanInfo = struct with fields:
    NumLinks: 2
    NumBSElements: [8 8]
    NumMSElements: [2 4]
    NumPaths: [16 16]
    SampleRate: [1.0000e+07 1.0000e+07]
    ChannelFilterDelay: [7 7]
    NumSamplesProcessed: 0

```

```

numTx    = chanInfo.NumBSElements(1);
Rs       = chanInfo.SampleRate(1);

```

Create a Spectrum Analyzer System object.

```

SA = dsp.SpectrumAnalyzer('SampleRate', Rs, ...
    'YLimits', [-170, -100], 'ShowLegend', true, ...
    'ChannelNames', {'MS 1 (8 meters away)', 'MS 2 (20 meters away)'});

```

Pass impulse signals through the two links and show spectra of the received signals at the two MS.

```

for i = 1:10
    x = [ones(1,numTx); zeros(frmLen-1, numTx)];
    y = wimChan(x);
    SA([y{1}(:,1), y{2}(:,1)]);
end

```

## More About

### WINNER II Sampling Rate

The signal sample rate ( $R_S$ ) for generating channel coefficients and performing channel filtering is calculated per link using the mobile station speed ( $V_{MS}$ ), half wavelength distance, and sample density. The sample rate for each link is available as a field in the info method return.

$$R_S = V_{MS} / (C / F_{center} / 2 / N_{SD}),$$

- For the MS speed,  $V_{MS}$ ,
  - When `ModelConfig.UniformTimeSampling` is set to 'no',  $V_{MS}$  is the speed of the MS for the corresponding link, derived from the `LayoutConfig.Stations(i).Velocity` field.
  - When `ModelConfig.UniformTimeSampling` is set to 'yes',  $V_{MS}$  is the maximum speed of the MS for all links.
- $C$  is the speed of light ( $2.99792458e8$  m/s).
- $F_{center}$  is `ModelConfig.CenterFrequency`.
- $N_{SD}$  is `ModelConfig.SampleDensity`.

## Channel Power

These conditions apply to the channel power of the `comm.WINNER2Channel` object:

- When path loss and shadowing are off, path gains are normalized. Specifically, path gains are normalized when the `ModelConfig.ShadowingModelUsed` and `ModelConfig.PathLossModelUsed` parameters are set to 'no'.
- When the `NormalizeChannelOutputs` property is `true`, the average gain of the channel is 0 dB.

**Package:** comm

Display information about WINNER2Channel object

## Syntax

```
s = info(obj)
```

## Description

`s = info(obj)` returns a structure containing information about the Winner2Channel System object characteristics. The information structure contains:

- `NumLinks` - Number of links in the system
- `NumBSElements` - Number of transmit antennas at the BS for each link
- `NumMSElements` - Number of receive antennas at the MS for each link
- `NumPaths` - Number of delay paths for each link
- `SampleRate` - Sample rate for each link
- `ChannelFilterDelay` - Channel filter delay per link, measured in samples
- `NumSamplesProcessed` - Number of samples the channel has processed since the last reset

**Introduced in R2016b**

# reset

**System object:** `comm.WINNER2Channel`

**Package:** `comm`

Reset states of `WINNER2Channel` object

## Syntax

`reset(obj)`

## Description

`reset(obj)` resets the states of the `Winner2Channel` System object.

If the `ModelConfig.RandomSeed` property of `obj` is empty, the `reset` method resets the filters only. Otherwise, the `reset` method resets the filters and also reinitializes the random number stream to the value of the `ModelConfig.RandomSeed` property.

**Introduced in R2016b**

## step

**System object:** comm.WINNER2Channel

**Package:** comm

Filter input signal through WINNER II fading channel

## Syntax

```
y = step(obj,x)
[y,pathGains] = step(obj,x)
```

## Description

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`y = step(obj,x)` filters input signal `x` through a WINNER II fading channel and returns the result in `y`. Both `x` and `y` are  $N_L$ -by-1 cell arrays, where  $N_L$  represents the number of links, as determined by the `LayoutConfig` property of `obj`. The  $i$ th element of `x` must be an  $N_S$ -by- $N_T(i)$  matrix of doubles.

- $N_S$  represents the number of samples to be generated and must be the same for all elements of `x`.
- $N_T(i)$  is the number of transmit antennas at the base station (BS) for the  $i$ th link, determined by the `LayoutConfig` property of `obj`.

If the channel has only one link or if all links have the same number of transmit antennas, `x` can also be an  $N_S$ -by- $N_T$  matrix of doubles. In this case, the same input signal is filtered through all the links. The  $i$ th element of `y` is an  $N_S$ -by- $N_R(i)$  matrix of doubles.  $N_R(i)$  is the number of receive antennas at the mobile station (MS) for the  $i$ th link, as determined by the `LayoutConfig` property of `obj`.

`[y,pathGains] = step(obj,x)` also returns the channel coefficients of the underlying WINNER II fading process. `pathGains` is an  $N_L$ -by-1 cell array. The  $i$ th element of

`pathGains` is an  $N_R(i)$ -by- $N_T(i)$ -by- $N_P(i)$ -by- $N_S$  array of complex doubles.  $N_P(i)$  is the number of paths for the  $i$ th link, as determined by the `LayoutConfig` property of `obj`.

$N_R$ ,  $N_T$ , and  $N_P$  are link specific.  $N_S$  is the same for all the links.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

**Introduced in R2016b**

# rxsite

Create radio frequency receiver site

## Description

Use the `rxsite` object to create a radio frequency receiver site.

## Creation

## Syntax

```
rx = rxsite  
rx = rxsite(Name,Value)
```

## Description

`rx = rxsite` creates a radio frequency receiver site.

`rx = rxsite(Name,Value)` sets properties using one or more name-value pairs. For example, `rx = rxsite('Name','RX Site')` creates a receiver site with name RX Site. Enclose each property name in quotes.

## Properties

### Name — Site name

character vector | string | row or column vector

Site name, specified as a character vector or as a row or column vector or as a string.

Example: 'Name','Site 3'

Example: RX.Name = 'Site 3'

Example: If you want to assign multiple values then - names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"]; RX = rxsite('Name', names)

Data Types: char | string

### **Latitude — Site latitude coordinates**

42.3021 (default) | numeric scalar | row or column vector

Site latitude coordinates, specified as a numeric scalar or a row or column vector in the range of range -90 to 90. Coordinates are defined using Earth ellipsoid model WGS-84. Latitude is the north/south angle.

Example: 'Latitude', 45.098

Example: RX = 45.098

Example: If you want to assign multiple values then - latitude = [42.3467, 42.3598, 42.3763]; RX = rxsite('Latitude', latitude)

### **Longitude — Site longitude coordinates**

-71.3764 (default) | numeric scalar | row or column vector

Site longitude coordinates, specified as a numeric scalar or a row or column vector. Coordinates are defined using Earth ellipsoid model WGS-84. Longitude is the east/west angle.

Example: 'Longitude', -68.890

Example: RX.Longitude = -68.890

Example: If you want to assign multiple values then - longitude = [-71.0972, -71.0545, -71.0611]; RX = rxsite('Longitude', longitude)

### **Antenna — Antenna element or array**

'isotropic' (default) | object | row vector

Antenna element or array specified as an object or 'isotropic'. By default, the antenna is 'isotropic', which defines an antenna that radiates uniformly in all directions.

### **AntennaAngle — Antenna x-axis angle**

0 (default) | numeric scalar | 2-by-1 vector | 2-by-N matrix

Antenna x-axis angle, specified as a numeric scalar, a 2-by-1 vector, or a 2-by-N matrix in degrees.

The numeric scalar is the azimuth angle measured counterclockwise from the east to the antenna x-axis.

In the 2-by-1 vector, the first element is the azimuth angle and the second element elevation angle. The elevation angle measures from the horizontal plane to antenna x-axis from -90 to 90 degrees.

Example: 'AntennaAngle',25

Example: RX.AntennaAngle = [25,-80]

Data Types: double

### **AntennaHeight — Antenna height above surface**

1 (default) | non-negative numeric scalar | row vector

Antenna height from the ground or building surface, specified as a non-negative numeric scalar in meters. Maximum value for this property is 6,371,000 m.

If the site coincides with the building, the height is measured from the top of the building to the center of the antenna. Otherwise, the height is measured from ground elevation to the center of the antenna.

Example: 'AntennaHeight',25

Example: RX.AntennaHeight = 15

Data Types:

### **SystemLoss — System loss**

0 (default) | nonnegative numeric scalar | row vector

System loss, specified as a non-negative numeric scalar or a row vector in dB.

System loss includes transmission line loss and any other miscellaneous system losses.

Example: 'SystemLoss',10

Example: RX.SystemLoss = 10

Data Types:

### **ReceiverSensitivity — Minimum received power to detect signal**

-100 (default) | numeric scalar | row vector

Minimum received power to detect the signal, specified as a numeric scalar or a row vector in dBm.

Example: 'ReceiverSensitivity',-80

Example: RX.ReceiverSensitivity = -80

Data Types: double

### Object Functions

show	Show site location on map
hide	Hide site location on map
distance	Distance between sites
angle	Angle between sites
elevation	Elevation of site
location	Location coordinates at a given distance and angle from site
sigstrength	Signal strength due to transmitter
los	Plot or compute the line-of-sight (LOS) visibility between sites on a map
link	Display communication link on map
pattern	Plot antenna radiation pattern on map

### Examples

#### Default Receiver Site

Create and show the default receiver site.

```
rx = rxsite
```

```
rx =
```

```
  rxsite with properties:
```

```
      Name: 'Site 2'  
      Latitude: 42.3021  
      Longitude: -71.3764  
      Antenna: 'isotropic'  
      AntennaAngle: 0  
      AntennaHeight: 1  
      SystemLoss: 0  
      ReceiverSensitivity: -100
```

```
show(rx)
```

**Introduced in R2017b**

# siteviewer

Create Site Viewer map display for visualizing sites

## Description

Use the `siteviewer` object to create a map viewer for visualizing transmitter and receiver sites.

---

**Note** Site Viewer is a 3-D map display and requires hardware graphics support for WebGL™.

---

## Creation

## Syntax

```
viewer = siteviewer  
viewer = siteviewer(Name,Value)
```

## Description

`viewer = siteviewer` creates a “Site Viewer” map display for visualizing transmitter or receiver sites.

`viewer = siteviewer(Name,Value)` creates a Site Viewer map display with properties specified by one or more name-value pairs. Properties you do not specify retain their default values.

## Properties

**Name — Caption to display on map viewer window**

'Site Viewer' (default) | character vector | string scalar

Caption to display on map viewer window, specified as a character vector or a string scalar.

Data Types: `char` | `string`

### **Position — Size and location of map viewer window in pixels**

four-element integer-valued vector

Size and location of map viewer window in pixels, specified as a four-element integer-valued vector in the form `[left bottom width height]`. The default value depends on the screen resolution such that the window lies in the center of the screen with a width of 800 pixels and a height of 600 pixels.

Data Types: `double`

### **Basemap — Map imagery used to visualize sites**

`'satellite'` (default) | `'streets'` | `'openstreetmap'` | `'darkwater'` | `'grayland'` | `'bluegreen'` | `'colorterrain'` | `'grayterrain'` | `'landcover'`

Map imagery used to visualize sites, specified as a one of the following:

- `'satellite'` - Satellite imagery provided by ESRI
- `'streets'` - Street maps provided by ESRI.
- `'openstreetmap'` - Street maps provided by OpenStreetMap.
- `'darkwater'` - Two-tone map with light gray for land and dark gray for water.
- `'grayland'` - Two-tone map with gray for land and white for water.
- `'bluegreen'` - Two-tone map with green for land and blue for water.
- `'colorterrain'` - Shaded relief map derived from elevation and climate.
- `'grayterrain'` - Shaded relief map in shades of gray.
- `'landcover'` - Shaded relief map derived from satellite data.

Data Types: `char` | `string`

### **Terrain — Data on which to visualize sites and perform terrain calculations**

`'gmted2010'` (default) | `'none'` | character vector | scalar

Data on which to visualize sites and perform terrain calculations, specified as a character vector or a scalar previously added using `addCustomTerrain` or one of the following options:

- 'none' - Terrain elevation is 0 everywhere.
- 'gmted2010' - USGS GMTED2010 terrain data. This option requires an internet connection.

This property is read-only once the Site Viewer is created.

For limitations, see “Limitations” (Antenna Toolbox).

Data Types: `char` | `string`

### **Buildings — Name of OpenStreetMap (.osm) file to use as buildings data**

`string` scalar | `character` vector

Name of the `OpenStreetMap (.osm)` file to use as buildings data, specified as a string scalar or a character vector. The file must be in the current directory, in a directory on the MATLAB path. You can also use a full or relative path to the file to specify the data. By default, this value is empty.

This property is read-only once the Site Viewer is created.

For limitations, see “Limitations” (Antenna Toolbox).

Data Types: `char` | `string`

## **Object Functions**

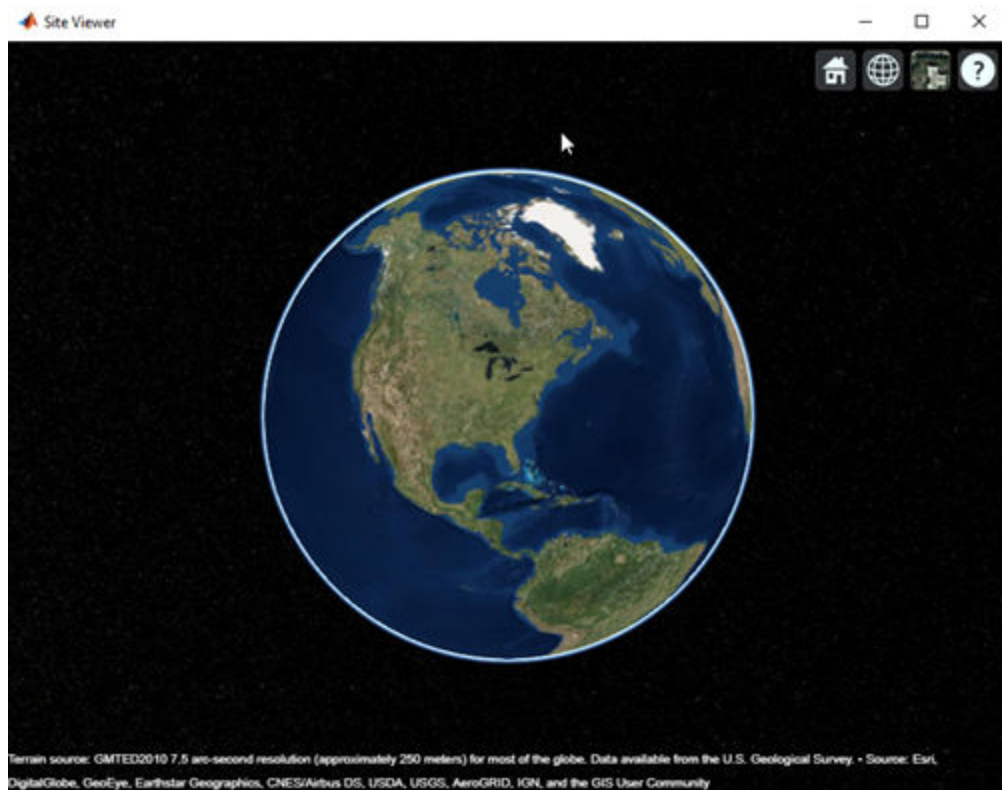

`clearMap` Clear map visualizations  
`close` Close map viewer window

## **Examples**

### **Default Site Viewer Map Display**

Create a default Site Viewer map display.

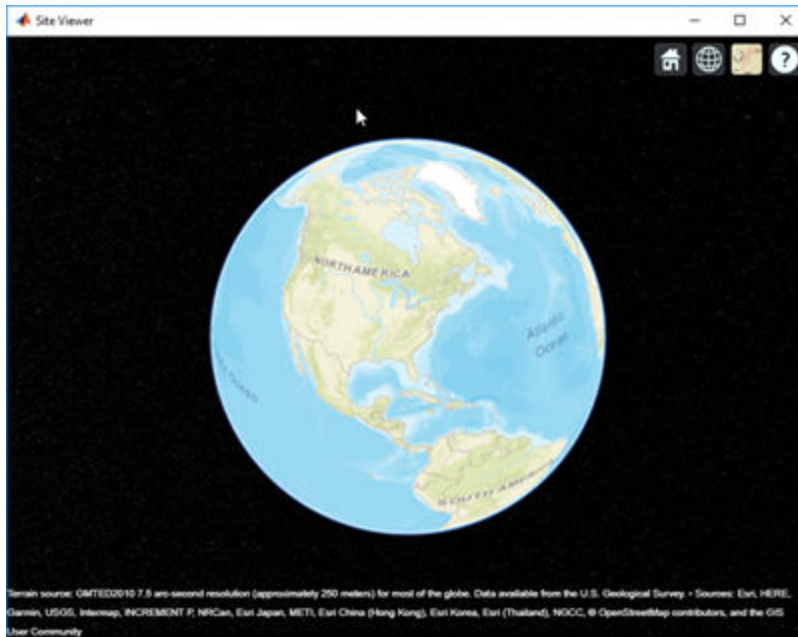

```
viewer = siteviewer;
```

### View Transmitter Site On Site Viewer

Launch a Site Viewer with streets basemap.

```
viewer = siteviewer("Basemap", "streets");
```

View a transmitter site on this map.

```
tx = txsite;  
show(tx)
```

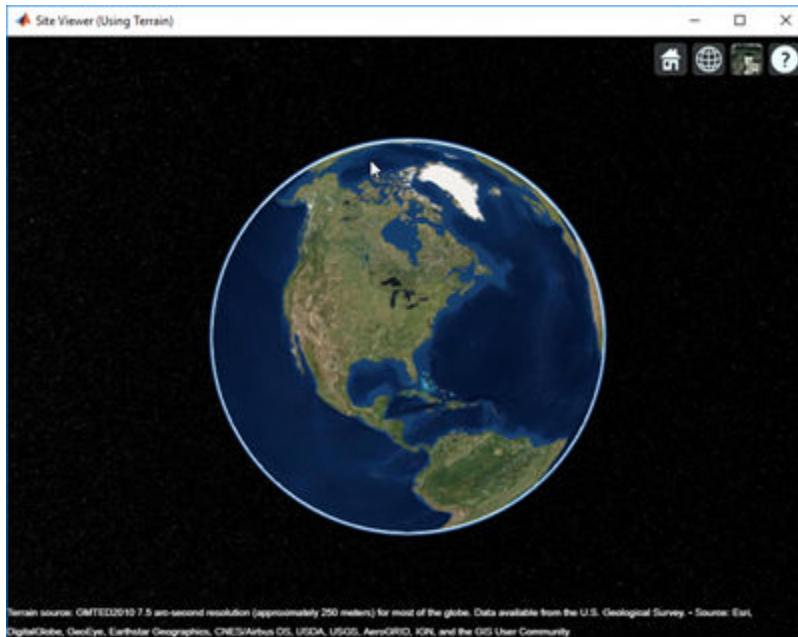

### Compare Coverage Maps

Launch two Site Viewer windows.

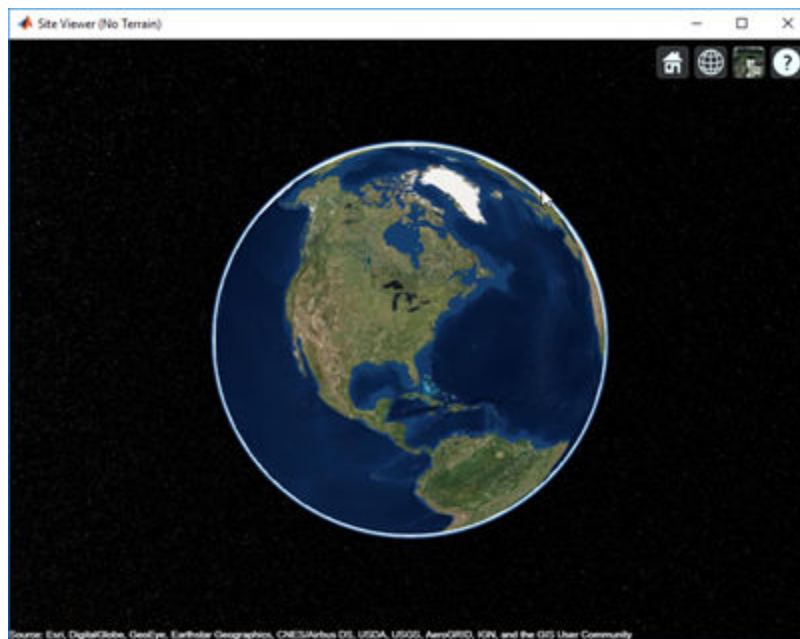

One Site Viewer window uses the terrain model.

```
viewer1 = siteviewer("Terrain", "gmted2010", "Name", "Site Viewer (Using Terrain)");
```

The second Site Viewer window does not use the terrain model.

```
viewer2 = siteviewer("Terrain", "none", "Name", "Site Viewer (No Terrain)");
```

Create a transmitter site.

```
tx = txsite;
```

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.

```
coverage(tx, "Map", viewer1)
```

## 4 System Objects — Alphabetical List

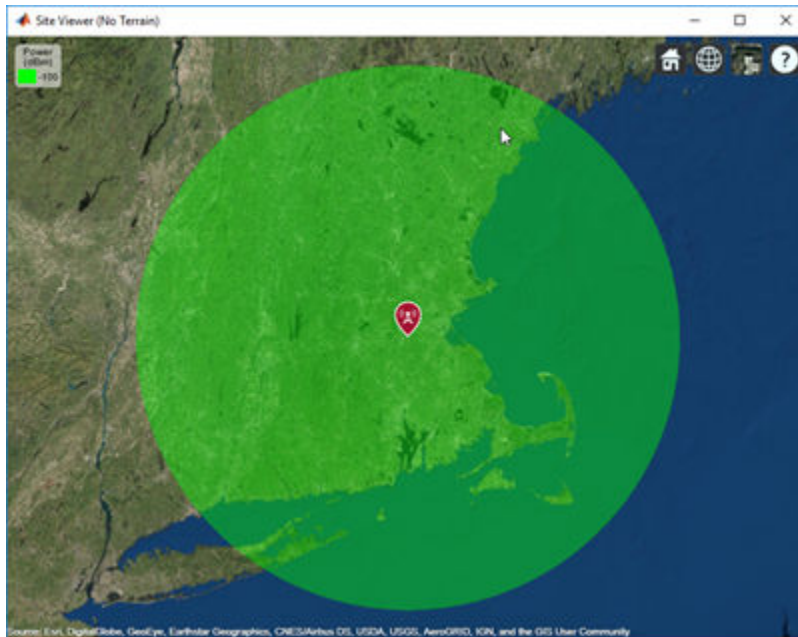

---

The map without terrain uses the free-space model by default.

coverage(tx, "Map", viewer2)

Close the maps.

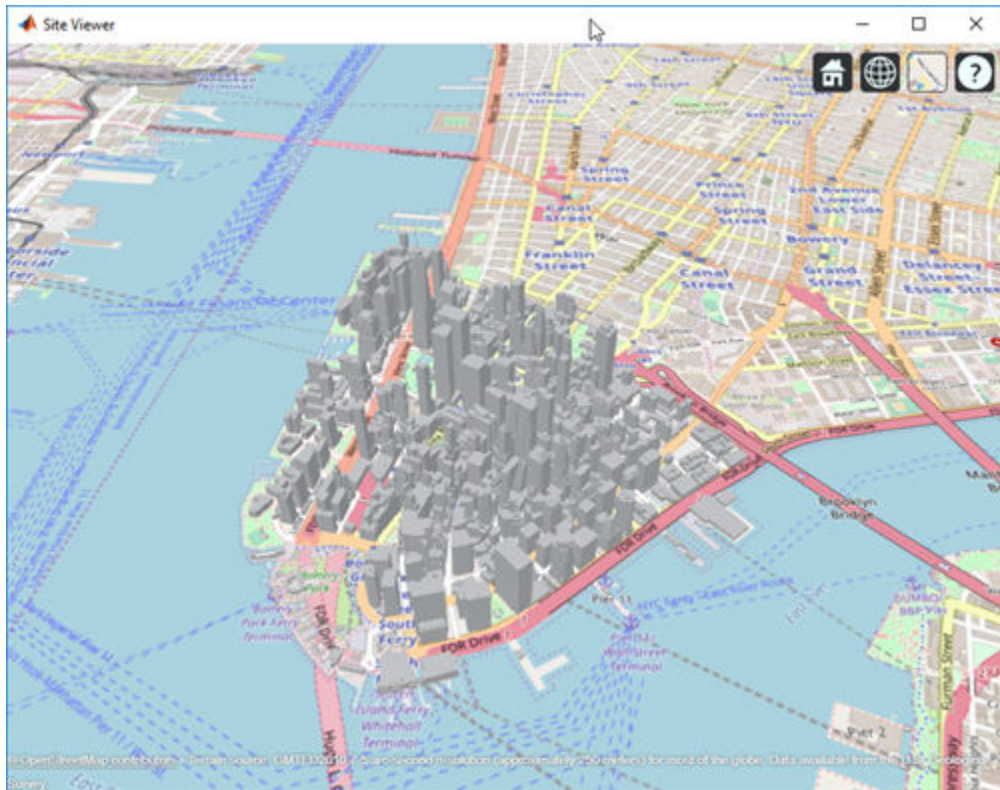

```
close(viewer1)  
close(viewer2)
```

### Site Viewer with Buildings

Launch siteviewer map window with basemap and buildings file.

```
viewer = siteviewer("Basemap", "openstreetmap", ...  
                  "Buildings", "manhattan.osm");
```

## 4 System Objects — Alphabetical List

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...  
           "Longitude",-74.0114,...  
           "AntennaHeight",50);  
show(tx)
```

## Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from siteviewer.

Initialize simulation variables to:

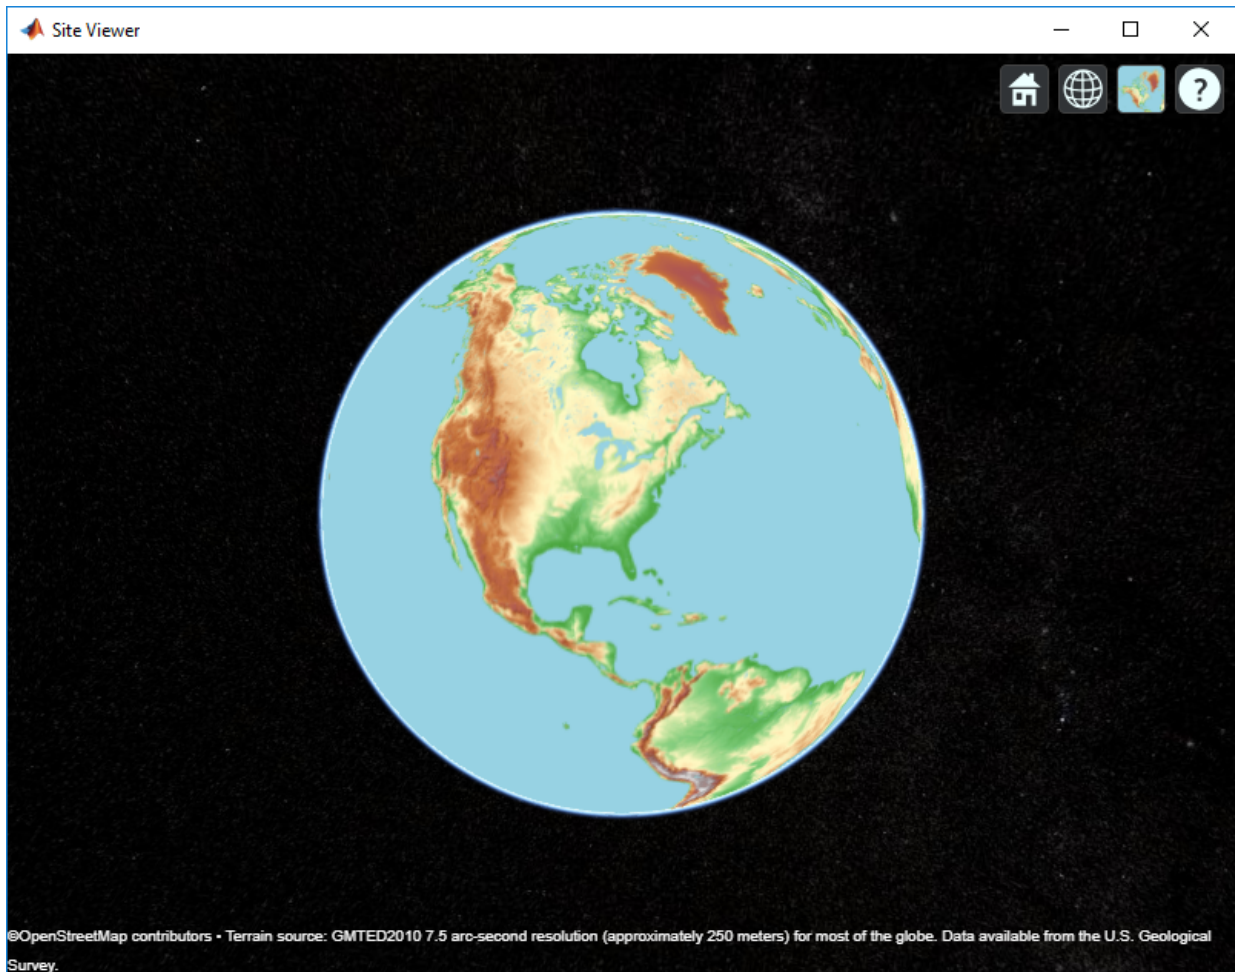

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.

- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';  
url = 'a.tile.opentopomap.org';  
copyright = char(uint8(169));  
attribution = copyright + "OpenStreetMap contributors";  
displayName = 'Open Topo Map';
```

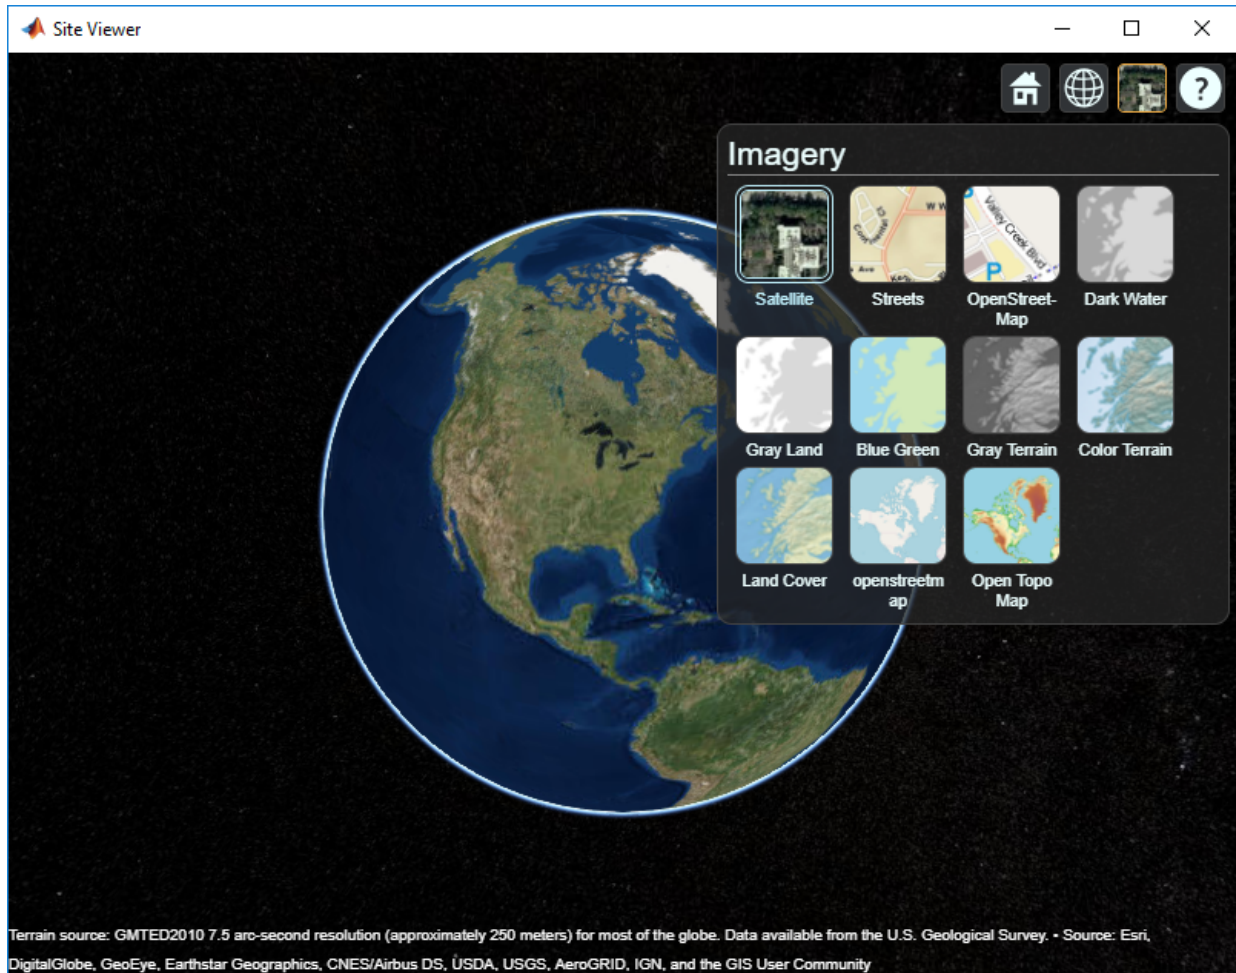

Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution,'DisplayName',displayName)  
viewer = siteviewer('Basemap',name);
```

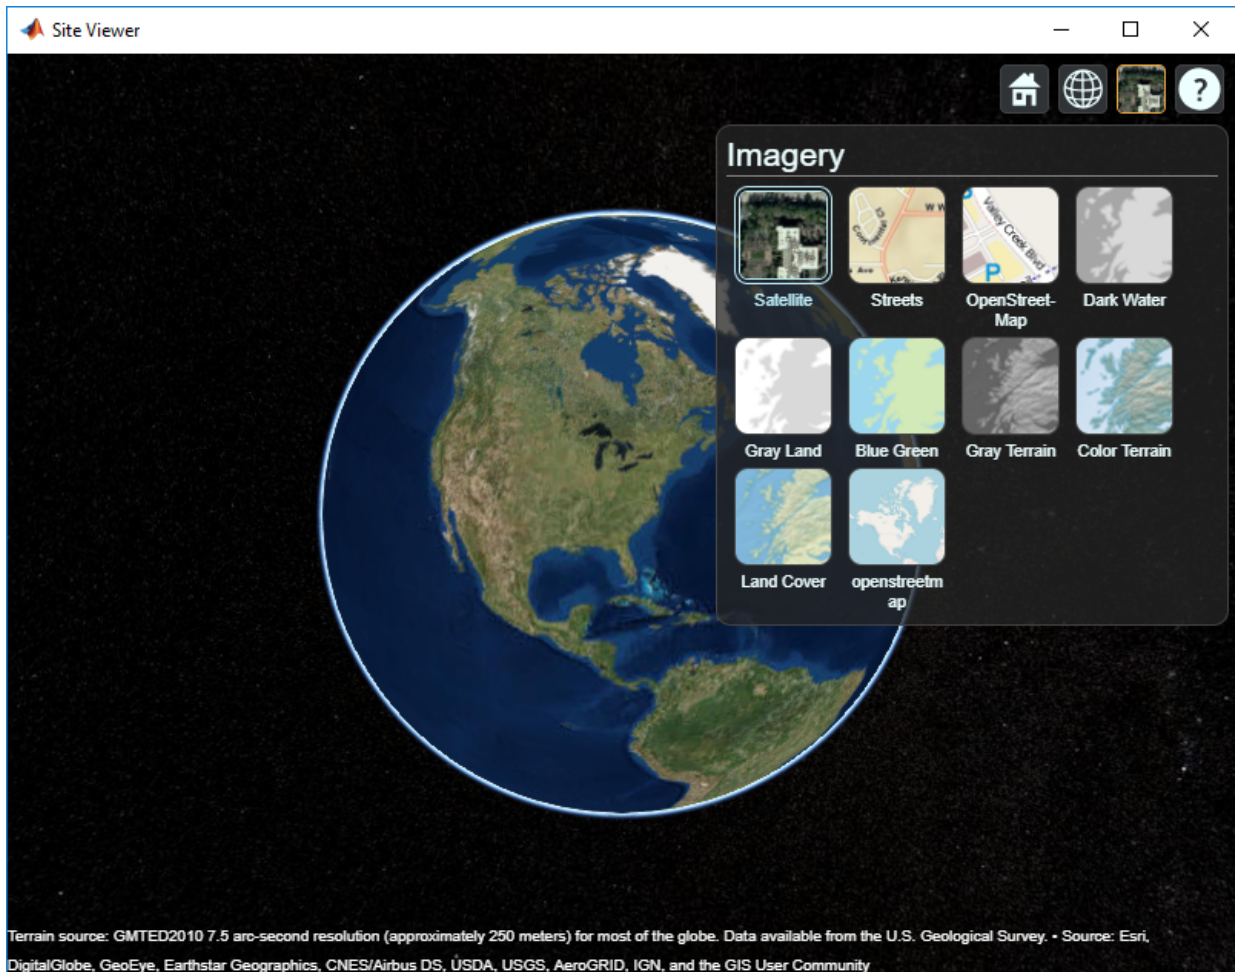

After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the 'Open Topo Map' icon in the Imagery tab.

```
siteviewer;
```

Use `removeCustomBasemap` to remove the custom basemap from future calls to `siteviewer`. Note the 'Open Topo Map' icon is no longer available in the Imagery tab.

```
removeCustomBasemap(name)  
siteviewer;
```

## Limitations

### Terrain

- Default terrain access requires Internet connection. If no internet connection exists, then Site Viewer automatically uses 'none' in the property Terrain.

- Custom DTED terrain files for use with `addCustomTerrain` must be acquired outside of MATLAB for example by using USGS EarthExplorer.
- When using custom terrain, analysis is restricted to the terrain region. For example, an error occurs if trying to show a `txsite` or `rxsite` outside of the region.

### **Buildings**

- OpenStreetMap files obtained from <https://www.openstreetmap.org> represent crowd-sourced map data, and the completeness and accuracy of the buildings data may vary depending on the map location.
- When downloading data from <https://www.openstreetmap.org>, select an export area larger than the desired area to ensure that all expected building features are fully captured. Building features at the edge of the selected export area may be missing.
- Building geometry and features are interpreted from the file according to the recommendations of OpenStreetMap for 3D buildings.

### **Topics**

“Site Viewer”

### **Introduced in R2019a**

## txsite

Create radio frequency transmitter site

### Description

Use txsite object to create a radio frequency transmitter site.

### Creation

### Syntax

```
tx = txsite
tx = txsite(Name,Value)
```

### Description

tx = txsite creates a radio frequency transmitter site.

tx = txsite(Name,Value) sets properties using one or more name-value pairs. For example, tx = txsite('Name','TX Site') creates a transmitter site with name TX Site. Enclose each property name in quotes.

### Properties

#### Name — Site name

character vector | string | row or column vector

Site name, specified as a character vector or string, or row or column vector of  $N$  elements.

Example: 'Name','Site 2'

Example: TX.Name = 'Fenway Park'

Example: If you want to assign multiple values then - names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"]; TX = txsite('Name', names)

Data Types: char | string

### **Latitude — Site latitude coordinates**

42.3001 (default) | numeric scalar | row or column vector

Site latitude coordinates, specified as a numeric scalar in the range of -90 to 90, or as a row or column vector of  $N$  elements. Coordinates are defined using Earth ellipsoid model WGS-84. Latitude is the north/south angle.

Example: 'Latitude', 45.098

Example: TX.Latitude = 45.098

Example: If you want to assign multiple values then - latitude = [42.3467, 42.3598, 42.3763]; TX = txsite('Latitude', latitude)

### **Longitude — Site longitude coordinates**

-71.3504 (default) | numeric scalar | row or column vector

Site longitude coordinates, specified as a numeric scalar or as a row or column vector of  $N$  elements. Coordinates are defined using Earth ellipsoid model WGS-84. Longitude is the east/west angle.

Example: 'Longitude', -68.890

Example: TX.Longitude = -71.0972

Example: If you want to assign multiple values then - longitude = [-71.0972, -71.0545, -71.0611]; TX = txsite('Longitude', longitude)

### **Antenna — Antenna element or array**

'isotropic' (default) | object | row vector

Antenna element or array specified as an object or 'isotropic'. By default, the antenna is 'isotropic', which defines an antenna that radiates uniformly in all directions.

### **AntennaAngle — Antenna x-axis angle**

0 (default) | numeric scalar | 2-by-1 vector | 2-by- $N$  matrix

Antenna x-axis angle, specified as a numeric scalar or a 2-by-1 vector or a 2-by- $N$  matrix in degrees.

The azimuth angle measured counterclockwise from the east to the antenna x-axis.

The elevation angle measures from the horizontal plane to antenna x-axis from -90 to 90 degrees.

Example: 'AntennaAngle',25

Example: TX.AntennaAngle = [25,-80]

### **AntennaHeight — Antenna height above surface**

10 (default) | non-negative numeric scalar | row vector

Antenna height from the ground or building surface, specified as a non-negative numeric scalar in meters. Maximum value for this property is 6,371,000 m.

If the site coincides with the building, the height is measured from the top of the building to the center of the antenna. Otherwise, the height is measured from ground elevation to the center of the antenna.

Example: 'AntennaHeight',25

Example: TX.AntennaHeight = 15

Data Types:

### **SystemLoss — System loss**

0 (default) | nonnegative numeric scalar | row vector

System loss, specified as a non-negative numeric scalar in dB.

System loss includes transmission line loss and any other miscellaneous system losses.

Example: 'SystemLoss',10

Example: txsite.SystemLoss = 10

Data Types:

### **TransmitterFrequency — Transmitter operating frequency**

1.9000e+09 (default) | numeric scalar | row vector

Transmitter operating frequency, specified as a numeric scalar in Hz. The range is from 1e3 to 200e9.

Example: 'TransmitterFrequency',30e9

Example: txsite.TransmitterFrequency = 30e9

Data Types: double

### **TransmitterPower — Signal power at transmitter output**

10 (default) | positive numeric scalar

Signal power at transmitter output, specified as a positive numeric scalar in watts. The transmitter out is connected to the antenna.

Example: 'TransmitterPower',30

Example: txsite.TransmitterPower = 30

Data Types: double

## **Object Functions**

show	Show site location on map
hide	Hide site location on map
distance	Distance between sites
angle	Angle between sites
elevation	Elevation of site
location	Location coordinates at a given distance and angle from site
los	Plot or compute the line-of-sight (LOS) visibility between sites on a map
coverage	Display coverage map
sinr	Display signal-to-interference-plus-noise ratio (SINR) map
pattern	Plot antenna radiation pattern on map

## **Examples**

### **Default Transmitter Site**

Create and view a transmitter site at a latitude of 42.3001 and a longitude of -71.3504.

```
tx = txsite('Name','MathWorks Apple Hill','Latitude',42.3001,...  
           'Longitude',-71.3504)
```

```
tx =  
    txsite with properties:
```

```
        Name: 'MathWorks Apple Hill'  
    Latitude: 42.3001
```

```
Longitude: -71.3504
Antenna: 'isotropic'
AntennaAngle: 0
AntennaHeight: 10
SystemLoss: 0
TransmitterFrequency: 1.9000e+09
TransmitterPower: 10
```

```
show(tx)
```

View the coverage of the antenna.

```
pattern(tx)
```
