## BER Analyzer

Analyze bit error rate (BER) performance of communications systems

### Description

The **BER Analyzer** app calculates BER as a function of the energy per bit to noise power spectral density ratio ( $E_b/N_0$ ). Using this app, you can:

- Plot theoretical BER vs.  $E_b/N_0$  estimates and upper bounds.
- Plot BER vs.  $E_b/N_0$  using the semianalytic technique. The semianalytic technique estimates BER performance by using a combination of simulation and analysis. Use this technique when the system error rate is small, for example,  $< 10^{-6}$ .
- Estimate BER performance by using MATLAB® functions or Simulink® models.

### Open the BER Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `bertool`.

### Examples

#### Theoretical Plot

Generate a theoretical estimate of BER performance for a 16-QAM link in AWGN.

Open the **BER Analysis** app.

```
bertool
```

Specify the  $E_b/N_0$  **range** as `0:10`.

Set **Modulation type** to QAM and **Modulation order** to 16.

Theoretical Semianalytic Monte Carlo

$E_b/N_0$  range: 0:10 dB

Channel type: AWGN

Modulation type: QAM

Modulation order: 16

Demodulation type:  
 Coherent  
 Noncoherent

Plot the BER curve by clicking **Plot**.

### Semianalytic Plot

Use the semianalytic technique to plot the BER for a QPSK link having rectangular pulses.

Open the **BER Analysis** app.

bertool

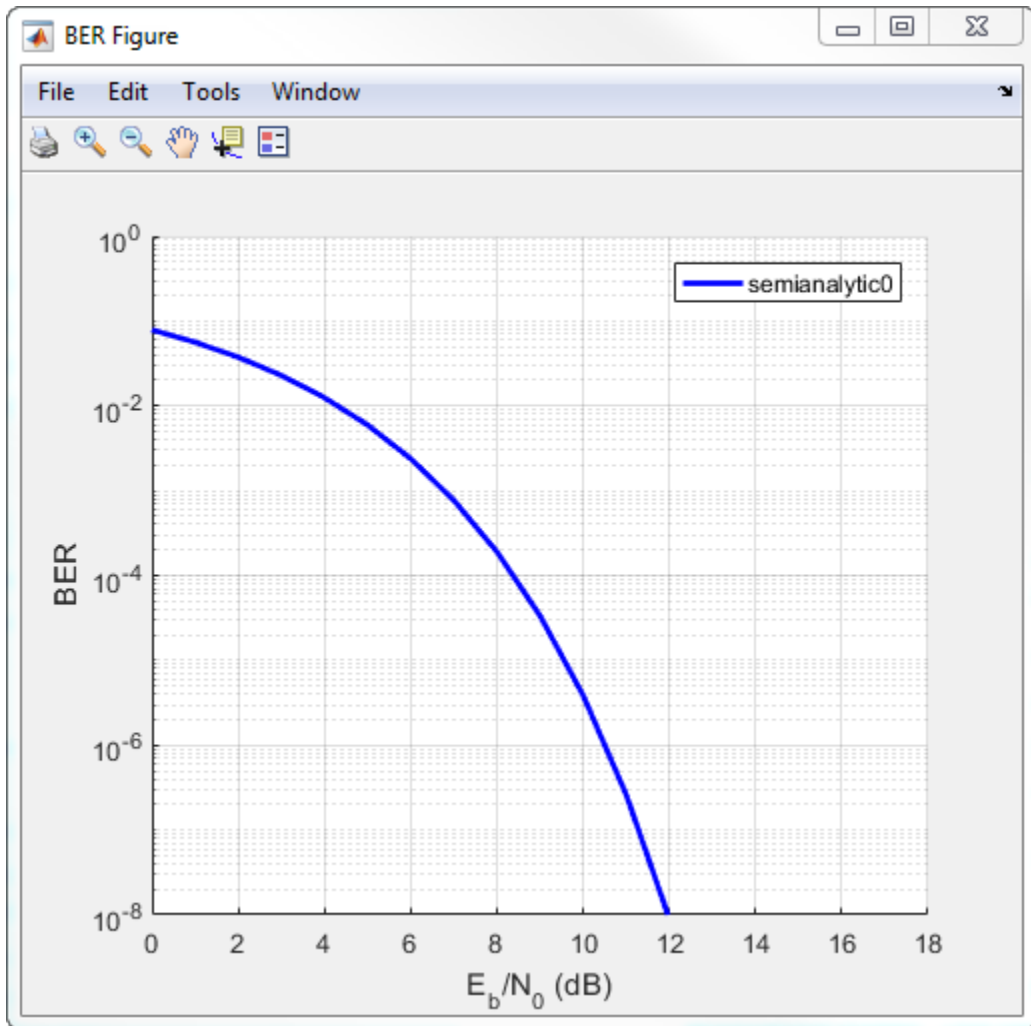

On the **Semianalytic** tab, set these parameters:

- Set the **Modulation order** to 4.
- Set the **Samples per symbol** parameter to 8.
- Set the **Transmitted signal** and **Received signal** parameters to `rectpulse(pskmod([0:3 0],4),8)`. To use the semianalytic technique, the number of symbols must exceed  $M^L$ , where  $M$  is the modulation order and  $L$  is the impulse response length. The impulse response is 1, so a minimum of five symbols is required.
- Specify the **Numerator** as ones(8,1)/8. These coefficients specify an ideal integrator having eight samples per symbol.

The screenshot shows the 'Semianalytic' tab of the BER Analyzer. The configuration is as follows:

- E<sub>b</sub>/N<sub>0</sub> range:** 0:18 dB
- Channel type:** AWGN
- Modulation type:** PSK
- Modulation order:** 4
- Differential encoding
- Samples per symbol:** 8
- Transmitted signal:** `rectpulse(pskmod([0:3 0],4),8)`
- Received signal:** `rectpulse(pskmod([0:3 0],4),8)`
- Receiver filter coefficients:**
  - Numerator:** `ones(8,1)/8`
  - Denominator:** 1

Plot the BER vs.  $E_b/N_0$  curve by clicking **Plot**.

### Monte Carlo Simulation

Simulate BER using a custom MATLAB function.

Open the **BER Analysis** app.

bertool

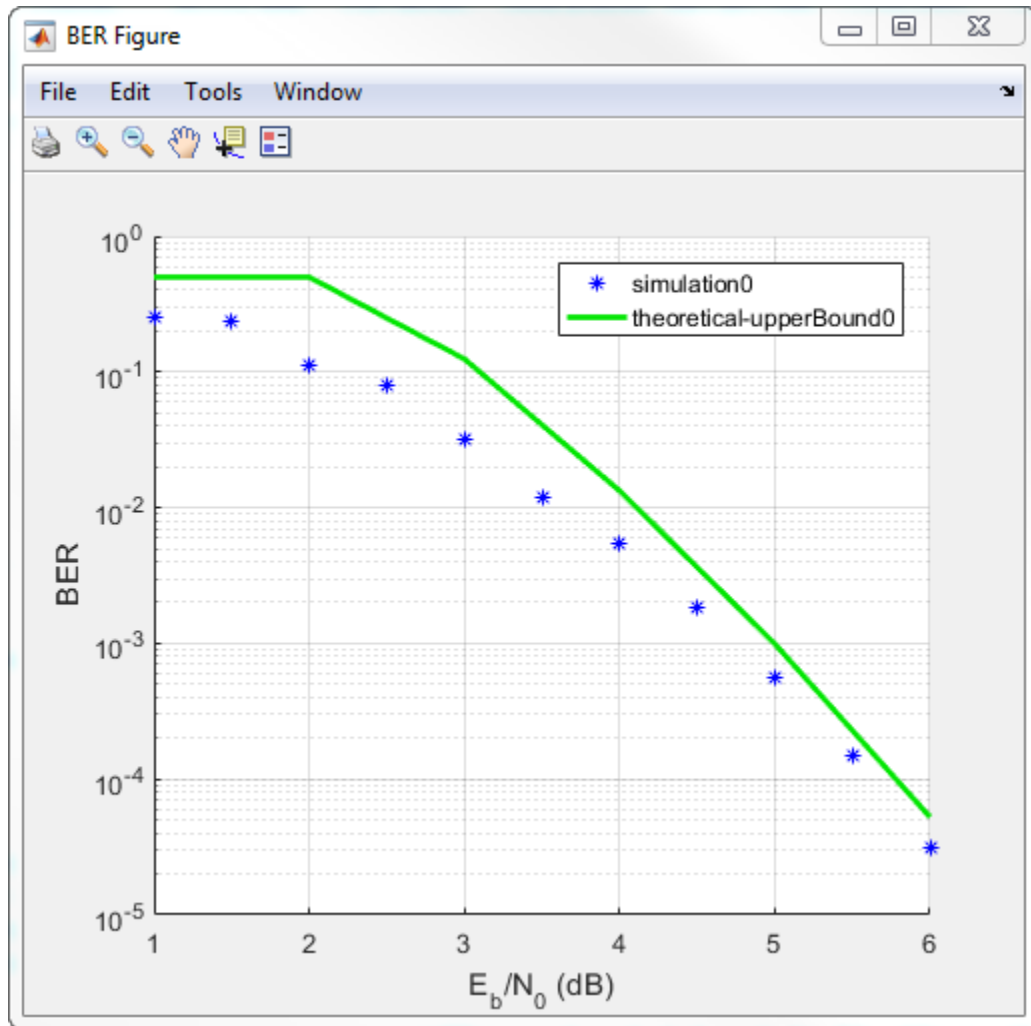

On the **Monte Carlo** tab, specify  $E_b/N_0$  range as 1 : .5 : 6.

To plot estimated BER values, run the simulation by clicking **Run**.

On the **Theoretical** tab, specify  $E_b/N_0$  range as 1 : 6 and set **Modulation order** to 4.

Enable convolutional coding by selecting the **Convolutional** check box.

Plot the upper bound of the BER curve by clicking **Plot**.

## Parameters

### Theoretical

**$E_b/N_0$  range** — Range of  $E_b/N_0$  values over which the BER is evaluated

0 : 18 (default) | vector

Specifies the range of  $E_b/N_0$  values, in dB, over which the BER is evaluated. The values in the range vector must be real.

Example: 5:10

**Channel type — Type of channel over which the BER is evaluated**

AWGN (default) | Rayleigh | Rician

Specifies the type of channel over which the BER is evaluated. The Rayleigh and Rician options correspond to flat fading channels.

**Modulation type — Modulation type of the communication link**

PSK (default) | DPSK | OQPSK | PAM | QAM | FSK | MSK | CPFSK

Specifies the modulation type of the communication link.

**Modulation order — Modulation order of the communication link**

2 (default) | 4 | 8 | 16 | 32 | 64

Specifies the modulation order of the communication link.

**Differential encoding — Differential encoding of the input data**

Off (default) | On

Specifies if the input data sequence is differentially encoded.

**Demodulation type — Demodulation type**

Coherent | Noncoherent

Specifies if Coherent or Noncoherent demodulation is used. This parameter is available only when the **Modulation type** is FSK or MSK.

**Channel coding — Channel coding used in estimating the BER**

None (default) | Convolutional | Block

Specifies the type of channel coding used to estimate the theoretical BER.

**Synchronization — Synchronization error**

Perfect synchronization (default) | Normalized timing error | RMS phase noise level

Specifies the synchronization error in the demodulation process. This parameter is available only when the **Modulation type** is PSK and the **Modulation order** is 2.

- When **Synchronization** is Normalized timing error, specify the normalized error as a real number from 0 to 0.5.
- When **Synchronization** is RMS phase noise level, specify the RMS phase noise as a nonnegative real number.

## Decision method — Decoding decision method

Hard (default) | Soft

Specify the method used to decode the received data. This parameter is available when either of these conditions exist:

- **Channel coding** is set to **Convolutional**
- **Channel coding** is set to **Block** and **Coding Type** is General

## Trellis — Convolutional code trellis

poly2trellis(7,[171 133]) (default) | structure

Specify the convolutional code trellis as a structure variable. You can generate this structure by using the `poly2trellis` function. The parameter is available only when the **Channel coding** parameter is **Convolutional**.

## Coding type — Specify block coding type

General (default) | Hamming | Golay | Reed-Solomon

Specify the block code used in the BER evaluation.

## N — Codeword length

positive integer

Specify the codeword length as a positive integer.

## K — Message length

positive integer

Specify the message length as a positive integer such that **K** is less than **N**.

## $d_{\min}$ — Minimum code distance

positive integer

Specify the minimum distance of the (N,K) block code as a positive integer. This parameter is available when the **Coding type** is General.

**Semianalytic****Samples per symbol — Samples per symbol**

16 (default) | positive integer

Specify the number of samples per symbol as a positive integer.

**Transmitted signal — Transmitted sample sequence**

```
rectpulse(step(comm.BPSKModulator, [0 1 1 0 0 1 1 1 1 0 1 1 0 0 0
0].'), 16) (default) | vector
```

Specify the transmit sequence as a real or complex column vector.

Data Types: double

**Received signal — Received sample sequence**

```
rectpulse(step(comm.BPSKModulator, [0 1 1 0 0 1 1 1 1 0 1 1 0 0 0
0].'), 16) (default) | vector
```

Specify the received sequence as a real or complex column vector.

Data Types: double

**Numerator — Numerator of the receive filter coefficients**

ones(16,1)/16 (default) | scalar | vector

Specify the numerator of the receive filter coefficients as a vector.

**Denominator — Denominator of the receive filter coefficients**

1 (default) | scalar | vector

Specify the denominator of the receive filter coefficients as a vector.

**Monte Carlo****Simulation MATLAB file or Simulink model — File name of the BER simulation**

character vector

Specify the name of the MATLAB file or Simulink model containing the simulation code.

**BER variable name — Name of the variable containing the BER simulation data**

character vector

Specify the name of the MATLAB workspace variable that contains the BER simulation data.

**Number of errors — Number of errors measured before simulation stop**

100 (default) | positive integer

Specify the number of errors that must be measured before the simulation stops. Typically, 100 measured errors are enough to produce an accurate BER estimate.

**Number of bits — Number of bits processed before simulation stop**

1e8 (default) | positive integer

Specify the number of bits that must be processed before the simulation stops. This parameter is used to prevent the simulation from running too long.

---

**Note** The Monte Carlo simulation stops when either the number of errors or number of bits threshold is reached.

# Eye Diagram Analyzer

(To be removed) Visualize and measure effects of impairments

---

**Note** `eyescope` will be removed in a future release. Use `comm.EyeDiagram` instead.

---

## Description

The **Eye Diagram Analyzer** app displays and measures the effects of various impairments. Using this app, you can:

- Visualize eye diagrams.
- Measure these quantities:
  - Horizontal and vertical eye openings
  - Random, deterministic, total, RMS, and peak-to-peak jitter
  - Rise and fall times
  - Signal-to-noise ratio
- Import and compare measurement results for eye diagrams of multiple signals.

## Open the Eye Diagram Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `eyescope`.

## Examples

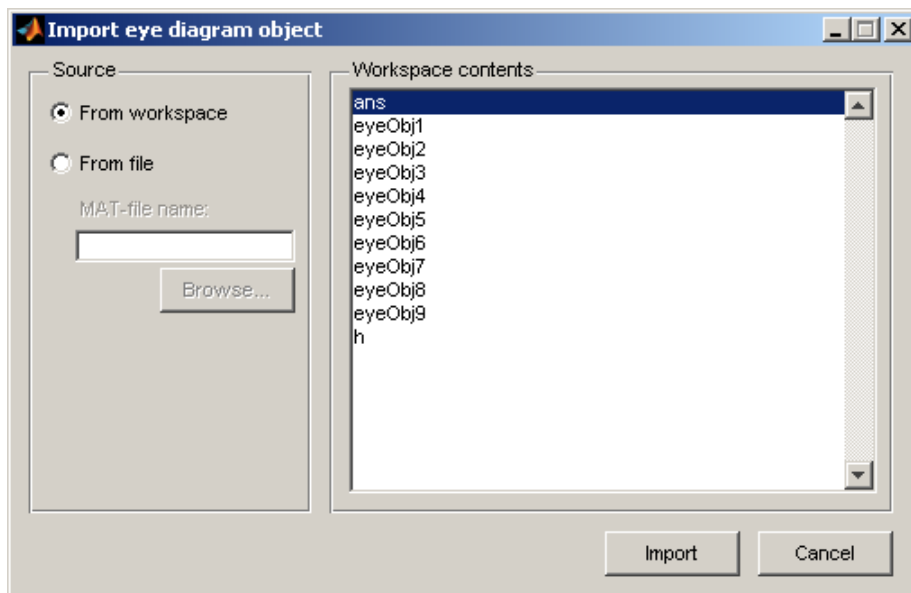

### Import Eye Diagrams and Compare Measurement Results

MATLAB software includes a set of data containing nine eye diagram objects, which you can import into EyeScope. While EyeScope can import eye diagram objects from either the workspace or a MAT-file, this introduction covers importing from the workspace.

EyeScope reconstructs the variable names it imports to reflect the origin of the eye diagram object.

- 1 Type `load commeye_EyeMeasureDemoData` at the MATLAB command line to load nine eye diagram objects into the MATLAB workspace.
- 2 Type `eyescope` at the MATLAB command line to start the EyeScope tool.
- 3 In the EyeScope window, select **File > Import Eye Diagram Object**.

The **Import eye diagram object** dialog box opens.

In this window, the **Workspace contents** panel displays all eye diagram objects available in the source location.

- 4 Select **eyeObj1** and click **Import**. EyeScope imports the object, displaying an image in the object plot and listing the file name in the **Eye diagram objects** list.

---

**Note** Object names associated with eye diagram objects that you import from the work space begin with the prefix `ws`.

---

Review the image and note the default **Eye diagram object settings** and **Measurements** selections. For more information, refer to the EyeScope on page 2-554 reference page.

- 5 In the EyeScope window, click the Import  button.
- 6 From the Import eye diagram object window, click to select `eyeObj5` then click the **Import** button.
  - The EyeScope window changes, displaying a new plot and adding `ws_eyeObj5` to the **Eye diagram objects** list. EyeScope displays the same settings and measurements for both eye diagram objects.
  - You can switch between the eye diagram plots EyeScope displays by clicking on an object name in the Eye diagram object list.
  - Next, click **`ws_eyeObj1`** and note the EyeScope plot and measurement values changes.

- 7 To change or remove measurements from the EyeScope display:
  - Select **Options > Measurements View**. The **Configure measurement view** shuttle control opens.

- Hold down the <Ctrl> key and click to select Vertical Opening, Rise Time, Fall Time, Eye SNR. Then click **Remove**.
- 8 From the left side of the shuttle control, select **Crossing Time** and **Crossing Amplitude** and then click **Add**. To display EyeScope with these new settings, click **OK**. The **Measurement** region displays Crossing Time and Crossing Amplitude at the bottom of the Measurements section.
- 9 Change the list order so that **Crossing Time** and **Crossing Amplitude** appear at the top of the list.
  - Select **Options > Measurements View**.
  - When the **Configure measurement view** shuttle control opens, hold down the <Ctrl> key and click to select **Crossing Time** and **Crossing Amplitude**.
  - Click the **Move Up** button until these selections appear at the top of the list. Then, click **OK**

- 10 Select **File > Save session as** and then type a file name in the pop-up window.
- 11 Import **ws\_eyeObj2**, **ws\_eyeObj3**, and **ws\_eyeObj4**. EyeScope now contains eye diagram objects 1, 5, 2, 3, and 4 in the list.
- 12 Select **ws\_eyeObj5**, and click the delete  button.
- 13 Click **File > Import Eye Diagram Object**, and select **ws\_eyeObj5**.
- 14 To compare measurement results for multiple eye diagram objects, click **View > Compare Measurement Results View**.

In the data set, random jitter increases from experiment 1 to experiment 5, as you can see in both the table and plot figure.

- 15 To include any data from the Measurements selection you chose earlier in this procedure, use the **Measurement selector**. Go to the **Measurement selector** and select **Total Jitter**. The object plot updates to display the additional measurements.

You can also remove measurements from the plot display. In the **Measurements selector**, select **Random Jitter** and **Deterministic Jitter**. The object plot updates, removing these two measurements.

- 16** To print the plot display, select **File > Print to Figure**. From **Figure** window, click the print button.

## Programmatic Use

eyescope calls an empty scope.

eyescope(obj) calls the eye scope and displays object obj.

## Compatibility Considerations

### eyescope will be removed

*Warns starting in R2017b*

Eye Diagram Analyzer will be removed in a future release. Use `comm.EyeDiagram` instead.

## **See Also**

`comm.EyeDiagram`

**Introduced in R2008b**

# Wireless Waveform Generator

Create, impair, visualize, and export modulated waveforms

## Description

The Wireless Waveform Generator app enables you to create, impair, visualize, and export modulated waveforms.

Using this app you can:

- Generate custom OFDM, QAM, and PSK modulated waveforms.
- Generate sine wave test waveforms.
- Generate Bluetooth modulated waveforms. This feature requires the Communications Toolbox Library for the Bluetooth<sup>®</sup> Protocol. To download this library, go to Get Add-Ons (MATLAB).
- Generate WLAN (802.11™) modulated waveforms. This feature requires the “WLAN Toolbox”.
- Generate LTE modulated waveforms. This feature requires the “LTE Toolbox”.
- Distort the waveform by adding RF impairments such as AWGN, phase offset, frequency offset, DC offset, IQ imbalance, and memoryless cubic nonlinearity.
- Visualize the waveform in constellation diagram, spectrum analyzer, OFDM grid, and time scope plots.
- Export the waveform to your workspace as a structure, to a *.mat* or a *.bb* file, or to a runnable MATLAB script.

---

**Note** You can use the MATLAB script to reproduce your waveform outside of the **Wireless Waveform Generator** app.

---

- Generate a waveform that you can transmit using a connected lab test instrument. The **Wireless Waveform Generator** app can transmit using instruments supported by the `rfsiggen` function. Use of the transmit feature in the **Wireless Waveform Generator** app requires “Instrument Control Toolbox”.

For more information, see “Using Wireless Waveform Generator App”.

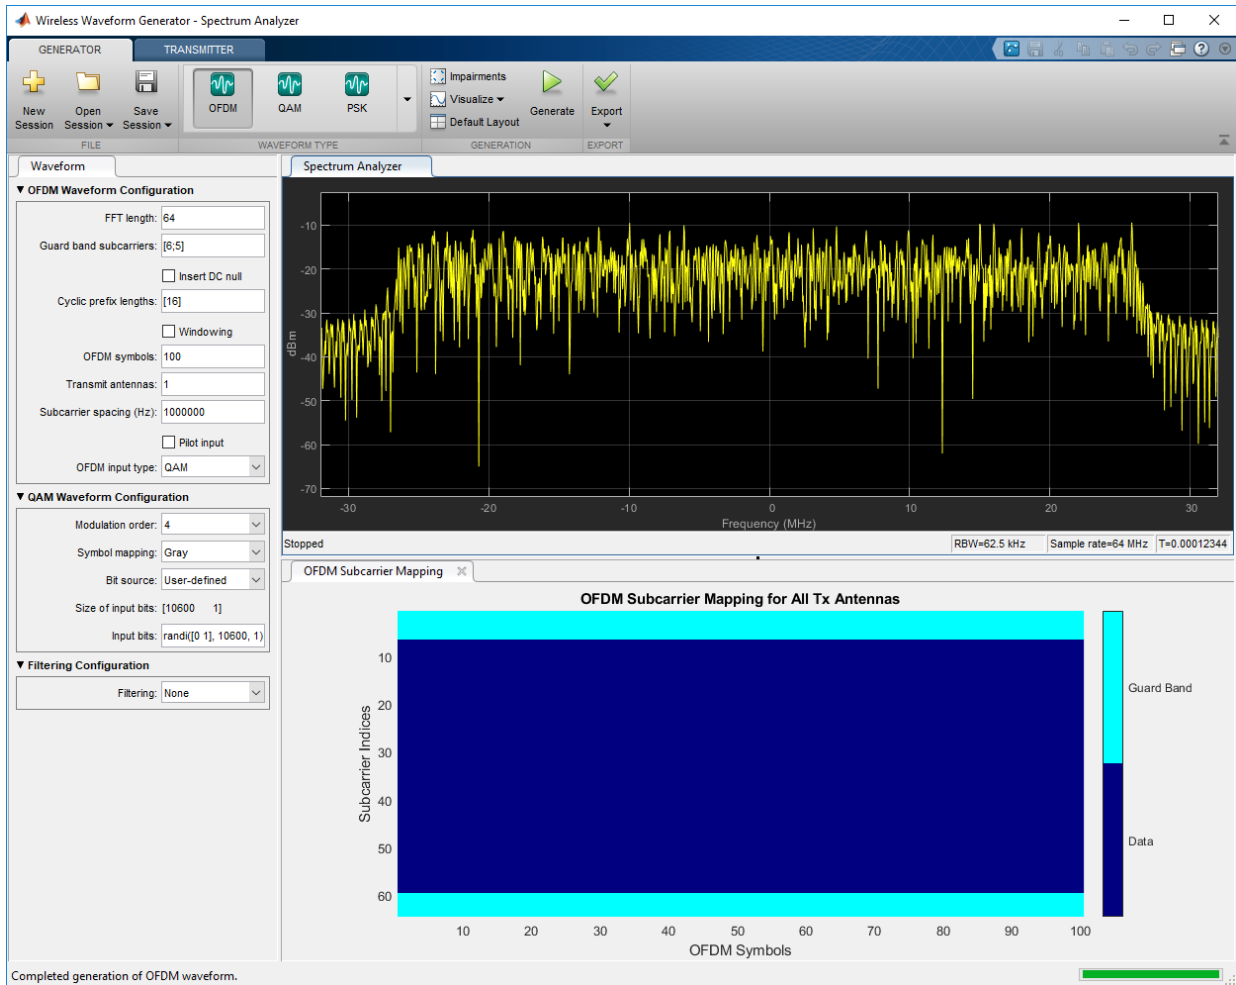

## Open the Wireless Waveform Generator App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon,  **Wireless Waveform G...**
- MATLAB command prompt: Enter `wirelessWaveformGenerator`

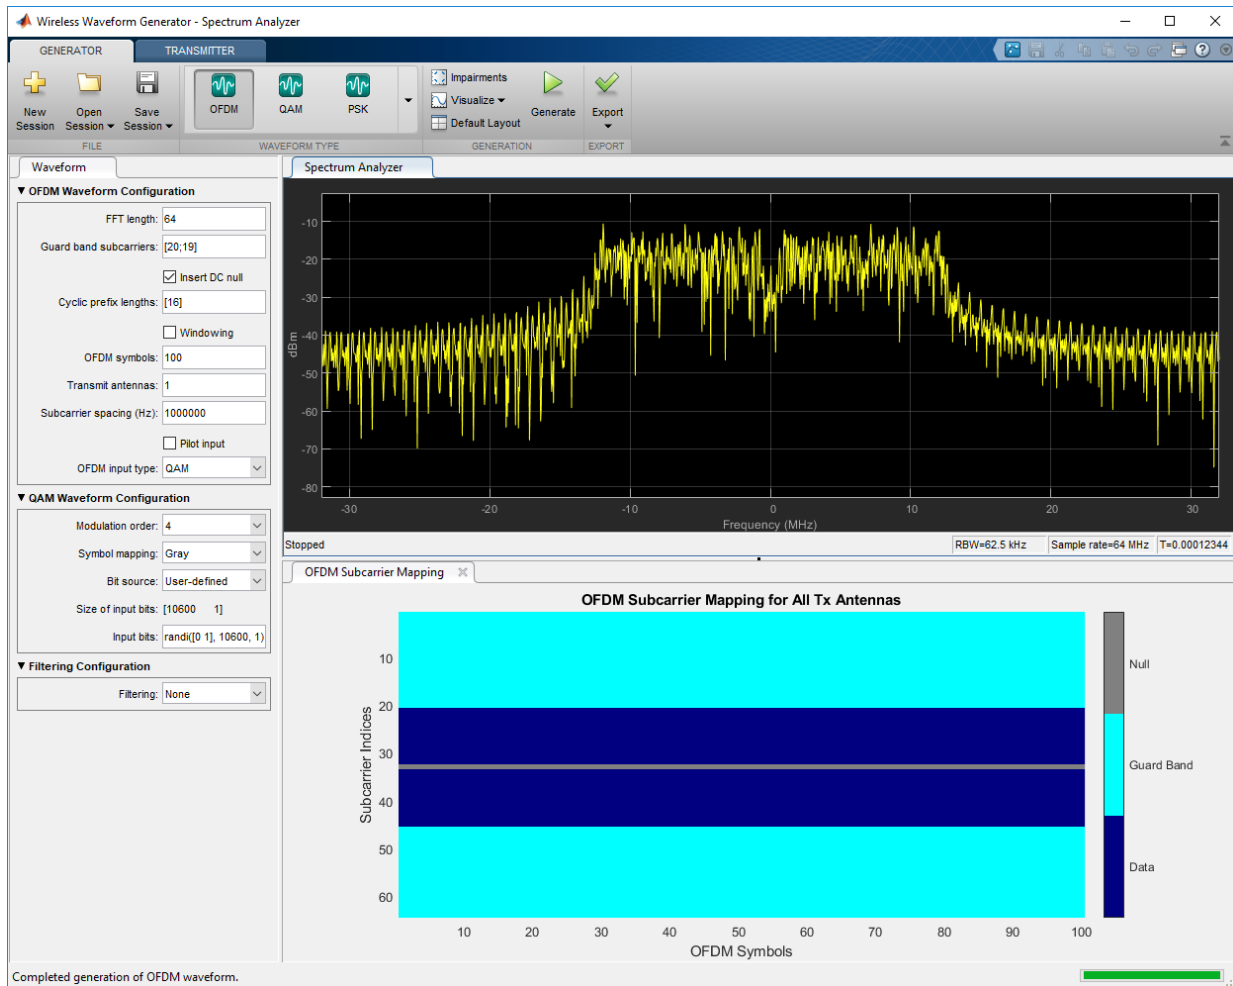

## Examples

### Generate OFDM Waveform

Open the **Wireless Waveform Generator** app and generate the default waveform by clicking **Generate**. The displayed waveform is an OFDM waveform with QPSK-modulated symbols.

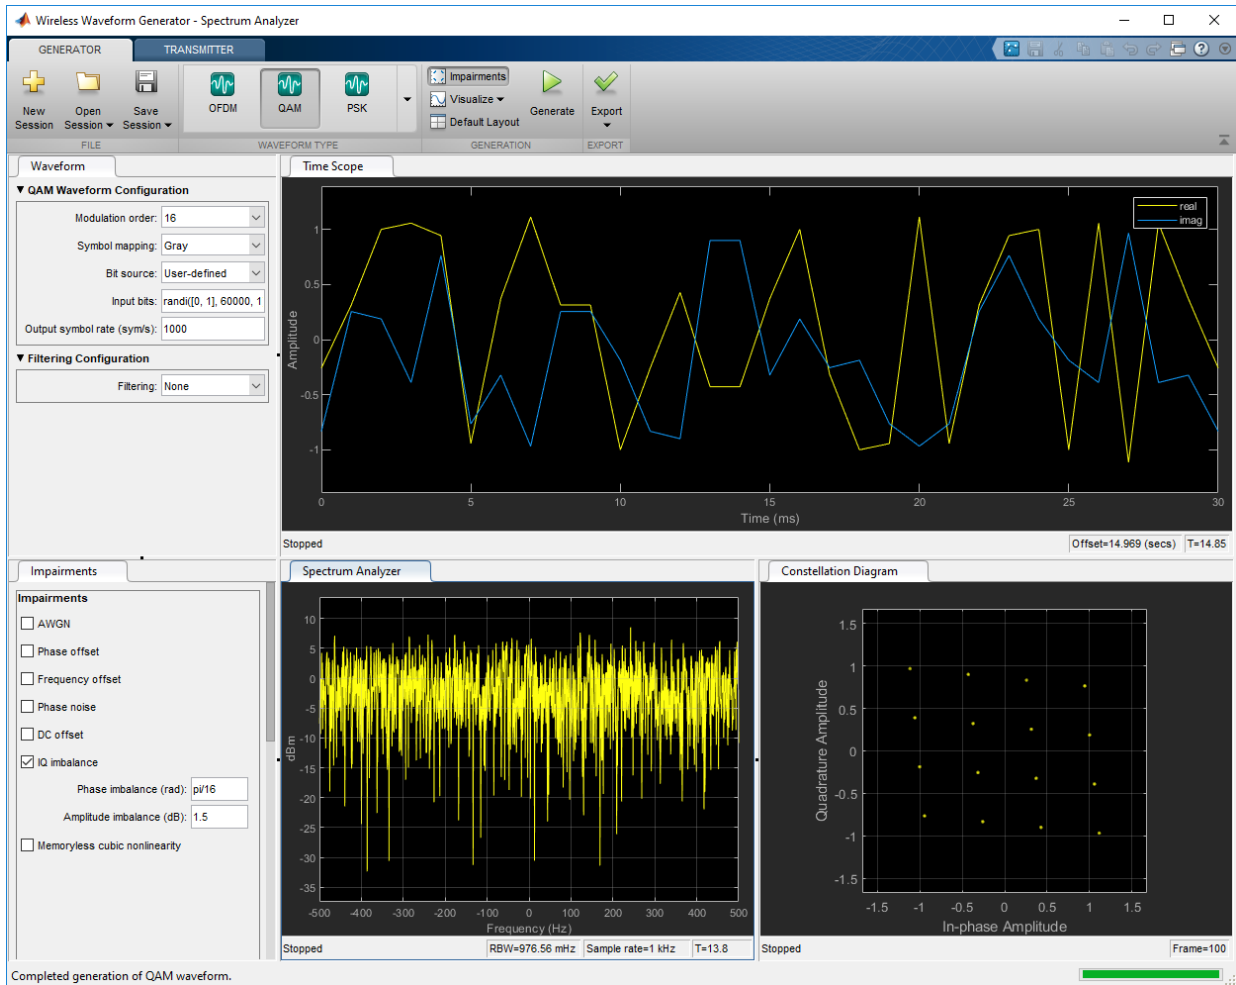

Click **Insert DC null** and increase the **Guard band subcarriers** to [20:19]. Click **Generate** again. The plotted waveform changes to reflect the updated configuration.

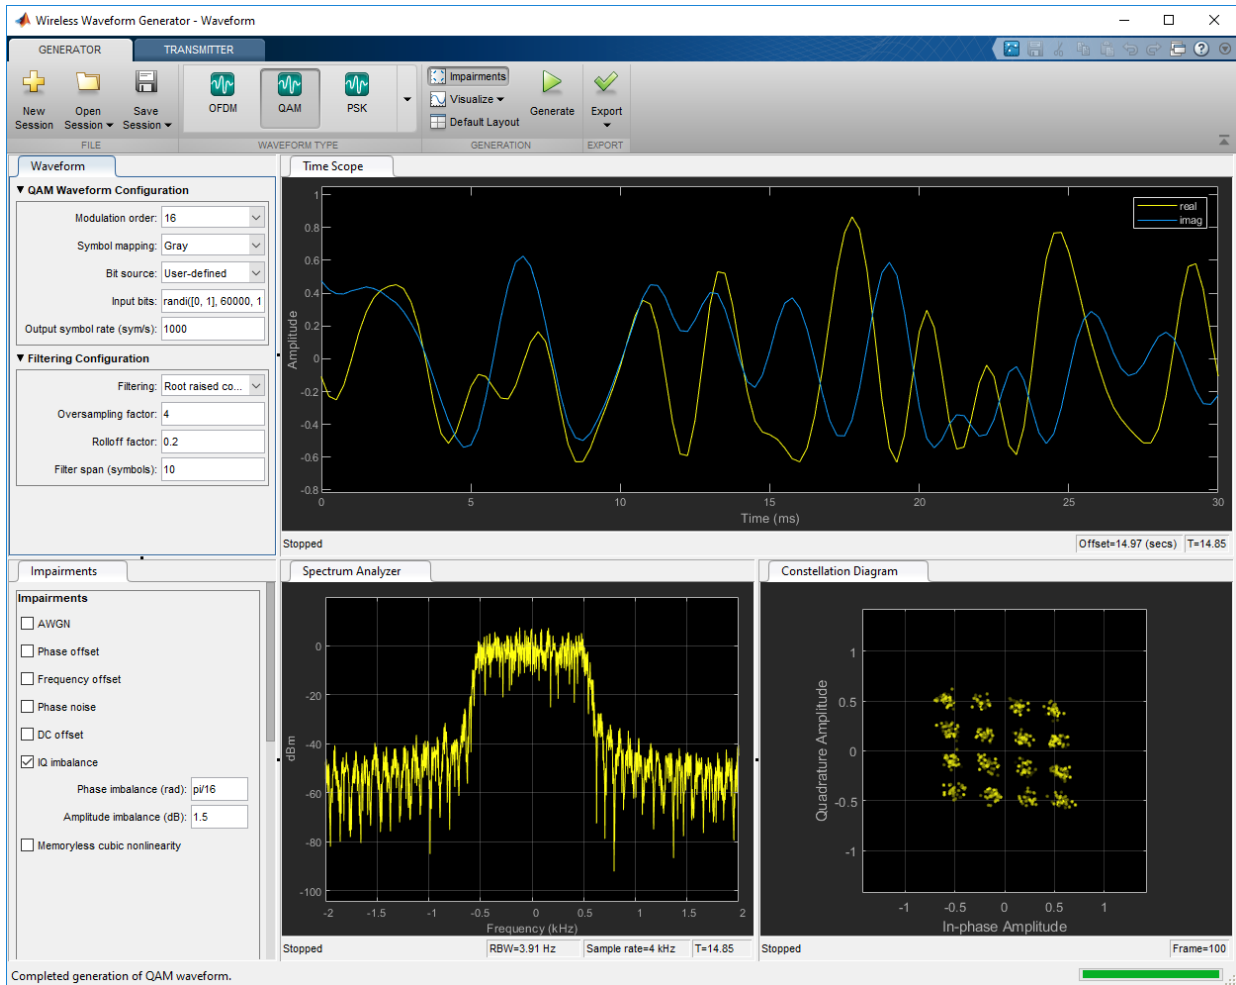

## Generate 16-QAM Waveform with Impairments

Open the **Wireless Waveform Generator** app and configure a 16-QAM waveform. Specify a phase imbalance of 11.25 degrees ( $\pi/16$  radians) and an amplitude imbalance of 1.5 dB. Click **Generate** to generate the waveform.

Select the **Filtering** parameter and apply root raised cosine filtering. Click **Generate** again to generate a waveform using the current configuration. The plotted waveform changes to reflect the updated configuration.

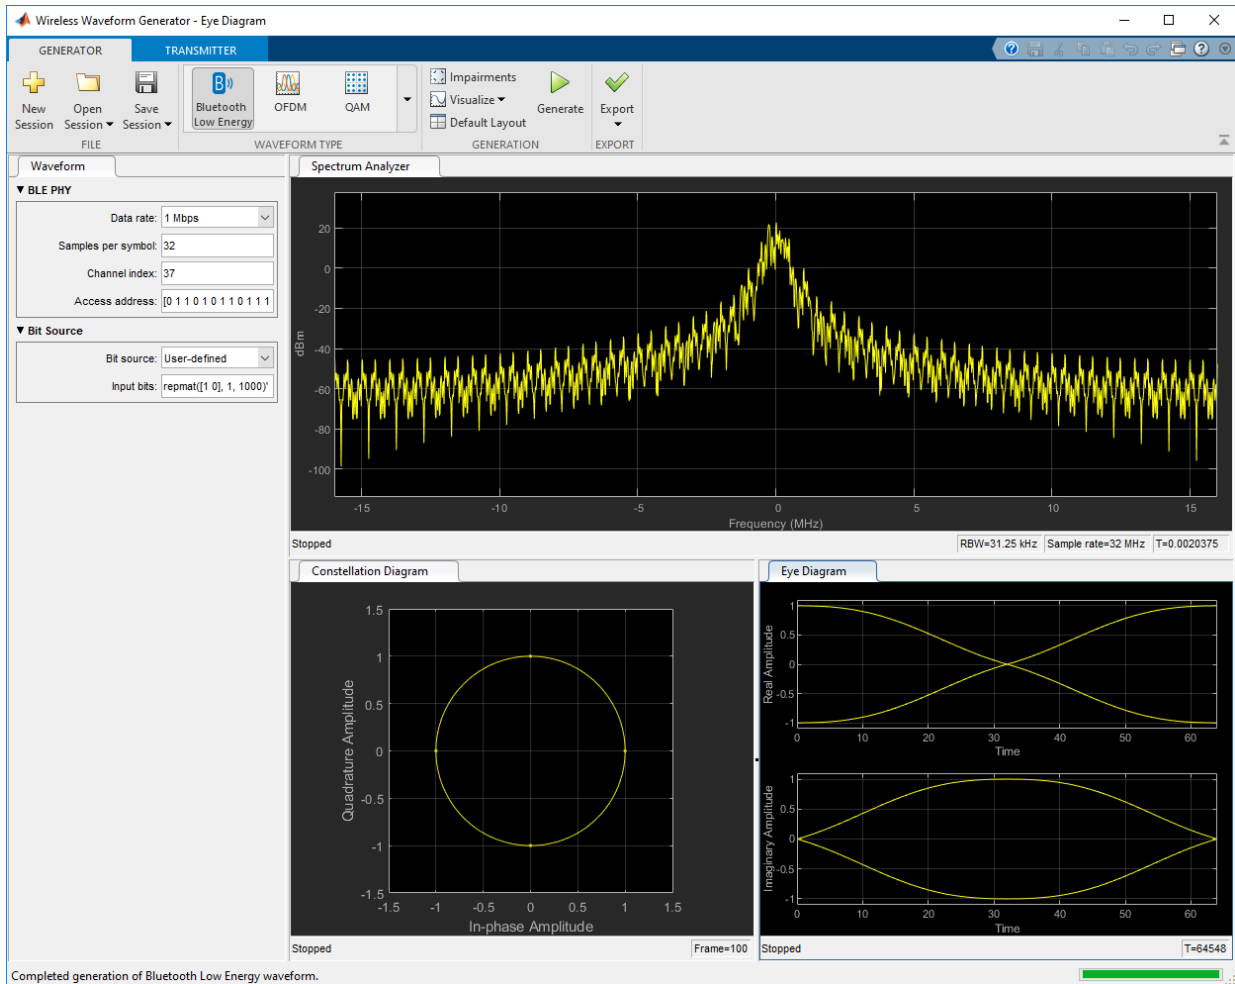

## Generate BLE Waveform

Open the **Wireless Waveform Generator** app and configure a Bluetooth low energy (BLE) waveform. To use the BLE feature, the app requires Communications Toolbox Library for the Bluetooth Protocol . In the **Waveform Type** section, click **Bluetooth Low Energy**. Change the bit source to **User-defined** and enter the input bits. Specify the value of **Samples per symbol** as 32. Click **Generate** to generate the BLE waveform. The

plotted waveform is a BLE waveform with GMSK-modulated samples. Change the visible plots by clicking **Visualize** and then selecting one or more options between Constellation Diagram, Time Scope and Eye Diagram.

## algdeintrlv

Restore ordering of symbols using algebraically derived permutation table

### Syntax

```
deintrlvd = algdeintrlv(data,num,'takeshita-costello',k,h)
deintrlvd = algdeintrlv(data,num,'welch-costas',alph)
```

### Description

`deintrlvd = algdeintrlv(data,num,'takeshita-costello',k,h)` restores the original ordering of the elements in `data` using a permutation table that is algebraically derived using the Takeshita-Costello method. `num` is the number of elements in `data` if `data` is a vector, or the number of rows of `data` if `data` is a matrix with multiple columns. In the Takeshita-Costello method, `num` must be a power of 2. The multiplicative factor, `k`, must be an odd integer less than `num`, and the cyclic shift, `h`, must be a nonnegative integer less than `num`. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`deintrlvd = algdeintrlv(data,num,'welch-costas',alph)` uses the Welch-Costas method. In the Welch-Costas method, `num+1` must be a prime number. `alph` is an integer between 1 and `num` that represents a primitive element of the finite field GF(`num+1`).

To use this function as an inverse of the `algintrlv` function, use the same inputs in both functions, except for the `data` input. In that case, the two functions are inverses in the sense that applying `algintrlv` followed by `algdeintrlv` leaves `data` unchanged.

### Examples

#### Interleave and Deinterleave Symbols

This example uses the Takeshita-Costello method of `algintrlv` and `algdeintrlv`.

Generate random data symbols to interleave. The number of rows of input data, num, must be a power of two.

```
num = 16;
ncols = 3;
data = rand(num,ncols)
```

```
data = 16×3
```

```

“Interleaving”

**Introduced before R2006a**

# algintrlv

Reorder symbols using algebraically derived permutation table

## Syntax

```
intrlvd = algintrlv(data,num,'takeshita-costello',k,h)
intrlvd = algintrlv(data,num,'welch-costas',alph)
```

## Description

`intrlvd = algintrlv(data,num,'takeshita-costello',k,h)` rearranges the elements in `data` using a permutation table that is algebraically derived using the Takeshita-Costello method. `num` is the number of elements in `data` if `data` is a vector, or the number of rows of `data` if `data` is a matrix with multiple columns. In the Takeshita-Costello method, `num` must be a power of 2. The multiplicative factor, `k`, must be an odd integer less than `num`, and the cyclic shift, `h`, must be a nonnegative integer less than `num`. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`intrlvd = algintrlv(data,num,'welch-costas',alph)` uses the Welch-Costas method. In the Welch-Costas method, `num+1` must be a prime number. `alph` is an integer between 1 and `num` that represents a primitive element of the finite field  $GF(num+1)$ . This means that every nonzero element of  $GF(num+1)$  can be expressed as `alph` raised to some integer power.

## Examples

### Reorder Symbols Using Algebraically Derived Permutation Table

This example illustrates how to use the Welch-Costas method of algebraic interleaving.

Define `num` such that `num+1` is prime. Create `data` to interleave.

```

num = 10;
ncols = 3; % Number of columns of data to interleave
data = randi([0 num-1],num,ncols); % Random data to interleave

```

Find primitive polynomials of the finite field  $GF(num+1)$ . The `gfprimfd` function represents each primitive polynomial as a row containing the coefficients in order of ascending powers.

```
pr = gfprimfd(1,'all',num+1)
```

```
pr = 4x2
```

```

     3     1
     4     1
     5     1
     9     1

```

Notice from the output that `pr` has two columns and that the second column consists solely of 1s. In other words, each primitive polynomial is a monic degree-one polynomial. This is because `num+1` is prime. As a result, to find the primitive element that is a root of each primitive polynomial, find a root of the polynomial by subtracting the first column of `pr` from `num+1`.

```
primel = (num+1)-pr(:,1) % Primitive elements of GF(num+1)
```

```
primel = 4x1
```

```

     8
     7
     6
     2

```

Now define `alph` as one of the elements of `primel` and use `algintrlv` to interleave.

```
alph = primel(1);
intrlvd = algintrlv(data,num,'Welch-Costas',alph);
```

## Algorithms

- A Takeshita-Costello interleaver uses a length-`num` cycle vector whose  $n$ th element is  $\text{mod}(k*(n-1)*n/2, \text{num})$  for integers  $n$  between 1 and `num`. The function creates a

permutation vector by listing, for each element of the cycle vector in ascending order, one plus the element's successor. The interleaver's actual permutation table is the result of shifting the elements of the permutation vector left by  $h$ . (The function performs all computations on numbers and indices modulo  $\text{num}$ .)

- A Welch-Costas interleaver uses a permutation that maps an integer  $K$  to  $\text{mod}(A^K, \text{num} + 1) - 1$ .

# amdemod

Amplitude demodulation

## Syntax

```
z = amdemod(y, Fc, Fs)
z = amdemod(y, Fc, Fs, ini_phase)
z = amdemod(y, Fc, Fs, ini_phase, carramp)
z = amdemod(y, Fc, Fs, ini_phase, carramp, num, den)
```

## Description

`z = amdemod(y, Fc, Fs)` returns a demodulated signal `z`, given the input amplitude modulated (AM) signal `y`, where the carrier signal has frequency `Fc`. The carrier signal and `y` have sampling frequency `Fs`. The modulated signal `y` has zero initial phase and zero carrier amplitude, resulting from a suppressed-carrier modulation.

---

**Note** The value of `Fs` must satisfy  $Fs \geq 2Fc$ .

---

`z = amdemod(y, Fc, Fs, ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = amdemod(y, Fc, Fs, ini_phase, carramp)` demodulates a signal created through transmitted-carrier modulation instead of suppressed-carrier modulation, where `carramp` is the carrier amplitude of the modulated signal.

`z = amdemod(y, Fc, Fs, ini_phase, carramp, num, den)` specifies the numerator and denominator of the lowpass Butterworth filter used in the demodulation. The numerator and denominator are generated by `[num,den] = butter(n, Fc*2/Fs)`, where `n` is the order of the lowpass filter.

## Examples

### Demodulate AM Signal

Set the carrier frequency to 10 kHz and sampling frequency to 80 kHz. Generate a time vector having a duration of 0.01 s.

```
fc = 10e3;  
fs = 80e3;  
t = (0:1/fs:0.01)';
```

Create a two-tone sinusoidal signal with frequencies 300 and 600 Hz.

```
s = sin(2*pi*300*t)+2*sin(2*pi*600*t);
```

Create a lowpass filter.

```
[num,den] = butter(10,fc*2/fs);
```

Amplitude modulate the signal s.

```
y = ammod(s,fc,fs);
```

Demodulate the received signal.

```
z = amdemod(y,fc,fs,0,0,num,den);
```

Plot the original and demodulated signals.

```
plot(t,s,'c',t,z,'b--')  
legend('Original Signal','Demodulated Signal')  
xlabel('Time (s)')  
ylabel('Amplitude')
```

The demodulated signal is nearly identical to the original signal.

## Input Arguments

### **y** — Amplitude modulated input signal

scalar | vector | matrix | 3-D array

Amplitude modulated input signal, specified as a scalar, vector, matrix, or 3-D array. Each element of **y** must be real.

Data Types: `single` | `double`

### **Fc — Carrier signal frequency**

positive real scalar

Carrier signal frequency in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

### **Fs — Sampling frequency**

positive real scalar

Sampling frequency of the carrier signal and input message signal in hertz (Hz), specified as a positive real scalar. To avoid aliasing, the value of  $F_s$  must satisfy  $F_s > 2(F_c + BW)$ , where  $BW$  is the bandwidth of the original modulated signal.

Data Types: `single` | `double`

### **ini\_phase — Initial phase**

real scalar

Initial phase of the modulated signal in radians, specified as a real scalar.

Data Types: `single` | `double`

### **carramp — Carrier amplitude**

real scalar

Carrier amplitude of the modulated signal, specified as a real scalar.

Data Types: `single` | `double`

### **num — Lowpass Butterworth filter numerator**

real scalar

Lowpass Butterworth filter numerator, specified as a real scalar.

Data Types: `single` | `double`

### **den — Lowpass Butterworth filter denominator**

real scalar

Lowpass Butterworth filter denominator, specified as a real scalar.

Data Types: `single` | `double`

## Output Arguments

### **z — Amplitude demodulated output signal**

scalar | vector | matrix | 3-D array

Amplitude demodulated output signal, returned as a scalar, vector, matrix, or 3-D array.

# ammod

Amplitude modulation

## Syntax

```
y = ammod(x,Fc,Fs)
y = ammod(x,Fc,Fs,ini_phase)
y = ammod(x,Fc,Fs,ini_phase,carramp)
```

## Description

`y = ammod(x,Fc,Fs)` returns an amplitude modulated (AM) signal `y`, given the input message signal `x`, where the carrier signal has frequency `Fc`. The carrier signal and `x` have a sampling frequency `Fs`. The modulated signal has zero initial phase and zero carrier amplitude, so the result is suppressed-carrier modulation.

---

**Note** The value of `Fs` must satisfy  $Fs \geq 2Fc$ .

---

`y = ammod(x,Fc,Fs,ini_phase)` specifies the initial phase in the modulated signal `y` in radians.

`y = ammod(x,Fc,Fs,ini_phase,carramp)` performs transmitted-carrier modulation instead of suppressed-carrier modulation where `carramp` is the carrier amplitude of the modulated signal.

## Examples

### Compare Double-Sideband and Single-Sideband Amplitude Modulation

Set the sample rate to 100 Hz. Create a time vector 100 seconds long.

```
fs = 100;  
t = (0:1/fs:100)';
```

Set the carrier frequency to 10 Hz. Generate a sinusoidal signal.

```
fc = 10;  
x = sin(2*pi*t);
```

Modulate  $x$  using single- and double-sideband AM.

```
ydouble = ammod(x,fc,fs);  
ysingle = ssbmod(x,fc,fs);
```

Create a spectrum analyzer object to plot the spectra of the two signals. Plot the spectrum of the double-sideband signal.

```
sa = dsp.SpectrumAnalyzer('SampleRate',fs, ...  
    'PlotAsTwoSidedSpectrum',false, ...  
    'YLimits',[-60 40]);  
step(sa,ydouble)
```

Plot the single-sideband spectrum.

```
step(sa,ysingle)
```

## Input Arguments

### **x** — Input message signal

scalar | vector | matrix | 3-D array

Input message signal, specified as a scalar, vector, matrix, or a 3-D array. Each element of **x** must be real.

Data Types: `single` | `double`

### **Fc** — Carrier signal frequency

positive real scalar

Carrier signal frequency in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

### **Fs — Sampling frequency**

positive real scalar

Sampling frequency of carrier signal and input message signal in hertz (Hz), specified as a positive real scalar. To avoid aliasing, the value of  $F_s$  must satisfy  $F_s > 2(F_c + BW)$ , where  $BW$  is the bandwidth of  $x$ .

Data Types: `single` | `double`

### **ini\_phase — Initial phase**

real scalar

Initial phase of the modulated signal in radians, specified as a real scalar.

Data Types: `single` | `double`

### **carramp — Carrier amplitude**

real scalar

Carrier amplitude of the modulated signal, specified as a real scalar.

Data Types: `single` | `double`

## Output Arguments

### **y — Amplitude modulated output signal**

scalar | vector | matrix | 3-D array

Amplitude modulated signal, returned as a scalar, vector, matrix, or 3-D array.

## apskdemod

Amplitude phase shift keying (APSK) demodulation

### Syntax

```
z = apskdemod(y,M,radii)
z = apskdemod(y,M,radii,phaseoffset)
z = apskdemod( ____,Name,Value)
```

### Description

`z = apskdemod(y,M,radii)` performs APSK demodulation of the input signal `y`, based on the specified number of constellation points per PSK ring, `M`, and the radius of each PSK ring, `radii`. For a description of APSK demodulation, see “APSK Hard Demodulation” on page 2-31 and “APSK Soft Demodulation” on page 2-32.

---

**Note** `apskdemod` specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use `pskdemod`.

---

`z = apskdemod(y,M,radii,phaseoffset)` specifies an initial phase offset for each PSK ring of the APSK modulated signal.

`z = apskdemod( ____,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

### Examples

## Demodulate 16-APSK Signal

Demodulate a 16-APSK signal that has an unequal number of constellation points on each circle. Plot the received constellation.

Define vectors for modulation order and PSK ring radii. Generate random 16-ary data symbols.

```
M = [4 12];  
radii = [1 2];  
modOrder = sum(M);
```

```
x = randi([0 modOrder-1],1000,1);
```

Apply APSK modulation to the data.

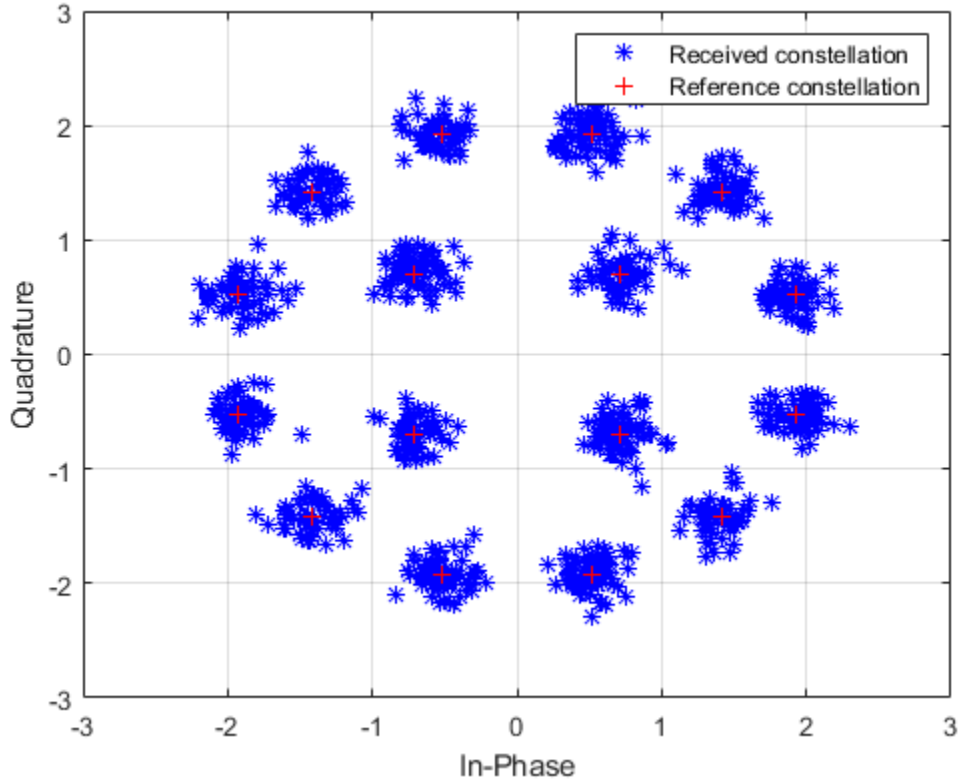

```
txSig = apskmod(x,M,radii);
```

Pass the modulated signal through a noisy channel.

```
snr = 20; % dB  
rxSig = awgn(txSig,snr,'measured');
```

Plot the transmitted (reference) signal points and the noisy received signal points.

```
plot(rxSig,'b*')  
hold on  
grid  
plot(txSig,'r+')  
xlim([-3 3])  
ylim([-3 3])  
xlabel('In-Phase')  
ylabel('Quadrature')  
legend('Received constellation','Reference constellation')
```

Demodulate the received signal and compare to the input data.

```
z = apskdemod(rxSig,M,radii);  
isequal(x,z)  
  
ans = logical  
1
```

## Demodulate 64-APSK Custom Symbol Mapped Signal

Demodulate a 64-APSK signal with custom symbol mapping. Compute hard decision bit output and verify that the input matches the output.

Define vectors for modulation order and PSK ring radii. Generate 100 symbols of random bit input.

```
M = [8 12 16 28]; % 4-PSK circles
modOrder = sum(M);
radii = [0.5 1 1.3 2];
x = randi([0 1],100*log2(modOrder),1);
```

Create a custom symbol mapping vector of binary mapping.

```
cmap = 0:63;
```

Modulate the data and plot the constellation.

```
y = apskmod(x,M,radii,'SymbolMapping',cmap,'inputType','bit', ...
    'PlotConstellation',true);
```

## Soft Bit Demodulate 32-APSK Signal

Demodulate a 32-APSK signal and calculate soft bits.

Define vectors for modulation order and PSK ring radii. Generate 10000 symbols of random bit data.

```
M = [16 16];  
modOrder = sum(M);  
radii = [0.6 1.2];  
numSym = 10000;  
x = randi([0 1], numSym*log2(modOrder),1);
```

Generate a reference constellation. Create a constellation diagram object.

```
refAPSK = apskmod(0:modOrder-1,M,radii);  
constDiagAPSK = comm.ConstellationDiagram('ReferenceConstellation',refAPSK, ...  
    'Title','Received Symbols','XLimits',[-2 2],'YLimits',[-2 2]);
```

Modulate the data.

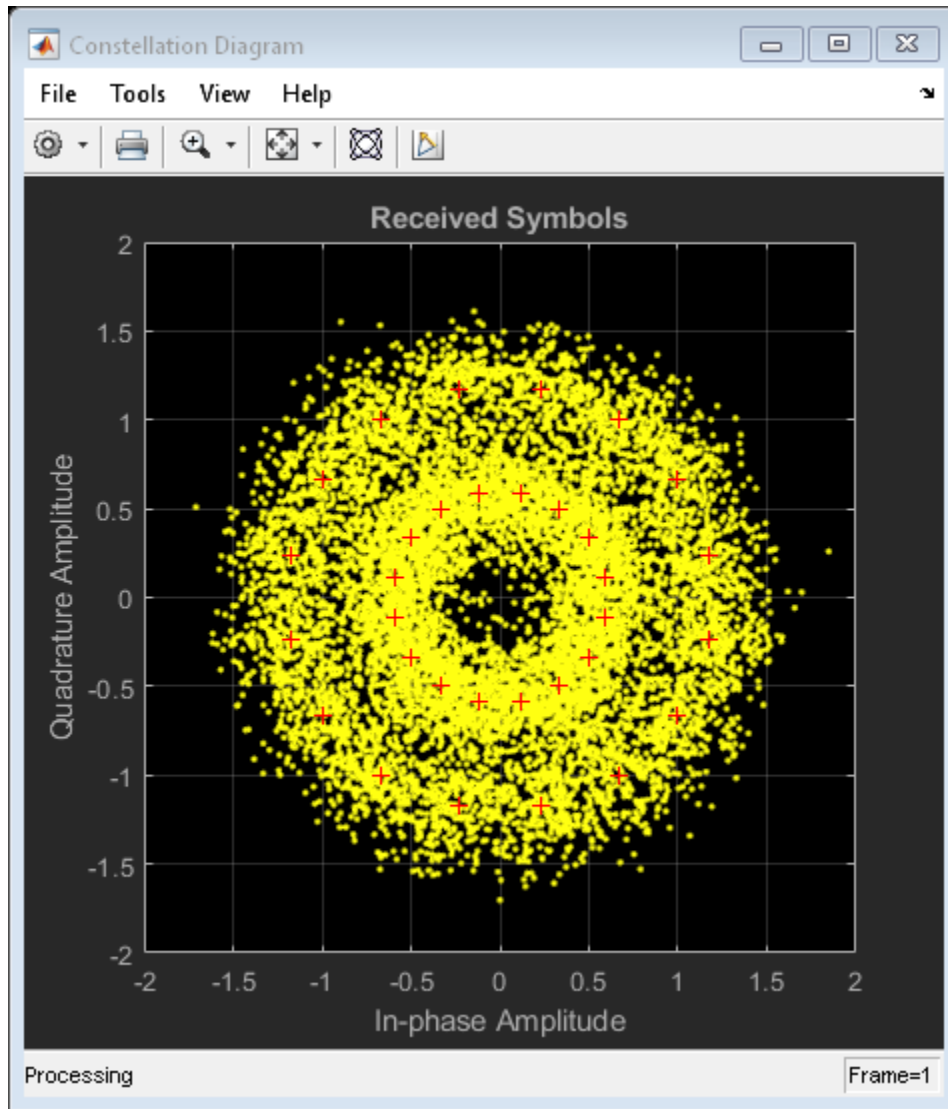

```
txSig = apskmod(x,M,radii,'InputType','bit');  
sigPow = var(txSig);
```

Pass the signal through a noisy channel.

```
snr = 15;  
rxSig = awgn(txSig,snr,sigPow,'linear');
```

Plot the reference and received constellation symbols.

```
constDiagAPSK(rxSig)
```

Demodulate the signal and compute soft bits.

```
z = apskdemod(rxSig,M,radii,'OutputType','approxllr', ...
    'NoiseVariance',sigPow/snr);
```

## Input Arguments

### **y** — APSK modulated signal

scalar | vector | matrix

APSK modulated signal, specified as a complex scalar, vector, or matrix. Each column is treated as an independent channel.

Data Types: double | single  
Complex Number Support: Yes

### **M** — Constellation points per PSK ring

vector

Constellation points per PSK ring, specified as a vector with more than one element. Vector elements indicate the number of constellation points in each PSK ring. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. Element values must be multiples of four and  $\text{sum}(M)$  must be a power of two. The modulation order is the total number of points in the signal constellation and equals the sum of the vector elements,  $\text{sum}(M)$ .

Example: [4 12 16] specifies a three PSK ring constellation with a modulation order of  $\text{sum}(M) = 32$ .

Data Types: double

### **radii** — PSK ring radii

vector

PSK ring radii, specified as a vector with the same length as  $M$ . The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. The elements must be positive and arranged in increasing order.

Example: [0.5 1 2] defines constellation PSK ring radii. The inner ring has a radius of 0.5, the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.

Data Types: double

### **phaseoffset** — PSK ring phase offsets

[ $\pi/M(1)$   $\pi/M(2)$  ...  $\pi/M(\text{end})$ ] (default) | scalar | vector

Phase offset of each PSK ring in radians, specified as a scalar or vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. The `phaseoffset` can be a scalar only if all the elements of `M` are the same value.

Example: `[pi/4 pi/12 pi/16]` defines three constellation PSK ring phase offsets. The inner ring has a phase offset of `pi/4`, the second ring has a phase offset of `pi/12`, and the outer ring has a phase offset of `pi/16`.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `y = apskdemod(x,M,radii,'OutputType','bit','OutputDataType','single');`

### SymbolMapping — Symbol mapping

`'gray'` | `'contourwise-gray'` | integer vector

Symbol mapping, specified as the comma-separated pair consisting of `SymbolMapping` and one of the following:

- `'contourwise-gray'` — Uses Gray mapping along the contour in phase dimension.
- `'gray'` — Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for `M` must be equal and all the values for `phaseoffset` must be equal. For a description of the Gray mapping used, see [2].
- integer vector — Use custom symbol mapping. Vector must consist of `sum(M)` unique elements with values from 0 to `(sum(M) - 1)`. The first element corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

The default symbol mapping depends on `M` and `phaseOffset`. When all the elements of `M` and `phaseOffset` are equal, the default is `'gray'`. For all other cases, the default is `'contourwise-gray'`.

Data Types: `double` | `char` | `string`

**OutputType — Output type**`'integer' (default) | 'bit' | 'llr' | 'approxllr'`

Output type, specified as the comma-separated pair consisting of `OutputType` and `'integer'`, `'bit'`, `'llr'`, or `'approxllr'`. For a description of the returned output, see `z`.

Data Types: `char` | `string`

**OutputDataType — Output data type**`'double' (default) | ...`

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and one of the indicated data types. Acceptable values for `OutputDataType` depend on the `OutputType` value.

<b>OutputType Value</b>	<b>Acceptable OutputDataType Values</b>
<code>'integer'</code>	<code>'double'</code> , <code>'single'</code> , <code>'int8'</code> , <code>'int16'</code> , <code>'int32'</code> , <code>'uint8'</code> , <code>'uint16'</code> , or <code>'uint32'</code>
<code>'bit'</code>	<code>'double'</code> , <code>'single'</code> , <code>'int8'</code> , <code>'int16'</code> , <code>'int32'</code> , <code>'uint8'</code> , <code>'uint16'</code> , <code>'uint32'</code> , or <code>'logical'</code>

**Dependencies**

This name-value pair argument applies only when `OutputType` is set to `'integer'` or `'bit'`.

Data Types: `char` | `string`

**NoiseVariance — Noise variance**`1 (default) | positive scalar | vector of positive values`

Noise variance, specified as the comma-separated pair consisting of `NoiseVariance` and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “APSK Soft Demodulation” on page 2-32 for algorithm selection considerations.

**Dependencies**

This name-value pair argument applies only when `OutputType` is set to `'llr'` or `'approxllr'`.

Data Types: `double`

**PlotConstellation — Option to plot constellation**

`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

## Output Arguments

**z — Demodulated signal**

`scalar` | `vector` | `matrix`

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of `z` depend on the specified `OutputType` value.

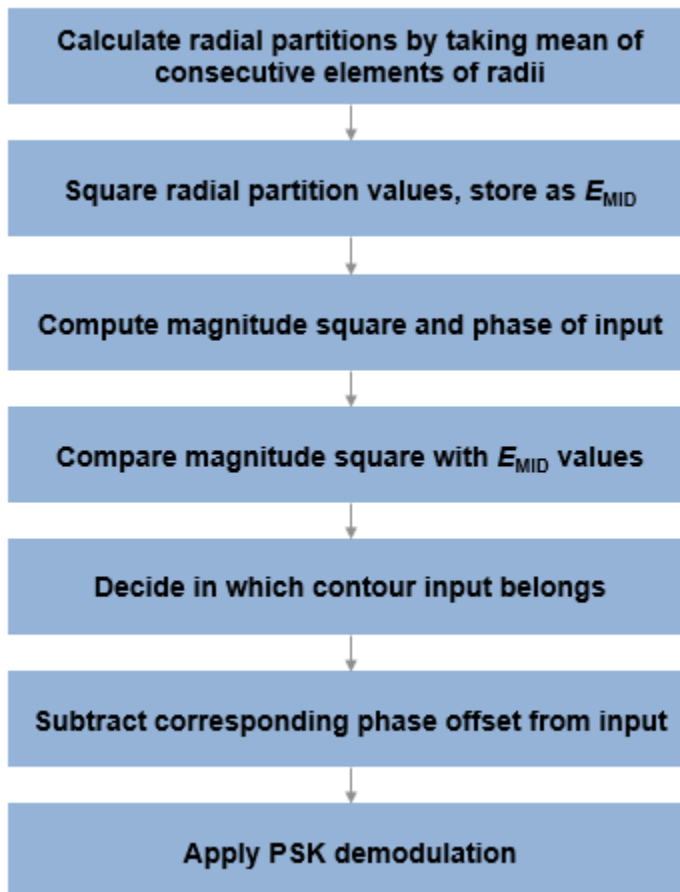

OutputType Value	Return Value of <code>apskdemod</code>	Dimensions of <code>z</code>
<code>'integer'</code>	Demodulated integer values from 0 to $(\text{sum}(M) - 1)$	<code>z</code> has the same dimensions as input <code>y</code> .
<code>'bit'</code>	Demodulated bits	The number of rows in <code>z</code> is $\log_2(\text{sum}(M))$ times the number of rows in <code>y</code> . Each demodulated symbol is mapped to a group of $\log_2(\text{sum}(M))$ elements in a column, where the first element represents the MSB and the last element represents the LSB.
<code>'llr'</code>	Log-likelihood ratio value for each bit	
<code>'approxllr'</code>	Approximate log-likelihood ratio value for each bit	

## More About

### APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [1].

## APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

---

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or -Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

---

# apskmod

Amplitude phase shift keying (APSK) modulation

## Syntax

```
y = apskmod(x,M,radii)
y = apskmod(x,M,radii,phaseoffset)
y = apskmod( ____,Name,Value)
```

## Description

`y = apskmod(x,M,radii)` performs APSK modulation on the input data, `x`, based on the specified number of constellation points per PSK ring, `M`, and the radius of each PSK ring, `radii`. For a description of APSK modulation, see “Algorithms” on page 2-44.

---

**Note** `apskmod` specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use `pskmod`.

---

`y = apskmod(x,M,radii,phaseoffset)` specifies an initial phase offset for each PSK ring of the APSK modulated signal.

`y = apskmod( ____,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

## Examples

### Apply APSK Modulation

Modulate data using APSK with an unequal number of constellation points on each circle.

Define vectors for modulation order and PSK ring radii. Generate data for constellation points.

```
M = [4 8 20];  
radii = [0.3 0.7 1.2];  
modOrder = sum(M);  
x = 0:modOrder-1;
```

Apply APSK modulation to the data.

```
y = apskmod(x,M,radii);
```

Plot the resulting constellation using a scatter plot.

```
scatterplot(y)
```

**Apply APSK Modulation with Phase Offset**

Modulate a random data sequence using APSK with zero phase offset for the inner circle and  $\pi/6$  phase offset for the outer circle.

Define vectors for modulation order, PSK ring radii, and PSK ring phase offset. Generate random data.

```
M = [8 8];  
modOrder = sum(M);  
radii = [0.5 1];  
phOff = [0 pi/6];  
  
x = randi([0 modOrder-1],100,1);
```

Apply APSK modulation to the data.

```
y = apskmod(x,M,radii,phOff);
```

Plot the resulting constellation using a scatter plot and observe the phase offset between the constellation circles.

```
scatterplot(y)
```

### Apply APSK Modulation Modifying Symbol Ordering

Plot APSK constellations for gray and custom symbol mappings.

Define vectors for modulation order and PSK ring radii. Generate bit data for constellation points.

```
M = [8 8];  
modOrder = sum(M);  
radii = [0.5 1.5];  
x = 0:modOrder-1;  
xBit = de2bi(x);
```

Apply APSK modulation to the data using the default phase offset. Since element values for M are equal and element values for phase offset are equal, the symbol mapping defaults to 'gray'. Binary input is used to highlight the Gray nature of the constellation. Plot the constellation.

```
y = apskmod(xBit,M,radii,'PlotConstellation',true,'InputType','bit');
```

Create a custom symbol mapping vector. This custom mapping happens to be another Gray mapping.

```
cmap = [0;1;9;8;12;13;5;4;2;3;11;10;14;15;7;6];
```

Apply APSK modulation with a custom symbol mapping. Plot the constellation. Binary input is used to highlight that the custom mapping defines different Gray symbol mapping.

```
z = apskmod(xBit,M,radii,'SymbolMapping',cmap,'PlotConstellation',true,'InputType','bi
```

### Apply APSK Modulation to Input Bits

Modulate a random bit sequence using APSK and output data type `single`. Pass the signal through a noisy channel and display the constellation diagram.

Define vectors for modulation order and PSK ring radii. Generate random binary data.

```
M = [8 12 20 24];  
radii = [0.8 1.2 2 2.5];  
bitsPerSym = log2(sum(M));
```

```
x = randi([0 1],2000*bitsPerSym,1);
```

Apply APSK modulation to the data and use a name-value pair to output as data type `single`.

```
y = apskmod(x,M,radii, 'InputType', 'bit', 'OutputDataType', 'single');
```

Pass through an AWGN channel with a 25 dB SNR.

```
yrec = awgn(y,25, 'measured');
```

Plot the received constellation as a scatter plot.

```
scatterplot(yrec)
```

## Input Arguments

### **x** — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of  $x$  must be binary values or integers in the range  $[0, (\text{sum}(M) - 1)]$ .

---

**Note** To process the input signal as binary elements, set the 'InputType' name-value pair to 'bit'. For binary inputs, the number of rows must be an integer multiple of

$\log_2(\text{sum}(M))$ . Groups of  $\log_2(\text{sum}(M))$  bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

### **M — Constellation points per PSK ring**

vector

Constellation points per PSK ring, specified as a vector with more than one element. Each vector element indicates the number of constellation points in its corresponding PSK ring. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. Element values must be multiples of four and  $\text{sum}(M)$  must be a power of two. The modulation order is the total number of points in the signal constellation and equals the sum of the vector elements,  $\text{sum}(M)$ .

Example: `[4 12 16]` specifies a three PSK ring constellation with a modulation order of  $\text{sum}(M) = 32$ .

Data Types: `double`

### **radii — Radius per PSK ring**

vector

Radius per PSK ring, specified as a vector with the same length as  $M$ . The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. The elements must be positive and arranged in increasing order.

Example: `[0.5 1 2]` defines radii for three constellation PSK rings. The inner ring has a radius of 0.5, the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.

Data Types: `double`

### **phaseoffset — Phase offset per PSK ring**

`[pi/M(1) pi/M(2) ... pi/M(end)]` (default) | `scalar` | `vector`

Phase offset per PSK ring in radians, specified as a scalar or vector with the same length as  $M$ . The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. The `phaseoffset` can be a scalar only if all the elements of  $M$  are the same value.

Example: `[pi/4 pi/12 pi/16]` defines three constellation PSK ring phase offsets. The inner ring has a phase offset of  $\pi/4$ , the second ring has a phase offset of  $\pi/12$ , and the outer ring has a phase offset of  $\pi/16$ .

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `y = apskmod(x,M,radii,'InputType','bit','OutputDataType','single');`

### SymbolMapping — Symbol mapping

'gray' | 'contourwise-gray' | integer vector

Symbol mapping, specified as the comma-separated pair consisting of 'SymbolMapping' and one of the following:

- 'contourwise-gray' — Uses Gray mapping along the contour in the phase dimension for each PSK ring.
- 'gray' — Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for `M` must be equal and all the values for `phaseOffset` must be equal. For a description of the Gray mapping used, see [2].
- integer vector — Use custom symbol mapping. Vector must consist of `sum(M)` unique elements with values in the range `[0, (sum(M) - 1)]`. The first element corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

The default symbol mapping depends on `M` and `phaseOffset`. When all the elements of `M` are equal and all the elements of `phaseOffset` are equal, the default is 'gray'. For all other cases, the default is 'contourwise-gray'.

Data Types: double | char | string

### InputType — Input type

'integer' (default) | 'bit'

Input type, specified as the comma-separated pair consisting of 'InputType' and either 'integer' or 'bit'. To use 'integer', the input signal must consist of integers in the range  $[0, (\text{sum}(M) - 1)]$ . To use 'bit', the input signal must contain binary values and the number of rows must be an integer multiple of  $\log_2(\text{sum}(M))$ .

Data Types: char | string

### **OutputDataType — Output data type**

'double' (default) | 'single'

Output data type, specified as the comma-separated pair consisting of 'OutputDataType' and either 'double' or 'single'.

Data Types: char | string

### **PlotConstellation — Plot reference constellation**

false (default) | true

Plot reference constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the reference constellation, set PlotConstellation to true.

Data Types: logical

## **Output Arguments**

### **y — APSK modulated signal**

scalar | vector | matrix

APSK modulated signal, returned as a complex scalar, vector, or matrix. The dimensions of y depend on the specified 'InputType' value.

<b>InputType</b>	<b>Dimensions of y</b>
'integer'	y has the same dimensions as input x.
'bit'	The number of rows in y equals the number of rows in x divided by $\log_2(\text{sum}(M))$ .

## **Algorithms**

The function implements a pure APSK constellation.

A pure M-APSK constellation is composed of  $N_C$  concentric rings or contours, each with uniformly spaced PSK points. The M-APSK constellation set is

$$\chi = \left\{ \begin{array}{ll} R_1 \exp \left( j \left( \frac{2\pi}{M_1} i + \theta_1 \right) \right), & i = 0, \dots, M_1 - 1, \\ R_2 \exp \left( j \left( \frac{2\pi}{M_2} i + \theta_2 \right) \right), & i = 0, \dots, M_2 - 1, \\ \vdots & \vdots \\ R_{N_C} \exp \left( j \left( \frac{2\pi}{M_{N_C}} i + \theta_{N_C} \right) \right), & i = 0, \dots, M_{N_C} - 1, \end{array} \right.$$

where

- The modulation order is equal to the sum of all  $M_l$  for  $l = 1, 2, \dots, N_C$ .
- $N_C$  is the number of concentric rings.  $N_C \geq 2$ .
- $M_l$  is the number of constellation points in the  $l$ th ring.
- $R_l$  is the radius of the  $l$ th ring.
- $\theta_l$  is the phase offset of the  $l$ th ring.
- $j = \sqrt{-1}$

## arithdeco

Decode binary code using arithmetic decoding

### Syntax

```
dseq = arithdeco(code,counts,len)
```

### Description

`dseq = arithdeco(code,counts,len)` decodes the binary arithmetic code in the vector `code` to recover the corresponding sequence of `len` symbols. The vector `counts` represents the source's statistics by listing the number of times each symbol of the source's alphabet occurs in a test data set. This function assumes that the data in `code` was produced by the `arithenco` function.

### Examples

#### Decode Sequence Using Arithmetic Code

Set the `counts` vector so that a one occurs 99% of the time.

```
counts = [99 1];
```

Set the sequence length to 1000. Generate a random sequence.

```
len = 1000;  
seq = randsrc(1,len,[1 2; .99 .01]);
```

Arithmetically encode the random sequence then, decode the encoded sequence.

```
code = arithenco(seq,counts);  
dseq = arithdeco(code,counts,length(seq));
```

Verify that the decoded sequence matches the original sequence.

```
isequal(seq,dseq)
```

```
ans = logical  
     1
```

## Algorithms

This function uses the algorithm described in [1].

# arithenco

Encode sequence of symbols using arithmetic coding

## Syntax

```
code = arithenco(seq,counts)
```

## Description

`code = arithenco(seq,counts)` generates the binary arithmetic code corresponding to the sequence of symbols specified in the vector `seq`. The vector `counts` represents the source's statistics by listing the number of times each symbol of the source's alphabet occurs in a test data set.

## Examples

### Encode Data Sequence with Arithmetic Code

This example illustrates the compression that arithmetic coding can accomplish in some situations. A source has a two-symbol alphabet and produces a test data set in which 99% of the symbols are 1s. Encoding 1000 symbols from this source produces a code vector having fewer than 1000 elements. The actual number of elements in encoded sequence varies depending on the particular random sequence.

Set `counts` so that a one occurs 99% of the time.

```
counts = [99 1];
```

Generate a random data sequence of length 1000.

```
len = 1000;  
seq = randsrc(1,len,[1 2; .99 .01]);
```

Encode the sequence and display the encoded length.

```
code = arithenco(seq,counts);  
s = size(code)  
  
s = 1×2  
    1    57
```

The length of the encoded sequence is only 5.7% of the length of the original sequence.

## Algorithms

This function uses the algorithm described in [1].

## awgn

Add white Gaussian noise to signal

### Syntax

```
out = awgn(in,snr)
out = awgn(in,snr,signalpower)

out = awgn(in,snr,signalpower,randobject)
out = awgn(in,snr,signalpower,seed)
out = awgn( ____,powertype)
```

### Description

`out = awgn(in,snr)` adds white Gaussian noise to the vector signal `in`. This syntax assumes that the power of `in` is 0 dBW.

`out = awgn(in,snr,signalpower)` accepts an input signal power value in dBW. To have the function measure the power of `in` before adding noise, specify `signalpower` as 'measured'.

`out = awgn(in,snr,signalpower,randobject)` accepts input combinations from prior syntaxes and a random number stream object to generate normal random noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-59.

`out = awgn(in,snr,signalpower,seed)` specifies a seed value for initializing the normal random number generator that is used when adding white Gaussian noise to the input signal. For information about producing repeatable noise samples, see “Tips” on page 2-59.

`out = awgn( ____,powertype)` specifies the signal and noise power type as 'dB' or 'linear' in addition to the input arguments in any of the previous syntaxes.

For the relationships between SNR and other measures of the relative power of the noise, such as  $E_s/N_0$ , and  $E_b/N_0$ , see “AWGN Channel Noise Level”.

## Examples

### Add AWGN to Sawtooth Signal

Create a sawtooth wave.

```
t = (0:0.1:10)';  
x = sawtooth(t);
```

Apply white Gaussian noise and plot the results.

```
y = awgn(x,10, 'measured');  
plot(t,[x y])  
legend('Original Signal', 'Signal with AWGN')
```

### General QAM Modulation in AWGN Channel

Transmit and receive data using a nonrectangular 16-ary constellation in the presence of Gaussian noise. Show the scatter plot of the noisy constellation and estimate the symbol error rate (SER) for two different signal-to-noise ratios.

Create a 16-QAM constellation based on the V.29 standard for telephone-line modems.

```
c = [-5 -5i 5 5i -3 -3-3i -3i 3-3i 3 3+3i 3i -3+3i -1 -1i 1 1i];
M = length(c);
```

Generate random symbols.

```
data = randi([0 M-1],2000,1);
```

Modulate the data by using the `genqammod` function. General QAM modulation is necessary because the custom constellation is not rectangular.

```
modData = genqammod(data,c);
```

Pass the signal through an AWGN channel having a 20 dB signal-to-noise ratio (SNR).

```
rxSig = awgn(modData,20, 'measured');
```

Display a scatter plot of the received signal and the reference constellation, `c`.

```
h = scatterplot(rxSig);  
hold on  
scatterplot(c,[],[], 'r*',h)  
grid  
hold off
```

Demodulate the received signal by using the `genqamdemod` function. Determine the number of symbol errors and the symbol error ratio.

```
demodData = genqamdemod(rxSig,c);  
[numErrors,ser] = symerr(data,demodData)
```

```
numErrors = 1
```

```
ser = 5.0000e-04
```

Repeat the transmission and demodulation process with an AWGN channel having a 10 dB SNR. Determine the symbol error rate for the reduced SNR. As expected, the performance degrades when the SNR is decreased.

```
rxSig = awgn(modData,10, 'measured');
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)

numErrors = 462

ser = 0.2310
```

### Repeatable AWGN with RandStream

Generate white Gaussian noise addition results using a `RandStream` object and “Class” (MATLAB).

Specify the power of  $X$  to be 0 dBW, add noise to produce an SNR of 10 dB, and utilize a local random stream.

```
S = RandStream('mt19937ar', 'Seed',5489);
signin = sqrt(2)*sin(0:pi/8:6*pi);
sigout1 = awgn(signin,10,0,S);
```

Add AWGN to `signin`. Use `isequal` to compare `sigout1` to `sigout2`. The outputs are not equal when the random stream was not reset.

```
sigout2 = awgn(signin,10,0,S);
isequal(sigout1,sigout2)
```

```
ans = logical
     0
```

Reset the random stream object, returning the object to its state prior to adding AWGN to `sigout1`. Add AWGN to `signin` and compare `sigout1` to `sigout3`. The outputs are equal after the random stream was reset.

```
reset(S);
sigout3 = awgn(signin,10,0,S);
isequal(sigout1,sigout3)
```

```
ans = logical
     1
```

## Input Arguments

### **in** — Input signal

scalar | vector | array

Input signal, specified as a scalar, vector, or array. The power of the input signal is assumed to be 0 dBW.

Data Types: double

Complex Number Support: Yes

### **snr** — Signal-to-noise ratio

scalar

Signal-to-noise ratio in dB, specified as a scalar.

---

**Note** When the noise is added, this function applies the same `snr` to all elements of the full input signal. Array input signals do not have a notion of independent channels. To consider multiple channels independently, see `comm.AWGNChannel`.

---

Data Types: double

### **signalpower** — Signal power

scalar | 'measured'

Signal power, specified as a scalar or 'measured'.

- When `signalpower` is a scalar, the value is used as the signal level of `in` to determine the appropriate noise level based on the value of `snr`.
- When `signalpower` is 'measured', the signal level of `in` is computed to determine the appropriate noise level based on the value of `snr`.

---

**Note** When you specify 'measured', this function computes the signal power using all elements of the full input signal. When the power is computed, array input signals do not have a notion of independent channels.

---

Data Types: double

### **randobject** — Random number stream object

RandStream object

Random number stream object, specified as a `RandStream` object. The state of the random stream object determines the sequence of numbers produced by the `randn` function. Configure the random stream object using the `reset` function and its properties.

`wgn` generates normal random noise samples using `randn`. The `randn` function uses one or more uniform values from the `RandStream` object to generate each normal value.

For information about producing repeatable noise samples, see “Tips” on page 2-59.

### **seed — Random number generator seed**

scalar

Random number generator seed value, specified as a scalar.

Data Types: `double`

### **powertype — Signal power unit**

'dB' (default) | 'linear'

Signal power unit, specified as 'dB' or 'linear'

- When `powertype` is 'dB', the `snr` is measured in dB and `signalpower` is measured in dBW.
- When `powertype` is 'linear', the `snr` is measured as a ratio and `signalpower` is measured in watts.

For the relationships between SNR and other measures of the relative power of the noise, such as  $E_s/N_0$ , and  $E_b/N_0$ , see “AWGN Channel Noise Level”.

## **Output Arguments**

### **out — Output signal**

scalar | vector | array

Output signal, returned as a scalar, vector, or array. The returned output signal is the input signal with white Gaussian noise added to it.

## Tips

- To generate repeatable white Gaussian noise samples, use one of these tips:
  - Provide a static seed value as an input to `wgn`.
  - Use the `reset` function on the `randobject` before passing it as an input to `awgn`.
  - Provide `randobject` in a known state as an input to `awgn`. For more information, see `RandStream`.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation supported, except for syntaxes that include a `RandStream` object.

# bchdec

BCH decoder

## Syntax

```
decoded = bchdec(code,N,K)
decoded = bchdec(code,N,K,paritypos)
[decoded,cnumerr] = bchdec( ___ )
[decoded,cnumerr,ccode] = bchdec( ___ )
```

## Description

`decoded = bchdec(code,N,K)` attempts to decode the received signal in `code` using an (N,K) BCH decoder with the narrow-sense generator polynomial. Parity symbols are at the end and the leftmost symbol is the most significant symbol.

In the `decoded` Galois array, each row represents the attempt at decoding the corresponding row in `code`.

`decoded = bchdec(code,N,K,paritypos)` specifies in `paritypos` whether the parity symbols in `code` were appended or prepended to the message in the coding operation.

`[decoded,cnumerr] = bchdec( ___ )` returns a column vector, `cnumerr`, where each element is the number of corrected errors in the corresponding row of `code`. You can return `cnumerr` with either of the preceding syntaxes.

`[decoded,cnumerr,ccode] = bchdec( ___ )` returns `ccode`, the corrected version of `code`.

## Examples

## Results of Error Correction

BCH-decode an input that has more errors per codeword than the error correcting capability of the BCH decoder. Decode a BCH coded message with two errors per codeword using a single-error correcting BCH decoder. View the effects of the error mismatch on the output codeword.

Check the number of errors per codeword a [63,57] BCH decoder is capable of correcting.

```
n = 63;
k = 57;
t = bchnumerr(n,k)
```

```
t = 1
```

The [63,57] BCH decoder is capable of correcting one error per codeword.

Create a random stream and use it to generate a GF array. Encode the message.

```
s = RandStream('swb2712','Seed',9973);
msg = gf(randi(s,[0 1],1,k));
code = bchenc(msg,n,k);
```

Add two errors per codeword and decode the errored code.

```
cnumerr2 = zeros(nchoosek(n,2),1);
nErrs = zeros(nchoosek(n,2),1);
cnumerrIdx = 1;
for idx1 = 1 : n-1
    %sprintf('idx1 for 2 errors = %d', idx1)
    for idx2 = idx1+1 : n
        errors = zeros(1,n);
        errors(idx1) = 1;
        errors(idx2) = 1;
        erroredCode = code + gf(errors);
        [decoded2, cnumerr2(cnumerrIdx)] ...
            = bchdec(erroredCode,n,k);
```

Encode the decoded message. Check that the re-encoded message differs from the errored message in only one bit.

```
if cnumerr2(cnumerrIdx) == 1
    code2 = bchenc(decoded2,n,k);
    nErrs(cnumerrIdx) = biterr(double(erroredCode.x), ...
```

```
        double(code2.x));  
    end  
    cnumerrIdx = cnumerrIdx + 1;  
end  
end
```

Plot the computed number of errors, based on the difference between the doubly-errored code and the re-encoded version of the initial decoding.

```
plot(nErrs)  
title('Number of Actual Errors')
```

All inputs with two errors were decoded to a codeword that differs in exactly one bit from the re-encoded version.

## Decode Received BCH Codeword in Noisy Channel

Set the BCH parameters for a Galois array of GF(2).

```
M = 4;
n = 2^M-1; % Codeword length
k = 5; % Message length
nwords = 10; % Number of words to encode
```

Create a message.

```
msgTx = gf(randi([0 1],nwords,k));
```

Find the error-correction capability.

```
t = bchnumerr(n,k)
```

```
t = 3
```

Encode the message.

```
enc = bchenc(msgTx,n,k);
```

Corrupt up to t bits in each codeword.

```
noisycode = enc + randerr(nwords,n,1:t);
```

Decode the noisy code.

```
msgRx = bchdec(noisycode,n,k);
```

Validate that the message was properly decoded.

```
isequal(msgTx,msgRx)
```

```
ans = logical
      1
```

Increase the number of possible errors, and generate another noisy codeword.

```
t2 = t + 1;
noisycode2 = enc + randerr(nwords,n,1:t2);
```

Decode the new received codeword.

```
[msgRx2,numerr] = bchdec(noisycode2,n,k);
```

Determine if the message was properly decoded by examining the number of corrected errors, `numerr`. Entries of -1 correspond to decoding failures, which occur when the codeword has more errors than can be corrected for the specified `[n,k]` pair.

```
numerr
```

```
numerr = 10x1
```

```
1  
2  
-1  
2  
3  
1  
-1  
4  
2  
3
```

Two of the ten transmitted codewords were not correctly received.

## Input Arguments

### **code** — Encoded message

Galois array

Encoded message, specified as a Galois array of symbols over GF(2). Each N-element row of `code` represents a corrupted systematic codeword.

For more information, see “Creating a Galois field array”.

### **N** — Codeword length

integer

Codeword length, specified as an integer of the form  $N = 2^M - 1$ , where  $M$  is an integer from 3 to 16. See “Tips” on page 2-66 for information about valid N values, valid (N,K) pairs, and error correcting capabilities for a given BCH code.

Example: 15 for  $M=4$

### **K — Message length**

integer

Message length, specified as an integer.  $N$  and  $K$  must produce a narrow-sense BCH code.

Example: 5 specifies a Galois array with five elements.

### **paritypos — Parity position**

'end' (default) | 'beginning'

Parity position, specified as 'end' or 'beginning'. Parity symbols are at the end or beginning of each word in the output Galois array. If `paritypos` is 'beginning', then a decoding failure causes `bchdec` to remove  $N-K$  symbols from the beginning rather than the end of the row.

## **Output Arguments**

### **decoded — Decoded message**

Galois array of symbols over  $GF(2)$

Decoded message, returned as a Galois array of symbols over  $GF(2)$ . Each row represents the attempt at decoding the corresponding row in `code`. A decoding failure occurs if `bchdec` detects more than  $T$  errors in a row of `code`, where  $T$  is the number of errors per codeword that the decoder is capable of correcting. When a decoding failure occurs, `bchdec` forms the corresponding row of `decoded` by removing  $N-K$  symbols from the end of the row of `code`. For more information, see “Error Correcting Capability” on page 2-66.

### **numerr — Number of corrected errors**

column vector

Number of corrected errors in the corresponding row of `code`, returned as a column vector. A value of -1 in `numerr` indicates a decoding failure in that row in `code`.

### **ccode — Corrected version of code**

Galois array

Corrected version of code, returned as a Galois array. `ccode` has the same format as the input `code`. If a decoding failure occurs in a certain row of `code`, the corresponding row in `ccode` contains that row unchanged.

## More About

### Error Correcting Capability

BCH decoders correct up to a specified number of errors per codeword based on the (N,K) pair used to BCH encode that message. The error correcting capability,  $T$ , of a given (N,K) pair is returned by `bchnumerr`. See “Tips” on page 2-66 for information about valid N values, valid (N,K) pairs, and error correcting capabilities for a given BCH code.

If the coded message contains more errors per codeword than the decoder is capable of correcting, the decoder is unlikely to decode to the correct codeword. For example, when a single-error-correcting BCH decoder ( $T=1$ ) is given an input with two errors per codeword, it decodes it to a valid codeword but not the correct codeword. When a double-error-correcting BCH decoder ( $T=2$ ) is given an input with three errors per codeword, the decoder sometimes decodes to an invalid codeword. The `cnumerr` and `ccode` output provide feedback to analyze the correctness of the decoded message.

### Tips

- To generate the list of valid (N,K) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.
- Valid values for  $N = 2^M - 1$ , where  $M$  is an integer from 3 through 16. The maximum allowable value of N is 65,535.

### Algorithms

`bchdec` uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see the works listed in “References” on page 2-67.

## bchenc

BCH encoder

### Syntax

```
code = bchenc(msg,N,K)
code = bchenc(msg,N,K,paritypos)
```

### Description

`code = bchenc(msg,N,K)` encodes the input message using an (N,K) BCH encoder that uses a narrow-sense generator polynomial. For a description of Bose-Chaudhuri-Hocquenghem (BCH) coding, see [1].

`code = bchenc(msg,N,K,paritypos)` appends or prepends the parity symbols to the encoded input message to form the output.

### Examples

#### Decode Received BCH Codeword in Noisy Channel

Set the BCH parameters for a Galois array of GF(2).

```
M = 4;
n = 2^M-1; % Codeword length
k = 5; % Message length
nwords = 10; % Number of words to encode
```

Create a message.

```
msgTx = gf(randi([0 1],nwords,k));
```

Find the error-correction capability.

```
t = bchnumerr(n,k)
```

```
t = 3
```

Encode the message.

```
enc = bchenc(msgTx,n,k);
```

Corrupt up to *t* bits in each codeword.

```
noisycode = enc + randerr(nwords,n,1:t);
```

Decode the noisy code.

```
msgRx = bchdec(noisycode,n,k);
```

Validate that the message was properly decoded.

```
isequal(msgTx,msgRx)
```

```
ans = logical
      1
```

Increase the number of possible errors, and generate another noisy codeword.

```
t2 = t + 1;
noisycode2 = enc + randerr(nwords,n,1:t2);
```

Decode the new received codeword.

```
[msgRx2,numerr] = bchdec(noisycode2,n,k);
```

Determine if the message was properly decoded by examining the number of corrected errors, *numerr*. Entries of -1 correspond to decoding failures, which occur when the codeword has more errors than can be corrected for the specified [*n*, *k*] pair.

```
numerr
```

```
numerr = 10×1
```

```
      1
      2
     -1
      2
      3
      1
     -1
```

4  
2  
3

Two of the ten transmitted codewords were not correctly received.

## Input Arguments

### **msg — Message to encode**

Galois array of symbols over GF(2)

Message to encode, specified as a Galois array of symbols over GF(2). Each K-element row of `msg` represents a message word, where the leftmost symbol is the most significant symbol.

For more information, see “Creating a Galois field array”.

Example: `msgTx = gf(randi([0 1],10,5))`, where `msgTx` is a 10-by-5 gf array.

### **N — Codeword length**

integer

Codeword length, specified as an integer of the form  $N = 2^M - 1$ , where  $M$  is an integer from 3 through 16. For more information, see “Tips” on page 2-71.

Example: 15 for  $M=4$

### **K — Message length**

integer

Message length, specified as an integer.  $N$  and  $K$  must produce a narrow-sense BCH code.

Example: 5 specifies a Galois array with five elements

### **paritypos — Parity position**

'end' (default) | 'beginning'

Parity position, specified as 'end' or 'beginning'. Parity symbols are at the end or beginning of each word in the output Galois array.

## Output Arguments

### code — Encoded message

Galois array

Encoded message, returned as a Galois array. Parity symbols are at the end or beginning of each word in the output Galois array. To specify the position of the parity symbols, use the `paritypos` argument.

## Tips

- To generate the list of valid (N,K) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.
- Valid values for  $N = 2^M - 1$ , where  $M$  is an integer from 3 through 16. The maximum allowable value of  $N$  is 65,535.

## bchgenpoly

Generator polynomial of BCH code

### Syntax

```
genpoly = bchgenpoly(n,k)
genpoly = bchgenpoly(n,k,prim_poly)
genpoly = bchgenpoly(n,k,prim_poly,outputFormat)
[genpoly,t] = bchgenpoly(...)
```

### Description

`genpoly = bchgenpoly(n,k)` returns the narrow-sense generator polynomial of a BCH code with codeword length  $n$  and message length  $k$ . The codeword length  $n$  must have the form  $2^m-1$  for some integer  $m$  between 3 and 16. The output `genpoly` is a Galois row vector that represents the coefficients of the generator polynomial in order of descending powers. The narrow-sense generator polynomial is  $\text{LCM}[m_1(x), m_2(x), \dots, m_t(x)]$ , where:

- $\text{LCM}$  represents the least common multiple,
- $m_i(x)$  represents the minimum polynomial corresponding to  $\alpha^i$ ,  $\alpha$  is a root of the default primitive polynomial for the field  $\text{GF}(n+1)$ ,
- and  $t$  represents the error-correcting capability of the code.

---

**Note** Although the `bchgenpoly` function performs intermediate computations in  $\text{GF}(n+1)$ , the final polynomial has binary coefficients. The output from `bchgenpoly` is a Galois vector in  $\text{GF}(2)$  rather than in  $\text{GF}(n+1)$ .

---

`genpoly = bchgenpoly(n,k,prim_poly)` is the same as the syntax above, except that `prim_poly` specifies the primitive polynomial for  $\text{GF}(n+1)$  that has  $\alpha$  as a root. `prim_poly` is either a polynomial character vector or an integer whose binary representation indicates the coefficients of the primitive polynomial in order of descending powers. To use the default primitive polynomial for  $\text{GF}(n+1)$ , set `prim_poly` to `[]`.

`genpoly = bchgenpoly(n,k,prim_poly,outputFormat)` is the same as the previous syntax, except that `outputFormat` specifies output data type. The value of `outputFormat` can be 'gf' or 'double' corresponding to Galois field and double data types respectively. The default value of `outputFormat` is 'gf'.

`[genpoly,t] = bchgenpoly(...)` returns `t`, the error-correction capability of the code.

## Examples

### Create a BCH Generator Polynomial

Create two BCH generator polynomials based on different primitive polynomials.

Set the codeword and message lengths, `n` and `k`.

```
n = 15;
k = 11;
```

Create the generator polynomial and return the error correction capability, `t`.

```
[genpoly,t] = bchgenpoly(15,11)
```

```
genpoly = GF(2) array.
```

```
Array elements =
```

```
1 0 0 1 1
```

```
t = 1
```

Create a generator polynomial for a (15,11) BCH code using a different primitive polynomial expressed as a character vector. Note that `genpoly2` differs from `genpoly`, which uses the default primitive.

```
genpoly2 = bchgenpoly(15,11,'D^4 + D^3 + 1')
```

```
genpoly2 = GF(2) array.
```

```
Array elements =
```

1 1 0 0 1

## Limitations

The maximum allowable value of  $n$  is 65535.

# bchnumerr

Number of correctable errors for BCH code

## Syntax

`T = bchnumerr(N)`

`T = bchnumerr(N, K)`

## Description

`T = bchnumerr(N)` returns all the possible combinations of message length,  $K$ , and number of correctable errors,  $T$ , for a BCH code of codeword length,  $N$ .

`T = bchnumerr(N, K)` returns the number of correctable errors,  $T$ , for an  $(N, K)$  BCH code.

## Examples

### Determine Message Length Combinations for BCH Code

Calculate the possible message length combinations for a BCH code word length of 15.

`T = bchnumerr(15)`

`T = 3×3`

15	11	1
15	7	2
15	5	3

### Compute the Correctable Errors for BCH Code

Calculate the number of correctable errors for BCH code 15, 11

```
T = bchnumerr(15,11)
```

```
T = 1
```

## Input Arguments

### **N — Codeword length**

integer scalar

Codeword length, specified as an integer scalar. N must have the form  $2^m-1$  for some integer, m, between 3 and 16.

Example: 15

Data Types: single | double

### **K — Message length**

integer scalar

Message length, specified as an integer scalar. N and K must produce a narrow-sense BCH code.

Example: 11

Data Types: single | double

## Output Arguments

### **T — Number of correctable errors**

scalar or matrix

Number of correctable errors, returned as a scalar or matrix value.

`bchnumerr(N)` returns a matrix with three columns. The first column lists N, the second column lists K, and the third column lists T.

bchnumerr(N, K) returns a scalar, which represents the number of correctable errors for the BCH code.

## berawgn

Bit error rate (BER) for uncoded AWGN channels

### Syntax

```
ber = berawgn(EbNo, 'pam', M)
ber = berawgn(EbNo, 'qam', M)
ber = berawgn(EbNo, 'psk', M, dataenc)
ber = berawgn(EbNo, 'oqpsk', dataenc)
ber = berawgn(EbNo, 'dpsk', M)
ber = berawgn(EbNo, 'fsk', M, coherence)
ber = berawgn(EbNo, 'fsk', 2, coherence, rho)
ber = berawgn(EbNo, 'msk', precoding)
ber = berawgn(EbNo, 'msk', precoding, coherence)
berlb = berawgn(EbNo, 'cpfsk', M, modindex, kmin)
[BER, SER] = berawgn(EbNo, ...)
```

### Description

#### For All Syntaxes

The `berawgn` function returns the BER of various modulation schemes over an additive white Gaussian noise (AWGN) channel. The first input argument, `EbNo`, is the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, the output `ber` is a vector of the same size, whose elements correspond to the different  $E_b/N_0$  levels. The supported modulation schemes, which correspond to the second input argument to the function, are in the following table.

Modulation Scheme	Second Input Argument
Phase shift keying (PSK)	'psk'
Offset quadrature phase shift keying (OQPSK)	'oqpsk'
Differential phase shift keying (DPSK)	'dpsk'

Modulation Scheme	Second Input Argument
Pulse amplitude modulation (PAM)	'pam'
Quadrature amplitude modulation (QAM)	'qam'
Frequency shift keying (FSK)	'fsk'
Minimum shift keying (MSK)	'msk'
Continuous phase frequency shift keying (CPFSK)	'cpfsk'

Most syntaxes also have an  $M$  input that specifies the alphabet size for the modulation.  $M$  must have the form  $2^k$  for some positive integer  $k$ . For all cases, the function assumes the use of a Gray-coded signal constellation.

## For Specific Syntaxes

`ber = berawgn(EbNo, 'pam', M)` returns the BER of uncoded PAM over an AWGN channel with coherent demodulation.

`ber = berawgn(EbNo, 'qam', M)` returns the BER of uncoded QAM over an AWGN channel with coherent demodulation. The alphabet size,  $M$ , must be at least 4. When  $k = \log_2 M$  is odd, a rectangular constellation of size  $M = I \times J$  is used, where  $I = 2^{\frac{k-1}{2}}$  and  $J = 2^{\frac{k+1}{2}}$ . When  $k$  is even, a square constellation of size  $2^{\frac{k}{2}} \times 2^{\frac{k}{2}}$  is used.

`ber = berawgn(EbNo, 'psk', M, dataenc)` returns the BER of coherently detected uncoded PSK over an AWGN channel. *dataenc* is either 'diff' for differential data encoding or 'nondiff' for nondifferential data encoding. If *dataenc* is 'diff',  $M$  must be no greater than 4.

`ber = berawgn(EbNo, 'oqpsk', dataenc)` returns the BER of coherently detected offset-QPSK over an uncoded AWGN channel.

`ber = berawgn(EbNo, 'dpsk', M)` returns the BER of uncoded DPSK modulation over an AWGN channel.

`ber = berawgn(EbNo, 'fsk', M, coherence)` returns the BER of orthogonal uncoded FSK modulation over an AWGN channel. *coherence* is either 'coherent' for coherent demodulation or 'noncoherent' for noncoherent demodulation.  $M$  must be no greater than 64 for 'noncoherent'.

`ber = berawgn(EbNo, 'fsk', 2, coherence, rho)` returns the BER for binary nonorthogonal FSK over an uncoded AWGN channel, where `rho` is the complex correlation coefficient. See “Nonorthogonal 2-FSK with Coherent Detection” for the definition of the complex correlation coefficient and how to compute it for nonorthogonal BFSK.

`ber = berawgn(EbNo, 'msk', precoding)` returns the BER of coherently detected MSK modulation over an uncoded AWGN channel. Setting `precoding` to 'off' returns results for conventional MSK while setting `precoding` to 'on' returns results for precoded MSK.

`ber = berawgn(EbNo, 'msk', precoding, coherence)` specifies whether the detection is coherent or noncoherent.

`berlb = berawgn(EbNo, 'cpfsk', M, modindex, kmin)` returns a lower bound on the BER of uncoded CPFSK modulation over an AWGN channel. `modindex` is the modulation index, a positive real number. `kmin` is the number of paths having the minimum distance; if this number is unknown, you can assume a value of 1.

`[BER, SER] = berawgn(EbNo, ...)` returns both the BER and SER.

## Examples

### Generate Theoretical BER Data for AWGN Channels

This example shows how to generate theoretical bit error rate data for several modulation schemes assuming an AWGN channel.

Create a vector of Eb/No values and set the modulation order, M.

```
EbNo = (0:10)';  
M = 4;
```

Generate theoretical BER data for QPSK modulation by using the `berawgn` function.

```
berQ = berawgn(EbNo, 'psk', M, 'nondiff');
```

Generate equivalent data for DPSK and FSK.

```
berD = berawgn(EbNo, 'dpsk', M);  
berF = berawgn(EbNo, 'fsk', M, 'coherent');
```

Plot the results.

```
semilogy(EbNo,[berQ berD berF])  
xlabel('Eb/No (dB)')  
ylabel('BER')  
legend('QPSK', 'DPSK', 'FSK')  
grid
```

## Limitations

The numerical accuracy of this function's output is limited by approximations related to the numerical implementation of the expressions.

You can generally rely on the first couple of significant digits of the function's output.

## Alternatives

As an alternative to the `berawgn` function, invoke the BERTool GUI (`bertool`), and use the **Theoretical** tab.

## bercoding

Bit error rate (BER) for coded AWGN channels

### Syntax

```
berub = bercoding(EbNo, 'conv', decision, coderate, dspec)
berub = bercoding(EbNo, 'block', 'hard', n, k, dmin)
berub = bercoding(EbNo, 'block', 'soft', n, k, dmin)
berapprox = bercoding(EbNo, 'Hamming', 'hard', n)
berub = bercoding(EbNo, 'Golay', 'hard', 24)
berapprox = bercoding(EbNo, 'RS', 'hard', n, k)
berapprox = bercoding(..., modulation)
```

### Description

`berub = bercoding(EbNo, 'conv', decision, coderate, dspec)` returns an upper bound or approximation on the BER of a binary convolutional code with coherent phase shift keying (PSK) modulation over an additive white Gaussian noise (AWGN) channel. `EbNo` is the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, `berub` is a vector of the same size, whose elements correspond to the different  $E_b/N_0$  levels. To specify hard-decision decoding, set *decision* to 'hard'; to specify soft-decision decoding, set *decision* to 'soft'. The convolutional code has code rate equal to `coderate`. The `dspec` input is a structure that contains information about the code's distance spectrum:

- `dspec.dfree` is the minimum free distance of the code.
- `dspec.weight` is the weight spectrum of the code.

To find distance spectra for some sample codes, use the `distspec` function or see [5] and [3].

---

**Note** The results for binary PSK and quadrature PSK modulation are the same. This function does not support M-ary PSK when M is other than 2 or 4.

---

`berub = bercoding(EbNo, 'block', 'hard', n, k, dmin)` returns an upper bound on the BER of an  $[n,k]$  binary block code with hard-decision decoding and coherent BPSK or QPSK modulation. `dmin` is the minimum distance of the code.

`berub = bercoding(EbNo, 'block', 'soft', n, k, dmin)` returns an upper bound on the BER of an  $[n,k]$  binary block code with soft-decision decoding and coherent BPSK or QPSK modulation. `dmin` is the minimum distance of the code.

`berapprox = bercoding(EbNo, 'Hamming', 'hard', n)` returns an approximation of the BER of a Hamming code using hard-decision decoding and coherent BPSK modulation. (For a Hamming code, if `n` is known, then `k` can be computed directly from `n`.)

`berub = bercoding(EbNo, 'Golay', 'hard', 24)` returns an upper bound of the BER of a Golay code using hard-decision decoding and coherent BPSK modulation. Support for Golay currently is only for `n=24`. In accordance with [3], the Golay coding upper bound assumes only the correction of 3-error patterns. Even though it is theoretically possible to correct approximately 19% of 4-error patterns, most decoders in practice do not have this capability.

`berapprox = bercoding(EbNo, 'RS', 'hard', n, k)` returns an approximation of the BER of  $(n,k)$  Reed-Solomon code using hard-decision decoding and coherent BPSK modulation.

`berapprox = bercoding(..., modulation)` returns an approximation of the BER for coded AWGN channels when you specify a *modulation* type. See the `berawgn` function for a listing of the supported modulation types.

## Examples

### Upper Bound on Theoretical BER for a Block Code

Find an upper bound on the theoretical BER of a (23,12) block code.

Set the example parameters.

```
n = 23;           % Codeword length
k = 12;           % Message length
dmin = 7;         % Minimum distance
EbNo = 1:10;      % Eb/No range (dB)
```

Estimate the BER.

```
berBlk = bercoding(EbNo, 'block', 'hard', n, k, dmin);
```

Plot the estimated BER.

```
berfit(EbNo, berBlk)  
ylabel('Bit Error Probability')  
title('BER Upper Bound vs. Eb/No, with Best Curve Fit')
```

### Estimate Coded BER Performance of 16-QAM in AWGN

Estimate the performance of a 16-QAM channel in AWGN when encoded with a (15,11) Reed-Solomon code using hard-decision decoding.

Set the input Eb/No range and determine the uncoded BER for 16-QAM.

```
ebno = (2:12)';  
uncodedBER = berawgn(ebno, 'qam', 16);
```

Estimate the coded BER for 16-QAM channel with a (15,11) Reed-Solomon code using hard decision decoding.

```
codedBER = bercoding(ebno, 'RS', 'hard', 15, 11, 'qam', 16);
```

Plot the estimated BER curves.

```
semilogy(ebno, [uncodedBER codedBER])  
grid  
legend('Uncoded BER', 'Coded BER')  
xlabel('Eb/No (dB)')  
ylabel('BER')
```

## Limitations

The numerical accuracy of this function's output is limited by

- Approximations in the analysis leading to the closed-form expressions that the function uses
- Approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

## Alternatives

As an alternative to the bercoding function, invoke the BERTool GUI (bertool) and use the **Theoretical** tab.

## berconfint

Bit error rate (BER) and confidence interval of Monte Carlo simulation

### Syntax

```
[ber,interval] = berconfint(nerrs,ntrials)
[ber,interval] = berconfint(nerrs,ntrials,level)
```

### Description

`[ber,interval] = berconfint(nerrs,ntrials)` returns the error probability estimate `ber` and the 95% confidence interval `interval` for a Monte Carlo simulation of `ntrials` trials with `nerrs` errors. `interval` is a two-element vector that lists the endpoints of the interval. If the errors and trials are measured in bits, the error probability is the bit error rate (BER); if the errors and trials are measured in symbols, the error probability is the symbol error rate (SER).

`[ber,interval] = berconfint(nerrs,ntrials,level)` specifies the confidence level as a real number between 0 and 1.

### Examples

If a simulation of a communication system results in 100 bit errors in  $10^6$  trials, the BER (bit error rate) for that simulation is the quotient  $10^{-4}$ . The command below finds the 95% confidence interval for the BER of the system.

```
nerrs = 100; % Number of bit errors in simulation
ntrials = 10^6; % Number of trials in simulation
level = 0.95; % Confidence level
[ber,interval] = berconfint(nerrs,ntrials,level)
```

The output below shows that, with 95% confidence, the BER for the system is between 0.0000814 and 0.0001216.

```
ber =
```

```
1.0000e-004
```

```
interval =
```

```
1.0e-003 *
```

```
0.0814    0.1216
```

For an example that uses the output of `berconfint` to plot error bars on a BER plot, see “Curve Fitting An Error Rate Plot”

## berfading

Bit error rate (BER) for Rayleigh and Rician fading channels

### Syntax

```
ber = berfading(EbNo, 'pam', M, divorder)
ber = berfading(EbNo, 'qam', M, divorder)
ber = berfading(EbNo, 'psk', M, divorder)
ber = berfading(EbNo, 'depsk', M, divorder)
ber = berfading(EbNo, 'oqpsk', divorder)
ber = berfading(EbNo, 'dpsk', M, divorder)
ber = berfading(EbNo, 'fsk', M, divorder, coherence)
ber = berfading(EbNo, 'fsk', 2, divorder, coherence, rho)
ber = berfading(EbNo, ..., K)
ber = berfading(EbNo, 'psk', 2, 1, K, phaserr)
[BER, SER] = berfading(EbNo, ...)
```

### Description

#### For All Syntaxes

The first input argument, `EbNo`, is the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, the output `ber` is a vector of the same size, whose elements correspond to the different  $E_b/N_0$  levels.

Most syntaxes also have an `M` input that specifies the alphabet size for the modulation. `M` must have the form  $2^k$  for some positive integer `k`.

`berfading` uses expressions that assume Gray coding. If you use binary coding, the results may differ.

For cases where diversity is used, the  $E_b/N_0$  on each diversity branch is `EbNo/divorder`, where `divorder` is the diversity order (the number of diversity branches) and is a positive integer.

## For Specific Syntaxes

`ber = berfading(EbNo, 'pam', M, divorder)` returns the BER for PAM over an uncoded Rayleigh fading channel with coherent demodulation.

`ber = berfading(EbNo, 'qam', M, divorder)` returns the BER for QAM over an uncoded Rayleigh fading channel with coherent demodulation. The alphabet size,  $M$ , must be at least 4. When  $k = \log_2 M$  is odd, a rectangular constellation of size  $M = I \times J$  is used, where  $I = 2^{\frac{k-1}{2}}$  and  $J = 2^{\frac{k+1}{2}}$ .

`ber = berfading(EbNo, 'psk', M, divorder)` returns the BER for coherently detected PSK over an uncoded Rayleigh fading channel.

`ber = berfading(EbNo, 'dpsk', M, divorder)` returns the BER for coherently detected PSK with differential data encoding over an uncoded Rayleigh fading channel. Only  $M = 2$  is currently supported.

`ber = berfading(EbNo, 'oqpsk', divorder)` returns the BER of coherently detected offset-QPSK over an uncoded Rayleigh fading channel.

`ber = berfading(EbNo, 'dpsk', M, divorder)` returns the BER for DPSK over an uncoded Rayleigh fading channel. For DPSK, it is assumed that the fading is slow enough that two consecutive symbols are affected by the same fading coefficient.

`ber = berfading(EbNo, 'fsk', M, divorder, coherence)` returns the BER for orthogonal FSK over an uncoded Rayleigh fading channel. `coherence` should be 'coherent' for coherent detection, or 'noncoherent' for noncoherent detection.

`ber = berfading(EbNo, 'fsk', 2, divorder, coherence, rho)` returns the BER for binary nonorthogonal FSK over an uncoded Rayleigh fading channel. `rho` is the complex correlation coefficient. See "Nonorthogonal 2-FSK with Coherent Detection" for the definition of the complex correlation coefficient and how to compute it for nonorthogonal BFSK.

`ber = berfading(EbNo, ..., K)` returns the BER over an uncoded Rician fading channel, where  $K$  is the ratio of specular to diffuse energy in linear scale. For the case of 'fsk', `rho` must be specified before  $K$ .

`ber = berfading(EbNo, 'psk', 2, 1, K, phaserr)` returns the BER of BPSK over an uncoded Rician fading channel with imperfect phase synchronization. `phaserr` is the standard deviation of the reference carrier phase error in radians.

[BER,SER] = berfading(EbNo, ...) returns both the BER and SER.

## Examples

### Estimate BER Performance of 16-QAM in Fading

Generate a vector of Eb/No values to evaluate.

```
EbNo = 8:2:20;
```

Initialize the BER results vector.

```
ber = zeros(length(EbNo),20);
```

Generate BER vs. Eb/No curves for 16-QAM in a fading channel. Vary the diversity order from 1 to 20.

```
for L = 1:20
    ber(:,L) = berfading(EbNo, 'qam',16,L);
end
```

Plot the results.

```
semilogy(EbNo,ber, 'b')
text(18.5, 0.02, sprintf('L=%d',1))
text(18.5, 1e-11, sprintf('L=%d',20))
title('QAM over fading channel with diversity order 1 to 20')
xlabel('E_b/N_0 (dB)')
ylabel('BER')
grid on
```

## Limitations

The numerical accuracy of this function's output is limited by approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

### Alternatives

As an alternative to the `berfading` function, invoke the BERTool GUI (`bertool`), and use the **Theoretical** tab.

## berfit

Fit curve to nonsmooth empirical bit error rate (BER) data

### Syntax

```
fitber = berfit(empEbNo,empber)
fitber = berfit(empEbNo,empber,fitEbNo)
fitber = berfit(empEbNo,empber,fitEbNo,options)
fitber = berfit(empEbNo,empber,fitEbNo,options,fittype)
[fitber,fitprops] = berfit(...)
berfit(...)
berfit(empEbNo,empber,fitEbNo,options,'all')
```

### Description

`fitber = berfit(empEbNo,empber)` fits a curve to the empirical BER data in the vector `empber` and returns a vector of fitted bit error rate (BER) points. The values in `empber` and `fitber` correspond to the  $E_b/N_0$  values, in dB, given by `empEbNo`. The vector `empEbNo` must be in ascending order and must have at least four elements.

---

**Note** The `berfit` function is intended for curve fitting or interpolation, *not* extrapolation. Extrapolating BER data beyond an order of magnitude below the smallest empirical BER value is inherently unreliable.

---

`fitber = berfit(empEbNo,empber,fitEbNo)` fits a curve to the empirical BER data in the vector `empber` corresponding to the  $E_b/N_0$  values, in dB, given by `empEbNo`. The function then evaluates the curve at the  $E_b/N_0$  values, in dB, given by `fitEbNo` and returns the fitted BER points. The length of `fitEbNo` must equal or exceed that of `empEbNo`.

`fitber = berfit(empEbNo,empber,fitEbNo,options)` uses the structure `options` to override the default options used for optimization. These options are the ones used by the `fminsearch` function. You can create the `options` structure using the `optimset` function. Particularly relevant fields are described in the table below.

Field	Description
<code>options.Display</code>	Level of display: 'off' (default) displays no output; 'iter' displays output at each iteration; 'final' displays only the final output; 'notify' displays output only if the function does not converge.
<code>options.MaxFunEvals</code>	Maximum number of function evaluations before optimization ceases. The default is $10^4$ .
<code>options.MaxIter</code>	Maximum number of iterations before optimization ceases. The default is $10^4$ .
<code>options.TolFun</code>	Termination tolerance on the closed-form function used to generate the fit. The default is $10^{-4}$ .
<code>options.TolX</code>	Termination tolerance on the coefficient values of the closed-form function used to generate the fit. The default is $10^{-4}$ .

`fitber = berfit(empEbNo,empber,fitEbNo,options,fittype)` specifies which closed-form function `berfit` uses to fit the empirical data, from the possible fits listed in “Algorithms” on page 2-105 below. *fittype* can be 'exp', 'exp+const', 'polyRatio', or 'doubleExp+const'. To avoid overriding default optimization options, use `options = []`.

`[fitber,fitprops] = berfit(...)` returns the MATLAB structure `fitprops`, which describes the results of the curve fit. Its fields are described in the table below.

Field	Description
<code>fitprops.fitType</code>	The closed-form function type used to generate the fit: 'exp', 'exp+const', 'polyRatio', or 'doubleExp+const'.
<code>fitprops.coeffs</code>	The coefficients used to generate the fit. If the function cannot find a valid fit, <code>fitprops.coeffs</code> is an empty vector.

Field	Description
<code>fitprops.sumSqErr</code>	The sum squared error between the log of the fitted BER points and the log of the empirical BER points.
<code>fitprops.exitState</code>	The exit condition of <code>berfit</code> : 'The curve fit converged to a solution.', 'The maximum number of function evaluations was exceeded.', or 'No desirable fit was found'.
<code>fitprops.funcCount</code>	The number of function evaluations used in minimizing the sum squared error function.
<code>fitprops.iterations</code>	The number of iterations taken in minimizing the sum squared error function. This is not necessarily equal to the number of function evaluations.

`berfit(...)` plots the empirical and fitted BER data.

`berfit(empEbNo, empber, fitEbNo, options, 'all')` plots the empirical and fitted BER data from all the possible fits, listed in the “Algorithms” on page 2-105 below, that return a valid fit. To avoid overriding default options, use `options = []`.

---

**Note** A valid fit must be

- real-valued
- monotonically decreasing
- greater than or equal to 0 and less than or equal to 1

If a fit does not confirm to this criteria, it is rejected.

---

## Examples

### Bit Error Rate Curve Fitting

These examples illustrate the syntax of the `berfit` function, but they use hard-coded or theoretical BER data for simplicity. For an example that uses empirical BER data from a simulation, see “Curve Fitting An Error Rate Plot”.

### Best fit for a sample set of data

```
EbN0 = 0:13;  
berdata = [.2 .15 .13 .12 .08 .09 .08 .07 .06 .04 .03 .02 .01 .004];  
berfit(EbN0,berdata);
```

Plot the best fit. The curve connects the points created by evaluating the fit expression at the values in `EbN0`. To make the curve look smoother, use a syntax like `berfit(EbN0,berdata,[0:0.2:13])`. This alternative syntax uses more points when plotting the curve, but it does not change the fit expression.

### **Fit for a BER curve with an error floor**

We generate the empirical BER array by simulating a channel with a null (`ch = [0.5 0.47]`) with BPSK modulation and linear MMSE equalizer at the receiver. We run the `berfit` with the 'all' option. The 'doubleExp+const' fit does not provide a valid fit, and the 'exp' fit type does not work well for this data. The 'exp+const' and 'polyRatio' fits closely match the simulated data.

```
EbN0 = -10:3:15;  
empBER = [0.3361 0.3076 0.2470 0.1878 0.1212 0.0845 0.0650 0.0540 0.0474];  
figure; berfit(EbN0, empBER, [], [], 'all');
```

### Use of the options input structure as well as the fitprops output structure

The 'notify' value for the display level causes the function to produce output when one of the attempted fits does not converge. The exitState field of the output structure also indicates which fit converges and which fit does not.

```
M = 8; EbN0 = 3:10;
berdata = berfading(EbN0,'psk',M,2); % Compute theoretical BER.
noisydata = berdata.*[.93 .92 1 .59 .08 .15 .01 .01];
% Say when fit fails to converge.
options = optimset('display','notify');

disp('*** Trying exponential fit.') % Poor fit
```

```
*** Trying exponential fit.

[fitber1,fitprops1] = berfit(EbN0,noisydata,EbN0,...
    options,'exp')

Exiting: Maximum number of function evaluations has been exceeded
- increase MaxFunEvals option.
Current function value: 2.749919

fitber1 = 1×8

    0.1247    0.0727    0.0376    0.0168    0.0064    0.0020    0.0005    0.0001

fitprops1 = struct with fields:
    fitType: 'exp'
    coeffs: [4x1 double]
    sumSqErr: 2.7499
    exitState: 'The maximum number of function evaluations has been exceeded'
    funcCount: 10001

    exitState: 'The curve fit converged to a solution'
    funcCount: 554
```

iterations: 331

## Algorithms

The `berfit` function fits the BER data using unconstrained nonlinear optimization via the `fminsearch` function. The closed-form functions that `berfit` considers are listed in the table below, where  $x$  is the  $E_b/N_0$  in linear terms (*not* dB) and  $f$  is the estimated BER. These functions were empirically found to provide close fits in a wide variety of situations, including exponentially decaying BERs, linearly varying BERs, and BER curves with error rate floors.

Value of <i>fittype</i>	Functional Expression
'exp'	$f(x) = a_1 \exp\left[\frac{-(x - a_2)^{a_3}}{a_4}\right]$
'exp+const'	$f(x) = a_1 \exp\left[\frac{-(x - a_2)^{a_3}}{a_4}\right] + a_5$
'polyRatio'	$f(x) = \frac{a_1 x^2 + a_2 x + a_3}{x^3 + a_4 x^2 + a_5 x + a_6}$
'doubleExp+const'	$a_1 \exp\left[\frac{-(x - a_2)^{a_3}}{a_4}\right] + a_5 \exp\left[\frac{-(x - a_6)^{a_7}}{a_8}\right] + a_9$

The sum squared error function that `fminsearch` attempts to minimize is

$$F = \sum [\log(\text{empirical BER}) - \log(\text{fitted BER})]^2$$

where the fitted BER points are the values in `fitber` and the sum is over the  $E_b/N_0$  points given in `empEbNo`. It is important to use the log of the BER values rather than the BER values themselves so that the high-BER regions do not dominate the objective function inappropriately.

## bersync

Bit error rate (BER) for imperfect synchronization

### Syntax

```
ber = bersync(EbNo,timerr,'timing')  
ber = bersync(EbNo,phaserr,'carrier')
```

### Description

`ber = bersync(EbNo,timerr,'timing')` returns the BER of uncoded coherent binary phase shift keying (BPSK) modulation over an additive white Gaussian noise (AWGN) channel with imperfect timing. The normalized timing error is assumed to have a Gaussian distribution. `EbNo` is the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, the output `ber` is a vector of the same size, whose elements correspond to the different  $E_b/N_0$  levels. `timerr` is the standard deviation of the timing error, normalized to the symbol interval. `timerr` must be between 0 and 0.5.

`ber = bersync(EbNo,phaserr,'carrier')` returns the BER of uncoded BPSK modulation over an AWGN channel with a noisy phase reference. The phase error is assumed to have a Gaussian distribution. `phaserr` is the standard deviation of the error in the reference carrier phase, in radians.

### Examples

#### Calculate Bit Error Rate (BER) for Imperfect Synchronization

The code below computes the BER of coherent BPSK modulation over an AWGN channel with imperfect timing. The example varies both `EbNo` and `timerr`. (When `timerr` assumes the final value of zero, the `bersync` command produces the same result as `berawgn(EbNo,'psk',2)`.)

```
EbNo = [4 8 12];  
timerr = [0.2 0.07 0];
```

```
ber = zeros(length(timerr),length(EbNo));
for ii = 1:length(timerr)
    ber(ii,:) = bersync(EbNo,timerr(ii),'timerr');
end
```

Display result using scientific notation.

```
format short e; ber
```

```
ber = 3×3
```

```

Switch back to default notation format.

```
format;
```

## Limitations

The numerical accuracy of this function's output is limited by

- Approximations in the analysis leading to the closed-form expressions that the function uses
- Approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

### Limitations Related to Extreme Values of Input Arguments

Inherent limitations in numerical precision force the function to assume perfect synchronization if the value of `timerr` or `phaserr` is very small. The table below indicates how the function behaves under these conditions.

Condition	Behavior of Function
<code>timerr &lt; eps</code>	<code>bersync(EbNo,timerr,'timing')</code> defined as <code>berawgn(EbNo,'psk',2)</code>

Condition	Behavior of Function
phaserr < eps	bersync(EbNo,phaserr,'carrier') defined as berawgn(EbNo,'psk',2)

## Algorithms

This function uses formulas from [3].

When the last input is 'timing', the function computes

$$\frac{1}{4\pi\sigma} \int_{-\infty}^{\infty} \exp\left(-\frac{\xi^2}{2\sigma^2}\right) \int_{\sqrt{2R}(1-2|\xi|)}^{\infty} \exp\left(-\frac{x^2}{2}\right) dx d\xi + \frac{1}{2\sqrt{2\pi}} \int_{\sqrt{2R}}^{\infty} \exp\left(-\frac{x^2}{2}\right) dx$$

where  $\sigma$  is the timerr input and R is the value of EbNo converted from dB to a linear scale.

When the last input is 'carrier', the function computes

$$\frac{1}{\pi\sigma} \int_{-\infty}^{\infty} \exp\left(-\frac{\phi^2}{2\sigma^2}\right) \int_{\sqrt{2R}\cos\phi}^{\infty} \exp\left(-\frac{y^2}{2}\right) dy d\phi$$

where  $\sigma$  is the phaserr input and R is the value of EbNo converted from dB to a linear scale.

## Alternatives

As an alternative to the bersync function, invoke the BERTool GUI (bertool) and use the **Theoretical** tab.

## bertool

Open bit error rate analysis GUI (BERTool)

### Syntax

```
bertool
```

### Description

`bertool` launches the Bit Error Rate Analysis Tool (BERTool). The BERTool application enables you to analyze the bit error rate (BER) performance of communications systems. BERTool computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB functions and Simulink models or with theoretical closed-form expressions for selected types of communication systems. See “BERTool” to learn more.

**Introduced before R2006a**

## bi2de

Convert binary vectors to decimal numbers

### Syntax

```
d =bi2de(b)
d = bi2de(b,flg)
d = bi2de(b,p)
d = bi2de(b,p,flg)
```

### Description

`d =bi2de(b)` converts a binary row vector `b` to a nonnegative decimal integer.

`d = bi2de(b,flg)` converts a binary row vector to a decimal integer, where `flg` determines the position of the most significant digit.

`d = bi2de(b,p)` converts a base-`p` row vector `b` to a nonnegative decimal integer.

`d = bi2de(b,p,flg)` converts a base-`p` row vector to a decimal integer, where `flg` determines the position of the most significant digit.

### Input Arguments

#### **b** — Binary input

row vector | matrix

Binary input specified as a row vector or matrix.

Example: `[0 1 0]`

Example: `[1 0 0; 1 0 1]`

---

**Note** `b` must represent an integer less than or equal to  $2^{52}$ .

---

**flg — MSB flag**

'right-msb' | 'left-msb'

Character vector that determines whether the first column corresponds to the lowest-order or highest-order digit. If omitted, `bi2de` assumes 'right-msb'.

**p — Base**

positive integer scalar

The base of the row vector that is converted to a decimal. Specify as a positive integer greater than or equal to 2.

Example: 4

## Output Arguments

**d — Decimal output**

scalar | vector

Decimal output converted from a base-`p` row vector `b`. Elements of `d` are nonnegative integers. If `b` is a matrix, each row represents a base-`p` number. In this case, the output `d` is a column vector in which each element is the decimal representation of the corresponding row of `b`.

## Examples

**Convert Binary Numbers to Decimals**

Generate a matrix that contains binary representations of five random numbers between 0 and 15. Convert the binary numbers to decimal integers.

```
b = randi([0 1],5,4);
d = bi2de(b)
```

```
d = 5×1
```

```
    1
    5
   14
```

11  
15

Convert a base-8 number to its decimal equivalent. Assign the most significant digit to the leftmost position. The output corresponds to  $4(8^3) + 2(8^2) + 7(8^1) + 1(8^0) = 2233$ .

```
d = bi2de([4 2 7 1],8,'left-msb')
```

```
d = 2233
```

# bin2gray

Convert positive integers into corresponding Gray-encoded integers

## Syntax

```
y = bin2gray(x,modulation,M)
[y,map] = bin2gray(x,modulation,M)
```

## Description

`y = bin2gray(x,modulation,M)` generates a Gray-encoded vector or matrix output `y` with the same dimensions as its input parameter `x`. `x` can be a scalar, vector, matrix, or 3-D array. `modulation` is the modulation type and must be `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`. `M` is the modulation order that can be an integer power of 2.

`[y,map] = bin2gray(x,modulation,M)` generates a Gray-encoded output `y` with its respective Gray-encoded constellation map, `map`.

You can use `map` output to label a Gray-encoded constellation. The `map` output gives the Gray encoded labels for the corresponding modulation. See the example below.

---

**Note** If you are converting binary coded data to Gray-coded data and modulating the result immediately afterwards, you should use the appropriate modulation object or function with the `'Gray'` option, instead of `bin2gray`.

---

## Examples

### Binary to Gray Symbol Mapping

This example shows how to use the `bin2gray` and `gray2bin` functions to map integer inputs from a natural binary order symbol mapping to a Gray coded signal constellation and vice versa, assuming 16-QAM modulation. In addition, a visual representation of the difference between Gray and binary coded symbol mappings is shown.

Create a complete vector of 16-QAM integers.

```
M= 16;  
x = (0:M-1)';
```

Convert the input vector from a natural binary order to a Gray encoded vector using `bin2gray`.

```
[y,mapy] = bin2gray(x, 'qam',M);
```

Convert the Gray encoded symbols, `y`, back to a binary ordering using `gray2bin`.

```
z = gray2bin(y, 'qam',M);
```

Verify that the original data, `x`, and the final output vector, `z` are identical.

```
isequal(x,z)
```

```
ans = logical  
     1
```

To create a constellation plot showing the different symbol mappings, use the `qammod` function to find the complex symbol values.

```
sym = qammod(x,M);
```

Plot the constellation symbols and label them using the Gray, `y`, and binary, `z`, output vectors. The binary representation of the Gray coded symbols is shown in black while the binary representation of the naturally ordered symbols is shown in red. Set the axes scaling so that all points are displayed.

```
scatterplot(sym,1,0, 'b*');  
for k = 1:16  
    text(real(sym(k))-0.3, imag(sym(k))+0.3, ...  
         dec2base(mapy(k),2,4));  
  
    text(real(sym(k))-0.3, imag(sym(k))-0.3, ...  
         dec2base(z(k),2,4), 'Color', [1 0 0]);  
end  
axis([-4 4 -4 4])
```

Observe that only a single bit differs between adjacent constellation points when using Gray coding.

## biterr

Number of bit errors and bit error rate (BER)

### Syntax

```
[number,ratio] = biterr(x,y)
[number,ratio] = biterr(x,y,k)
[number,ratio] = biterr(x,y,k,flag)
[number,ratio,individual] = biterr( ___ )
```

### Description

`[number,ratio] = biterr(x,y)` compares the unsigned binary representation of elements in `x` to those in `y`. The function returns `number`, the number of bits that differ in the comparison, and `ratio`, the ratio of `number` to the total number of bits. The function determines the order in which it compares `x` and `y` based on their sizes. For more details, see Algorithms on page 2-125 section.

`[number,ratio] = biterr(x,y,k)` also specifies `k`, the maximum number of bits for each element in `x` and `y`. If the unsigned binary representation of any element in `x` or `y` is more than `k` digits, the function errors.

`[number,ratio] = biterr(x,y,k,flag)` specifies a `flag` to override default settings for how the function compares the elements and computes the outputs. For more information, see Algorithms on page 2-126 section.

`[number,ratio,individual] = biterr( ___ )` returns the binary comparison result of `x` and `y` as matrix `individual`. You can specify any of the input argument combination from the previous syntaxes.

### Examples

### Bit Error Rate Computation

Create two binary matrices.

```
x = [0 0; 0 0; 0 0; 0 0]
```

```
x = 4x2
```

```
0    0
0    0
0    0
0    0
```

```
y = [0 0; 0 0; 0 0; 1 1]
```

```
y = 4x2
```

```
0    0
0    0
0    0
1    1
```

Determine the number of bit errors.

```
numerrs = biterr(x,y)
```

```
numerrs = 2
```

Compute the number of column-wise errors .

```
numerrs = biterr(x,y,[],'column-wise')
```

```
numerrs = 1x2
```

```
1    1
```

Compute the number of row-wise errors.

```
numerrs = biterr(x,y,[],'row-wise')
```

```
numerrs = 4x1
```

```
0
```

```
0
0
2
```

Compute the number of overall errors. Behavior is the same as the default behaviour.

```
numerrs = biterr(x,y,[],'overall')
numerrs = 2
```

### Estimate Bit Error Rate for 64-QAM in AWGN

Demodulate a noisy 64-QAM signal and estimate the bit error rate (BER) for a range of Eb/No values. Compare the BER estimate to theoretical values.

Set the simulation parameters.

```
M = 64; % Modulation order
k = log2(M); % Bits per symbol
EbNoVec = (5:15)'; % Eb/No values (dB)
numSymPerFrame = 100; % Number of QAM symbols per frame
```

Initialize the results vector.

```
berEst = zeros(size(EbNoVec));
```

The main processing loop executes these steps.

- Generate binary data and convert to 64-ary symbols.
- QAM-modulate the data symbols.
- Pass the modulated signal through an AWGN channel.
- Demodulate the received signal.
- Convert the demodulated symbols into binary data.
- Calculate the number of bit errors.

The `while` loop continues to process data until either 200 errors are encountered or  $1e7$  bits are transmitted.

```
for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
```

```
snrdB = EbNoVec(n) + 10*log10(k);
% Reset the error and bit counters
numErrs = 0;
numBits = 0;

while numErrs < 200 && numBits < 1e7
    % Generate binary data and convert to symbols
    dataIn = randi([0 1],numSymPerFrame,k);
    dataSym = bi2de(dataIn);

    % QAM modulate using 'Gray' symbol mapping
    txSig = qammod(dataSym,M);

    % Pass through AWGN channel
    rxSig = awgn(txSig,snrdB,'measured');

    % Demodulate the noisy signal
    rxSym = qamdemod(rxSig,M);
    % Convert received symbols to bits
    dataOut = de2bi(rxSym,k);

    % Calculate the number of bit errors
    nErrors = biterr(dataIn,dataOut);

    % Increment the error and bit counters
    numErrs = numErrs + nErrors;
    numBits = numBits + numSymPerFrame*k;
end

% Estimate the BER
berEst(n) = numErrs/numBits;
end
```

Determine the theoretical BER curve by using the `berawgn` function.

```
berTheory = berawgn(EbNoVec, 'qam', M);
```

Plot the estimated and theoretical BER data. The estimated BER data points are well aligned with the theoretical curve.

```
semilogy(EbNoVec,berEst, '*')
hold on
semilogy(EbNoVec,berTheory)
grid
legend('Estimated BER', 'Theoretical BER')
```

```
xlabel('Eb/No (dB)')  
ylabel('Bit Error Rate')
```

## Input Arguments

**x, y** — Inputs to be compared (as separate arguments)

vector | matrix

Inputs to be compared, specified as separate arguments, as a vector or matrix of nonnegative integer elements. The function converts each element of  $x$  and  $y$  to its unsigned binary representation for comparison.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **k** — Maximum number of bits for input elements

positive integer

Maximum number of bits for input elements of `x` and `y`, specified as a positive integer. If the number of bits required for binary representation of any element in `x` or `y` is greater than `k`, the function errors.

If you do not set `k`, the function sets it as the number of bits in the binary representation of the largest element in `x` and `y`.

Data Types: `single` | `double`

### **flag** — Flag to override default settings

`'overall'` | `'row-wise'` | `'column-wise'`

Flag to override default settings of the function, specified as `'overall'`, `'row-wise'`, or `'column-wise'`. Flag specifies how the function compares elements in inputs `x`, `y` and computes the output. For more details, see the Algorithms on page 2-126 section.

Data Types: `string` | `char`

## Output Arguments

### **number** — Number of bit errors

nonnegative integer | integer vector

Number of bit errors, returned as a nonnegative integer or integer vector.

Data Types: `single` | `double`

### **ratio** — Bit error rate

scalar

Bit error rate, returned as a scalar. `ratio` is the number of bit errors, `number`, to the total number of bits used in the binary representation. The total number of bits is `k` times the number of entries in the smaller of the inputs `x`, `y`.

### **individual** — Binary comparison result of each input element

matrix

Binary comparison result of each input element in  $x$  and  $y$ , returned as a matrix whose dimensions are those of the larger of  $x$  and  $y$ . Each element specifies the number of bits by which the elements in the pair differ.

Data Types: `single` | `double`

## Algorithms

### Comparing Inputs Based on Sizes

The function uses the sizes of  $x$  and  $y$  to determine the order in which it compares their elements.

- If inputs are matrices of the same dimensions, then the function compares the inputs element by element. `number` is a nonnegative integer in this case. For example, see case (a) in the figure.
- If one input is a matrix and the other input is a column vector, then the function compares each column of the matrix element by element with the column vector. The number of rows in the matrix must be equal to the length of the column vector. In other words, if the matrix has dimensions  $m$ -by- $n$ , then the column vector must have dimensions  $m$ -by-1. For example, see case (b) in the figure.
- If one input is a matrix and the other input is a row vector, then the function compares each row of the matrix element by element with the row vector. The number of columns in the matrix must be equal to the length of the row vector. In other words, if the matrix has dimensions  $m$ -by- $n$ , then the row vector must have dimensions 1-by- $n$ . For example, see case (c) in the figure.

## Comparing Inputs Based on Flag

This table describes how the output is computed based on the different values of `flag`. `x` is considered as a matrix in this table and the size of `y` is varied.

Size of <code>y</code>	<code>flag</code> Value	Type of Comparison	number Value	Total Number of Bits
Matrix	'overall' (default)	Element by element	Total number of bit errors	k times the number of elements in <code>y</code>
	'row-wise'	<i>m</i> th row of <code>x</code> to <i>m</i> th row of <code>y</code>	Column vector whose elements represent the bit errors in each row	k times the number of elements in <code>y</code>
	'column-wise'	<i>m</i> th column of <code>x</code> to <i>m</i> th column of <code>y</code>	Row vector whose elements represent the bit errors in each column	k times the number of elements in <code>y</code>
Row vector	'overall'	<code>y</code> to each row of <code>x</code>	Total number of bit errors	k times the number of elements of <code>x</code>
	'row-wise' (default)	<code>y</code> to each row of <code>x</code>	Column vector whose elements represent the bit errors in each row of <code>x</code>	k times the size of <code>y</code>
Column vector	'overall'	<code>y</code> to each column of <code>x</code>	Total number of bit errors	k times the number of elements of <code>x</code>

---

Size of y	flag Value	Type of Comparison	number Value	Total Number of Bits
	'column-wise' (default)	y to each column of x	Row vector whose elements represent bit errors in each column of x	k times the size of y

# bleATTPDU

Generate BLE ATT PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
attPDU = bleATTPDU(cfgATT)
```

## Description

`attPDU = bleATTPDU(cfgATT)` generates a Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU) corresponding to the BLE ATT PDU configuration object `cfgATT`.

## Examples

### Generate BLE ATT PDUs

Generate two unique BLE ATT PDUs of type 'Read by type request' and 'Error response'.

Create a BLE ATT PDU configuration object with default settings.

```
cfgATT = bleATTPDUConfig;
```

Change the BLE ATT PDU opcode as 'Read by type request'. View the applicable properties of the opcode 'Read by type request'.

```
cfgATT.Opcode = 'Read by type request'
```

```

cfgATT =
  bleATTPDUConfig with properties:
      Opcode: 'Read by type request'
      StartHandle: '0001'
      EndHandle: 'FFFF'
      AttributeType: '2800'

```

Generate a BLE ATT PDU using the corresponding configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

```

attPDU = 7x2 char array
    '08'
    '01'
    '00'
    'FF'
    'FF'
    '00'
    '28'

```

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode to 'Error response'. View the applicable properties of the opcode 'Error response'.

```
cfgATT = bleATTPDUConfig('Opcode','Error response')
```

```

cfgATT =
  bleATTPDUConfig with properties:
      Opcode: 'Error response'
      RequestedOpcode: 'Read request'
      AttributeHandle: '0001'
      ErrorMessage: 'Invalid handle'

```

Generate a BLE ATT PDU corresponding to this configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

```

attPDU = 5x2 char array
    '01'
    '0A'

```

```
'01'  
'00'  
'01'
```

## Input Arguments

**cfgATT** — BLE ATT PDU configuration object

bleATTPDUConfig object

BLE ATT PDU configuration object, specified as a bleATTPDUConfig object. This value defines the type of BLE ATT PDU and its applicable properties.

## Output Arguments

**attPDU** — Generated BLE ATT PDU

character array

Generated BLE ATT PDU, returned as a character array. Each row in this array is the hexadecimal representation of an octet.

Decode BLE ATT PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
[status, cfgATT] = bleATTPDUDecode(attPDU)
```

## Description

[status, cfgATT] = bleATTPDUDecode(attPDU) decodes the specified Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU), returning the corresponding BLE ATT PDU configuration object, cfgATT, and the decoding status, status.

## Examples

### Decode BLE ATT PDUs

Decode two unique BLE ATT PDUs of type 'Read by type request' and 'Error response'.

Create a BLE ATT PDU configuration object with default settings.

```
cfgATT = bleATTPDUConfig;
```

Change the BLE ATT PDU opcode as 'Read by type request'. View the applicable properties of the opcode 'Read by type request'.

```
cfgATT.Opcode = 'Read by type request'
```

```

cfgATT =
  bleATTPDUConfig with properties:
      Opcode: 'Read by type request'
      StartHandle: '0001'
      EndHandle: 'FFFF'
      AttributeType: '2800'

```

Generate a BLE ATT PDU using the corresponding configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

```
attPDU = 7x2 char array
'08'
'01'
'00'
'FF'
'FF'
'00'
'28'

```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode 'Read by type request'.

```
[status, cfg] = bleATTPDUDecode(attPDU)
```

```
status =
Success
```

```
cfg =
  bleATTPDUConfig with properties:
      Opcode: 'Read by type request'
      StartHandle: '0001'
      EndHandle: 'FFFF'
      AttributeType: '2800'

```

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode as 'Error response'. View the applicable properties of the opcode 'Error response'.

```
cfgATT = bleATTPDUConfig('Opcode', 'Error response')
```

```
cfgATT =
  bleATTPDUConfig with properties:
      Opcode: 'Error response'
  RequestedOpcode: 'Read request'
  AttributeHandle: '0001'
  ErrorMessage: 'Invalid handle'
```

Generate a BLE ATT PDU using the corresponding configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

```
attPDU = 5x2 char array
'01'
'0A'
'01'
'00'
'01'
```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode 'Error response'.

```
[status, cfg] = bleATTPDUDecode(attPDU)
```

```
status =
Success
```

```
cfg =
  bleATTPDUConfig with properties:
      Opcode: 'Error response'
  RequestedOpcode: 'Read request'
  AttributeHandle: '0001'
  ErrorMessage: 'Invalid handle'
```

### Decode Corrupted BLE ATT PDU

Specify a BLE ATT PDU containing corrupted data values.

```
attPDU = ['09'; '03'; '01'; '00'; '18'; '0D']; % Sample corrupted BLE ATT PDU
```

Decode the specified BLE ATT PDU. The returned status indicates that the decoding failed due to mismatched attribute data lengths. In case of failed decoding, BLE ATT PDU configuration object, 'cfgATT', displays no properties.

```
[status, cfgATT] = bleATTPDUDecode(attPDU)
```

```
status =  
MismatchAttributeDataLength
```

```
cfgATT =  
  bleATTPDUConfig with properties:
```

## Input Arguments

### **attPDU** — BLE ATT PDU

character vector | string scalar | numeric vector | character array

BLE ATT PDU, specified as one of these values:

- Character vector — This vector represent octets in hexadecimal format.
- String scalar — This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represent octets in decimal format.
- n-by-2 character array — Each row represent an octet in hexadecimal format.

Data Types: char | uint8 | uint16 | uint32 | double | string

## Output Arguments

### **cfgATT** — BLE ATT PDU configuration object

bleATTPDUConfig object

BLE ATT PDU configuration object, returned as a bleATTPDUConfig object. This value denotes the decoded BLE ATT PDU configuration.

### **status** — Packet decoding status

nonpositive integer

Packet decoding status, returned as a nonpositive number of type `blePacketDecodeStatus`. This value represents the result of an ATT PDU decoding. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status according to this table.

<b>Enumeration Value</b>	<b>Member of Enumeration Class</b>	<b>Decoding Status</b>
0	Success	Packet decoding succeeded
-401	UnsupportedATTOpcode	Invalid ATT opcode
-402	IncompleteATTPDU	Incomplete ATT PDU
-403	InvalidATTReqOpcodeInErrorResp	Invalid requested opcode in "Error Response" PDUs
-404	InvalidATTErrorCode	Invalid error code
-405	InvalidATTRxMTU	Invalid received MTU
-406	InvalidAttributeHandleRange	Invalid attribute handle range
-407	InvalidAttributeType	Invalid attribute type flag
-408	InvalidATTExecuteWriteFlag	Invalid execute write flag
-409	MismatchAttributeDataLength	Length mismatches with actual length
-410	InvalidATTDataFormat	Invalid Data Format

An enumeration value other than 0 means that the BLE ATT PDU decoding failed. If the decoding fails, object `cfgATT` displays no output.

# bleGAPDataBlock

Generate BLE GAP data block

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
dataBlock = bleGAPDataBlock(cfgGAP)
```

## Description

`dataBlock = bleGAPDataBlock(cfgGAP)` generates a Bluetooth low energy (BLE) generic access profile (GAP) data block of type advertising data (AD) or scan response data (SRD) corresponding to the BLE GAP data block configuration object `cfgGAP`.

## Examples

### Generate BLE GAP AD Blocks

Generate three unique BLE GAP AD blocks: first one with AD types 'Flags' and 'Tx power level', the second one with AD types 'Advertising interval' and 'Local name' and the third one with AD type 'Flags' and having simultaneous support for low energy (LE) and basic rate/enhanced data rate (BR/EDR) at the host.

Create a configuration object for a BLE GAP AD block and specify the AD types as 'Flags' and 'Tx power level'. Assign the values of LED discoverability as 'Limited' and Tx power level as 45.

```
cfgGAP = bleGAPDataBlockConfig;  
cfgGAP.AdvertisingDataTypes = {'Flags'; 'Tx power level'};
```

```

cfgGAP.LEDiscoverability    = 'Limited';
cfgGAP.TxPowerLevel        = 45;

```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
```

```

dataBlock = 6x2 char array
    '02'
    '01'
    '05'
    '02'
    '0A'
    '2D'

```

Create a configuration object for a BLE GAP AD block, this time with advertising data types as 'Advertising interval' and 'Local name'. Specify the values of the advertising interval as 48, the local name as 'MathWorks' and the local name shortening as true.

```

cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
    {'Advertising interval', ...
    'Local name'});
cfgGAP.AdvertisingInterval = 48;
cfgGAP.LocalName           = 'MathWorks';
cfgGAP.LocalNameShortening = true;

```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
```

```

dataBlock = 15x2 char array
    '03'
    '1A'
    '30'
    '00'
    '0A'
    '08'
    '4D'
    '61'
    '74'
    '68'
    '57'
    '6F'

```

```
'72'  
'6B'  
'73'
```

Create a configuration object for a BLE GAP AD block with type 'Flags'. Specify the values of LE discoverability as 'Limited', BR/EDR support as `true`, and simultaneous support for LE and BR/EDR as 'Host'.

```
cfgGAP = bleGAPDataBlockConfig;  
cfgGAP.LEDiscoverability = 'Limited';  
cfgGAP.BREDR = true;  
cfgGAP.LE = 'Host';
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
```

```
dataBlock = 3x2 char array  
'02'  
'01'  
'11'
```

## Input Arguments

### **cfgGAP** — BLE GAP data block configuration object

`bleGAPDataBlockConfig` (default) | object

BLE GAP data block configuration object, specified as a `bleGAPDataBlockConfig` object. This value defines the type of BLE GAP data block and its applicable properties.

## Output Arguments

### **dataBlock** — Generated BLE GAP data block

character array

Generated BLE GAP data block, returned as a character array. Each row in this array is the hexadecimal representation of an octet.

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
```

## Description

`[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)` decodes a Bluetooth low energy (BLE) generic access profile (GAP) data block, `dataBlock`, of the type advertising data (AD) or scan response data (SRD), returning the decoding status, `status`, and the BLE GAP data block configuration object, `cfgGAP`.

## Examples

### Decode BLE GAP AD Blocks

Decode two unique BLE GAP AD blocks: one with AD types 'Flags' and 'Tx power level' and the other with AD types 'Advertising interval' and 'Local name'.

Create a configuration object for a BLE GAP AD block. Specify the AD types as 'Flags' and 'Tx power level'. Set the values of LE discoverability as 'Limited' and Tx power level to 45. View the properties of the configuration object 'cfgGAP'.

```
cfgGAP = bleGAPDataBlockConfig;  
cfgGAP.AdvertisingDataTypes = {'Flags'; 'Tx power level'};
```

```
cfgGAP.LEDiscoverability = 'Limited';
cfgGAP.TxPowerLevel = 45
```

```
cfgGAP =
  bleGAPDataBlockConfig with properties:
```

```
    AdvertisingDataTypes: {2x1 cell}
    LEDiscoverability: 'Limited'
    BREDR: 0
    TxPowerLevel: 45
```

Generate a BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP);
```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful. View the output of 'status' and 'cfgGAP'.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
```

```
status =
  Success
```

```
cfgGAP =
  bleGAPDataBlockConfig with properties:
```

```
    AdvertisingDataTypes: {2x1 cell}
    LEDiscoverability: 'Limited'
    BREDR: 0
    TxPowerLevel: 45
```

Create another BLE GAP AD block configuration object, this time specifying AD types 'Advertising interval' and 'Local name'. Set the values of advertising interval as 48, local name as 'MathWorks', and local name shortening as true. View the properties of the configuration object 'cfgGAP'.

```
cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
    {'Advertising interval','Local name'});
cfgGAP.AdvertisingInterval = 48;
cfgGAP.LocalName = 'MathWorks';
cfgGAP.LocalNameShortening = true
```

```
cfgGAP =
  bleGAPDataBlockConfig with properties:
```

```
AdvertisingDataTypes: {2x1 cell}
    LocalName: 'MathWorks'
LocalNameShortening: 1
AdvertisingInterval: 48
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP);
```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful. View the output of 'status' and 'cfgGAP'.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
```

```
status =
Success
```

```
cfgGAP =
bleGAPDataBlockConfig with properties:
```

```
AdvertisingDataTypes: {2x1 cell}
    LocalName: 'MathWorks'
LocalNameShortening: 1
AdvertisingInterval: 48
```

### Decode Corrupted BLE GAP AD Block

Specify a BLE GAP AD block containing corrupted data values.

```
dataBlock = ['010106010202']; % Sample BLE GAP AD block with corrupted data values
```

Decode the specified BLE GAP AD block. The returned status indicates that the decoding failed due to the corrupted input BLE GAP AD block. In this case, when decoding fails, the BLE GAP AD block configuration object, 'cfgGAP', displays no properties.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
```

```
status =
MismatchGAPADLength
```

```
cfgGAP =
  bleGAPDataBlockConfig with properties:
```

## Input Arguments

### **dataBlock** — BLE GAP data block

character vector | string scalar | numeric vector | character array

BLE GAP data block, specified as one of these values:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0, 255] — This vector represents octets in decimal format.
- *n*-by-2 character array — Each row represents an octet in hexadecimal format.

Data Types: char | string | double

## Output Arguments

### **status** — BLE GAP data block decoding status

nonpositive integer

BLE GAP data block decoding status, returned as a nonpositive integer of type `blePacketDecodeStatus`. This value represents the result of an BLE GAP data block decoding. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status according to this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	Success	Packet decoding succeeded
-201	InvalidGAPADLength	GAP AD length is not valid

-202	MismatchGAPADLength	Received AD length does not match with actual length
-203	UnsupportedGAPADType	Advertising data type is not valid or not supported
-204	InvalidGAPAdvertisingInterval	Advertising interval is not valid
-205	InvalidGAPConnectionIntervalRange	Invalid connection interval
-206	InvalidGAPConnectionIntervalMinimum	Invalid interval minimum
-207	InvalidGAPConnectionIntervalMaximum	Invalid interval maximum

An enumeration value other than 0 means that the BLE GAP data block decoding failed. If the decoding fails, object `cfgGAP` displays no output.

### **cfgGAP — BLE GAP data block configuration object**

`bleGAPDataBlockConfig` | object

BLE GAP data block configuration object, returned as a `bleGAPDataBlockConfig` object. This value defines the type of BLE GAP data block and its applicable properties.

# bleIdealReceiver

Ideal receiver for BLE PHY waveform

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
[bits,accessAddr] = bleIdealReceiver(waveform)
[bits,accessAddr] = bleIdealReceiver(waveform,Name,Value)
```

## Description

[bits,accessAddr] = bleIdealReceiver(waveform) decodes the Bluetooth low energy (BLE) waveform, generated by bleWaveformGenerator , and returns the received bits, bits, and the access address information, accesAddr.

[bits,accessAddr] = bleIdealReceiver(waveform,Name,Value) also specifies options using one or more name-value pair arguments. For example, 'Mode' , 'LE2M' specifies the physical (PHY) layer transmission mode of the desired BLE waveform.

## Examples

### Decode BLE Waveform Using Default Settings

Create an input message column vector of length 1000 containing random binary values. Generate a BLE transmit waveform from the transmission bits by using the bleWaveformGenerator function.

```
txBits = randi([0 1],1000,1);
txWaveform = bleWaveformGenerator(txBits);
```

Pass the transmit waveform through a noisy channel and obtain the received waveform.

```
snr = 30; % specified in dB
rxWaveform = awgn(txWaveform,snr);
```

Recover data bits from the received BLE waveform using `bleIdealReceiver`. Check for the number of bit errors in the recovered bits. The returned value indicates that the BLE waveform was successfully decoded.

```
[rxBits,accessAddr] = bleIdealReceiver(rxWaveform);
numErr = biterr(txBits,rxBits)

numErr = 0
```

### Decode BLE Waveform Using Specified Name-Value Pairs

Specify the values of PHY generating mode, channel index and samples per symbol (sps).

```
phyMode = 'LE125K';
chanIndex = 2;
sps = 4;
```

Generate transmission bits containing random binary values. Obtain the BLE transmit waveform from the transmission bits and the specified name-value pairs using the `bleWaveformGenerator` function.

```
txBits = randi([0 1],100,1);
txWaveform = bleWaveformGenerator(txBits,'Mode',phyMode,...
    'SamplesPerSymbol',sps,'ChannelIndex',chanIndex);
```

Recover the data bits, and then compare them with the transmission bits. The result indicates that the transmission bits match the recovered data bits, meaning the BLE waveform was successfully decoded.

```
rxBits = bleIdealReceiver(txWaveform,'Mode',phyMode,...
    'SamplesPerSymbol',sps,'ChannelIndex',chanIndex);
isequal(txBits,rxBits)

ans = logical
     1
```

## Input Arguments

### waveform — Received time-domain signal

complex-valued vector

Received time-domain signal, specified as a complex-valued signal with size  $N_s$ -by-1, where  $N_s$  represents the number of received samples. The values of  $N_s$  depend on the 'Mode' and 'SamplesPerSymbol' (sps) name-value pairs, according to the constraints specified in this table. For example, if the value of 'Mode' is 'LE1M' and the value of 'SamplesPerSymbol' is 4 then the value of  $N_s$  must be greater than or equal to 160 and a multiple of 'SamplesPerSymbol'.

Value of 'Mode'	Value of $N_s$	Multiple of
'LE1M'	$\geq 40 \times sps$	$sps$
'LE2M'	$\geq 48 \times sps$	$sps$
'LE500K'	$\geq 376 \times sps$	$2 \times sps$
'LE125K'	$\geq 376 \times sps$	$8 \times sps$

Data Types: double | single

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `bleIdealReceiver(waveform, 'Mode', 'LE2M', 'ChannelIndex', 36)`

### Mode — PHY transmission mode

'LE1M' (default) | 'LE2M' | 'LE500K' | 'LE125K'

PHY transmission mode, specified as the comma-separated pair consisting of 'Mode' and 'LE1M', 'LE2M', 'LE500K', or 'LE125K'. This value indicates the type of PHY used to decode the received BLE waveform.

Data Types: string | char

### ChannelIndex — Channel Index

37 (default) | integer in the range [0, 39]

Channel index, specified as the comma-separated pair consisting of 'ChannelIndex' and an integer in the range [0, 39]. For data channels, this value must be in the range [0, 36]. For advertising channels, this value must be in the range [37, 39]. This value is used by the data-dewhitening block.

Data Types: `single` | `double`

### **SamplesPerSymbol — Samples per symbol**

8 (default) | positive integer

Samples per symbol, specified as the comma-separated pair consisting of 'SamplesPerSymbol' and a positive integer. This value is used for the Gaussian frequency shift keying (GFSK) modulation.

Data Types: `single` | `double`

## **Output Arguments**

### **bits — Payload bits**

column vector

Payload bits, returned as a column vector of maximum length 260 bytes. This output represents the recovered information bits.

### **accessAddr — Access address information**

32-bit column vector

Access address information, returned as a 32-bit column vector. This output is used by the higher layers for validating a packet.

# bleL2CAPFrame

Generate BLE L2CAP frame

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
L2CAPFrame = bleL2CAPFrame(cfgL2CAP)
L2CAPFrame = bleL2CAPFrame(cfgL2CAP,SDU)
```

## Description

`L2CAPFrame = bleL2CAPFrame(cfgL2CAP)` generates a Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) frame, `L2CAPFrame`, for a given BLE L2CAP configuration object, `cfgL2CAP`. Use this syntax to generate the signaling frames.

`L2CAPFrame = bleL2CAPFrame(cfgL2CAP,SDU)` generates a BLE L2CAP frame, `L2CAPFrame`, for a given BLE L2CAP configuration object `cfgL2CAP` and the upper-layer payload service data unit (SDU), `SDU`. Use this syntax to generate the data frames.

## Examples

### Generate BLE L2CAP Signaling Command Frame

Create a BLE L2CAP configuration object, ' `cfgL2CAP` ', and view the corresponding default properties.

```
cfgL2CAP = bleL2CAPFrameConfig
cfgL2CAP =
    bleL2CAPFrameConfig with properties:
```

```
ChannelIdentifier: '0005'  
CommandType: 'Credit based connection request'  
SignalIdentifier: '01'  
SourceChannelIdentifier: '0040'  
LEPSM: '001F'  
MaxTransmissionUnit: 23  
MaxPDUPayloadSize: 23  
Credits: 1
```

Change the value of credits to 10.

```
cfgL2CAP.Credits          = 10;
```

Generate a BLE L2CAP signaling command frame from the corresponding configuration object.

```
l2capFrame = bleL2CAPFrame(cfgL2CAP)
```

```
l2capFrame = 18x2 char array
```

```
'0E'  
'00'  
'05'  
'00'  
'14'  
'01'  
'0A'  
'00'  
'1F'  
'00'  
'40'  
'00'  
'17'  
'00'  
'17'  
'00'  
'0A'  
'00'
```

## Generate BLE L2CAP Data Frames

Generate two unique BLE L2CAP data frames: one with SDU from the attribute protocol (ATT) layer as '0A0100' and the other with an upper-layer payload SDU, '0A01E2D3'.

Create a BLE L2CAP configuration object, 'cfgL2CAP', and view the default properties.

```
cfgL2CAP = bleL2CAPFrameConfig
cfgL2CAP =
  bleL2CAPFrameConfig with properties:
      ChannelIdentifier: '0005'
      CommandType: 'Credit based connection request'
      SignalIdentifier: '01'
      SourceChannelIdentifier: '0040'
      LEPSM: '001F'
      MaxTransmissionUnit: 23
      MaxPDUPayloadSize: 23
      Credits: 1
```

Change the value of channel identifier to '0004'.

```
cfgL2CAP.ChannelIdentifier = '0004'; % Channel identifier for ATT
```

Generate a BLE L2CAP data frame from 'cfgL2CAP', specifying the upper-layer payload SDU from the ATT layer as '0A0100'.

```
l2capFrame = bleL2CAPFrame(cfgL2CAP, "0A0100")
```

```
l2capFrame = 7x2 char array
'03'
'00'
'04'
'00'
'0A'
'01'
'00'
```

Create another BLE L2CAP configuration object, 'cfgL2CAP', with default properties. Set the value of channel identifier to '007A'.

```
cfgL2CAP = bleL2CAPFrameConfig;
cfgL2CAP.ChannelIdentifier = '007A'; % Dynamic channel identifier
```

Generate a BLE L2CAP data frame from 'cfgL2CAP', specifying the upper-layer payload SDU as '0A01E2D3'.

```
l2capFrame = bleL2CAPFrame(cfgL2CAP, ['0A'; '01'; 'E2'; 'D3'])
```

```
l2capFrame = 10x2 char array
    '06'
    '00'
    '7A'
    '00'
    '04'
    '00'
    '0A'
    '01'
    'E2'
    'D3'
```

## Input Arguments

### **cfgL2CAP** — BLE L2CAP configuration object

bleL2CAPFrameConfig object

BLE L2CAP configuration object, specified as a bleL2CAPFrameConfig object. The function uses this object to configure the BLE L2CAP frame and its applicable properties.

### **SDU** — Upper-layer payload

character vector | string scalar | numeric vector | character array

Upper-layer payload, specified as one of these types:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0, 255] — This vector represents octets in decimal format.
- *n*-by-2 character array — Each row represents an octet in hexadecimal format.

Data Types: char | double | string

## Output Arguments

### **L2CAPFrame — Generated BLE L2CAP frame**

character array

Generated BLE L2CAP frame, returned as a character array. Each row of the array represents an octet in hexadecimal format. This value represents the output BLE L2CAP frame.

# bleL2CAPFrameDecode

Decode BLE L2CAP frame

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
[status, cfgL2CAP, SDU] = bleL2CAPFrameDecode(L2CAPFrame)
```

## Description

[status, cfgL2CAP, SDU] = bleL2CAPFrameDecode(L2CAPFrame) decodes the specified Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) frame, L2CAPFrame. The function returns the decoding status, status, the corresponding BLE L2CAP configuration object, cfgL2CAP, and the upper-layer payload service data unit (SDU), SDU.

## Examples

### Decode BLE L2CAP Data Frame with SDU

Create a BLE L2CAP configuration object, 'cfgL2CAP', with default properties and view the applicable properties. Change the value of channel identifier to '0004'.

```
cfgL2CAP = bleL2CAPFrameConfig
cfgL2CAP =
    bleL2CAPFrameConfig with properties:
        ChannelIdentifier: '0005'
```

```

        CommandType: 'Credit based connection request'
        SignalIdentifier: '01'
        SourceChannelIdentifier: '0040'
            LEPSM: '001F'
        MaxTransmissionUnit: 23
        MaxPDUPayloadSize: 23
        Credits: 1

```

```
cfgL2CAP.ChannelIdentifier = '0004'; % Channel identifier for ATT
```

Generate a BLE L2CAP data frame from 'cfgL2CAP', specifying the upper-layer payload SDU from attribute protocol (ATT) layer as '0A0100'.

```
L2CAPFrame = bleL2CAPFrame(cfgL2CAP, "0A0100");
```

Decode the generated BLE L2CAP data frame. The returned status indicates decoding was successful. View the output of 'status', 'cfgL2CAP' and the 'SDU'.

```
[status, cfgL2CAP, SDU] = bleL2CAPFrameDecode(L2CAPFrame)
```

```
status =
Success
```

```
cfgL2CAP =
bleL2CAPFrameConfig with properties:
```

```
    ChannelIdentifier: '0004'
```

```
SDU = 3x2 char array
```

```
    '0A'
    '01'
    '00'
```

## Decode Corrupted BLE L2CAP Frame

Specify a BLE L2CAP frame containing corrupted data values.

```
l2capFrame = ['090005000107040060005000']; % Sample frame
```

Decode the specified BLE L2CAP frame. The returned status indicates that the decoding failed due to the corrupted input L2CAP frame. In this case, when decoding fails, the

output displays the reason of failure and the BLE L2CAP frame configuration object, 'cfgL2CAP', displays no properties.

```
[status, cfgL2CAP, SDU] = bleL2CAPFrameDecode(l2capFrame)
```

```
status =  
MismatchL2CAPHeaderLength
```

```
cfgL2CAP =  
bleL2CAPFrameConfig with properties:
```

```
SDU =
```

```
1x0 empty char array
```

## Input Arguments

### L2CAPFrame — BLE L2CAP frame

character vector | string scalar | numeric vector | character array

BLE L2CAP frame, specified as one of these values:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0, 255] — This vector represents octets in decimal format.
- *n*-by-2 character array — Each row represents an octet in hexadecimal format.

Data Types: char | double | string

## Output Arguments

### status — Packet decoding status

nonpositive integer

Packet decoding status, returned as a nonpositive integer of type `blePacketDecodeStatus`. This value represents the result of decoding a BLE L2CAP

frame. Each value of status corresponds to a member of the blePacketDecodeStatus enumeration class, which indicates the packet decoding status according to this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	Success	Packet decoding succeeded
-301	InvalidL2CAPConnectionIntervalRange	Invalid connection intervals
-302	InvalidL2CAPSlaveLatency	Invalid slave latency
-303	InvalidLECredits	Invalid low energy (LE) credits
-304	L2CAPSegmentationUnsupported	Segmentation is not supported
-305	MismatchL2CAPHeaderLength	Length mismatches with actual length
-306	IncompleteL2CAPDataFrame	L2CAP data frame is not sufficient to decode
-307	InvalidL2CAPChannelIdentifier	Invalid L2CAP channel identifier
-308	InvalidL2CAPCommand	Invalid L2CAP command code
-309	InvalidL2CAPCommandRejectReason	Invalid command reject reason code
-310	InvalidL2CAPParameterUpdateResult	Invalid parameters update result
-311	InvalidL2CAPConnectionResult	Invalid connection result code
-312	IllegalL2CAPSignalIdentifier	Illegal signal identifier in L2CAP
-313	InvalidL2CAPConnectionIntervalMinimum	Invalid interval minimum
-314	InvalidL2CAPConnectionIntervalMaximum	Invalid interval maximum

-315	InvalidL2CAPConnectionTimeout	Invalid connection timeout
-316	InvalidLEPSM	Invalid LE protocol/service multiplexer
-317	InvalidL2CAPChannelMTU	Invalid maximum transmission unit
-318	InvalidL2CAPChannelMPS	Invalid maximum PDU payload size
-319	InvalidL2CAPSDULength	Invalid SDU length
-320	MismatchL2CAPSignalFrameLength	Length mismatches with actual length
-321	IncompleteL2CAPSignalFrame	L2CAP signal frame is not valid or not sufficient

An enumeration value other than 0 means that the BLE ATT PDU decoding failed. If the decoding fails, object `cfgATT` displays no output.

### **cfgL2CAP — BLE L2CAP frame configuration object**

`bleL2CAPFrameConfig` object

BLE L2CAP frame configuration object, returned as a `bleL2CAPFrameConfig` object. This value denotes the decoded BLE L2CAP frame configuration.

### **SDU — Upper-layer payload**

character array

Upper-layer payload, returned as a character array. Each row represents an octet in hexadecimal format.

Data Types: `char` | `string`

**Introduced in R2019b**

# bleLLAdvertisingChannelPDU

Generate BLE LL advertising channel PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv)
```

## Description

`pdu = bleLLAdvertisingChannelPDU(cfgLLAdv)` generates a Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU) corresponding to the BLE LL advertising channel PDU configuration object `cfgLLAdv`.

## Examples

### Generate BLE LL Advertising Channel PDUs

Generate two unique BLE LL advertising channel PDUs: first one of the type 'Advertising indication' using advertising data '020106' and the other of type 'Connection indication' using a set of data channels to be used.

Create a BLE LL advertising channel PDU configuration object, 'cfgLLAdv', with the opcode as 'Advertising indication' by using advertising data '020106'. View the configured properties corresponding to the opcode.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig;  
cfgLLAdv.AdvertisingData = '020106'
```

```

cfgLLAdv =
  bleLLAdvertisingChannelPDUConfig with properties:
      PDUType: 'Advertising indication'
      ChannelSelection: 'Algorithm1'
      AdvertiserAddressType: 'Random'
      AdvertiserAddress: '0123456789AB'
      AdvertisingData: [3x2 char]

```

Generate the BLE LL advertising channel PDU by using the corresponding configuration object. Display the PDU length in octets.

```

pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);
numel(pdu)/8

ans = 14

```

Display the first octet of the generated BLE LL advertising channel PDU.

```

pdu(1:8)

ans = 8×1

    0
    0
    0
    0
    0
    0
    1
    0

```

Create another BLE LL advertising channel PDU configuration object, this time using the name-value pairs. Change the BLE LL advertising channel PDU opcode to 'Connection indication'. View the active configured properties of the specified opcode.

```

cfgLLAdv = bleLLAdvertisingChannelPDUConfig('PDUType', ...
      'Connection indication')

cfgLLAdv =
  bleLLAdvertisingChannelPDUConfig with properties:
      PDUType: 'Connection indication'

```

```
ChannelSelection: 'Algorithm1'
AdvertiserAddressType: 'Random'
AdvertiserAddress: '0123456789AB'
InitiatorAddressType: 'Random'
InitiatorAddress: '0123456789CD'
AccessAddress: '01234567'
CRCInitialization: '012345'
WindowSize: 1
WindowOffset: 0
ConnectionInterval: 6
SlaveLatency: 0
ConnectionTimeout: 10
UsedChannels: [1x37 double]
HopIncrement: 5
SleepClockAccuracy: '251 to 500 ppm'
```

Specify the value of connection interval as 8 and the set of data channels as [0 4 12 16 18 24 25]. View the configured properties.

```
cfgLLAdv.ConnectionInterval = 8; % in milliseconds
cfgLLAdv.UsedChannels       = [0 4 12 16 18 24 25]
```

```
cfgLLAdv =
  bleLLAdvertisingChannelPDUConfig with properties:
```

```
    PDUType: 'Connection indication'
ChannelSelection: 'Algorithm1'
AdvertiserAddressType: 'Random'
AdvertiserAddress: '0123456789AB'
InitiatorAddressType: 'Random'
InitiatorAddress: '0123456789CD'
AccessAddress: '01234567'
CRCInitialization: '012345'
WindowSize: 1
WindowOffset: 0
ConnectionInterval: 8
SlaveLatency: 0
ConnectionTimeout: 10
UsedChannels: [0 4 12 16 18 24 25]
HopIncrement: 5
SleepClockAccuracy: '251 to 500 ppm'
```

Generate the BLE LL advertising channel PDU from the corresponding configuration object. Display the PDU length in octets.

```
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);  
numel(pdu)/8
```

```
ans = 39
```

Display the first octet of the generated BLE LL advertising channel PDU.

```
pdu(1:8)
```

```
ans = 8×1
```

```
1  
0  
1  
0  
0  
0  
1  
1
```

## Input Arguments

**cfgLLAdv** — BLE LL advertising channel PDU configuration object

bleLLAdvertisingChannelPDUConfig object

BLE LL advertising channel PDU configuration object, specified as a bleLLAdvertisingChannelPDUConfig object. This value defines the type of generated BLE LL advertising channel PDU and its applicable properties.

## Output Arguments

**pdu** — Generated BLE LL advertising channel PDU

binary column vector

Generated BLE LL advertising channel PDU, returned as a binary column vector. This value represents the output BLE LL advertising channel PDU.

# bleLLAdvertisingChannelPDUDecode

Decode BLE LL advertising channel PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu)
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu, Name, Value)
```

## Description

[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu) decodes the specified Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU), returning the decoding status, status, and the corresponding BLE LL advertising channel PDU configuration object, cfgLLAdv.

[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu, Name, Value) sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, 'InputFormat', 'octets' specifies the input BLE LL advertising channel PDU in the form of octets.

## Examples

### Decode BLE LL Advertising Channel PDU Given in Bits

Create a BLE LL advertising channel PDU configuration object, 'cfgLLAdv', with default settings and view the corresponding applicable properties.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig
```

```
cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
        PDUType: 'Advertising indication'
        ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
        AdvertisingData: [3x2 char]
```

Generate the BLE LL advertising channel PDU from the corresponding configuration object.

```
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);
```

Decode the generated BLE LL advertising channel PDU. The returned status indicates decoding is successful. View the output of 'status' and 'cfgLLAdv'.

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu)
```

```
status =
    Success
```

```
cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
        PDUType: 'Advertising indication'
        ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
        AdvertisingData: [3x2 char]
```

### Decode BLE LL Advertising Channel PDU Given in Octets

Specify a sample BLE LL advertising channel PDU in octets.

```
pdu = 'C409AB8967452301020106A8F1DF'; % Sample PDU in octets
```

Decode the specified BLE LL advertising channel PDU by specifying 'InputFormat' to 'octets'. The returned status indicates decoding is successful. View the output of 'status' and 'cfgLLData'.

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu, ...
    'InputFormat', 'octets')

status =
Success

cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:

        PDUType: 'Scan response'
        ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
        ScanResponseData: [3x2 char]
```

### Decode Corrupted BLE LL Advertising Channel PDU

Specify a BLE LL advertising channel PDU containing corrupted data values.

```
pdu = 'D409AB89674523010201'; % Sample corrupted PDU
```

Decode the specified BLE LL advertising channel PDU. The returned status indicates that the decoding failed due to corrupted input BLE LL advertising channel PDU. In case of failed decoding, the reason of failure is indicated and the BLE LL advertising channel PDU configuration object, 'cfgLLAdv', displays no properties.

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu, ...
    'InputFormat', 'octets')

status =
CRCFailed

cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
```

# Input Arguments

### **pdu** — BLE LL advertising channel PDU

character vector | string scalar | numeric vector | character array | binary vector

BLE LL advertising channel PDU, specified as one of these types:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represents octets in decimal format.
- n-by-2 character array — Each row represents an octet in hexadecimal format.
- Binary vector — This vector represents the BLE LL advertising channel PDU bits.

Data Types: char | double | string

# Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode('pdu', 'InputFormat', 'octets')`

### **InputFormat** — BLE LL advertising channel PDU format

'bits' (default) | 'octets'

BLE LL advertising channel PDU format, specified as 'bits' or 'octets'. When specified as 'bits', the `InputFormat` is a binary vector. When specified as 'octets', `InputFormat` is a numeric vector representing octets in decimal format or a character array or a string scalar representing octets in hexadecimal format.

Data Types: char | string

## Output Arguments

### status — BLE LL advertising channel PDU decoding status

nonpositive integer

BLE LL advertising channel PDU decoding status, returned as a nonpositive number of type `blePacketDecodeStatus`. This value represents the result of BLE LL advertising channel PDU decoding. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status listed in this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	Success	Packet decoding succeeded
-1	CRCFailed	Link Layer PDU is corrupted
-2	LLPDULengthMismatch	Length field does not match with actual PDU length
-3	InvalidLLSlaveLatency	Invalid slave latency
-4	InvalidLLConnectionTimeout	Invalid connection timeout
-5	InvalidLLWindowSize	Invalid window size
-6	InvalidLLWindowOffset	Invalid window offset
-7	InvalidLLConnectionInterval	Invalid connection interval
-8	InvalidLLChannelMap	Invalid channel map
-51	IncompleteLLAdvertisingChannelPDU	Insufficient octets in advertising channel PDU
-52	InvalidLLHopIncrement	Invalid hop increment value
-53	InvalidLLAdvertisingDataLength	Invalid advertising data
-54	InvalidLLScanResponseDataLength	Invalid scan response data
-55	UnsupportedLLAdvertisingPDUType	Unsupported advertising channel PDU

An enumeration value other than 0 means that the BLE LL advertising channel PDU decoding failed. If the decoding fails, object `cfgLLAdv` displays no output.

### **cfgLLAdv — BLE LL advertising channel PDU configuration object**

`bleLLAdvertisingChannelPDUConfig` object

BLE LL advertising channel configuration object, returned as a `bleLLAdvertisingChannelPDUConfig` object. This value represents the decoded BLE LL advertising channel PDU configuration.

# bleLLDataChannelPDU

Generate BLE LL data channel PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
pdu = bleLLDataChannelPDU(cfgLLData)
pdu = bleLLDataChannelPDU(cfgLLData,LLPayload)
```

## Description

`pdu = bleLLDataChannelPDU(cfgLLData)` generates a Bluetooth low energy (BLE) link layer (LL) data channel protocol data unit (PDU), `pdu`, for a given BLE LL data channel configuration object `cfgLLData`. This syntax is used for generating BLE LL control PDUs.

`pdu = bleLLDataChannelPDU(cfgLLData,LLPayload)` generates a BLE LL data channel PDU, `pdu`, containing the upper-layer payload `LLPayload` for a given BLE LL data channel configuration object `cfgLLData`. This syntax is used for generating BLE LL data PDUs.

## Examples

### Generate BLE LL Control PDU of Type Connection Update Indication

Create a BLE LL control PDU configuration object for a control PDU using the default configuration. View the corresponding default properties.

```
cfgControl = bleLLControlPDUConfig
```

```
cfgControl =
    bleLLControlPDUConfig with properties:
        Opcode: 'Connection update indication'
        WindowSize: 1
        WindowOffset: 0
        ConnectionInterval: 6
        SlaveLatency: 0
        ConnectionTimeout: 10
        Instant: 0
```

Create a BLE LL data channel PDU configuration object for a control PDU of type 'Connection update indication' by configuring the values of link layer identifier (LLID) as 'Control' and ControlConfig as 'cfgControl'. View the corresponding properties.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID', 'Control', ...
    'ControlConfig', cfgControl)
```

```
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
        LLID: 'Control'
        NESN: 0
        SequenceNumber: 0
        MoreData: 0
        ControlConfig: [1x1 bleLLControlPDUConfig]
```

Generate a BLE LL data channel PDU of type 'Connection update indication' by using the configuration object 'cfgLLData'. Display the PDU length in octets.

```
pdu = bleLLDataChannelPDU(cfgLLData);
numel(pdu)/8
```

```
ans = 17
```

Display the first octet of the generated BLE LL data channel PDU.

```
pdu(1:8)
```

```
ans = 8×1
```

```
1
```

```

### Generate BLE LL Data PDU Using Upper-Layer Payload

Create a BLE LL data channel PDU configuration object, 'cfgLLData', for a data PDU by using the default configuration. View the corresponding default properties.

```
cfgLLData = bleLLDataChannelPDUConfig
```

```
cfgLLData =
```

```
  bleLLDataChannelPDUConfig with properties:
```

```

          LLID: 'Data (continuation fragment/empty)'
          NESN: 0
SequenceNumber: 0
          MoreData: 0

```

Generate a BLE LL data PDU by using the corresponding configuration object, 'cgLLData' and the upper-layer payload '030004000A0100'. Display the PDU length in octets.

```
pdu = bleLLDataChannelPDU(cfgLLData, '030004000A0100');
numel(pdu)/8
```

```
ans = 12
```

Display the first octet of the generated BLE LL data PDU.

```
pdu(1:8)
```

```
ans = 8×1
```

```

## Input Arguments

### **cfgLLData — BLE LL data channel configuration object**

`bleLLDataChannelPDUConfig` object

BLE LL data channel configuration object, specified as a `bleLLDataChannelPDUConfig` object. This object is used to configure the BLE LL data channel PDU and its applicable properties.

### **LLPayload — Upper-layer payload**

character vector | string scalar | numeric vector | character array

Upper-layer payload, specified as one of these types:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represents octets in decimal format.
- n-by-2 character array — Each row represents an octet in hexadecimal format.

Data Types: `char` | `double` | `string`

## Output Arguments

### **pdu — Generated BLE LL data channel PDU**

binary vector

Generated BLE LL data channel PDU, returned as a binary column vector. This value represents the output BLE LL data channel PDU.

## bleLLDataChannelPDUDecode

Decode BLE LL data channel PDU

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

### Syntax

```
[status, cfgLLData, LLPayload] = bleLLDataChannelPDUDecode(pdu,  
CRCinit)  
[status, cfgLLData, LLPayload] = bleLLDataChannelPDUDecode(pdu, CRCinit  
Name, Value)
```

### Description

[status, cfgLLData, LLPayload] = bleLLDataChannelPDUDecode(pdu, CRCinit) decodes a Bluetooth low energy (BLE) link layer (LL) data channel protocol data unit (PDU), returning the decoding status, status, the BLE LL data channel PDU configuration object, cfgLLData, and the upper-layer payload, LLPayload. The CRCinit denotes the initialization value of cyclic redundancy check (CRC).

[status, cfgLLData, LLPayload] = bleLLDataChannelPDUDecode(pdu, CRCinit Name, Value) sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, 'InputFormat', 'bits' specifies the format of input BLE LL data channel PDU in bits.

### Examples

## Decode BLE LL Data Channel PDU Given in Bits

Create a BLE LL data channel PDU configuration object by using default settings and view the corresponding applicable properties.

```
cfgLLData = bleLLDataChannelPDUConfig

cfgLLData =
    bleLLDataChannelPDUConfig with properties:

        LLID: 'Data (continuation fragment/empty)'
        NESN: 0
    SequenceNumber: 0
        MoreData: 0
```

Initialize and set the LLID value to 'start fragment/complete' indicating the BLE LL data channel PDU with the upper-layer payload. Initialize the cyclic redundancy check (CRC) value to 'ED321C'.

```
cfgLLData.LLID = 'Data (start fragment/complete)';
cfgLLData.CRCInitialization = 'ED321C';
crcInit = 'ED321C'; % CRC initialization value
```

Generate the BLE LL data channel PDU with upper-layer payload given in hexadecimal octets.

```
pdu = bleLLDataChannelPDU(cfgLLData, '030004000A0100');
```

Decode the generated BLE LL data channel PDU. The returned status indicates decoding is successful. View the output of 'status', 'cfgLLData' and 'llPayload'.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(pdu, crcInit)

status =
    Success

cfgLLData =
    bleLLDataChannelPDUConfig with properties:

        LLID: 'Data (start fragment/complete)'
        NESN: 0
    SequenceNumber: 0
        MoreData: 0
```

```
llPayload = 7x2 char array
'03'
'00'
'04'
'00'
'0A'
'01'
'00'
```

### Decode BLE LL Data Channel PDU Given in Octets

Specify a sample BLE LL data channel PDU in octets.

```
pdu = '030C000100000060000000A0000000FCD2A6'; % Sample PDU in octets
```

Initialize the CRC value.

```
crcInit = 'ED323C'; % CRC initialization value
```

Decode the specified BLE LL data channel PDU by specifying 'InputFormat' to 'octets'. The specified PDU is a control PDU. The returned status indicates decoding is successful. View the output of 'status', 'cfgLLData' and 'llPayload'. You can see the decoded configuration of the specified PDU in the 'ControlConfig' property of 'cfgLLData'.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(...
    pdu, crcInit, ...
    'InputFormat', ...
    'octets')
```

```
status =
Success
```

```
cfgLLData =
bleLLDataChannelPDUConfig with properties:

    LLID: 'Control'
    NESN: 0
SequenceNumber: 0
    MoreData: 0
ControlConfig: [1x1 bleLLControlPDUConfig]
```

```
llPayload =
    1x0 empty char array
```

## Decode Corrupted BLE LL Data Channel PDU

Specify a BLE LL data channel PDU containing corrupted data values. Initialize the CRC value.

```
pdu = '040C00010000060000000A00'; % Sample corrupted PDU
crcInit = 'CD3234'; % CRC initialization value
```

Decode the specified BLE LL data channel PDU. The returned status indicates that the decoding failed due to the corrupted BLE LL data channel PDU. If the decoding fails, the reason is indicated and the BLE LL data channel PDU configuration object, 'cfgLLData', displays no properties.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(...
    pdu, crcInit, ...
    'InputFormat', ...
    'octets')
```

```
status =
    CRCFailed
```

```
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
```

```
llPayload =
    1x0 empty char array
```

## Input Arguments

### pdu — BLE LL data channel PDU

character vector | string scalar | numeric vector | character array | binary vector

BLE LL data channel PDU, specified as one of these values:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represents octets in decimal format.
- n-by-2 character array — Each row represents an octet in hexadecimal format.
- Binary vector — This vector represents BLE LL data channel PDU bits.

Data Types: char | string | double

### **CRCinit** — CRC initialization value

character vector | string scalar

CRC initialization value, specified as a 6-element character vector or a string scalar representing 3-octet hexadecimal value.

Data Types: char | string

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[status, cfgLLData, LLPayload] = bleLLDecodeDataChannelPDU('pdu', 'CRCInit', 'InputFormat', 'octets')`

### **InputFormat** — BLE LL data channel PDU format

'bits' (default) | 'octets'

BLE LL data channel PDU format, specified as 'bits' or 'octets'. When specified as 'bits', `InputFormat` is a binary vector. When specified as 'octets', `InputFormat` is a numeric vector representing octets in decimal format or a character array or a string scalar representing octets in hexadecimal format.

Data Types: char | string | double

## Output Arguments

### status — BLE LL data channel PDU decoding status

nonpositive integer

BLE LL data channel PDU decoding status, returned as a nonpositive number of type `blePacketDecodeStatus`. This value represents the result of a BLE LL data channel PDU decoding. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status as listed in this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	Success	Packet decoding succeeded
-1	CRCFailed	Link Layer PDU is corrupted
-2	LLPDULengthMismatch	Length field does not match with actual PDU length
-3	InvalidLLSlaveLatency	Invalid slave latency
-4	InvalidLLConnectionTimeout	Invalid connection timeout
-5	InvalidLLWindowSize	Invalid window size
-6	InvalidLLWindowOffset	Invalid window offset
-7	InvalidLLConnectionInterval	Invalid connection interval
-8	InvalidLLChannelMap	Invalid channel map
-101	IncompleteLLDataChannelPDU	Insufficient octets in data channel PDU
-102	InvalidLLID	Invalid LLID
-103	UnsupportedLLOpCode	Unsupported opcode
-104	InvalidLLErrorCode	Invalid error code
-105	InvalidBluetoothVersion	Invalid version
-106	ExpectedNonZeroPayload	Nonzero payload expected

-107	MICNotSupported	Payload contains MIC
------	-----------------	----------------------

An enumeration value other than 0 means that the BLE LL data channel PDU decoding failed. If decoding fails, object `cfgLLData` displays no output.

### **cfgLLData — BLE LL data channel configuration object**

`bleLLDataChannelPDUConfig` object

BLE LL data channel configuration object, returned as a `bleLLDataChannelPDUConfig` object. This value represents the decoded BLE LL data channel PDU configuration.

### **LLPayload — Upper-layer payload**

array

Upper-layer payload, returned as a character array where each row is the hexadecimal representation of an octet.

# bleWaveformGenerator

Waveform generator for BLE PHY

---

**Note Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons” (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

---

## Syntax

```
waveform = bleWaveformGenerator(message)
waveform = bleWaveformGenerator(message,Name,Value)
```

## Description

`waveform = bleWaveformGenerator(message)` generates `waveform`, a time-domain Bluetooth low energy (BLE) physical layer (PHY) waveform by using the input information bits `message`.

`waveform = bleWaveformGenerator(message,Name,Value)` also specifies options using one or more name-value pair arguments. For example, 'Mode', 'LE2M' specifies the generating mode value of the desired BLE waveform.

## Examples

### Generate BLE Waveform Using Default Settings

Create an input message column vector of length 2056 containing random binary values. Set the symbol rate to default value.

```
message = randi([0 1],2056,1);
symbolRate = 1e6;
```

Generate the BLE waveform.

```
waveform = bleWaveformGenerator(message);
```

Create a `dsp.SpectrumAnalyzer` System object to display the frequency spectrum of the generated BLE waveform. Set the sample rate of the frequency spectrum.

```
scope = dsp.SpectrumAnalyzer;  
scope.SampleRate = 8*symbolRate;
```

Plot the BLE waveform.

```
scope(waveform);
```

### Generate BLE Waveform Using Specified Name-Value Pairs

Create an input message column vector of length 640 containing random binary values.

```
message = randi([0 1],640,1);
```

Specify the values of generating mode, channel index, samples per symbol and access address. Set symbol rate to default value.

```
phyMode = 'LE125K';  
chanIdx = 2;  
sps = 4;  
accAdd = [1 1 1 1 0 1 0 0 1 1 0 1 0 0 1 0 0 1 1 0 1 1 1 0 1 ...  
          0 1 0 1 1 0 0].';  
symbolRate = 1e6;
```

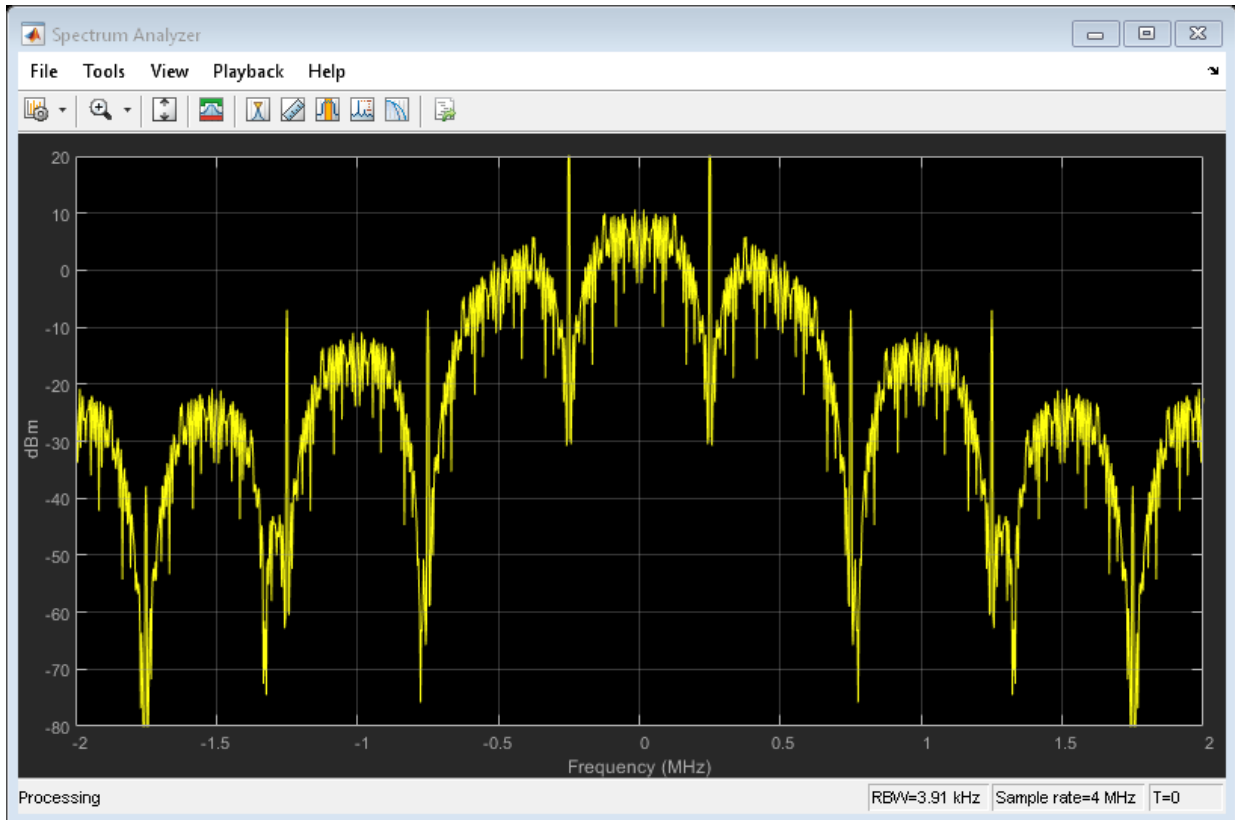

Create a `dsp.SpectrumAnalyzer` System object to display the frequency spectrum of the generated BLE waveform. Set the sample rate of the frequency spectrum.

```
scope = dsp.SpectrumAnalyzer;  
scope.SampleRate = sps*symbolRate;
```

Generate the BLE waveform using specified name-value pair arguments. Plot the BLE waveform.

```
waveform = bleWaveformGenerator(message, 'Mode', phyMode, ...  
    'SamplesPerSymbol', sps, 'ChannelIndex', chanIdx, 'AccessAddress', accAdd);  
scope(waveform);
```

## Input Arguments

### **message** — Input message bits

binary-valued column vector

Input message bits, specified as a binary-valued column vector of numerical or logical values. This message contains the protocol data unit (PDU) and cyclic redundancy check (CRC) data. The maximum length of this value is 2080 bits.

Data Types: `double` | `logical` | `single` | `int`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `bleWaveformGenerator(message, 'Mode', 'LE2M', 'ChannelIndex', 36)`

#### Mode — Generating mode

'LE1M' (default) | 'LE2M' | 'LE500K' | 'LE125K'

Generating mode, specified as the comma-separated pair consisting of 'Mode' and 'LE1M', 'LE2M', 'LE500K', or 'LE125K'. This value indicates the type of BLE waveform.

Data Types: `string` | `char`

#### ChannelIndex — Channel Index

37 (default) | integer in the range [0, 39]

Channel index, specified as the comma-separated pair consisting of 'ChannelIndex' and an integer in the range [0, 39]. For data channels, this value must be in the range [0, 36]. For advertising channels, this value must be in the range [37, 39]. This value is used by the data-whitening block to randomize the bits.

Data Types: `single` | `double`

#### SamplesPerSymbol — Samples per symbol

8 (default) | positive integer

Samples per symbol, specified as the comma-separated pair consisting of 'SamplesPerSymbol' and a positive integer. This value is used for the Gaussian frequency-shift keying (GFSK) modulation.

Data Types: `single` | `double`

#### AccessAddress — Access address

[0 1 1 0 1 0 1 1 0 1 1 1 1 0 1 1 0 0 1 0 0 0 1 0 1 1 1 0 0 0 1]'  
(default) | 32-bit column vector

Access address, specified as the comma-separated pair consisting of 'AccessAddress' and a 32-bit column vector of numerical or logical values.

Data Types: `logical` | `single` | `double` | `int`

## Output Arguments

### **waveform** — Output time-domain waveform

complex-valued column vector

Output time-domain waveform, returned as a complex-valued column vector of size  $N_s$ -by-1, where  $N_s$  represents the number of time-domain samples. The `waveform` is generated in the form of complex in-phase quadrature (IQ) samples.

## References

## bsc

Binary symmetric channel

### Syntax

```
ndata = bsc(data,probability)
ndata = bsc(data,probability,streamhandle)
ndata = bsc(data,probability,seed)
[ndata,err] = bsc(____)
```

### Description

`ndata = bsc(data,probability)` passes the binary input signal `data` through a binary symmetric channel having the specified error probability. The channel introduces a bit error and processes each element of the input `data` independently. `data` must be an array of binary numbers or a Galois array in GF(2). `probability` must be a scalar from 0 to 1.

`ndata = bsc(data,probability,streamhandle)` accepts a random stream handle to generate uniform noise samples by using `rand`. Providing a random stream handle or using the `reset` function on the default random stream object enables you to generate repeatable noise samples. For more information, see `RandStream`.

`ndata = bsc(data,probability,seed)` accepts a seed value, for initializing the uniform random number generator, `rand`. If you want to generate repeatable noise samples, then either reset the random stream input before calling `bsc` or use the same seed input.

`[ndata,err] = bsc(____)` returns an array containing the channel errors, using any of the preceding syntaxes.

## Examples

### Add Bit Errors to Bit Stream

Using the `bsc` function, introduce bit errors in the bits in a random matrix with probability 0.15.

```
z = randi([0 1],100,100); % Random matrix
nz = bsc(z,.15); % Binary symmetric channel
[numerrs, pcterrs] = biterr(z,nz) % Number and percentage of errors

numerrs = 1509
pcterrs = 0.1509
```

The output below is typical. For relatively small sets of data, the percentage of bit errors is not exactly 15% in most trials. If the size of the matrix `z` is large, the bit error percentage will be closer to the exact probability you specify.

### Check for Errors After Decoding

Using the `bsc` function, introduce bit errors in the bits in a random matrix with probability 0.01. Use Viterbi decoder to decode message data.

Define trellis for Viterbi decoder. Generate and encode message data.

```
trel = poly2trellis([4 3],[4 5 17;7 4 2]);
msg = ones(10000,1);
```

Create objects for convolutional encoder, Viterbi decoder, and error rate calculator.

```
hEnc = comm.ConvolutionalEncoder(trel);
hVitDec = comm.ViterbiDecoder(trel, 'InputFormat','hard', 'TracebackDepth',...
    2, 'TerminationMethod', 'Truncated');
hErrorCalc = comm.ErrorRate;
```

Encode the message data. Introduce bit errors. Display the total number of errors.

```
code = hEnc(msg);
[ncode,err] = bsc(code,.01);
numchanerrs = sum(sum(err))

numchanerrs = 158
```

Decode the data and check the number of errors after decoding.

```
dcode = hVitDec(ncode);  
berVec = hErrorCalc(msg, dcode);  
ber = berVec(1)
```

```
ber = 0.0049
```

```
numsyserrs = berVec(2)
```

```
numsyserrs = 49
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation supported, except for syntaxes that include a `RandStream` object.

### Topics

“Design a Rate 2/3 Feedforward Encoder Using Simulink”

**Introduced before R2006a**

## cdma2000ForwardReferenceChannels

Define cdma2000 forward reference channel

### Syntax

```
cfg = cdma2000ForwardReferenceChannels(wv)
cfg = cdma2000ForwardReferenceChannels(wv,numchips)
cfg = cdma2000ForwardReferenceChannels(BSTM-RC,numchips,P,M)
cfg = cdma2000ForwardReferenceChannels(traffic,numchips,F-SCH-SPEC)
```

### Description

`cfg = cdma2000ForwardReferenceChannels(wv)` returns a structure, `cfg`, that defines the cdma2000® forward link parameters given the input waveform identifier, `wv`. To generate a forward link reference channel waveform, pass this structure to the `cdma2000ForwardWaveformGenerator` function.

For all syntaxes, `cdma2000ForwardReferenceChannels` creates a configuration structure that is compliant with the cdma2000 physical layer specification [1].

`cfg = cdma2000ForwardReferenceChannels(wv,numchips)` specifies the number of chips to generate.

`cfg = cdma2000ForwardReferenceChannels(BSTM-RC,numchips,P,M)` returns the data structure for the BSTM-RC waveform identifiers, given the total traffic channel power, `P`, and the number of traffic channels, `M`. For more information on base station testing, see Table 6.5.2-1 of [2].

`cfg = cdma2000ForwardReferenceChannels(traffic,numchips,F-SCH-SPEC)` returns the data structure for the specified traffic channel, `traffic`, and the forward supplemental channel (F-SCH) and frame length combination, `F-SCH-SPEC`. If omitted, `F-SCH-SPEC` has a default value of the lowest F-SCH data rate allowable for a 20 ms frame length, given the radio configuration specified by `traffic`.

## Examples

### Generate Waveform for RC2 Forward Traffic Channels

Create a parameter structure, `config`, for all forward traffic channels (F-FCH and F-SCCH) that are supported by radio configuration 2.

```
config = cdma2000ForwardReferenceChannels('ALL-RC2')
```

```
config = struct with fields:
    SpreadingRate: 'SR1'
    Diversity: 'NTD'
    QOF: 'QOF1'
    PNOffset: 0
    LongCodeState: 0
    PowerNormalization: 'Off'
    OversamplingRatio: 4
    FilterType: 'cdma2000Long'
    InvertQ: 'Off'
    EnableModulation: 'Off'
    ModulationFrequency: 0
    NumChips: 1000
    FPICH: [1x1 struct]
    FAPICH: [1x1 struct]
    FTDPICH: [1x1 struct]
    FATDPICH: [1x1 struct]
    FPCH: [1x1 struct]
    FSYNC: [1x1 struct]
    FBCCH: [1x1 struct]
    FCACH: [1x1 struct]
    FCCCH: [1x1 struct]
    FCPCCH: [1x1 struct]
    FQPCH: [1x1 struct]
    FFCH: [1x1 struct]
    FOCNS: [1x1 struct]
    FSCCH: [1x1 struct]
```

Examine the fields for the Forward Fundamental Channel (F-FCH). The data rate is 14,400 bps and the frame length is 20 ms.

```
config.FFCH
```

```
ans = struct with fields:
    Enable: 'On'
    Power: 0
    RadioConfiguration: 'RC2'
        DataRate: 14400
        FrameLength: 20
        LongCodeMask: 0
        EnableCoding: 'On'
        DataSource: {'PN9' [1]}
        WalshCode: 7
        EnableQOF: 'off'
    PowerControlEnable: 'off'
```

Generate the complex waveform using the corresponding waveform generator function.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

A waveform composed of the channels specified by each substructure of `config` is generated by `cdma2000ForwardWaveformGenerator`.

### Generate CDMA200 Waveform Containing Sync Channel Message

Create a reference channel, specify the sync channel message as the data source, add the `SyncMessage` structure to the `FSYNC` substructure. Generate the waveform using this reference channel configuration.

Create a reference channel for testing a base station using radio configuration 3.

```
config = cdma2000ForwardReferenceChannels('BSTM-RC3');
```

Adjust the Forward Sync Channel (F-SYNC) settings. Set a relative channel power of 0.0 dB and specify the sync channel message as the data source.

```
config.FSYNC.Power = 0.0;
config.FSYNC.DataSource = 'SyncMessage';
```

Define the sync channel message structure (for `P_REV = 6` (IS-2000-0)) and add it to the `config.FSYNC` substructure. Display the `FSYNC` structure.

```
sm = struct();
sm.P_REV = 6; % Protocol Revision field
```

```

sm.MIN_P_REV = 6; % Minimum Protocol Revision field
sm.SID = hex2dec('14B'); % System Identifier field
sm.NID = 1; % Network Identification field
sm.PILOT_PN = 0; % Pilot PN Offset field
sm.LC_STATE = hex2dec('20000000000'); % Long Code State field
sm.SYS_TIME = hex2dec('36AE0924C'); % System Time field
sm.LP_SEC = 0; % Leap Second field
sm.LTM_OFF = 0; % Local Time Offset field
sm.DAYLT = 0; % Daylight Savings Time Indicator field
sm.PRAT = 0; % Paging Channel Data Rate field
sm.CDMA_FREQ = hex2dec('2F6'); % CDMA Frequency field
sm.EXT_CDMA_FREQ = hex2dec('2F6'); % Extended CDMA Frequency field

config.FSYNC.SyncMessage = sm;

config.FSYNC

ans = struct with fields:
    Enable: 'On'
    Power: 0
    EnableCoding: 'On'
    DataSource: 'SyncMessage'
    SyncMessage: [1x1 struct]

```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

### Generate F-CCCH Waveform

Create a structure for a 2000-chip forward common control channel (F-CCCH). Specify a 38,400 bps data rate, a 5 ms frame length, and an accompanying broadcast control channel (F-BCCH) with a 9600 bps data rate.

```

config = cdma2000ForwardReferenceChannels('CONTROL-38400-5-9600',2000)

config = struct with fields:
    SpreadingRate: 'SR1'
    Diversity: 'NTD'
    QOF: 'QOF1'
    PNOffset: 0

```

```
    LongCodeState: 0
    PowerNormalization: 'Off'
    OversamplingRatio: 4
        FilterType: 'cdma2000Long'
            InvertQ: 'Off'
        EnableModulation: 'Off'
    ModulationFrequency: 0
        NumChips: 2000
            FPICH: [1x1 struct]
            FPCH: [1x1 struct]
            FCCCH: [1x1 struct]
            FBCCH: [1x1 struct]
```

Verify that the F-CCCH and F-BCCH data rates are 38,400 bps and 9600 bps, respectively.

```
config.FCCCH.DataRate
```

```
ans = 38400
```

```
config.FBCCH.DataRate
```

```
ans = 9600
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

### Generate Waveform for Base Station Testing

Create a reference channel for testing a base station using radio configuration 3. Specify the number of chips, the total power allocated to the individual channels, and the number of traffic channels. The FFCH substructure is a structure array whose dimensions are set by the number of traffic channels.

```
config = cdma2000ForwardReferenceChannels('BSTM-RC3',1000,-3,4)
```

```
config = struct with fields:
    SpreadingRate: 'SR1'
    Diversity: 'NTD'
    QOF: 'QOF1'
    PNOffset: 0
    LongCodeState: 0
```

```

PowerNormalization: 'Off'
OversamplingRatio: 4
    FilterType: 'cdma2000Long'
        InvertQ: 'Off'
    EnableModulation: 'Off'
ModulationFrequency: 0
    NumChips: 1000
        FPICH: [1x1 struct]
        FSYNC: [1x1 struct]
        FPCH: [1x1 struct]
        FFCH: [1x4 struct]

```

Verify that the length of the FFCH substructure corresponds to the number of specified traffic channels, 4.

```
length(config.FFCH)
```

```
ans = 4
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

## Generate F-SCH Waveform

Create a traffic channel using radio configuration 7 composed of a 614,400 bps forward supplemental channel (F-SCH) having a 20 ms frame length. Set the number of chips to 5000.

```
config = cdma2000ForwardReferenceChannels('TRAFFIC-RC7-4800', ...
    5000, 'F-SCH-614400-20')
```

```

config = struct with fields:
    SpreadingRate: 'SR3'
    Diversity: 'NTD'
        QOF: 'QOF1'
    PNOffset: 0
    LongCodeState: 0
    PowerNormalization: 'Off'
    OversamplingRatio: 4
    FilterType: 'cdma2000Long'

```

```

        InvertQ: 'Off'
    EnableModulation: 'Off'
ModulationFrequency: 0
        NumChips: 5000
            FPICH: [1x1 struct]
            FFCH: [1x1 struct]
            FSCH: [1x1 struct]
    
```

This channel uses spreading rate 3, 'SR3', which has a 3.75 MHz bandwidth.

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

## Input Arguments

### wv — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector. The input typically identifies the channel type, radio configuration, data rate, and frame length. To specify wv, connect the substrings with hyphens, for example, 'CONTROL-19200-10-4800'.

Parameter Field	Values				Description
	Substring 1	Substring 2	Substring 3	Substring 4	
wv	'FPICH-ONLY'				Generates a waveform containing a pilot channel only.
	'CONTROL'	9600 19200	20 10   20	4800   9600   19200	Character vector representing the forward common control

Parameter Field	Values				Description
	Substring 1	Substring 2	Substring 3	Substring 4	
		38400	5   10   20		channel (F-CCCH) data rate in bps, the frame length in ms, and the forward broadcast control channel (F-BCCH) data rate in bps. Specify 'CONTROL-9600-20-9600' to create a structure variable, wv, with a 9600 bps F-CCCH data rate, a 20 ms frame length, and a 9600 bps F-BCCH data rate.
	'TRAFFIC'	RC1	1200   2400   4800   9600	N/A	Character vector representing the radio configuration and the forward fundamental channel (F-FCH) data rate in bps.
		RC2   RC5   RC8   RC9	1800   3600   7200   14400		

Parameter Field	Values				Description
	Substring 1	Substring 2	Substring 3	Substring 4	
		RC3   RC4   RC6   RC7	1500   2700   4800   9600		Specify 'TRAFFIC-RC9-14400' to create a channel with radio configuration 9 having a 14400 bps F-FCH data rate.
	'BSTM'	RC1   RC2   RC3   RC4   RC5   RC6   RC7   RC8   RC9	N/A	N/A	Models for testing the base station transmitter. Specify 'BSTM-RC1' to create a structure for base station testing with radio configuration 1.

Parameter Field	Values				Description
	Substring 1	Substring 2	Substring 3	Substring 4	
	'ALL'	RC1   RC2   RC3   RC4   RC5   RC6   RC7   RC8   RC9	N/A	N/A	Returns all channels that are supported for the specified radio configuration. Specify 'ALL-RC4' to create a structure containing all traffic channels for radio configuration 4.

Example: 'CONTROL-9600-20-9600'

Example: 'TRAFFIC-RC9-7200'

Example: 'ALL-RC5'

Data Types: char

### **numchips — Number of chips**

1000 (default) | positive integer scalar

Number of chips, specified as a positive integer.

Example: 1024

Data Types: double

### **BSTM-RC — BSTM reference channel type**

'BSTM-RC1' | 'BSTM-RC2' | 'BSTM-RC3' | 'BSTM-RC4' | 'BSTM-RC5' | 'BSTM-RC6' |  
'BSTM-RC7' | 'BSTM-RC8' | 'BSTM-RC9'

BSTM reference channel type, specified as a character vector. For more information, see Table 6.5.2-1 of [2].

Example: 'BSTM-RC8'

Data Types: char

**P — Power budget allocated to traffic channels**

0 (default) | real scalar

Power budget allocated to all traffic channels, specified in decibels as a real scalar.

Example: 5

Data Types: double

**M — Number of traffic channels**

6 (default) | positive integer scalar

Number of traffic channels, specified as a positive integer.

Example: 8

Data Types: double

**traffic — Traffic configuration**

character vector

Traffic channel configuration, specified as a character vector. The table shows the supported traffic channel configurations.

Radio Configuration	Traffic Channel Configuration			
1	'TRAFFIC-RC1-1200'	'TRAFFIC-RC1-2400'	'TRAFFIC-RC1-4800'	'TRAFFIC-RC1-9600'
2	'TRAFFIC-RC2-1800'	'TRAFFIC-RC2-3600'	'TRAFFIC-RC2-7200'	'TRAFFIC-RC2-14400'
3	'TRAFFIC-RC3-1500'	'TRAFFIC-RC3-2700'	'TRAFFIC-RC3-4800'	'TRAFFIC-RC3-9600'
4	'TRAFFIC-RC4-1500'	'TRAFFIC-RC4-2700'	'TRAFFIC-RC4-4800'	'TRAFFIC-RC4-9600'
5	'TRAFFIC-RC5-1800'	'TRAFFIC-RC5-3600'	'TRAFFIC-RC5-7200'	'TRAFFIC-RC5-14400'

Radio Configuration	Traffic Channel Configuration			
6	'TRAFFIC-RC6-1500'	'TRAFFIC-RC6-2700'	'TRAFFIC-RC6-4800'	'TRAFFIC-RC6-9600'
7	'TRAFFIC-RC7-1500'	'TRAFFIC-RC7-2700'	'TRAFFIC-RC7-4800'	'TRAFFIC-RC7-9600'
8	'TRAFFIC-RC8-1800'	'TRAFFIC-RC8-3600'	'TRAFFIC-RC8-7200'	'TRAFFIC-RC8-14400'
9	'TRAFFIC-RC9-1800'	'TRAFFIC-RC9-3600'	'TRAFFIC-RC9-7200'	'TRAFFIC-RC9-14400'

Example: 'TRAFFIC-RC6-4800' is a traffic channel that uses radio configuration 6 with a 4800 bps data rate.

Data Types: char

### F-SCH-SPEC — Forward supplemental channel data rate and frame length

character vector

Forward supplemental channel data rate and frame length, specified as a character vector. The supported data rate and frame length combinations are summarized in the table.

Radio Configuration	Frame Length		
	20 ms	40 ms	80 ms
3   4   6   7	'F-SCH-1500-20'   'F-SCH-2700-20'   'F-SCH-4800-20'   'F-SCH-9600-20'   'F-SCH-19200-20'   'F-SCH-38400-20'   'F-SCH-76800-20'   'F-SCH-153600-20'	'F-SCH-1350-40'   'F-SCH-2400-40'   'F-SCH-4800-40'   'F-SCH-9600-40'   'F-SCH-19200-40'   'F-SCH-38400-40'   'F-SCH-76800-40'	'F-SCH-1200-80'   'F-SCH-2400-80'   'F-SCH-4800-80'   'F-SCH-9600-80'   'F-SCH-19200-80'   'F-SCH-38400-80'
4   6   7	'F-SCH-307200-20'	'F-SCH-153600-40'	'F-SCH-76800-80'

Radio Configuration	Frame Length		
	20 ms	40 ms	80 ms
7	'F-SCH-614400-20'	'F-SCH-307200-40'	'F-SCH-153600-80'
5   8   9	'F-SCH-1800-20'   'F-SCH-3600-20'   'F-SCH-7200-20'   'F-SCH-14400-20'   'F-SCH-28800-20'   'F-SCH-57600-20'   'F-SCH-115200-20'   'F-SCH-230400-20'	'F-SCH-1800-40'   'F-SCH-3600-40'   'F-SCH-7200-40'   'F-SCH-14400-40'   'F-SCH-28800-40'   'F-SCH-57600-40'   'F-SCH-115200-40'	'F-SCH-1800-80'   'F-SCH-3600-80'   'F-SCH-7200-80'   'F-SCH-14400-80'   'F-SCH-28800-80'   'F-SCH-57600-80'
8   9	'F-SCH-460800-20'	'F-SCH-230400-40'	'F-SCH-115200-80'
9	'F-SCH-1036800-20'	'F-SCH-518400-40'	'F-SCH-259200-80'

For more data rate information for the cdma2000 forward links, see tables 3.1.3.1.3-2 and 3.1.3.1.3-4 of [1].

Example: 'F-SCH-460800-20' is a supplemental channel with a 460,800 bps data rate and a 20 ms frame length.

Data Types: char

## Output Arguments

### cfg — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

### Top-Level Parameters and Substructures

Parameter Field	Values	Description
<b>SpreadingRate</b>	'SR1'   'SR3'	Spreading rate of the waveform. SR1 corresponds to a 1.2288 Mcps carrier. SR3 corresponds to a 3.6864 Mcps carrier.  SR3 supports direct sequence spreading only.
<b>Diversity</b>	'NTD'   'OTD'   'STS'	Transmit diversity type (applicable only for SR1), where NTD is no transmit diversity, OTD is orthogonal transmit diversity, and STS is space time spreading
<b>QOF</b>	'QOF1'   'QOF2'   'QOF3'	Quasi-orthogonal function type
<b>PNOffset</b>	Nonnegative scalar integer	PN offset of the base station
<b>LongCodeState</b>	Positive scalar integer	Initial long code state
<b>PowerNormalization</b>	'Off'   'NormalizeTo0dB'   'NoiseFillTo0dB'	Power normalization of the waveform
<b>NumChips</b>	Positive scalar integer	Number of chips in the waveform
<b>FilterType</b>	'cdma2000Long'   'cdma2000Short'   'Off'   'Custom'	Type of output filtering
<b>CustomFilterCoefficients</b>	Real vector	Custom filter coefficients, used only when the FilterType field is set to 'Custom'
<b>OversamplingRatio</b>	Positive scalar integer	Oversampling ratio at output
<b>InvertQ</b>	'Off'   'On'	Negate the quadrature output
<b>EnableModulation</b>	'Off'   'On'	Enable carrier modulation
<b>ModulationFrequency</b>	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
<b>FPICH</b>	Structure	See <b>FPICH Substructure</b> . Optional.
<b>FAPICH</b>	Structure	See <b>FAPICH Substructure</b> . Optional.
<b>FTDPICH</b>	Structure	See <b>FTDPICH Substructure</b> . Optional.

Parameter Field	Values	Description
FATDPICH	Structure	See <b>FATDPICH Substructure</b> . Optional.
FSYNC	Structure	See <b>FSYNC Substructure</b> . Optional.
FPCH	Structure	See <b>FPCH Substructure</b> . Optional.
FCCCH	Structure	See <b>FCCCH Substructure</b> . Optional.
FCACH	Structure	See <b>FCACH Substructure</b> . Optional.
FQPCH	Structure	See <b>FQPCH Substructure</b> . Optional.
FCPCCH	Structure	See <b>FCPCCH Substructure</b> . Optional.
FBCCH	Structure	See <b>FBCCH Substructure</b> . Optional.
FFCH	Structure	See <b>FFCH Substructure</b> . Optional.
FDCCH	Structure	See <b>FDCCH Substructure</b> . Optional.
FSCCH	Structure	See <b>FSCCH Substructure</b> . Optional.
FSCH	Structure	See <b>FSCH Substructure</b> . Optional.
FOCNS	Structure	See <b>FOCNS Substructure</b> . Optional.

### FPICH Substructure

Include the FPICH substructure in the `cfg` structure to configure the forward pilot channel (F-PICH). The FPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On'   'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

### FAPICH Substructure

Include the FAPICH substructure in the `cfg` structure to configure the forward auxiliary pilot channel (F-APICH). The FAPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On'   'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64   128   256   512	Walsh code length

Parameter Field	Values	Description
<b>WalshCode</b>	Nonnegative integer scalar, such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier

### FTDPICH Substructure

Include the FTDPICH substructure in the `cfg` structure to configure the forward transmit diversity pilot Channel (F-TDPICH). The FTDPICH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)

### FATDPICH

Include the FATDPICH substructure in the `cfg` structure to configure the forward auxiliary transmit diversity pilot channel (F-ATDPICH). The FATDPICH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>WalshLength</b>	64   128   256, 512	Walsh code length
<b>WalshCode</b>	Nonnegative integer scalar, such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier

### FSYNC Substructure

Include the FSYNC substructure in the `cfg` structure to configure the forward sync channel (F-SYNC). The FSYNC substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: { 'PN Type', RN Seed }, binary vector, or 'SyncMessage'.  Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or a 'SyncMessage' character vector.
<b>SyncMessage</b>	Structure	See <b>SyncMessage Substructure</b> . Optional.

### SyncMessage Substructure

If the DataSource field of the FSYNC substructure is set to 'SyncMessage', add the SyncMessage substructure to the cfg.FSYNC substructure to configure the sync channel message. The SyncMessage substructure contains these fields.

Parameter Field	Typical Value	Description
P_REV	6	Protocol revision field
MIN_P_REV	6	Minimum protocol revision field
SID	hex2dec( '14B' )	System identifier field
NID	1	Network identification field
PILOT_PN	0	Pilot PN offset field
LC_STATE	hex2dec( '200000000000' )	Long code state field
SYS_TIME	hex2dec( '36AE0924C' )	System time field
LP_SEC	0	Leap second field
LTM_OFF	0	Local time offset field
DAYLT	0	Daylight savings time indicator field

Parameter Field	Typical Value	Description
PRAT	0	Paging channel data rate field
CDMA_FREQ	hex2dec('2F6')	CDMA frequency field
EXT_CDMA_FREQ	hex2dec('2F6')	Extended CDMA frequency field

### FPCH Substructure

Include the FPCH substructure in the `cfg` substructure to configure the forward paging channel (F-PCH). The FPCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	4800   9600	Data rate (bps)
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>WalshCode</b>	Nonnegative integer scalar, such that $0 \leq \text{WalshCode} \leq 7$	Walsh code number
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed}, binary vector, or a paging message character vector.  Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.  Paging message options include 'PagingMessage1', 'PagingMessage2', and 'PagingMessage3'.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or one of three paging messages. For a description of paging message contents see footnote 1.

Parameter Field	Values	Description
<b>1</b>	When the <code>DataSource</code> enumeration specifies one of the paging message options, simulated paging message data is used as input to the F-PCH physical channel:	<ul style="list-style-type: none"> <li>'PagingMessage1' — Streams a 7680 bit sequence (800 ms at fullrate) of paging message contents onto the channel that includes the General Page Message, the CDMA Channel List Message, the Extended System Parameter Message, the Extended Neighbor List Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a nonsequential pattern.</li> <li>'PagingMessage2' — Streams a 2304 bit sequence (240 ms at fullrate) of paging message contents onto the channel that includes a truncated version of the full 'PagingMessage1' content.</li> <li>'PagingMessage3' — Streams an 864 bit sequence (90 ms at fullrate) of paging message contents onto the channel that includes the Neighbor List Message, the CDMA Channel List Message, the General Page Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a sequential pattern.</li> </ul> <p>For more information on the F-PCH contents, refer to 3GPP2 C.S0004, Table 3.1.2.3.1.1.2-1.</p>

### FCCCH Substructure

Include the FCCCH substructure in the `cfg` structure to configure the forward common control channel (F-CCCH). The FCCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	9600   19200   38400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>CodingType</b>	'conv'   'turbo'	Type of error correction coding
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number

Parameter Field	Values	Description
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9- ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FCACH Substructure

Include the FCACH substructure in the `cfg` structure to configure the forward common assignment channel (F-CACH). The FCACH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>CodingType</b>	'conv'   'turbo'	Type of error correction coding
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq$ <code>WalshCode</code> $\leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9- ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FQPCH Substructure

Include the FQPCH substructure in the `cfg` structure to configure the forward quick paging channel (F-QPCH). The FQPCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	2400   4800	Data rate (bps)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FCPCCH Substructure

Include the FCPCCH substructure in the `cfg` structure to configure the forward common power control channel (F-CPCCH). The FCPCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 63$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding

Parameter Field	Values	Description
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FBCCH Substructure

Include the FBCCH substructure in the `cfg` structure to configure the forward broadcast control channel (F-BCCH). The FBCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	4800   9600   19200	Data rate (bps)
<b>CodingType</b>	'conv'   'turbo'	Type of error correction coding
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 127$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FFCH Substructure

Include the FFCH substructure in the `cfg` structure to configure the forward fundamental traffic channel (F-FCH). The FFCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>RadioConfiguration</b>	'RC1' through 'RC9'	Radio configuration channel
<b>DataRate</b>	1200   1500   1800   2400   2700   3600   4800   7200   9600   14400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableQOF</b>	'On'   'Off'	Enable QOF spreading
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>PowerControlEnable</b>	'On'   'Off'	Enable or disable power control subchannel
<b>PowerControlPower</b>	Real scalar	Power control subchannel power (relative to F-FCH)

Parameter Field	Values	Description
<b>PowerControlDataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Power control subchannel data source

### FDCCH Substructure

Include the FDCCH substructure in the `cfg` structure to configure the forward dedicated control channel (F-DCCH). The FDCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>RadioConfiguration</b>	'RC3' through 'RC9'	Radio configuration channel
<b>DataRate</b>	9600   14400	Data rate (bps)
<b>FrameLength</b>	5   20	Frame length (ms)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableQOF</b>	'On'   'Off'	Enable QOF spreading
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FSCCH Substructure

Include the FSCCH substructure in the `cfg` structure to configure the forward supplemental code channel (F-SCCH). The FSCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>RadioConfigurat ion</b>	'RC1'   'RC2'	Radio configuration channel
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FSCH Substructure

Include the FSCH substructure in the `cfg` structure to configure the forward supplemental channel (F-SCH). The FSCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>RadioConfigurat ion</b>	'RC3'   'RC4'   'RC5'   'RC6'   'RC7'   'RC8'   'RC9'	Radio configuration channel

Parameter Field	Values	Description
<b>DataRate</b>	1200   1350   1500   1800   2400   2700   3600   4800   7200   9600   14400   19200   28800   38400   57600   76800   115200   153600   230400   307200	Data rate (bps)
<b>FrameLength</b>	20   40   80	Frame length (ms)
<b>CodingType</b>	'Conv'   'Turbo'	Channel coding type, convolutional or turbo
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableQOF</b>	'On'   'Off'	Enable QOF spreading
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FOCNS Substructure

Include the FOCNS substructure in the `cfg` structure to configure orthogonal channel noise source information. The FOCNS substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>WalshLength</b>	64   128   256	Walsh code length

Parameter Field	Values	Description
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number

**Introduced in R2015b**

# cdma2000ForwardWaveformGenerator

Generate cdma2000 forward link waveform

## Syntax

```
[waveform1, waveform2] = cdma2000ForwardWaveformGenerator(cfg)
```

## Description

[waveform1, waveform2] = cdma2000ForwardWaveformGenerator(cfg) returns the cdma2000 forward link baseband primary waveform, waveform1, and the forward link diversity waveform, waveform2, as defined by the parameter definition structure, cfg.

The top-level parameters and lower-level substructures of cfg specify the waveform and channel properties the function uses to generate a cdma2000 waveform. You can generate cfg by using the cdma2000ForwardReferenceChannels function. The top-level parameters of cfg are SpreadingRate, Diversity, QOF, PNOffset, LongCodeState, PowerNormalization, CustomFilterCoefficients, OversamplingRatio, FilterType, InvertQ, EnableModulation, ModulationFrequency, and NumChips. To enable specific channels, add their associated substructures, for example, the forward paging channel, FPCH.

---

**Note** The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all combinations of spreading rate, radio configuration, frame length, and data rate are supported. To ensure that the input argument is valid, use the cdma2000ForwardReferenceChannels function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

---

## Examples

### Generate Waveform for RC2 Forward Traffic Channels

Create a parameter structure, `config`, for all forward traffic channels (F-FCH and F-SCCH) that are supported by radio configuration 2.

```
config = cdma2000ForwardReferenceChannels('ALL-RC2')
```

```
config = struct with fields:
    SpreadingRate: 'SR1'
    Diversity: 'NTD'
    QOF: 'QOF1'
    PNOffset: 0
    LongCodeState: 0
    PowerNormalization: 'Off'
    OversamplingRatio: 4
    FilterType: 'cdma2000Long'
    InvertQ: 'Off'
    EnableModulation: 'Off'
    ModulationFrequency: 0
    NumChips: 1000
    FPICH: [1x1 struct]
    FAPICH: [1x1 struct]
    FTDPICH: [1x1 struct]
    FATDPICH: [1x1 struct]
    FPCH: [1x1 struct]
    FSYNC: [1x1 struct]
    FBCCH: [1x1 struct]
    FCACH: [1x1 struct]
    FCCCH: [1x1 struct]
    FCPCCH: [1x1 struct]
    FQPCH: [1x1 struct]
    FFCH: [1x1 struct]
    FOCNS: [1x1 struct]
    FSCCH: [1x1 struct]
```

Examine the fields for the Forward Fundamental Channel (F-FCH). The data rate is 14,400 bps and the frame length is 20 ms.

```
config.FFCH
```

```
ans = struct with fields:
    Enable: 'On'
    Power: 0
    RadioConfiguration: 'RC2'
```

```

        DataRate: 14400
        FrameLength: 20
        LongCodeMask: 0
        EnableCoding: 'On'
        DataSource: {'PN9' [1]}
        WalshCode: 7
        EnableQOF: 'Off'
        PowerControlEnable: 'Off'

```

Generate the complex waveform using the corresponding waveform generator function.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

A waveform composed of the channels specified by each substructure of `config` is generated by `cdma2000ForwardWaveformGenerator`.

### Generate Forward Traffic Channel for RC4

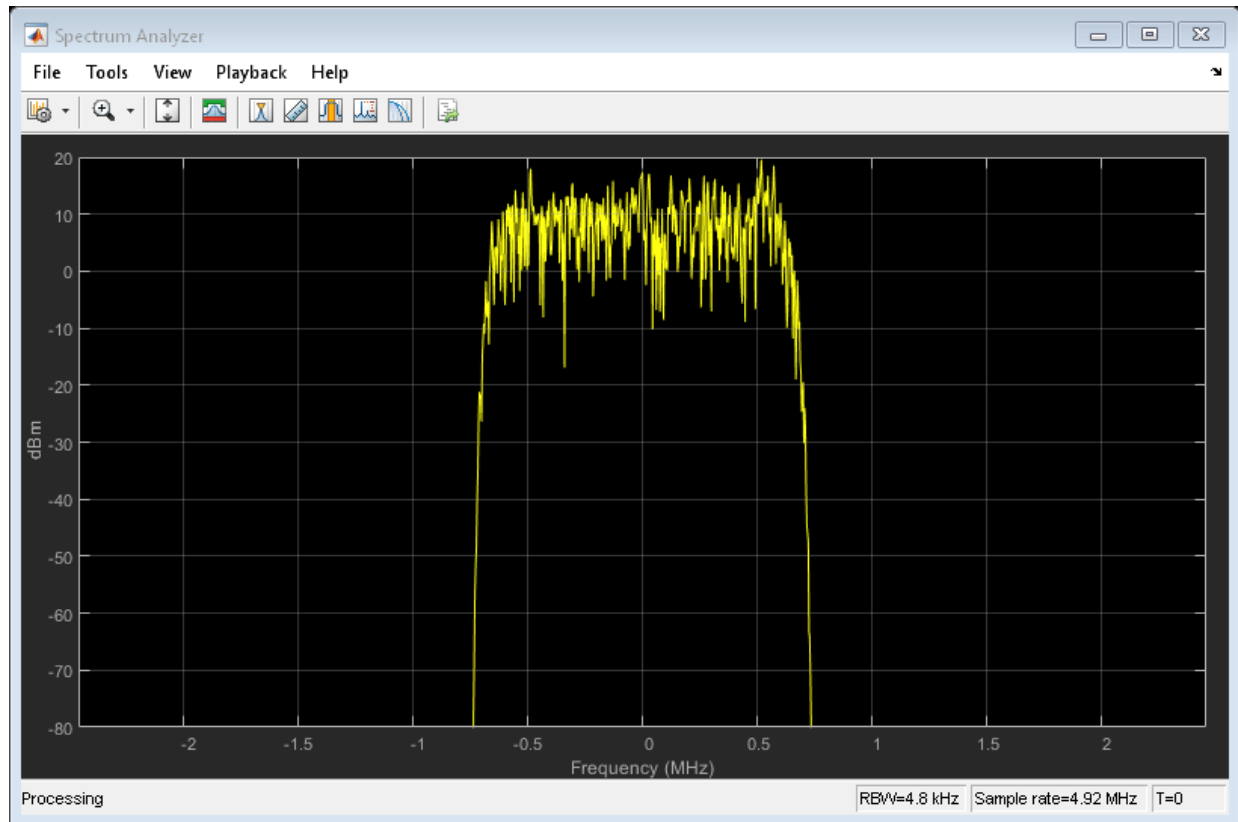

Configure a cdma2000 forward link supporting a 307.2 kbps forward supplemental channel (F-SCH) using radio configuration 4.

```
config = cdma2000ForwardReferenceChannels('TRAFFIC-RC4-4800',5000, ...
    'F-SCH-307200-20');
```

Generate the waveform and plot its spectrum. The sample rate is equal to the product of the chip rate and the oversampling ratio. RC4 uses spreading rate 1, which is equivalent to a 1.2288 Mcps chip rate.

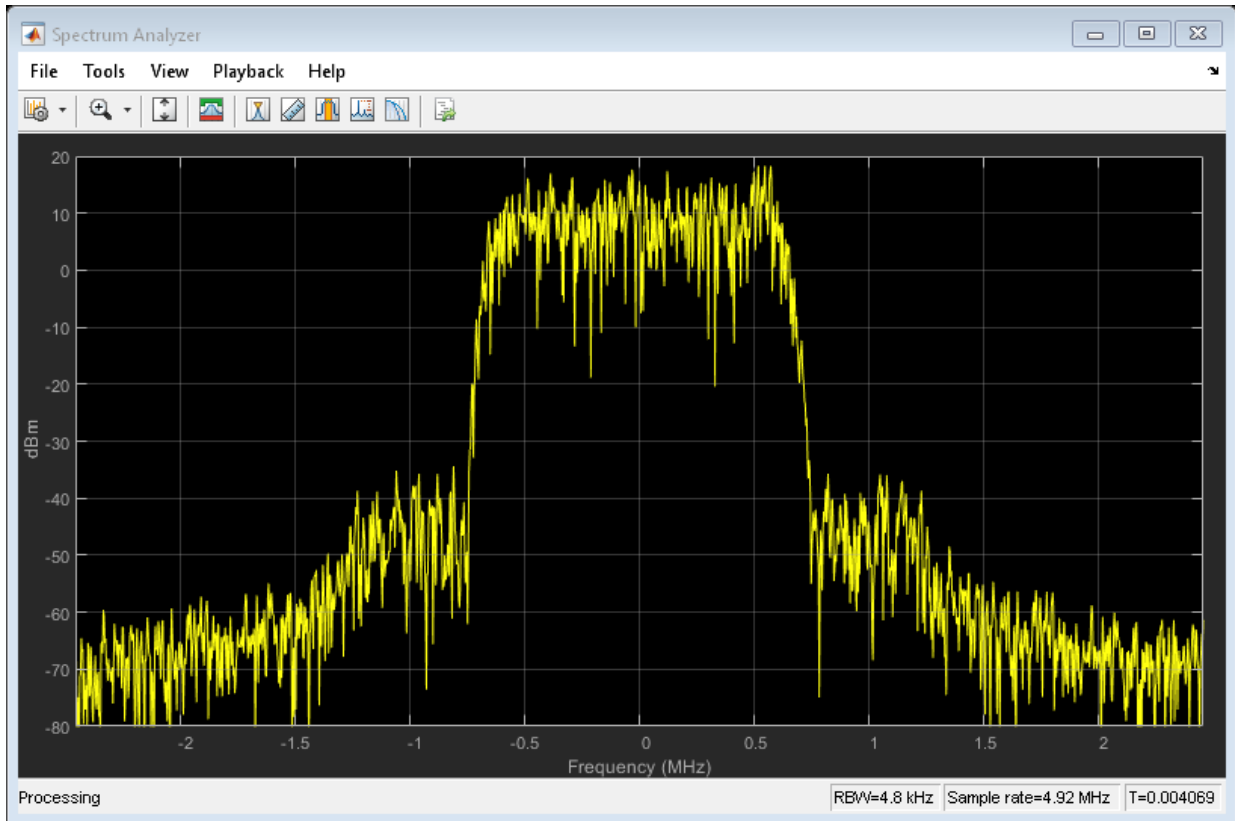

```
wv = cdma2000ForwardWaveformGenerator(config);
fs = 1.2288e6 * config.OversamplingRatio;

sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)
```

Change the filter type to 'cdma2000Short' and plot the spectrum.

```
config.FilterType = 'cdma2000Short';  
wv = cdma2000ForwardWaveformGenerator(config);  
step(sa,wv)
```

The 'cdma2000Short' filter does not provide as much out-of-band attenuation as does the 'cdma2000Long' filter.

### **Generate cdma2000 Waveform with Two Forward Supplemental Channels**

Create a parameter structure that specifies a forward traffic channel. Use it to generate a forward channel waveform.

Create a parameter structure specifying a traffic channel consisting of a 4800 bps fundamental channel, 5000 chips, and a 614.4 kbps supplemental channel (F-SCH) having a 20 ms frame duration.

```
cfg = cdma2000ForwardReferenceChannels('TRAFFIC-RC7-4800', ...  
    5000, 'F-SCH-614400-20');
```

Based on the first F-SCH, create a second F-SCH.

```
cfg(2).FSCH = cfg.FSCH;
```

Set the data rate of the second F-SCH to 38.4 kbps. Set the frame duration to 40 ms.

```
cfg(2).FSCH.DataRate = 38400;  
cfg(2).FSCH.FrameLength = 40;  
cfg.FSCH
```

```
ans = struct with fields:  
    Enable: 'On'  
    Power: 0  
    RadioConfiguration: 'RC7'  
    DataRate: 614400  
    FrameLength: 20  
    LongCodeMask: 0  
    EnableCoding: 'On'  
    DataSource: {'PN9' [1]}  
    WalshCode: 2  
    EnableQOF: 'off'  
    CodingType: 'conv'
```

```
ans = struct with fields:  
    Enable: 'On'  
    Power: 0  
    RadioConfiguration: 'RC7'  
    DataRate: 38400  
    FrameLength: 40  
    LongCodeMask: 0  
    EnableCoding: 'On'  
    DataSource: {'PN9' [1]}  
    WalshCode: 2  
    EnableQOF: 'off'  
    CodingType: 'conv'
```

Set the Walsh code of the second F-SCH so that it is not identical to the Walsh code of the first F-SCH.

```
cfg(2).FSCH.WalshCode = 3;
```

Generate the forward link waveform.

```
wv = cdma2000ForwardWaveformGenerator(cfg);
```

## Input Arguments

**cfg** — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

### Top-Level Parameters and Substructures

Parameter Field	Values	Description
<b>SpreadingRate</b>	'SR1'   'SR3'	Spreading rate of the waveform. SR1 corresponds to a 1.2288 Mcps carrier. SR3 corresponds to a 3.6864 Mcps carrier.  SR3 supports direct sequence spreading only.
<b>Diversity</b>	'NTD'   'OTD'   'STS'	Transmit diversity type (applicable only for SR1), where NTD is no transmit diversity, OTD is orthogonal transmit diversity, and STS is space time spreading
<b>QOF</b>	'QOF1'   'QOF2'   'QOF3'	Quasi-orthogonal function type
<b>PNOffset</b>	Nonnegative scalar integer	PN offset of the base station
<b>LongCodeState</b>	Positive scalar integer	Initial long code state
<b>PowerNormalization</b>	'Off'   'NormalizeTo0dB'   'NoiseFillTo0dB'	Power normalization of the waveform
<b>NumChips</b>	Positive scalar integer	Number of chips in the waveform
<b>FilterType</b>	'cdma2000Long'   'cdma2000Short'   'Off'   'Custom'	Type of output filtering

Parameter Field	Values	Description
<b>CustomFilterCoefficients</b>	Real vector	Custom filter coefficients, used only when the <code>FilterType</code> field is set to 'Custom'
<b>OversamplingRatio</b>	Positive scalar integer	Oversampling ratio at output
<b>InvertQ</b>	'Off'   'On'	Negate the quadrature output
<b>EnableModulation</b>	'Off'   'On'	Enable carrier modulation
<b>ModulationFrequency</b>	Nonnegative scalar integer	Carrier modulation frequency (applies when <code>EnableModulation</code> is 'On')
<b>FPICH</b>	Structure	See <b>FPICH Substructure</b> . Optional.
<b>FAPICH</b>	Structure	See <b>FAPICH Substructure</b> . Optional.

<b>FSCH</b>	Structure	See <b>FSCH Substructure</b> . Optional.
<b>FOCNS</b>	Structure	See <b>FOCNS Substructure</b> . Optional.

### FPICH Substructure

Include the FPICH substructure in the `cfg` structure to configure the forward pilot channel (F-PICH). The FPICH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)

### FAPICH Substructure

Include the FAPICH substructure in the `cfg` structure to configure the forward auxiliary pilot channel (F-APICH). The FAPICH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>WalshLength</b>	64   128   256   512	Walsh code length
<b>WalshCode</b>	Nonnegative integer scalar, such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier

### FTDPICH Substructure

Include the FTDPICH substructure in the `cfg` structure to configure the forward transmit diversity pilot Channel (F-TDPICH). The FTDPICH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)

### FATDPICH

Include the FATDPICH substructure in the `cfg` structure to configure the forward auxiliary transmit diversity pilot channel (F-ATDPICH). The FATDPICH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel

Parameter Field	Values	Description
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>WalshLength</b>	64   128   256, 512	Walsh code length
<b>WalshCode</b>	Nonnegative integer scalar, such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier

### FSYNC Substructure

Include the FSYNC substructure in the `cfg` structure to configure the forward sync channel (F-SYNC). The FSYNC substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed}, binary vector, or 'SyncMessage'.  Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or a 'SyncMessage' character vector.
<b>SyncMessage</b>	Structure	See <b>SyncMessage Substructure</b> . Optional.

### SyncMessage Substructure

If the `DataSource` field of the FSYNC substructure is set to 'SyncMessage', add the `SyncMessage` substructure to the `cfg.FSYNC` substructure to configure the sync channel message. The `SyncMessage` substructure contains these fields.

Parameter Field	Typical Value	Description
<code>P_REV</code>	6	Protocol revision field

Parameter Field	Typical Value	Description
MIN_P_REV	6	Minimum protocol revision field
SID	hex2dec ( ' 14B ' )	System identifier field
NID	1	Network identification field
PILOT_PN	0	Pilot PN offset field
LC_STATE	hex2dec ( ' 200000000000 ' )	Long code state field
SYS_TIME	hex2dec ( ' 36AE0924C ' )	System time field
LP_SEC	0	Leap second field
LTM_OFF	0	Local time offset field
DAYLT	0	Daylight savings time indicator field
PRAT	0	Paging channel data rate field
CDMA_FREQ	hex2dec ( ' 2F6 ' )	CDMA frequency field
EXT_CDMA_FREQ	hex2dec ( ' 2F6 ' )	Extended CDMA frequency field

### FPCH Substructure

Include the FPCH substructure in the `cfg` substructure to configure the forward paging channel (F-PCH). The FPCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	4800   9600	Data rate (bps)
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>WalshCode</b>	Nonnegative integer scalar, such that $0 \leq \text{WalshCode} \leq 7$	Walsh code number
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding

Parameter Field	Values	Description
<b>DataSource</b>	<p>Cell array: { 'PN Type', RN Seed}, binary vector, or a paging message character vector.</p> <p>Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.</p> <p>Paging message options include 'PagingMessage1', 'PagingMessage2', and 'PagingMessage3'.</p>	<p>Data source. Specify a standard PN sequence with a random number seed, a binary vector, or one of three paging messages. For a description of paging message contents see footnote 1.</p>
<p><b>1</b> When the DataSource enumeration specifies one of the paging message options, simulated paging message data is used as input to the F-PCH physical channel:</p> <ul style="list-style-type: none"> <li>• 'PagingMessage1' — Streams a 7680 bit sequence (800 ms at fullrate) of paging message contents onto the channel that includes the General Page Message, the CDMA Channel List Message, the Extended System Parameter Message, the Extended Neighbor List Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a nonsequential pattern.</li> <li>• 'PagingMessage2' — Streams a 2304 bit sequence (240 ms at fullrate) of paging message contents onto the channel that includes a truncated version of the full 'PagingMessage1' content.</li> <li>• 'PagingMessage3' — Streams an 864 bit sequence (90 ms at fullrate) of paging message contents onto the channel that includes the Neighbor List Message, the CDMA Channel List Message, the General Page Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a sequential pattern.</li> </ul> <p>For more information on the F-PCH contents, refer to 3GPP2 C.S0004, Table 3.1.2.3.1.1.2-1.</p>		

### FCCCH Substructure

Include the FCCCH substructure in the `cfg` structure to configure the forward common control channel (F-CCCH). The FCCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	9600   19200   38400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>CodingType</b>	'conv'   'turbo'	Type of error correction coding
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FCACH Substructure

Include the FCACH substructure in the `cfg` structure to configure the forward common assignment channel (F-CACH). The FCACH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>CodingType</b>	'conv'   'turbo'	Type of error correction coding

Parameter Field	Values	Description
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FQPCH Substructure

Include the FQPCH substructure in the `cfg` structure to configure the forward quick paging channel (F-QPCH). The FQPCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	2400   4800	Data rate (bps)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding

Parameter Field	Values	Description
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FCPCCH Substructure

Include the FCPCCH substructure in the `cfg` structure to configure the forward common power control channel (F-CPCCH). The FCPCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 63$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FBCCH Substructure

Include the FBCCH substructure in the `cfg` structure to configure the forward broadcast control channel (F-BCCH). The FBCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	4800   9600   19200	Data rate (bps)
<b>CodingType</b>	'conv'   'turbo'	Type of error correction coding
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 127$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FFCH Substructure

Include the FFCH substructure in the `cfg` structure to configure the forward fundamental traffic channel (F-FCH). The FFCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>RadioConfigurat ion</b>	'RC1' through 'RC9'	Radio configuration channel
<b>DataRate</b>	1200   1500   1800   2400   2700   3600   4800   7200   9600   14400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)

Parameter Field	Values	Description
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableQOF</b>	'On'   'Off'	Enable QOF spreading
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>PowerControlEnable</b>	'On'   'Off'	Enable or disable power control subchannel
<b>PowerControlPower</b>	Real scalar	Power control subchannel power (relative to F-FCH)
<b>PowerControlDataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Power control subchannel data source

### FDCCH Substructure

Include the FDCCH substructure in the `cfg` structure to configure the forward dedicated control channel (F-DCCH). The FDCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
<b>RadioConfigurat ion</b>	'RC3' through 'RC9'	Radio configuration channel
<b>DataRate</b>	9600   14400	Data rate (bps)
<b>FrameLength</b>	5   20	Frame length (ms)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableQOF</b>	'On'   'Off'	Enable QOF spreading
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FSCCH Substructure

Include the FSCCH substructure in the `cfg` structure to configure the forward supplemental code channel (F-SCCH). The FSCCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>RadioConfigurat ion</b>	'RC1'   'RC2'	Radio configuration channel
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding

Parameter Field	Values	Description
<b>DataSource</b>	Cell array: { 'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FSCH Substructure

Include the FSCH substructure in the `cfg` structure to configure the forward supplemental channel (F-SCH). The FSCH substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>RadioConfiguration</b>	'RC3'   'RC4'   'RC5'   'RC6'   'RC7'   'RC8'   'RC9'	Radio configuration channel
<b>DataRate</b>	1200   1350   1500   1800   2400   2700   3600   4800   7200   9600   14400   19200   28800   38400   57600   76800   115200   153600   230400   307200	Data rate (bps)
<b>FrameLength</b>	20   40   80	Frame length (ms)
<b>CodingType</b>	'Conv'   'Turbo'	Channel coding type, convolutional or turbo
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 255$	Walsh code number
<b>LongCodeMask</b>	Positive scalar integer	Long code identifier

Parameter Field	Values	Description
<b>EnableQOF</b>	'On'   'Off'	Enable QOF spreading
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### FOCNS Substructure

Include the FOCNS substructure in the `cfg` structure to configure orthogonal channel noise source information. The FOCNS substructure contains these fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>WalshLength</b>	64   128   256	Walsh code length
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number

## Output Arguments

### **waveform1** — Modulated baseband waveform comprising the primary physical channels

complex vector array

Modulated baseband waveform comprising the primary `cdma2000` physical channels, returned as a complex vector array.

**waveform2 — Modulated baseband waveform comprising the diversity physical channels**

complex vector array

Modulated baseband waveform comprising the diversity cdma2000 physical channels, returned as a complex vector array.

**Introduced in R2015b**

## cdma2000ReverseReferenceChannels

Define cdma2000 reverse reference channel

### Syntax

```
cfg = cdma2000ReverseReferenceChannels(wv)
cfg = cdma2000ReverseReferenceChannels(wv,numchips)
cfg = cdma2000ReverseReferenceChannels(traffic,numchips,R-SCH-SPEC)
```

### Description

`cfg = cdma2000ReverseReferenceChannels(wv)` returns a structure, `cfg`, that defines the cdma2000 reverse link parameters given the input waveform identifier, `wv`. Pass the structure to the `cdma2000ReverseWaveformGenerator` function to generate a reverse link reference channel waveform.

For all syntaxes, `cdma2000ReverseReferenceChannels` creates a configuration structure that is compliant with the physical layer specification for cdma2000 systems described in [1].

`cfg = cdma2000ReverseReferenceChannels(wv,numchips)` specifies the number of chips to generate.

`cfg = cdma2000ReverseReferenceChannels(traffic,numchips,R-SCH-SPEC)` returns `cfg` for the specified traffic channel, `traffic`, and the reverse supplemental channel (R-SCH) and frame length combination, `R-SCH-SPEC`.

### Examples

#### Generate Reverse Common Control Channel Waveform

Generate the structure corresponding to the reverse common control channel (R-CCCH) having a 19,200 bps data rate and 10 ms frames.

```
config = cdma2000ReverseReferenceChannels('R-CCCH-19200-10');
```

Verify that the R-CCCH substructure is configured for the correct data rate and frame duration.

```
config.RCCCH
```

```
ans = struct with fields:
    Enable: 'On'
    Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
    DataSource: {'PN9' [1]}
    DataRate: 19200
    FrameLength: 10
    WalshCode: 1
```

Generate the reverse channel waveform using the corresponding waveform generator function, `cdma2000ReverseWaveformGenerator`.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

## Generate Reverse Channels for RC1 and RC6

Create a configuration structure to generate all possible channels associated with radio configuration 1 in which the number of chips is specified as 2500.

```
config = cdma2000ReverseReferenceChannels('ALL-RC1',2500)
```

```
config = struct with fields:
    RadioConfiguration: 'RC1'
    PowerNormalization: 'Off'
    OversamplingRatio: 4
    FilterType: 'cdma2000Long'
    InvertQ: 'Off'
    EnableModulation: 'Off'
    ModulationFrequency: 0
    NumChips: 2500
    RFCH: [1x1 struct]
    RACH: [1x1 struct]
    RSCCH: [1x1 struct]
```

The structure contains substructures corresponding to the R-FCH, R-ACH, and R-SCCH channels.

Call the function again using radio configuration 6.

```
config = cdma2000ReverseReferenceChannels('ALL-RC6',2500)
```

```
config = struct with fields:
    RadioConfiguration: 'RC6'
    PowerNormalization: 'Off'
    OversamplingRatio: 4
    FilterType: 'cdma2000Long'
    InvertQ: 'Off'
    EnableModulation: 'Off'
    ModulationFrequency: 0
    NumChips: 2500
    RFCH: [1x1 struct]
    RPICH: [1x1 struct]
    REACH: [1x1 struct]
    RCCCH: [1x1 struct]
    RDCCH: [1x1 struct]
    RSCH1: [1x1 struct]
    RSCH2: [1x1 struct]
```

The channels supported by RC6 differ from those supported by RC1. They include R-FCH, R-PICH, R-EACH, R-CCCH, R-DCCH, R-SCH1, and R-SCH2.

Create the waveform corresponding to the set of RC6 channels.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

### Generate Reverse Supplemental Channel

Create a configuration structure using radio configuration 3 with a reverse fundamental channel (R-FCH). Specify a 2700 bps data rate and a reverse supplemental channel (R-SCH) having a 76,800 bps data rate and an 80 ms frame length.

```
config = cdma2000ReverseReferenceChannels('TRAFFIC-RC3-2700',2000, ...
    'R-SCH-76800-80');
```

Verify that the R-FCH data rate is 2700 bps and the first R-SCH data rate is 76,800 bps with an 80 ms frame length.

```
config.RFCH.DataRate
```

```
ans = 2700
```

```
config.RSCH1.DataRate
```

```
ans = 76800
```

```
config.RSCH1.FrameLength
```

```
ans = 80
```

Generate the corresponding waveform.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

## Input Arguments

### **wv** — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector. The input typically identifies the channel type, radio configuration, data rate, and frame length. To specify **wv**, connect the substrings with hyphens, for example, 'TRAFFIC-RC2-3600'.

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
<b>wv</b>	'R-PICH-ONLY'			Generates a waveform containing a pilot channel only.
	'R-CCCH'	9600	20	Character vector representing the Reverse
19200		10   20		

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
		38400	5   10   20	Common Control Channel (R-CCCH) data rate in bps and the frame length in ms. Specify 'R-CCCH-9600-20' to create a structure variable, wv, with a 9600 bps R-CCCH data rate and a 20 ms frame length.
	'TRAFFIC'	RC1	1200   2400   4800   9600	Character vector representing the radio configuration and the Reverse Fundamental Channel (R-FCH) data rate in bps. Specify 'TRAFFIC-RC6-14400', corresponds to radio configuration 6 with a 14400 bps R-FCH data rate.
		RC2   RC4   RC6	1800   3600   7200   14400	
		RC3   RC5   RC6	1500   2700   4800   9600	
	'R-EACH'	9600	20	Reverse Enhanced Access Channel waveforms. Specify 'R-
		19200	10   20	

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
		38400	5   10   20	EACH-38400-5' to create a structure corresponding to an R-EACH channel with a 38400 bps data rate and a 5 ms frame length.
	'R-PICH-R-FCH'			Specify tests for the mobile transmitter in accordance with [2].
	'ALL'	RC1   RC2   RC3   RC4   RC5   RC6	N/A	Returns all channels that are supported for the specified radio configuration. Specify 'ALL-RC4' to create a structure containing all traffic channels for radio configuration 4.

Example: 'R-CCCH-9600-20' is a R-CCH channel having a 9600 bps data rate and a 20 ms frame length.

Example: 'R-EACH-38400-5' is a R-EACH channel having a 38,400 bps data rate and a 5 ms frame length.

Data Types: char

**numchips – Number of chips**

1000 (default) | positive integer scalar

Number of chips, specified as a positive integer.

Example: 2048

Data Types: double

**traffic — Traffic configuration**

character vector

Traffic channel configuration, specified as a character vector. The table shows the valid configurations.

<b>Radio Configuration</b>	<b>Traffic Channel Configuration</b>			
1	'TRAFFIC-RC1-1200'	'TRAFFIC-RC1-2400'	'TRAFFIC-RC1-4800'	'TRAFFIC-RC1-9600'
2	'TRAFFIC-RC2-1800'	'TRAFFIC-RC2-3600'	'TRAFFIC-RC2-7200'	'TRAFFIC-RC2-14400'
3	'TRAFFIC-RC3-1500'	'TRAFFIC-RC3-2700'	'TRAFFIC-RC3-4800'	'TRAFFIC-RC3-9600'
4	'TRAFFIC-RC4-1800'	'TRAFFIC-RC4-3600'	'TRAFFIC-RC4-7200'	'TRAFFIC-RC4-14400'
5	'TRAFFIC-RC5-1500'	'TRAFFIC-RC5-2700'	'TRAFFIC-RC5-4800'	'TRAFFIC-RC5-9600'
6	'TRAFFIC-RC6-1800'	'TRAFFIC-RC6-3600'	'TRAFFIC-RC6-7200'	'TRAFFIC-RC6-14400'

Example: 'TRAFFIC-RC4-1800' is a traffic channel using radio configuration 4 and having an R-FCH with an 1800 bps data rate .

Data Types: char

**R-SCH-SPEC — Reverse Supplemental Channel data rate and frame length**

character vector

Specify the R-SCH data rate and frame length as a character vector. If omitted, R-SCH-SPEC defaults to the lowest R-SCH data rate allowable for a 20 ms frame length given the radio configuration specified by `traffic`. The table summarizes the supported data rate and frame length combinations.

Radio Configuration	Frame Length		
	20 ms	40 ms	80 ms
3   5	'R-SCH-1500-20'   'R-SCH-2700-20'   'R-SCH-4800-20'   'R-SCH-9600-20'   'R-SCH-19200-20'   'R-SCH-38400-20'   'R-SCH-76800-20'   'R-SCH-153600-20'   'R-SCH-307200-20'	'R-SCH-1350-40'   'R-SCH-2400-40'   'R-SCH-4800-40'   'R-SCH-9600-40'   'R-SCH-19200-40'   'R-SCH-38400-40'   'R-SCH-76800-40'   'R-SCH-153600-40'	'R-SCH-1350-80'   'R-SCH-2400-80'   'R-SCH-4800-80'   'R-SCH-9600-80'   'R-SCH-19200-80'   'R-SCH-38400-80'   'R-SCH-76800-80'
5	'R-SCH-614400-20'	'R-SCH-307200-40'	'R-SCH-153600-80'
4   6	'R-SCH-1800-20'   'R-SCH-3600-20'   'R-SCH-7200-20'   'R-SCH-14400-20'   'R-SCH-28800-20'   'R-SCH-57600-20'   'R-SCH-115200-20'   'R-SCH-230400-20'	'R-SCH-1800-40'   'R-SCH-3600-40'   'R-SCH-7200-40'   'R-SCH-14400-40'   'R-SCH-28800-40'   'R-SCH-57600-40'   'R-SCH-115200-40'	'R-SCH-1800-80'   'R-SCH-3600-80'   'R-SCH-7200-80'   'R-SCH-14400-80'   'R-SCH-28800-80'   'R-SCH-57600-80'
6	'R-SCH-460800-20'   'R-SCH-1036800-20'	'R-SCH-230400-40'   'R-SCH-518400-40'	'R-SCH-115200-80'   'R-SCH-259200-80'

Additional data rate information for the cdma2000 reverse links is given in Tables 2.1.3.1.3-1 and 2.1.3.1.3-2 of [1].

Example: 'R-SCH-153600-20' is an R-SCH having a 153,600 bps data rate and a 20 ms frame length.

Data Types: char

## Output Arguments

### cfg — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

#### Top-Level Parameters and Substructures

Parameter Field	Values	Description
<b>RadioConfiguration</b>	'RC1'   'RC2'   'RC3'   'RC4'   'RC5'   'RC6'	Radio configuration of the reverse channel. The spreading rate of the waveform is derived from the radio configuration. Spreading rate 1, SR1, corresponds to a 1.2288 Mcps carrier and is associated with RC1 through RC4. Spreading rate 3, SR3, corresponds to a 3.6864 Mcps carrier and is associated with RC5 and RC6.
<b>PowerNormalization</b>	'Off'   'NormalizeTo0dB'	Power normalization of the waveform
<b>NumChips</b>	Positive scalar integer	Number of chips in the waveform
<b>OversamplingRatio</b>	Positive scalar integer	Oversampling ratio at output
<b>FilterType</b>	'cdma2000Long'   'cdma2000Short'   'Off'   'Custom'	Type of output filtering
<b>CustomFilterCoefficients</b>	Real vector	Custom filter coefficients used only when the <b>FilterType</b> field is set to 'Custom'
<b>InvertQ</b>	'Off'   'On'	Negate the quadrature output
<b>EnableModulation</b>	'Off'   'On'	Enable carrier modulation
<b>ModulationFrequency</b>	Nonnegative scalar integer	Carrier modulation frequency (applies when <b>EnableModulation</b> is 'On')
<b>RPICH</b>	Structure	See <b>RPICH Substructure</b> . Optional.
<b>RACH</b>	Structure	See <b>RACH Substructure</b> . Optional.

Parameter Field	Values	Description
REACH	Structure	See <b>REACH Substructure</b> . Optional.
RCCCH	Structure	See <b>RCCCH Substructure</b> . Optional.
RDCCH	Structure	See <b>RDCCH Substructure</b> . Optional.
RFCH	Structure	See <b>RFCH Substructure</b> . Optional.
RSCCH	Structure	See <b>RSCCH Substructure</b> . Optional.
RSCH1	Structure	See <b>RSCH1 Substructure</b> . Optional.
RSCH2	Structure	See <b>RSCH2 Substructure</b> . Optional.

### RPICH Substructure

Include the RPICH substructure in the `cfg` structure to configure the Reverse Pilot Channel (R-PICH). The RPICH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>PowerControlEnable</b>	'On'   'Off'	Enable or disable power control subchannel
<b>PowerControlPower</b>	Real scalar	Power control subchannel power (relative to R-PICH)
<b>PowerControlDataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Power control subchannel data source

### RACH Substructure

Include the RACH substructure in the `cfg` structure to configure the Reverse Access Channel (R-ACH). The RACH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or a binary vector.  Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

### REACH Substructure

Include the REACH substructure in the `cfg` structure to configure the Reverse Enhanced Access Channel (R-EACH). The REACH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	9600   19200   38400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq$ WalshCode $\leq 7$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or a binary vector.  Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

### RCCCH Substructure

Include the RCCCH substructure in the `cfg` structure to configure the Reverse Common Control Channel (R-CCCH). The RCCCH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	9600   19200   38400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>CodingType</b>	'conv'   'turbo'	Type of error control coding
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 7$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RDCCH Substructure

Include the RDCCH substructure in the `cfg` structure to configure the Reverse Dedicated Control Channel (R-DCCH). The RDCCH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>FrameLength</b>	5   20	Frame length (ms)

Parameter Field	Values	Description
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 15$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RFCH Substructure

Include the RFCH substructure in the `cfg` structure to configure the Reverse Fundamental Traffic Channel (R-FCH). The RFCH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	1200   1500   1800   2400   2700   3600   4800   7200   9600   14400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 15$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding

Parameter Field	Values	Description
<b>DataSource</b>	Cell array, { 'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RSCCH Substructure

Include the RSCCH substructure in the `cfg` structure to configure the Reverse Supplemental Code Channel (R-SCCH). The RSCCH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array, { 'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RSCH1 Substructure

Include the RSCH1 substructure in the `cfg` structure to configure the Reverse Supplemental Channel 1 (R-SCH 1). The RSCH1 substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel

Parameter Field	Values	Description
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	1200   1350   1500   1800   2400   2700   3600   4800   7200   9600   14400   19200   28800   38400   57600   76800   115200   153600   230400   259200   307200   460800   518400   614400   1036800	Data rate (bps)
<b>FrameLength</b>	20   40   80	Frame length (ms)
<b>WalshLength</b>	2   4	Walsh code length
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RSCH2 Substructure

Include the RSCH2 substructure in the `cfg` structure to configure the Reverse Supplemental Channel 2 (R-SCH 2). The RSCH2 substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel

Parameter Field	Values	Description
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	1200   1350   1500   1800   2400   2700   3600   4800   7200   9600   14400   19200   28800   38400   57600   76800   115200   153600   230400   259200   307200   460800   518400   614400   1036800	Data rate (bps)
<b>FrameLength</b>	20   40   80	Frame length (ms)
<b>WalshLength</b>	4   8	Walsh code length
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

Data Types: struct

# cdma2000ReverseWaveformGenerator

Generate cdma2000 reverse link waveform

## Syntax

```
waveform = cdma2000ReverseWaveformGenerator(cfg)
```

## Description

`waveform = cdma2000ReverseWaveformGenerator(cfg)` returns the cdma2000 reverse link baseband waveform, `waveform` as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties used by the function to generate a cdma2000 waveform. You can generate the input argument by using the `cdma2000ReverseReferenceChannels` function. The top-level parameters of `cfg` are `RadioConfiguration`, `LongCodeState`, `PowerNormalization`, `OversamplingRatio`, `FilterType`, `InvertQ`, `EnableModulation`, `ModulationFrequency`, and `NumChips`. To enable specific channels, add their associated substructures, for example, the reverse dedicated control channel, `RDCCH`.

---

**Note** The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all combinations of spreading rate, radio configuration, frame length, and data rate are supported. To ensure that the input argument is valid, use the `cdma2000ReverseReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

---

## Examples

### Generate Reverse Common Control Channel Waveform

Generate the structure corresponding to the reverse common control channel (R-CCCH) having a 19,200 bps data rate and 10 ms frames.

```
config = cdma2000ReverseReferenceChannels('R-CCCH-19200-10');
```

Verify that the R-CCCH substructure is configured for the correct data rate and frame duration.

```
config.RCCCH
```

```
ans = struct with fields:
    Enable: 'On'
    Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
    DataSource: {'PN9' [1]}
    DataRate: 19200
    FrameLength: 10
    WalshCode: 1
```

Generate the reverse channel waveform using the corresponding waveform generator function, `cdma2000ReverseWaveformGenerator`.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

### Generate R-SCH Channels for RC5

Create a configuration structure for a reverse channel having an R-FCH with a 4800 bps data rate and two R-SCHs. Specify that each R-SCH have a 153,600 bps data rate using RC5.

```
config = cdma2000ReverseReferenceChannels('TRAFFIC-RC5-4800',5000, ...
    'R-SCH-153600-40');
```

Determine the sample rate. Because RC5 corresponds to SR3, the chip rate is 3.6864 Mcps. Multiply by the oversampling ratio to obtain the sample rate.

```
fs = 3.6864e6*config.OversamplingRatio;
```

Generate the reverse link waveform.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Plot the spectrum of the resultant waveform.

```
sa = dsp.SpectrumAnalyzer('SampleRate',fs);  
step(sa,wv)
```

### Generate cdma2000 Waveform with Two Reverse Supplemental Channels

Create a parameter structure specifying a reverse traffic channel containing a pair of supplemental channels and generate the corresponding waveform.

Create a parameter structure specifying a traffic channel consisting of a 14,400 bps fundamental channel, 2000 chips, and a 57,600 bps supplemental channel (R-SCH) pair having a 40 ms frame duration.

```
cfg = cdma2000ReverseReferenceChannels('TRAFFIC-RC4-14400',2000,'F-SCH-57600-40');
```

Create a second R-SCH pair by copying the R-SCH fields from the existing pair.

```
cfg(2).RSCH1 = cfg.RSCH1;  
cfg(2).RSCH2 = cfg.RSCH2;
```

Set the data rate of the second R-SCH pair to 28,800 bps.

```
cfg(2).RSCH1.DataRate = 28800;  
cfg(2).RSCH2.DataRate = 28800;
```

Set the Walsh codes of the second pair so that they differ from the first pair.

```
cfg(2).RSCH1.WalshCode = 4;  
cfg(2).RSCH2.WalshCode = 5;
```

Verify that the data rates are set correctly and that no two supplemental channels share the same Walsh code.

`cfg.RSCH1`

```
ans = struct with fields:  
    Enable: 'On'  
    Power: 0  
    LongCodeMask: 0  
    EnableCoding: 'On'  
    DataSource: {'PN9' [1]}  
    DataRate: 57600  
    FrameLength: 40  
    WalshLength: 2  
    WalshCode: 0
```

```
ans = struct with fields:  
    Enable: 'On'  
    Power: 0  
    LongCodeMask: 0  
    EnableCoding: 'On'  
    DataSource: {'PN9' [1]}  
    DataRate: 28800
```

```

    FrameLength: 40
    WalshLength: 2
    WalshCode: 4

```

cfg.RSCH2

```

ans = struct with fields:
    Enable: 'On'
    Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
    DataSource: {'PN9' [1]}
    DataRate: 57600
    FrameLength: 40
    WalshLength: 2
    WalshCode: 1

```

```

ans = struct with fields:
    Enable: 'On'
    Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
    DataSource: {'PN9' [1]}
    DataRate: 28800
    FrameLength: 40
    WalshLength: 2
    WalshCode: 5

```

Generate the reverse link waveform.

```
wv = cdma2000ReverseWaveformGenerator(cfg);
```

## Input Arguments

**cfg** — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

**Top-Level Parameters and Substructures**

Parameter Field	Values	Description
<b>RadioConfiguration</b>	'RC1'   'RC2'   'RC3'   'RC4'   'RC5'   'RC6'	Radio configuration of the reverse channel. The spreading rate of the waveform is derived from the radio configuration. Spreading rate 1, SR1, corresponds to a 1.2288 Mcps carrier and is associated with RC1 through RC4. Spreading rate 3, SR3, corresponds to a 3.6864 Mcps carrier and is associated with RC5 and RC6.
<b>PowerNormalization</b>	'Off'   'NormalizeTo0dB'	Power normalization of the waveform
<b>NumChips</b>	Positive scalar integer	Number of chips in the waveform
<b>OversamplingRatio</b>	Positive scalar integer	Oversampling ratio at output
<b>FilterType</b>	'cdma2000Long'   'cdma2000Short'   'Off'   'Custom'	Type of output filtering
<b>CustomFilterCoefficients</b>	Real vector	Custom filter coefficients used only when the FilterType field is set to 'Custom'
<b>InvertQ</b>	'Off'   'On'	Negate the quadrature output
<b>EnableModulation</b>	'Off'   'On'	Enable carrier modulation
<b>ModulationFrequency</b>	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
<b>RPICH</b>	Structure	See <b>RPICH Substructure</b> . Optional.
<b>RACH</b>	Structure	See <b>RACH Substructure</b> . Optional.
<b>REACH</b>	Structure	See <b>REACH Substructure</b> . Optional.
<b>RCCCH</b>	Structure	See <b>RCCCH Substructure</b> . Optional.
<b>RDCCH</b>	Structure	See <b>RDCCH Substructure</b> . Optional.
<b>RFCH</b>	Structure	See <b>RFCH Substructure</b> . Optional.
<b>RSCCH</b>	Structure	See <b>RSCCH Substructure</b> . Optional.
<b>RSCH1</b>	Structure	See <b>RSCH1 Substructure</b> . Optional.
<b>RSCH2</b>	Structure	See <b>RSCH2 Substructure</b> . Optional.

### RPICH Substructure

Include the RPICH substructure in the `cfg` structure to configure the Reverse Pilot Channel (R-PICH). The RPICH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>PowerControlEnable</b>	'On'   'Off'	Enable or disable power control subchannel
<b>PowerControlPower</b>	Real scalar	Power control subchannel power (relative to R-PICH)
<b>PowerControlDataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Power control subchannel data source

### RACH Substructure

Include the RACH substructure in the `cfg` structure to configure the Reverse Access Channel (R-ACH). The RACH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding

Parameter Field	Values	Description
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or a binary vector.  Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

### REACH Substructure

Include the REACH substructure in the `cfg` structure to configure the Reverse Enhanced Access Channel (R-EACH). The REACH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	9600   19200   38400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 7$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or a binary vector.  Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

### RCCCH Substructure

Include the RCCCH substructure in the `cfg` structure to configure the Reverse Common Control Channel (R-CCCH). The RCCCH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	9600   19200   38400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>CodingType</b>	'conv'   'turbo'	Type of error control coding
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 7$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array: {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RDCCH Substructure

Include the RDCCH substructure in the `cfg` structure to configure the Reverse Dedicated Control Channel (R-DCCH). The RDCCH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>FrameLength</b>	5   20	Frame length (ms)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 15$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding

Parameter Field	Values	Description
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RFCH Substructure

Include the RFCH substructure in the `cfg` structure to configure the Reverse Fundamental Traffic Channel (R-FCH). The RFCH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>DataRate</b>	1200   1500   1800   2400   2700   3600   4800   7200   9600   14400	Data rate (bps)
<b>FrameLength</b>	5   10   20	Frame length (ms)
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq 15$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RSCCH Substructure

Include the RSCCH substructure in the `cfg` structure to configure the Reverse Supplemental Code Channel (R-SCCH). The RSCCH substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RSCH1 Substructure

Include the RSCH1 substructure in the `cfg` structure to configure the Reverse Supplemental Channel 1 (R-SCH 1). The RSCH1 substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
<b>DataRate</b>	1200   1350   1500   1800   2400   2700   3600   4800   7200   9600   14400   19200   28800   38400   57600   76800   115200   153600   230400   259200   307200   460800   518400   614400   1036800	Data rate (bps)
<b>FrameLength</b>	20   40   80	Frame length (ms)
<b>WalshLength</b>	2   4	Walsh code length
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### RSCH2 Substructure

Include the RSCH2 substructure in the `cfg` structure to configure the Reverse Supplemental Channel 2 (R-SCH 2). The RSCH2 substructure contains the following fields.

Parameter Field	Values	Description
<b>Enable</b>	'On'   'Off'	Enable or disable the channel
<b>Power</b>	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
<b>DataRate</b>	1200   1350   1500   1800   2400   2700   3600   4800   7200   9600   14400   19200   28800   38400   57600   76800   115200   153600   230400   259200   307200   460800   518400   614400   1036800	Data rate (bps)
<b>FrameLength</b>	20   40   80	Frame length (ms)
<b>WalshLength</b>	4   8	Walsh code length
<b>WalshCode</b>	Nonnegative integer scalar such that $0 \leq \text{WalshCode} \leq \text{WalshLength} - 1$	Walsh code number
<b>LongCodeMask</b>	42-bit binary number	Long code identifier
<b>EnableCoding</b>	'On'   'Off'	Enable or disable channel coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

## Output Arguments

**waveform** — Modulated baseband waveform comprising the physical channels  
complex vector array

Modulated baseband waveform comprising the cdma2000 physical channels, returned as a complex vector array.

## References

- [1] 3GPP2 C.S0002-F v2.0. "Physical Layer Standard for cdma2000 Spread Spectrum Systems." *3rd Generation Partnership Project 2*.

## See Also

`cdma2000ForwardWaveformGenerator` | `cdma2000ReverseReferenceChannels`

**Introduced in R2015b**

## cma

(To be removed) Construct constant modulus algorithm (CMA) object

---

**Note** will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

---

## Syntax

```
alg = cma(stepsize)
alg = cma(stepsize,leakagefactor)
```

## Description

The `cma` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

---

**Note** After you use either `lineareq` or `dfe` to create a CMA equalizer object, you should initialize the equalizer object's `Weights` property with a nonzero vector. Typically, CMA is used with differential modulation; otherwise, the initial weights are very important. A typical vector of initial weights has a 1 corresponding to the center tap and 0s elsewhere.

---

`alg = cma(stepsize)` constructs an adaptive algorithm object based on the constant modulus algorithm (CMA) with a step size of `stepsize`.

`alg = cma(stepsize,leakagefactor)` sets the leakage factor of the CMA. `leakagefactor` must be between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.

## Properties

The table below describes the properties of the CMA adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
AlgType	Fixed value, 'Constant Modulus'
StepSize	CMA step size parameter, a nonnegative real number
LeakageFactor	CMA leakage factor, a real number between 0 and 1

## Examples

### Create a Linear Equalizer using CMA

Use the constant modulus algorithm (CMA) to create an adaptive equalizer object.

Set the number of weights and the step size for the equalizer.

```
nWeights = 1;  
stepSize = 0.1;
```

Create an adaptive algorithm object using the `cma` function.

```
alg = cma(stepSize);
```

Construct a linear equalizer using the algorithm object.

```
eqObj = lineareq(nWeights,alg)
```

```
eqObj =
```

```
      EqType: 'Linear Equalizer'  
      AlgType: 'Constant Modulus'  
      nWeights: 1  
      nSampPerSym: 1  
      SigConst: [-1 1]  
      StepSize: 0.1000
```

```
LeakageFactor: 1
Weights: 0
WeightInputs: 0
ResetBeforeFiltering: 1
NumSamplesProcessed: 0
```

## Algorithms

Referring to the schematics in “Equalization”, define  $w$  as the vector of all weights  $w_i$  and define  $u$  as the vector of all inputs  $u_i$ . Based on the current set of weights,  $w$ , this adaptive algorithm creates the new set of weights given by

$$w = (\text{LeakageFactor}) w + (\text{StepSize}) u^* e$$

where the  $*$  operator denotes the complex conjugate.

## Compatibility Considerations

### **cma will be removed**

*Not recommended starting in R2019a*

cma will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

# comm\_links

Library link information for Communications Toolbox blocks

## Syntax

```
comm_links  
comm_links(sys)  
comm_links(sys,color)
```

## Description

`comm_links` returns a structure with two elements. Each element contains a cell array of strings containing names of library blocks in the current system. The blocks are grouped into two categories: obsolete and current. Blocks at all levels of the model are analyzed.

`comm_links(sys)` works as above on the named system `sys`, instead of the current system.

`comm_links(sys,color)` additionally colors all obsolete blocks according to the specified `color`. `color` is one of the following strings: 'blue', 'green', 'red', 'cyan', 'magenta', 'yellow', or 'black'.

Obsolete blocks are blocks that are no longer supported. They might or might not work properly.

Current blocks are supported and represent the latest block functionality.

`commlib`

### **Description**

`commlib` opens the latest version of the Communications Toolbox block library.

### **See Also**

`dsplib`

**Introduced before R2006a**

## commscope

(To be removed) Package of communications scope classes

---

**Note** `commscope.eyediagram` will be removed in a future release. Use `comm.ConstellationDiagram` and `comm.EyeDiagram` instead.

---

## Syntax

`h = commscope.<type>(...)`

## Description

`h = commscope.<type>(...)` returns a communications scope object `h` of type `type`.

Type `help commscope` to get a complete list of available types.

Each `type` of communications scope object is equipped with functions for simulation and visualization. Type `help commscope.<type>` to get the complete help on a specific communications scope object, for example `help commscope.eyediagram`.

## Compatibility Considerations

### **commscope will be removed**

*Warns starting in R2017b*

`commscope.eyediagram` will be removed in a future release. Use `comm.ConstellationDiagram` and `comm.EyeDiagram` instead.

# commscope.eyediagram

(To be removed) Eye diagram analysis

---

**Note** `commscope.eyediagram` will be removed in a future release. Use `comm.EyeDiagram` instead.

---

## Syntax

```
h = commscope.eyediagram
h = commscope.eyediagram(property1,value1,...)
```

## Description

`h = commscope.eyediagram` constructs an eye diagram object, `h`, with default properties. This syntax is equivalent to:

```
H = commscope.eyediagram('SamplingFrequency', 10000, ...
    'SamplesPerSymbol', 100, ...
    'SymbolsPerTrace', 2, ...
    'MinimumAmplitude', -1, ...
    'MaximumAmplitude', 1, ...
    'AmplitudeResolution', 0.0100, ...
    'MeasurementDelay', 0, ...
    'PlotType', '2D Color', ...
    'PlotTimeOffset', 0, ...
    'PlotPDFRange', [0 1], ...
    'ColorScale', 'linear', ...
    'RefreshPlot', 'on');
```

`h = commscope.eyediagram(property1,value1,...)` constructs an eye diagram object, `h`, with properties as specified by property/value pairs.

The eye diagram object creates a series of vertical histograms from zero to  $T$  seconds, at  $T_s$  second intervals, where  $T$  is a multiple of the symbol duration of the input signal and  $T_s$  is the sampling time. A vertical histogram is defined as the histogram of the amplitude of the input signal at a given time. The histogram information is used to obtain an

approximation to the probability density function (PDF) of the input amplitude distribution. The histogram data is used to generate '2D Color' plots, where the color indicates the value of the PDF, and '3D Color' plots. The '2D Line' plot is obtained by constructing an eye diagram from the last  $n$  traces stored in the object, where a trace is defined as the segment of the input signal for a  $T$  second interval.

You can change the plot type by setting the `PlotType` property. The following plots are examples of each type.

**2D-Color Eye Diagram**

**3D-Color Eye Diagram**

### 2D-Line Eye Diagram

To see a detailed demonstration of this object's use, type `showdemo scattereyedemo;` at the command line.

## Properties

An eye diagram scope object has the properties shown on the following table. All properties are writable except for the ones explicitly noted otherwise.

Property	Description
Type	Type of scope object ('Eye Diagram'). This property is not writable.
SamplingFrequency	Sampling frequency of the input signal in hertz.

<b>Property</b>	<b>Description</b>
SamplesPerSymbol	Number of samples used to represent a symbol. An increase in SamplesPerSymbol improves the resolution of an eye diagram.
SymbolRate	The symbol rate of the input signal. This property is not writable and is automatically computed based on SamplingFrequency and SamplesPerSymbol.
SymbolsPerTrace	The number of symbols spanned on the time axis of the eye diagram scope.
MinimumAmplitude	Minimum amplitude of the input signal. Signal values less than this value are ignored both for plotting and for measurement computation.
MaximumAmplitude	Maximum amplitude of the input signal. Signal values greater than this value are ignored both for plotting and for measurement computation.
AmplitudeResolution	The resolution of the amplitude axis. The amplitude axis is created from MinimumAmplitude to MaximumAmplitude with AmplitudeResolution steps.
MeasurementDelay	The time in seconds the scope waits before starting to collect data.
PlotType	Type of the eye diagram plot. The choices are '2D Color' (two dimensional eye diagram, where color intensity represents the probability density function values), '3D Color' (three dimensional eye diagram, where the z-axis represents the probability density function values), and '2D Line' (two dimensional eye diagram, where each trace is represented by a line).
NumberOfStoredTraces	The number of traces stored to display the eye diagram in '2D Line' mode.
PlotTimeOffset	The plot time offset input values must reside in the closed interval $[-T_{sym} T_{sym}]$ , where $T_{sym}$ is the symbol duration. Since the eye diagram is periodic, if the value you enter is out of range, it wraps to a position on the eye diagram that is within range.

Property	Description
RefreshPlot	The switch that controls the plot refresh style. The choices are 'on' (the eye diagram plot is refreshed every time the update method is called) and 'off' (the eye diagram plot is not refreshed when the update method is called).
PlotPDFRange	The range of the PDF values that will be displayed in the '2D Color' mode. The PDF values outside the range are set to a constant mask color.
ColorScale	The scale used to represent the color, the z-axis, or both. The choices are 'linear' (linear scale) and 'log' (base ten logarithmic scale).
SamplesProcessed	The number of samples processed by the eye diagram object. This value does not include the discarded samples during the MeasurementDelay period. This property is not writable.
OperationMode	When the operation mode is complex signal, the eye diagram collects and plots data on both the in-phase component and the quadrature component. When the operation mode is real signal, the eye diagram collects and plots real signal data.
Measurements	An eye diagram can display various types of measurements. All measurements are done on both the in-phase and quadrature signal, unless otherwise stated. For more information, see the Measurements section.

The resolution of the eye diagram in '2D Color' and '3D Color' modes can be increased by increasing SamplingFrequency, decreasing AmplitudeResolution, or both.

Changing MinimumAmplitude, MaximumAmplitude, AmplitudeResolution, SamplesPerSymbol, SymbolsPerTrace, and MeasurementDelay resets the measurements and updates the eye diagram.

## Methods

An eye diagram object is equipped with seven methods for inspection, object management, and visualization.

### update

This method updates the eye diagram object data.

`update(h, x)` updates the collected data of the eye diagram object `h` with the input `x`.

If the `RefreshPlot` property is set to `'on'`, the `update` method also refreshes the eye diagram figure.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off')

% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
    'SNR', 20);
x = step(hChan,0.5*sin(2*pi*(0:1/100:10))+j*cos(2*pi*(0:1/100:10)));
% update the eyediagram
update(h, x);
% Check the number of processed samples
h.SamplesProcessed
```

### plot

This method displays the eye diagram figure.

The `plot` method has three usage cases:

`plot(h)` plots the eye diagram for the eye diagram object `h` with the current colormap or the default `linespec`.

`plot(h, cmap)`, when used with the `plottype` set to `'2D Color'` or `'3D Color'`, plots the eye diagram for the object `h`, and sets the colormap to `cmap`.

`plot(h, linespec)`, when used with the `plottype` set to `'2D Line'`, plots the eye diagram for the object `h` using `linespec` as the line specification. See the help for `plot` for valid `linespecs`.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram;
% Prepare a noisy sinusoid as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
    'SNR', 20);
x = step(hChan, 0.5*sin(2*pi*(0:1/100:10))+ j*0.5*cos(2*pi*(0:1/100:10)));
% Update the eye diagram
update(h, x);
% Display the eye diagram figure
plot(h)

% Display the eye diagram figure with jet colormap
plot(h, jet(64))

% Display 2D Line eye diagram with red dashed lines
h.PlotType = '2D Line';
plot(h, 'r--')
```

## **exportdata**

This method exports the eye diagram data.

`[VERHIST EYEL HORHISTX HORHISTRF] = EXPORTDATA(H)` Exports the eye diagram data collected by the `eyediagram` object `H`.

`VERHIST` is a matrix that holds the vertical histogram, which is also used to plot `'2D Color'` and `'3D Color'` eye diagrams.

`EYEL` is a matrix that holds the data used to plot `2D Line` eye diagram. Each row of the `EYEL` holds one trace of the input signal.

`HORHISTX` is a matrix that holds the crossing point histogram data collected for the values defined by the `CrossingAmplitudes` property of the `MeasurementSetup` object. `HORHISTX(i, :)` represents the histogram for `CrossingAmplitudes(i)`.

`HORHISTRF` is a matrix that holds the crossing point histograms for rise and fall time levels. `HORHISTRF(i,:)` represents the histogram for `AmplitudeThreshold(i)`.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off');
% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
    'SNR', 20);
x = step(hChan, 0.5*sin(2*pi*(0:1/100:10))+ j*0.5*cos(2*pi*(0:1/100:10)));
% Update the eyediagram
update(h, x);
% Export the data
[eyec eyel horhistx horhistrf] = exportdata(h);
% Plot line data
t=0:1/h.SamplingFrequency:h.SymbolsPerTrace/h.SymbolRate;
plot(t, real(eyel)); xlabel('time (s)');...
    ylabel('Amplitude (AU)'); grid on;
% Plot 2D Color data
t=0:1/h.SamplingFrequency:h.SymbolsPerTrace/h.SymbolRate;
a=h.MinimumAmplitude:h.AmplitudeResolution:h.MaximumAmplitude;
imagesc(t,a,eyec); xlabel('time (s)'); ylabel('Amplitude (AU)');
```

## reset

This method resets the eye diagram object.

`reset(h)` resets the eye diagram object `h`. Resetting `h` clears all the collected data.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off');
% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
    'SNR', 20);
x = step(hChan, 0.5*sin(2*pi*(0:1/100:10))+ j*0.5*cos(2*pi*(0:1/100:10)));
update(h, x); % update the eyediagram
h.SamplesProcessed % Check the number of processed samples
reset(h); % reset the object
h.SamplesProcessed % Check the number of processed samples
```

## copy

This method copies the eye diagram object.

`h = copy(ref_obj)` creates a new eye diagram object `h` and copies the properties of object `h` from properties of `ref_obj`.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram('MinimumAmplitude', -3, ...
    'MaximumAmplitude', 3);
disp(h); % display object properties
h1 = copy(h)
```

### **disp**

This method displays properties of the eye diagram object.

`disp(h)` displays relevant properties of eye diagram object `h`.

If a property is not relevant to the object's configuration, it is not displayed. For example, for a `commscope.eyediagram` object, the `ColorScale` property is not relevant when `PlotType` property is set to `'2D Line'`. In this case the `ColorScale` property is not displayed.

The following is an example of its use:

```
% Create an eye diagram scope object
h = commscope.eyediagram;
% Display object properties
disp(h);
h = commscope.eyediagram('PlotType', '2D Line')
```

### **close**

This method closes the eye diagram object figure.

`close(h)` closes the figure of the eye diagram object `h`.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram;
% Call the plot method to display the scope
plot(h);
% Wait for 1 seconds
```

```
pause(1)
% Close the scope
close(h)
```

## analyze

This methods executes eye diagram measurements. `analyze(h)` executes the eye diagram measurements on the collected data of the eye diagram scope object *h*. The results of the measurements are stored in the Measurements property of *h*. See “Measurements” on page 2-295 for more information.

In some cases, the `analyze` method cannot determine a measurement value. If this problem occurs, verify that your settings for measurement setup values or the eye diagram are valid.

## Measurements

You can obtain the following measurements on an eye diagram:

- Amplitude Measurements
  - Eye Amplitude
  - Eye Crossing Amplitude
  - Eye Crossing Percentage
  - Eye Height
  - Eye Level
  - Eye SNR
  - Quality Factor
  - Vertical Eye Opening
- Time Measurements
  - Deterministic Jitter
  - Eye Crossing Time
  - Eye Delay
  - Eye Fall Time

- Eye Rise Time
- Eye Width
- Horizontal Eye Opening
- Peak-to-Peak Jitter
- Random Jitter
- RMS Jitter
- Total Jitter

Measurements assume that the eye diagram object has valid data. A valid eye diagram has two distinct eye crossing points and two distinct eye levels.

The deterministic jitter, horizontal eye opening, quality factor, random jitter, and vertical eye opening measurements utilize a dual-Dirac algorithm. *Jitter* is the deviation of a signal's timing event from its intended (ideal) occurrence in time [1]. Jitter can be represented with a dual-Dirac model. A dual-Dirac model assumes that the jitter has two components: deterministic jitter (DJ) and random jitter (RJ). The DJ PDF comprises two delta functions, one at  $\mu_L$  and one at  $\mu_R$ . The RJ PDF is assumed to be Gaussian with zero mean and variance  $\sigma$ .

The *Total Jitter (TJ) PDF* is the convolution of these two PDFs, which is composed of two Gaussian curves with variance  $\sigma$  and mean values  $\mu_L$  and  $\mu_R$ . See the following figure.

The dual-Dirac model is described in [5] in more detail. The amplitude of the two Dirac functions may not be the same. In such a case, the analyze method estimates these amplitudes,  $\rho_L$  and  $\rho_R$ .

## Amplitude Measurements

You can use the vertical histogram to obtain a variety of amplitude measurements. For complex signals, measurements are done on both in-phase and the quadrature components, unless otherwise specified.

**Note** For amplitude measurements, at least one bin per vertical histogram must reach 10 hits before the measurement is taken, ensuring higher accuracy.

---

### Eye Amplitude (EyeAmplitude)

*Eye Amplitude*, measured in Amplitude Units (AU), is defined as the distance between two neighboring eye levels. For an NRZ signal, there are only two levels: the high level (level 1 in figure) and the low level (level 0 in figure). The eye amplitude is the difference of these two values, as shown in figure [3].

### Eye Crossing Amplitude (EyeCrossingLevel)

*Eye crossing amplitudes* are the amplitude levels at which the eye crossings occur, measured in Amplitude Units (AU). The analyze method calculates this value using the mean value of the vertical histogram at the crossing times [3]. See the following figure.

The next figure shows the vertical histogram at the first eye crossing time.

### Eye Crossing Percentage (EyeOpeningVer)

*Eye Crossing Percentage* is the location of the eye crossing levels as a percentage of the eye amplitude.

### Eye Height (EyeHeight)

*Eye Height*, measured in Amplitude Units (AU), is defined as the  $3\sigma$  distance between two neighboring eye levels.

For an NRZ signal, there are only two levels: the high level (level 1 in figure) and the low level (level 0 in figure). The eye height is the difference of the two  $3\sigma$  points, as shown in the next figure. The  $3\sigma$  point is defined as the point that is three standard deviations away from the mean value of a PDF.

### Eye Level (EyeLevel)

*Eye Level* is the amplitude level used to represent data bits, measured in Amplitude Units (AU).

For an ideal NRZ signal, there are two eye levels:  $+A$  and  $-A$ . The analyze method calculates eye levels by estimating the mean value of the vertical histogram in a window around the EyeDelay, which is also the 50% point between eye crossing times [3]. The width of this window is determined by the EyeLevelBoundary property of the eye measurement setup object, shown in the next figure.

The analyze method calculates the mean value of all the vertical histograms within the eye level boundaries. The mean vertical histogram appears in the following figure. There are two distinct PDFs, one for each eye level. The mean values of the individual histograms are the eye levels as shown in this figure.

### Eye SNR (EyeSNR)

*Eye signal-to-noise ratio* is defined as the ratio of the eye amplitude to the sum of the standard deviations of the two eye levels. It can be expressed as:

$$\text{SNR} = \frac{L_1 - L_0}{\sigma_1 + \sigma_0}$$

where  $L_1$  and  $L_0$  represent eye level 1 and 0, respectively, and  $\sigma_1$  and  $\sigma_2$  are the standard deviation of eye level 1 and 0, respectively.

For an NRZ signal, eye level 1 corresponds to the high level, and the eye level 0 corresponds to low level.

### **Quality Factor (QualityFactor)**

The analyze method calculates *Quality Factor* the same way as the eye SNR. However, instead of using the mean and standard deviation values of the vertical histogram for  $L_1$  and  $\sigma_1$ , the analyze method uses the mean and standard deviation values estimated using the dual-Dirac method. [2] See dual-Dirac section for more detail.

### **Vertical Eye Opening (EyeOpeningVer)**

*Vertical Eye Opening* is defined as the vertical distance between two points on the vertical histogram at EyeDelay that corresponds to the BER value defined by the BERThreshold property of the eye measurement setup object. The analyze method calculates this measurement taking into account the random and deterministic components using a dual-Dirac model [5] (see the Dual Dirac Section). A typical BER value for the eye opening measurements is  $10^{-12}$ , which approximately corresponds to the  $7\sigma$  point assuming a Gaussian distribution.

## **Time Measurements**

You can use the horizontal histogram of an eye diagram to obtain a variety of timing measurements.

---

**Note** For time measurements, at least one bin per horizontal histogram must reach 10 hits before the measurement is taken.

---

### **Deterministic Jitter (JitterDeterministic)**

*Deterministic Jitter* is the deterministic component of the jitter. You calculate it using the tail mean value, which is estimated using the dual-Dirac method as follows [5]:

$$DJ = \mu_L - \mu_R$$

where  $\mu_L$  and  $\mu_R$  are the mean values returned by the dual-Dirac algorithm.

### Eye Crossing Time (EyeCrossingTime)

Eye crossing times are calculated as the mean of the horizontal histogram for each crossing point, around the reference amplitude level. This value is measured in seconds. The mean value of all the horizontal PDFs is calculated in a region defined by the CrossingBandWidth property of the eye measurement setup object.

The region is from  $-A_{\text{total}} * BW$  to  $+A_{\text{total}} * BW$ , where  $A_{\text{total}}$  is the total amplitude range of the eye diagram (i.e.,  $A_{\text{total}} = A_{\text{max}} - A_{\text{min}}$ ) and  $BW$  is the crossing band width, shown in the following figure.

The following figure shows the average PDF in this region. Because this example assumes two symbols per trace, there are two crossing points.

---

**Note** When an eye crossing time measurement falls within the  $[-0.5/F_s, 0)$  seconds interval, the time measurement wraps to the end of the eye diagram, i.e., the measurement wraps by  $2 \cdot T_s$  seconds (where  $T_s$  is the symbol time). For a complex signal case, the analyze method issues a warning if the crossing time measurement of the in-phase branch wraps while that of the quadrature branch does not (or vice versa).

To avoid the time-wrapping or a warning, add a half-symbol duration delay to the current value in the `MeasurementDelay` property of the eye diagram object. This additional delay repositions the eye in the approximate center of the scope.

---

### Eye Delay (`EyeDelay`)

Eye Delay is the distance from the midpoint of the eye to the time origin, measured in seconds. The analyze method calculates this distance using the crossing time. For a symmetric signal, `EyeDelay` is also the best sampling point.

### **Eye Fall Time (EyeFallTime)**

*Eye Fall Time* is the mean time between the high and low threshold values defined by the `AmplitudeThreshold` property of the eye measurement setup object. The previous figure shows the fall time calculated from 10% to 90% of the eye amplitude.

### **Eye Rise Time (EyeRiseTime)**

*Eye Rise Time* is the mean time between the low and high threshold values defined by the `AmplitudeThreshold` property of the eye measurement setup object. The following figure shows the rise time calculated from 10% to 90% of the eye amplitude.

**Eye Width (EyeWidth)**

*Eye Width* is the horizontal distance between two points that are three standard deviations ( $3\sigma$ ) from the mean eye crossing times, towards the center of the eye. The value for *Eye Width* measurements is seconds.

### Horizontal Eye Opening (EyeOpeningHor)

*Horizontal Eye Opening* is the horizontal distance between two points on the horizontal histogram that correspond to the *BER* value defined by the *BERThreshold* property of the eye measurement setup object. The measurement is taken at the amplitude value defined by the *ReferenceAmplitude* property of the eye measurement setup object. It is calculated taking into account the random and deterministic components using a dual-Dirac model [5] (see the Dual Dirac Section).

A typical *BER* value for the eye opening measurements is  $10^{-12}$ , which approximately corresponds to the  $7\sigma$  point assuming a Gaussian distribution.

### Peak-to-Peak Jitter (JitterP2P)

*Peak-To-Peak Jitter* is the difference between the extreme data points of the histogram.

### Random Jitter (JitterRandom)

*Random Jitter* is defined as the Gaussian unbounded component of the jitter. The analyze method calculates it using the tail standard deviation estimated using the dual-Dirac method as follows [5]:

$$RJ = (Q_L + Q_R) * \sigma$$

where

$$Q_L = \sqrt{2} * \operatorname{erfc}^{-1}\left(\frac{2 * BER}{\rho_L}\right)$$

and

$$Q_R = \sqrt{2} * \operatorname{erfc}^{-1}\left(\frac{2 * BER}{\rho_R}\right)$$

*BER* is the bit error ratio at which the random jitter is calculated. It is defined with the *BERThreshold* property of the eye measurement setup object.

### **RMS Jitter (JitterRMS)**

*RMS Jitter* is the standard deviation of the jitter calculated from the horizontal histogram.

### **Total Jitter (JitterTotal)**

*Total Jitter* is the sum of the random jitter and the deterministic jitter [5].

## **Measurement Setup Parameters**

A number of set-up parameters control eye diagram measurements. This section describes these set-up parameters and the measurements they affect.

### **Eye Level Boundaries**

*Eye Level Boundaries* are defined as a percentage of the symbol duration. The analyze method calculates the eye levels by averaging the vertical histogram within a given time interval defined by the eye level boundaries. A common value you can use for NRZ signals is 40% to 60%. For RZ signals, a narrower band of 5% is more appropriate. The default setting for *Eye level Boundaries* is a 2-by-1 vector where the first element is the lower boundary and the second element is the upper boundary. When the eye level boundary changes, the object recalculates this value.

## Reference Amplitude

*Reference Amplitude* is the boundary value at which point the signal crosses from one signal level to another. Reference amplitude represents the decision boundary of the modulation scheme. This value is used to perform jitter measurements. The default setting for *Reference Amplitude* is a 2-by-1 double vector where the first element is the lower boundary and the second element is the upper boundary. Setting the reference amplitude resets the eye diagram.

The crossing instants of the input signal are detected and recorded as crossing times. A common value you can use for NRZ signals is 0. For RZ signals, you can use the mean value of 1 and 0 levels. Reference amplitude is stored in a 2-by-N matrix, where the first row is the in-phase values and second row is the quadrature values. See Eye Crossing Time for more information.

## Crossing Bandwidth

*Crossing Bandwidth* is the amplitude band used to measure the crossing times of the eye diagram. *Crossing Bandwidth* represents a percentage of the amplitude span of the eye diagram, typically 5%. See Eye Crossing Time for more information. The default setting for *Crossing Bandwidth* is 0.0500.

## Bit Error Rate Threshold

The eye opening measurements, random, and total jitter measurements are performed at a given BER value. This BER value defines the BER threshold. A typical value is  $1e^{-12}$ . The default setting for *Bit Error Threshold* is  $1.0000e^{-12}$ . When the bit error rate threshold changes, the object recalculates this value.

## Amplitude Threshold

The rise time of the signal is defined as the time required for the signal to travel from the lower amplitude threshold to the upper amplitude threshold. The fall time, measured from the upper amplitude threshold to the lower amplitude threshold, is defined as a percentage of the eye amplitude. The default setting is 10% for the lower threshold and 90% for the upper threshold. Setting the amplitude threshold resets the eye diagram. See Eye Rise Time and Eye Fall Time for more information.

## Jitter Hysteresis

You can use the *JitterHysteresis* property of the eye measurement setup object to remove the effect of noise from the horizontal histogram estimation. The default value for *JitterHysteresis* is zero. Setting the jitter hysteresis value resets the eye diagram.

If channel noise impairs the signal being tested, as shown in the following figure, the signal may seem like it crosses the reference amplitude level multiple times during a single 0-1 or 1-0 transition.

See the zoomed—in image for more detail.

To eliminate the effect of noise, define a hysteresis region between two threshold values:  $A_{\text{ref}} + \Delta A$  and  $A_{\text{ref}} - \Delta A$ , where  $A_{\text{ref}}$  is the reference amplitude value and  $\Delta A$  is the jitter hysteresis value. If the signal crosses both threshold values, level crossing is declared. Then, linear interpolation calculates the crossing point in the horizontal histogram estimation.

## Compatibility Considerations

### **commscope.eyediagram will be removed**

*Warns starting in R2017b*

commscope.eyediagram will be removed in a future release. Use comm.EyeDiagram instead.

`comm.EyeDiagram`

**Introduced in R2007b**

# commsrc.combinedjitter

Construct combined jitter generator object

## Syntax

```
combJitt = commsrc.combinedjitter
combJitt = commsrc.combinedjitter(Name,Value)
```

## Description

`combJitt = commsrc.combinedjitter` constructs a default combined jitter generator object, `combJitt`, with all jitter components disabled.

Use the object to generate jitter samples that include any combination of random, periodic, and Dirac components.

`combJitt = commsrc.combinedjitter(Name,Value)` creates a combined jitter generator object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

A combined jitter generator object includes these properties. You can edit all properties, except those explicitly noted.

Property	Description
Type	Type of object, Combined Jitter Generator. This property is not writable.
SamplingFrequency	Sampling frequency of the input signal in hertz. Default value 1e4.

<b>Property</b>	<b>Description</b>
RandomJitter	Variable to enable the random jitter generator. Specify as either 'off' (default) or 'on'.
RandomStd	Standard deviation of the random jitter generator in seconds. Applies when RandomJitter is 'on'. Default value 1e-4.
PeriodicJitter	Variable to enable the periodic jitter generator. Specify as either 'off' (default) or 'on'.
PeriodicNumber	Number of sinusoidal components. The PeriodicNumber must be a finite positive scalar integer. Applies when PeriodicJitter is 'on'. Default value 1.
PeriodicAmplitude	Amplitude of each sinusoidal component of the periodic jitter in seconds. Applies when PeriodicJitter is 'on'. Default value 5e-4.
PeriodicFrequencyHz	Frequency of each sinusoidal component of the periodic jitter measured in Hz. Applies when PeriodicJitter is 'on'. Default value is 200.
PeriodicPhase	Phase of each sinusoidal component of the periodic jitter in radians. Applies when PeriodicJitter is 'on'. Default value 0.
DiracJitter	Variable to enable the Dirac jitter generator. Specify as either 'off' (default) or 'on'.
DiracNumber	Number of Dirac components. The DiracNumber must be a finite positive scalar integer. Applies when DiracJitter is 'on'. Default value 2.
DiracDelta	Time delay of each Dirac component in seconds. Applies when DiracJitter is 'on'. Default value [-5.e-4 5.e-4].
DiracProbability	Probability of each Dirac component represented as a vector of length DiracNumber. The sum of the probabilities must equal one. Applies when DiracJitter is 'on'. Default value [0.5 0.5].

## Object Functions

A combined jitter generator object has three object functions, as described in this section.

### **generate**

This object function generates jitter samples based on the jitter generator object. It has one input argument, which is the number of samples in a frame. Its output is a single-column vector of length  $N$ . You can call this object function using this syntax:

```
x = generate(combJitt,N)
```

where `combJitt` is the generator object,  $N$  is the number of output samples, and  $x$  is a real single-column vector.

### **reset**

This object function resets the internal states of the combined jitter generator. You can call this object function using this syntax:

```
reset(combJitt)
```

where `combJitt` is the generator object.

### **disp**

Display the properties of the combined generator object, `combJitt`. You can call this object function using this syntax:

```
disp(combJitt)
```

where `combJitt` is the generator object.

## Examples

### **Generate Combined Random and Periodic Jitter**

Generate 500 jitter samples composed of random and periodic components.

Create a `commsrc.combinedjitter` object configured to apply a combination of random and periodic jitter components. Use name-value pairs to enable `RandomJitter` and `PeriodicJitter`, and to assign jitter settings. Set the standard deviation of the random jitter to  $2e-4$  seconds, the periodic jitter amplitude to  $5e-4$  seconds, and the periodic jitter frequency to 2 Hz.

```
numSamples = 500;
combJitt = commsrc.combinedjitter(...
    'RandomJitter','on', ...
    'RandomStd',2e-4, ...
    'PeriodicJitter','on', ...
    'PeriodicAmplitude',5e-4, ...
    'PeriodicFrequencyHz',200)

combJitt =
           Type: 'Combined Jitter Generator'
    SamplingFrequency: 10000
           RandomJitter: 'on'
           RandomStd: 2.0000e-04
           PeriodicJitter: 'on'
           PeriodicNumber: 1
           PeriodicAmplitude: 5.0000e-04
    PeriodicFrequencyHz: 200
           PeriodicPhase: 0
           DiracJitter: 'off'
```

Use the `generate` method to create the combined jitter samples.

```
y = generate(combJitt,numSamples);
x = [0:numSamples-1];
```

Plot the jitter samples. You can see the Gaussian and periodic nature of the combined jitter.

```
plot(x/combJitt.SamplingFrequency,y)
xlabel('Time (seconds)')
ylabel('Jitter (seconds)')
```

### Display commsrc.combinedjitter Object Settings

Create a `commsrc.combinedjitter` object. Display the default object property values.

```
combJitt = commsrc.combinedjitter;  
disp(combJitt)  
  
Type: 'Combined Jitter Generator'  
SamplingFrequency: 10000  
RandomJitter: 'off'  
PeriodicJitter: 'off'  
DiracJitter: 'off'
```

Create a `commsrc.combinedjitter` object with random, periodic, and Dirac jitters enabled. Display the object property values.

```
combJitt = commsrc.combinedjitter('RandomJitter','on', ...  
    'PeriodicJitter','on','DiracJitter','on');  
disp(combJitt)
```

```
                Type: 'Combined Jitter Generator'  
SamplingFrequency: 10000  
    RandomJitter: 'on'  
        RandomStd: 1.0000e-04  
    PeriodicJitter: 'on'  
    PeriodicNumber: 1  
    PeriodicAmplitude: 5.0000e-04  
PeriodicFrequencyHz: 200  
    PeriodicPhase: 0  
        DiracJitter: 'on'  
    DiracNumber: 2  
        DiracDelta: [-5.0000e-04 5.0000e-04]  
    DiracProbability: [0.5000 0.5000]
```

### Generate Non-return-to-zero Pattern Signal

Generate a binary non-return-to-zero (NRZ) signal utilizing the pattern generator object. View the NRZ signal with and without jitter applied to the signal.

Initialize system parameters.

```
Fs = 10000;           % Sample rate  
Rs = 50;             % Symbol rate (Sps)  
sps = Fs/Rs;        % Number of samples per symbol  
Trise = 1/(5*Rs);   % Rise time of the NRZ signal  
Tfall = 1/(5*Rs);   % Fall time of the NRZ signal  
frameLen = 100;     % Number of symbols in a frame  
spt = 200;          % Number of samples per trace on eye diagram
```

Create a pattern generator object with no jitter component assigned.

```
src = commsrc.pattern('SamplingFrequency', Fs, ...  
    'SamplesPerSymbol', sps, ...  
    'RiseTime', Trise, ...  
    'FallTime', Tfall)
```

```
src =  
    Type: 'Pattern Generator'  
    SamplingFrequency: 10000  
    SamplesPerSymbol: 200  
    SymbolRate: 50  
    PulseType: 'NRZ'  
    OutputLevels: [-1 1]  
    RiseTime: 0.0040  
    FallTime: 0.0040  
    DataPattern: 'PRBS7'  
    Jitter: [1x1 commsrc.combinedjitter]
```

**src.Jitter**

```
ans =  
    Type: 'Combined Jitter Generator'  
    SamplingFrequency: 10000  
    RandomJitter: 'off'  
    PeriodicJitter: 'off'  
    DiracJitter: 'off'
```

Generate an NRZ signal and view the eye diagram of the signal.

```
message = generate(src,frameLen);  
eyediagram(message,spt)
```

Add inter-symbol-interference (ISI) to an NRZ signal. ISI is modeled by two equal amplitude Dirac functions. Create a combined jitter object with Dirac jitter and assign it to the pattern generator object.

```
jitterSrc = commsrc.combinedjitter('DiracJitter','on', ...
    'DiracDelta',0.05/Rs*[-1 1]);
src.Jitter = jitterSrc
```

```
src =
    Type: 'Pattern Generator'
    SamplingFrequency: 10000
    SamplesPerSymbol: 200
    SymbolRate: 50
    PulseType: 'NRZ'
    OutputLevels: [-1 1]
    RiseTime: 0.0040
    FallTime: 0.0040
    DataPattern: 'PRBS7'
```

```
Jitter: [1x1 commsrc.combinedjitter]
```

Generate an NRZ signal that has jitter added to it and view the eye diagram of the signal.

```
reset(src);  
message = generate(src, frameLen);  
eyediagram(message, spt)
```

### Functions

`commsrc.pattern`

**Topics**

“Eye Diagram Measurements”

**Introduced in R2015a**

## commsrc.pattern

Construct pattern generator object

### Syntax

```
h = commsrc.pattern
h = commsrc.pattern(Name, Value)
```

### Description

`h = commsrc.pattern` constructs a pattern generator object, `h`.

The pattern generator object produces modulated data patterns. The object can be used to inject jitter into modulated signals.

`h = commsrc.pattern(Name, Value)` creates a combined jitter generator object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

### Properties

A pattern generator object includes these properties. You can edit all properties, except those explicitly noted.

Property	Description
Type	Type of pattern generator object ('Pattern Generator'). This property is not writable.
SamplingFrequency	Sampling frequency of the input signal in hertz.
SymbolRate	The symbol rate of the input signal. This property depends upon the <code>SamplingFrequency</code> and <code>SamplesPerSymbol</code> properties. This property is not writable.

<b>Property</b>	<b>Description</b>
SamplesPerSymbol	The number of samples representing a symbol. SamplesPerSymbol must be an integer. This property affects SymbolRate.
PulseType	The type of pulse the object generates. Pulse types available: return-to-zero ('RZ') and non-return-to-zero ('NRZ'). The initial condition for an 'NRZ' pulse is 0.
OutputLevels	Amplitude levels that correspond to the symbol indices. For an 'NRZ' pulse, specify as a 1-by-2 vector. The first element of the 1-by-2 vector corresponds to the 0th symbol (data bit value 0). The second element corresponds to the 1st symbol (data bit value 1). For an 'RZ' pulse, specify as a scalar and the value corresponds to the data bit value 1.
DutyCycle	The duty cycle of the pulse the object generates. Displays calculated duty cycle based on pulse parameters. This property is not writable.
RiseTime	Specifies 10% to 90% rise time of the pulse in seconds.
PulseDuration	Pulse duration in seconds defined by IEEE STD 181 standard. See the Return-to-Zero (RZ) Signal Conversion: Ideal Pulse to STD-181 figure in the "Object Functions" on page 2-325. Applies when PulseType is 'RZ'.
FallTime	Fall time of the pulse in seconds, specified as a percentage from 10 to 90.
DataPattern	The bit sequence the object uses, specified as 'PRBS5', 'PRBS6', ..., 'PRBS15', 'PRBS23', 'PRBS31', and 'User Defined'.
UserDataPattern	User-defined bit pattern consisting of a vector of ones and zeroes. Applies when DataPattern is 'User Defined'.

Property	Description
Jitter	Jitter characteristics, specified as a <code>commsrc.combinedjitter</code> object. Use this property to configure Random, Periodic and Dual Dirac Jitter.

## Object Functions

A pattern generator object has five object functions, as described in this section.

### generate

This object function outputs a frame worth of modulated and interpolated symbols. It has one input argument, which is the number of symbols in a frame. Its output is a column vector. You can call the object function using this syntax:

```
x = generate(h, N)
```

where `h` is the handle to the object, `N` is the number of output symbols, and `x` is a column vector whose length is `N` multiplied by `h.SamplesPerSymbol`.

### reset

This object function resets the pattern generator to its default state. The property values do not reset unless they relate to the state of the object. This object function has no input arguments.

### idealtostd181

This object function converts the ideal pulse specifications to IEEE STD-181 specifications. The ideal 0% to 100% span rise time (`tr`) and fall time (`tf`) are converted to 10% to 90% spans with a 50% pulse width duration (`pw`). Call the `idealtostd181` object function using this syntax:

```
h = idealtostd181(tr,tf,pw)
```

The object function sets the appropriate properties. The IEEE STD-181 Return-to-Zero (RZ) signal parameters are shown in this figure.

### **std181toideal**

The `std181toideal` object function converts the IEEE STD-181 pulse specifications, stored in the pattern generator, to ideal pulse specifications. The function converts the rise and fall times from 10% - 90% span to 0% - 100% span, and converts the 50% pulse duration to pulse width. Call the `std181toideal` object function using this syntax:

```
[tr tf pw] = std181toideal(h)
```

where `h` is the pattern generator object handle, `tr` is the ideal 0% - 100% rise time, `tf` is the ideal 0% - 100% fall time, and `pw` is the ideal pulse width. The ideal pulse non-return-to-zero (NRZ) signal parameters are shown in this figure.

Use the property values for IEEE STD-181 specifications.

## computedcd

The `computedcd` object function computes the duty cycle distortion,  $DCD$ , of the pulse defined by the pattern generator object  $h$ .

$DCD$  represents the ratio of the pulse on duration to the pulse off duration. For an NRZ pulse, on duration is the duration the pulse spends above the symbol boundary level. Off duration is the duration the pulse spends below zero. Call the `computedcd` object function using this syntax:

```
dcd = computedcd(h)
```

The software calculates  $DCD$  given  $t_R$ ,  $t_F$ ,  $T_{sym}$ . This formula assumes that the symbol boundary level is zero.

$$T_h = (A_h - A_l) * \frac{t_R}{A_l} + (A_h - A_l) * \frac{t_F}{A_l} + PW_+$$

$$T_l = (A_h - A_l) * \frac{t_R}{A_l} + (A_h - A_l) * \frac{t_F}{A_l} + PW_-$$

$$DCD = \frac{T_h}{T_l}$$

Where  $T_h$  is the duration of the high signal,  $T_l$  is the duration of the low signal, and  $DCD$  represents the ratio of the duration of the high signal to the low signal.

## Examples

### Display commsrc.pattern Object Settings

Create a `commsrc.pattern` object. Display the default object property values.

```
h = commsrc.pattern;
disp(h)

                Type: 'Pattern Generator'
SamplingFrequency: 10000
SamplesPerSymbol: 100
SymbolRate: 100
PulseType: 'NRZ'
OutputLevels: [-1 1]
RiseTime: 0
FallTime: 0
DataPattern: 'PRBS7'
Jitter: [1x1 commsrc.combinedjitter]
```

### Generate Non-return-to-zero Pattern Signal

Generate a binary non-return-to-zero (NRZ) signal utilizing the pattern generator object. View the NRZ signal with and without jitter applied to the signal.

Initialize system parameters.

```
Fs = 10000;           % Sample rate
Rs = 50;              % Symbol rate (Sps)
sps = Fs/Rs;         % Number of samples per symbol
Trise = 1/(5*Rs);    % Rise time of the NRZ signal
Tfall = 1/(5*Rs);    % Fall time of the NRZ signal
frameLen = 100;      % Number of symbols in a frame
spt = 200;           % Number of samples per trace on eye diagram
```

Create a pattern generator object with no jitter component assigned.

```
src = commsrc.pattern('SamplingFrequency', Fs, ...
                     'SamplesPerSymbol', sps, ...
                     'RiseTime', Trise, ...
                     'FallTime', Tfall)
```

```
src =  
    Type: 'Pattern Generator'  
    SamplingFrequency: 10000  
    SamplesPerSymbol: 200  
    SymbolRate: 50  
    PulseType: 'NRZ'  
    OutputLevels: [-1 1]  
    RiseTime: 0.0040  
    FallTime: 0.0040  
    DataPattern: 'PRBS7'  
    Jitter: [1x1 commsrc.combinedjitter]
```

**src.Jitter**

```
ans =  
    Type: 'Combined Jitter Generator'  
    SamplingFrequency: 10000  
    RandomJitter: 'off'  
    PeriodicJitter: 'off'  
    DiracJitter: 'off'
```

Generate an NRZ signal and view the eye diagram of the signal.

```
message = generate(src,frameLen);  
eyediagram(message,spt)
```

Add inter-symbol-interference (ISI) to an NRZ signal. ISI is modeled by two equal amplitude Dirac functions. Create a combined jitter object with Dirac jitter and assign it to the pattern generator object.

```
jitterSrc = commsrc.combinedjitter('DiracJitter','on', ...  
    'DiracDelta',0.05/Rs*[-1 1]);  
src.Jitter = jitterSrc
```

```
src =  
    Type: 'Pattern Generator'  
    SamplingFrequency: 10000  
    SamplesPerSymbol: 200  
    SymbolRate: 50  
    PulseType: 'NRZ'  
    OutputLevels: [-1 1]  
    RiseTime: 0.0040  
    FallTime: 0.0040  
    DataPattern: 'PRBS7'
```

```
Jitter: [1x1 commsrc.combinedjitter]
```

Generate an NRZ signal that has jitter added to it and view the eye diagram of the signal.

```
reset(src);  
message = generate(src, frameLen);  
eyediagram(message, spt)
```

## commsrc.pn

Create PN sequence generator object

### Syntax

```
h = commsrc.pn
h = commsrc.pn(property1,value1,...)
```

### Description

`h = commsrc.pn` creates a default PN sequence generator object *h*, and is equivalent to the following:

```
H = commsrc.pn('GenPoly',      [1 0 0 0 0 1 1], ...
               'InitialStates', [0 0 0 0 0 1], ...
               'CurrentStates', [0 0 0 0 0 1], ...
               'Mask',          [0 0 0 0 0 1], ...
               'NumBitsOut',    1)
```

or

```
H = commsrc.pn('GenPoly',      [1 0 0 0 0 1 1], ...
               'InitialStates', [0 0 0 0 0 1], ...
               'CurrentStates', [0 0 0 0 0 1], ...
               'Shift',         0, ...
               'NumBitsOut',    1)
```

`h = commsrc.pn(property1,value1,...)` creates a PN sequence generator object, *h*, with properties you specify as property/value pairs.

### Properties

A PN sequence generator has the properties shown on the following table. All properties are writable except for the ones explicitly noted otherwise.

<b>Property</b>	<b>Description</b>
GenPoly	Generator polynomial vector array of bits; must be descending order
InitialStates	Vector array (with length of the generator polynomial order) of initial shift register values (in bits)
CurrentStates	Vector array (with length of the generator polynomial order) of present shift register values (in bits)
NumBitsOut	Number of bits to output at each <code>generate</code> method invocation
Mask or Shift	A mask vector of binary 0 and 1 values is used to specify which shift register state bits are XORed to produce the resulting output bit value.  Alternatively, a scalar shift value may be used to specify an equivalent shift (either a delay or advance) in the output sequence.

The 'GenPoly' property values specify the shift register connections. Enter these values as either a binary vector or a vector of exponents of the nonzero terms of the generator polynomial in descending order of powers. For the binary vector representation, the first and last elements of the vector must be 1. For the descending-ordered polynomial representation, the last element of the vector must be 0. For more information and examples, see the LFSR SSRG Details section of this page.

## Methods

A PN sequence generator is equipped with the following methods.

### **generate**

Generate [NumBitsOut x 1] PN sequence generator values

**reset**

Set the `CurrentStates` values to the `InitialStates` values

**getshift**

Get the actual or equivalent `Shift` property value

**getmask**

Get the actual or equivalent `Mask` property value

**copy**

Make an independent copy of a `commsrc.pn` object

**disp**

Display PN sequence generator object properties

## Side Effects of Setting Certain Properties

### Setting the GenPoly Property

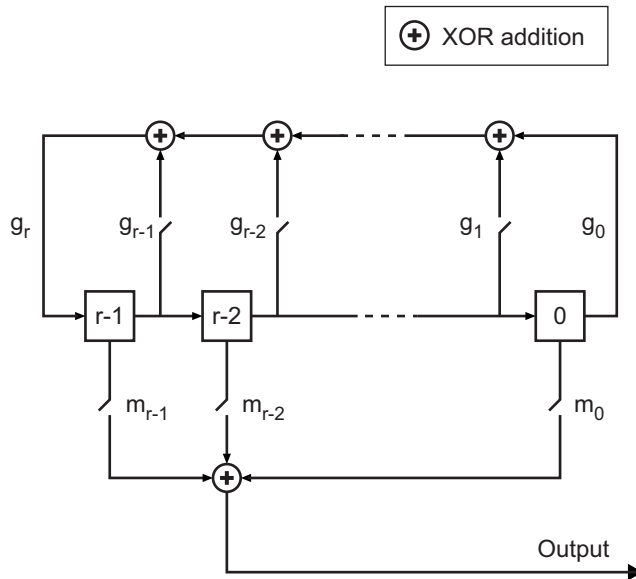

Every time this property is set, it will reset the entire object. In addition to changing the polynomial values, `'CurrentStates'`, `'InitialStates'`, and `'Mask'` will be set to their default values (`'NumBitsOut'` will remain the same), and no warnings will be issued.

### Setting the InitialStates Property

Every time this property is set, it will also set `'CurrentStates'` to the new `'InitialStates'` setting.

## LFSR SSRG Details

The `generate` method produces a pseudorandom noise (PN) sequence using a linear feedback shift register (LFSR). The LFSR is implemented using a simple shift register generator (SSRG, or Fibonacci) configuration, as shown below.

All  $r$  registers in the generator update their values at each time step according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The shift register is described by the 'GenPoly' property (generator polynomial), which is a primitive binary polynomial in  $z$ ,  $g_r z^r + g_{r-1} z^{r-1} + g_{r-2} z^{r-2} + \dots + g_0$ . The coefficient  $g_k$  is 1 if there is a connection from the  $k$ th register, as labeled in the preceding diagram, to the adder. The leading term  $g_r$  and the constant term  $g_0$  of the 'GenPoly' property must be 1 because the polynomial must be primitive.

You can specify the **Generator polynomial** parameter using either of these formats:

- A vector that lists the coefficients of the polynomial in descending order of powers. The first and last entries must be 1. Note that the length of this vector is one more than the degree of the generator polynomial.
- A vector containing the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0.

For example,  $[1\ 0\ 0\ 0\ 0\ 0\ 1\ 0\ 1]$  and  $[8\ 2\ 0]$  represent the same polynomial,  $p(z) = z^8 + z^2 + 1$ .

The **Initial states** parameter is a vector specifying the initial values of the registers. The **Initial states** parameter must satisfy these criteria:

- All elements of the **Initial states** vector must be binary numbers.
- The length of the **Initial states** vector must equal the degree of the generator polynomial.

---

**Note** At least one element of the **Initial states** vector must be nonzero in order for the block to generate a nonzero sequence. That is, the initial state of at least one of the registers must be nonzero.

---

For example, the following table indicates two sets of parameter values that correspond to a generator polynomial of  $p(z) = z^8 + z^2 + 1$ .

Quantity	Example 1	Example 2
<b>Generator polynomial</b>	$g1 = [1\ 0\ 0\ 0\ 0\ 0\ 1\ 0\ 1]$	$g2 = [8\ 2\ 0]$
Degree of generator polynomial	8, which is $\text{length}(g1) - 1$	8
<b>Initial states</b>	$[1\ 0\ 0\ 0\ 0\ 0\ 1\ 0]$	$[1\ 0\ 0\ 0\ 0\ 0\ 1\ 0]$

**Output mask vector (or scalar shift value)** shifts the starting point of the output sequence. With the default setting for this parameter, the only connection is along the arrow labeled  $m_0$ , which corresponds to a shift of 0. The parameter is described in greater detail below.

You can shift the starting point of the PN sequence with **Output mask vector (or scalar shift value)**. You can specify the parameter in either of two ways:

- An integer representing the length of the shift
- A binary vector, called the *mask vector*, whose length is equal to the degree of the generator polynomial

The difference between the block's output when you set **Output mask vector (or scalar shift value)** to 0, versus a positive integer  $d$ , is shown in the following table.

	<b>T = 0</b>	<b>T = 1</b>	<b>T = 2</b>	...	<b>T = d</b>	<b>T = d+1</b>
<b>Shift = 0</b>	$x_0$	$x_1$	$x_2$	...	$x_d$	$x_{d+1}$
<b>Shift = d</b>	$x_d$	$x_{d+1}$	$x_{d+2}$	...	$x_{2d}$	$x_{2d+1}$

Alternatively, you can set **Output mask vector (or scalar shift value)** to a binary vector, corresponding to a polynomial in  $z$ ,  $m_{r-1}z^{r-1} + m_{r-2}z^{r-2} + \dots + m_1z + m_0$ , of degree at most  $r-1$ . The mask vector corresponding to a shift of  $d$  is the vector that represents  $m(z) = z^d$  modulo  $g(z)$ , where  $g(z)$  is the generator polynomial. For example, if the degree of the generator polynomial is 4, then the mask vector corresponding to  $d = 2$  is  $[0 \ 1 \ 0 \ 0]$ , which represents the polynomial  $m(z) = z^2$ . The preceding schematic diagram shows how **Output mask vector (or scalar shift value)** is implemented when you specify it as a mask vector. The default setting for **Output mask vector (or scalar shift value)** is  $\theta$ . You can calculate the mask vector using the Communications Toolbox function `shift2mask`.

## Sequences of Maximum Length

If you want to generate a sequence of the maximum possible length for a fixed degree,  $r$ , of the generator polynomial, you can set **Generator polynomial** to a value from the following table. See Proakis, John G., *Digital Communications*, Third edition, New York, McGraw Hill, 1995 for more information about the shift-register configurations that these polynomials represent.

<b>r</b>	<b>Generator Polynomial</b>	<b>r</b>	<b>Generator Polynomial</b>

## Examples

### Setting Up PN Sequence Generator

Set up a PN sequence generator. Define the polynomial in binary vector format or exponential vector format.

This figure defines a PN sequence generator with a generator polynomial

$$p(z) = z^6 + z + 1.$$

Define this PN sequence generator as follows:

```
h1 = commsrc.pn('GenPoly', [1 0 0 0 0 1 1], 'Mask', [1 1 0 1 0 1]);
h2 = commsrc.pn('GenPoly', [1 0 0 0 0 1 1], 'Shift', 22);
mask2shift ([1 0 0 0 0 1 1],[1 1 0 1 0 1])
```

```
ans = 22
```

Alternatively, you can input GenPoly as the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers:

```
h = commsrc.pn('GenPoly', [6 1 0], 'Mask', [1 1 0 1 0 1])
```

```
h =
    GenPoly: [1 0 0 0 0 1 1]
  InitialStates: [0 0 0 0 0 1]
  CurrentStates: [0 0 0 0 0 1]
         Mask: [1 1 0 1 0 1]
  NumBitsOut: 1
```

### General commsrc.pn Use

Typically `commsrc.pn` is used to output pseudorandom data streams.

Construct a PN object.

```
h = commsrc.pn('Shift',0);
```

Output 10 PN bits.

```
set(h,'NumBitsOut',10);  
generate(h)
```

```
ans = 10×1
```

```
1  
0  
0  
0  
0  
0  
1  
0  
0  
0
```

Output 10 more PN bits.

```
generate(h)
```

```
ans = 10×1
```

```
0  
1  
1  
0  
0  
0  
1  
0  
1  
0
```

Reset the object to the initial shift register state values.

```
reset(h);
```

Output 4 PN bits.

```
set(h, 'NumBitsOut', 4);  
generate(h)
```

```
ans = 4×1
```

```
1  
0  
0  
0
```

### Copied commsrc.pn Object Behavior

When a `commsrc.pn` object is copied, its states are also copied. Subsequent outputs from the copied object are likely to be different from the initial outputs from the original object.

Construct a PN object and output a sequence from it.

```
h = commsrc.pn('Shift', 0);  
set(h, 'NumBitsOut', 5);  
generate(h)
```

```
ans = 5×1
```

```
1  
0  
0  
0  
0
```

Make a copy of `h`. Generate a sequence from the copied object. Because the copy was made after the state of `h` changed, the initial sequence generated by `g` is different from the initial sequence generated from `h`.

```
g=copy(h);  
generate(g)
```

```
ans = 5×1
```

```
0
```

```
1  
0  
0  
0
```

But if `g` is reset, it generates the same sequence that `h` generated.

```
reset(g);  
generate(g)
```

```
ans = 5×1
```

```
1  
0  
0  
0  
0
```

**Introduced in R2009a**

## commtest.ErrorRate

(To be removed) Create error rate test console

### Compatibility

commtest.ErrorRate will be removed in a future release. Use comm.ErrorRate or bertool instead. For more information, see “Compatibility Considerations” on page 2-369.

### Syntax

```
h = commtest.ErrorRate
h = commtest.ErrorRate(sys)
h = commtest.ErrorRate(sys, 'PropertyName', PropertyValue, ...)
h = commtest.ErrorRate('PropertyName', PropertyValue, ...)
```

### Description

h = commtest.ErrorRate returns an error rate test console, h. The error rate test console runs simulations of a system under test to obtain error rates.

h = commtest.ErrorRate(sys) returns an error rate test console, error rate test console, h, with each specified property set to the h, with an attached system under test, SYS.

h = commtest.ErrorRate(sys, 'PropertyName', PropertyValue, ...) returns an error rate test console, h, with an attached system under test, sys. Each specified property, 'PropertyName', is set to the specified value, PropertyValue.

h = commtest.ErrorRate('PropertyName', PropertyValue, ...) returns an error rate test console, h, with each specified property 'PropertyName', set to the specified value, PropertyValue.

## Properties

The error rate test console object has the properties in the following table. Setting any property resets the object. A property that is irrelevant is one that you can set, but its value does not affect measurements. Similarly, you cannot display irrelevant properties using the `disp` method. You can write to all properties, except for the ones explicitly noted otherwise.

Property	Description
Description	'Error Rate Test Console'. Read-only.
SystemUnderTestName	System under test name. Read-only.
FrameLength	<p>Specify the length of the transmission frame at each iteration. This property becomes relevant only when the system under test registers a valid test input.</p> <ul style="list-style-type: none"> <li>• If the system under test registers a <code>NumTransmissions</code> test input and calls its <code>getInput</code> method, the error rate test console returns the value stored in <code>FrameLength</code>. Using an internal data source, the system under test uses this value to generate a transmission frame of the specified length.</li> <li>• If the system under test registers a <code>DiscreteRandomSource</code> test input and calls its <code>getInput</code> method, the test console generates and returns a frame of symbols. The length of the frame of symbols matches the <code>FrameLength</code> property. This property defaults to 500.</li> </ul>

Property	Description
IterationMode	<p>Specify how the object determines simulation points.</p> <ul style="list-style-type: none"> <li>• If set to <b>Combinatorial</b>, the object performs simulations for all possible combinations of registered test parameter sweep values.</li> <li>• If set to <b>Indexed</b>, the object performs simulations for all indexed sweep value sets. The <math>i^{th}</math> sweep value set consists of the <math>i^{th}</math> element of every sweep value vector for each registered test parameter. All sweep value vectors must have equal length, except for values that are unit length.</li> </ul> <p>Note that for the following sweep parameter settings:</p> <ul style="list-style-type: none"> <li>• Parameter1 = [a<sub>1</sub> a<sub>2</sub>]</li> <li>• Parameter2 = [b<sub>1</sub> b<sub>2</sub>]</li> <li>• Parameter3 = [c<sub>1</sub>]</li> </ul> <p>In Indexed Mode, the test console performs simulations for the following sweep parameter sets:</p> <p>(a<sub>1</sub>, b<sub>1</sub>, c<sub>1</sub>)</p> <p>(a<sub>2</sub>, b<sub>2</sub>, c<sub>1</sub>)</p> <p>In Combinatorial Mode, the test console performs simulations for the following sweep parameter sets:</p> <p>(a<sub>1</sub>, b<sub>1</sub>, c<sub>1</sub>)</p> <p>(a<sub>1</sub>, b<sub>2</sub>, c<sub>1</sub>)</p> <p>(a<sub>2</sub>, b<sub>1</sub>, c<sub>1</sub>)</p> <p>(a<sub>2</sub>, b<sub>2</sub>, c<sub>1</sub>)</p>

---

Property	Description
SystemResetMode	<p data-bbox="546 302 1332 331">Specify the stage of a simulation run at which the system resets.</p> <ul data-bbox="546 361 1332 493" style="list-style-type: none"><li data-bbox="546 361 1332 423">• Setting to <code>Reset at new simulation point</code> resets the system under test at the beginning of a new simulation point.</li><li data-bbox="546 435 1332 493">• Setting to <code>Reset at every iteration</code> resets the system under test at every iteration.</li></ul>

Property	Description
SimulationLimitOption	<p>Specify how to stop the simulation for each sweep parameter point.</p> <ul style="list-style-type: none"> <li>• If set to <code>Number of transmissions</code> the simulation for a sweep parameter point stops when the number of transmissions equals the value for <code>MaxNumTransmissions</code>.</li> <li>• Set <code>TransmissionCountTestPoint</code> to the name of the registered test point containing the transmission count you are comparing to <code>MaxNumTransmissions</code>.</li> <li>• If set to <code>Number of errors</code> the simulation for a sweep parameter point stops when the number of errors equals the value for <code>MinNumErrors</code>.</li> <li>• Set the <code>ErrorCountTestPoint</code> to the name of the registered test point containing the error count you are comparing to the <code>MinNumErrors</code>.</li> <li>• Setting to <code>Number of errors or transmissions</code> stops the simulation for a sweep parameter point when meeting one of two conditions. <ul style="list-style-type: none"> <li>• The simulation stops when the number of transmissions equals the value for <code>MaxNumTransmissions</code>.</li> <li>• The simulation stops when obtaining the number of errors matching <code>NumErrors</code>.</li> </ul> </li> <li>• Setting this property to <code>Number of errors and transmissions</code> stops the simulation for a sweep parameter point when meeting the following condition. <ul style="list-style-type: none"> <li>• The simulation stops when the number of transmissions <i>and</i> the number errors have at least reached the values in <code>MinNumTransmissions</code> and <code>MinNumErrors</code>.</li> </ul> </li> </ul> <p>Set <code>TransmissionCountTestPoint</code> to the name of the registered test point that contains the transmission count you are comparing to the <code>MaxNumTransmissions</code> property.</p>

Property	Description
	<p>To control the simulation length, set <code>ErrorCountTestPoint</code> to the name of the registered test point containing the error count you are comparing to <code>MinNumErrors</code>.</p> <p>Call the <code>info</code> method of the error rate test console to see the valid registered test point names.</p>
MaxNumTransmissions	<p>Specify the maximum number of transmissions the object counts before stopping the simulation for a sweep parameter point. This property becomes relevant only when <code>SimulationLimitOption</code> is <code>Number of transmissions</code> or <code>Number of errors</code> or <code>transmissions</code>.</p> <ul style="list-style-type: none"> <li>• When setting <code>SimulationLimitOption</code> to <code>Number of transmissions</code> the simulation for each sweep parameter point stops when reaching the number of transmissions <code>MaxNumTransmissions</code> specifies.</li> <li>• Setting <code>SimulationLimitOption</code> to <code>Number of errors</code> or <code>transmissions</code> stops the simulation for each sweep parameter point for one of two conditions. <ul style="list-style-type: none"> <li>• The simulation stops when completing the number of transmissions <code>MaxNumTransmissions</code> specifies.</li> <li>• The simulation stops when obtaining the number of errors <code>MinNumErrors</code> specifies.</li> </ul> </li> </ul> <p>The <code>TransmissionCountTestPoint</code> property supplies the name of a registered test point containing the count transmission type. Calling the <code>info</code> method of the error rate test console displays the valid registered test points. If this property contains registered test points, the test console runs iterations equal to the value for <code>MaxNumTransmissions</code> for each sweep parameter point. If this property has no registered test parameters, the test console runs the number of iterations equal to the value for <code>MaxNumTransmissions</code> and stops. The value defaults to 1000.</p>

Property	Description
MinNumErrors	<p>Specify the minimum number of errors the object counts before stopping the simulation for a sweep parameter point. This property becomes relevant only when setting the <code>SimulationLimitOption</code> to <code>Number of errors</code> or <code>Number of errors or transmissions</code>.</p> <ul style="list-style-type: none"> <li>• When setting <code>SimulationLimitOption</code> to <code>Number of errors</code> the simulation for each parameter point stops when reaching the number of errors you specify for the <code>MinNumErrors</code> property.</li> <li>• When setting the <code>SimulationLimitOption</code> property to <code>Number of errors or transmissions</code> the simulation for each sweep parameter point stops for one of two conditions. <ul style="list-style-type: none"> <li>• The simulation stops when reaching the number of errors you specify for the <code>MaxNumTransmissions</code> property.</li> <li>• The simulation stops when reaching the number of errors you specify for the <code>MinNumErrors</code> property.</li> </ul> </li> </ul> <p>Specify the type of errors the error count uses by setting the <code>ErrorCountTestPoint</code> property to the name of a registered test point containing the count. Call the <code>info</code> method of the error rate test console to see the valid registered test point names. This value defaults to 100.</p>
TransmissionCountTestPoint	<p>Specify and register a test point containing the transmission count that controls the test console simulation stop mechanism. This property becomes relevant only when setting <code>SimulationLimitOption</code> to <code>Number of transmissions</code>, <code>Number of errors or transmissions</code>, or <code>Number of errors and transmissions</code>. In this scenario, if you register a test point, and <code>TransmissionCountTestPoint</code> equals <code>Not set</code>, the value of this property automatically updates to that of the registered test point name. Call the <code>info</code> method to see the valid test point names.</p>

Property	Description
ErrorCountTestPoint	Specify and register the name of a test point containing the error count that controls the simulation stop mechanism. This property is only relevant when setting the SimulationLimitOption property to Number of errors, Number of errors or transmissions, or Number of errors and transmissions. In this scenario, if you register a test point, and ErrorCountTestPoint equals Not set, the value of this property automatically updates to that of the registered test point name. Call the info method to see the valid test point names.

## Methods

The error rate test console object has the following methods:

### run

Runs a simulation.

Runs the number of error rate simulations you specify for a system under test with a specified set of parameter values. If a Parallel Computing Toolbox™ license is available and a parpool is open, then the object distributes the iterations among the number of workers available.

### getResults

Returns the simulation results.

`r = getResults(h)` returns the simulation results, *r*, for the test console, *h*. *r* is an object of the type you specify using `testconsole.Results`. It contains the simulation data for all the registered test points and methods to parse the data and plot it.

### info

Returns a report of the current test console settings.

`info(h)` displays the current test console settings, such as registered test parameters and registered test points.

### **reset**

Resets the error rate test console.

`reset(h)` resets test parameters and test probes and then clears all simulation results of test console, *h*.

### **attachSystem**

Attaches a system to test console.

`attachSystem(ho,sys)` attaches a valid user-defined system, *sys*, to the test console, *h*.

### **detachSystem**

Detaches the system from the test console.

`detachSystem(h)` detaches a system from the test console, *h*. This method also clears the registered test inputs, test parameters, test probes, and test points.

### **setTestParameterSweepValues**

Sets test parameter sweep values.

`setTestParameterSweepValues(h,name,sweep)` specifies a set of sweep values, 'sweep', for the registered test parameter, 'name', in the test console, *h*. You only specify sweep values for registered test parameters. *sweep* must have values within the specified range of the test parameter. It can be a row vector of numeric values, or a cell array of char values. Display the valid ranges using the `getTestParameterValidRanges` method.

`setTestParameterSweepValues(h,name1,sweep1,name2,sweep2...)` simultaneously specifies sweep values for multiple registered test parameters.

### **getTestParameterSweepValues**

Returns test parameter sweep values.

`getTestParameterSweepValues(h,name)` gets the sweep values currently specified for the registered test parameter, name, in the test console, h.

## **getTestParameterValidRanges**

Returns the test parameter valid ranges.

`getTestParameterValidRanges(h,name)` gets the valid ranges for a registered test parameter, name, in the test console, h.

## **registerTestPoint**

Registers a test point.

`registerTestPoint(h, name, actprobe,expprobe)` registers a new test point object, name, to the error rate test console, h. The test point must contain a pair of registered test probes, actprobe, and expprobe. actprobe contains actual data, and expprobe contains expected data. The object compares the data from these probes and obtains error rate values. The error rate calculation uses a default error rate calculator function that simply performs one-to-one comparisons of the data vectors available in the probes.

`registerTestPoint(h, name, actprobe,expprobe, handle)` adds the handle, handle, to a user-defined error calculation function that compares the data in the probes and then obtains error rate results.

The user-defined error calculation function must comply with the following syntax: [ecnt tcnt] = functionName(act, exp, udata) where

- ecnt output corresponds to the error count
- tcnt output is the number of transmissions used to obtain the error count
- act and exp correspond to actual and expected data

The error rate test console sets the inputs to the data available in the pair of test point probes, actprobe, and expprobe.

udata is a data input that the system under test passes to the test console at run time, using the `setUserData` method. udata contains the data necessary to compute errors, such as delays and data buffers.

The error rate test console passes the data that the system under test logs to the error calculation functions for all the registered test points. Calling the `info` method returns the

names of the registered test points and the error rate calculator functions associated with them. It also returns the names of the registered test probes.

### **unregisterTestPoint**

Unregister a test point.

`unregisterTestPoint(h,name)` removes the test point, name, from the test console, h.

## **Examples**

### **Error Rate Simulation Sweeps**

The `commtest.ErrorRate` and `testconsole.Results` object packages will be removed in a future release. They can be used to perform parameter sweeps to analyze communication system performance. This example demonstrates a workflow that uses them and along with recommended alternate workflows.

### **Multiple Parameter Sweep and Parallel Run using `commtest.ErrorRate`**

Obtain bit error rate and symbol error rate of an M-PSK system for different modulation orders and EbNo values. System under test is `commtest.MPSKSystem`.

```
% Create an M-ary PSK system
systemUnderTest = commtest.MPSKSystem;
```

```
% Instantiate an Error Rate Test Console and attach the system
errorRateTester = commtest.ErrorRate(systemUnderTest);
```

Warning: `commtest.ErrorRate` will be removed in the future. Use `comm.ErrorRate` or `berton`

```
errorRateTester.SimulationLimitOption = 'Number of errors or transmissions';
errorRateTester.MaxNumTransmissions = 1e5;
```

```
% Set sweep values for simulation test parameters
setTestParameterSweepValues(errorRateTester, 'M', 2.^[1 2 3 4], 'EbNo', (-5:10))
```

```
% Register a test point
registerTestPoint(errorRateTester, 'MPSK_BER', 'TxInputBits', 'RxOutputBits')
```

```
% Get information about the simulation settings
info(errorRateTester)
```

```
Test console name:          commtest.ErrorRate
System under test name:    commtest.MPSKSystem
Available test inputs:    NumTransmissions, RandomIntegerSource
Registered test inputs:   NumTransmissions
Registered test parameters: EbNo, M
Registered test probes:   RxOutputBits, RxOutputSymbols, TxInputBits, TxInputSymbols
Registered test points:   MPSK_BER
Metric calculator functions: @commtest.ErrorRate.defaultErrorCalculator
Test metrics:             ErrorCount, TransmissionCount, ErrorRate
```

```
% Run the M-PSK simulations
run(errorRateTester)
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
12 workers available for parallel computing. Simulations will be distributed among these workers.
Running simulations...
```

```
% Get the results
```

```
mpskResults = getResults(errorRateTester);
```

```
Warning: testconsole.Results will be removed in the future. See <a href="matlab:helpviewer" data-bbox="155 528 1000 546">matlab:helpviewer</a>
```

```
% Get a semi-log scale plot of EbNo versus bit error rate for
% different values of modulation order M
```

```
mpskResults.TestParameter2 = 'M';
semilogy(mpskResults, '*-')
```

### Multiple Parameter Sweep and Parallel Run using nested for loops and `comm.ErrorRate`

Run an error rate simulation over  $M=2^{(1:4)}$  and  $EbNo=-5:10$ . Use `comm.ErrorRate` to collect both bit error rate (BER) and symbol error rate (SER) data. Run the simulations to collect a minimum of 100 symbol errors or for a maximum of  $1e5$  symbols.

```
% Set the M sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester, 'M')
```

```
ans = 1x4
```

```
     2     4     8    16
```

```

MSweep = 2.^[1 2 3 4];

% Set EbNo sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester, 'EbNo')

ans = 1×16

    -5    -4    -3    -2    -1     0     1     2     3     4     5     6     7     8

EbNoSweep = -5:10;

% Set minimum number of errors same as the commtest.ErrorRate object
errorRateTester.MinNumErrors

ans = 100

```

### Multiple Variable Sweeps using BERTool

BERTool computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB® functions and Simulink® models or with theoretical closed-form expressions for selected types of communication systems. The `bertool` function opens the BERTool. Here BERTool is configured to call the simulation defined in the function `mpsksim` included below.

```
function [ber,numBits] = mpsksim(EbNo,minNumErrs,maxNumBits)
% Import the Java class for BERTool, so that you will be able to stop the simulation us
import com.mathworks.toolbox.comm.BERTool;
```

```
frameLength = 500;
```

```

M = 16; % Can be 2, 4, 8, 16
bitsPerSymbol = log2(M);

maxNumSymbols = maxNumBits/bitsPerSymbol;

SNR = EbNo + 10*log10(bitsPerSymbol);

% Initialize variables related to exit criteria.
numBitErrors = 0;
numSymbols = 0;

while (numBitErrors < minNumErrs) || (numSymbols < maxNumSymbols)

    % Check if the user clicked the Stop button of BERTool.
    if (BERTool.getSimulationStop)
        break;
    end

    % Generate frameLength source outputs
    txMsg = randi([0 M-1],frameLength,1);
    numSymbols = numSymbols+frameLength;

    % Modulate the data
    txOutput = pskmod(txMsg,M,0,'gray');
    % Pass data through an AWGN channel with current SNR value
    chnlOutput = awgn(txOutput,SNR,'measured',[],'dB');
    % Demodulate the data
    rxOutput = pskdemod(chnlOutput,M,0,'gray');

    % Convert symbol streams to bit streams
    bTx = de2bi(txMsg,bitsPerSymbol,'left-msb');
    bTx = bTx(:);
    bRx = de2bi(rxOutput,bitsPerSymbol,'left-msb');
    bRx = bRx(:);

    % Calculate number of bit errors
    numBitErrors = numBitErrors+sum(bTx~=bRx);
end

% Assign values to the output variables.
numBits = numSymbols*bitsPerSymbol;
ber = numBitErrors/numBits;

```

Configure BERTool as follows.

Set  $M=2$  in the `mpsksim` function and click Run. Set the **BER Data Set** name to 'M=2'.

Confidence Level	Fit	Plot	BER Data Set	$E_b/N_0$ (dB)	BER	# of Bits

### Parallel SNR Sweep using BERTool

Using `parfor`, run each simulation point in parallel by configuring your simulation function similar to the `mpsksim_parfor` function included below. Since `parfor` cannot work with the Java class for BERTool, you will not be able to stop the simulation using the **Stop** button.

```
function [ber,numBits] = mpsksim_parfor(EbNo,minNumErrs,maxNumBits)

% Find out if there is a parallel pool and how many workers are available
if license('test','Distrib_Computing_Toolbox')
    p = gcp;
    if isempty(p)
        numWorkers = 1;
    else
        numWorkers = p.NumWorkers;
    end
else
    numWorkers = 1;
end

M = 2;
bitsPerSymbol = log2(M);

maxNumSymbols = maxNumBits/bitsPerSymbol;

minNumErrorsPerWorker = minNumErrs/numWorkers;
maxNumSymbolsPerWorker = maxNumSymbols/numWorkers;
frameLength = 500;

SNR = EbNo + 10*log10(bitsPerSymbol);

% Initialize variables related to exit criteria.
numBitErrors = zeros(numWorkers,1);
numSymbols = zeros(numWorkers,1);

parfor worker = 1:numWorkers
    while (numBitErrors(worker) < minNumErrorsPerWorker) ...
        || (numSymbols(worker) < maxNumSymbolsPerWorker)

        % Generate frameLength source outputs
        txMsg = randi([0 M-1],frameLength,1);
        numSymbols(worker) = numSymbols(worker)+frameLength;
```

```

% Modulate the data
txOutput = pskmod(txMsg, M, 0, 'gray');
% Pass data through an AWGN channel with current SNR value
chnlOutput = awgn(txOutput,SNR,'measured',[],'dB');
% Demodulate the data
rxOutput = pskdemod(chnlOutput,M,0,'gray');

% Convert symbol streams to bit streams
bTx = de2bi(txMsg,bitsPerSymbol,'left-msb');
bTx = bTx(:);
bRx = de2bi(rxOutput,bitsPerSymbol,'left-msb');
bRx = bRx(:);

% Calculate number of bit errors
numBitErrors(worker) = numBitErrors(worker)+sum(bTx~=bRx);
end
end

% Assign values to the output variables.
ber = sum(numBitErrors)/sum(numSymbols);
numBits = sum(numSymbols)*bitsPerSymbol;

```

## Compatibility Considerations

### **commtest.ErrorRate will be removed**

*Warns starting in R2019b*

commtest.ErrorRate will be removed in a future release. Use comm.ErrorRate or bertool instead. The “Error Rate Simulation Sweeps” on page 2-354 example demonstrates alternate workflows using comm.ErrorRate and bertool.

## compand

Source code mu-law or A-law compressor or expander

### Syntax

```
out = compand(in,Mu,v)
out = compand(in,Mu,v,'mu/compressor')
out = compand(in,Mu,v,'mu/expander')
out = compand(in,A,v,'A/compressor')
out = compand(in,A,v,'A/expander')
```

### Description

`out = compand(in,Mu,v)` implements a  $\mu$ -law compressor for the input vector `in`. `Mu` specifies  $\mu$ , and `v` is the input signal's maximum magnitude. `out` has the same dimensions and maximum magnitude as `in`.

`out = compand(in,Mu,v,'mu/compressor')` is the same as the syntax above.

`out = compand(in,Mu,v,'mu/expander')` implements a  $\mu$ -law expander for the input vector `in`. `Mu` specifies  $\mu$  and `v` is the input signal's maximum magnitude. `out` has the same dimensions and maximum magnitude as `in`.

`out = compand(in,A,v,'A/compressor')` implements an A-law compressor for the input vector `in`. The scalar `A` is the A-law parameter, and `v` is the input signal's maximum magnitude. `out` is a vector of the same length and maximum magnitude as `in`.

`out = compand(in,A,v,'A/expander')` implements an A-law expander for the input vector `in`. The scalar `A` is the A-law parameter, and `v` is the input signal's maximum magnitude. `out` is a vector of the same length and maximum magnitude as `in`.

---

**Note** The prevailing parameters used in practice are  $\mu=255$  and  $A=87.6$ .

---

## Examples

### **$\mu$ -Law Compression and Expansion**

Generate a data sequence.

```
data = 2:2:12;
```

Compress the input sequence using an  $\mu$ -law compander. The typical value for  $\mu$  is 255. The data ranges between 8.1 and 12 instead of between 2 and 12.

```
compressed = compand(data,255,max(data),'mu/compressor')
```

```
compressed = 1×6
```

```
    8.1644    9.6394   10.5084   11.1268   11.6071   12.0000
```

Expand the compressed signal. The expanded sequence is nearly identical to the original.

```
expanded = compand(compressed,255,max(data),'mu/expander')
```

```
expanded = 1×6
```

```
    2.0000    4.0000    6.0000    8.0000   10.0000   12.0000
```

### **A-Law Compression and Expansion**

Generate a data sequence.

```
data = 1:5;
```

Compress the input sequence using an A-law compander. The typical value for A is 87.5. The data ranges between 3.5 and 5 instead of between 1 and 5.

```
compressed = compand(data,87.6,max(data),'a/compressor')
```

```
compressed = 1×5
```

```
3.5296    4.1629    4.5333    4.7961    5.0000
```

Expand the compressed signal. The expanded sequence is nearly identical to the original.

```
expanded = comand(compressed,87.6,max(data),'a/expander')
```

```
expanded = 1x5
```

```
1.0000    2.0000    3.0000    4.0000    5.0000
```

## Algorithms

For a given signal  $x$ , the output of the  $\mu$ -law compressor is

$$y = \frac{V \log(1 + \mu|x|/V)}{\log(1 + \mu)} \text{sgn}(x)$$

where  $V$  is the maximum value of the signal  $x$ ,  $\mu$  is the  $\mu$ -law parameter of the compander,  $\log$  is the natural logarithm, and  $\text{sgn}$  is the signum function (`sign` in MATLAB).

The output of the A-law compressor is

$$y = \begin{cases} \frac{A|x|}{1 + \log A} \text{sgn}(x) & \text{for } 0 \leq |x| \leq \frac{V}{A} \\ \frac{V(1 + \log(A|x|/V))}{1 + \log A} \text{sgn}(x) & \text{for } \frac{V}{A} < |x| \leq V \end{cases}$$

where  $A$  is the A-law parameter of the compander and the other elements are as in the  $\mu$ -law case.

## convdeintrlv

Restore ordering of symbols using shift registers

### Syntax

```
deintrlved = convdeintrlv(data,nrows,slope)
[deintrlved,state] = convdeintrlv(data,nrows,slope)
[deintrlved,state] = convdeintrlv(data,nrows,slope,init_state)
```

### Description

`deintrlved = convdeintrlv(data,nrows,slope)` restores the ordering of elements in `data` by using a set of `nrows` internal shift registers. The delay value of the  $k$ th shift register is  $(nrows - k) * slope$ , where  $k = 1, 2, 3, \dots, nrows$ . Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[deintrlved,state] = convdeintrlv(data,nrows,slope)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[deintrlved,state] = convdeintrlv(data,nrows,slope,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver.

### Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `convintrlv` function, use the same `nrows` and `slope` inputs in both functions. In that case, the two functions are inverses in the sense that applying `convintrlv` followed by `convdeintrlv` leaves data unchanged, after you take their combined delay of  $nrows * (nrows - 1) * slope$  into account. To learn more about delays of convolutional interleavers, see “Delays of Convolutional Interleavers”.

### Examples

The example in “Effect of Delays on Recovery of Convolutionally Interleaved Data Using MATLAB” uses `convdeintrlv` and illustrates how you can handle the delay of the interleaver/deinterleaver pair when recovering data.

The example on the reference page for `muxdeintrlv` illustrates how to use the `state` output and `init_state` input with that function; the process is analogous for this function.

## convenc

Convolutionally encode binary data

### Syntax

```
code = convenc(msg,trellis)
code = convenc(msg,trellis,puncpat)
code = convenc(msg,trellis,...,init_state)
[code,final_state] = convenc(...)
```

### Description

`code = convenc(msg,trellis)` encodes the binary vector `msg` using the convolutional encoder whose MATLAB trellis structure is `trellis`. For details about MATLAB trellis structures, see “Trellis Description of a Convolutional Code”. Each symbol in `msg` consists of  $\log_2(\text{trellis.numInputSymbols})$  bits. The vector `msg` contains one or more symbols. The output vector `code` contains one or more symbols, each of which consists of  $\log_2(\text{trellis.numOutputSymbols})$  bits.

`code = convenc(msg,trellis,puncpat)` is the same as the syntax above, except that it specifies a puncture pattern, `puncpat`, to allow higher rate encoding. `puncpat` must be a vector of 1s and 0s, where the 0s indicate the punctured bits. `puncpat` must have a length of at least  $\log_2(\text{trellis.numOutputSymbols})$  bits.

`code = convenc(msg,trellis,...,init_state)` allows the encoder registers to start at a state specified by `init_state`. `init_state` is an integer between 0 and `trellis.numStates - 1` and must be the last input parameter.

`[code,final_state] = convenc(...)` encodes the input message and also returns the encoder's state in `final_state`. `final_state` has the same format as `init_state`.

### Examples

### Create Convolutional Codes

Encode five two-bit symbols using a rate 2/3 convolutional code.

```
data = randi([0 1],10,1);  
trellis1 = poly2trellis([5 4],[23 35 0; 0 5 13]);  
code1 = convenc(data,poly2trellis([5 4],[23 35 0; 0 5 13]));
```

Verify that the encoded output is 15 bits, 3/2 times the length of the input sequence, data.

```
length(code1)
```

```
ans = 15
```

Define the encoder's trellis structure explicitly and then use convenc to encode 10 one-bit symbols.

```
trellis2 = struct('numInputSymbols',2,'numOutputSymbols',4,...  
'numStates',4,'nextStates',[0 2;0 2;1 3;1 3],...  
'outputs',[0 3;1 2;3 0;2 1]);  
code2 = convenc(randi([0 1],10,1),trellis2);
```

Use the final and initial state arguments when invoking convenc. Encode part of data , recording final state for later use.

```
[code3,fstate] = convenc(data(1:6),trellis1);
```

Encode the rest of data, using fstate as an input argument.

```
code4 = convenc(data(7:10),trellis1,fstate);
```

Verify that the [code3; code4] matches code1.

```
isequal(code1,[code3; code4])
```

```
ans = logical  
     1
```

## Trellis Structure for 1/2 Feedforward Convolutional Encoder

Create a trellis structure for a rate 1/2 feedforward convolutional code. Use the trellis to encode and decode a random bit stream.

Create a trellis structure. Set the constraint length to 7 and specify the code generator as a cell array of polynomial character vectors.

```
trellis = poly2trellis(7,{'1 + x^3 + x^4 + x^5 + x^6', ...
    '1 + x + x^3 + x^4 + x^6'})

trellis = struct with fields:
    numInputSymbols: 2
    numOutputSymbols: 4
    numStates: 64
    nextStates: [64x2 double]
    outputs: [64x2 double]
```

Generate random binary data, convolutionally encode the data, and decode the data using the Viterbi algorithm.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
decodedData = vitdec(codedData,trellis,34,'trunc','hard');
```

Verify the decoded data has no bit errors.

```
biterr(data,decodedData)

ans = 0
```

## Estimate BER for Hard and Soft Decision Viterbi Decoding

Estimate bit error rate (BER) performance for hard-decision and soft-decision Viterbi decoders in AWGN. Compare the performance to that of an uncoded 64-QAM link.

Set the simulation parameters.

```
clear; close all
rng default
M = 64; % Modulation order
```

```
k = log2(M);           % Bits per symbol
EbNoVec = (4:10)';    % Eb/No values (dB)
numSymPerFrame = 1000; % Number of QAM symbols per frame
```

Initialize the BER results vectors.

```
berEstSoft = zeros(size(EbNoVec));
berEstHard = zeros(size(EbNoVec));
```

Set the trellis structure and traceback length for a rate 1/2, constraint length 7, convolutional code.

```
trellis = poly2trellis(7,[171 133]);
tbl = 32;
rate = 1/2;
```

The main processing loops performs these steps:

- Generate binary data.
- Convolutionally encode the data.
- Apply QAM modulation to the data symbols. Specify unit average power for the transmitted signal.
- Pass the modulated signal through an AWGN channel.
- Demodulate the received signal using hard decision and approximate LLR methods. Specify unit average power for the received signal.
- Viterbi decode the signals using hard and unquantized methods.
- Calculate the number of bit errors.

The while loop continues to process data until either 100 errors are encountered or 1e7 bits are transmitted.

```
for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
    snrdB = EbNoVec(n) + 10*log10(k*rate);
    % Noise variance calculation for unity average signal power.
    noiseVar = 10.^(-snrdB/10);
    % Reset the error and bit counters
    [numErrsSoft,numErrsHard,numBits] = deal(0);

    while numErrsSoft < 100 && numBits < 1e7
        % Generate binary data and convert to symbols
        dataIn = randi([0 1],numSymPerFrame*k,1);
```

```

% Convolutionally encode the data
dataEnc = convenc(dataIn,trellis);

% QAM modulate
txSig = qammod(dataEnc,M,'InputType','bit','UnitAveragePower',true);

% Pass through AWGN channel
rxSig = awgn(txSig,snrdB,'measured');

% Demodulate the noisy signal using hard decision (bit) and
% soft decision (approximate LLR) approaches.
rxDataHard = qamdemod(rxSig,M,'OutputType','bit','UnitAveragePower',true);
rxDataSoft = qamdemod(rxSig,M,'OutputType','approxllr', ...
    'UnitAveragePower',true,'NoiseVariance',noiseVar);

% Viterbi decode the demodulated data
dataHard = vitdec(rxDataHard,trellis,tbl,'cont','hard');
dataSoft = vitdec(rxDataSoft,trellis,tbl,'cont','unquant');

% Calculate the number of bit errors in the frame. Adjust for the
% decoding delay, which is equal to the traceback depth.
numErrsInFrameHard = biterr(dataIn(1:end-tbl),dataHard(tbl+1:end));
numErrsInFrameSoft = biterr(dataIn(1:end-tbl),dataSoft(tbl+1:end));

% Increment the error and bit counters
numErrsHard = numErrsHard + numErrsInFrameHard;
numErrsSoft = numErrsSoft + numErrsInFrameSoft;
numBits = numBits + numSymPerFrame*k;

end

% Estimate the BER for both methods
berEstSoft(n) = numErrsSoft/numBits;
berEstHard(n) = numErrsHard/numBits;
end

```

Plot the estimated hard and soft BER data. Plot the theoretical performance for an uncoded 64-QAM channel.

```

semilogy(EbNoVec,[berEstSoft berEstHard],'-*')
hold on
semilogy(EbNoVec,berawgn(EbNoVec,'qam',M))
legend('Soft','Hard','Uncoded','location','best')
grid

```

```
xlabel('Eb/No (dB)')  
ylabel('Bit Error Rate')
```

As expected, the soft decision decoding produces the best results.

## Examples

For some commonly used puncture patterns for specific rates and polynomials, see the last three references.

## convintrlv

Permute symbols using shift registers

### Syntax

```
intrlv = convintrlv(data,nrows,slope)
[intrlv,state] = convintrlv(data,nrows,slope)
[intrlv,state] = convintrlv(data,nrows,slope,init_state)
```

### Description

`intrlv = convintrlv(data,nrows,slope)` permutes the elements in `data` by using a set of `nrows` internal shift registers. The delay value of the  $k$ th shift register is  $(k-1)*slope$ , where  $k = 1, 2, 3, \dots, nrows$ . Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[intrlv,state] = convintrlv(data,nrows,slope)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[intrlv,state] = convintrlv(data,nrows,slope,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding deinterleaver.

### Examples

The example below shows that `convintrlv` is a special case of the more general function `muxintrlv`. Both functions yield the same numerical results.

```
x = randi([0 1],100,1); % Original data
nrows = 5; % Use 5 shift registers
slope = 3; % Delays are 0, 3, 6, 9, and 12.
```

```
y = convintrlv(x,nrows,slope); % Interleaving using convintrlv.  
delay = [0:3:12]; % Another way to express set of delays  
y1 = muxintrlv(x,delay); % Interleave using muxintrlv.  
isequal(y,y1)
```

The output below shows that `y`, obtained using `convintrlv`, and `y1`, obtained using `muxintrlv`, are the same.

```
ans =
```

```
1
```

Another example using this function is in “Effect of Delays on Recovery of Convolutionally Interleaved Data Using MATLAB”.

The example on the `muxdeintrlv` reference page illustrates how to use the state output and `init_state` input with that function; the process is analogous for this function.

## convmtx

Convolution matrix of Galois field vector

### Syntax

```
A = convmtx(c,n)
```

### Description

A *convolution matrix* is a matrix, formed from a vector, whose inner product with another vector is the convolution of the two vectors.

`A = convmtx(c,n)` returns a convolution matrix for the Galois vector `c`. The output `A` is a Galois array that represents convolution with `c` in the sense that `conv(c,x)` equals

- `A*x`, if `c` is a column vector and `x` is any Galois column vector of length `n`. In this case, `A` has `n` columns and `m+n-1` rows.
- `x*A`, if `c` is a row vector and `x` is any Galois row vector of length `n`. In this case, `A` has `n` rows and `m+n-1` columns.

### Examples

The code below illustrates the equivalence between using the `conv` function and multiplying by the output of `convmtx`.

```
m = 4;  
c = gf([1; 9; 3],m); % Column vector  
n = 6;  
x = gf(randi([0 2^m-1],n,1),m);  
ck1 = isequal(conv(c,x), convmtx(c,n)*x) % True  
ck2 = isequal(conv(c',x'),x'*convmtx(c',n)) % True
```

The output is

```
ck1 =
```

1

ck2 =

1

## cosets

Produce cyclotomic cosets for Galois field

## Syntax

```
cst = cosets(m)
```

## Description

`cst = cosets(m)` produces cyclotomic cosets mod  $2^m - 1$ . Each element of the cell array `cst` is a Galois array that represents one cyclotomic coset.

A cyclotomic coset is a set of elements that share the same minimal polynomial. Together, the cyclotomic cosets mod  $2^m - 1$  form a partition of the group of nonzero elements of  $GF(2^m)$ . For more details on cyclotomic cosets, see the works listed in “References” on page 2-389.

## Examples

The commands below find and display the cyclotomic cosets for  $GF(8)$ . As an example of interpreting the results, `c{2}` indicates that  $A$ ,  $A^2$ , and  $A^2 + A$  share the same minimal polynomial, where  $A$  is a primitive element for  $GF(8)$ .

```
c = cosets(3);  
c{1}'  
c{2}'  
c{3}'
```

The output is below.

```
ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =
```

```
1
```

ans = GF(2<sup>3</sup>) array. Primitive polynomial = D<sup>3</sup>+D+1 (11 decimal)

## **crc.detector**

Construct CRC detector object

### **Syntax**

```
h= crc.detector(polynomial)
```

```
h= crc.detector(generatorObj)
```

```
h= crc.detector('Polynomial', polynomial, 'param1', val1, etc.)
```

```
h= crc.detector
```

### **Description**

`h= crc.detector(polynomial)` constructs a CRC detector object H defined by the generator polynomial POLYNOMIAL

`h= crc.detector(generatorObj)` constructs a CRC detector object H defined by the parameters found in the CRC generator object GENERATOROBJ

`h= crc.detector('property1', val1, ...)` constructs a CRC detector object H with properties as specified by PROPERTY/VALUE pairs.

`h= crc.detector` constructs a CRC detector object H with default properties. It constructs a CRC-CCITT detector, and is equivalent to:

```
h=
crc.detector('Polynomial','0x1021','InitialState','0xFFFF','ReflectI
nput',false,'ReflectRemainder',false,'FinalXOR','0x0000')
```

### **Properties**

The following table describes the properties of a CRC detector object. All properties are writable, except Type.

Property	Description
Type	Specifies the object as a 'CRC Detector'.
Polynomial	The generator polynomial that defines connections for a linear feedback shift register. This property can be specified as a binary vector representing descending powers of the polynomial. In this case, the leading '1' of the polynomial must be included. It can also be specified as a string, prefaced by '0x', that is a hexadecimal representation of the descending powers of the polynomial. In this case, the leading '1' of the polynomial is omitted.
InitialState	The initial contents of the shift register. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.
ReflectInput	A Boolean quantity that specifies whether the input data should be flipped on a bitwise basis prior to entering the shift register.
ReflectRemainder	A Boolean quantity that specifies whether the binary output CRC checksum should be flipped around its center after the input data is completely through the shift register.

Property	Description
FinalXOR	The value with which the CRC checksum is to be XORed just prior to detecting the input data. This property can be specified as a binary scalar, a binary vector or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.

A detect method is used with the object to detect errors in digital transmission.

## CRC Generation Algorithm

For information pertaining to the CRC generation algorithm, see “Cyclic Redundancy Check Codes”.

## Detector Method

[OUTDATA ERROR] = DETECT(H, INDATA) detects transmission errors in the encoded input message INDATA by regenerating a CRC checksum using the CRC detector object H. The detector then compares the regenerated checksum with the checksum appended to INDATA. The binary-valued INDATA can be either a column vector or a matrix. If it is a matrix, each column is considered to be a separate channel. OUTDATA is identical to the input message INDATA, except that it has the CRC checksum stripped off. ERROR is a 1xC logical vector indicating if the encoded message INDATA has errors, where C is the number of channels in INDATA. An ERROR value of 0 indicates no errors, and a value of 1 indicates errors.

## Examples

The following three examples demonstrate the use of constructing an object. The fourth example demonstrates use of the detect method.

```
% Construct a CRC detector with a polynomial
% defined by x^4+x^3+x^2+x+1:
h = crc.detector([1 1 1 1 1])
```

This example generates the following output:

h =

```

        Type: CRC Detector
      Polynomial: 0xF
    InitialState: 0x0
      ReflectInput: false
    ReflectRemainder: false
        FinalXOR: 0x0

```

```

% Construct a CRC detector with a polynomial
% defined by  $x^3+x+1$ , with
% zero initial states, and with an all-ones
% final XOR value:
h = crc.detector('Polynomial', [1 0 1 1], ...
'InitialState', [0 0 0], 'FinalXOR', [1 1 1])

```

This example generates the following output:

h =

```

        Type: CRC Detector
      Polynomial: [1 0 1 1]
    InitialState: [0 0 0]
      ReflectInput: false
    ReflectRemainder: false
        FinalXOR: [1 1 1]

```

```

% Construct a CRC detector with a polynomial
% defined by  $x^4+x^3+x^2+x+1$ ,
% all-ones initial states, reflected input, and all-zeros
% final XOR value:
h = crc.detector('Polynomial', '0xF', 'InitialState', ...
'0xF', 'ReflectInput', true, 'FinalXOR', '0x0')

```

This example generates the following output:

h =

```

        Type: CRC Detector
      Polynomial: 0xF
    InitialState: 0xF
      ReflectInput: true
    ReflectRemainder: false
        FinalXOR: 0x0

```

```
% Create a CRC-16 CRC generator, then use it to generate
% a checksum for the
% binary vector represented by the
% ASCII sequence '123456789'.
% Introduce an error, then detect it
% using a CRC-16 CRC detector.
gen = crc.generator('Polynomial', '0x8005', 'ReflectInput', ...
true, 'ReflectRemainder', true);
det = crc.detector('Polynomial', '0x8005', 'ReflectInput', ...
true, 'ReflectRemainder', true);
% The message below is an ASCII representation
% of the digits 1-9
msg = reshape(de2bi(49:57, 8, 'left-msb'), 72, 1);
encoded = generate(gen, msg);
encoded(1) = ~encoded(1);           % Introduce an error
[outdata error] = detect(det, encoded); % Detect the error
noErrors = isequal(msg, outdata)   % Should be 0
error                                     % Should be 1
```

This example generates the following output:

```
noErrors =
```

```
0
```

```
error =
```

```
1
```

## **crc.generator**

Construct CRC generator object

### **Syntax**

```
h = crc.generator(polynomial)
```

```
h = crc.generator(detectorObj)
```

```
h = crc.generator('Polynomial', polynomial, 'param1', val1, etc.)
```

```
h = crc.generator
```

### **Description**

`h = crc.generator(polynomial)` constructs a CRC generator object *H* defined by the generator polynomial *POLYNOMIAL*.

`h = crc.generator(detectorObj)` constructs a CRC generator object *H* defined by the parameters found in the CRC detector object *DETECTOROBJ*.

`h = crc.generator('property1', val1, ...)` constructs a CRC generator object *H* with properties as specified by the *PROPERTY/VALUE* pairs.

`h = crc.generator` constructs a CRC generator object *H* with default properties. It constructs a CRC-CCITT generator, and is equivalent to: `h = crc.generator('Polynomial', '0x1021', 'InitialState', '0xFFFF', ...`

`'ReflectInput', false, 'ReflectRemainder', false, 'FinalXOR', '0x0000')`.

### **Properties**

The following table describes the properties of a CRC generator object. All properties are writable, except *Polynomial*.

<b>Property</b>	<b>Description</b>
Polynomial	The generator polynomial that defines connections for a linear feedback shift register. This property can be specified as a binary vector representing descending powers of the polynomial. In this case, the leading '1' of the polynomial must be included. It can also be specified as a string, prefaced by '0x', that is a hexadecimal representation of the descending powers of the polynomial. In this case, the leading '1' of the polynomial is omitted.
InitialState	The initial contents of the shift register. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.
ReflectInput	A Boolean quantity that specifies whether the input data should be flipped on a bitwise basis prior to entering the shift register.
ReflectRemainder	A Boolean quantity that specifies whether the binary output CRC checksum should be flipped around its center after the input data is completely through the shift register.

Property	Description
FinalXOR	The value with which the CRC checksum is to be XORed just prior to being appended to the input data. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.

## CRC Generation Algorithm

For information pertaining to the CRC generation algorithm, refer to the “CRC Non-Direct Algorithm” section of the Communications Toolbox User's Guide.

## Generator Method

encoded = generate(h, msg) generates a CRC checksum for an input message using the CRC generator object H. It appends the checksum to the end of MSG. The binary-valued MSG can be either a column vector or a matrix. If it is a matrix, then each column is considered to be a separate channel.

## Usage Example

The following examples demonstrate the use of this object.

```
% Construct a CRC generator with a polynomial defined
% by x^4+x^3+x^2+x+1:
h = crc.generator([1 1 1 1 1])

% Construct a CRC generator with a polynomial defined
% by x^4+x^3+x^2+x+1, all-ones initial states, reflected
% input, and all-zeros final XOR value:
h = crc.generator('Polynomial', '0xF', 'InitialState', ...
'0xF', 'ReflectInput', true, 'FinalXOR', '0x0')

% Create a CRC-16 CRC generator, then use it to generate
% a checksum for the
% binary vector represented by the ASCII sequence '123456789'.
```

```
gen = crc.generator('Polynomial', '0x8005', ...
    'ReflectInput', true, 'ReflectRemainder', true);
% The message below is an ASCII representation of ...
% the digits 1-9
msg = reshape(de2bi(49:57, 8, 'left-msb'), 72, 1);
encoded = generate(gen, msg);

% Construct a CRC generator with a polynomial defined
% by  $x^3+x+1$ , with zero initial states,
% and with an all-ones final XOR value:
h = crc.generator('Polynomial', [1 0 1 1], ...
    'InitialState', [0 0 0], ...
    'FinalXOR', [1 1 1])
```

### Introduced in R2008a

## cyclgen

Produce parity-check and generator matrices for cyclic code

### Syntax

```
h = cyclgen(n, pol)
h = cyclgen(n, pol, opt)
[h, g] = cyclgen(...)
[h, g, k] = cyclgen(...)
```

### Description

For all syntaxes, the codeword length is  $n$  and the message length is  $k$ . A polynomial can generate a cyclic code with codeword length  $n$  and message length  $k$  if and only if the polynomial is a degree- $(n-k)$  divisor of  $x^n-1$ . (Over the binary field  $GF(2)$ ,  $x^n-1$  is the same as  $x^{n+1}$ .) This implies that  $k$  equals  $n$  minus the degree of the generator polynomial.

`h = cyclgen(n, pol)` produces an  $(n-k)$ -by- $n$  parity-check matrix for a systematic binary cyclic code having codeword length  $n$ . The row vector `pol` gives the binary coefficients, in order of ascending powers, of the degree- $(n-k)$  generator polynomial. Alternatively, you can specify `pol` as a polynomial character vector. For more information, see “Character Representation of Polynomials”.

`h = cyclgen(n, pol, opt)` is the same as the syntax above, except that the argument `opt` determines whether the matrix should be associated with a systematic or nonsystematic code. The values for `opt` are 'system' and 'nonsys'.

`[h, g] = cyclgen(...)` is the same as `h = cyclgen(...)`, except that it also produces the  $k$ -by- $n$  generator matrix `g` that corresponds to the parity-check matrix `h`.

`[h, g, k] = cyclgen(...)` is the same as `[h, g] = cyclgen(...)`, except that it also returns the message length `k`.

## Examples

### Parity Check and Generator Matrices for Binary Cyclic Codes

Create parity check and generator matrices for a binary cyclic code having codeword length 7 and message length 4.

Create the generator polynomial using `cyclpoly`.

```
pol = cyclpoly(7,4);
```

Create the parity check and generator matrices. The parity check matrix `parmat` has a 3-by-3 identity matrix embedded in its leftmost columns.

```
[parmat,genmat,k] = cyclgen(7,pol)
```

```
parmat = 3×7
```

1	0	0	1	1	1	0
0	1	0	0	1	1	1
0	0	1	1	1	0	1

```
genmat = 4×7
```

1	0	1	1	0	0	0
1	1	1	0	1	0	0
1	1	0	0	0	1	0
0	1	1	0	0	0	1

```
k = 4
```

Create a parity check matrix in which the code is not systematic. The matrix `parmatn` does not have an embedded 3-by-3 identity matrix.

```
parmatn = cyclgen(7,pol,'nonsys')
```

```
parmatn = 3×7
```

1	1	1	0	1	0	0
0	1	1	1	0	1	0
0	0	1	1	1	0	1

Create the parity check and generator matrices for a (7,3) binary cyclic code. As this is a systematic code, there is a 4-by-4 identity matrix in the leftmost columns of `parmat2`.

```
parmat2 = cyclgen(7, '1 + x^2 + x^3 + x^4')
```

```
parmat2 = 4×7
```

```
 1  0  0  0  1  1  0
 0  1  0  0  0  1  1
 0  0  1  0  1  1  1
 0  0  0  1  1  0  1
```

# cyclopoly

Produce generator polynomials for cyclic code

## Syntax

```
pol = cyclopoly(n,k)
pol = cyclopoly(n,k,opt)
```

## Description

For all syntaxes, a polynomial is represented as a row containing the coefficients in order of ascending powers.

`pol = cyclopoly(n,k)` returns the row vector representing one nontrivial generator polynomial for a cyclic code having codeword length  $n$  and message length  $k$ .

`pol = cyclopoly(n,k,opt)` searches for one or more nontrivial generator polynomials for cyclic codes having codeword length  $n$  and message length  $k$ . The output `pol` depends on the argument `opt` as shown in the table below.

<b>opt</b>	<b>Significance of pol</b>	<b>Format of pol</b>
'min'	One generator polynomial having the smallest possible weight	Row vector representing the polynomial
'max'	One generator polynomial having the greatest possible weight	Row vector representing the polynomial
'all'	All generator polynomials	Matrix, each row of which represents one such polynomial
a positive integer, $L$	All generator polynomials having weight $L$	Matrix, each row of which represents one such polynomial

The weight of a binary polynomial is the number of nonzero terms it has. If no generator polynomial satisfies the given conditions, the output `pol` is empty and a warning message is displayed.

## Examples

### Cyclic Code Generator Polynomials

Create [15,4] cyclic code generator polynomials.

Use the input `'all'` to show all possible generator polynomials for a [15,4] cyclic code.

Use the input `'max'` to show that  $1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + x^{11}$  is one such polynomial that has the largest number of nonzero terms.

```
c1 = cyclpoly(15,4,'all')
```

```
c1 = 3×12
```

```
  1   1   0   0   0   1   1   0   0   0   1   1
  1   0   0   1   1   0   1   0   1   1   1   1
  1   1   1   1   0   1   0   1   1   0   0   1
```

```
c2 = cyclpoly(15,4,'max')
```

```
c2 = 1×12
```

```
  1   1   1   1   0   1   0   1   1   0   0   1
```

This command shows that no generator polynomial for a [15,4] cyclic code has exactly three nonzero terms.

```
c3 = cyclpoly(15,4,3)
```

```
Warning: No cyclic generator polynomial satisfies the given constraints.
```

```
c3 =
```

```
 []
```

## Algorithms

If *opt* is 'min', 'max', or omitted, polynomials are constructed by converting decimal integers to base  $p$ . Based on the decimal ordering, `gfprimfd` returns the first polynomial it finds that satisfies the appropriate conditions. This algorithm is similar to the one used in `gfprimfd`.

## Topics

"Block Codes"

**Introduced before R2006a**

## de2bi

Convert decimal numbers to binary vectors

### Syntax

```
b = de2bi(d)
b = de2bi(d,n)
b = de2bi(d,n,p)
b = de2bi(d,[],p)
b = de2bi(d,...,flg)
```

### Description

`b = de2bi(d)` converts a nonnegative decimal integer `d` to a binary row vector. If `d` is a vector, the output `b` is a matrix in which each row is the binary form of the corresponding element in `d`.

`b = de2bi(d,n)` has an output with `n` columns.

`b = de2bi(d,n,p)` converts a nonnegative decimal integer `d` to a base-`p` row vector.

`b = de2bi(d,[],p)` specifies the base, `p`.

`b = de2bi(d,...,flg)` uses `flg` to determine whether the first column of `b` contains the lowest-order or highest-order digits.

### Input Arguments

#### **d** — Decimal input

scalar | vector | matrix

Decimal input which can be a scalar, vector, or matrix. Specify elements as nonnegative integers. If `d` is a matrix, it is treated like the column vector `d(:)`.

Example: 4

Example: [10; 5]

---

**Note** To ensure an accurate conversion, *d* must be less than or equal to  $2^{52}$ .

---

### **n — Number of output columns**

positive integer scalar

The number of output columns specified as a positive scalar. If necessary, the binary representation of *d* is padded with extra zeros.

Example: 3

### **p — Base**

positive integer scalar

An integer that specifies the base of the output *b*. Specify as an integer greater than or equal to 2. The first column of *b* is the lowest base-*p* digit. The output is padded with extra zeros if necessary so that it has *n* columns. If *d* is a nonnegative decimal vector, the output *b* is a matrix in which each row is the base-*p* form of the corresponding element in *d*. If *d* is a matrix, *de2bi* treats it like the vector *d*(:).

Example: 8

### **flag — MSB flag**

'right-msb' | 'left-msb'

Character vector that determines whether the first column of *b* contains the lowest-order or highest-order digits. If omitted, *de2bi* assumes 'right-msb'.

## **Output Arguments**

### **b — Binary output**

vector | matrix

Binary representation of *d* in the form of a row vector or matrix.

## **Examples**

**Convert Decimals to Binary Numbers**

Convert decimals 1 through 10 into their equivalent binary representations.

```
d = (1:10)';  
b = de2bi(d);  
[d b]
```

```
ans = 10×5
```

```
 1  1  0  0  0  
 2  0  1  0  0  
 3  1  1  0  0  
 4  0  0  1  0  
 5  1  0  1  0  
 6  0  1  1  0  
 7  1  1  1  0  
 8  0  0  0  1  
 9  1  0  0  1  
10  0  1  0  1
```

Convert 3 and 9 into binary numbers. Each value is represented by a four-element row.

```
b = de2bi([3 9])
```

```
b = 2×4
```

```
 1  1  0  0  
 1  0  0  1
```

Repeat the conversion with the number of columns set to 5. The output is now padded with zeros in the fifth column.

```
bb = de2bi([3 9],5)
```

```
bb = 2×5
```

```
 1  1  0  0  0  
 1  0  0  1  0
```

Convert the decimals 1 through 6 to their base 3 equivalents. Set the leftmost bit as the most significant digit.

```
d = (1:6)';  
t = de2bi(d,[],3,'left-msb');  
[d t]
```

```
ans = 6x3
```

```
 1     0     1  
 2     0     2  
 3     1     0  
 4     1     1  
 5     1     2  
 6     2     0
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

### See Also

bi2de

## decode

Block decoder

### Syntax

```
msg = decode(code,n,k,'hamming/fmt',prim_poly)
msg = decode(code,n,k,'linear/fmt',genmat,trt)
msg = decode(code,n,k,'cyclic/fmt',genpoly,trt)
msg = decode(code,n,k)
[msg,err] = decode(...)
[msg,err,ccode] = decode(...)
[msg,err,ccode,cerr] = decode(...)
```

### Optional Inputs

Input	Default Value
<i>fmt</i>	binary
prim_poly	gfprimdf(m) where $n = 2^m - 1$
genpoly	cyclpoly(n,k)
trt	Uses syndtable to create the syndrome decoding table associated with the method's parity-check matrix

### Description

#### For All Syntaxes

The decode function aims to recover messages that were encoded using an error-correction coding technique. The technique and the defining parameters must match those that were used to encode the original signal.

The “For All Syntaxes” on page 2-507 section on the `encode` reference page explains the meanings of  $n$  and  $k$ , the possible values of *fmt*, and the possible formats for *code* and *msg*. You should be familiar with the conventions described there before reading the rest of this section. Using the `decode` function with an input argument *code* that was *not* created by the `encode` function might cause errors.

## For Specific Syntaxes

`msg = decode(code,n,k,'hamming/fmt',prim_poly)` decodes *code* using the Hamming method. For this syntax,  $n$  must have the form  $2^m-1$  for some integer  $m$  greater than or equal to 3, and  $k$  must equal  $n-m$ . *prim\_poly* is a polynomial character vector or a row vector that gives the binary coefficients, in order of ascending powers, of the primitive polynomial for  $GF(2^m)$  that is used in the encoding process. The default value of *prim\_poly* is `gfprimdf(m)`. The decoding table that the function uses to correct a single error in each codeword is `syndtable(hamngen(m))`.

`msg = decode(code,n,k,'linear/fmt',genmat,trt)` decodes *code*, which is a linear block code determined by the  $k$ -by- $n$  generator matrix *genmat*. *genmat* is required as input. `decode` tries to correct errors using the decoding table *trt*, where *trt* is a  $2^{(n-k)}$ -by- $n$  matrix.

`msg = decode(code,n,k,'cyclic/fmt',genpoly,trt)` decodes the cyclic code *code* and tries to correct errors using the decoding table *trt*, where *trt* is a  $2^{(n-k)}$ -by- $n$  matrix. *genpoly* is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of the binary generator polynomial of the code. The default value of *genpoly* is `cyclpoly(n,k)`. By definition, the generator polynomial for an  $[n, k]$  cyclic code must have degree  $n-k$  and must divide  $x^n-1$ .

`msg = decode(code,n,k)` is the same as `msg = decode(code,n,k,'hamming/binary')`.

`[msg,err] = decode(...)` returns a column vector *err* that gives information about error correction. If the code is a convolutional code, *err* contains the metric calculations used in the decoding decision process. For other types of codes, a nonnegative integer in the *r*th row of *err* indicates the number of errors corrected in the *r*th *message* word; a negative integer indicates that there are more errors in the *r*th word than can be corrected.

`[msg,err,ccode] = decode(...)` returns the corrected code in *ccode*.

`[msg,err,ccode,cerr] = decode(...)` returns a column vector `cerr` whose meaning depends on the format of `code`:

- If `code` is a binary vector, a nonnegative integer in the  $r$ th row of `vec2matcerr` indicates the number of errors corrected in the  $r$ th *codeword*; a negative integer indicates that there are more errors in the  $r$ th codeword than can be corrected.
- If `code` is not a binary vector, `cerr = err`.

## Examples

### Encoding and Decoding with Linear Block Codes

Encode and decode corrupted data using three types of linear block codes.

#### Hamming Code

Set the code parameters.

```
n = 15;           % Code length
k = 11;           % Message length
```

Create a binary message having length  $k$ .

```
data = randi([0 1],k,1);
```

Encode the message.

```
encData = encode(data,n,k,'hamming/binary');
```

Introduce an error in the 4th bit of the encoded sequence.

```
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'hamming/binary');
```

```
numerr = biterr(data,decData)
```

```
numerr = 0
```

## Linear Block Code

Set the code parameters.

```
n = 7;           % Code length
k = 3;           % Message length
```

Create a binary message having length k.

```
data = randi([0 1],k,1);
```

Create a cyclic generator polynomial. Then, create a parity-check matrix and convert it into a generator matrix.

```
pol = cyclpoly(n,k);
parmat = cyclgen(n,pol);
genmat = gen2par(parmat);
```

Encode the message sequence by using the generator matrix.

```
encData = encode(data,n,k,'linear/binary',genmat);
```

Introduce an error in the 3rd bit of the encoded sequence.

```
encData(3) = ~encData(3);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'linear/binary',genmat);
```

```
Single-error patterns loaded in decoding table. 8 rows remaining.
2-error patterns loaded. 1 rows remaining.
3-error patterns loaded. 0 rows remaining.
```

```
numerr = biterr(data,decData)
```

```
numerr = 0
```

## Cyclic Code

Set the code parameters.

```
n = 15;           % Code length
k = 5;           % Message length
```

Create a binary message having length  $k$ .

```
data = randi([0 1],k,1);
```

Create a generator polynomial for a cyclic code. Create a parity-check matrix by using the generator polynomial.

```
gpoly = cyclpoly(n,k);  
parmat = cyclgen(n,gpoly);
```

Create a syndrome decoding table by using the parity-check matrix.

```
trt = syndtable(parmat);
```

```
Single-error patterns loaded in decoding table. 1008 rows remaining.  
2-error patterns loaded. 918 rows remaining.  
3-error patterns loaded. 648 rows remaining.  
4-error patterns loaded. 243 rows remaining.  
5-error patterns loaded. 0 rows remaining.
```

Encode the data by using the generator polynomial.

```
encData = encode(data,n,k,'cyclic/binary',gpoly);
```

Introduce errors in the 4th and 7th bits of the encoded sequence.

```
encData(4) = ~encData(4);  
encData(7) = ~encData(7);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'cyclic/binary',gpoly,trt);
```

```
numerr = biterr(data,decData)
```

```
numerr = 0
```

## Algorithms

Depending on the decoding method, `decode` relies on such lower-level functions as `hammgen`, `syndtable`, and `cyclgen`.

## deintrlv

Restore ordering of symbols

### Syntax

```
deintrlvd = deintrlv(data,elements)
```

### Description

`deintrlvd = deintrlv(data,elements)` restores the original ordering of the elements of `data` by acting as an inverse of `intrlv`. If `data` is a length-`N` vector or an `N`-row matrix, `elements` is a length-`N` vector that permutes the integers from 1 to `N`. To use this function as an inverse of the `intrlv` function, use the same `elements` input in both functions. In that case, the two functions are inverses in the sense that applying `intrlv` followed by `deintrlv` leaves `data` unchanged.

### Examples

The code below illustrates the inverse relationship between `intrlv` and `deintrlv`.

```
p = randperm(10); % Permutation vector
a = intrlv(10:10:100,p); % Rearrange [10 20 30 ... 100].
b = deintrlv(a,p) % Deinterleave a to restore ordering.
```

The output is

```
b =
    10    20    30    40    50    60    70    80    90   100
```

# dfc

(To be removed) Construct decision-feedback equalizer object

---

**Note** will be removed in a future release. Use `comm.DecisionFeedback` instead.

---

## Syntax

```
eqobj = dfe(nfwdweights,nfbkweights,alg)
eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst)
eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst,nsamp)
```

## Description

The `dfc` function creates an equalizer object that you can use with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`eqobj = dfe(nfwdweights,nfbkweights,alg)` constructs a decision feedback equalizer object. The equalizer's feedforward and feedback filters have `nfwdweights` and `nfbkweights` symbol-spaced complex weights, respectively, which are initially all zeros. `alg` describes the adaptive algorithm that the equalizer uses; you should create `alg` using any of these functions: `lms`, `signlms`, `normlms`, `varlms`, `rls`, or `cma`. The signal constellation of the desired output is `[-1 1]`, which corresponds to binary phase shift keying (BPSK).

`eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst)` specifies the signal constellation vector of the desired output.

`eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst,nsamp)` constructs a DFE with a fractionally spaced forward filter. The forward filter has `nfwdweights` complex weights spaced at  $T/nsamp$ , where  $T$  is the symbol period and `nsamp` is a positive integer. `nsamp = 1` corresponds to a symbol-spaced forward filter.

## Properties

The table below describes the properties of the decision feedback equalizer object. To learn how to view or change the values of a decision feedback equalizer object, see “Equalization”.

---

**Note** To initialize or reset the equalizer object `eqobj`, enter `reset(eqobj)`.

---

Property	Description
<code>EqType</code>	Fixed value, 'Decision Feedback Equalizer'
<code>AlgType</code>	Name of the adaptive algorithm represented by <code>alg</code>
<code>nWeights</code>	Number of weights in the forward filter and the feedback filter, in the format <code>[nfdweights, nfbkweights]</code> . The number of weights in the forward filter must be at least 1.
<code>nSampPerSym</code>	Number of input samples per symbol (equivalent to <code>nsamp</code> input argument). This value relates to both the equalizer structure (see the use of <code>K</code> in “Equalization”) and an assumption about the signal to be equalized.
<code>RefTap</code> (except for CMA equalizers)	Reference tap index, between 1 and <code>nfdweights</code> . Setting this to a value greater than 1 effectively delays the reference signal with respect to the equalizer's input signal.
<code>SigConst</code>	Signal constellation, a vector whose length is typically a power of 2.
<code>Weights</code>	Vector that concatenates the complex coefficients from the forward filter and the feedback filter. This is the set of $w_i$ values in the schematic in “Equalization”.

Property	Description
WeightInputs	Vector that concatenates the tap weight inputs for the forward filter and the feedback filter. This is the set of $u_i$ values in the schematic in “Equalization”.
ResetBeforeFiltering	If 1, each call to <code>equalize</code> resets the state of <code>eqobj</code> before equalizing. If 0, the equalization process maintains continuity from one call to the next.
NumSamplesProcessed	Number of samples the equalizer processed since the last reset. When you create or reset <code>eqobj</code> , this property value is 0.
Properties specific to the adaptive algorithm represented by <code>alg</code>	See reference page for the adaptive algorithm function that created <code>alg</code> : <code>lms</code> , <code>signlms</code> , <code>normlms</code> , <code>varlms</code> , <code>rls</code> , or <code>cma</code> .

## Relationships Among Properties

If you change `nWeights`, MATLAB maintains consistency in the equalizer object by adjusting the values of the properties listed below.

Property	Adjusted Value
Weights	<code>zeros(1, sum(nWeights))</code>
WeightInputs	<code>zeros(1, sum(nWeights))</code>
StepSize (Variable-step-size LMS equalizers)	<code>InitStep*ones(1, sum(nWeights))</code>
InvCorrMatrix (RLS equalizers)	<code>InvCorrInit*eye(sum(nWeights))</code>

## Examples

### Decision Feedback Equalization with LMS Adaptation

Equalize a signal using a decision feedback equalizer with least mean square (LMS) adaptation.

## Set Up Transmitter

Create a QPSK modulated transmission signal containing random message data. Pass the signal through an arbitrary channel filter to add signal distortion.

```
M = 4; % Alphabet size for modulation
msg = randi([0 M-1],2500,1); % Random message
hMod = comm.QPSKModulator('PhaseOffset',0);
modmsg = hMod(msg); % Modulate using QPSK
chan = [.986; .845; .237; .123+.31i]; % Channel coefficients
filtmsg = filter(chan,1,modmsg); % Introduce channel distortion
```

## Set Up Equalizer

Create a DFE object that has 5 forward taps, 3 feedback taps. Specify the least mean square algorithm inline when creating the equalizer object. Initialize additional equalizer properties.

```
dfeObj = dfe(5,3,lms(0.01));
% Set the signal constellation
dfeObj.SigConst = hMod((0:M-1)');
% Maintain continuity between calls to equalize
dfeObj.ResetBeforeFiltering = 0;
% Define initial coefficients to help convergence
dfeObj.Weights = [0 1 0 0 0 0 0 0];
```

## Equalize Received Signal

```
eqRxSig = equalize(dfeObj,filtmsg);
```

## Plot Results

Compare the first 200 equalized symbols (*initial*) to the remaining equalized signal (*final*).

```
initial = eqRxSig(1:200);
plot(real(initial),imag(initial),'+')
hold on
final = eqRxSig(end-200:end);
plot(real(final),imag(final),'ro')
legend('initial', 'final')
```

Equalization of the received signal converges within approximately 200 samples.

### Apply a Decision Feedback Equalizer (DFE) to An 8-PSK Modulated Signal

Apply a decision feedback equalizer (DFE) to an 8-PSK modulated signal impaired by a frequency selective channel. The DFE uses 600 training symbols.

Create a PSK modulator System object™ and set the modulation order to 8.

```
modulator = comm.PSKModulator('ModulationOrder',8);
```

Create a column vector of 8-ary random integer symbols. Seed the random number generator, rng, to produce a predictable sequence of numbers.

```
rng(12345);
data = randi([0 7],5000,1);
```

Use the modulator System object to modulate the random data.

```
modData = modulator(data);
```

Create a Rayleigh channel System object to define a static frequency selective channel with four taps. Pass the modulated data through the channel object.

```
chan = comm.RayleighChannel('SampleRate',1000, ...
    'PathDelays',[0 0.002 0.004 0.008],'AveragePathGains',[0 -3 -6 -9]);
rxSig = chan(modData);
```

Create a DFE equalizer that has 10 feed forward taps and five feedback taps. The equalizer uses the LMS update method with a step size of 0.01.

```
numFFTaps = 10;
numFBTaps = 5;
equalizerDFE = dfe(numFFTaps,numFBTaps,lms(0.01));
```

Set the SigConst property of the DFE equalizer to match the 8-PSK modulator reference constellation. The reference constellation is determined by using the constellation method. For decision directed operation, the DFE must use the same signal constellation as the transmission scheme.

```
equalizerDFE.SigConst = constellation(modulator).';
```

Equalize the signal to remove the effects of channel distortion. Use the first 600 symbols to train the equalizer.

```
trainlen = 600;
[eqSig,detectedSig] = equalize(equalizerDFE,rxSig, ...
    modData(1:trainlen));
```

Plot the received signal, equalizer output after training, and the ideal signal constellation.

```
hScatter = scatterplot(rxSig,1,trainlen,'bx');
hold on
scatterplot(eqSig,1,trainlen,'g.',hScatter);
scatterplot(equalizerDFE.SigConst,1,0,'m*',hScatter);
legend('Received signal','Equalized signal',...
    'Ideal signal constellation');
hold off
```

Create a PSK demodulator System object. Use the object to demodulate the received signal before and after equalization.

```
demod = comm.PSKDemodulator('ModulationOrder',8);  
demodSig = demod(rxSig);  
demodEqualizedSig = demod(detectedSig);
```

Compute the error rates for the two demodulated signals and compare the results.

```
errorCalc = comm.ErrorRate;  
nonEqualizedSER = errorCalc(data(trainlen+1:end), ...  
    demodSig(trainlen+1:end));  
reset(errorCalc)  
equalizedSER = errorCalc(data(trainlen+1:end), ...  
    demodEqualizedSig(trainlen+1:end));  
disp('Symbol error rates with and without equalizer:')  
disp([equalizedSER(1) nonEqualizedSER(1)])
```

The equalizer helps eliminate the distortion introduced by the frequency selective channel and reduces the error rate.

## Compatibility Considerations

### **dfc will be removed**

*Not recommended starting in R2019a*

dfc will be removed in a future release. Use `comm.DecisionFeedback` instead.

## dftmtx

Discrete Fourier transform matrix in Galois field

### Syntax

```
dm = dftmtx(alph)
```

### Description

`dm = dftmtx(alph)` returns a Galois array that represents the discrete Fourier transform operation on a Galois vector, with respect to the Galois scalar `alph`. The element `alph` is a primitive  $n$ th root of unity in the Galois field  $GF(2^m) = GF(n+1)$ ; that is,  $n$  must be the smallest positive value of  $k$  for which  $\text{alph}^k$  equals 1. The discrete Fourier transform has size  $n$  and `dm` is an  $n$ -by- $n$  array. The array `dm` represents the transform in the sense that `dm` times any length- $n$  Galois column vector yields the transform of that vector.

---

**Note** The inverse discrete Fourier transform matrix is `dftmtx(1/alph)`.

---

### Examples

The example below illustrates the discrete Fourier transform and its inverse, with respect to the element `gf(3,4)`. The example examines the first  $n$  powers of that element to make sure that only the  $n$ th power equals one. Afterward, the example transforms a random Galois vector, undoes the transform, and checks the result.

```
m = 4;
n = 2^m-1;
a = 3;
alph = gf(a,m);
mp = minpol(alph);
if (mp(1)==1 && isprimitive(mp)) % Check that alph has order n.
    disp('alph is a primitive nth root of unity.')
    dm = dftmtx(alph);
```

```
idm = dftmtx(1/alph);  
x = gf(randi([0 2^m-1],n,1),m);  
y = dm*x; % Transform x.  
z = idm*y; % Recover x.  
ck = isequal(x,z)  
end
```

The output is

alph is a primitive nth root of unity.

ck =

1

## Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, alph must be a primitive nth root of unity in the Galois field  $GF(2^m)$ , where m is an integer between 1 and 8.

## Algorithms

The element  $dm(a,b)$  equals  $\text{alph}^{((a-1)*(b-1))}$ .

## distspec

Compute distance spectrum of convolutional code

### Syntax

```
spect = distspec(trellis,n)
spect = distspec(trellis)
```

### Description

`spect = distspec(trellis,n)` computes the free distance and the first `n` components of the weight and distance spectra of a linear convolutional code. Because convolutional codes do not have block boundaries, the weight spectrum and distance spectrum are semi-infinite and are most often approximated by the first few components. The input `trellis` is a valid MATLAB trellis structure, as described in “Trellis Description of a Convolutional Code”. The output, `spect`, is a structure with these fields:

Field	Meaning
<code>spect.dfree</code>	Free distance of the code. This is the minimum number of errors in the encoded sequence required to create an error event.
<code>spect.weight</code>	A length- <code>n</code> vector that lists the total number of information bit errors in the error events enumerated in <code>spect.event</code> .
<code>spect.event</code>	A length- <code>n</code> vector that lists the number of error events for each distance between <code>spect.dfree</code> and <code>spect.dfree+n-1</code> . The vector represents the first <code>n</code> components of the distance spectrum.

`spect = distspec(trellis)` is the same as `spect = distspec(trellis,1)`.

## Examples

The example below performs these tasks:

- Computes the distance spectrum for the rate 2/3 convolutional code that is depicted on the reference page for the `poly2trellis` function
- Uses the output of `distspec` as an input to the `bercoding` function, to find a theoretical upper bound on the bit error rate for a system that uses this code with coherent BPSK modulation
- Plots the upper bound using the `berfit` function

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
spect = distspec(trellis,4)
berub = bercoding(1:10,'conv','hard',2/3,spect); % BER bound
berfit(1:10,berub); ylabel('Upper Bound on BER'); % Plot.
```

The output and plot are below.

```
trellis =

    numInputSymbols: 4
    numOutputSymbols: 8
        numStates: 128
    nextStates: [128x4 double]
        outputs: [128x4 double]

spect =

    dfree: 5
    weight: [1 6 28 142]
    event: [1 2 8 25]
```

## Algorithms

The function uses a tree search algorithm implemented with a stack, as described in [2].

# doppler

Construct Doppler spectrum structure

## Syntax

```
s = doppler(specType)
s = doppler(specType, fieldValue)
s = doppler('BiGaussian', Name, Value)
```

## Description

`s = doppler(specType)` constructs a Doppler spectrum structure of type `specType` for use with a fading channel System object. The returned structure, `s`, has default values for its dependent fields.

`s = doppler(specType, fieldValue)` constructs a Doppler spectrum structure of type `specType` for use with a fading channel System object. The returned structure, `s`, has its dependent field specified to `fieldValue`.

`s = doppler('BiGaussian', Name, Value)` constructs a BiGaussian Doppler spectrum structure for use with a fading channel System object. The returned structure, `s`, has dependent fields specified by `Name, Value` pair arguments.

## Examples

### Construct a Flat Doppler Spectrum Structure

Construct a flat Doppler structure variable for use with channel objects such as `comm.RayleighChannel`.

Invoke the `doppler` function to create a flat Doppler structure variable.

```
s = doppler('Flat')
```

```
s = struct with fields:  
    SpectrumType: 'Flat'
```

### Create a Bell Doppler Structure Variable

Use the `doppler` function to create a Doppler structure variable having the Bell spectrum.

```
s = doppler('Bell')  
  
s = struct with fields:  
    SpectrumType: 'Bell'  
    Coefficient: 9
```

### Construct a Rounded Doppler Spectrum Structure with Specified Polynomial

Specify the coefficients of the Doppler spectrum structure variable.

Construct a Rounded Doppler spectrum structure with coefficients `a0`, `a2`, and `a4` set to 2, 6, and 1, respectively.

```
s = doppler('Rounded', [2, 6, 1])  
  
s = struct with fields:  
    SpectrumType: 'Rounded'  
    Polynomial: [2 6 1]
```

### Construct a BiGaussian Doppler Spectrum Structure with Specified Field Values

Use the `doppler` function to create a Doppler spectrum structure with the parameters specified for a BiGaussian spectrum.

```
s = doppler('BiGaussian', 'NormalizedCenterFrequencies', ...  
    [.1 .85], 'PowerGains', [1 2])
```

```
s = struct with fields:
    SpectrumType: 'BiGaussian'
    NormalizedStandardDeviations: [0.7071 0.7071]
    NormalizedCenterFrequencies: [0.1000 0.8500]
    PowerGains: [1 2]
```

The `NormalizedStandardDeviations` field is set to the default value. The `NormalizedCenterFrequencies`, and `PowerGains` fields are set to the values specified from the input arguments.

## Input Arguments

### **specType** — Spectrum type of Doppler spectrum structure for use with fading channel System object

'Jakes' | 'Flat' | 'Rounded' | 'Bell' | 'Asymmetric Jakes' | 'Restricted Jakes' | 'Gaussian' | 'BiGaussian'

The spectrum type of a Doppler spectrum structure for use with a fading channel System object. Specify this value as a character vector.

The analytical expression for each Doppler spectrum type is described in the “Algorithms” on page 2-436 section.

Data Types: char

### **fieldValue** — Value of dependent field of Doppler spectrum structure

scalar | vector

The value of the dependent field of the Doppler spectrum structure, specified as a scalar or vector of built-in data type. If you do not specify `fieldValue`, the dependent fields of the spectrum type use the default values.

Spectrum Type	Dependent Field	Description	Default Value
Jakes	—	—	—
Flat	—	—	—

Spectrum Type	Dependent Field	Description	Default Value
Rounded	Polynomial	1-by-3 vector of real finite values, representing the polynomial coefficients, $a_0$ , $a_2$ and $a_4$	[1 -1.72 0.785]
Bell	Coefficient	Nonnegative, finite, real scalar representing the Bell spectrum coefficient	9
Asymmetric Jakes	NormalizedFrequencyInterval	1-by-2 vector of real values between -1 and 1, inclusive, representing the minimum and maximum normalized Doppler shifts	[0 1]
Restricted Jakes	NormalizedFrequencyInterval	1-by-2 vector of real values between 0 and 1, inclusive, representing the minimum and maximum normalized Doppler shifts	[0 1]
Gaussian	NormalizedStandardDeviation	Normalized standard deviation of the Gaussian Doppler spectrum, specified as a positive, finite, real scalar	0.7071
BiGaussian	NormalizedStandardDeviations	Normalized standard deviations of the BiGaussian Doppler spectrum, specified as a positive, finite, real 1-by-2 vector	[0.7071 0.7071]

Spectrum Type	Dependent Field	Description	Default Value
	NormalizedCenterFrequencies	Normalized center frequencies of the BiGaussian Doppler spectrum specified as a real 1-by-2 vector whose elements fall between -1 and 1	[0 0]
	PowerGains	Linear power gains of the BiGaussian Doppler spectrum specified as a real nonnegative 1-by-2 vector	[0.5 0.5]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `s=doppler('BiGaussian', 'NormalizedStandardDeviations', [.8 .75], 'NormalizedCenterFrequencies', [-.8 0], 'PowerGains', [.6 .6])`

### NormalizedStandardDeviations — Normalized standard deviations of first and second Gaussian functions

[1/sqrt(2) 1/sqrt(2)] (default) | 1-by-2 vector

The normalized standard deviation of the first and second Gaussian functions. You can specify this value as a 1-by-2 vector of positive, finite, real values, of built-in data types.

When you do not specify this dependent field, the default value is [1/sqrt(2) 1/sqrt(2)].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NormalizedCenterFrequencies** — Normalized center frequencies of first and second Gaussian functions

[0 0] (default) | 1-by-2 vector

The normalized center frequencies of the first and second Gaussian functions. You can specify this value as a 1-by-2 vector of real values between -1 and 1, of built-in data types.

When you do not specify this dependent field, the default value is [0 0].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PowerGains** — Power gains of first and second Gaussian functions

[0.5 0.5] (default) | 1-by-2 vector

The power gains of the first and second Gaussian functions. You can specify this value as a 1-by-2 nonnegative, finite, real vector of built-in data types.

When you do not specify this dependent field, the default value is [0.5 0.5].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Algorithms

The following algorithms represent the analytical expressions for each Doppler spectrum type. In each case,  $f_d$  denotes the maximum Doppler shift (`MaximumDopplerShift` property) of the associated fading channel System object.

### Jakes

The theoretical Jakes Doppler spectrum,  $S(f)$  has the analytic formula

$$S(f) = \frac{1}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \quad |f| \leq f_d$$

## Flat

The theoretical Flat Doppler spectrum,  $S(f)$  has the analytic formula

$$S(f) = \frac{1}{2f_d}, |f| \leq f_d$$

## Rounded

The theoretical Rounded Doppler spectrum,  $S(f)$  has the analytic formula

$$S(f) = C_r \left[ a_0 + a_2 \left( \frac{f}{f_d} \right)^2 + a_4 \left( \frac{f}{f_d} \right)^4 \right], |f| \leq f_d$$

where

$$C_r = \frac{1}{2f_d \left[ a_0 + \frac{a_2}{3} + \frac{a_4}{5} \right]}$$

and you can specify  $[a_0, a_2, a_4]$  in the dependent field, `polynomial`.

## Bell

The theoretical Bell Doppler spectrum,  $S(f)$  has the analytic formula

$$S(f) = \frac{C_b}{1 + A \left( \frac{f}{f_d} \right)^2}$$

$$|f| \leq f_d$$

where

$$C_b = \frac{\sqrt{A}}{\pi f_d}$$

You can specify  $A$  in the dependent field, `coefficient`.

## Asymmetric Jakes

The theoretical Asymmetric Jakes Doppler spectrum,  $S(f)$  has the analytic formula

$$S(f) = \frac{A_a}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \quad -f_d \leq f_{\min} \leq f \leq f_{\max} \leq f_d$$

$$A_a = \frac{1}{\frac{2}{\pi} \left[ \sin^{-1} \left( \frac{f_{\max}}{f_d} \right) - \sin^{-1} \left( \frac{f_{\min}}{f_d} \right) \right]}$$

where you can specify  $f_{\min}/f_d$  and  $f_{\max}/f_d$  in the dependent field, `NormalizedFrequencyInterval`.

## Restricted Jakes

The theoretical Restricted Jakes Doppler spectrum,  $S(f)$  has the analytic formula

$$S(f) = \frac{A_r}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \quad 0 \leq f_{\min} \leq |f| \leq f_{\max} \leq f_d$$

where

$$A_r = \frac{1}{\frac{2}{\pi} \left[ \sin^{-1} \left( \frac{f_{\max}}{f_d} \right) - \sin^{-1} \left( \frac{f_{\min}}{f_d} \right) \right]}$$

where you can specify  $f_{\min}/f_d$  and  $f_{\max}/f_d$  in the dependent field, `NormalizedFrequencyInterval`.

## Gaussian

The theoretical Gaussian Doppler spectrum,  $S(f)$  has the analytic formula

$$S_G(f) = \frac{1}{\sqrt{2\pi\sigma_G^2}} \exp\left(-\frac{f^2}{2\sigma_G^2}\right)$$

You can specify  $\sigma_G/f_d$  in the dependent field, `NormalizedStandardDeviation`.

## BiGaussian

The theoretical BiGaussian Doppler spectrum,  $S(f)$  has the analytic formula

$$S_G(f) = A_G \left[ \frac{C_{G1}}{\sqrt{2\pi\sigma_{G1}^2}} \exp\left(-\frac{(f - f_{G1})^2}{2\sigma_{G1}^2}\right) + \frac{C_{G2}}{\sqrt{2\pi\sigma_{G2}^2}} \exp\left(-\frac{(f - f_{G2})^2}{2\sigma_{G2}^2}\right) \right]$$

where  $A_G = \frac{1}{C_{G1} + C_{G2}}$  is a normalization coefficient.

You can specify  $\sigma_{G1}/f_d$  and  $\sigma_{G2}/f_d$  in the `NormalizedStandardDeviations` dependent field.

You can specify  $f_{G1}/f_d$  and  $f_{G2}/f_d$  in the `NormalizedCenterFrequencies` dependent field.

$C_{G1}$  and  $C_{G2}$  are power gains that you can specify in the `PowerGains` dependent field.

## doppler.ajakes

(To be removed) Construct asymmetrical Doppler spectrum object

### Syntax

```
dop = doppler.ajakes(freqminmaxajakes)
dop = doppler.ajakes
```

---

**Note** `doppler.ajakes` will be removed in a future release. Use `doppler('Asymmetric Jakes', ...)` instead.

---

### Description

The `doppler.ajakes` function creates an asymmetrical Jakes (AJakes) Doppler spectrum object. This object is to be used for the `DopplerSpectrum` property of a channel object created with the `rayleighchan` or the `ricianchan` functions.

`dop = doppler.ajakes(freqminmaxajakes)`, where `freqminmaxajakes` is a row vector of two finite real numbers between -1 and 1, creates a Jakes Doppler spectrum that is nonzero only for normalized (by the maximum Doppler shift  $f_d$ , in Hz) frequencies  $f_{norm}$  such that  $-1 \leq f_{min, norm} \leq f_{norm} \leq f_{max, norm} \leq 1$ , where  $f_{min, norm}$  is given by `freqminmaxajakes(1)` and  $f_{max, norm}$  is given by `freqminmaxajakes(2)`. The maximum Doppler shift  $f_d$  is specified by the `MaxDopplerShift` property of the channel object. Analytically:  $f_{min, norm} = f_{min}/f_d$  and  $f_{max, norm} = f_{max}/f_d$ , where  $f_{min}$  is the minimum Doppler shift (in hertz) and  $f_{max}$  is the maximum Doppler shift (in hertz).

When `dop` is used as the `DopplerSpectrum` property of a channel object, space `freqminmaxajakes(1)` and `freqminmaxajakes(2)` by more than 1/50. Assigning a smaller spacing results in `freqminmaxajakes` being reset to the default value of `[0 1]`.

`dop = doppler.ajakes` creates an asymmetrical Doppler spectrum object with a default `freqminmaxajakes = [0 1]`. This syntax is equivalent to constructing a Jakes Doppler spectrum that is nonzero only for positive frequencies.

## Properties

The AJakes Doppler spectrum object contains the following properties.

Property	Description
SpectrumType	Fixed value, 'AJakes'
FreqMinMaxAJakes	Vector of minimum and maximum normalized Doppler shifts, two real finite numbers between -1 and 1

## Theory and Applications

The Jakes power spectrum is based on the assumption that the angles of arrival at the mobile receiver are uniformly distributed [1]: the spectrum then covers the frequency range from  $-f_d$  to  $f_d$ ,  $f_d$  being the maximum Doppler shift. When the angles of arrival are not uniformly distributed, then the Jakes power spectrum does not cover the full Doppler bandwidth from  $-f_d$  to  $f_d$ . The AJakes Doppler spectrum object covers the case of a power spectrum that is nonzero only for frequencies  $f$  such that  $-f_d \leq f_{\min} \leq f \leq f_{\max} \leq f_d$ . It is an asymmetrical spectrum in the general case, but becomes a symmetrical spectrum if  $f_{\min} = -f_{\max}$ .

The normalized AJakes Doppler power spectrum is given analytically by:

$$S(f) = \frac{A_a}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \quad -f_d \leq f_{\min} \leq f \leq f_{\max} \leq f_d$$

$$A_a = \frac{1}{\frac{1}{\pi} \left[ \sin^{-1} \left( \frac{f_{\max}}{f_d} \right) - \sin^{-1} \left( \frac{f_{\min}}{f_d} \right) \right]}$$

where  $f_{\min}$  and  $f_{\max}$  denote the minimum and maximum frequencies where the spectrum is nonzero. You can determine these values from the probability density function of the angles of arrival.

### Examples

The following MATLAB code first creates a Rayleigh channel object with a maximum Doppler shift of  $f_d = 10$  Hz. It then creates an AJakes Doppler object with minimum normalized Doppler shift  $f_{\min, \text{norm}} = -0.2$  and maximum normalized Doppler shift  $f_{\max, \text{norm}} = 0.05$ . The Doppler object is then assigned to the `DopplerSpectrum` property of the channel object. The channel then has a Doppler spectrum that is nonzero for frequencies  $f$  such that  $-f_d \leq f_{\min} \leq f \leq f_{\max} \leq f_d$ , where  $f_{\min} = f_{\min, \text{norm}} \times f_d = -2$  Hz and  $f_{\max} = f_{\max, \text{norm}} \times f_d = 0.5$  Hz.

```
chan = rayleighchan(1/1000, 10);  
dop_ajakes = doppler.ajakes([-0.2 0.05]);  
chan.DopplerSpectrum = dop_ajakes;  
chan.DopplerSpectrum
```

This code returns:

```
SpectrumType: 'AJakes'  
FreqMinMaxAJakes: [-0.2000 0.0500]
```

## doppler.bell

(To be removed) Construct bell-shaped Doppler spectrum object

### Syntax

```
doppler.bell
doppler.bell(coeffbell)
```

---

**Note** `doppler.ajakes` will be removed in a future release. Use `doppler('Bell', ...)` instead.

---

### Description

`doppler.bell` creates a bell Doppler spectrum object. You can use this object with the `DopplerSpectrum` property of any channel object created with either the `rayleighchan` function, the `ricianchan` function, or `comm.MIMOChannel System object™`.

`dop = doppler.bell` creates a bell Doppler spectrum object with default coefficient.

`dop = doppler.bell(coeffbell)` creates a bell Doppler spectrum object with coefficient given by `coeffbell`, where `coeffbell` is a positive, finite, real scalar.

### Properties

The bell Doppler spectrum object has the following properties.

Property	Description
<code>SpectrumType</code>	Fixed value, 'Bell'
<code>CoeffBell</code>	Bell spectrum coefficient, positive real finite scalar.

## Theory and Applications

A bell spectrum was proposed in [1] for the Doppler spectrum of indoor MIMO channels, for 802.11n channel modeling.

The normalized bell Doppler spectrum is given analytically by:

$$S(f) = \frac{C_b}{1 + A \left(\frac{f}{f_d}\right)^2}$$

where

$$|f| \leq f_d$$

and

$$C_b = \frac{\sqrt{A}}{\pi f_d}$$

$f_d$  represents the maximum Doppler shift specified for the channel object, and  $A$  represents a positive real finite scalar (`CoeffBell`). The indoor MIMO channel model of IEEE 802.11n [1] uses the following parameter:  $A = 9$ . Since the channel is modeled as Rician fading with a fixed line-of-sight (LOS) component, a Dirac delta is also present in the Doppler spectrum at  $f = 0$ .

## Examples

Construct a bell Doppler spectrum object with a coefficient of 8.5. Assign it to a Rayleigh channel object with one path.

```
dop = doppler.bell(8.5);  
chan = rayleighchan(1e-5, 10);  
chan.DopplerSpectrum = dop;
```

## doppler.bigaussian

(To be removed) Construct bi-Gaussian Doppler spectrum object

---

**Note** `doppler.bigaussian` will be removed in a future release. Use `doppler('BiGaussian', ...)` instead.

---

### Syntax

```
dop = doppler.bigaussian(property1,value1,...)
dop = doppler.bigaussian
```

### Description

The `doppler.bigaussian` function creates a bi-Gaussian Doppler spectrum object to be used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` function or the `ricianchan` function).

`dop = doppler.bigaussian(property1,value1,...)` creates a bi-Gaussian Doppler spectrum object with properties as specified by the property/value pairs. If you do not specify a value for a property, the property is assigned a default value.

`dop = doppler.bigaussian` creates a bi-Gaussian Doppler spectrum object with default properties. The constructed Doppler spectrum object is equivalent to a single Gaussian Doppler spectrum centered at zero frequency. The equivalent command with property/value pairs is:

```
dop = doppler.bigaussian('SigmaGaussian1', 1/sqrt(2), ...
    'SigmaGaussian2', 1/sqrt(2), ...
    'CenterFreqGaussian1', 0, ...
    'CenterFreqGaussian2', 0, ...
    'GainGaussian1', 0.5, ...
    'GainGaussian2', 0.5)
```

## Properties

The bi-Gaussian Doppler spectrum object contains the following properties.

Property	Description
SpectrumType	Fixed value, 'BiGaussian'
SigmaGaussian1	Normalized standard deviation of first Gaussian function (real positive finite scalar value)
SigmaGaussian2	Normalized standard deviation of second Gaussian function (real positive finite scalar value)
CenterFreqGaussian1	Normalized center frequency of first Gaussian function (real scalar value between -1 and 1)
CenterFreqGaussian2	Normalized center frequency of second Gaussian function (real scalar value between -1 and 1)
GainGaussian1	Power gain of first Gaussian function (linear scale, real nonnegative finite scalar value)
GainGaussian2	Power gain of second Gaussian function (linear scale, real nonnegative finite scalar value)

All properties are writable except for the SpectrumType property.

The properties SigmaGaussian1, SigmaGaussian2, GainGaussian1, and GainGaussian2 are normalized by the MaxDopplerShift property of the associated channel object.

Analytically, the normalized standard deviations of the first and second Gaussian functions are determined as  $\sigma_{G1, norm} = \sigma_{G1}/f_d$  and  $\sigma_{G2, norm} = \sigma_{G2}/f_d$ , respectively, where  $\sigma_{G1}$  and  $\sigma_{G2}$  are the standard deviations of the first and second Gaussian functions, and  $f_d$  is the maximum Doppler shift, in hertz. Similarly, the normalized center frequencies of the first and second Gaussian functions are determined as  $f_{G1, norm} = f_{G1}/f_d$  and  $f_{G2, norm} = f_{G2}/f_d$ , respectively, where  $f_{G1}$  and  $f_{G2}$  are the center frequencies of the first

and second Gaussian functions. The properties `GainGaussian1` and `GainGaussian2` correspond to the power gains  $C_{G1}$  and  $C_{G2}$ , respectively, of the two Gaussian functions.

## Theory and Applications

The bi-Gaussian power spectrum consists of two frequency-shifted Gaussian spectra. The COST207 channel models ([1], [2], [3]) specify two distinct bi-Gaussian Doppler spectra, GAUS1 and GAUS2, to be used in modeling long echos for urban and hilly terrain profiles.

The normalized bi-Gaussian Doppler spectrum is given analytically by:

$$S_G(f) = A_G \left[ \frac{C_{G1}}{\sqrt{2\pi\sigma_{G1}^2}} \exp\left(-\frac{(f - f_{G1})^2}{2\sigma_{G1}^2}\right) + \frac{C_{G2}}{\sqrt{2\pi\sigma_{G2}^2}} \exp\left(-\frac{(f - f_{G2})^2}{2\sigma_{G2}^2}\right) \right]$$

where  $\sigma_{G1}$  and  $\sigma_{G2}$  are standard deviations,  $f_{G1}$  and  $f_{G2}$  are center frequencies,  $C_{G1}$  and  $C_{G2}$  are power gains, and  $A_G = \frac{1}{C_{G1} + C_{G2}}$  is a normalization coefficient.

If either  $f_{G1} = 0$  or  $f_{G2} = 0$ , a frequency-shifted Gaussian Doppler spectrum is obtained.

## Examples

The following MATLAB code first creates a bi-Gaussian Doppler spectrum object with the same parameters as that of a COST 207 GAUS2 Doppler spectrum. It then creates a Rayleigh channel object with a maximum Doppler shift of  $f_d = 30$  and assigns the constructed Doppler spectrum object to its `DopplerSpectrum` property.

```
dop_bigaussian = doppler.bigaussian('SigmaGaussian1', 0.1, ...
    'SigmaGaussian2', 0.15, 'CenterFreqGaussian1', 0.7, ...
    'CenterFreqGaussian2', -0.4, 'GainGaussian1', 1, ...
    'GainGaussian2', 1/10^1.5)
chan = rayleighchan(1e-3, 30);
chan.DopplerSpectrum = dop_bigaussian;
```

# doppler.flat

(To be removed) Construct flat Doppler spectrum object

---

**Note** `doppler.flat` will be removed in a future release. Use `doppler('Flat')` instead.

---

## Syntax

```
dop = doppler.flat
```

## Description

`dop = doppler.flat` creates a flat Doppler spectrum object that is to be used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function). The maximum Doppler shift of the flat Doppler spectrum object is specified by the `MaxDopplerShift` property of the channel object.

## Properties

The flat Doppler spectrum object contains only one property, `SpectrumType`, which is read-only and has a fixed value of `'Flat'`.

## Theory and Applications

In a 3-D isotropic scattering environment, where the angles of arrival are uniformly distributed in the azimuth and elevation planes, the Doppler spectrum is found theoretically to be flat [2]. A flat Doppler spectrum is also specified in some cases of the ANSI J-STD-008 reference channel models for PCS, for both outdoor (pedestrian) and indoor (commercial) [1] applications.

The normalized flat Doppler power spectrum is given analytically by:

$$S(f) = \frac{1}{2f_d}, |f| \leq f_d$$

where  $f_d$  is the maximum Doppler frequency.

## Examples

## doppler.gaussian

(To be removed) Construct Gaussian Doppler spectrum object

### Syntax

```
dop = doppler.gaussian  
dop = doppler.gaussian(sigmagaussian)
```

---

**Note** `doppler.gaussian` will be removed in a future release. Use `doppler('Gaussian', ...)` instead.

---

### Description

The `doppler.gaussian` function creates a Gaussian Doppler spectrum object that is to be used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function).

`dop = doppler.gaussian` creates a Gaussian Doppler spectrum object with a default standard deviation (normalized by the maximum Doppler shift  $f_d$ , in Hz)  $\sigma_{G, norm} = 1/\sqrt{2}$ . The maximum Doppler shift  $f_d$  is specified by the `MaxDopplerShift` property of the channel object. Analytically,  $\sigma_{G, norm} = \sigma_G/f_d = 1/\sqrt{2}$ , where  $\sigma_G$  is the standard deviation of the Gaussian Doppler spectrum.

`dop = doppler.gaussian(sigmagaussian)` creates a Gaussian Doppler spectrum object with a normalized  $f_d$  (by the maximum Doppler shift  $f_d$ , in Hz)  $\sigma_{G, norm}$  of value `sigmagaussian`.

### Properties

The Gaussian Doppler spectrum object contains the following properties.

Property	Description
SpectrumType	Fixed value, 'Gaussian'
SigmaGaussian	Normalized standard deviation of the Gaussian Doppler spectrum (a real positive number)

## Theory and Applications

The Gaussian power spectrum is considered to be a good model for multipath components with long delays in UHF communications [3]. It is also proposed as a model for the aeronautical channel [2]. A Gaussian Doppler spectrum is also specified in some cases of the ANSI J-STD-008 reference channel models for PCS applications, for both outdoor (wireless loop) and indoor (residential, office) [1]. The normalized Gaussian Doppler power spectrum is given analytically by:

$$S_G(f) = \frac{1}{\sqrt{2\pi}\sigma_G^2} \exp\left(-\frac{f^2}{2\sigma_G^2}\right)$$

An alternate representation is [4]:

$$S_G(f) = \frac{1}{f_c} \sqrt{\frac{\ln 2}{\pi}} \exp\left(-(\ln 2) \left(\frac{f}{f_c}\right)^2\right)$$

where  $f_c = \sigma_G \sqrt{2 \ln 2}$  is the 3 dB cutoff frequency. If you set  $f_c = f_d \sqrt{\ln 2}$ , where  $f_d$  is the maximum Doppler shift, or equivalently  $\sigma_G = f_d / \sqrt{2}$ , the Doppler spread of the Gaussian power spectrum becomes equal to the Doppler spread of the Jakes power spectrum, where Doppler spread is defined as:

$$\sigma_D = \sqrt{\frac{\int_{-\infty}^{\infty} f^2 S(f) df}{\int_{-\infty}^{\infty} S(f) df}}$$

## Examples

The following code creates a Rayleigh channel object with a maximum Doppler shift of  $f_d = 10$ . It then creates a Gaussian Doppler spectrum object with a normalized standard deviation of  $\sigma_{G,\text{norm}} = 0.5$ , and assigns it to the `DopplerSpectrum` property of the channel object.

```
chan = rayleighchan(1/1000,10);  
dop_gaussian = doppler.gaussian(0.5);  
chan.DopplerSpectrum = dop_gaussian;
```

# doppler.jakes

(To be removed) Construct Jakes Doppler spectrum object

## Syntax

---

**Note** `doppler.jakes` will be removed in a future release. Use `doppler('Jakes')` instead.

---

## Description

`dop = doppler.jakes` creates a Jakes Doppler spectrum object that is to be used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function). The maximum Doppler shift of the Jakes Doppler spectrum object is specified by the `MaxDopplerShift` property of the channel object. By default, channel objects are created with a Jakes Doppler spectrum.

## Properties

The Jakes Doppler spectrum object contains only one property, `SpectrumType`, which is read-only and has a fixed value of `'Jakes'`.

## Theory and Applications

The Jakes Doppler power spectrum model is actually due to Gans [2], who analyzed the Clarke-Gilbert model ([1], [3], and [5]). The Clarke-Gilbert model is also called the *classical model*.

The Jakes Doppler power spectrum applies to a mobile receiver. It derives from the following assumptions [6]:

- The radio waves propagate horizontally.

- At the mobile receiver, the angles of arrival of the radio waves are uniformly distributed over  $[-\pi, \pi]$ .
- At the mobile receiver, the antenna is omnidirectional (i.e., the antenna pattern is circular-symmetrical).

The normalized Jakes Doppler power spectrum is given analytically by:

$$S(f) = \frac{1}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \quad |f| \leq f_d$$

where  $f_d$  is the maximum Doppler frequency.

## Examples

Create a Rayleigh channel object with a maximum Doppler shift of  $f_d=10$  Hertz. Then, create a Jakes Doppler spectrum object and assigns it to the `DopplerSpectrum` property of the channel object.

```
chan = rayleighchan(1/1000,10);
dop_gaussian = doppler.jakes;
chan.DopplerSpectrum = dop_gaussian
```

# doppler.rjakes

(To be removed) Construct restricted Jakes Doppler spectrum object

## Syntax

```
dop = doppler.rjakes
dop = doppler.rjakes(freqminmaxrjakes)
```

---

**Note** `doppler.rjakes` will be removed in a future release. Use `doppler('Restricted Jakes', ...)` instead.

---

## Description

The `doppler.rjakes` function creates a restricted Jakes (RJakes) Doppler spectrum object that is used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function).

`dop = doppler.rjakes` creates a Doppler spectrum object equivalent to the Jakes Doppler spectrum. The maximum Doppler shift of the RJakes Doppler spectrum object is specified by the `MaxDopplerShift` property of the channel object.

`dop = doppler.rjakes(freqminmaxrjakes)`, where `freqminmaxrjakes` is a row vector of two finite real numbers between 0 and 1, creates a Jakes Doppler spectrum. This spectrum is nonzero only for normalized frequencies (by the maximum Doppler shift,  $f_d$ , in Hertz),  $f_{norm}$ , such that  $0 \leq f_{min, norm} \leq |f_{norm}| \leq f_{max, norm} \leq 1$ , where  $f_{min, norm}$  is given by `freqminmaxrjakes(1)` and  $f_{max, norm}$  is given by `freqminmaxrjakes(2)`. The maximum Doppler shift  $f_d$  is specified by the `MaxDopplerShift` property of the channel object. Analytically,  $f_{min, norm} = f_{min}/f_d$  and  $f_{max, norm} = f_{max}/f_d$ , where  $f_{min}$  is the minimum Doppler shift (in Hertz) and  $f_{max}$  is the maximum Doppler shift (in Hertz).

When `dop` is used as the `DopplerSpectrum` property of a channel object, `freqminmaxrjakes(1)` and `freqminmaxrjakes(2)` should be spaced by more than 1/50. Assigning a smaller spacing results in `freqminmaxrjakes` being reset to the default value of `[0 1]`.

## Properties

The RJakes Doppler spectrum object contains the following properties.

Property	Description
SpectrumType	Fixed value, 'RJakes'
FreqMinMaxRJakes	Vector of minimum and maximum normalized Doppler shifts (two real finite numbers between 0 and 1)

## Theory and Applications

The Jakes power spectrum is based on the assumption that the angles of arrival at the mobile receiver are uniformly distributed [1], where the spectrum covers the frequency range from  $-f_d$  to  $f_d$ ,  $f_d$  being the maximum Doppler shift. When the angles of arrival are not uniformly distributed, the Jakes power spectrum does not cover the full Doppler bandwidth from  $-f_d$  to  $f_d$ . This exception also applies to the case where the antenna pattern is directional. This type of spectrum is known as *restricted Jakes* [3]. The RJakes Doppler spectrum object covers only the case of a symmetrical power spectrum, which is nonzero only for frequencies  $f$  such that  $0 \leq f_{\min} \leq |f| \leq f_{\max} \leq f_d$ .

The normalized RJakes Doppler power spectrum is given analytically by:

$$S(f) = \frac{A_r}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \quad 0 \leq f_{\min} \leq |f| \leq f_{\max} \leq f_d$$

where

$$A_r = \frac{1}{\frac{2}{\pi} \left[ \sin^{-1} \left( \frac{f_{\max}}{f_d} \right) - \sin^{-1} \left( \frac{f_{\min}}{f_d} \right) \right]}$$

$f_{\min}$  and  $f_{\max}$  denote the minimum and maximum frequencies where the spectrum is nonzero. They can be determined from the probability density function of the angles of arrival.

## Examples

The following code first creates a Rayleigh channel object with a maximum Doppler shift of  $f_d = 10$ . It then creates an RJakes Doppler object with minimum normalized Doppler shift  $f_{\min, \text{norm}} = 0.14$  and maximum normalized Doppler shift  $f_{\max, \text{norm}} = 0.9$ .

The Doppler object is assigned to the `DopplerSpectrum` property of the channel object. The channel then has a Doppler spectrum that is nonzero for frequencies  $f$  such that  $0 \leq f_{\min} \leq |f| \leq f_{\max} \leq f_d$ , where  $f_{\min} = f_{\min, \text{norm}} \times f_d = 1.4$  Hz and  $f_{\max} = f_{\max, \text{norm}} \times f_d = 9$  Hz.

```
chan = rayleighchan(1/1000, 10);
dop_rjakes = doppler.rjakes([0.14 0.9]);
chan.DopplerSpectrum = dop_rjakes;
chan.DopplerSpectrum
```

The output is:

```
      SpectrumType: 'RJakes'
FreqMinMaxRJakes: [0.1400 0.9000]
```

# doppler.rounded

(To be removed) Construct rounded Doppler spectrum object

## Syntax

```
dop = doppler.rounded  
dop = doppler.rounded(coeffrounded)
```

---

**Note** `doppler.rounded` will be removed in a future release. Use `doppler('Rounded', ...)` instead.

---

## Description

The `doppler.rounded` function creates a rounded Doppler spectrum object that is used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function).

`dop = doppler.rounded` creates a rounded Doppler spectrum object with default polynomial coefficients  $a_0 = 1$ ,  $a_2 = -1.72$ ,  $a_4 = 0.785$  (see “Theory and Applications” on page 2-464 for the meaning of these coefficients). The maximum Doppler shift  $f_d$  (in Hertz) is specified by the `MaxDopplerShift` property of the channel object.

`dop = doppler.rounded(coeffrounded)`, where `coeffrounded` is a row vector of three finite real numbers, creates a rounded Doppler spectrum object with polynomial coefficients,  $a_0$ ,  $a_2$ ,  $a_4$ , given by `coeffrounded(1)`, `coeffrounded(2)`, and `coeffrounded(3)`, respectively.

## Properties

The rounded Doppler spectrum object contains the following properties.

Property	Description
SpectrumType	Fixed value, 'Rounded'
CoeffRounded	Vector of three polynomial coefficients (real finite numbers)

## Theory and Applications

A rounded spectrum is proposed as an approximation to the measured Doppler spectrum of the scatter component of fixed wireless channels at 2.5 GHz [1]. However, the shape of the spectrum is influenced by the center carrier frequency.

The normalized rounded Doppler spectrum is given analytically by a polynomial in  $f$  of order four, where only the even powers of  $f$  are retained:

$$S(f) = C_r \left[ a_0 + a_2 \left( \frac{f}{f_d} \right)^2 + a_4 \left( \frac{f}{f_d} \right)^4 \right], |f| \leq f_d$$

where

$$C_r = \frac{1}{2f_d \left[ a_0 + \frac{a_2}{3} + \frac{a_4}{5} \right]}$$

$f_d$  is the maximum Doppler shift, and  $a_0$ ,  $a_2$ ,  $a_4$  are real finite coefficients. The fixed wireless channel model of IEEE 802.16 [1] uses the following parameters:  $a_0 = 1$ ,  $a_2 = -1.72$ , and  $a_4 = 0.785$ . Because the channel is modeled as Rician fading with a fixed line-of-sight (LOS) component, a Dirac delta is also present in the Doppler spectrum at  $f = 0$ .

## Examples

The following code creates a Rician channel object with a maximum Doppler shift of  $f_d = 10$ . It then creates a rounded Doppler spectrum object with polynomial coefficients  $a_0 = 1.0$ ,  $a_2 = -0.5$ ,  $a_4 = 1.5$ , and assigns it to the `DopplerSpectrum` property of the channel object.

```
chan = ricianchan(1/1000,10,1);  
dop_rounded = doppler.rounded([1.0 -0.5 1.5]);  
chan.DopplerSpectrum = dop_rounded;
```

## dpcmdeco

Decode using differential pulse code modulation

### Syntax

```
sig = dpcmdeco(indx,codebook,predictor)
[sig,quanterror] = dpcmdeco(indx,codebook,predictor)
```

### Description

`sig = dpcmdeco(indx,codebook,predictor)` implements differential pulse code demodulation to decode the vector `indx`. The vector `codebook` represents the predictive-error quantization codebook. The vector `predictor` specifies the predictive transfer function. If the transfer function has predictive order  $M$ , `predictor` has length  $M+1$  and an initial entry of 0. To decode correctly, use the same codebook and predictor in `dpcmenco` and `dpcmdeco`.

See “Represent Partitions”, “Represent Codebooks”, or the `quantiz` reference page, for a description of the formats of `partition` and `codebook`.

`[sig,quanterror] = dpcmdeco(indx,codebook,predictor)` is the same as the syntax above, except that the vector `quanterror` is the quantization of the predictive error based on the quantization parameters. `quanterror` is the same size as `sig`.

---

**Note** You can estimate the input parameters `codebook`, `partition`, and `predictor` using the function `dpcmopt`.

---

### Examples

See “Example: DPCM Encoding and Decoding” and “Example: Comparing Optimized and Nonoptimized DPCM Parameters” for examples that use `dpcmdeco`.

# dpcmenco

Encode using differential pulse code modulation

## Syntax

```
indx = dpcmenco(sig,codebook,partition,predictor)
[indx,quants] = dpcmenco(sig,codebook,partition,predictor)
```

## Description

`indx = dpcmenco(sig,codebook,partition,predictor)` implements differential pulse code modulation to encode the vector `sig`. `partition` is a vector whose entries give the endpoints of the partition intervals. `codebook`, a vector whose length exceeds the length of `partition` by one, prescribes a value for each partition in the quantization. `predictor` specifies the predictive transfer function. If the transfer function has predictive order  $M$ , `predictor` has length  $M+1$  and an initial entry of 0. The output vector `indx` is the quantization index.

See “Differential Pulse Code Modulation” for more about the format of `predictor`. See “Represent Partitions”, “Represent Partitions”, or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

`[indx,quants] = dpcmenco(sig,codebook,partition,predictor)` is the same as the syntax above, except that `quants` contains the quantization of `sig` based on the quantization parameters. `quants` is a vector of the same size as `sig`.

---

**Note** If `predictor` is an order-one transfer function, the modulation is called a *delta modulation*.

---

## Examples

See “Example: DPCM Encoding and Decoding” and “Example: Comparing Optimized and Nonoptimized DPCM Parameters” for examples that use `dpcmenco`.

## References

## dpcmopt

Optimize differential pulse code modulation parameters

### Syntax

```
predictor = dpcmopt(training_set,ord)
[predictor,codebook,partition] = dpcmopt(training_set,ord,len)
[predictor,codebook,partition] = dpcmopt(training_set,ord,ini_cb)
```

### Description

`predictor = dpcmopt(training_set,ord)` returns a vector representing a predictive transfer function of order `ord` that is appropriate for the training data in the vector `training_set`. `predictor` is a row vector of length `ord+1`. See “Represent Predictors” for more about its format.

---

**Note** `dpcmopt` optimizes for the data in `training_set`. For best results, `training_set` should be similar to the data that you plan to quantize.

---

`[predictor,codebook,partition] = dpcmopt(training_set,ord,len)` is the same as the syntax above, except that it also returns corresponding optimized codebook and partition vectors `codebook` and `partition`. `len` is an integer that prescribes the length of `codebook`. `partition` is a vector of length `len-1`. See “Represent Partitions”, “Represent Codebooks”, or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

`[predictor,codebook,partition] = dpcmopt(training_set,ord,ini_cb)` is the same as the first syntax, except that it also returns corresponding optimized codebook and partition vectors `codebook` and `partition`. `ini_cb`, a vector of length at least 2, is the initial guess of the codebook values. The output `codebook` is a vector of the same length as `ini_cb`. The output `partition` is a vector whose length is one less than the length of `codebook`.

## Examples

See “Example: Comparing Optimized and Nonoptimized DPCM Parameters” for an example that uses dpcmopt.

## dpskdemod

Differential phase shift keying demodulation

### Syntax

```
z = dpskdemod(y,M)
z = dpskdemod(y,M,phaserot)
z = dpskdemod(y,M,phaserot,symorder)
```

### Description

`z = dpskdemod(y,M)` demodulates the complex envelope, `y`, of a DPSK-modulated signal having modulation order `M`.

`z = dpskdemod(y,M,phaserot)` specifies the phase rotation of the DPSK modulation.

`z = dpskdemod(y,M,phaserot,symorder)` also specifies the symbol order.

### Examples

#### DPSK Demodulation

Demodulate DPSK data in a communication channel in which a phase shift is introduced.

Generate a 4-ary data vector and modulate it using DPSK.

```
M = 4; % Alphabet size
dataIn = randi([0 M-1],1000,1); % Random message
txSig = dpskmod(dataIn,M); % Modulate
```

Apply the random phase shift resulting from the transmission process.

```
rxSig = txSig*exp(2i*pi*rand());
```

Demodulate the received signal.

```
dataOut = dpskdemod(rxSig,M);
```

The modulator and demodulator have the same initial condition. However, only the received signal experiences a phase shift. As a result, the first demodulated symbol is likely to be in error. Therefore, you should always discard the first symbol when using DPSK.

Find the number of symbol errors.

```
errs = symerr(dataIn,dataOut)
```

```
errs = 1
```

One symbol is in error. Repeat the error calculation after discarding the first symbol.

```
errs = symerr(dataIn(2:end),dataIn(2:end))
```

```
errs = 0
```

## Input Arguments

### **y** — DPSK-modulated input signal

vector | matrix

DPSK-modulated input signal, specified as a real or complex vector or matrix. If *y* is a matrix, the function processes the columns independently.

Data Types: double | single

Complex Number Support: Yes

### **M** — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: double | single

### **phaserot** — Phase rotation

0 (default) | scalar | []

Phase rotation of the DPSK modulation, specified in radians as a real scalar. The total phase shift per symbol is the sum of `phaserot` and the phase generated by the differential modulation.

If you specify `phaserot` as empty, then `dspkdemod` uses a phase rotation of 0 degrees.

Example: `pi/4`

Data Types: `double` | `single`

### **symorder — Symbol order**

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

## Output Arguments

### **z — DPSK-demodulated output signal**

`vector` | `matrix`

DPSK-demodulated output signal, returned as a vector or matrix having the same number of columns as input signal `y`.

---

**Note** The differential algorithm used in this function compares two successive elements of a modulated signal. To determine the first element of vector `z`, or the first row of matrix `z`, the function uses an initial phase rotation of  $\theta$ .

---

Data Types: `double` | `single`

## Extended Capabilities

## dpskmod

Differential phase shift keying modulation

### Syntax

```
y = dpskmod(x,M)  
y = dpskmod(x,M,phaserot)  
y = dpskmod(x,M,phaserot,symorder)
```

### Description

`y = dpskmod(x,M)` modulates the input signal using differential phase shift keying (DPSK) with modulation order `M`.

`y = dpskmod(x,M,phaserot)` specifies the phase rotation of the DPSK modulation.

`y = dpskmod(x,M,phaserot,symorder)` also specifies the symbol order.

### Examples

#### View Signal Trajectory of DPSK-Modulated Signal

Plot the output of the `dpskmod` function to view the possible transitions between DPSK symbols.

Set the modulation order to 4 to model DQPSK modulation.

```
M = 4;
```

Generate a sequence of 4-ary random symbols.

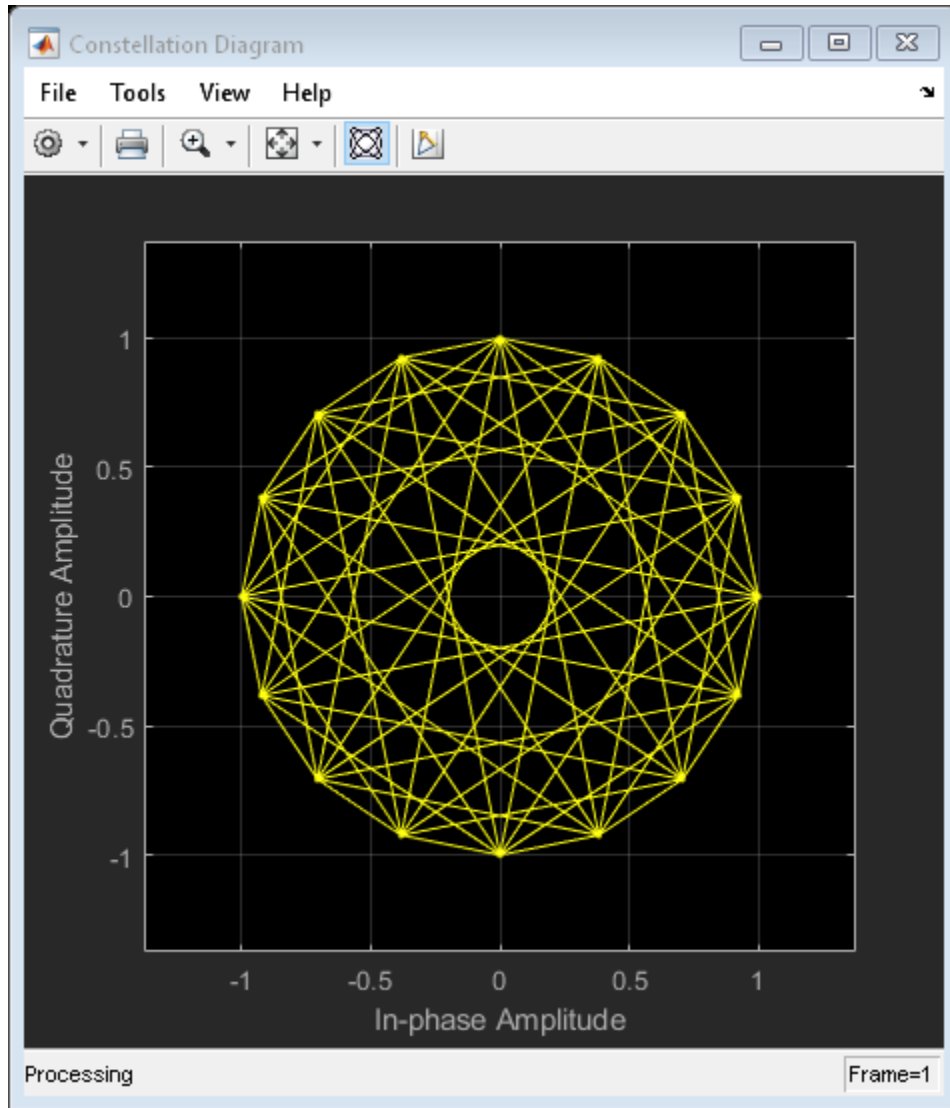

```
x = randi([0 M-1],500,1);
```

Apply DQPSK modulation to the input symbols.

```
y = dpskmod(x,M,pi/8);
```

Specify a constellation diagram object to display a signal trajectory diagram and without displaying the corresponding reference constellation. Display the trajectory.

```
cd = comm.ConstellationDiagram('ShowTrajectory',true,'ShowReferenceConstellation',false);  
cd(y)
```

## Input Arguments

**x** — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. The elements of `x` must have values in the range of `[0, M - 1]`.

Data Types: `double` | `single`

### **M — Modulation order**

integer power of two

Modulation order, specified as an integer power of two.

Example: `2` | `4` | `16`

Data Types: `double` | `single`

### **phaserot — Phase rotation**

`0` (default) | scalar | `[]`

Phase rotation of the DPSK modulation, specified in radians as a real scalar. The total phase shift per symbol is the sum of `phaserot` and the phase generated by the differential modulation.

If you specify `phaserot` as empty, then `dpskmod` uses a phase rotation of 0 degrees.

Example: `pi/4`

Data Types: `double` | `single`

### **symorder — Symbol order**

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

## **Output Arguments**

### **y — DPSK-modulated output signal**

vector | matrix

Complex baseband representation of a DPSK-modulated output signal, returned as vector or matrix. The columns represent independent channels.

---

**Note** An initial phase rotation of 0 is used in determining the first element of the output  $y$  (or the first row of  $y$  if it is a matrix with multiple rows), because two successive elements are required for a differential algorithm.

---

Data Types: `double` | `single`

## Extended Capabilities

## dvbs2ldpc

Low-density parity-check codes from DVB-S.2 standard

### Syntax

$H = \text{dvbs2ldpc}(r)$

### Description

$H = \text{dvbs2ldpc}(r)$  returns the parity-check matrix of the LDPC code with code rate  $r$  from the DVB-S.2 standard.  $H$  is a sparse logical matrix.

Possible values for  $r$  are  $1/4$ ,  $1/3$ ,  $2/5$ ,  $1/2$ ,  $3/5$ ,  $2/3$ ,  $3/4$ ,  $4/5$ ,  $5/6$ ,  $8/9$ , and  $9/10$ . The block length of the code is 64800.

The default parity-check matrix (32400-by-64800) corresponds to an irregular LDPC code with the structure shown in the following table.

Row	Number of 1s Per Row
1	6
2 to 32400	7

Column	Number of 1s Per Column
1 to 12960	8
12961 to 32400	3

Columns 32401 to 64800 form a lower triangular matrix. Only the elements on its main diagonal and the subdiagonal immediately below are 1s. This LDPC code is used in conjunction with a BCH code in the Digital Video Broadcasting standard DVB-S.2 to achieve a packet error rate below  $10^{-7}$  at about 0.7 dB to 1 dB from the Shannon limit.

### Examples

### Create LDPC Code Parity Check Matrix from DVB-S.2

Create an LDPC parity check matrix for a code rate of 3/5 from the DVB-S.2 standard.

```
p = dvbs2ldpc(3/5);
```

Create an LDPC encoder object from the parity check matrix `p`.

```
enc = comm.LDPCEncoder(p);
```

The parity check matrix has dimensions of (N-K)-by-N. Determine the length of the input message.

```
msgLength = size(p,2) - size(p,1)
```

```
msgLength = 38880
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constants. Expressions or variables are allowed if their values do not change.

### See Also

# dvbsapskdemod

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) demodulation

## Syntax

```
z = dvbsapskdemod(y,M,stdSuffix)
z = dvbsapskdemod(y,M,stdSuffix,codeIDF)
z = dvbsapskdemod(y,M,stdSuffix,codeIDF,frameLength)
z = dvbsapskdemod( ____,Name,Value)
```

## Description

`z = dvbsapskdemod(y,M,stdSuffix)` demodulates an APSK input signal, `y`, that was modulated in accordance with the digital video broadcast (DVB) standard identified by `stdSuffix` and the modulation order, `M`. For a description of DVB-compliant APSK demodulation, see “DVB Compliant APSK Hard Demodulation” on page 2-491 and “DVB Compliant APSK Soft Demodulation” on page 2-492.

`z = dvbsapskdemod(y,M,stdSuffix,codeIDF)` specifies code identifier `codeIDF`, to use when selecting the demodulation parameters.

`z = dvbsapskdemod(y,M,stdSuffix,codeIDF,frameLength)` specifies `codeIDF` and `frameLength` to use when selecting the demodulation parameters.

`z = dvbsapskdemod( ____,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, 'OutputDataType', 'double' specifies the desired output data type. Specify name-value pair arguments after all other input arguments.

## Examples

### Demodulate DVB-S2X Specific 64-APSK Signal

Demodulate a 64-APSK signal that was modulated as specified in DVB-S2X. Compute hard decision integer output and verify that the output matches the input.

Set the modulation order and standard suffix. Generate random data.

```
M = 64;  
std = 's2x';  
x = randi([0 M-1],1000,1);
```

Modulate the data.

```
y = dvbsapskmod(x,M,std);
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = dvbsapskdemod(y,M,std);  
isequal(z,x)
```

```
ans = logical  
     1
```

### Demodulate DVB-S2 Specific 32-APSK Signal

Demodulate a 32-APSK signal that was modulated as specified in DVB-S2. Compute hard decision bit output and verify that the output matches the input.

Set the modulation order, standard suffix, and code identifier. Generate random bit data.

```
M = 32;  
std = 's2';  
codeIDF = '4/5';  
numBitsPerSym = log2(M);  
x = randi([0 1],100*numBitsPerSym,1,'uint32');
```

Modulate the data. Use a name-value pair to specify bit input data.

```
y = dvbsapskmod(x,M,std,codeIDF,'InputType','bit');
```

Demodulate the received signal. Compare the demodulated data to the original data.

```

z = dvbsapskdemod(y,M,std,'4/5','OutputType','bit', ...
'OutputDataType','uint32');
isequal(z,x)

ans = logical
     1

```

### Soft Bit Demodulate DVB-SH Specific 16-APSK Signal

Demodulate a DVB-SH compliant 16-APSK signal and calculate soft bits.

Set the modulation order and generate a random bit sequence.

```

M = 16;
std = 'sh';
numSym = 20000;
numBitsPerSym = log2(M);
x = randi([0 1],numSym*numBitsPerSym,1);

```

Modulate the data. Use a name-value pair to specify bit input data.

```
txSig = dvbsapskmod(x,M,std,'InputType','bit');
```

Pass the modulated signal through a noisy channel.

```
rxSig = awgn(txSig,10,'measured');
```

View the constellation of the received signal using a scatter plot.

```
scatterplot(rxSig)
```

DVB-SH compliant constellations have unit average power. Demodulate the signal, computing soft bits using the approximate LLR algorithm.

```
z = dvbspskdemod(rxSig,M,std,'OutputType','approxllr', ...  
                'NoiseVariance',0.1);
```

## Input Arguments

**y** — APSK modulated signal

scalar | vector | matrix

APSK modulated signal, specified as a complex scalar, vector, or matrix. When  $y$  is a matrix, each column is treated as an independent channel.

$y$  must be modulated in accordance with Digital Video Broadcasting (DVB) - Satellite Communications standard DVB-S2, DVB-S2X or DVB-SH. For more information, see [1], [2], and [3].

Data Types: `single` | `double`  
Complex Number Support: Yes

### **M — Modulation order**

`integer`

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Data Types: `double`

### **stdSuffix — Standard suffix**

`'s2'` | `'s2x'` | `'s2h'`

Standard suffix for DVBS modulation variant, specified as `'s2'`, `'s2x'`, or `'s2h'`.

Data Types: `char` | `string`

### **codeIDF — Code identifier**

`char` | `string`

Code identifier, specified as a character vector or string. This table lists the acceptable codeIDF values.

<b>Constellation Order (M)</b>	<b>Applicable Standard (stdSuffix)</b>	<b>Acceptable Code Identifier (CodeIDF) Values</b>
16	's2' or 's2x'	'2/3', '3/4', '4/5', '5/6', '8/9', '9/10'

Constellation Order (M)	Applicable Standard (stdSuffix)	Acceptable Code Identifier (CodeIDF) Values
16	's2x'	'26/45', '3/5', '28/45', '23/36', '25/36', '13/18', '7/9', '77/90', '100/180', '96/180', '90/180', '18/30', '20/30'
32	's2' or 's2x'	'3/4', '4/5', '5/6', '8/9', '9/10'
32	's2x'	'32/45', '11/15', '7/9', '2/3'
64	's2x'	'11/15', '7/9', '4/5', '5/6', '128/180'
128	's2x'	'3/4', '7/9'
256	's2x'	'32/45', '3/4', '116/180', '20/30', '124/180', '22/30'

For more information, refer to Tables 9 and 10 in the DVB-S2 standard [1] and Table 17a in the DVB-S2X standard [2].

**Dependencies**

This input argument applies only when `stdSuffix` is set to 's2' or 's2x'.

Data Types: char | string

**frameLength — Frame length**

'normal' (default) | 'short'

Frame length, specified as 'normal' or 'short'. The function uses `frameLength` and `codeIDF` to select the modulation parameters.

**Dependencies**

This input argument applies only when `stdSuffix` is set to 's2' or 's2x'.

Data Types: char | string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `y = dvbsapskdemod(x,M,stdSuffix,'InputType','bit','OutputDataType','single');`

### OutputType — Output type

`'integer'` (default) | `'bit'` | `'llr'` | `'approxllr'`

Output type, specified as the comma-separated pair consisting of `OutputType` and `'integer'`, `'bit'`, `'llr'`, or `'approxllr'`. For a description of returned output, see [z](#).

Data Types: `char` | `string`

### OutputDataType — Output data type

`'double'` (default) | ...

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and one of the indicated data types. Acceptable values for `OutputDataType` depend on the `OutputType` value.

OutputType Value	Acceptable OutputDataType Values
<code>'integer'</code>	<code>'double'</code> , <code>'single'</code> , <code>'int8'</code> , <code>'int16'</code> , <code>'int32'</code> , <code>'uint8'</code> , <code>'uint16'</code> , or <code>'uint32'</code>
<code>'bit'</code>	<code>'double'</code> , <code>'single'</code> , <code>'int8'</code> , <code>'int16'</code> , <code>'int32'</code> , <code>'uint8'</code> , <code>'uint16'</code> , <code>'uint32'</code> , or <code>'logical'</code>

### Dependencies

This name-value pair argument applies only when `OutputType` is set to `'integer'` or `'bit'`.

Data Types: `char` | `string`

### UnitAveragePower — Unit average power flag

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `UnitAveragePower` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1] and [2].

---

**Note** When `stdSuffix` is set to `'sh'`, the constellation always has unit average power.

---

### Dependencies

This name-value pair argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `logical`

### NoiseVariance — Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of `NoiseVariance` and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “DVB Compliant APSK Soft Demodulation” on page 2-492 for algorithm selection considerations.

### Dependencies

This name-value pair argument applies only when `OutputType` is set to `'llr'` or `'approxllr'`.

Data Types: `double`

### PlotConstellation — Option to plot constellation

`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: logical

## Output Arguments

### **z** — Demodulated signal

scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of the output vary depending on the specified `OutputType` value.

OutputType Value	Return Value of dvbsapskdemod	Dimensions of z
'integer'	Demodulated integer values from 0 to (M - 1)	z has the same dimensions as input y.
'bit'	Demodulated bits	The number of rows in z is $\log_2(\text{sum}(M))$ times the number of rows in y. Each demodulated symbol is mapped to a group of $\log_2(\text{sum}(M))$ elements in a column, where the first element represents the MSB and the last element represents the LSB.
'llr'	Log-likelihood ratio value for each bit	
'approxllr'	Approximate log-likelihood ratio value for each bit	

## More About

### DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see specified in [1], [2], and [3], respectively.

### DVB Compliant APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [4].

## DVB Compliant APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

---

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- $-\infty$  or  $\infty$  if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

---

# dvbsapskmod

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) modulation

## Syntax

```
y = dvbsapskmod(x,M,stdSuffix)
y = dvbsapskmod(x,M,stdSuffix,codeIDF)
y = dvbsapskmod(x,M,stdSuffix,codeIDF,frameLength)
y = dvbsapskmod( ____,Name,Value)
```

## Description

`y = dvbsapskmod(x,M,stdSuffix)` performs APSK modulation on the input signal, `x`, in accordance with the digital video broadcast (DVB) standard identified by `stdSuffix` and the modulation order, `M`.

`y = dvbsapskmod(x,M,stdSuffix,codeIDF)` specifies the code identifier, `codeIDF`, to use when selecting the modulation parameters.

`y = dvbsapskmod(x,M,stdSuffix,codeIDF,frameLength)` specifies `codeIDF` and `frameLength` to use when selecting the modulation parameters.

`y = dvbsapskmod( ____,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, 'OutputDataType', 'double' specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

## Examples

### Apply DVB-S2X 32-APSK Modulation to Data

Modulate data using the DVB-S2X standard specified 32-APSK modulation scheme. Display the result in a scatter plot.

Set the modulation order and the suffix identifying the DVB-S2X standard. Create a data vector with all possible symbols.

```
M = 32;  
stdSuffix = 's2x';  
x = (0:M-1);
```

Modulate the data.

```
y = dvbsapskmod(x,M,stdSuffix);
```

Display the constellation using a scatter plot.

```
scatterplot(y)
```

### **Apply DVB-S2X 64-APSK Modulation Specifying Code Identifier**

Modulate data using 64-APSK as specified in DVB-S2X standard. Plot constellation for different code identifiers.

Set the modulation order and standard suffix. Generate 1000 symbols of random data in one channel.

```
M = 64;  
std = 's2x';  
x = randi([0 M-1],1000,1);
```

Modulate the data according to the 64-APSK constellation for the code identifier 7/9 and plot the reference constellation.

```
y1 = dvbsapskmod(x,M,std,'7/9','PlotConstellation',true);
```

**DVB-S2x 64(8+16+20+20)-APSK with Code Rate 7/9, UnitAveragePower=false**

Modulate setting the code identifier to 132/180 and observe the constellation structure differences.

```
y2 = dvbsapskmod(x,M,std,'132/180','PlotConstellation',true);
```

### DVB-S2x 64(4+12+20+28)-APSK with Code Rate 132/180, UnitAveragePower=false

#### Apply DVB-S2 16-APSK Modulation Change Frame Length

Modulate data using 16-APSK as specified in DVB-S2 standard for normal and short frame lengths. Compute the output signal power.

Set the modulation order and the standard suffix. Generate random bit data for 1000 symbols in one channel.

```
M = 16;
std = 's2';
x = randi([0 1],1000*log2(M),1);
```

Set the input type to bit and modulate the data according to the 16-APSK constellation for code identifier 2/3. Use the default normal frame length.

```
y1 = dvbsapskmod(x,M,std,'2/3','InputType','bit');
```

Modulate the data using different settings, set the code-identifier to 8/9 and use a short frame length.

```
y2 = dvbsapskmod(x,M,std,'8/9','short','InputType','bit');
```

The average power of the modulated signal changes based on the code identifier. Compute the average power of the modulated signals.

```
y1avgPow = mean(abs(y1).^2)
```

```
y1avgPow = 0.7590
```

```
y2avgPow = mean(abs(y2).^2)
```

```
y2avgPow = 0.7716
```

### Normalize 16-APSK Modulated DVB Signals by Average Power

Modulate data applying 16-APSK as specified in the DVB-SH and DVB-S2 standards. Normalize the modulator output so that it has an average signal power of 1 W.

Set the modulation order and generate all possible symbols.

```
M = 16;  
x = 0:M-1;
```

Modulate the data applying 16-APSK as specified in DVB-SH. Use a name-value pair to specify single data type output.

```
y1 = dvbsapskmod(x,M,'sh','OutputDataType','single');
```

Modulate the data applying 16-APSK as specified in DVB-S2. Use a name-value pair to specify single data type output.

```
y2 = dvbsapskmod(x,M,'s2','OutputDataType','single');
```

Modulate the data applying 16-APSK as specified in DVB-S2. Use name-value pairs to set unit average power to true and to specify single data type output.

```
y3 = dvbsapskmod(x,M, 's2', 'UnitAveragePower', true, 'OutputDataType', 'single');
```

Check which signals have unit average power.

```
y1avgPow = mean(abs(y1).^2)
```

```
y1avgPow = single
          1
```

```
y2avgPow = mean(abs(y2).^2)
```

```
y2avgPow = single
          0.7752
```

```
y3avgPow = mean(abs(y3).^2)
```

```
y3avgPow = single
          1.0000
```

## Input Arguments

### **x** — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of **x** must be binary values or integers that range from 0 to ( $M - 1$ ), where  $M$  is the modulation order.

---

**Note** To process the input signal as binary elements, set 'InputType' value to 'bit'. For binary inputs, the number of rows must be an integer multiple of  $\log_2(M)$ . A group of  $\log_2(M)$  bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

---

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical

### **M** — Modulation order

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Data Types: double

**stdSuffix — Standard suffix**

's2' | 's2x' | 'sh'

Standard suffix for DVBS modulation variant, specified as 's2', 's2x', or 'sh'.

Data Types: char | string

**codeIDF — Code identifier**

char | string

Code identifier, specified as a character vector or string. This table lists the acceptable codeIDF values.

Constellation Order (M)	Applicable Standard (stdSuffix)	Acceptable Code Identifier (CodeIDF) Values
16	's2' or 's2x'	'2/3', '3/4', '4/5', '5/6', '8/9', '9/10'
16	's2x'	'26/45', '3/5', '28/45', '23/36', '25/36', '13/18', '7/9', '77/90', '100/180', '96/180', '90/180', '18/30', '20/30'
32	's2' or 's2x'	'3/4', '4/5', '5/6', '8/9', '9/10'
32	's2x'	'32/45', '11/15', '7/9', '2/3'
64	's2x'	'11/15', '7/9', '4/5', '5/6', '128/180'
128	's2x'	'3/4', '7/9'
256	's2x'	'32/45', '3/4', '116/180', '20/30', '124/180', '22/30'

For more information, refer to Tables 9 and 10 in the DVB-S2 standard, [1], and Table 17a in the DVB-S2X standard, [2].

**Dependencies**

This input argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `char` | `string`

**frameLength — Frame length**

`'normal'` (default) | `'short'`

Frame length, specified as `'normal'` or `'short'`. `frameLength` and `codeIDF` are used to determine the modulation parameters.

**Dependencies**

This input argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `char` | `string`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

Example: `y = dvbsapskmod(x,M,std,'InputType','bit','OutputDataType','single');`

**InputType — Input type**

`'integer'` (default) | `'bit'`

Input type, specified as the comma-separated pair consisting of `'InputType'` and either `'integer'` or `'bit'`. To use `'integer'`, the input signal must consist of integer values from 0 to  $(M - 1)$ . To use `'bit'`, the input signal must contain binary values and the number of rows must be an integer multiple of  $\log_2(M)$ .

Data Types: `char` | `string`

**UnitAveragePower — Unit average power flag**

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is

false, the function scales the constellation based on specifications in the relevant standard, as described in [1] and [2].

---

**Note** When `stdSuffix` is set to 'sh', the constellation always has unit average power.

---

### Dependencies

This name-value pair argument applies only when `stdSuffix` is set to 's2' or 's2x'.

Data Types: `logical`

### OutputDataType — Output data type

'double' (default) | 'single'

Output data type, specified as the comma-separated pair consisting of 'OutputDataType' and either 'double' or 'single'.

Data Types: `char` | `string`

### PlotConstellation — Option to plot constellation

false (default) | true

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the constellation, set `PlotConstellation` to true.

Data Types: `logical`

## Output Arguments

### y — Modulated signal

scalar | vector | matrix

Modulated signal, returned as a complex scalar, vector, or matrix. The dimensions of y depend on the specified 'InputType' value.

'InputType' Value	Dimensions of y
'integer'	y has the same dimensions as input x.

'InputType' Value	Dimensions of y
'bit'	The number of rows in y equals the number of rows in x divided by $\log_2(M)$ .

Data Types: double | single

## More About

### DVB-S2/S2X/SH

# encode

Block encoder

## Syntax

```
code = encode(msg,n,k,'linear/fmt',genmat)
code = encode(msg,n,k,'cyclic/fmt',genpoly)
code = encode(msg,n,k,'hamming/fmt',prim_poly)
code = encode(msg,n,k)
[code,added] = encode(...)
```

## Optional Inputs

Input	Default Value
<i>fmt</i>	binary
genpoly	cyclpoly(n,k)
prim_poly	gfprimdf(n-k)

## Description

### For All Syntaxes

The encode function encodes messages using one of the following error-correction coding methods:

- Linear block
- Cyclic
- Hamming

For all of these methods, the codeword length is  $n$  and the message length is  $k$ .

`msg`, which represents the messages, can have one of several formats. The **Information Formats** table shows which formats are allowed for `msg`, how the argument `fmt` should reflect the format of `msg`, and how the format of the output code depends on these choices. The examples in the table are for  $k = 4$ . If `fmt` is not specified as input, its default value is `binary`.

### Information Formats

Dimension of <code>msg</code>	Value of <code>fmt</code> Argument	Dimension of code
Binary column or row vector	<code>binary</code>	Binary column or row vector
Example: <code>msg = [0 1 1 0, 0 1 0 1, 1 0 0 1].'</code>		
Binary matrix with $k$ columns	<code>binary</code>	Binary matrix with $n$ columns
Example: <code>msg = [0 1 1 0; 0 1 0 1; 1 0 0 1]</code>		
Column or row vector of integers in the range $[0, 2^k - 1]$	<code>decimal</code>	Column or row vector of integers in the range $[0, 2^n - 1]$
Example: <code>msg = [6, 10, 9].'</code>		

---

**Note** If  $2^n$  or  $2^k$  is large, use the default `binary` format instead of the `decimal` format. This is because the function uses a binary format internally, while the roundoff error associated with converting many bits to large decimal numbers and back might be substantial.

---

### For Specific Syntaxes

`code = encode(msg, n, k, 'linear/fmt', genmat)` encodes `msg` using `genmat` as the generator matrix for the linear block encoding method. `genmat`, a  $k$ -by- $n$  matrix, is required as input.

`code = encode(msg, n, k, 'cyclic/fmt', genpoly)` encodes `msg` and creates a systematic cyclic code. `genpoly` is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of the binary generator polynomial. The default value of `genpoly` is `cyclpoly(n, k)`. By definition, the generator polynomial for an  $[n, k]$  cyclic code must have degree  $n - k$  and must divide  $x^n - 1$ .

`code = encode(msg,n,k,'hamming/fmt',prim_poly)` encodes `msg` using the Hamming encoding method. For this syntax, `n` must have the form  $2^m-1$  for some integer `m` greater than or equal to 3, and `k` must equal `n-m`. `prim_poly` is a polynomial character vector or a row vector that gives the binary coefficients, in order of ascending powers, of the primitive polynomial for  $GF(2^m)$  that is used in the encoding process. The default value of `prim_poly` is the default primitive polynomial `gfprimdf(m)`.

`code = encode(msg,n,k)` is the same as `code = encode(msg,n,k,'hamming/binary')`.

`[code,added] = encode(...)` returns the additional variable `added`. `added` is the number of zeros that were placed at the end of the message matrix before encoding in order for the matrix to have the appropriate shape. “Appropriate” depends on `n`, `k`, the shape of `msg`, and the encoding method.

## Examples

### Encoding and Decoding with Linear Block Codes

Encode and decode corrupted data using three types of linear block codes.

#### Hamming Code

Set the code parameters.

```
n = 15;           % Code length
k = 11;          % Message length
```

Create a binary message having length `k`.

```
data = randi([0 1],k,1);
```

Encode the message.

```
encData = encode(data,n,k,'hamming/binary');
```

Introduce an error in the 4th bit of the encoded sequence.

```
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'hamming/binary');  
numerr = biterr(data,decData)  
numerr = 0
```

### Linear Block Code

Set the code parameters.

```
n = 7;           % Code length  
k = 3;           % Message length
```

Create a binary message having length k.

```
data = randi([0 1],k,1);
```

Create a cyclic generator polynomial. Then, create a parity-check matrix and convert it into a generator matrix.

```
pol = cyclpoly(n,k);  
parmat = cyclgen(n,pol);  
genmat = gen2par(parmat);
```

Encode the message sequence by using the generator matrix.

```
encData = encode(data,n,k,'linear/binary',genmat);
```

Introduce an error in the 3rd bit of the encoded sequence.

```
encData(3) = ~encData(3);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'linear/binary',genmat);
```

```
Single-error patterns loaded in decoding table. 8 rows remaining.  
2-error patterns loaded. 1 rows remaining.  
3-error patterns loaded. 0 rows remaining.
```

```
numerr = biterr(data,decData)
```

```
numerr = 0
```

### Cyclic Code

Set the code parameters.

```
n = 15;           % Code length
k = 5;           % Message length
```

Create a binary message having length k.

```
data = randi([0 1],k,1);
```

Create a generator polynomial for a cyclic code. Create a parity-check matrix by using the generator polynomial.

```
gpoly = cyclpoly(n,k);
parmat = cyclgen(n,gpoly);
```

Create a syndrome decoding table by using the parity-check matrix.

```
trt = syndtable(parmat);
```

```
Single-error patterns loaded in decoding table. 1008 rows remaining.
2-error patterns loaded. 918 rows remaining.
3-error patterns loaded. 648 rows remaining.
4-error patterns loaded. 243 rows remaining.
5-error patterns loaded. 0 rows remaining.
```

Encode the data by using the generator polynomial.

```
encData = encode(data,n,k,'cyclic/binary',gpoly);
```

Introduce errors in the 4th and 7th bits of the encoded sequence.

```
encData(4) = ~encData(4);
encData(7) = ~encData(7);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'cyclic/binary',gpoly,trt);
numerr = biterr(data,decData)
```

```
numerr = 0
```

### Algorithms

Depending on the encoding method, `encode` relies on such lower-level functions as `hamngen` and `cyclgen`.

**Introduced before R2006a**

# equalize

(To be removed) Equalize signal using equalizer object

---

**Note** will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

---

## Syntax

```
y = equalize(eqobj,x)
y = equalize(eqobj,x,trainsig)
[y,yd] = equalize(...)
[y,yd,e] = equalize(...)
```

## Description

`y = equalize(eqobj,x)` processes the baseband signal vector `x` with equalizer object `eqobj` and returns the equalized signal vector `y`. At the end of the process, `eqobj` contains updated state information such as equalizer weight values and input buffer values. To construct `eqobj`, use the `lineareq` or `dfe` function. The `equalize` function assumes that the signal `x` is sampled at `nsamp` samples per symbol, where `nsamp` is the value of the `nSampPerSym` property of `eqobj`. For adaptive algorithms other than CMA, the equalizer adapts in decision-directed mode using a detector specified by the `SigConst` property of `eqobj`. The delay of the equalizer is  $(eqobj.RefTap - 1) / eqobj.nSampPerSym$ .

Note that  $(eqobj.RefTap - 1)$  must be an integer multiple of `nSampPerSym`. For a fractionally-spaced equalizer, the taps are spaced at fractions of a symbol period. The reference tap pertains to training symbols, and thus, must coincide with a whole number of symbols (i.e., an integer number of samples per symbol). `eqobj.RefTap=1` corresponds to the first symbol, `eqobj.RefTap=nSampPerSym+1` to the second, and so on. Therefore  $(eqobj.RefTap - 1)$  must be an integer multiple of `nSampPerSym`.

If `eqobj.ResetBeforeFiltering` is 0, `equalize` uses the existing state information in `eqobj` when starting the equalization operation. As a result, `equalize(eqobj,[x1`

`x2]`) is equivalent to `[equalize(eqobj,x1) equalize(eqobj,x2)]`. To reset `eqobj` manually, apply the `reset` function to `eqobj`.

If `eqobj.ResetBeforeFiltering` is 1, `equalize` resets `eqobj` before starting the equalization operation, overwriting any previous state information in `eqobj`.

`y = equalize(eqobj,x,trainseq)` initially uses a training sequence to adapt the equalizer. After processing the training sequence, the equalizer adapts in decision-directed mode. The vector length of `trainseq` must be less than or equal to `length(x) - (eqobj.RefTap-1)/eqobj.nSampPerSym`.

`[y,yd] = equalize(...)` returns the vector `yd` of detected data symbols.

`[y,yd,e] = equalize(...)` returns the result of the error calculation. For adaptive algorithms other than CMA, `e` is the vector of errors between `y` and the reference signal, where the reference signal consists of the training sequence or detected symbols.

## Examples

### Equalize Using a Training Sequence

You can equalize a signal by using the `equalize` function to apply an adaptive equalizer object to the signal. The `equalize` function also updates the equalizer.

In typical applications, an equalizer begins by using a known sequence of transmitted symbols when adapting the equalizer weights. The known sequence, called a *training sequence*, enables the equalizer to gather information about the channel characteristics. After the equalizer finishes processing the training sequence, it adapts the equalizer weights in decision-directed mode using a detected version of the output signal. To use a training sequence when invoking the `equalize` function, include the symbols of the training sequence as an input vector.

Note as an exception, that CMA equalizers do not use a training sequence. If an equalizer object is based on CMA, you should not include a training sequence as an input vector.

This code illustrates how to use `equalize` with a training sequence. The training sequence in this case is just the beginning of the transmitted message.

### Set up parameters and signals.

```
M = 4; % Alphabet size for modulation
msg = randi([0 M-1],1500,1); % Random message
qpskMod = comm.QPSKModulator('PhaseOffset',0);
modmsg = qpskMod(msg); % Modulate using QPSK.
trainlen = 500; % Length of training sequence
chan = [.986; .845; .237; .123+.311i]; % Channel coefficients
filtmsg = filter(chan,1,modmsg); % Introduce channel distortion.
```

### Equalize the received signal.

```
eq1 = lineareq(8, lms(0.01)); % Create an equalizer object.
eq1.SigConst = qpskMod((0:M-1)'); % Set signal constellation.
[symbolest,yd] = equalize(eq1,filtmsg,modmsg(1:trainlen)); % Equalize.
```

### Compute error rates with and without equalization

Determine the number of errors that occurred in trying to recover the modulated message with and without the equalizer. The symbol error rates show that the equalizer improves the performance significantly.

```
qpskDemod = comm.QPSKDemodulator('PhaseOffset',0);
demodmsg_noeq = qpskDemod(filtmsg); % Demodulate unequalized signal.
demodmsg = qpskDemod(yd); % Demodulate detected signal from equalizer.
errorCalc = comm.ErrorRate; % ErrorRate calculator
ser_noEq = errorCalc(msg(trainlen+1:end), demodmsg_noeq(trainlen+1:end));
reset(errorCalc)
ser_Eq = errorCalc(msg(trainlen+1:end),demodmsg(trainlen+1:end));
disp('Symbol error rates with and without equalizer:')
```

Symbol error rates with and without equalizer:

```
disp([ser_Eq(1) ser_noEq(1)])
      0      0.3230
```

### Plot the signals

Create a scatter plot showing the signal before and after equalization, as well as the reference signal constellation for QPSK modulation. The points of the equalized signal are clustered more closely around the points of the reference signal constellation, indicating the signal improvement from equalization.

```
h = scatterplot(filtmsg,1,trainlen,'bx'); hold on;
scatterplot(symbolest,1,trainlen,'g.',h);
```

```
scatterplot(eq1.SigConst,1,0,'k*',h);
legend('Filtered signal','Equalized signal',...
       'Ideal signal constellation');
hold off;
```

For more examples that use training sequences, see “Adaptive Equalization”.

### Equalizing Multiple Times Varying Mode

If you invoke `equalize` multiple times with the same equalizer object to equalize a series of signal vectors, you might use a training sequence the first time you call the function and omit the training sequence in subsequent calls. Each iteration of the `equalize`

function after the first one operates completely in decision-directed mode. However, because the `ResetBeforeFiltering` property of the equalizer object is set to 0, the `equalize` function uses the existing state information in the equalizer object when starting equalization operation for each iteration. As a result, the training affects all equalization operations, not just the first.

Notice in this code that the first call to `equalize` uses a training sequence as an input argument, and the second call to `equalize` omits a training sequence.

### Set up the signal transmission

Create a signal, QPSK modulate it, then filter it through a distortion channel.

```
M = 4; % Alphabet size for modulation
msg = randi([0 M-1],1500,1); % Random message
qpskMod = comm.QPSKModulator('PhaseOffset',0);
modmsg = qpskMod(msg); % Modulate using QPSK
```

```
chan = [.986; .845; .237; .123+.31i]; % Channel coefficients
filtmsg = filter(chan,1,modmsg); % Introduce channel distortion
```

### Set up equalizer

Specify equalizer parameters and create an lms equalizer object

```
trainlen = 500; % Length of training sequence
eqlms = lineareq(8, lms(0.01)); % Create an equalizer object
eqlms.SigConst = qpskMod((0:M-1)'); % Set signal constellation parameter in the equalizer
```

Maintain continuity between calls to `equalize`.

```
eqlms.ResetBeforeFiltering = 0;
```

### Equalize the received signal in pieces

Process the training sequence.

```
s1 = equalize(eqlms,filtmsg(1:trainlen),modmsg(1:trainlen));
```

Process some of the data in decision-directed mode.

```
s2 = equalize(eqlms,filtmsg(trainlen+1:800));
```

Process the rest of the data in decision-directed mode.

```
s3 = equalize(eqlms, filtmsg(801:end));
```

Concatenate the signal segments to get the full output of equalizer.

```
s = [s1; s2; s3];
```

### Delays from Equalization

For proper equalization using adaptive algorithms other than CMA, you should set the reference tap so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay between the modulator output and the equalizer output is equal to  $(\text{RefTap} - 1) / n\text{SampPerSym}$  symbols. Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap in a linear equalizer, or the center tap of the forward filter in a decision-feedback equalizer.

For CMA equalizers, the expression above does not apply because a CMA equalizer has no reference tap. If you need to know the delay, you can find it empirically after the equalizer weights have converged. Use the `xcorr` function to examine cross-correlations of the modulator output and the equalizer output.

### Techniques for Working with Delays

Here are some typical ways to take a delay of  $D$  into account by padding or truncating data:

- Pad your original data with  $D$  extra symbols at the end. Before comparing the original data with the received data, omit the first  $D$  symbols of the received data. In this approach, all the original data (not including the padding) is accounted for in the received data.
- Before comparing the original data with the received data, omit the last  $D$  symbols of the original data and the first  $D$  symbols of the received data. In this approach, some of the original symbols are not accounted for in the received data.

This example illustrates the second approach by omitting the last  $D$  symbols to account for the delay. For an example that illustrates both approaches in the context of interleavers, see “Delays of Convolutional Interleavers”.

Create a random signal and BPSK modulate it. Assign a portion of the signal as a training signal.

```

M = 2; % Use BPSK modulation
msg = randi([0 M-1],1000,1); % Random data
bpskMod = comm.BPSKModulator('PhaseOffset',0);
modmsg = bpskMod(msg); % Modulate
trainlen = 100; % Length of training sequence
trainsig = modmsg(1:trainlen); % Training sequence

```

Define an equalizer and equalize the received signal.

```

eqlin = lineareq(3,normlms(.0005,.0001),pskmod(0:M-1,M));
eqlin.RefTap = 2; % Set reference tap of equalizer.
[eqsig,detsym] = equalize(eqlin,modmsg,trainsig); % Equalize.

```

Demodulate the detected signal.

```

bpskDemod = comm.BPSKDemodulator('PhaseOffset',0);
detmsg = bpskDemod(detsym);

```

Compute bit error rate while compensating for delay introduced by RefTap and ignoring training sequence.

```

D = (eqlin.RefTap-1)/eqlin.nSampPerSym;
hErrorCalc = comm.ErrorRate('ReceiveDelay',D);
berVec = step(hErrorCalc, msg(trainlen+1:end), detmsg(trainlen+1:end));
ber = berVec(1)

```

```
ber = 0
```

```
numerrs = berVec(2)
```

```
numerrs = 0
```

## Compatibility Considerations

### **equalize will be removed**

*Not recommended starting in R2019a*

equalize will be removed. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

# evdoForwardReferenceChannels

Define 1xEV-DO forward reference channel

## Syntax

```
cfg = evdoForwardReferenceChannels(wv)
cfg = evdoForwardReferenceChannels(wv,numpackets)
```

## Description

`cfg = evdoForwardReferenceChannels(wv)` returns a structure, `cfg`, that defines 1xEV-DO forward link parameters given the input waveform identifier, `wv`. Pass this structure to the `evdoForwardWaveformGenerator` function to generate a forward link reference channel waveform.

For all syntaxes, `evdoForwardReferenceChannels` creates a configuration structure that is compliant with the cdma2000 high data rate packet specification, [1].

`cfg = evdoForwardReferenceChannels(wv,numpackets)` specifies the number of packets to be generated.

## Examples

### Generate 1xEV-DO Release 0 Forward Link Waveform

Create a configuration structure for a Release 0 channel having a 921.6 kbps data rate and transmitted over two slots.

```
config = evdoForwardReferenceChannels('Re10-921600-2');
```

Display the number of slots and the data rate.

```
config.PacketSequence
```

```
ans = struct with fields:
  MACIndex: 0
  DataRate: 921600
  NumSlots: 2
```

Generate the complex waveform using the associated waveform generator function, `evdoForwardWaveformGenerator`.

```
wv = evdoForwardWaveformGenerator(config);
```

### Generate 1xEV-DO Revision A Forward Link Waveform

Create a structure to transmit a Revision A 1xEV-DO channel consisting of three 1024-bit packets transmitted over 2 slots with a 64-bit preamble length.

```
config = evdoForwardReferenceChannels('RevA-1024-2-64',3);
```

Verify that the function created a 1-by-3 structure array. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=3x4 struct
  MACIndex
  PacketSize
  NumSlots
  PreambleLength
```

Examine the first structure element to verify the packet size, number of slots, and preamble length match what you specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
  MACIndex: 0
  PacketSize: 1024
  NumSlots: 2
  PreambleLength: 64
```

Generate the waveform.

```
wv = evdoForwardWaveformGenerator(config);
```

## Input Arguments

### **wv** — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector.

Parameter Field	Values	Description
<b>wv</b>	'Rel0-38400-16'   'Rel0-76800-8'   'Rel0-153600-4'   'Rel0-307200-2'   'Rel0-307200-4'   'Rel0-614400-1'   'Rel0-614400-2'   'Rel0-921600-2'   'Rel0-1228800-1'   'Rel0-1228800-2'   'Rel0-1843200-1'   'Rel0-2457600-1'	Character vector representing the 1xEV-DO Release 0 reference channel with data rate in bps and number of slots. For example, you can specify 'Rel0-153600-4' to create a structure that represents a reference channel with a 153,600 bps data rate and uses four slots.

Parameter Field	Values	Description
	'RevA-128-1-64'   'RevA-128-2-128'   'RevA-128-4-256'   'RevA-128-4-1024'   'RevA-128-8-512'   'RevA-256-1-64'   'RevA-256-2-128'   'RevA-256-4-256'   'RevA-256-4-1024'   'RevA-256-8-512'   'RevA-256-16-1024'   'RevA-512-1-64'   'RevA-512-2-64'   'RevA-512-2-128'   'RevA-512-4-128'   'RevA-512-4-256'   'RevA-512-4-1024'   'RevA-512-8-512'   'RevA-512-16-1024'   'RevA-1024-1-64'   'RevA-1024-2-64'   'RevA-1024-2-128'   'RevA-1024-4-128'   'RevA-1024-4-256'   'RevA-1024-8-512'   'RevA-1024-16-1024'   'RevA-2048-1-64'   'RevA-2048-2-64'   'RevA-2048-4-128'   'RevA-3072-1-64'   'RevA-3072-2-64'   'RevA-4096-1-64'   'RevA-4096-2-64'   'RevA-5120-1-64'   'RevA-5120-2-64'	Character vector representing the 1xEV-DO Revision A reference channel with the packet size in bits, the number of slots, and the preamble length in chips. For example, you can specify 'RevA-256-1-64' to create a reference channel having a 256-bit packet, transmitted in one slot, with a 64-bit preamble length.

Example: 'Rel0-614400-2'

Example: 'RevA-4096-2-64'

Data Types: char

### **numpackets — Number of packets**

1 (default) | positive integer scalar

Number of packets, specified as a positive integer.

Example: 4

Data Types: double

## Output Arguments

### **cfg — Configuration of the parameters and channels used by the waveform generator**

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

#### **Top-Level Parameters and Substructures**

Parameter Field	Values	Description
<b>Release</b>	'Release0'   'RevisionA'	1xEV-DO
<b>PNOffset</b>	Nonnegative scalar integer [0, 511]	PN offset of the base station
<b>IdleSlotsWithControl</b>	'Off'   'On'	Include idle slots with control channels
<b>EnableControl</b>	'Off'   'On'	Enable control signaling
<b>NumChips</b>	Positive scalar integer	Number of chips in the waveform
<b>OversamplingRatio</b>	Positive scalar integer [1, 8]	Oversampling ratio at output
<b>FilterType</b>	'cdma2000Long'   'cdma2000short'   'Custom'   'Off'	Select filter type or disable filtering

Parameter Field	Values	Description
<b>CustomFilterCoefficients</b>	Real vector	Custom filter coefficients (applies when the <b>FilterType</b> field is set to 'Custom')
<b>InvertQ</b>	'Off'   'On'	Negate the quadrature output
<b>EnableModulation</b>	'Off'   'On'	Enable carrier modulation
<b>ModulationFrequency</b>	Nonnegative scalar integer	Carrier modulation frequency (applies when <b>EnableModulation</b> is 'On')
<b>PacketSequence</b>	Structure	See <b>PacketSequence</b> substructure.
<b>PacketDataSources</b>	Structure	See <b>PacketDataSources</b> substructure.

### PacketSequence Substructure

Include the **PacketSequence** substructure in the **cfg** structure to define a sequence of data packets for consecutive transmission. The **PacketSequence** substructure contains these fields.

Parameter Field	Values	Description
<b>MACIndex</b>	Positive scalar integer	MAC index associated with the packet
<b>Release 0</b>		
<b>DataRate</b>	38400   76800   153600   307200   614400   921600   1228800   1843200   2457600	Data rate (bps)
<b>NumSlots</b>	Positive scalar integer	Number of slots
<b>Revision A</b>		
<b>PacketSize</b>	128   256   512   1024   2048   3072   4096   5120	Packet size (bits)
<b>NumSlots</b>	1   2   4   8   16	Number of slots
<b>PreambleLength</b>	64   128   256   512   1024	Preamble length (chips)

### PacketDataSources Substructure

Include a **PacketDataSources** substructure in the **cfg** structure to define a set of matching data sources for each MAC index. The **PacketDataSources** substructure contains these fields.

Parameter Field	Values	Description
<b>MACIndex</b>	Positive scalar integer	MAC index associated with the packet
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>EnableCoding</b>	'Off'   'On'	Enable error correction coding

evdoForwardWaveformGenerator | evdoReverseReferenceChannels

**Introduced in R2015b**

## evdoForwardWaveformGenerator

Generate 1xEV-DO forward link waveform

### Syntax

```
waveform = evdoForwardWaveformGenerator(cfg)
```

### Description

`waveform = evdoForwardWaveformGenerator(cfg)` returns the 1xEV-DO forward link waveform as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties the function uses to generate a 1xEV-DO waveform. You can generate `cfg` by using the `evdoForwardReferenceChannels` function.

---

**Note** The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all parameter combinations are supported. To ensure that the input argument is valid, use the `evdoForwardReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

---

### Examples

#### Generate 1xEV-DO Revision A Forward Link Waveform

Create a structure to transmit a Revision A 1xEV-DO channel consisting of three 1024-bit packets transmitted over 2 slots with a 64-bit preamble length.

```
config = evdoForwardReferenceChannels('RevA-1024-2-64',3);
```

Verify that the function created a 1-by-3 structure array. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=3x4 struct
    MACIndex
    PacketSize
    NumSlots
    PreambleLength
```

Examine the first structure element to verify the packet size, number of slots, and preamble length match what you specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
    MACIndex: 0
    PacketSize: 1024
    NumSlots: 2
    PreambleLength: 64
```

Generate the waveform.

```
wv = evdoForwardWaveformGenerator(config);
```

### Generate 1xEV-DO Forward Link Waveform with Custom Filter

Create a structure to generate two packets of a 1.8 Mbps Release 0 channel.

```
config = evdoForwardReferenceChannels('Re10-1843200-1',2);
```

Calculate the sample rate of the waveform.

```
fs = 1.2288e6 * config.OversamplingRatio;
```

Disable the internal filter of the `evdoForwardWaveformGenerator` function. Generate the 1xEV-DO waveform. Plot the spectrum of the waveform.

```
config.FilterType = 'off';
wv = evdoForwardWaveformGenerator(config);

sa = dsp.SpectrumAnalyzer('SampleRate', fs);
step(sa,wv)
```

Create a lowpass FIR filter with a 500 kHz passband, a 750 kHz stopband, and a stopband attenuation of 60 dB.

```
d = designfilt('lowpassfir', ...
    'PassbandFrequency', 500e3, ...
    'StopbandFrequency', 750e3, ...
    'StopbandAttenuation', 60, ...
    'SampleRate', fs);
```

Change the filter type to 'Custom' and specify the coefficients from the digital filter, d.

```
config.FilterType = 'Custom';
config.CustomFilterCoefficients = d.Coefficients;
```

Generate the waveform using the custom filter coefficients.

```
wv = evdoForwardWaveformGenerator(config);
Plot the spectrum of the filtered 1xEV-DO waveform.
step(sa,wv)
```

The filter attenuates the waveform by 60 dB for frequencies outside of  $\pm 750$  kHz.

## Input Arguments

**cfg** — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

**Top-Level Parameters and Substructures**

Parameter Field	Values	Description
<b>Release</b>	'Release0'   'RevisionA'	1xEV-DO
<b>PNOffset</b>	Nonnegative scalar integer [0, 511]	PN offset of the base station

<b>PacketSequence</b>	Structure	See <b>PacketSequence substructure</b> .
<b>PacketDataSources</b>	Structure	See <b>PacketDataSources substructure</b> .

**PacketSequence Substructure**

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

Parameter Field	Values	Description
<b>MACIndex</b>	Positive scalar integer	MAC index associated with the packet

Parameter Field	Values	Description
<b>Release 0</b>		
<b>DataRate</b>	38400   76800   153600   307200   614400   921600   1228800   1843200   2457600	Data rate (bps)
<b>NumSlots</b>	Positive scalar integer	Number of slots
<b>Revision A</b>		
<b>PacketSize</b>	128   256   512   1024   2048   3072   4096   5120	Packet size (bits)
<b>NumSlots</b>	1   2   4   8   16	Number of slots
<b>PreambleLength</b>	64   128   256   512   1024	Preamble length (chips)

#### PacketDataSources Substructure

Include a `PacketDataSources` substructure in the `cfg` structure to define a set of matching data sources for each MAC index. The `PacketDataSources` substructure contains these fields.

Parameter Field	Values	Description
<b>MACIndex</b>	Positive scalar integer	MAC index associated with the packet
<b>DataSource</b>	Cell array, { 'PN Type', RN Seed } or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>EnableCoding</b>	'Off'   'On'	Enable error correction coding

## Output Arguments

**waveform** — **Modulated baseband waveform comprising the primary physical channels**

complex vector array

Modulated baseband waveform comprising the primary cdma2000 physical channels, returned as a complex vector array.

**Introduced in R2015b**

# evdoReverseReferenceChannels

Define 1xEV-DO reverse reference channel

## Syntax

```
cfg = evdoReverseReferenceChannels(wv)
cfg = evdoReverseReferenceChannels(wv,numpackets)
```

## Description

`cfg = evdoReverseReferenceChannels(wv)` returns a structure, `cfg`, that defines 1xEV-DO reverse link parameters given the input waveform identifier, `wv`. Pass this structure to the `evdoReverseWaveformGenerator` function to generate a reverse link reference channel waveform.

For all syntaxes, `evdoReverseReferenceChannels` creates a structure that is compliant with the cdma2000 high data rate packet specification,[1].

`cfg = evdoReverseReferenceChannels(wv,numpackets)` specifies the number of packets to be generated.

## Examples

### Generate 1xEV-DO Reverse Channel Waveform

Create a structure to generate a Release 0, 1xEV-DO waveform having a 19.2 kbps data rate.

```
config = evdoReverseReferenceChannels('Re10-19200');
```

Verify that the packet has a data rate of 19.2 kbps.

```
config.PacketSequence.DataRate
```

```
ans = 19200
```

Generate the complex waveform.

```
wv = evdoReverseWaveformGenerator(config);
```

### Generate 1xEV-DO Revision A Reverse Link Waveform

Create a structure for a Revision A 1xEV-DO channel having 2048-bit packets, transmitted in 12 slots. Specify that five packets are transmitted.

```
config = evdoReverseReferenceChannels('RevA-2048-12',5);
```

Verify that a 1-by-5 structure array is created. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=5x6 struct
    Power
    DataSource
    EnableCoding
    PayloadSize
    NumSlots
    DataRate
```

Examine the first structure element to verify the packet size and the number of slots are as specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
    Power: 0
    DataSource: {'PN9' [1]}
    EnableCoding: 'On'
    PayloadSize: 2048
    NumSlots: 12
    DataRate: 102400
```

Generate the waveform.

```
wv = evdoReverseWaveformGenerator(config);
```

## Input Arguments

### **wv** — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector.

Parameter Field	Values	Description
<b>wv</b>	'Rel0-9600'   'Rel0-19200'   'Rel0-38400'   'Rel0-76800'   'Rel0-153600'	Character vector representing the 1xEV-DO Release 0 data rate in bps. For example, you can specify 'Rel0-153600' to create a structure corresponding to a Release 0 reference channel having a 153,600 bps data rate.

Parameter Field	Values	Description
	'RevA-128-4' 'RevA-128-8' 'RevA-128-12' 'RevA-128-16' 'RevA-256-4' 'RevA-256-8' 'RevA-256-12' 'RevA-256-16' 'RevA-512-4' 'RevA-512-8' 'RevA-512-12' 'RevA-512-16' 'RevA-768-4' 'RevA-768-8' 'RevA-768-12' 'RevA-768-16' 'RevA-1024-4' 'RevA-1024-8' 'RevA-1024-12' 'RevA-1024-16' 'RevA-1536-4' 'RevA-1536-8' 'RevA-1536-12' 'RevA-1536-16' 'RevA-2048-4' 'RevA-2048-8' 'RevA-2048-12' 'RevA-2048-16' 'RevA-3072-4' 'RevA-3072-8' 'RevA-3072-12' 'RevA-3072-16' 'RevA-4096-4' 'RevA-4096-8' 'RevA-4096-12' 'RevA-4096-16' 'RevA-6144-4'	Character vector representing the 1xEV-DO Revision A packet size in bits and the number of slots. For example, you can specify 'RevA-256-4' to create a structure corresponding to a Revision A reference channel having 256-bit packets and transmitted in four slots.

Parameter Field	Values	Description
	'RevA-6144-8'   'RevA-6144-12'   'RevA-6144-16'   'RevA-8192-4'   'RevA-8192-8'   'RevA-8192-12'   'RevA-8192-16'   'RevA-12288-4'   'RevA-12288-8'   'RevA-12288-12'   'RevA-12288-16'	

Example: 'Rel0-38400'

Example: 'RevA-3072-12'

Data Types: char

#### **numpackets — Number of packets**

1 (default) | positive integer scalar

Number of packets, specified as a positive integer.

Example: 2

Data Types: double

## **Output Arguments**

### **cfg — Configuration of the parameters and channels used by the waveform generator**

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

**Top-Level Parameters and Substructures**

Parameter Field	Values	Description
<b>Release</b>	'Release0'   'RevisionA'	1xEV-DO applicable standard
<b>LongCodeMaskI</b>	42-bit binary number	Long code identifier for in-phase channel
<b>LongCodeMaskQ</b>	42-bit binary number	Long code identifier for quadrature channel
<b>NumChips</b>	Positive scalar integer	Number of chips in the waveform
<b>OversamplingRatio</b>	Positive scalar integer	Oversampling ratio at output
<b>FilterType</b>	'cdma2000Long'   'cdma2000Short'   'Custom'   'Off'	Specify the filter type or disable filtering
<b>CustomFilterCoefficients</b>	Real vector	Custom filter coefficients (applies when <b>FilterType</b> is set to 'Custom')
<b>InvertQ</b>	'Off'   'On'	Negate the quadrature output
<b>EnableModulation</b>	'Off'   'On'	Enable carrier modulation
<b>ModulationFrequency</b>	Nonnegative scalar integer	Carrier modulation frequency (applies when <b>EnableModulation</b> is 'On')
<b>ACKChannel</b>	Structure	See <b>ACKChannel</b> substructure.
<b>PilotChannel</b>	Structure	See <b>PilotChannel</b> substructure.
<b>AuxPilotChannel</b>	Not present or structure	See <b>AuxPilotChannel</b> substructure.
<b>PacketSequence</b>	Structure	See <b>PacketSequence</b> substructure.

**ACKChannel Substructure**

Include the **ACKChannel** substructure in the **cfg** structure to specify the acknowledgment channel. The **ACKChannel** substructure contains these fields.

Parameter Fields	Values	Description
<b>Enable</b>	'On'   'Off'	Character vector to enable or disable the channel
<b>Power</b>	Real scalar	Channel power (dBW)

Parameter Fields	Values	Description
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### PilotChannel Substructure

Include the PilotChannel substructure in the cfg structure to specify the pilot channel. The PilotChannel substructure contains these fields.

Parameter Fields	Values	Description
<b>Enable</b>	'On'   'Off'	Character vector to enable or disable the channel
<b>Power</b>	Real scalar	Channel power (dBW)
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>EnableCoding</b>	'On'   'Off'	Enable channel coding

### AuxPilotChannel Substructure

Include the AuxPilotChannel substructure in the cfg structure to specify the auxiliary pilot channel, which is available only for Revision A. The AuxPilotChannel substructure contains these fields.

Parameter Fields	Values	Description
<b>Enable</b>	'On'   'Off'	Character vector to enable or disable the channel
<b>Power</b>	Real scalar	Channel power (dBW)

Parameter Fields	Values	Description
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>EnableCoding</b>	'On'   'Off'	Enable channel coding

### PacketSequence Substructure

Include the PacketSequence substructure in the `cfg` structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

Parameter Field	Values	Description
<b>Power</b>	Real scalar	MAC index associated with the packet
<b>EnableCoding</b>	'Off'   'On'	Enable error correction coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>Release 0</b>		
<b>DataRate</b>	9600   19200   38400   76800   153600	Data rate (bps)
<b>Revision A</b>		
<b>PacketSize</b>	128   256   512   768   1024   1536   2048   3072   4096   6144   8192   12288	Packet size (bits)
<b>NumSlots</b>	4   8   12   16	Number of slots

Data Types: struct

**Introduced in R2015b**

# evdoReverseWaveformGenerator

Generate 1xEV-DO reverse link waveform

## Syntax

```
waveform = evdoReverseWaveformGenerator(cfg)
```

## Description

`waveform = evdoReverseWaveformGenerator(cfg)` returns the 1xEV-DO reverse link waveform as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties used by the function to generate a 1xEV-DO waveform. You can generate `cfg` by using the `evdoReverseReferenceChannels` function.

---

**Note** The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all parameter combinations are supported. To ensure that the input argument is valid, use the `evdoReverseReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

---

## Examples

### Generate 1xEV-DO Reverse Channel Waveform

Create a structure to generate a Release 0, 1xEV-DO waveform having a 19.2 kbps data rate.

```
config = evdoReverseReferenceChannels('Re10-19200');
```

Verify that the packet has a data rate of 19.2 kbps.

```
config.PacketSequence.DataRate  
ans = 19200  
  
Generate the complex waveform.  
wv = evdoReverseWaveformGenerator(config);
```

### **Generate 1xEV-DO Reverse Link Waveform with Custom Filter**

Create a structure to generate four packets of a Revision A channel having 768-bit packets transmitted over eight slots.

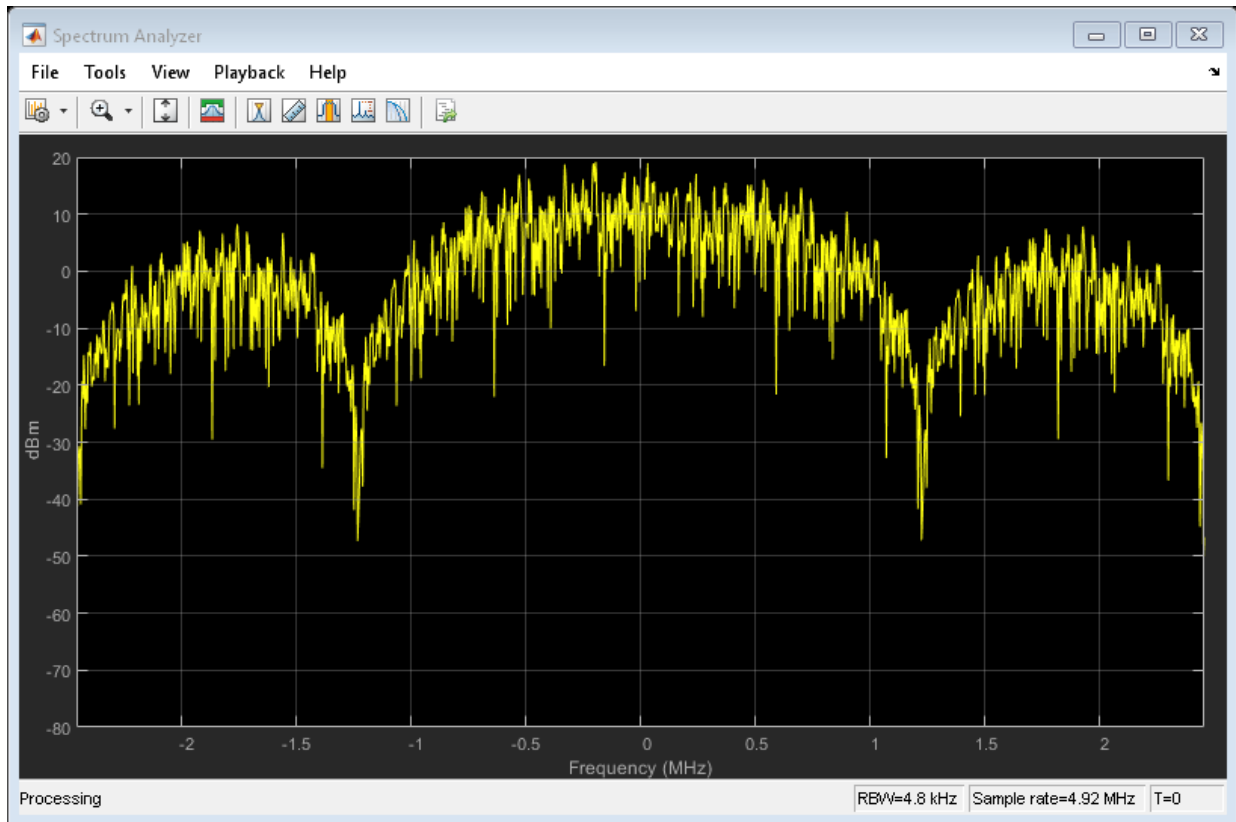

```
config = evdoReverseReferenceChannels('RevA-768-8',4);
```

Calculate the sample rate of the waveform.

```
fs = 1.2288e6 * config.OversamplingRatio;
```

Disable the internal filter of the `evdoReverseWaveformGenerator`. Generate the 1xEV-DO waveform. Plot the spectrum of the waveform.

```
config.FilterType = 'off';  
wv = evdoReverseWaveformGenerator(config);  
  
sa = dsp.SpectrumAnalyzer('SampleRate',fs);  
step(sa,wv)
```

Create a lowpass FIR filter with a 500 kHz passband, a 750 kHz stopband, and a stopband attenuation of 60 dB.

```
d = designfilt('lowpassfir', ...
    'PassbandFrequency',500e3, ...
    'StopbandFrequency',750e3, ...
    'StopbandAttenuation',60, ...
    'SampleRate',fs);
```

Change the filter type to 'Custom' and specify the coefficients from the digital filter, d.

```
config.FilterType = 'Custom';
config.CustomFilterCoefficients = d.Coefficients;
```

Generate the waveform using the custom filter coefficients.

```
wv = evdoReverseWaveformGenerator(config);
```

Plot the spectrum of the filtered 1xEV-DO waveform.

```
step(sa,wv)
```

The filter attenuates the waveform by 60 dB for frequencies outside of  $\pm 750$  kHz.

## Input Arguments

**cfg** — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

**Top-Level Parameters and Substructures**

Parameter Field	Values	Description
<b>Release</b>	'Release0'   'RevisionA'	1xEV-DO applicable standard
<b>LongCodeMaskI</b>	42-bit binary number	Long code identifier for in-phase channel
<b>LongCodeMaskQ</b>	42-bit binary number	Long code identifier for quadrature channel
<b>NumChips</b>	Positive scalar integer	Number of chips in the waveform
<b>OversamplingRatio</b>	Positive scalar integer	Oversampling ratio at output
<b>FilterType</b>	'cdma2000Long'   'cdma2000Short'   'Custom'   'Off'	Specify the filter type or disable filtering
<b>CustomFilterCoefficients</b>	Real vector	Custom filter coefficients (applies when <b>FilterType</b> is set to 'Custom')
<b>InvertQ</b>	'Off'   'On'	Negate the quadrature output
<b>EnableModulation</b>	'Off'   'On'	Enable carrier modulation
<b>ModulationFrequency</b>	Nonnegative scalar integer	Carrier modulation frequency (applies when <b>EnableModulation</b> is 'On')
<b>ACKChannel</b>	Structure	See <b>ACKChannel substructure</b> .
<b>PilotChannel</b>	Structure	See <b>PilotChannel substructure</b> .
<b>AuxPilotChannel</b>	Not present or structure	See <b>AuxPilotChannel substructure</b> .
<b>PacketSequence</b>	Structure	See <b>PacketSequence substructure</b> .

**ACKChannel Substructure**

Include the **ACKChannel** substructure in the **cfg** structure to specify the acknowledgment channel. The **ACKChannel** substructure contains these fields.

Parameter Fields	Values	Description
<b>Enable</b>	'On'   'Off'	Character vector to enable or disable the channel

Parameter Fields	Values	Description
<b>Power</b>	Real scalar	Channel power (dBW)
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

### PilotChannel Substructure

Include the `PilotChannel` substructure in the `cfg` structure to specify the pilot channel. The `PilotChannel` substructure contains these fields.

Parameter Fields	Values	Description
<b>Enable</b>	'On'   'Off'	Character vector to enable or disable the channel
<b>Power</b>	Real scalar	Channel power (dBW)
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>EnableCoding</b>	'On'   'Off'	Enable channel coding

### AuxPilotChannel Substructure

Include the `AuxPilotChannel` substructure in the `cfg` structure to specify the auxiliary pilot channel, which is available only for Revision A. The `AuxPilotChannel` substructure contains these fields.

Parameter Fields	Values	Description
<b>Enable</b>	'On'   'Off'	Character vector to enable or disable the channel

Parameter Fields	Values	Description
<b>Power</b>	Real scalar	Channel power (dBW)
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>EnableCoding</b>	'On'   'Off'	Enable channel coding

### PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

Parameter Field	Values	Description
<b>Power</b>	Real scalar	MAC index associated with the packet
<b>EnableCoding</b>	'Off'   'On'	Enable error correction coding
<b>DataSource</b>	Cell array, {'PN Type', RN Seed} or binary vector.  Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
<b>Release 0</b>		
<b>DataRate</b>	9600   19200   38400   76800   153600	Data rate (bps)
<b>Revision A</b>		
<b>PacketSize</b>	128   256   512   768   1024   1536   2048   3072   4096   6144   8192   12288	Packet size (bits)

Parameter Field	Values	Description
NumSlots	4   8   12   16	Number of slots

## Output Arguments

**waveform** — **Modulated baseband waveform comprising the physical channels**

complex vector array

Modulated baseband waveform comprising the 1xEV-DO physical channels, returned as a complex vector array.

## eyediagram

Generate eye diagram

### Syntax

```
eyediagram(x,n)
eyediagram(x,n,period)
eyediagram(x,n,period,offset)
eyediagram(x,n,period,offset,plotstring)
eyediagram(x,n,period,offset,plotstring,h)
h = eyediagram(...)
```

### Description

`eyediagram(x,n)` creates an eye diagram for the signal `x`, plotting `n` samples in each trace. `n` must be an integer greater than 1. The labels on the horizontal axis of the diagram range between  $-1/2$  and  $1/2$ . The function assumes that the first value of the signal, and every `n`th value thereafter, occur at integer times. The interpretation of `x` and the number of plots depend on the shape and complexity of `x`:

- If `x` is a real two-column matrix, `eyediagram` interprets the first column as in-phase components and the second column as quadrature components. The two components appear in different subplots of a single figure window.
- If `x` is a complex vector, `eyediagram` interprets the real part as in-phase components and the imaginary part as quadrature components. The two components appear in different subplots of a single figure window.
- If `x` is a real vector, `eyediagram` interprets it as a real signal. The figure window contains a single plot.

`eyediagram(x,n,period)` is the same as the syntax above, except that the labels on the horizontal axis range between  $-\text{period}/2$  and  $\text{period}/2$ .

`eyediagram(x,n,period,offset)` is the same as the syntax above, except that the function assumes that the  $(\text{offset}+1)$ st value of the signal, and every `n`th value

thereafter, occur at times that are integer multiples of `period`. The variable `offset` must be a nonnegative integer between 0 and `n-1`.

`eyediagram(x,n,period,offset,plotstring)` is the same as the syntax above, except that `plotstring` determines the plotting symbol, line type, and color for the plot. `plotstring` is a character vector whose format and meaning are the same as in the `plot` function. The default value is `'b-'`, which produces a blue solid line.

`eyediagram(x,n,period,offset,plotstring,h)` is the same as the syntax above, except that the eye diagram is in the figure whose handle is `h`, rather than in a new figure. `h` must be a handle to a figure that `eyediagram` previously generated.

---

**Note** You cannot use `hold on` to plot multiple signals in the same figure.

---

`h = eyediagram(...)` is the same as the earlier syntaxes, except that `h` is the handle to the figure that contains the eye diagram.

## Examples

For an online demonstration, type `showdemo scattereyedemo`.

## See Also

`comm.EyeDiagram` | `plot` | `scatterplot`

**Introduced before R2006a**

# EyeScope

(To be removed) Launch eye diagram scope for eye diagram object H

---

**Note** `eyescope` will be removed in a future release. Use `comm.EyeDiagram` instead.

---

## Syntax

`eyescope`  
`eyescope(h)`

## Description

Eye Diagram Scope is a graphical user interface (GUI) that enables you to visualize and measure the effects that various impairments, such as noise, jitter, and filtering, have on a modulated signal. The scope performs a probability density function (pdf) analysis on the signal to illustrate its trajectory in time, and to calculate such quantities as eye SNR, RMS jitter, rise time, and fall time. The scope also enables you to import and compare measurement results for eye diagrams of multiple signals.

There are two ways to call EyeScope:

- `eyescope` calls an empty scope
- `eyescope(h)` calls the scope and displays object h

---

**Note** You can call EyeScope with an eye diagram object as the input argument. EyeScope uses the `inputname` function to resolve the caller's work space name for the argument. If the `inputname` function cannot resolve the caller's work space name, then EyeScope uses a default name. To learn about the cases when EyeScope cannot determine the work space name, type `help inputname` at the MATLAB command line.

---

For more information, see “Eye Diagram Analysis”.

## Starting EyeScope

To start EyeScope from the MATLAB command line, type:

```
eyescope
```

The following figure shows an EyeScope that does not have an eye diagram object loaded in its memory.

Alternatively, you can start EyeScope so it displays an eye diagram object. To start EyeScope so it displays an eye diagram object, type the following at the MATLAB command line:

```
eyescope(h)
```

---

**Note**  $h$  is a handle to an eye diagram object in the workspace.

---

# The EyeScope Environment

- “EyeScope Menu Bar” on page 2-556
- “Eye Diagram Object Plot and Plot Controls” on page 2-556
- “Eye Diagram Object Settings Panel” on page 2-558
- “Measurements” on page 2-559

## EyeScope Menu Bar

EyeScope Menu Bar

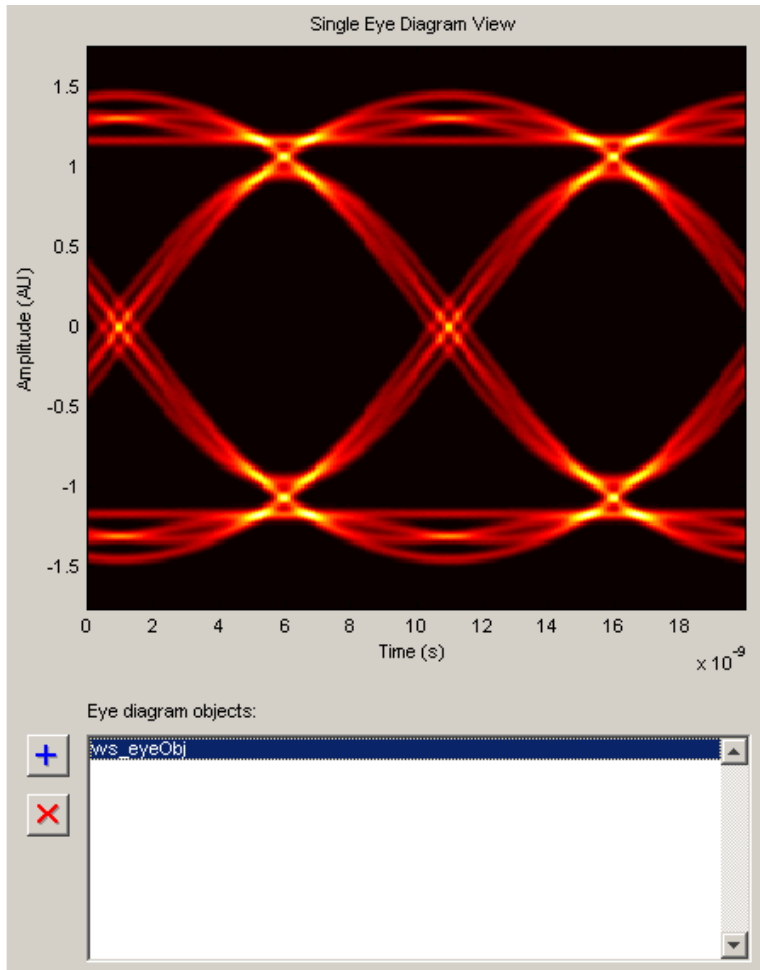

The EyeScope menu bar is comprised of four menus: File, Options, View, and Help.

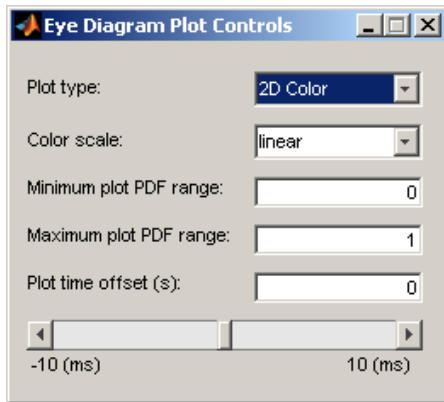

- Use the **File** menu to control the session management functions, import an eye diagram object into EyeScope, and export an eye diagram plot.
- Use the **Options** menu to setup the eye diagram scope by selecting which eye diagram settings and measurements EyeScope displays.
- Use the **View** menu to toggle between Single eye diagram view or Compare measurement results view, and to add or modify a legend for the eye diagram plot.
- The **Help** menu is used to access help pertaining to the eye diagram object and EyeScope.

## Eye Diagram Object Plot and Plot Controls

The Eye diagram object plot is the region of the GUI where the eye diagram plot appears.

Eye diagram plot controls are user-configurable settings that specify plot type, color scale, minimum and maximum plot PDF range, and plot time offset for the eye diagram being analyzed. To access the EyeScope plot controls **Options > Eye Diagram Plot Controls**

---

**Note** The value for the **Plot time offset** parameter can either be entered directly into the text box or set using the slide bar control.

---

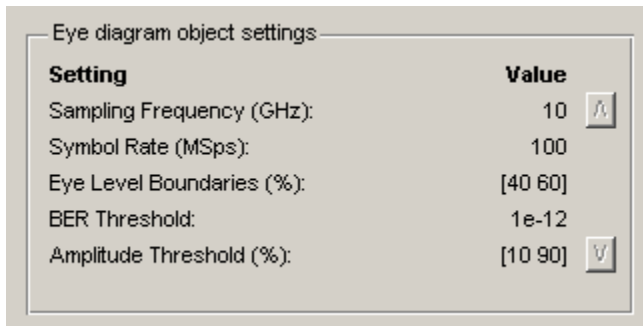

For more information pertaining to the eye diagram properties, refer to the `commscope.eyediagram` reference page.

### Eye Diagram Object Settings Panel

The eye diagram object settings panel displays the eye diagram object settings. The default EyeScope configuration displays the following eye diagram object settings:

- Sampling frequency
- Symbol rate
- Eye level boundaries
- BER threshold
- Amplitude threshold

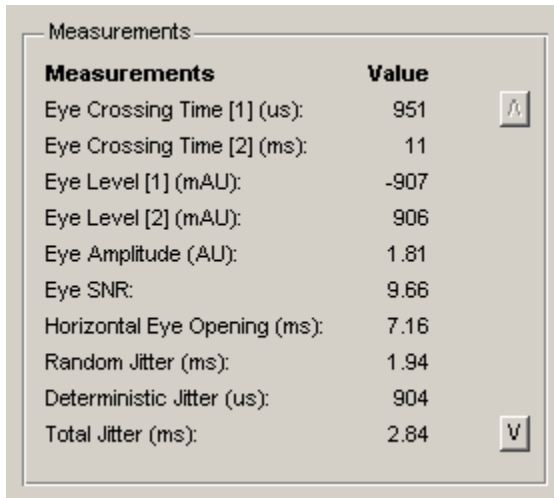

Setting	Value
Sampling Frequency (GHz):	10 <input type="button" value="A"/>
Symbol Rate (MSps):	100
Eye Level Boundaries (%):	[40 60]
BER Threshold:	1e-12
Amplitude Threshold (%):	[10 90] <input type="button" value="V"/>

To specify which eye diagram object settings display in EyeScope, refer to “Selecting Which Eye Diagram Object Settings To Display” on page 2-565. If you select additional eye diagram object settings to display in EyeScope, use the scroll buttons to view all of the settings.

## Measurements

The Measurements panel displays the eye diagram measurement settings. The default EyeScope configuration displays the following eye diagram object measurements:

- Horizontal Eye Opening
- Random Jitter
- Deterministic Jitter
- Total Jitter
- RMS Jitter
- Peak to Peak Jitter
- Vertical Opening
- Rise Time
- Fall Time
- Eye SNR

The screenshot shows a dialog box titled "Measurements" with a table of measurement data. The table has two columns: "Measurements" and "Value". There are also two small buttons, one with an upward arrow and one with a downward arrow, located to the right of the table.

Measurements	Value
Eye Crossing Time [1] (us):	951
Eye Crossing Time [2] (ms):	11
Eye Level [1] (mAU):	-907
Eye Level [2] (mAU):	906
Eye Amplitude (AU):	1.81
Eye SNR:	9.66
Horizontal Eye Opening (ms):	7.16
Random Jitter (ms):	1.94
Deterministic Jitter (us):	904
Total Jitter (ms):	2.84

To select which eye diagram measurements EyeScope displays, refer to “Selecting Which Eye Diagram Measurements To Display” on page 2-566. If you select additional eye diagram object measurements to display in EyeScope, use the scroll buttons to view all of the settings.

## Using EyeScope

- “Starting EyeScope with an Argument” on page 2-560
- “Starting a new Session” on page 2-561
- “Opening a Session” on page 2-561
- “Saving a Session” on page 2-562
- “Importing an Eye Diagram Object” on page 2-563
- “Printing to a Figure” on page 2-564
- “Selecting Which Eye Diagram Object Settings To Display” on page 2-565
- “Selecting Which Eye Diagram Measurements To Display” on page 2-566

## Starting EyeScope with an Argument

You can start EyeScope so it is displaying an eye diagram object. To start EyeScope so it is displaying an eye diagram object, type the following at the MATLAB command line:

eyescope(h)

---

**Note** *h* is a handle to an eye diagram object presently in the workspace.

---

## Starting a new Session

Starting a new session purges EyeScope memory, returning EyeScope to an empty plot display. If changes have been made to an open session and you start a new session, you will be prompted to save the open session.

## Opening a Session

To open session, choose the file name and location of the session file. The file extensions for a session file is .eds, which stands for eye diagram scope. If changes have been made to a session that is presently open and you try to open up a new session, you will be prompted to save the session that is presently open before the new session can start.

To open a session:

- 1 Click **File > Open Session**.

The Select File To Open Window appears.

- 2 Navigate to the EyeScope session file you want, and click **Open**.

## Saving a Session

The Save Session selection saves the current session, updating the session file. A session file includes the eye diagram object, eyescope options, and plot control selections.

If you attempt to save a session that you have not previously saved, EyeScope will prompt you for a file name and location. Otherwise, the session is saved to the previously selected file.

To save a session, follow these steps:

- 1 Click **File > Save Session**.
- 2 Navigate to the folder where you want to save the EyeScope session file and click **Save**.

## Importing an Eye Diagram Object

The **Import** menu selection imports an eye diagram object from either the workspace or a MAT-file to EyeScope. The imported variable name will be reconstructed to reflect the origin of the eye diagram object, as follows:

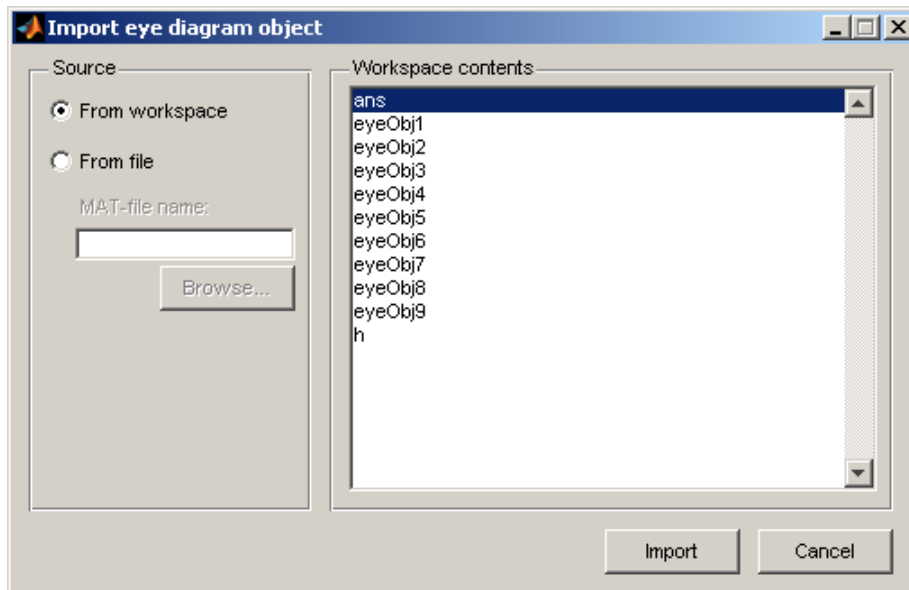

- If an object is imported from the workspace, the variable name will be *ws\_object name*, where *object name* is the name of the original variable.
- If the object is imported from a MATLAB file, then the file name (without the path) precedes the object name.

Importing an object creates a copy of the object, using the naming convention previously described. EyeScope displays the object's contents as configured when the object was imported. EyeScope does not track any object changes made in the workspace (or to the MATLAB file) from which the object was imported.

To import an eye diagram object:

### 1 Click **File > Import Eye Diagram Object**

The Import eye diagram object window appears.

The contents panel of the Import eye diagram object window displays all eye diagram objects available in the source location.

- 2 From the Import eye diagram object window, select the source for the object being imported.
  - Select **From workspace** to import an eye diagram object directly from the workspace.
  - Select **From File** to choose an eye diagram object file that was previously saved and click **Browse** to select the file to be loaded.
- 3 Click **Import**.

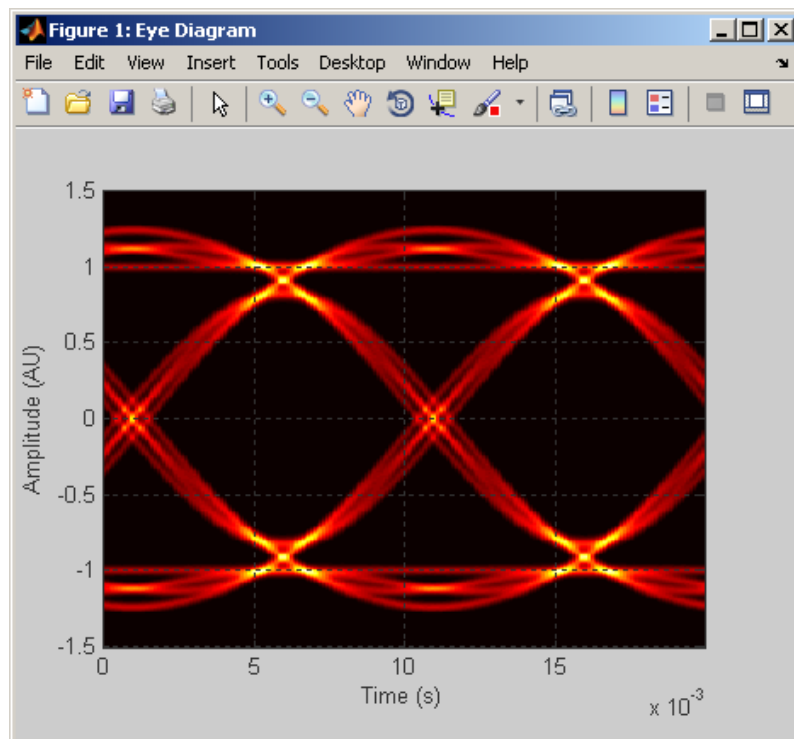

### Printing to a Figure

EyeScope allows you to print an eye diagram plot to a separate MATLAB figure window. From the MATLAB figure window, along with other tasks, you can print, zoom, or edit the plot.

To export an eye diagram figure:

- Click **File > Print to Figure**

The MATLAB figure window, containing the exported image, appears.

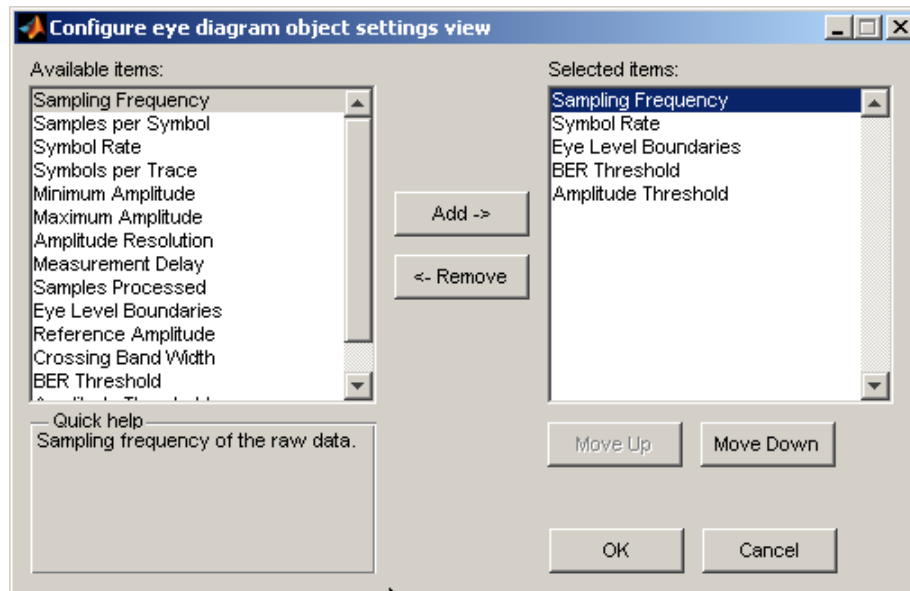

## Selecting Which Eye Diagram Object Settings To Display

The **Eye Diagram Object Settings View** allows you to select which object settings display in the eye diagram object settings panel. You make your selections in the Configure eye diagram object settings view window, where a shuttle control allows you to add, remove, or reorder the settings you are displaying.

To add an eye diagram object setting:

- 1 Click **Options > Eye Diagram Object Settings View**

The Configure eye diagram object settings view window appears.

- 2 Locate any items to be added in the list of **Available items**, and left-click to select.

---

**Note** To select multiple items, you can either press and hold the <Shift> key and left-click or press and hold the <Ctrl> key and left-click.

---

When you select an item, the **Quick help** panel displays information about the item. If you select multiple items, **Quick help** displays information pertaining to the last item you select.

- 3 Click **Add**.

---

**Note** Using the **Move Up** or **Move Down** buttons, you can change the order in which the eye diagrams settings you select appear.

---

- 4 Click **OK**.

## Selecting Which Eye Diagram Measurements To Display

You can modify the contents of the measurement panel by selecting which eye diagram measurements display in the eye diagram object settings panel. You make your selections

in the Configure measurements view window, where a shuttle control allows you to add, remove, or reorder the settings you are including.

### Adding An Eye Diagram Measurement Setting

#### 1 Click **Options > Measurements View**

The Configure measurements window appears.

#### 2 Locate any items to be added in the list of **Available items**, and left-click to select.

---

**Note** To select multiple items, you can either press and hold the <Shift> key and left-click or press and hold the <Ctrl> key and left-click.

---

When you select an item, the **Quick help** panel displays information about the item. If you select multiple items, **Quick help** displays information pertaining to the last item you select.

#### 3 Click **Add**.

---

**Note** Using the **Move Up** or **Move Down** buttons, you can change the order in which the eye diagrams settings you select appear.

---

- 4 Click **OK** .

## Compatibility Considerations

## fft

Discrete Fourier transform

## Syntax

`fft(x)`

## Description

`fft(x)` is the discrete Fourier transform (DFT) of the Galois vector  $x$ . If  $x$  is in the Galois field  $GF(2^m)$ , the length of  $x$  must be  $2^m - 1$ .

## Examples

### Discrete Fourier Transform of Galois Vector

Set the order of the Galois field. Because  $x$  is in the Galois field  $(2^4)$ , the length of  $x$  must be  $2^m - 1$ .

```
m = 4;  
n = 2^m - 1;
```

Generate a random GF vector.

```
x = gf(randi([0 2^m - 1], n, 1), m);
```

Perform the Fourier transform.

```
y = fft(x);
```

Invert the transform.

```
z = ifft(y);
```

Confirm that the inverse transform  $z = x$ .

```
isequal(z,x)
ans = logical
      1
```

### Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words,  $x$  must be in the Galois field  $GF(2^m)$ , where  $m$  is an integer between 1 and 8.

### Algorithms

If  $x$  is a column vector, `fft` applies `dftmtx` to the primitive element of the Galois field and multiplies the resulting matrix by  $x$ .

## filter (channel)

(To be removed) Filter signal with channel object

### Syntax

```
y = filter(chan,x)
```

---

**Note** This function will be removed in a future release. Use function associated with `comm.RicianChannel` or `comm.RayleighChannel` instead.

---

### Description

`y = filter(chan,x)` processes the baseband signal vector `x` with the channel object `chan`. The result is the signal vector `y`. The final state of the channel is stored in `chan`. You can construct `chan` using either `rayleighchan` or `ricianchan`. The `filter` function assumes `x` is sampled at frequency  $1/ts$ , where `ts` equals the `InputSamplePeriod` property of `chan`.

If `chan.ResetBeforeFiltering` is `0`, `filter` uses the existing state information in `chan` when starting the filtering operation. As a result, `filter(chan,[x1 x2])` is equivalent to `[filter(chan,x1) filter(chan,x2)]`. To reset `chan` manually, apply the reset function to `chan`.

If `chan.ResetBeforeFiltering` is `1`, `filter` resets `chan` before starting the filtering operation, overwriting any previous state information in `chan`.

## filter (Galois field)

1-D digital filter over Galois field

### Syntax

```
y = filter(b,a,x)
[y,zf] = filter(b,a,x)
```

### Description

`y = filter(b,a,x)` filters the data in the vector `x` with the filter described by numerator coefficient vector `b` and denominator coefficient vector `a`. The vectors `b`, `a`, and `x` must be Galois vectors in the same field. If `a(1)` is not equal to 1, `filter` normalizes the filter coefficients by `a(1)`. As a result, `a(1)` must be nonzero.

The filter is a *Direct Form II Transposed* implementation of the standard difference equation shown here:

$$a(1)*y(n) = b(1)*x(n) + b(2)*x(n-1) + \dots + b(nb+1)*x(n-nb) \dots \\ - a(2)*y(n-1) - \dots - a(na+1)*y(n-na)$$

`[y,zf] = filter(b,a,x)` returns the final conditions of the filter delays in the Galois vector `zf`. The length of the vector `zf` is `max(size(a),size(b))-1`.

### Examples

#### Filter a Galois Field

When using the Galois 1-D digital filter function, the data is normalized by the first element of the denominator coefficient vector.

```
a = gf([2 3 5 7],3);
b = gf([1 3],3);
x = gf(randi([0,7],10,1),3);
filt_x = filter(b,a,x)
```

```
filt_x = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =
```

```
6  
6  
3  
4  
7  
4  
2  
2  
0  
5
```

The first coefficient of the denominator coefficient vector,  $a(1) = 2$ . To confirm the function normalizes the data, manually normalize the filtered data. Use `isequal` to compare the outputs, we see they are equal.

```
filt_x2 = a(1) * filter(b/a(1),a,x)
```

```
filt_x2 = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =
```

```
6  
6  
3  
4  
7  
4  
2  
2  
0  
5
```

```
isequal(filt_x,filt_x2)
```

```
ans = logical
```

```
1
```

# fmdemod

Frequency demodulation

## Syntax

```
z = fmdemod(y,Fc,Fs,freqdev)
z = fmdemod(y,Fc,Fs,freqdev,ini_phase)
```

## Description

`z = fmdemod(y,Fc,Fs,freqdev)` returns a demodulated signal `z`, given the input frequency modulated (FM) signal `y`, where the carrier signal has frequency `Fc` and sampling rate `Fs`. `freqdev` is the frequency deviation of the modulated signal.

---

### Note

- The value of `Fs` must satisfy  $Fs \geq 2Fc$ .
  - The value of `freqdev` must satisfy  $freqdev < Fc$ .
- 

`z = fmdemod(y,Fc,Fs,freqdev,ini_phase)` specifies the initial phase of the modulated signal in radians.

## Examples

### FM Modulate and Demodulate Sinusoidal Signal

Set the sampling frequency to 1kHz and carrier frequency to 200 Hz. Generate a time vector having a duration of 0.2 s.

```
fs = 1000;
fc = 200;
t = (0:1/fs:0.2)';
```

Create two-tone sinusoidal signal with frequencies 30 and 60 Hz.

```
x = sin(2*pi*30*t)+2*sin(2*pi*60*t);
```

Set the frequency deviation to 50 Hz.

```
fDev = 50;
```

Frequency modulate x.

```
y = fmod(x,fc,fs,fDev);
```

Demodulate z.

```
z = fmdemod(y,fc,fs,fDev);
```

Plot the original and demodulated signals.

```
plot(t,x,'c',t,z,'b--');  
xlabel('Time (s)')  
ylabel('Amplitude')  
legend('Original Signal','Demodulated Signal')
```

The demodulated signal closely approximates the original.

## Input Arguments

### **y** — Frequency modulated input signal

scalar | vector | matrix | 3-D array

Frequency modulated input signal, specified as a scalar, vector, matrix, or 3-D array. Each element of **y** must be real.

Data Types: `single` | `double`

**Fc — Carrier frequency**

positive real scalar

Carrier frequency in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`**Fs — Sampling rate**

positive real scalar

Sampling rate in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`**freqdev — Frequency deviation**

positive real scalar

Frequency deviation of the modulated signal in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`**ini\_phase — Initial phase**

real scalar

Initial phase of the modulated signal in radians, specified as a real scalar.

Data Types: `single` | `double`

## Output Arguments

**z — Frequency demodulated output signal**

scalar | vector | matrix | 3-D array

Frequency demodulated signal, returned as a scalar, vector, matrix, or 3-D array.

# fmmod

Frequency modulation

## Syntax

```
y = fmmod(x,Fc,Fs,freqdev)
y = fmmod(x,Fc,Fs,freqdev,ini_phase)
```

## Description

`y = fmmod(x,Fc,Fs,freqdev)` returns a frequency modulated (FM) signal `y`, given the input message signal `x`, where the carrier signal has frequency `Fc` and sampling rate `Fs`. `freqdev` is the frequency deviation of the modulated signal.

---

### Note

- The value of `Fs` must satisfy  $Fs \geq 2Fc$ .
  - The value of `freqdev` must satisfy  $freqdev < Fc$ .
- 

`y = fmmod(x,Fc,Fs,freqdev,ini_phase)` specifies the initial phase of the modulated signal.

## Examples

### FM Modulate a Sinusoidal Signal

Set the sampling frequency to 1kHz and carrier frequency to 200 Hz. Generate a time vector having a duration of 0.2 s.

```
fs = 1000;
fc = 200;
t = (0:1/fs:0.2)';
```

Create two tone sinusoidal signal with frequencies 30 and 60 Hz.

```
x = sin(2*pi*30*t)+2*sin(2*pi*60*t);
```

Set the frequency deviation to 50 Hz.

```
fDev = 50;
```

Frequency modulate x.

```
y = fmod(x,fc,fs,fDev);
```

Plot the original and modulated signals.

```
plot(t,x,'c',t,y,'b--')  
xlabel('Time (s)')  
ylabel('Amplitude')  
legend('Original Signal','Modulated Signal')
```

## Input Arguments

### **x** — Input message signal

scalar | vector | matrix | 3-D array

Input message signal, specified as a scalar, vector, matrix, or a 3-D array. Each element of  $x$  must be real.

Data Types: single | double

### **Fc** — Carrier frequency

positive real scalar

Carrier frequency in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

### **Fs — Sampling rate**

positive real scalar

Sampling rate in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

### **freqdev — Frequency deviation**

positive real scalar

Frequency deviation of the modulated signal in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

### **ini\_phase — Initial phase**

real scalar

Initial phase of the modulated signal in radians, specified as a real scalar.

Data Types: `single` | `double`

## Output Arguments

### **y — Frequency modulated output signal**

scalar | vector | matrix | 3-D array

Frequency modulated signal, returned as a scalar, vector, matrix, or 3-D array.

# fskdemod

Frequency shift keying demodulation

## Syntax

```
z = fskdemod(y,M,freq_sep,nsamp)
z = fskdemod(y,M,freq_sep,nsamp,Fs)
z = fskdemod(y,M,freq_sep,nsamp,Fs,symbol_order)
```

## Description

`z = fskdemod(y,M,freq_sep,nsamp)` noncoherently demodulates the complex envelope `y` of a signal using the frequency shift key method. `M` is the alphabet size and must be an integer power of 2. `freq_sep` is the frequency separation between successive frequencies in Hz. `nsamp` is the required number of samples per symbol and must be a positive integer greater than 1. The sampling frequency is 1 Hz. If `y` is a matrix with multiple rows and columns, the function processes the columns independently.

`z = fskdemod(y,M,freq_sep,nsamp,Fs)` specifies the sampling frequency in Hz.

`z = fskdemod(y,M,freq_sep,nsamp,Fs,symbol_order)` specifies how the function assigns binary words to corresponding integers. If `symbol_order` is set to 'bin' (default), the function uses a natural binary-coded ordering. If `symbol_order` is set to 'gray', it uses a Gray-coded ordering.

## Examples

### Modulation and Demodulation of an FSK Signal in AWGN

Pass an FSK signal through an AWGN channel and estimate the resulting bit error rate (BER). Compare the estimated BER to the theoretical value.

Set the simulation parameters.

```

M = 2;           % Modulation order
k = log2(M);    % Bits per symbol
EbNo = 5;       % Eb/No (dB)
Fs = 16;        % Sample rate (Hz)
nsamp = 8;      % Number of samples per symbol
freqsep = 10;   % Frequency separation (Hz)

Generate random data symbols.

data = randi([0 M-1],5000,1);

Apply FSK modulation.

txsig = fskmod(data,M,freqsep,nsamp,Fs);

Pass the signal through an AWGN channel

rxSig = awgn(txsig,EbNo+10*log10(k)-10*log10(nsamp),...
    'measured',[],'dB');

Demodulate the received signal.

dataOut = fskdemod(rxSig,M,freqsep,nsamp,Fs);

Calculate the bit error rate.

[num,BER] = biterr(data,dataOut);

Determine the theoretical BER and compare it to the estimated BER. Your BER value
might vary because the example uses random numbers.

BER_theory = berawgn(EbNo,'fsk',M,'noncoherent');
[BER BER_theory]

ans = 1x2

    0.0958    0.1029

```

# fskmod

Frequency shift keying modulation

## Syntax

```

y = fskmod(x,M,freq_sep,nsamp)
y = fskmod(x,M,freq_sep,nsamp,Fs)
y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont)
y = FSKMOD(x,M,freq_sep,nsamp,Fs,phase_cont,symbol_order)

```

## Description

`y = fskmod(x,M,freq_sep,nsamp)` outputs the complex envelope `y` of the modulation of the message signal `x` using frequency shift keying modulation. `M` is the alphabet size and must be an integer power of 2. The message signal must consist of integers between 0 and `M-1`. `freq_sep` is the desired separation between successive frequencies in Hz. `nsamp` denotes the number of samples per symbol in `y` and must be a positive integer greater than 1. The sampling rate of `y` is 1 Hz. By the Nyquist sampling theorem, `freq_sep` and `M` must satisfy  $(M-1)*freq\_sep \leq 1$ . If `x` is a matrix with multiple rows and columns, the function processes the columns independently.

`y = fskmod(x,M,freq_sep,nsamp,Fs)` specifies the sampling rate of `y` in Hz. Because the Nyquist sampling theorem implies that the maximum frequency must be no larger than  $Fs/2$ , the inputs must satisfy  $(M-1)*freq\_sep \leq Fs$ .

`y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont)` specifies the phase continuity. Set `phase_cont` to 'cont' to force phase continuity across symbol boundaries in `y`, or 'discont' to avoid forcing phase continuity. The default is 'cont'.

`y = FSKMOD(x,M,freq_sep,nsamp,Fs,phase_cont,symbol_order)` specifies how the function assigns binary words to corresponding integers. If `symbol_order` is set to 'bin' (default), the function uses a natural binary-coded ordering. If `symbol_order` is set to 'gray', it uses a Gray-coded ordering.

## Examples

### FSK Signal Spectrum Plot

Generate an FSK modulated signal and display its spectral characteristics.

Set the function parameters.

```
M = 4;           % Modulation order
freqsep = 8;    % Frequency separation (Hz)
nsamp = 8;      % Number of samples per symbol
Fs = 32;        % Sample rate (Hz)
```

Generate random M-ary symbols.

```
x = randi([0 M-1],1000,1);
```

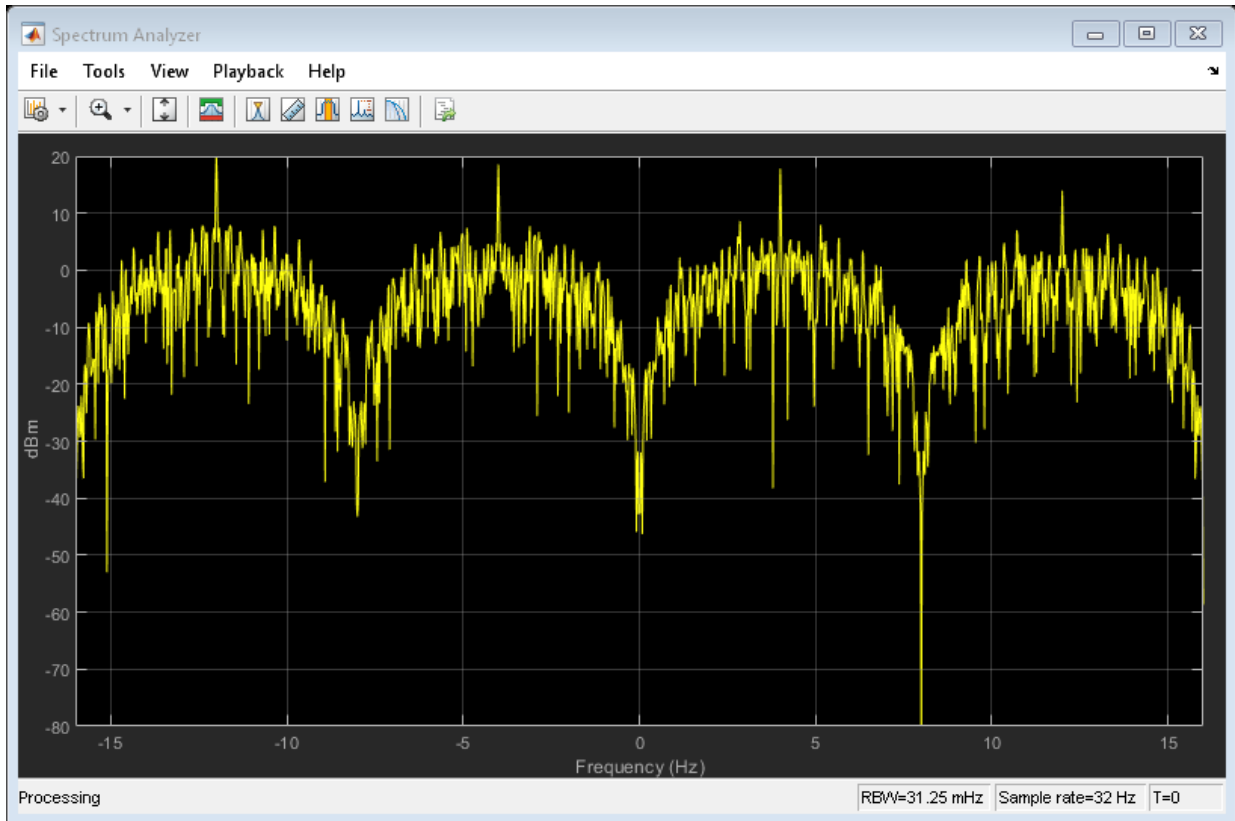

Apply FSK modulation.

```
y = fskmod(x,M,freqsep,nsamp,Fs);
```

Create a spectrum analyzer System object? and use its `step` method to display a plot of the signal spectrum.

```
h = dsp.SpectrumAnalyzer('SampleRate',Fs);
step(h,y)
```

## hex2poly

Convert hexadecimal character vector to binary coefficients

### Syntax

```
b = hex2poly(hex)
b = hex2poly(hex,ord)
```

### Description

`b = hex2poly(hex)` converts a hexadecimal character vector, `hex`, to a vector of binary coefficients, `b`.

`b = hex2poly(hex,ord)` specifies the power order, `ord`, of the coefficients that comprise the output. If omitted, `ord` is 'descending'.

### Examples

#### Convert Hexadecimal Polynomial to Binary Vector

Convert the hexadecimal polynomial '1AF' to a vector of binary coefficients. The coefficients represent the polynomial  $x^8 + x^7 + x^5 + x^3 + x^2 + x + 1$ .

```
b = hex2poly('1AF')
```

```
b = 1×9
```

```
    1    1    0    1    0    1    1    1    1
```

### Convert Hexadecimal into Ascending Order Binary Vector

Convert hexadecimal '0x82608EDB' to a vector of binary coefficients. Specify that the binary coefficients are in ascending order.

```
b = hex2poly('0x82608EDB','ascending')
```

```
b = 1×32
```

```
    1    1    0    1    1    0    1    1    0    1    1    1    0    0
```

The binary representation corresponds to a polynomial of  $x^{31} + x^{25} + x^{22} + x^{21} + x^{15} + x^{11} + x^{10} + x^9 + x^7 + x^6 + x^4 + x^3 + x + 1$ .

## Input Arguments

### hex — Hexadecimal number

character vector

Hexadecimal number, specified as a character vector.

Example: 'FF'

Example: '0x3FA'

Data Types: char

### ord — Power order

'descending' (default) | 'ascending'

Power order of the vector of binary coefficients, specified as a character vector having a value of 'ascending' or 'descending'.

Data Types: char

## Output Arguments

### b — Binary coefficients

vector

Binary coefficients representing a polynomial, returned as a row vector having length equal to  $p + 1$ , where  $p$  is the order of hexadecimal input.

Data Types: double

## See Also

dec2hex | oct2poly

**Introduced in R2015b**

# oct2poly

Convert octal number to binary coefficients

## Syntax

```
b = oct2poly(oct)
b = oct2poly(oct,ord)
```

## Description

`b = oct2poly(oct)` converts an octal number, `oct`, to a vector of binary coefficients, `b`.

`b = oct2poly(oct,ord)` specifies the power order, `ord`, of the coefficients that comprise the output. If omitted, `ord` is 'descending'.

## Examples

### Convert Octal Number to Binary Vector

Convert the octal number 11 to a binary vector.

```
b = oct2poly(11)
```

```
b = 1×4
```

```
    1    0    0    1
```

The binary vector corresponds to the polynomial  $x^3 + 1$ .

## Convert Octal Number to Ascending Order Binary Vector

Convert the octal number 65 to an ascending order binary vector.

```
b = oct2poly(65, 'ascending')
```

```
b = 1×6
```

```
    1    0    1    0    1    1
```

Sixty-five octal is the generator polynomial of a (15,10) Hamming code in the Bluetooth v4.0 standard. The binary representation of 65 octal is 110101 and the GF(2) polynomial is  $1 + x^2 + x^4 + x^5$  or [1 0 1 0 1 1] in ascending powers.

## Input Arguments

### oct — Octal number

scalar

Octal number, specified as a positive integer scalar.

Example: 15

Example: 3177

Data Types: double

### ord — Power order

'descending' (default) | 'ascending'

Power order of the binary coefficients vector, specified as a character vector having a value of 'ascending' or 'descending'.

Data Types: char

## Output Arguments

### b — Binary coefficients

vector

Binary coefficients representing a polynomial, returned as a row vector having length equal to  $p + 1$ , where  $p$  is the order of octal input.

Data Types: double

# plotPhaseNoiseFilter

Plot response of phase noise filter block

## Syntax

```
plotPhaseNoiseFilter(blockname)
```

## Description

`plotPhaseNoiseFilter(blockname)` plots the response of the phase noise filter associated with the Phase Noise block specified by the variable `blockname`.

## Examples

### View Filter Response of Phase Noise Block

This example shows how to use the `plotPhaseNoiseFilter` function to view the filter response of a Phase Noise block in a Simulink model.

Load a Simulink model that contains a Phase Noise block. The `load_system` command loads a model into memory without making its model window visible. The function will also work with models whose window is visible. The example, `slex_phasenoise`, contains a Phase Noise block.

```
load_system('slex_phasenoise')
```

Run the `plotPhaseNoiseFilter` function to view the filter response of the block Phase Noise.

```
plotPhaseNoiseFilter('slex_phasenoise/Phase Noise')
```

## Input Arguments

**blockname** — Phase noise block name

character vector

The name of a Phase Noise block in a Simulink model

Example: `plotPhaseNoiseFilter('Model Name/Phase Noise')`

Data Types: char

## **See Also**

Phase Noise

**Introduced in R2014b**

## gen2par

Convert between parity-check and generator matrices

### Syntax

```
parmat = gen2par(genmat)
genmat = gen2par(parmat)
```

### Description

`parmat = gen2par(genmat)` converts the standard-form binary generator matrix `genmat` into the corresponding parity-check matrix `parmat`.

`genmat = gen2par(parmat)` converts the standard-form binary parity-check matrix `parmat` into the corresponding generator matrix `genmat`.

The standard forms of the generator and parity-check matrices for an  $[n,k]$  binary linear block code are shown in the table below

Type of Matrix	Standard Form	Dimensions
Generator	$[I_k \ P]$ or $[P \ I_k]$	$k$ -by- $n$
Parity-check	$[-P' \ I_{n-k}]$ or $[I_{n-k} \ -P']$	$(n-k)$ -by- $n$

where  $I_k$  is the identity matrix of size  $k$  and the  $'$  symbol indicates matrix transpose. Two standard forms are listed for each type, because different authors use different conventions. For *binary* codes, the minus signs in the parity-check form listed above are irrelevant; that is,  $-1 = 1$  in the binary field.

### Examples

## Convert Parity-Check Matrix for a Hamming Code to Generator Matrix

Convert the parity-check matrix for a Hamming code into the corresponding generator matrix and back again.

Create the parity-check matrix.

```
parmat = hammgen(3)
```

```
parmat = 3×7
```

```

1  0  0  1  0  1  1
0  1  0  1  1  1  0
0  0  1  0  1  1  1
```

Convert the parity-check matrix into the corresponding generator matrix.

```
genmat = gen2par(parmat)
```

```
genmat = 4×7
```

```

1  1  0  1  0  0  0
0  1  1  0  1  0  0
1  1  1  0  0  1  0
1  0  1  0  0  0  1
```

Convert the generator matrix back again. The output, `parmat2`, should be the same as the original matrix, `parmat`.

```
parmat2 = gen2par(genmat)
```

```
parmat2 = 3×7
```

```

1  0  0  1  0  1  1
0  1  0  1  1  1  0
0  0  1  0  1  1  1
```

# genqamdemod

General quadrature amplitude demodulation

## Syntax

```
z = genqamdemod(y, const)
```

## Description

`z = genqamdemod(y, const)` demodulates the complex envelope `y` of a quadrature amplitude modulated signal. The complex vector `const` specifies the signal mapping. If `y` is a matrix with multiple rows, the function processes the columns independently.

## Examples

### General QAM Modulation and Demodulation

Create the points that describe a hexagonal constellation.

```
inphase = [1/2 1 1 1/2 1/2 2 2 5/2];  
quadr = [0 1 -1 2 -2 1 -1 0];  
inphase = [inphase; -inphase]; inphase = inphase(:);  
quadr = [quadr; quadr]; quadr = quadr(:);  
const = inphase + 1i*quadr;
```

Plot the constellation.

```
h = scatterplot(const);
```

Generate input data symbols. Modulate the symbols using this constellation.

```
x = [3 8 5 10 7];
y = genqammod(x,const);
```

Demodulate the modulated signal, y.

```
z = genqamdemod(y,const);
```

Plot the modulated signal in same figure.

```
hold on;
scatterplot(y,1,0,'ro',h);
legend('Constellation','Modulated signal');
```

Determine the number of symbol errors between the demodulated data to the original sequence.

```
numErrs = symerr(x,z)
```

```
numErrs = 0
```

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

# genqammod

General quadrature amplitude modulation

## Syntax

```
y = genqammod(x, const)
```

## Description

`y = genqammod(x, const)` outputs the complex envelope `y` of the modulation of the message signal `x` using quadrature amplitude modulation. The message signal must consist of integers between 0 and `length(const) - 1`. The complex vector `const` specifies the signal mapping. If `x` is a matrix with multiple rows, the function processes the columns independently.

## Examples

### General QAM Modulation and Demodulation

Create the points that describe a hexagonal constellation.

```
inphase = [1/2 1 1 1/2 1/2 2 2 5/2];  
quadr = [0 1 -1 2 -2 1 -1 0];  
inphase = [inphase;-inphase]; inphase = inphase(:);  
quadr = [quadr;quadr]; quadr = quadr(:);  
const = inphase + 1i*quadr;
```

Plot the constellation.

```
h = scatterplot(const);
```

Generate input data symbols. Modulate the symbols using this constellation.

```
x = [3 8 5 10 7];  
y = genqammod(x,const);
```

Demodulate the modulated signal, y.

```
z = genqamdemod(y,const);
```

Plot the modulated signal in same figure.

```
hold on;  
scatterplot(y,1,0,'ro',h);  
legend('Constellation','Modulated signal');
```

Determine the number of symbol errors between the demodulated data to the original sequence.

```
numErrs = symerr(x,z)
```

```
numErrs = 0
```

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

# gf

Create Galois field array

## Syntax

```
x_gf = gf(x,m)
x_gf = gf(x,m,prim_poly)
x_gf = gf(x)
```

## Description

`x_gf = gf(x,m)` creates a Galois field array from the matrix `x`. The Galois field has  $2^m$  elements, where `m` is an integer between 1 and 16. The elements of `x` must be integers between 0 and  $2^m-1$ . The output `x_gf` is a variable that MATLAB recognizes as a Galois field array, rather than an array of integers. As a result, when you manipulate `x_gf` using operators or functions such as `+` or `det`, MATLAB works within the Galois field you have specified.

---

**Note** To learn how to manipulate `x_gf` using familiar MATLAB operators and functions, see “Galois Field Computations”. To learn how the integers in `x` represent elements of  $GF(2^m)$ , see “How Integers Correspond to Galois Field Elements”.

---

`x_gf = gf(x,m,prim_poly)` is the same as the previous syntax, except it uses the primitive polynomial `prim_poly` to define the field. `prim_poly` is a polynomial character vector or the integer representation of a primitive polynomial. For example, the number 37 represents the polynomial  $D^5+D^2+1$  because the binary form of 37 is 1 0 0 1 0 1. For more information, see “Default Primitive Polynomials” on page 2-615.

`x_gf = gf(x)` creates a  $GF(2)$  array from the matrix `x`. Each element of `x` must be 0 or 1.

## Examples

**Create Sequence of GF(16) Elements**

Set the order of the Galois field to 16, where the order equals  $2^m$ . The elements of  $x$  must range from 0 to  $2^m - 1$ .

```
m = 4;  
x = [3 2 9];  
y = gf(x,m)
```

```
y = GF(2^4) array. Primitive polynomial = D^4+D+1 (19 decimal)
```

```
Array elements =
```

```
3 2 9
```

**Create GF Sequence with Specified Primitive Polynomial**

Create a sequence of integers. Create a Galois field array, where  $m = 5$ .

```
x = [17 8 11 27];  
y = gf(x,5)
```

```
y = GF(2^5) array. Primitive polynomial = D^5+D^2+1 (37 decimal)
```

```
Array elements =
```

```
17 8 11 27
```

Determine all possible primitive polynomials for  $GF(2^5)$ .

```
pp = primpoly(5,'all')
```

```
Primitive polynomial(s) =
```

```
D^5+D^2+1  
D^5+D^3+1  
D^5+D^3+D^2+D^1+1  
D^5+D^4+D^2+D^1+1
```

```
D^5+D^4+D^3+D^1+1
D^5+D^4+D^3+D^2+1
```

```
pp = 6×1
```

```
37
41
47
55
59
61
```

Generate a GF array using the primitive polynomial that has a decimal equivalent of 59.

```
z = gf(x,5, 'D5+D4+D3+D+1')
```

```
z = GF(2^5) array. Primitive polynomial = D^5+D^4+D^3+D+1 (59 decimal)
```

```
Array elements =
```

```
17 8 11 27
```

## More About

### Default Primitive Polynomials

This table lists the default primitive polynomial used for each Galois field array  $GF(2^M)$ . To use a different primitive polynomial, specify `prim_poly` as an input argument. `prim_poly` must be in the range  $[(2^M+1), (2^{(M+1)}-1)]$  and must indicate an irreducible polynomial. For more information, see “Specifying the Primitive Polynomial”.

<b><i>M</i></b>	<b>Default Primitive Polynomial</b>	<b>Integer Representation</b>
1	$D + 1$	3
2	$D^2 + D + 1$	7
3	$D^3 + D + 1$	11

<b>M</b>	<b>Default Primitive Polynomial</b>	<b>Integer Representation</b>
4	$D^4 + D + 1$	19
5	$D^5 + D^2 + 1$	37
6	$D^6 + D + 1$	67
7	$D^7 + D^3 + 1$	137
8	$D^8 + D^4 + D^3 + D^2 + 1$	285
9	$D^9 + D^4 + 1$	529
10	$D^{10} + D^3 + 1$	1033
11	$D^{11} + D^2 + 1$	2053
12	$D^{12} + D^6 + D^4 + D + 1$	4179
13	$D^{13} + D^4 + D^3 + D + 1$	8219
14	$D^{14} + D^{10} + D^6 + D + 1$	17475
15	$D^{15} + D + 1$	32771
16	$D^{16} + D^{12} + D^3 + D + 1$	69643

## Galois Computations

Operations supported for Galois field arrays include:

<b>Operation</b>	<b>Description</b>
+ -	Addition and subtraction of Galois arrays
* / \	Matrix multiplication and division of Galois arrays
.* ./ .\	Elementwise multiplication and division of Galois arrays
^	Matrix exponentiation of Galois array

Operation	Description
<code>.^</code>	Elementwise exponentiation of Galois array
<code>'.'</code>	Transpose of Galois array
<code>==, ~=</code>	Relational operators for Galois arrays
<code>all</code>	True if all elements of a Galois vector are nonzero
<code>any</code>	True if any element of a Galois vector is nonzero
<code>conv</code>	Convolution of Galois vectors
<code>convmtx</code>	Convolution matrix of Galois field vector
<code>deconv</code>	Deconvolution and polynomial division
<code>det</code>	Determinant of square Galois matrix
<code>dftmtx</code>	Discrete Fourier transform matrix in a Galois field
<code>diag</code>	Diagonal Galois matrices and diagonals of a Galois matrix
<code>fft</code>	Discrete Fourier transform
<code>filter (gf)</code>	One-dimensional digital filter over a Galois field
<code>ifft</code>	Inverse discrete Fourier transform
<code>inv</code>	Inverse of Galois matrix
<code>length</code>	Length of Galois vector
<code>log</code>	Logarithm in a Galois field
<code>lu</code>	Lower-Upper triangular factorization of Galois array
<code>minpol</code>	Find the minimal polynomial for a Galois element
<code>mldivide</code>	Matrix left division $\backslash$ of Galois arrays
<code>polyval</code>	Evaluate polynomial in Galois field
<code>rank</code>	Rank of a Galois array
<code>reshape</code>	Reshape Galois array

Operation	Description
roots	Find polynomial roots across a Galois field
size	Size of Galois array
tril	Extract lower triangular part of Galois array
triu	Extract upper triangular part of Galois array

# gfadd

Add polynomials over Galois field

## Syntax

```
c = gfadd(a,b)
c = gfadd(a,b,p)
c = gfadd(a,b,p,len)
c = gfadd(a,b,field)
```

## Description

---

**Note** This function performs computations in  $GF(p^m)$  where  $p$  is prime. To work in  $GF(2^m)$ , apply the  $+$  operator to Galois arrays of equal size. For details, see “Example: Addition and Subtraction”.

---

`c = gfadd(a,b)` adds two  $GF(2)$  polynomials,  $a$  and  $b$ , which can be either polynomial character vectors or numeric vectors. If  $a$  and  $b$  are vectors of the same orientation but different lengths, then the shorter vector is zero-padded. If  $a$  and  $b$  are matrices they must be of the same size.

`c = gfadd(a,b,p)` adds two  $GF(p)$  polynomials, where  $p$  is a prime number.  $a$ ,  $b$ , and  $c$  are row vectors that give the coefficients of the corresponding polynomials in order of ascending powers. Each coefficient is between 0 and  $p-1$ . If  $a$  and  $b$  are matrices of the same size, the function treats each row independently.

`c = gfadd(a,b,p,len)` adds row vectors  $a$  and  $b$  as in the previous syntax, except that it returns a row vector of length `len`. The output  $c$  is a truncated or extended representation of the sum. If the row vector corresponding to the sum has fewer than `len` entries (including zeros), extra zeros are added at the end; if it has more than `len` entries, entries from the end are removed.

`c = gfadd(a,b,field)` adds two  $GF(p^m)$  elements, where  $m$  is a positive integer.  $a$  and  $b$  are the exponential format of the two elements, relative to some primitive element

of  $\text{GF}(p^m)$ . `field` is the matrix listing all elements of  $\text{GF}(p^m)$ , arranged relative to the same primitive element. `c` is the exponential format of the sum, relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats. If `a` and `b` are matrices of the same size, the function treats each element independently.

## Examples

### Add Two GF Arrays

Sum  $2 + 3x + x^2$  and  $4 + 2x + 3x^2$  over  $\text{GF}(5)$ .

```
x = gfadd([2 3 1],[4 2 3],5)
```

```
x = 1×3
```

```
    1    0    4
```

Add the two polynomials and display the first two elements.

```
y = gfadd([2 3 1],[4 2 3],5,2)
```

```
y = 1×2
```

```
    1    0
```

For prime number `p` and exponent `m`, create a matrix listing all elements of  $\text{GF}(p^m)$  given primitive polynomial  $2 + 2x + x^2$ .

```
p = 3;
m = 2;
primpoly = [2 2 1];
field = gftuple((-1:p^m-2)',primpoly,p);
```

Sum  $A^2$  and  $A^4$ . The result is `A`.

```
g = gfadd(2,4,field)
```

```
g = 1
```

## gfconv

Multiply polynomials over Galois field

### Syntax

```
c = gfconv(a,b)
c = gfconv(a,b,p)
c = gfconv(a,b,field)

c = gfconv(polys)
c = gfconv(polys,p)
c = gfconv(polys,field)
```

### Description

`c = gfconv(a,b)` returns a row vector that specifies the GF(2) polynomial coefficients in order of ascending powers. The returned vector results from the multiplication of GF(2) polynomials `a` and `b`. The polynomial degree of the resulting GF(2) polynomial `c` equals the degree of `a` plus the degree of `b`.

For additional information, see “Tips” on page 2-627.

`c = gfconv(a,b,p)` multiplies two GF(`p`) polynomials, where `p` is a prime number. `a`, `b`, and `c` are in the same Galois field. `a`, `b`, and `c` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range  $[0, p-1]$ .

`c = gfconv(a,b,field)` multiplies two GF( $p^m$ ) polynomials, where `field` is a matrix containing the  $m$ -tuple of all elements in GF( $p^m$ ). `p` is a prime number, and `m` is a positive integer. `a`, `b`, and `c` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically  $[-\text{Inf}, 0, 1, 2, \dots]$ . The elements in exponential format represent the `field` elements  $[0, 1, \alpha, \alpha^2, \dots]$  relative to some primitive element  $\alpha$  of GF( $p^m$ ).

`c = gfconv(polys)` returns a row vector that specifies the GF(2) polynomial coefficients in order of ascending powers. The returned vector results from the

multiplication of the GF(2) polynomials specified in `polys`. The polynomial degree of the resulting GF(2) polynomial `c` equals the sum of the degrees of the polynomials contained in `polys`. Use this syntax when `polys` specifies polynomials as a cell array of character vectors or as a string array.

`c = gfconv(polys,p)` multiplies the GF( $p$ ) polynomials specified in `polys`, where  $p$  is a prime number. `polys` and `c` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range  $[0, p-1]$ . `a`, `b`, and `c` are in the same Galois field.

`c = gfconv(polys,field)` multiplies the GF( $p^m$ ) polynomials in `polys`, where `field` is a matrix containing the  $m$ -tuple of all elements in GF( $p^m$ ).  $p$  is a prime number, and  $m$  is a positive integer. `a`, `b`, and `c` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically  $[-\text{Inf}, 0, 1, 2, \dots]$ . The elements in exponential format represent the `field` elements  $[0, 1, \alpha, \alpha^2, \dots]$  relative to some primitive element  $\alpha$  of GF( $p^m$ ).

## Examples

### Multiply GF(2) Polynomials

Multiply  $1 + 2x + 3x^2 + 4x^3$  and  $1 + x$  three times. Represent the polynomials as row vectors, character vectors, and strings.

```
c_rv = gfconv([1 1 0 1],[1 1])
```

```
c_rv = 1x5
```

```
1 0 1 1 1
```

```
c_cv = gfconv('1 + x + x^3','1 + x')
```

```
c_cv = 1x5
```

```
1 0 1 1 1
```

```
c_s = gfconv("1 + x + x^3","1 + x")
```

```
c_s = 1x5
```

```
1 0 1 1 1
```

The results corresponds to  $1 + x^2 + x^3 + x^4$ .

### Multiply Polynomials Over GF(3)

Multiply  $1 + x + x^4$  and  $x + x^2$  over the Galois field GF(3).

```
gfc = gfconv([1 1 0 0 1],[0 1 1],3)
```

```
gfc = 1×7
```

```
0 1 2 1 0 1 1
```

The result corresponds to  $x + 2x^2 + x^3 + x^5 + x^6$ .

### Multiply Polynomials Over GF(2<sup>4</sup>) Using Field Input

Multiply  $1 + 2x + 3x^2 + 4x^3 + 5x^4$  and  $1 + x$  in the Galois field GF(2<sup>4</sup>).

```
field = gftuple([-1:2^4-2]',4,2);
```

```
c = gfconv('1 + 2x + 3x^2 + 4x^3 + 5x^4','1 + x',field)
```

```
c = 1×6
```

```
2 6 7 8 9 6
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(c)
```

```
2 + 6 X + 7 X2 + 8 X3 + 9 X4 + 6 X5
```

### Multiply GF(2) Polynomials Specified As Cell Array

Create a cell array containing three polynomials that result in the DVB-S2 generator polynomial for  $t = 3$  when multiplied together.

```
polyCell = {'1 + x + x3 + x5 + x14', ...
            '1 + x6 + x8 + x11 + x14', '1 + x + x2 + x6 + x9 + x10 + x14'};
gp = gfconv(polyCell); % DVB-S2 for t=3
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(gp)
```

```

      4      6      8      10     11     13     16     17     20     24     25     26     27
1 + X  + X  + X  + X  + X  + X  + X  + X  + X  + X  + X  + X
      30     31     32     33     34     35     36     37     38     39     42
      + X  + X  + X  + X  + X  + X  + X  + X  + X  + X  + X
```

### Multiply Polynomials Expressed As Strings in GF(2<sup>4</sup>) Using Field Input

Multiply  $1 + 2x + 3x^2 + 4x^3 + 5x^4$ ,  $1 + x$ , and  $1 + x^3$  in the Galois field  $GF(2^4)$ .

```
field = gftuple((-1:2^4-2)', 4, 2);
c = gfconv(["1 + 2x + 3x^2 + 4x^3 + 5x^4", "1 + x", "1 + x^3"], field)

c = 1x9
```

```
      4      13     14      9      2      1      7      8      8
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(c)
```

```

      2      3      4      5      6      7      8
4 + 13 X + 14 X  + 9 X  + 2 X  + X  + 7 X  + 8 X  + 8 X
```

## Input Arguments

### **a — Galois field polynomial**

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. **a** can be either a “Character Representation of Polynomials” or numeric vector.

**a** and **b** must both be  $GF(p)$  polynomials or  $GF(p^m)$  polynomials, where  $p$  is prime. The value of  $p$  is as specified when included, 2 when omitted, or implied when **field** is specified.

Example: `[1 2 3 4]` is the polynomial  $1+2x+3x^2+4x^3$  in  $GF(5)$  expressed as a row vector.

Data Types: `double` | `char` | `string`

### **b — Galois field polynomial**

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. **b** can be either a “Character Representation of Polynomials” or numeric vector.

**a** and **b** must both be  $GF(p)$  polynomials or  $GF(p^m)$  polynomials, where  $p$  is prime. The value of  $p$  is as specified when included, 2 when omitted, or implied when **field** is specified.

Example: `'1 + x'` is a polynomial in  $GF(2^4)$  expressed as a character vector.

Data Types: `double` | `char` | `string`

### **p — Prime number**

2 (default) | prime number

Prime number, specified as a prime number.

Data Types: `double`

### **field — $m$ -tuple of all elements in $GF(p^m)$**

matrix

$m$ -tuple of all elements in  $GF(p^m)$ , specified as a matrix. **field** is the matrix listing all elements of  $GF(p^m)$ , arranged relative to the same primitive element. To generate the  $m$ -tuple of all elements in  $GF(p^m)$ , use

```
field =gftuple([-1:p^m-2]',m,p)
```

The coefficients, specified in exponential format, represent the field elements in  $\text{GF}(p^m)$ . For an explanation of these formats, see “Representing Elements of Galois Fields”.

Data Types: `double`

### **polys** — Galois field polynomial list

cell array of character vectors | string array

Galois field polynomial list, specified as a cell array of character vectors or a string array.

Example: `["1+x+x3+x5+x14", "1+x6+x8+x11+x14"]` is a string array of polynomials.

Data Types: `cell` | `string`

## Output Arguments

### **c** — Galois field polynomial

row vector

Galois field polynomial, returned as a row vector of the polynomial coefficients in order of ascending powers. The polynomial degree of the resulting  $\text{GF}(p^m)$  polynomial `c` equals the sum of the degrees of the input polynomials. `c` is in the same Galois field as the input polynomials.

## Tips

- The `gfconv` function performs computations in  $\text{GF}(p^m)$ , where  $p$  is prime, and  $m$  is a positive integer. It multiplies polynomials over a Galois field. To work in  $\text{GF}(2^m)$ , you can also use the `conv` function of the `gf` object with Galois arrays. For details, see “Multiplication and Division of Polynomials”.
- To multiply elements of a Galois field, use `gfmul` instead of `gfconv`. Algebraically, multiplying polynomials over a Galois field is equivalent to convolving vectors containing the coefficients of the polynomials. This convolution operation uses arithmetic over the same Galois field.

## gfcosets

Produce cyclotomic cosets for Galois field

### Syntax

```
c = gfcosets(m)
c = gfcosets(m,p)
```

### Description

---

**Note** This function performs computations in  $GF(p^m)$ , where  $p$  is prime. To work in  $GF(2^m)$ , use the `cosets` function.

---

`c = gfcosets(m)` produces cyclotomic cosets mod( $2^m - 1$ ). Each row of the output GFCS contains one cyclotomic coset.

`c = gfcosets(m,p)` produces the cyclotomic cosets for  $GF(p^m)$ , where  $m$  is a positive integer and  $p$  is a prime number.

The output matrix `c` is structured so that each row represents one coset. The row represents the coset by giving the exponential format of the elements of the coset, relative to the default primitive polynomial for the field. For a description of exponential formats, see “Representing Elements of Galois Fields”.

The first column contains the coset leaders. Because the lengths of cosets might vary, entries of `NaN` are used to fill the extra spaces when necessary to make `c` rectangular.

A cyclotomic coset is a set of elements that all satisfy the same minimal polynomial. For more details on cyclotomic cosets, see the works listed in “References” on page 2-630.

### Examples

The command below finds the cyclotomic cosets for  $GF(9)$ .

```
c = gfcosets(2,3)
```

The output is

```
c =  
    0   NaN  
    1    3  
    2    6  
    4   NaN  
    5    7
```

The `gfminpol` function can check that the elements of, for example, the third row of `c` indeed belong in the same coset.

```
m = [gfminpol(2,2,3); gfminpol(6,2,3)] % Rows are identical.
```

The output is

```
m =  
    1    0    1  
    1    0    1
```

# gfdeconv

Divide polynomials over Galois field

## Syntax

```
[q, r] = gfdeconv(b, a)
[q, r] = gfdeconv(b, a, p)
[q, r] = gfdeconv(b, a, field)
```

## Description

`[q, r] = gfdeconv(b, a)` returns the quotient `q` and remainder `r` as row vectors that specify GF(2) polynomial coefficients in order of ascending powers. The returned vectors result from the division `b` by `a`. `a`, `b`, and `q` are in GF(2).

For additional information, see “Tips” on page 2-635.

`[q, r] = gfdeconv(b, a, p)` divides two GF(`p`) polynomials, where `p` is a prime number. `b`, `a`, and `q` are in the same Galois field. `b`, `a`, `q`, and `r` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range `[0, p-1]`.

`[q, r] = gfdeconv(b, a, field)` divides two GF( $p^m$ ) polynomials, where `field` is a matrix containing the  $m$ -tuple of all elements in GF( $p^m$ ). `p` is a prime number, and `m` is a positive integer. `b`, `a`, and `q` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically `[-Inf, 0, 1, 2, ...]`. The elements in exponential format represent the `field` elements `[0, 1,  $\alpha$ ,  $\alpha^2$ , ...]` relative to some primitive element  $\alpha$  of GF( $p^m$ ).

## Examples

**Divide Polynomials in GF(3)**

Divide  $x + x^3 + x^4$  by  $1 + x$  in the Galois field GF(3) three times. Represent the polynomials as row vectors, character vectors, and strings.

```
p = 3;
```

Represent the polynomials using row vectors and divide them in GF(3).

```
b = [0 1 0 1 1];  
a = [1 1];  
[q_rv,r_rv] = gfdeconv(b,a,p)
```

```
q_rv = 1×4
```

```
    1    0    0    1
```

```
r_rv = 2
```

To confirm the output, compare the original Galois field polynomials to the result of adding the remainder to the product of the quotient and the divisor.

```
bnew = gfadd(gfconv(q_rv,a,p),r_rv,p);  
isequal(b,bnew)
```

```
ans = logical  
     1
```

Represent the polynomials using character vectors and divide them in GF(3).

```
b = 'x + x^3 + x^4';  
a = '1 + x';  
[q_cv,r_cv] = gfdeconv(b,a,p)
```

```
q_cv = 1×4
```

```
    1    0    0    1
```

```
r_cv = 2
```

Represent the polynomials using strings and divide them in GF(3) .

```
b = "x + x^3 + x^4";
a = "1 + x";
[q_s,r_s] = gfdeconv(b,a,p)
```

```
q_s = 1×4
```

```
    1    0    0    1
```

```
r_s = 2
```

Use the `gfpretty` function to display the result without the remainder in polynomial form.

```
gfpretty(q_s)
```

$$1 + X^3$$

### Check for Irreducibility and Primitiveness Over $\text{GF}(3^k)$

In the Galois field  $\text{GF}(3)$ , output polynomials of the form  $x^k - 1$  for  $k$  in the range  $[2, 8]$  that are evenly divisible by  $1 + x^2$ . An irreducible polynomial over  $\text{GF}(p)$  of degree at least 2 is primitive if and only if it does not divide  $-1 + x^k$  evenly for any positive integer  $k$  less than  $p^m - 1$ . For more information, see the `gfprimck` function.

The irreducibility of  $1 + x^2$  over  $\text{GF}(3)$ , along with the polynomials that are output, indicates that  $1 + x^2$  is not primitive for  $\text{GF}(3^2)$ .

```
p = 3; m = 2;
a = [1 0 1]; % 1+x^2
for ii = 2:p^m-1
    b = gfrepconv(ii); % x^ii
    b(1) = p-1; % -1+x^ii
    [quot,remd] = gfdeconv(b,a,p);
    % Display -1+x^ii if a divides it evenly.
    if remd==0
        multiple{ii}=b;
        gfpretty(b)
    end
end
```

end  
end

$$2 + X^4$$

$$2 + X^8$$

## Input Arguments

### **b** — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. **b** can be either a “Character Representation of Polynomials” or numeric vector.

**a** and **b** must both be  $GF(p)$  polynomials or  $GF(p^m)$  polynomials, where  $p$  is prime. The value of  $p$  is as specified when included, 2 when omitted, or implied when `field` is specified.

Example: '1 + x' is a polynomial in  $GF(2^4)$  expressed as a character vector.

Data Types: double | char | string

### **a** — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. **a** can be either a “Character Representation of Polynomials” or numeric vector.

**a** and **b** must both be  $GF(p)$  polynomials or  $GF(p^m)$  polynomials, where  $p$  is prime. The value of  $p$  is as specified when included, 2 when omitted, or implied when `field` is specified.

Example: [1 2 3 4] is the polynomial  $1+2x+3x^2+4x^3$  in  $GF(5)$  expressed as a row vector.

Data Types: double | char | string

### **p** — Prime number

2 (default) | prime number

Prime number, specified as a prime number.

Data Types: double

### **field** — *m*-tuple of all elements in $GF(p^m)$

matrix

*m*-tuple of all elements in  $GF(p^m)$ , specified as a matrix. `field` is the matrix listing all elements of  $GF(p^m)$ , arranged relative to the same primitive element. To generate the *m*-tuple of all elements in  $GF(p^m)$ , use

```
field =gftuple([-1:p^m-2]',m,p)
```

The coefficients, specified in exponential format, represent the field elements in  $GF(p^m)$ . For an explanation of these formats, see “Representing Elements of Galois Fields”.

Data Types: double

## Output Arguments

### **q** — Galois field polynomial

row vector

Galois field polynomial, returned as a row vector of the polynomial coefficients in order of ascending powers. `q` is the quotient from the division of `b` by `a` and is in the same Galois field as the input polynomials.

### **r** — Division remainder

scalar | row vector

Division remainder, returned as a scalar or a row vector of the polynomial coefficients in order of ascending powers. `r` is the remainder resulting from the division of `b` by `a`.

## Tips

- The `gfdeconv` function performs computations in  $GF(p^m)$ , where  $p$  is prime, and  $m$  is a positive integer. It divides polynomials over a Galois field. To work in  $GF(2^m)$ , use the `deconv` function of the `gf` object with Galois arrays. For details, see “Multiplication and Division of Polynomials”.

- To divide elements of a Galois field, you can also use `gfdiv` instead of `gfdeconv`. Algebraically, dividing polynomials over a Galois field is equivalent to deconvolving vectors containing the coefficients of the polynomials. This deconvolution operation uses arithmetic over the same Galois field.

## gfddiv

Divide elements of Galois field

### Syntax

```
quot = gfddiv(b,a)
quot = gfddiv(b,a,p)
quot = gfddiv(b,a,field)
```

### Description

---

**Note** This function performs computations in  $GF(p^m)$ , where  $p$  is prime. To work in  $GF(2^m)$ , apply the `./` operator to Galois arrays. For details, see “Example: Division”.

---

The `gfddiv` function divides elements of a Galois field. (To divide polynomials over a Galois field, use `gfdeconv` instead.)

`quot = gfddiv(b,a)` divides  $b$  by  $a$  in  $GF(2)$  element-by-element.  $a$  and  $b$  are scalars, vectors or matrices of the same size. Each entry in  $a$  and  $b$  represents an element of  $GF(2)$ . The entries of  $a$  and  $b$  are either 0 or 1.

`quot = gfddiv(b,a,p)` divides  $b$  by  $a$  in  $GF(p)$  and returns the quotient.  $p$  is a prime number. If  $a$  and  $b$  are matrices of the same size, the function treats each element independently. All entries of  $b$ ,  $a$ , and `quot` are between 0 and  $p-1$ .

`quot = gfddiv(b,a,field)` divides  $b$  by  $a$  in  $GF(p^m)$  and returns the quotient.  $p$  is a prime number and  $m$  is a positive integer. If  $a$  and  $b$  are matrices of the same size, then the function treats each element independently. All entries of  $b$ ,  $a$ , and `quot` are the exponential formats of elements of  $GF(p^m)$  relative to some primitive element of  $GF(p^m)$ . `field` is the matrix listing all elements of  $GF(p^m)$ , arranged relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats.

In all cases, an attempt to divide by the zero element of the field results in a “quotient” of NaN.

## Examples

The code below displays lists of multiplicative inverses in GF(5) and GF(25). It uses column vectors as inputs to `gfdiv`.

```
% Find inverses of nonzero elements of GF(5).
p = 5;
b = ones(p-1,1);
a = [1:p-1]';
quot1 = gfdiv(b,a,p);
disp('Inverses in GF(5):')
disp('element inverse')
disp([a, quot1])

% Find inverses of nonzero elements of GF(25).
m = 2;
field = gftuple([-1:p^m-2]',m,p);
b = zeros(p^m-1,1); % Numerator is zero since 1 = alpha^0.
a = [0:p^m-2]';
quot2 = gfdiv(b,a,field);
disp('Inverses in GF(25), expressed in EXPONENTIAL FORMAT with')
disp('respect to a root of the default primitive polynomial:')
disp('element inverse')
disp([a, quot2])
```

## gffilter (prime Galois field)

Filter data using polynomials over prime Galois field

### Syntax

```
y = gffilter(b,a,x)
y = gffilter(b,a,x,p)
```

### Description

---

**Note** This function performs computations in  $GF(p^m)$ , where  $p$  is prime. To work in  $GF(2^m)$ , use the `filter` function with Galois arrays. For details, see “Filtering”.

---

`y = gffilter(b,a,x)` filters the data in vector `x` with the filter described by vectors `b` and `a`. The vectors `b`, `a` and `x` must be in  $GF(2)$ , that is, be binary and `y` is also in  $GF(2)$ .

`y = gffilter(b,a,x,p)` filters the data `x` using the filter described by vectors `a` and `b`. `y` is the filtered data in  $GF(p)$ . `p` is a prime number, and all entries of `a` and `b` are between 0 and `p-1`.

By definition of the filter, `y` solves the difference equation

$$a(1)y(n) = b(1)x(n)+b(2)x(n-1)+b(3)x(n-2)+\dots+b(B+1)x(n-B) \\ -a(2)y(n-1)-a(3)y(n-2)-\dots-a(A+1)y(n-A)$$

where

- `A+1` is the length of the vector `a`
- `B+1` is the length of the vector `b`
- `n` varies between 1 and the length of the vector `x`.

The vector `a` represents the degree- $n_a$  polynomial

$$a(1)+a(2)x+a(3)x^2+\dots+a(A+1)x^A$$

### Examples

The impulse response of a particular filter is given in the code and diagram below.

```
b = [1 0 0 1 0 1 0 1];  
a = [1 0 1 1];  
y = gffilter(b,a,[1,zeros(1,19)]);  
stem(y);  
axis([0 20 -.1 1.1])
```

## gflinq

Find particular solution of  $Ax = b$  over prime Galois field

### Syntax

```
x = gflinq(A,b)
x = gflinq(A,b,p)
[x,vld] = gflinq(...)
```

### Description

---

**Note** This function performs computations in  $GF(p)$ , where  $p$  is prime. To work in  $GF(2^m)$ , apply the `\` or `/` operator to Galois arrays. For details, see “Solving Linear Equations”.

---

`x = gflinq(A,b)` outputs a particular solution of the linear equation  $Ax = b$  in  $GF(2)$ . The elements in `a`, `b` and `x` are either 0 or 1. If the equation has no solution, then `x` is empty.

`x = gflinq(A,b,p)` returns a particular solution of the linear equation  $Ax = b$  over  $GF(p)$ , where  $p$  is a prime number. If `A` is a  $k$ -by- $n$  matrix and `b` is a vector of length  $k$ , `x` is a vector of length  $n$ . Each entry of `A`, `x`, and `b` is an integer between 0 and  $p-1$ . If no solution exists, `x` is empty.

`[x,vld] = gflinq(...)` returns a flag `vld` that indicates the existence of a solution. If `vld = 1`, the solution `x` exists and is valid; if `vld = 0`, no solution exists.

### Examples

The code below produces some valid solutions of a linear equation over  $GF(3)$ .

```
A = [2 0 1;
     1 1 0;
     1 1 2];
```

```
% An example in which the solutions are valid
[x,vld] = gflneq(A,[1;0;0],3)
```

The output is below.

```
x =
    2
    1
    0
```

```
vld =
    1
```

By contrast, the command below finds that the linear equation has *no* solutions.

```
[x2,vld2] = gflneq(zeros(3,3),[2;0;0],3)
```

The output is below.

This linear equation has no solution.

```
x2 =
    []

vld2 =
    0
```

## Algorithms

`gflneq` uses Gaussian elimination.

## gfminpol

Find minimal polynomial of Galois field element

### Syntax

```
pol = gfminpol(k,m)
pol = gfminpol(k,m,p)
pol = gfminpol(k,prim_poly,p)
```

### Description

---

**Note** This function performs computations in  $GF(p^m)$ , where  $p$  is prime. To work in  $GF(2^m)$ , use the `minpol` function with Galois arrays. For details, see “Minimal Polynomials”.

---

`pol = gfminpol(k,m)` produces a minimal polynomial for each entry in  $k$ .  $k$  must be either a scalar or a column vector. Each entry in  $k$  represents an element of  $GF(2^m)$  in exponential format. That is,  $k$  represents  $\alpha^k$ , where  $\alpha$  is a primitive element in  $GF(2^m)$ . The  $i$ th row of `pol` represents the minimal polynomial of  $k(i)$ . The coefficients of the minimal polynomial are in the base field  $GF(2)$  and listed in order of ascending exponents.

`pol = gfminpol(k,m,p)` finds the minimal polynomial of  $A^k$  over  $GF(p)$ , where  $p$  is a prime number,  $m$  is an integer greater than 1, and  $A$  is a root of the default primitive polynomial for  $GF(p^m)$ . The format of the output is as follows:

- If  $k$  is a nonnegative integer, `pol` is a row vector that gives the coefficients of the minimal polynomial in order of ascending powers.
- If  $k$  is a vector of length `len` all of whose entries are nonnegative integers, `pol` is a matrix having `len` rows; the  $r$ th row of `pol` gives the coefficients of the minimal polynomial of  $A^{k(r)}$  in order of ascending powers.

`pol = gfminpol(k,prim_poly,p)` is the same as the first syntax listed, except that  $A$  is a root of the primitive polynomial for  $GF(p^m)$  specified by `prim_poly`. `prim_poly` is a

polynomial character vector or a row vector that gives the coefficients of the degree- $m$  primitive polynomial in order of ascending powers.

## Examples

The syntax `gfminpol(k,m,p)` is used in the sample code in “Characterization of Polynomials”.

# gfmul

Multiply elements of Galois field

## Syntax

```
c = gfmul(a,b,p)
c = gfmul(a,b,field)
```

## Description

---

**Note** This function performs computations in  $GF(p^m)$  where  $p$  is prime. To work in  $GF(2^m)$ , apply the `.*` operator to Galois arrays. For details, see “Example: Multiplication”.

---

The `gfmul` function multiplies elements of a Galois field. (To multiply polynomials over a Galois field, use `gfconv` instead.)

`c = gfmul(a,b,p)` multiplies  $a$  and  $b$  in  $GF(p)$ . Each entry of  $a$  and  $b$  is between 0 and  $p-1$ .  $p$  is a prime number. If  $a$  and  $b$  are matrices of the same size, the function treats each element independently.

`c = gfmul(a,b,field)` multiplies  $a$  and  $b$  in  $GF(p^m)$ , where  $p$  is a prime number and  $m$  is a positive integer.  $a$  and  $b$  represent elements of  $GF(p^m)$  in exponential format relative to some primitive element of  $GF(p^m)$ . `field` is the matrix listing all elements of  $GF(p^m)$ , arranged relative to the same primitive element.  $c$  is the exponential format of the product, relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats. If  $a$  and  $b$  are matrices of the same size, the function treats each element independently.

## Examples

“Arithmetic in Galois Fields” contains examples. Also, the code below shows that

$$A^2 \cdot A^4 = A^6$$

where  $A$  is a root of the primitive polynomial  $2 + 2x + x^2$  for  $GF(9)$ .

```
p = 3; m = 2;  
prim_poly = [2 2 1];  
field = gftuple([-1:p^m-2]',prim_poly,p);  
a = gfmul(2,4,field)
```

The output is

a =

6

## gfpretty

Polynomial in traditional format

### Syntax

```
gfpretty(a)  
gfpretty(a,st)  
gfpretty(a,st,n)
```

### Description

`gfpretty(a)` displays a polynomial in a traditional format, using  $X$  as the variable and the entries of the row vector `a` as the coefficients in order of ascending powers. The polynomial is displayed in order of ascending powers. Terms having a zero coefficient are not displayed.

`gfpretty(a,st)` is the same as the first syntax listed, except that the content of `st` is used as the variable instead of  $X$ .

`gfpretty(a,st,n)` is the same as the first syntax listed, except that the content of `st` is used as the variable instead of  $X$ , and each line of the display has width `n` instead of the default value of 79.

---

**Note** For all syntaxes: If you do not use a fixed-width font, the spacing in the display might not look correct.

---

### Examples

Display statements about the elements of GF(81).

```
p = 3; m = 4;  
ii = randi([1,p^m-2],1,1); % Random exponent for prim element  
primpolys = gfprimfd(m,'all',p);  
[rows, cols] = size(primpolys);
```

```

jj = randi([1,rows],1,1); % Random primitive polynomial

disp('If A is a root of the primitive polynomial')
gfpretty(primpolys(jj,:)) % Polynomial in X
disp('then the element')
gfpretty([zeros(1,ii),1], 'A') % The polynomial A^ii
disp('can also be expressed as')
gfpretty(gftuple(ii,m,p), 'A') % Polynomial in A

```

Below is a sample of the output.

If A is a root of the primitive polynomial

$$2 + 2X^3 + X^4$$

then the element

$$A^{22}$$

can also be expressed as

$$2 + A^2 + A^3$$

## See Also

## gfprimck

Check whether polynomial over Galois field is primitive

### Syntax

```
ck = gfprimck(a)
ck = gfprimck(a,p)
```

### Description

---

**Note** This function performs computations in  $GF(p^m)$ , where  $p$  is prime. If you are working in  $GF(2^m)$ , use the `isprimitive` function. For details, see *Finding Primitive Polynomials* in “Primitive Polynomials and Element Representations”.

---

`ck = gfprimck(a)` checks whether the degree- $m$   $GF(2)$  polynomial  $a$  is a primitive polynomial for  $GF(2^m)$ , where  $m = \text{length}(a) - 1$ . The output `ck` is as follows:

- -1 if  $a$  is not an irreducible polynomial
- 0 if  $a$  is irreducible but not a primitive polynomial for  $GF(p^m)$
- 1 if  $a$  is a primitive polynomial for  $GF(p^m)$

`ck = gfprimck(a,p)` checks whether the degree- $m$   $GF(P)$  polynomial  $a$  is a primitive polynomial for  $GF(p^m)$ .  $p$  is a prime number.

$a$  is either a polynomial character vector or a row vector representing the polynomial by listing its coefficients in ascending order. For example, in  $GF(5)$ , `'4 + 3x + 2x^3'` and `[4 3 0 2]` are equivalent.

This function considers the zero polynomial to be “not irreducible” and considers all polynomials of degree zero or one to be primitive.

## Examples

“Characterization of Polynomials” contains examples.

## Algorithms

An irreducible polynomial over  $GF(p)$  of degree at least 2 is primitive if and only if it does not divide  $x^k - 1$  for any positive integer  $k$  smaller than  $p^m - 1$ .

## gfprimdf

Provide default primitive polynomials for Galois field

### Syntax

```
pol = gfprimdf(m)
pol = gfprimdf(m,p)
```

### Description

---

**Note** This function performs computations in  $\text{GF}(p^m)$ , where  $p$  is prime. To work in  $\text{GF}(2^m)$ , use the `primpoly` function. For details, see *Finding Primitive Polynomials* in “Primitive Polynomials and Element Representations”.

---

`pol = gfprimdf(m)` outputs the default primitive polynomial `pol` in  $\text{GF}(2^m)$ .

`pol = gfprimdf(m,p)` returns the row vector that gives the coefficients, in order of ascending powers, of the default primitive polynomial for  $\text{GF}(p^m)$ .  $m$  is a positive integer and  $p$  is a prime number.

### Examples

The command below shows that  $2 + x + x^2$  is the default primitive polynomial for  $\text{GF}(5^2)$ .

```
pol = gfprimdf(2,5)
pol =
```

```
    2    1    1
```

The code below displays the default primitive polynomial for each of the fields  $\text{GF}(3^m)$ , where  $m$  ranges between 3 and 5.

```
for m = 3:5
    gfpretty(gfprimdf(m,3))
end
```

The output is below.

$$1 + 2 X + X^3$$

$$2 + X + X^4$$

$$1 + 2 X + X^5$$

## gfprimfd

Find primitive polynomials for Galois field

### Syntax

```
pol = gfprimfd(m,opt,p)
```

### Description

---

**Note** This function performs computations in  $GF(p^m)$ , where  $p$  is prime. To work in  $GF(2^m)$ , use the `primpoly` function. For details, see *Finding Primitive Polynomials* in “Primitive Polynomials and Element Representations”.

---

- If  $m = 1$ ,  $pol = [1 \ 1]$ .
- A polynomial is represented as a row containing the coefficients in order of ascending powers.

`pol = gfprimfd(m,opt,p)` searches for one or more primitive polynomials for  $GF(p^m)$ , where  $p$  is a prime number and  $m$  is a positive integer. If  $m = 1$ ,  $pol = [1 \ 1]$ . If  $m > 1$ , the output `pol` depends on the argument `opt` as shown in the table below. Each polynomial is represented in `pol` as a row containing the coefficients in order of ascending powers.

<b>opt</b>	<b>Significance of pol</b>	<b>Format of pol</b>
'min'	One primitive polynomial for $GF(p^m)$ having the smallest possible number of nonzero terms	The row vector representing the polynomial
'max'	One primitive polynomial for $GF(p^m)$ having the greatest possible number of nonzero terms	The row vector representing the polynomial

opt	Significance of pol	Format of pol
'all'	All primitive polynomials for $GF(p^m)$	A matrix, each row of which represents one such polynomial
A positive integer	All primitive polynomials for $GF(p^m)$ that have <i>opt</i> nonzero terms	A matrix, each row of which represents one such polynomial

## Examples

The code below seeks primitive polynomials for  $GF(81)$  having various other properties. Notice that `fourterms` is empty because no primitive polynomial for  $GF(81)$  has exactly four nonzero terms. Also notice that `fewterms` represents a *single* polynomial having three terms, while `threeterms` represents *all* of the three-term primitive polynomials for  $GF(81)$ .

```
p = 3; m = 4; % Work in GF(81).
fewterms = gfprimfd(m, 'min', p)
threeterms = gfprimfd(m, 3, p)
fourterms = gfprimfd(m, 4, p)
```

The output is below.

```
fewterms =
```

```
    2    1    0    0    1
```

```
threeterms =
```

```

### Algorithms

`gfprimfd` tests for primitivity using `gfprimck`. If *opt* is 'min', 'max', or omitted, polynomials are constructed by converting decimal integers to base *p*. Based on the decimal ordering, `gfprimfd` returns the first polynomial it finds that satisfies the appropriate conditions.

# gfrank

Compute rank of matrix over Galois field

## Syntax

```
rk = gfrank(A,p)
```

## Description

---

**Note** This function performs computations in  $\text{GF}(p)$  where  $p$  is prime. If you are working in  $\text{GF}(2^m)$ , use the rank function with Galois arrays. For details, see “Computing Ranks”.

---

`rk = gfrank(A,p)` calculates the rank of the matrix  $A$  in  $\text{GF}(p)$ , where  $p$  is a prime number.

## Examples

In the code below, `gfrank` says that the matrix  $A$  has less than full rank. This conclusion makes sense because the determinant of  $A$  is zero mod  $p$ .

```
A = [1 0 1;
     2 1 0;
     0 1 1];
p = 3;
det_a = det(A); % Ordinary determinant of A
detmodp = rem(det(A),p); % Determinant mod p
rankp = gfrank(A,p);
disp(['Determinant = ',num2str(det_a)])
disp(['Determinant mod p is ',num2str(detmodp)])
disp(['Rank over GF(p) is ',num2str(rankp)])
```

The output is below.

Determinant = 3  
Determinant mod p is 0  
Rank over GF(p) is 2

### **Algorithms**

gf rank uses an algorithm similar to Gaussian elimination.

**Introduced before R2006a**

## gfrepcov

Convert one binary polynomial representation to another

### Syntax

```
polystandard = gfrepcov(poly2)
```

### Description

Two logical ways to represent polynomials over GF(2) are listed below.

- 1** [A\_0 A\_1 A\_2 ... A\_(m-1)] represents the polynomial

$$A_0 + A_1x + A_2x^2 + \dots + A_{(m-1)}x^{m-1}$$

Each entry A\_k is either one or zero.

- 2** [A\_0 A\_1 A\_2 ... A\_(m-1)] represents the polynomial

$$x^{A_0} + x^{A_1} + x^{A_2} + \dots + x^{A_{(m-1)}}$$

Each entry A\_k is a nonnegative integer. All entries must be distinct.

Format **1** is the standard form used by the Galois field functions in this toolbox, but there are some cases in which format **2** is more convenient.

`polystandard = gfrepcov(poly2)` converts from the second format to the first, for polynomials of degree *at least* 2. `poly2` and `polystandard` are row vectors. The entries of `poly2` are distinct integers, and at least one entry must exceed 1. Each entry of `polystandard` is either 0 or 1.

### Examples

The command below converts the representation format of the polynomial  $1 + x^2 + x^5$ .

```
polystandard = gfrepcov([0 2 5])
```

polystandard =

1 0 1 0 0 1

## groots

Find roots of polynomial over prime Galois field

### Syntax

```
rt = groots(f,m,p)
rt = groots(f,prim_poly,p)
[rt,rt_tuple] = groots(...)
[rt,rt_tuple,field] = groots(...)
```

### Description

---

**Note** This function performs computations in  $GF(p^m)$ , where  $p$  is prime. To work in  $GF(2^m)$ , use the `roots` function with Galois arrays. For details, see “Roots of Polynomials”.

---

For all syntaxes,  $f$  is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of a degree- $d$  polynomial.

---

**Note** `groots` lists each root exactly once, ignoring multiplicities of roots.

---

`rt = groots(f,m,p)` finds roots in  $GF(p^m)$  of the polynomial that  $f$  represents.  $rt$  is a column vector each of whose entries is the exponential format of a root. The exponential format is relative to a root of the default primitive polynomial for  $GF(p^m)$ .

`rt = groots(f,prim_poly,p)` finds roots in  $GF(p^m)$  of the polynomial that  $f$  represents.  $rt$  is a column vector each of whose entries is the exponential format of a root. The exponential format is relative to a root of the degree- $m$  primitive polynomial for  $GF(p^m)$  that `prim_poly` represents.

`[rt,rt_tuple] = groots(...)` returns an additional matrix `rt_tuple`, whose  $k$ th row is the polynomial format of the root `rt(k)`. The polynomial and exponential formats are both relative to the same primitive element.

`[rt,rt_tuple,field] = gfroots(...)` returns additional matrices `rt_tuple` and `field`. `rt_tuple` is described in the preceding paragraph. `field` gives the list of elements of the extension field. The list of elements, the polynomial format, and the exponential format are all relative to the same primitive element.

---

**Note** For a description of the various formats that `gfroots` uses, see “Representing Elements of Galois Fields”.

---

## Examples

“Roots of Polynomials” contains a description and example of the use of `gfroots`.

The code below finds the polynomial format of the roots of the primitive polynomial  $2 + x^3 + x^4$  for GF(81). It then displays the roots in traditional form as polynomials in `alph`. (The output is omitted here.) Because `prim_poly` is both the primitive polynomial and the polynomial whose roots are sought, `alph` itself is a root.

```
p = 3; m = 4;
prim_poly = [2 0 0 1 1]; % A primitive polynomial for GF(81)
f = prim_poly; % Find roots of the primitive polynomial.
[rt,rt_tuple] = gfroots(f,prim_poly,p);
% Display roots as polynomials in alpha.
for ii = 1:length(rt_tuple)
    gfprefy(rt_tuple(ii,:), 'alpha')
end
```

## gfsb

Subtract polynomials over Galois field

### Syntax

```
c = gfsb(a,b,p)
c = gfsb(a,b,p,len)
c = gfsb(a,b,field)
```

### Description

---

**Note** This function performs computations in  $GF(p^m)$ , where  $p$  is prime. To work in  $GF(2^m)$ , apply the `-` operator to Galois arrays of equal size. For details, see “Example: Addition and Subtraction”.

---

`c = gfsb(a,b,p)` calculates  $a$  minus  $b$ , where  $a$  and  $b$  represent polynomials over  $GF(p)$  and  $p$  is a prime number.  $a$ ,  $b$ , and  $c$  are row vectors that give the coefficients of the corresponding polynomials in order of ascending powers. Each coefficient is between 0 and  $p-1$ . If  $a$  and  $b$  are matrices of the same size, the function treats each row independently. Alternatively,  $a$  and  $b$  can be represented as polynomial character vectors.

`c = gfsb(a,b,p,len)` subtracts row vectors as in the syntax above, except that it returns a row vector of length `len`. The output  $c$  is a truncated or extended representation of the answer. If the row vector corresponding to the answer has fewer than `len` entries (including zeros), extra zeros are added at the end; if it has more than `len` entries, entries from the end are removed.

`c = gfsb(a,b,field)` calculates  $a$  minus  $b$ , where  $a$  and  $b$  are the exponential format of two elements of  $GF(p^m)$ , relative to some primitive element of  $GF(p^m)$ .  $p$  is a prime number and  $m$  is a positive integer. `field` is the matrix listing all elements of  $GF(p^m)$ , arranged relative to the same primitive element.  $c$  is the exponential format of the answer, relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats. If  $a$  and  $b$  are matrices of the same size, the function treats each element independently.

## Examples

### Subtract Two GF Arrays

Calculate  $(2 + 3x + x^2) - (4 + 2x + 3x^2)$  over GF(5).

```
x = gfsb([2 3 1],[4 2 3],5)
```

```
x = 1×3
```

```
    3    1    3
```

Subtract the two polynomials and display the first two elements.

```
y = gfsb([2 3 1],[4 2 3],5,2)
```

```
y = 1×2
```

```
    3    1
```

For prime number  $p$  and exponent  $m$ , create a matrix listing all elements of GF( $p^m$ ) given primitive polynomial  $2 + 2x + x^2$ .

```
p = 3;  
m = 2;  
primpoly = [2 2 1];  
field = gftuple((-1:p^m-2)',primpoly,p);
```

Subtract  $A^4$  from  $A^2$ . The result is  $A^7$ .

```
g = gfsb(2,4,field)
```

```
g = 7
```

## gftable

Generate file to accelerate Galois field computations

### Syntax

```
gftable(m,prim_poly);
```

### Description

`gftable(m,prim_poly)` generates a file that can help accelerate computations in the field  $GF(2^m)$  as described by the *nondefault* primitive polynomial `prim_poly`, which can be either a polynomial character vector or an integer. `prim_poly` represents a primitive polynomial for  $GF(2^m)$ , where  $1 < m < 16$ , using the format described in “Specifying the Primitive Polynomial”. The function places the file, called `userGftable.mat`, in your current working folder. If necessary, the function overwrites any writable existing version of the file.

---

**Note** If `prim_poly` is the default primitive polynomial for  $GF(2^m)$  listed in the table on the `gf` reference page, this function has no effect. A MAT-file in your MATLAB installation already includes information that facilitates computations with respect to the default primitive polynomial.

---

### Examples

In the example below, you expect `t3` to be similar to `t1` and to be significantly smaller than `t2`, assuming that you do not already have a `userGftable.mat` file that includes the `(m, prim_poly)` pair (8, 501). Notice that before executing the `gftable` command, MATLAB displays a warning and that after executing `gftable`, there is no warning. By executing the `gftable` command you save the GF table for faster calculations.

```
% Sample code to check how much gftable improves speed.
tic; a = gf(repmat([0:2^8-1],1000,1),8); b = a.^100; t1 = toc;
tic; a = gf(repmat([0:2^8-1],1000,1),8,501); b = a.^100; t2 = toc;
```

```
gftable(8,501); % Include this primitive polynomial in the file.  
tic; a = gf(repmat([0:2^8-1],1000,1),8,501); b = a.^100; t3 = toc;
```

## gftrunc

Minimize length of polynomial representation

### Syntax

```
c = gftrunc(a)
```

### Description

`c = gftrunc(a)` truncates a row vector, `a`, that gives the coefficients of a GF( $p$ ) polynomial in order of ascending powers. If  $a(k) = 0$  whenever  $k > d + 1$ , the polynomial has degree  $d$ . The row vector `c` omits these high-order zeros and thus has length  $d + 1$ .

### Examples

In the code below, zeros are removed from the end, but *not* from the beginning or middle, of the row-vector representation of  $x^2 + 2x^3 + 3x^4 + 4x^7 + 5x^8$ .

```
c = gftrunc([0 0 1 2 3 0 0 4 5 0 0])  
c =
```

```
    0    0    1    2    3    0    0    4    5
```

### See Also

**Introduced before R2006a**

## gftuple

Simplify or convert Galois field element formatting

### Syntax

```
tp = gftuple(a,m)
tp = gftuple(a,prim_poly)
tp = gftuple(a,m,p)
tp = gftuple(a,prim_poly,p)
tp = gftuple(a,prim_poly,p,prim_ck)
[tp,expform] = gftuple(...)
```

### Description

---

**Note** This function performs computations in  $\text{GF}(p^m)$ , where  $p$  is prime. To perform equivalent computations in  $\text{GF}(2^m)$ , apply the `.^` operator and the `log` function to Galois arrays. For more information, see “Example: Exponentiation” and “Example: Elementwise Logarithm”.

---

### For All Syntaxes

`gftuple` serves to simplify the polynomial or exponential format of Galois field elements, or to convert from one format to another. For an explanation of the formats that `gftuple` uses, see “Representing Elements of Galois Fields”.

In this discussion, the format of an element of  $\text{GF}(p^m)$  is called “simplest” if all exponents of the primitive element are

- Between 0 and  $m-1$  for the polynomial format
- Either `-Inf`, or between 0 and  $p^{m-2}$ , for the exponential format

For all syntaxes, `a` is a matrix, each row of which represents an element of a Galois field. The format of `a` determines how MATLAB interprets it:

- If  $\mathbf{a}$  is a column of integers, MATLAB interprets each row as an *exponential* format of an element. Negative integers are equivalent to  $-\infty$  in that they all represent the zero element of the field.
- If  $\mathbf{a}$  has more than one column, MATLAB interprets each row as a *polynomial* format of an element. (Each entry of  $\mathbf{a}$  must be an integer between 0 and  $p-1$ .)

The exponential or polynomial formats mentioned above are all relative to a primitive element specified by the *second* input argument. The second argument is described below.

### For Specific Syntaxes

`tp = gftuple(a,m)` returns the simplest polynomial format of the elements that  $\mathbf{a}$  represents, where the  $k$ th row of  $\mathbf{tp}$  corresponds to the  $k$ th row of  $\mathbf{a}$ . The formats are relative to a root of the default primitive polynomial for  $\text{GF}(2^m)$ , where  $m$  is a positive integer.

`tp = gftuple(a,prim_poly)` is the same as the syntax above, except that `prim_poly` is a polynomial character vector or a row vector that lists the coefficients of a degree  $m$  primitive polynomial for  $\text{GF}(2^m)$  in order of ascending exponents.

`tp = gftuple(a,m,p)` is the same as `tp = gftuple(a,m)` except that 2 is replaced by a prime number  $p$ .

`tp = gftuple(a,prim_poly,p)` is the same as `tp = gftuple(a,prim_poly)` except that 2 is replaced by a prime number  $p$ .

`tp = gftuple(a,prim_poly,p,prim_ck)` is the same as `tp = gftuple(a,prim_poly,p)` except that `gftuple` checks whether `prim_poly` represents a polynomial that is indeed primitive. If not, then `gftuple` generates an error and  $\mathbf{tp}$  is not returned. The input argument `prim_ck` can be any number or character vector; only its existence matters.

`[tp,expform] = gftuple(...)` returns the additional matrix `expform`. The  $k$ th row of `expform` is the simplest exponential format of the element that the  $k$ th row of  $\mathbf{a}$  represents. All other features are as described in earlier parts of this “Description” section, depending on the input arguments.

## Examples

- “List of All Elements of a Galois Field” (end of section)
- “Converting to Simplest Polynomial Format”

As another example, the `gftuple` command below generates a list of elements of  $GF(p^m)$ , arranged relative to a root of the default primitive polynomial. Some functions in this toolbox use such a list as an input argument.

```
p = 5; % Or any prime number
m = 4; % Or any positive integer
field = gftuple([-1:p^m-2]',m,p);
```

Finally, the two commands below illustrate the influence of the *shape* of the input matrix. In the first command, a column vector is treated as a sequence of elements expressed in exponential format. In the second command, a row vector is treated as a single element expressed in polynomial format.

```
tp1 = gftuple([0; 1],3,3)
tp2 = gftuple([0, 0, 0, 1],3,3)
```

The output is below.

tp1 =

```
    1    0    0
    0    1    0
```

tp2 =

```
    2    1    0
```

The outputs reflect that, according to the default primitive polynomial for  $GF(3^3)$ , the relations below are true.

$$\alpha^0 = 1 + 0\alpha + 0\alpha^2$$

$$\alpha^1 = 0 + 1\alpha + 0\alpha^2$$

$$0 + 0\alpha + 0\alpha^2 + \alpha^3 = 2 + \alpha + 0\alpha^2$$

## **Algorithms**

`gftuple` uses recursive callbacks to determine the exponential format.

# gfweight

Calculate minimum distance of linear block code

## Syntax

```
wt = gfweight(genmat)
wt = gfweight(genmat, 'gen')
wt = gfweight(parmat, 'par')
wt = gfweight(genpoly, n)
```

## Description

The minimum distance, or minimum weight, of a linear block code is defined as the smallest positive number of nonzero entries in any n-tuple that is a codeword.

`wt = gfweight(genmat)` returns the minimum distance of the linear block code whose generator matrix is `genmat`.

`wt = gfweight(genmat, 'gen')` returns the minimum distance of the linear block code whose generator matrix is `genmat`.

`wt = gfweight(parmat, 'par')` returns the minimum distance of the linear block code whose parity-check matrix is `parmat`.

`wt = gfweight(genpoly, n)` returns the minimum distance of the *cyclic* code whose codeword length is `n` and whose generator polynomial is represented by `genpoly`. `genpoly` is a polynomial character vector or a row vector that gives the coefficients of the generator polynomial in order of ascending powers.

## Examples

### Calculate Minimum Distance of Linear Block Code

Calculate the minimum distance of a cyclic code using several methods.

Create the generate polynomial for a (7,4) cyclic code.

```
n = 7;
genpoly = cyclpoly(n,4);
```

Calculate the minimum distance for the cyclic code using:

- 1 Generator polynomial `genmat`
- 2 Parity check matrix `parmat`
- 3 Generator polynomial `genpoly`
- 4 Generator polynomial specified as a character vector

```
[parmat, genmat] = cyclgen(n,genpoly);
wts = [gfweight(genmat,'gen') gfweight(parmat,'par'),...
       gfweight(genpoly,n) gfweight('1+x2+x3',n)]
```

```
wts = 1×4
```

```
     3     3     3     3
```

# gray2bin

Convert Gray-encoded positive integers to corresponding Gray-decoded integers

## Syntax

```
y = gray2bin(x,modulation,M)
[y,map] = gray2bin(x,modulation,M)
```

## Description

`y = gray2bin(x,modulation,M)` generates a Gray-decoded output vector or matrix `y` with the same dimensions as its input parameter `x`. `x` can be a scalar, vector, matrix, or 3-D array. `modulation` is the modulation type and must be `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`. `M` is the modulation order that can be an integer power of 2.

`[y,map] = gray2bin(x,modulation,M)` generates a Gray-decoded output `y` with its respective Gray-encoded constellation map, `map`.

You can use `map` output to label a Gray-encoded constellation. The `map` output gives the Gray encoded labels for the corresponding modulation. See the example below.

---

**Note** If you are converting binary coded data to Gray-coded data and modulating the result immediately afterwards, you should use the appropriate modulation object or function with the `'Gray'` option, instead of `BIN2GRAY`.

---

## Examples

### Binary to Gray Symbol Mapping

This example shows how to use the `bin2gray` and `gray2bin` functions to map integer inputs from a natural binary order symbol mapping to a Gray coded signal constellation and vice versa, assuming 16-QAM modulation. In addition, a visual representation of the difference between Gray and binary coded symbol mappings is shown.

Create a complete vector of 16-QAM integers.

```
M= 16;  
x = (0:M-1)';
```

Convert the input vector from a natural binary order to a Gray encoded vector using `bin2gray`.

```
[y,mapy] = bin2gray(x, 'qam',M);
```

Convert the Gray encoded symbols, `y`, back to a binary ordering using `gray2bin`.

```
z = gray2bin(y, 'qam',M);
```

Verify that the original data, `x`, and the final output vector, `z` are identical.

```
isequal(x,z)  
  
ans = logical  
     1
```

To create a constellation plot showing the different symbol mappings, use the `qammod` function to find the complex symbol values.

```
sym = qammod(x,M);
```

Plot the constellation symbols and label them using the Gray, `y`, and binary, `z`, output vectors. The binary representation of the Gray coded symbols is shown in black while the binary representation of the naturally ordered symbols is shown in red. Set the axes scaling so that all points are displayed.

```
scatterplot(sym,1,0, 'b*');  
for k = 1:16  
    text(real(sym(k))-0.3, imag(sym(k))+0.3, ...  
         dec2base(mapy(k),2,4));  
  
    text(real(sym(k))-0.3, imag(sym(k))-0.3, ...  
         dec2base(z(k),2,4), 'Color', [1 0 0]);  
end  
axis([-4 4 -4 4])
```

Observe that only a single bit differs between adjacent constellation points when using Gray coding.

# **gsmCheckTimeMask**

Inspect GSM burst against time mask

## **Syntax**

```
gsmCheckTimeMask(gsmCfg)  
gsmCheckTimeMask(gsmCfg,tn)
```

```
pf = gsmCheckTimeMask(gsmCfg)  
pf = gsmCheckTimeMask(gsmCfg,tn)
```

## **Description**

`gsmCheckTimeMask(gsmCfg)` plots the burst for the first time slot and the upper and lower time masks for the input GSM configuration object. The `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties of the configuration object define the power level versus time characteristics. For more information, see “Time Mask” on page 2-697.

`gsmCheckTimeMask(gsmCfg,tn)` plots the burst for the specified time slot, `tn`.

`pf = gsmCheckTimeMask(gsmCfg)` returns a pass or fail result for the specified configuration object indicating compliance of the burst in the first time slot with the time mask defined in the GSM standard. For more information, see “Time Mask” on page 2-697.

`pf = gsmCheckTimeMask(gsmCfg,tn)` returns a pass or fail result indicating compliance of the burst in the specified time slot, `tn`.

## **Examples**

### Check GSM Burst Against Time Mask

Create a GSM uplink TDMA frame configuration object with default settings. The GSM TDMA frame has eight time slots. Check the burst in the first time slot against the time mask specified by the GSM standard.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig;
```

Use the `gsmCheckTimeMask` function to view the time mask and verify that the configured rise and fall characteristics of the burst comply with the time mask specified in the GSM standard. Plot the GSM burst and time mask. When no time slot number is provided, the `gsmCheckTimeMask` function shows the first time slot, `TN=0`.

```
pf = gsmCheckTimeMask(cfggsmul);  
if pf  
    disp('Time mask test passed.')else  
    disp('Time mask test failed.')end
```

```
Time mask test passed.
```

```
gsmCheckTimeMask(cfggsmul);
```

Adjust the rise time of the GSM uplink TDMA frame configuration object, specifying a value that causes a time mask failure.

```
cfggsmul.RiseTime = 5
```

```
cfggsmul =  
  gsmUplinkConfig with properties:
```

```
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 5
      RiseDelay: 0
```

```
FallTime: 2  
FallDelay: 0
```

Use the `gsmCheckTimeMask` function to inspect the time mask of `cfggsmul`. The pass or fail result shows that the `cfggsmul` configuration now fails the time mask and the plot shows the upper time mask fails.

```
pf = gsmCheckTimeMask(cfggsmul);  
if pf  
    disp('Time mask test passed.')else  
    disp('Time mask test failed.')end
```

```
Time mask test failed.
```

```
gsmCheckTimeMask(cfggsmul);
```

### Check GSM Burst in Specified Time Slot Against Time Mask

Create a GSM uplink TDMA frame configuration object with default settings. The GSM TDMA frame has eight time slots. Check the burst in the specified time slot against the time mask specified by the GSM standard.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmul = gsmDownlinkConfig;
```

Use the `gsmCheckTimeMask` function to view the time mask and verify that the configured rise and fall characteristics of the burst in the specified time slot comply with the time mask specified by the GSM standard. Plot the GSM burst and time mask.

```
tn = 6; % Time slot number 6
pf = gsmCheckTimeMask(cfggsmul,tn);
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

Time mask test passed.

```
gsmCheckTimeMask(cfggsmul,tn);
```

Adjust the fall delay of the GSM downlink TDMA frame configuration object, specifying a value that causes a time mask failure.

```
cfggsmul.FallDelay = 4
```

```
cfggsmul =  
  gsmDownlinkConfig with properties:  
  
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]  
  SamplesPerSymbol: 16  
          TSC: [0 1 2 3 4 5 6 7]  
  Attenuation: [0 0 0 0 0 0 0 0]  
    RiseTime: 2  
   RiseDelay: 0  
    FallTime: 2  
   FallDelay: 4
```

Use the `gsmCheckTimeMask` function to inspect the time mask of `cfggsmul`. The pass or fail result shows that the `cfggsmul` configuration now fails the time mask and the plot shows the upper time mask fails.

```
pf = gsmCheckTimeMask(cfggsmul,tn);  
if pf  
    disp('Time mask test passed.')else  
    disp('Time mask test failed.')end
```

```
Time mask test failed.
```

```
gsmCheckTimeMask(cfggsmul,tn);
```

### Check Time Mask for GSM Bursts

Create GSM downlink and uplink TDMA frame configuration objects that use the various burst types available.

- Normal bursts and bursts with no data are valid for downlink and uplink frames.
- Frequency correction, synchronization, and dummy bursts are valid in downlink frames only.
- Access bursts are valid in uplink frames only.

View time masks for the different burst types against the time mask specified by the GSM standard for the downlink and uplink frames.

Create a GSM downlink TDMA frame configuration object that configures the times slot bursts as [NB FB SB Dummy Off Off Off Off].

```
cfggsmdl = gsmDownlinkConfig('BurstType',["NB" "FB" "SB" "Dummy" "Off" "Off" "Off" "Of
```

```
cfggsmdl =
```

```
gsmDownlinkConfig with properties:
```

```

    BurstType: [NB    FB    SB    Dummy    Off    Off    Off    Off]
SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0

```

Use the `gsmCheckTimeMask` function to view the time mask for the different time slot burst types. For downlink GSM TDMA frames the same time mask limits applies for all burst types.

```
for tn = 0:4
    [dlbt,dlbtVal] = enumeration(cfggsmdl.BurstType);
    dlBurstInfo = ['Downlink (TN=',num2str(tn),'), BurstType: ',dlbtVal{tn+1}];
    disp(dlBurstInfo)
    gsmCheckTimeMask(cfggsmdl,tn);
end
```

```
Downlink (TN=0), BurstType: NB
```

Downlink (TN=1), BurstType: FB

Downlink (TN=2), BurstType: SB

Downlink (TN=3), BurstType: Dummy

Downlink (TN=4), BurstType: Off

Create a GSM uplink TDMA frame configuration object that configures the times slot bursts as [NB AB Off Off Off Off Off Off].

```
cfggsmul = gsmUplinkConfig('BurstType',["NB" "AB" "Off" "Off" "Off" "Off" "Off" "Off"])
```

```
cfggsmul =  
gsmUplinkConfig with properties:
```

```
    BurstType: [NB    AB    Off    Off    Off    Off    Off    Off]
 SamplesPerSymbol: 16
           TSC: [0  1  2  3  4  5  6  7]
 Attenuation: [0  0  0  0  0  0  0  0]
           RiseTime: 2
           RiseDelay: 0
```

```
    FallTime: 2  
    FallDelay: 0
```

Use the `gsmCheckTimeMask` function to view the time masks for the different time slot burst types. For uplink GSM TDMA frames the access burst has a shorter time mask than the normal burst or no data burst.

```
for tn = 0:2  
    [ulbt,ulbtVal] = enumeration(cfggsmul.BurstType);  
    ulBurstInfo = ['Uplink (TN=',num2str(tn),'), BurstType: ',ulbtVal{tn+1}];  
    disp(ulBurstInfo)  
    gsmCheckTimeMask(cfggsmul,tn);  
end
```

```
Uplink (TN=0), BurstType: NB
```

Uplink (TN=1), BurstType: AB

Uplink (TN=2), BurstType: Off

## Input Arguments

### **gsmCfg — GSM configuration**

`gsmUplinkConfig` object | `gsmDownlinkConfig` object

GSM configuration, specified as a `gsmUplinkConfig` or `gsmDownlinkConfig` object.

### **tn — Time slot number**

0 (default) | integer in the range [0, 7]

Time slot number, specified as an integer in the range [0, 7].

Data Types: double

## Output Arguments

**pf — Pass or fail result**

0 | 1

Pass or fail result, returned as:

- 1 if the time mask passes
- 0 if the time mask fails

For more information, see “Time Mask” on page 2-697.

## More About

### Time Mask

The time mask defines the allowable transmitted power level versus time for time slot bursts in a GSM TDMA frame. This figure, from Annex B of TS 45.005, shows the upper and lower power limits for the time mask of a burst.

“GSM TDMA Frame Parameterization for Waveform Generation”

**Introduced in R2019b**

# **gsmFrame**

Create GSM waveform

## **Syntax**

```
gsmWaveform = gsmFrame(gsmCfg)
gsmWaveform = gsmFrame(gsmCfg, numFrames)
```

## **Description**

`gsmWaveform = gsmFrame(gsmCfg)` creates a GSM waveform with one TDMA frame based on the input GSM configuration object. The encrypted bit field of the transmission data bursts is filled with random data. For more information, see “GSM Frames, Time Slots, and Bursts” on page 2-708.

`gsmWaveform = gsmFrame(gsmCfg, numFrames)` creates a GSM waveform, with `numFrames` identically configured TDMA frames. In each frame, the encrypted bit field of the transmission data bursts is filled with random data. For more information, see “GSM Frames, Time Slots, and Bursts” on page 2-708.

## **Examples**

### **Create GSM Uplink Waveform**

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
cfggsmul =
    gsmUplinkConfig with properties:
```

```

        BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0

```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```

wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000

```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```

waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on

```

```
title('GSM Uplink Waveform - Phase')  
xlabel('Time (ms)')  
ylabel('Phase (rad)')
```

### Create GSM Uplink Waveform Containing Five TDMA Frames

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing five TDMA frames. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 3 dB of attenuation in the last time slot to help identify the end of each frame.

```
cfggsmul = gsmUplinkConfig('Attenuation',[0 0 0 0 0 0 0 3])

cfggsmul =
  gsmUplinkConfig with properties:

      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
  SamplesPerSymbol: 16
           TSC: [0 1 2 3 4 5 6 7]
  Attenuation: [0 0 0 0 0 0 0 3]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the frame length in samples to a variable, `spf`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
  BandwidthTimeProduct: 0.3000
  BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
  BurstLengthInSamples: 2500
  FrameLengthInSamples: 20000
```

```
spf = wfInfo.FrameLengthInSamples;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform. The last time slot of each frame is 3 dB less than the other time slots in that frame.

```
numFrames = 5;
waveform = gsmFrame(cfggsmul,numFrames);

t = 8*(0:length(waveform)-1)/spf;
```

```
numTS = 8*numFrames;  
subplot(2,1,1)  
plot(t,abs(waveform))  
grid on  
axis([0 numTS 0 1.2])  
title('GSM Uplink Waveform - Amplitude')  
xlabel('Time Slots')  
ylabel('Amplitude')  
subplot(2,1,2)  
plot(t,unwrap(angle(waveform)))  
grid on  
title('GSM Uplink Waveform - Phase')  
xlabel('Time Slots')  
ylabel('Phase (rad)')
```

## Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
```

```
cfggsmdl =  
    gsmDownlinkConfig with properties:
```

```
        BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
```

```
wfInfo = struct with fields:  
    SymbolRate: 2.7083e+05  
    SampleRate: 4.3333e+06  
    BandwidthTimeProduct: 0.3000  
    BurstLengthInSymbols: 156.2500  
    NumBurstsPerFrame: 8  
    BurstLengthInSamples: 2500  
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

## Input Arguments

### **gsmCfg** — GSM configuration

`gsmUplinkConfig` object | `gsmDownlinkConfig` object

GSM configuration, specified as a `gsmUplinkConfig` or `gsmDownlinkConfig` object.

### **numFrames** — Number of TDMA frames

16 (default) | positive integer

Number of TDMA frames in the waveform, specified as a positive integer.

Data Types: double

## Output Arguments

### **gsmWaveform** — Output time-domain waveform

complex-valued column vector

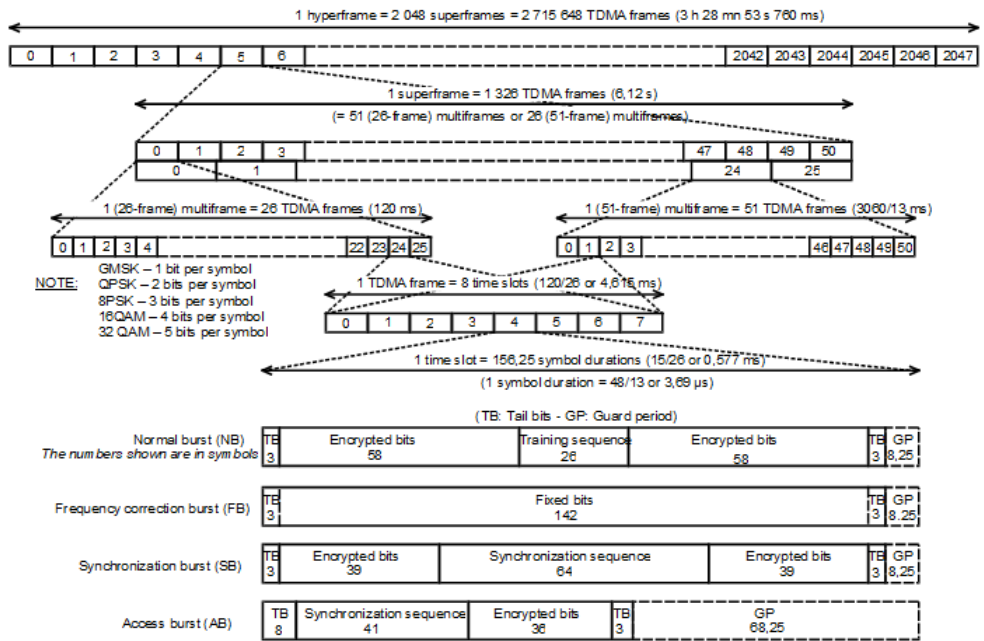

Output time-domain waveform, returned as a complex-valued column vector of length  $N_s$ , where  $N_s$  represents the number of time-domain samples. The function generates this waveform in the form of complex in-phase quadrature (IQ) samples.

## More About

### **GSM Frames, Time Slots, and Bursts**

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of 15/26 ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

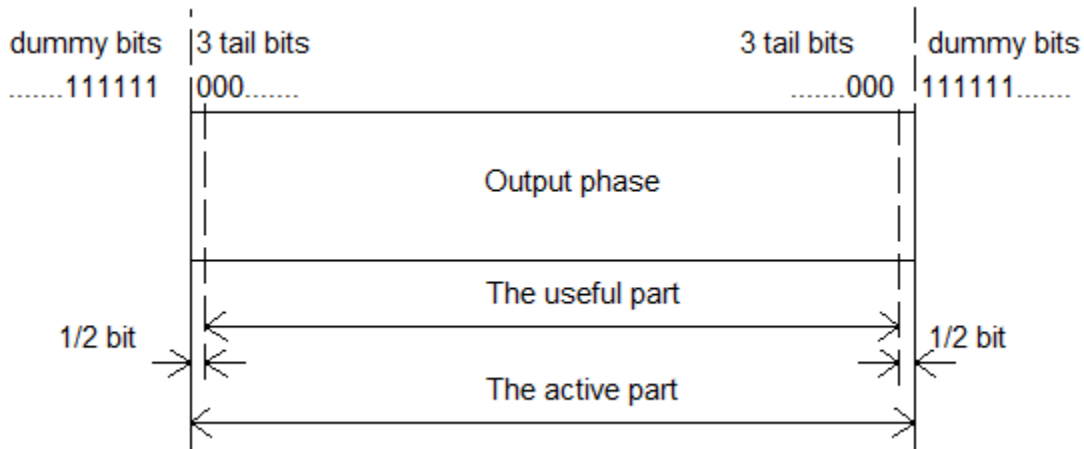

This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

*Useful duration*, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BNO and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2

of 3GPP TS 45.004, shows the leading and trailing 1/2 bit difference between the useful and active parts of the burst.

For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

## Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, ..., BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,0,1,1,1,0,0,0,1,0,1,1,0,1,1,1)
2	(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,1,0,0,1,0,0,0,0,1,1,1,0)

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, ..., BN86)
3	(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,1,0,0,0,1,1,1,1,0)
4	(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,1,1,0,1,0,1,1)
5	(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,1,0,0,1,1,1,0,1,0)
6	(1,0,1,0,0,1,1,1,1,1,0,1,1,0,0,0,1,0,1,0,0,1,1,1,1,1)
7	(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,1,0,0)

For more information, see Section 5.2.3 in 3GPP TS 45.002.

# gsmInfo

View GSM waveform information

## Syntax

```
infostruct= gsmInfo(gsmCfg)
```

## Description

`infostruct= gsmInfo(gsmCfg)` returns a structure containing characteristic waveform information for the input GSM configuration object.

## Examples

### View GSM Configuration Object Information

View information from downlink and uplink GSM configuration objects.

Create a GSM downlink configuration object with default settings and use `gsmInfo` to view the waveform information structure.

```
cfgDL = gsmDownlinkConfig;
infostructDL = gsmInfo(cfgDL)

infostructDL = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

Create a GSM uplink configuration object with default settings and use `gsmInfo` to view the waveform information structure.

```
cfgUL = gsmUplinkConfig;
infostructUL = gsmInfo(cfgUL)

infostructUL = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

### Create GSM Uplink Waveform Containing Five TDMA Frames

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing five TDMA frames. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 3 dB of attenuation in the last time slot to help identify the end of each frame.

```
cfggsmul = gsmUplinkConfig('Attenuation',[0 0 0 0 0 0 0 3])

cfggsmul =
    gsmUplinkConfig with properties:
        BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
        SamplesPerSymbol: 16
        TSC: [0 1 2 3 4 5 6 7]
        Attenuation: [0 0 0 0 0 0 0 3]
        RiseTime: 2
        RiseDelay: 0
        FallTime: 2
        FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the frame length in samples to a variable, `spf`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
spf = wfInfo.FrameLengthInSamples;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform. The last time slot of each frame is 3 dB less than the other time slots in that frame.

```
numFrames = 5;
waveform = gsmFrame(cfggsmul,numFrames);

t = 8*(0:length(waveform)-1)/spf;

numTS = 8*numFrames;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 numTS 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time Slots')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time Slots')
ylabel('Phase (rad)')
```

## Input Arguments

### **gsmCfg** — GSM configuration

`gsmUplinkConfig` object | `gsmDownlinkConfig` object

GSM configuration, specified as a `gsmUplinkConfig` or `gsmDownlinkConfig` object.

## Output Arguments

### **infostruct — Structure containing object information**

struct

Structure containing these fields with information about the characteristic GSM waveform based on the input configuration object.

### **SymbolRate — GSM symbol rate**

positive integer

GSM symbol rate in symbols per second, returned as a positive integer.

### **SampleRate — GSM sample rate**

positive integer

GSM sample rate in samples per second, returned as a positive integer.

### **BandwidthTimeProduct — Product of bandwidth and symbol time of Gaussian pulse**

positive integer

Product of bandwidth and symbol time of Gaussian pulse for the GMSK modulator, returned as a positive integer.

### **BurstLengthInSymbols — GSM burst length**

positive scalar

GSM burst length in symbols, returned as a positive scalar.

### **NumBurstsPerFrame — Number of bursts in GSM TDMA frame**

positive integer

Number of bursts in a GSM TDMA frame, returned as a positive integer.

### **BurstLengthInSamples — GSM burst length**

positive integer

GSM burst length in samples, returned as a positive integer.

### **FrameLengthInSamples — GSM frame length**

positive integer

GSM frame length in samples, returned as a positive integer.

**Introduced in R2019b**

## hammgen

Produce parity-check and generator matrices for Hamming code

### Syntax

```
h = hammgen(m)
h = hammgen(m, pol)
[h, g] = hammgen(...)
[h, g, n, k] = hammgen(...)
```

### Description

For all syntaxes, the codeword length is  $n$ .  $n$  has the form  $2^m - 1$  for some positive integer  $m$  greater than or equal to 2. The message length,  $k$ , has the form  $n - m$ .

`h = hammgen(m)` produces an  $m$ -by- $n$  parity-check matrix for a Hamming code having codeword length  $n = 2^m - 1$ . The input  $m$  is a positive integer greater than or equal to 2. The message length of the code is  $n - m$ . The binary primitive polynomial used to produce the Hamming code is the default primitive polynomial for  $GF(2^m)$ , represented by `gfprimdf(m)`.

`h = hammgen(m, pol)` produces an  $m$ -by- $n$  parity-check matrix for a Hamming code having codeword length  $n = 2^m - 1$ . The input  $m$  is a positive integer greater than or equal to 2. The message length of the code is  $n - m$ . `pol` is a row vector that gives the coefficients, in order of ascending powers, of the binary primitive polynomial for  $GF(2^m)$  that is used to produce the Hamming code. Alternatively, you can specify `pol` as a polynomial character vector. `hammgen` produces an error if `pol` represents a polynomial that is not, in fact, primitive.

`[h, g] = hammgen(...)` is the same as `h = hammgen(...)` except that it also produces the  $k$ -by- $n$  generator matrix `g` that corresponds to the parity-check matrix `h`.  $k$ , the message length, equals  $n - m$ , or  $2^m - 1 - m$ .

`[h, g, n, k] = hammgen(...)` is the same as `[h, g] = hammgen(...)` except that it also returns the codeword length  $n$  and the message length  $k$ .

---

**Note** If your value of  $m$  is less than 25 and if your primitive polynomial is the default primitive polynomial for  $GF(2^m)$ , the syntax `hammgen(m)` is likely to be faster than the syntax `hammgen(m, pol)`.

---

## Examples

### Generate Hamming Code Parity Check Matrices

Generate Hamming code matrices given codeword length.

Generate the parity check matrix  $h$ , the generator matrix  $g$ , the codeword length  $n$ , and the message length  $k$  for the Hamming code with  $m = 3$ .

```
[h,g,n,k] = hammgen(3)
```

```
h = 3x7
```

```

1   0   0   1   0   1   1
0   1   0   1   1   1   0
0   0   1   0   1   1   1
```

```
g = 4x7
```

```

1   1   0   1   0   0   0
0   1   1   0   1   0   0
1   1   1   0   0   1   0

# hank2sys

Convert Hankel matrix to linear system model

## Syntax

```
[num,den] = hank2sys(h,ini,tol)
[num,den,sv] = hank2sys(h,ini,tol)
[a,b,c,d] = hank2sys(h,ini,tol)
[a,b,c,d,sv] = hank2sys(h,ini,tol)
```

## Description

`[num,den] = hank2sys(h,ini,tol)` converts a Hankel matrix `h` to a linear system transfer function with numerator `num` and denominator `den`. The vectors `num` and `den` list the coefficients of their respective polynomials in ascending order of powers of  $z^{-1}$ . The argument `ini` is the system impulse at time zero. If `tol > 1`, `tol` is the order of the conversion. If `tol < 1`, `tol` is the tolerance in selecting the conversion order based on the singular values. If you omit `tol`, its default value is 0.01. This conversion uses the singular value decomposition method.

`[num,den,sv] = hank2sys(h,ini,tol)` returns a vector `sv` that lists the singular values of `h`.

`[a,b,c,d] = hank2sys(h,ini,tol)` converts a Hankel matrix `h` to a corresponding linear system state-space model. `a`, `b`, `c`, and `d` are matrices. The input parameters are the same as in the first syntax above.

`[a,b,c,d,sv] = hank2sys(h,ini,tol)` is the same as the syntax above, except that `sv` is a vector that lists the singular values of `h`.

## Examples

```
h = hankel([1 0 1]);
[num,den,sv] = hank2sys(h,0,.01)
```

The output is

num =

```
      0    1.0000    0.0000    1.0000
```

den =

```
  1.0000    0.0000    0.0000    0.0000
```

sv =

```
  1.6180  
  1.0000  
  0.6180
```

# heldeintrlv

Restore ordering of symbols permuted using `helintrlv`

## Syntax

```
[deintrlved, state] = heldeintrlv(data, col, ngrp, stp)
[deintrlved, state] = heldeintrlv(data, col, ngrp, stp, init_state)
deintrlved = heldeintrlv(data, col, ngrp, stp, init_state)
```

## Description

`[deintrlved, state] = heldeintrlv(data, col, ngrp, stp)` restores the ordering of symbols in `data` by placing them in an array row by row and then selecting groups in a helical fashion to place in the output, `deintrlved`. `data` must have `col*ngrp` elements. If `data` is a matrix with multiple rows and columns, it must have `col*ngrp` rows, and the function processes the columns independently. `state` is a structure that holds the final state of the array. `state.value` stores input symbols that remain in the `col` columns of the array and do not appear in the output.

The function uses the array internally for its computations. The array has unlimited rows indexed by 1, 2, 3, ..., and `col` columns. The function initializes the top of the array with zeros. It then places `col*ngrp` symbols from the input into the next `ngrp` rows of the array. The function places symbols from the array in the output, `intrlved`, placing `ngrp` symbols at a time; the `k`th group of `ngrp` symbols comes from the `k`th column of the array, starting from row  $1+(k-1)*stp$ . Some output symbols are default values of 0 rather than input symbols; similarly, some input symbols are left in the array and do not appear in the output.

`[deintrlved, state] = heldeintrlv(data, col, ngrp, stp, init_state)` initializes the array with the symbols contained in `init_state.value` instead of zeros. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver. In this syntax, some output symbols are default values of 0, some are input symbols from `data`, and some are initialization values from `init_state.value`.

`deintrlv` = `heldeintrlv(data,col,ngrp,stp,init_state)` is the same as the syntax above, except that it does not record the deinterleaver's final state. This syntax is appropriate for the last in a series of calls to this function. However, if you plan to call this function again to continue the deinterleaving process, the syntax above is more appropriate.

### Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `helintrlv` function, use the same `col`, `ngrp`, and `stp` inputs in both functions. In that case, the two functions are inverses in the sense that applying `helintrlv` followed by `heldeintrlv` leaves data unchanged, after you take their combined delay of  $\text{col} * \text{ngrp} * \text{ceil}(\text{stp} * (\text{col} - 1) / \text{ngrp})$  into account. To learn more about delays of convolutional interleavers, see “Delays of Convolutional Interleavers”.

---

**Note** Because the delay is an integer multiple of the number of symbols in `data`, you must use `heldeintrlv` at least *twice* (possibly more times, depending on the actual delay value) before the function returns results that represent more than just the delay.

---

### Examples

Recover interleaved data, taking into account the delay of the interleaver-deinterleaver pair.

```
col = 4; ngrp = 3; stp = 2; % Helical interleaver parameters
% Compute the delay of interleaver-deinterleaver pair.
delayval = col * ngrp * ceil(stp * (col-1)/ngrp);

len = col*ngrp; % Process this many symbols at one time.
data = randi([0 9],len,1); % Random symbols
data_padded = [data; zeros(delayval,1)]; % Pad with zeros.

% Interleave zero-padded data.
[i1,istate] = helintrlv(data_padded(1:len),col,ngrp,stp);
[i2,istate] = helintrlv(data_padded(len+1:2*len),col,ngrp, ...
    stp,istate);
i3 = helintrlv(data_padded(2*len+1:end),col,ngrp,stp,istate);

% Deinterleave.
```

```
[d1,dstate] = heldeintrlv(i1,col,ngroup,step);  
[d2,dstate] = heldeintrlv(i2,col,ngroup,step,dstate);  
d3 = heldeintrlv(i3,col,ngroup,step,dstate);  
  
% Check the results.  
d0 = [d1; d2; d3]; % All the deinterleaved data  
d0_trunc = d0(delayval+1:end); % Remove the delay.  
ser = symerr(data,d0_trunc)
```

The output below shows that no symbol errors occurred.

```
ser =  
  
    0
```

## helintrlv

Permute symbols using helical array

### Syntax

```
intrlv = helintrlv(data,col,ngroup,step)
[intrlv,state] = helintrlv(data,col,ngroup,step)
[intrlv,state] = helintrlv(data,col,ngroup,step,init_state)
```

### Description

`intrlv = helintrlv(data,col,ngroup,step)` permutes the symbols in `data` by placing them in an unlimited-row array in helical fashion and then placing rows of the array in the output, `intrlv`. `data` must have `col*ngroup` elements. If `data` is a matrix with multiple rows and columns, it must have `col*ngroup` rows, and the function processes the columns independently.

The function uses the array internally for its computations. The array has unlimited rows indexed by 1, 2, 3,..., and `col` columns. The function partitions `col*ngroup` symbols from the input into consecutive groups of `ngroup` symbols. The function places the `k`th group in the array along column `k`, starting from row `1+(k-1)*step`. Positions in the array that do not contain input symbols have default values of 0. The function places `col*ngroup` symbols from the array in the output, `intrlv`, by reading the first `ngroup` rows sequentially. Some output symbols are default values of 0 rather than input symbols; similarly, some input symbols are left in the array and do not appear in the output.

`[intrlv,state] = helintrlv(data,col,ngroup,step)` returns a structure that holds the final state of the array. `state.value` stores input symbols that remain in the `col` columns of the array and do not appear in the output.

`[intrlv,state] = helintrlv(data,col,ngroup,step,init_state)` initializes the array with the symbols contained in `init_state.value`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding deinterleaver. In this syntax, some output symbols are default values of 0, some are input symbols from `data`, and some are initialization values from `init_state.value`.

## Examples

The example below rearranges the integers from 1 to 24.

```
% Interleave some symbols. Record final state of array.
[i1,state] = helintrlv([1:12]',3,4,1);
% Interleave more symbols, remembering the symbols that
% were left in the array from the earlier command.
i2 = helintrlv([13:24]',3,4,1,state);

disp('Interleaved data:')
disp([i1,i2]')
disp('Values left in array after first interleaving operation:')
state.value{:}
```

During the successive calls to `helintrlv`, it internally creates the three-column arrays

```
[1  0  0;
 2  5  0;
 3  6  9;
 4  7 10;
 0  8 11;
 0  0 12]
```

and

```
[13  8 11;
 14 17 12;
 15 18 21;
 16 19 22;
  0 20 23;
  0  0 24]
```

In the second array shown above, the 8, 11, and 12 are values left in the array from the previous call to the function. Specifying the `init_state` input in the second call to the function causes it to use those values rather than the default values of 0.

The output from this example is below. (The matrix has been transposed for display purposes.) The interleaved data comes from the top four rows of the three-column arrays shown above. Notice that some of the symbols in the first half of the interleaved data are default values of 0, some of the symbols in the second half of the interleaved data were left in the array from the first call to `helintrlv`, and some of the input symbols (20, 23, and 24) do not appear in the interleaved data at all.

Interleaved data:

Columns 1 through 10

```
  1   0   0   2   5   0   3   6   9   4
13   8  11  14  17  12  15  18  21  16
```

Columns 11 through 12

```
  7  10
19  22
```

Values left in array after first interleaving operation:

```
ans =
```

```
    []
```

```
ans =
```

```
    8
```

```
ans =
```

```
   11   12
```

The example on the reference page for `heldeintrlv` also uses this function.

## helscandeintrlv

Restore ordering of symbols in helical pattern

### Syntax

```
deintrlvd = helscandeintrlv(data,Nrows,Ncols,hstep)
```

### Description

`deintrlvd = helscandeintrlv(data,Nrows,Ncols,hstep)` rearranges the elements in `data` by filling a temporary matrix with the elements in a helical fashion and then sending the matrix contents to the output row by row. `Nrows` and `Ncols` are the dimensions of the temporary matrix. `hstep` is the slope of the diagonal, that is, the amount by which the row index increases as the column index increases by one. `hstep` must be a nonnegative integer less than `Nrows`.

Helical fashion means that the function places input elements along diagonals of the temporary matrix. The number of elements in each diagonal is exactly `Ncols`, after the function wraps past the edges of the matrix when necessary. The function traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

To use this function as an inverse of the `helscanintrlv` function, use the same `Nrows`, `Ncols`, and `hstep` inputs in both functions. In that case, the two functions are inverses in the sense that applying `helscanintrlv` followed by `helscandeintrlv` leaves `data` unchanged.

### Examples

The command below rearranges a vector using a 3-by-4 temporary matrix and diagonals of slope 1.

```
d = helscandeintrlv(1:12,3,4,1)
d =
```

```
Columns 1 through 10
```

```
1    10    7    4    5    2    11    8    9    6
```

```
Columns 11 through 12
```

```
3    12
```

Internally, the function creates the 3-by-4 temporary matrix

```
[1 10 7 4;
 5 2 11 8;
 9 6 3 12]
```

using length-four diagonals. The function then sends the elements, row by row, to the output `d`.

# helscanintrlv

Reorder symbols in helical pattern

## Syntax

```
intrlvd = helscanintrlv(data,Nrows,Ncols,hstep)
```

## Description

`intrlvd = helscanintrlv(data,Nrows,Ncols,hstep)` rearranges the elements in `data` by filling a temporary matrix with the elements row by row and then sending the matrix contents to the output in a helical fashion. `Nrows` and `Ncols` are the dimensions of the temporary matrix. `hstep` is the slope of the diagonal, that is, the amount by which the row index increases as the column index increases by one. `hstep` must be a nonnegative integer less than `Nrows`.

Helical fashion means that the function selects elements along diagonals of the temporary matrix. The number of elements in each diagonal is exactly `Ncols`, after the function wraps past the edges of the matrix when necessary. The function traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

## Examples

The command below rearranges a vector using diagonals of two different slopes.

```
i1 = helscanintrlv(1:12,3,4,1) % Slope of diagonal is 1.  
i2 = helscanintrlv(1:12,3,4,2) % Slope of diagonal is 2.
```

The output is below.

```
i1 =  
Columns 1 through 10  
    1     6    11     4     5    10     3     8     9     2  
Columns 11 through 12  
    7    12
```

```
i2 =  
Columns 1 through 10  
    1    10     7     4     5     2    11     8     9     6  
Columns 11 through 12  
    3    12
```

In each case, the function internally creates the temporary 3-by-4 matrix

```
[1 2 3 4;  
 5 6 7 8;  
 9 10 11 12]
```

To form `i1`, the function forms each slope-one diagonal by moving one row down and one column to the right. The first diagonal contains 1, 6, 11, and 4, while the second diagonal starts with 5 because that is beneath 1 in the temporary matrix.

To form `i2`, the function forms each slope-two diagonal by moving two rows down and one column to the right. The first diagonal contains 1, 10, 7, and 4, while the second diagonal starts with 5 because that is beneath 1 in the temporary matrix.

# hide

**Package:** comm

Hide scope window

## Syntax

```
hide(scope)
```

## Description

hide(scope) hides the window of the System object scope.

## Examples

### Hide and Show Scope

Create a comm.ConstellationDiagram object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

### Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

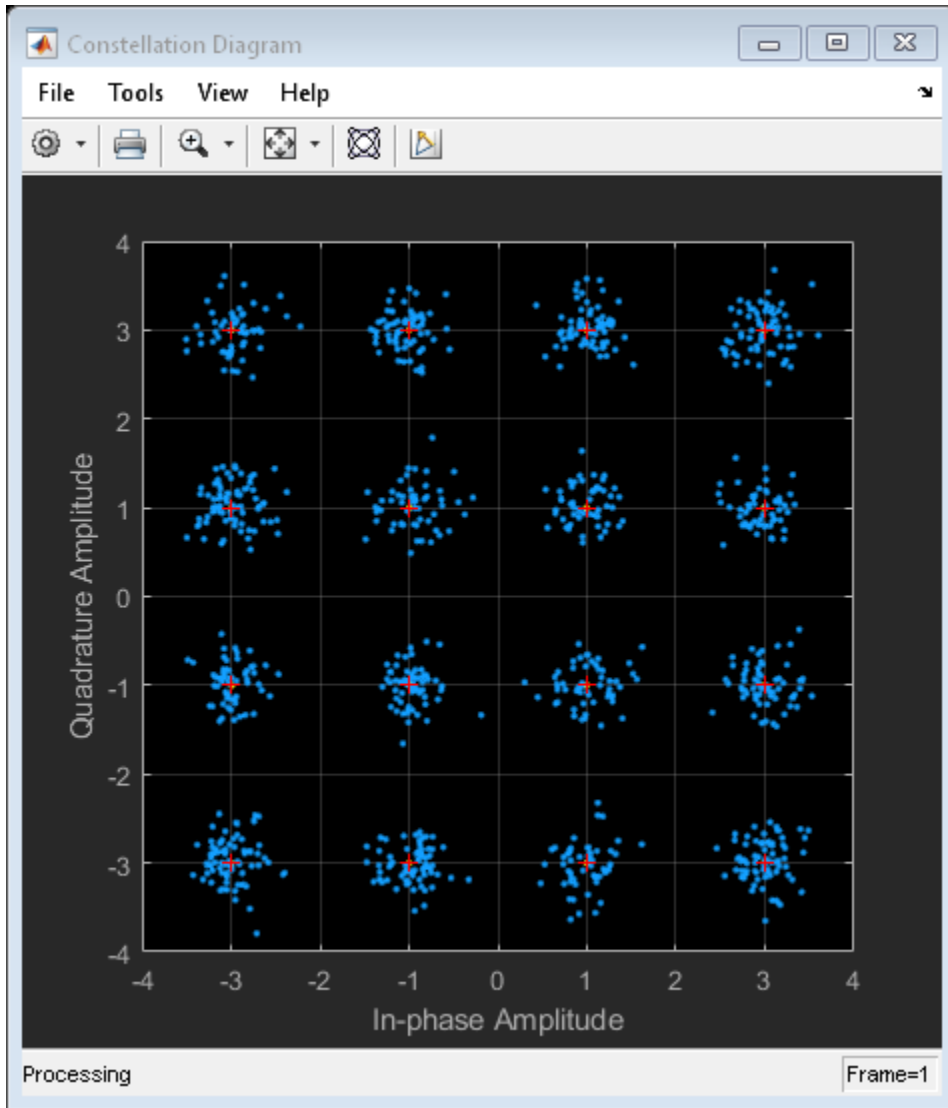

```
M = 16;
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4], 'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

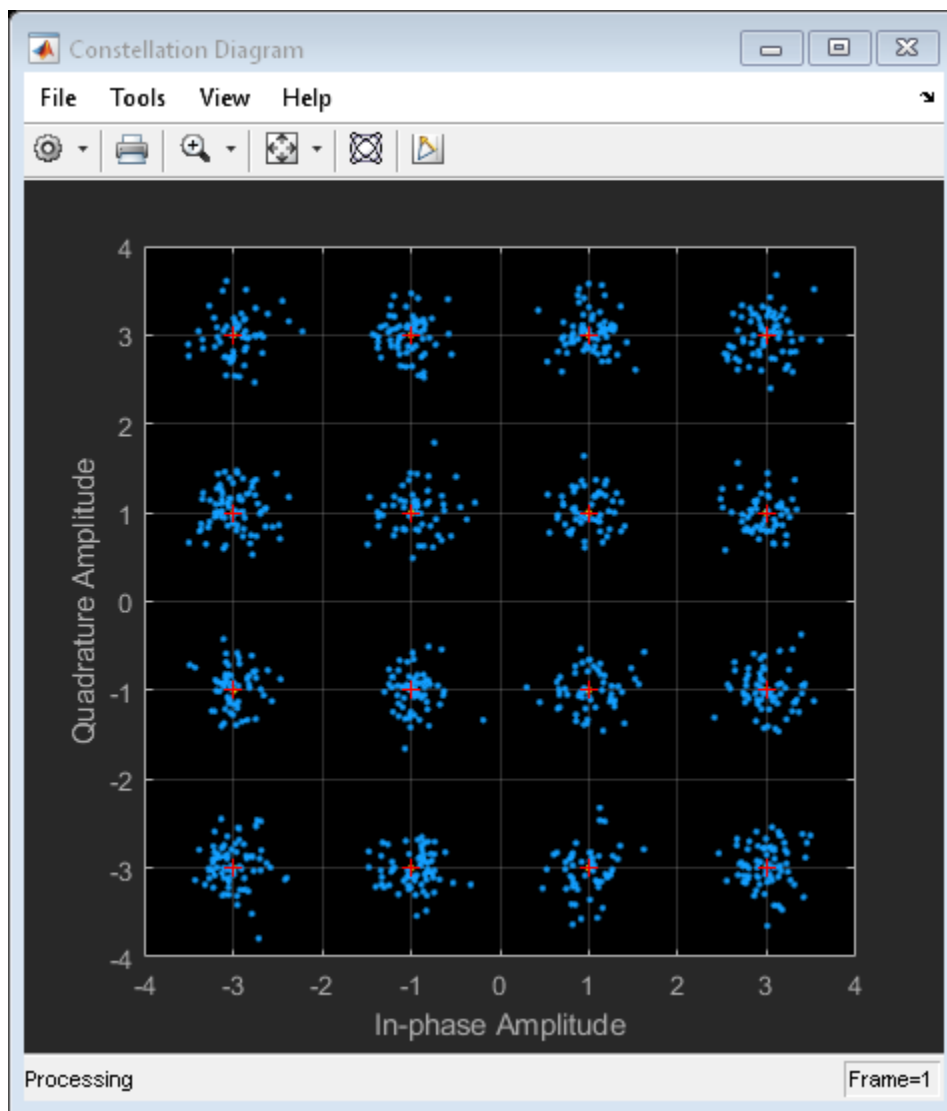

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

## Input Arguments

### **scope** — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` or `comm.EyeDiagram` System object.

Example: `scope = comm.EyeDiagram;`

# hilbiir

Design Hilbert transform IIR filter

## Syntax

```
hilbiir
hilbiir(ts)
hilbiir(ts,dly)
hilbiir(ts,dly,bandwidth)
hilbiir(ts,dly,bandwidth,tol)
[num,den] = hilbiir(...)
[num,den,sv] = hilbiir(...)
[a,b,c,d] = hilbiir(...)
[a,b,c,d,sv] = hilbiir(...)
```

## Description

The function `hilbiir` designs a Hilbert transform filter. The output is either

- A plot of the filter's impulse response, or
- A quantitative characterization of the filter, using either a transfer function model or a state-space model

## Background Information

An ideal Hilbert transform filter has the transfer function  $H(s) = -j \operatorname{sgn}(s)$ , where  $\operatorname{sgn}(\cdot)$  is the signum function (`sign` in MATLAB). The impulse response of the Hilbert transform filter is

$$h(t) = \frac{1}{\pi t}$$

Because the Hilbert transform filter is a noncausal filter, the `hilbiir` function introduces a group delay, `dly`. A Hilbert transform filter with this delay has the impulse response

$$h(t) = \frac{1}{\pi(t - dly)}$$

## Choosing a Group Delay Parameter

The filter design is an approximation. If you provide the filter's group delay as an input argument, these two suggestions can help improve the accuracy of the results:

- Choose the sample time `ts` and the filter's group delay `dly` so that `dly` is at least a few times larger than `ts` and `rem(dly, ts) = ts/2`. For example, you can set `ts` to `2*dly/N`, where `N` is a positive integer.
- At the point `t = dly`, the impulse response of the Hilbert transform filter can be interpreted as `0`, `-Inf`, or `Inf`. If `hilbiir` encounters this point, it sets the impulse response there to zero. To improve accuracy, avoid the point `t = dly`.

## Syntaxes for Plots

Each of these syntaxes produces a plot of the impulse response of the filter that the `hilbiir` function designs, as well as the impulse response of a corresponding ideal Hilbert transform filter.

`hilbiir` plots the impulse response of a fourth-order digital Hilbert transform filter with a one-second group delay. The sample time is `2/7` seconds. In this particular design, the tolerance index is `0.05`. The plot also displays the impulse response of the ideal Hilbert transform filter with a one-second group delay.

`hilbiir(ts)` plots the impulse response of a fourth-order Hilbert transform filter with a sample time of `ts` seconds and a group delay of `ts*7/2` seconds. The tolerance index is `0.05`. The plot also displays the impulse response of the ideal Hilbert transform filter having a sample time of `ts` seconds and a group delay of `ts*7/2` seconds.

`hilbiir(ts,dly)` is the same as the syntax above, except that the filter's group delay is `dly` for both the ideal filter and the filter that `hilbiir` designs. See “Choosing a Group Delay Parameter” on page 2-740 above for guidelines on choosing `dly`.

`hilbiir(ts,dly,bandwidth)` is the same as the syntax above, except that `bandwidth` specifies the assumed bandwidth of the input signal and that the filter design might use a compensator for the input signal. If `bandwidth = 0` or `bandwidth > 1/(2*ts)`, `hilbiir` does not use a compensator.

`hilbiir(ts,dly,bandwidth,tol)` is the same as the syntax above, except that `tol` is the tolerance index. If `tol < 1`, the order of the filter is determined by

$$\frac{\text{truncated-singular-value}}{\text{maximum-singular-value}} < \text{tol}$$

If `tol > 1`, the order of the filter is `tol`.

## Syntaxes for Transfer Function and State-Space Quantities

Each of these syntaxes produces quantitative information about the filter that `hilbiir` designs, but does *not* produce a plot. The input arguments for these syntaxes (if you provide any) are the same as those described in “Syntaxes for Plots” on page 2-740.

`[num,den] = hilbiir(...)` outputs the numerator and denominator of the IIR filter's transfer function.

`[num,den,sv] = hilbiir(...)` outputs the numerator and denominator of the IIR filter's transfer function, and the singular values of the Hankel matrix that `hilbiir` uses in the computation.

`[a,b,c,d] = hilbiir(...)` outputs the discrete-time state-space model of the designed Hilbert transform filter. `a`, `b`, `c`, and `d` are matrices.

`[a,b,c,d,sv] = hilbiir(...)` outputs the discrete-time state-space model of the designed Hilbert transform filter, and the singular values of the Hankel matrix that `hilbiir` uses in the computation.

## Examples

For an example using the function's default values, type one of the following commands at the MATLAB prompt.

```
hilbiir
[num,den] = hilbiir
```

### Algorithms

The `hilbiir` function calculates the impulse response of the ideal Hilbert transform filter response with a group delay. It fits the response curve using a singular-value decomposition method. See the book by Kailath [1].

# huffmandeco

Huffman decoder

## Syntax

```
dsig = huffmandeco(comp,dict)
```

## Description

`dsig = huffmandeco(comp,dict)` decodes the numeric Huffman code vector `comp` using the code dictionary `dict`. The argument `dict` is an N-by-2 cell array, where N is the number of distinct possible symbols in the original signal that was encoded as `comp`. The first column of `dict` represents the distinct symbols and the second column represents the corresponding codewords. Each codeword is represented as a numeric row vector, and no codeword in `dict` is allowed to be the prefix of any other codeword in `dict`. You can generate `dict` using the `huffmandict` function and `comp` using the `huffmanenco` function. If all signal values in `dict` are numeric, `dsig` is a vector; if any signal value in `dict` is alphabetical, `dsig` is a one-dimensional cell array.

## Examples

### Huffman Encoding and Decoding

Create unique symbols, and assign probabilities of occurrence to them.

```
symbols = 1:6;  
p = [.5 .125 .125 .125 .0625 .0625];
```

Create a Huffman dictionary based on the symbols and their probabilities.

```
dict = huffmandict(symbols,p);
```

Generate a vector of random symbols.

```
sig = randsrc(100,1,[symbols; p]);
```

Encode the random symbols.

```
comp = huffmanenco(sig,dict);
```

Decode the data. Verify that the decoded data matches the original data.

```
dsig = huffmandeco(comp,dict);  
isequal(sig,dsig)
```

```
ans = logical  
     1
```

Convert the original signal to binary, and determine its length.

```
binarySig = de2bi(sig);  
seqLen = numel(binarySig)
```

```
seqLen = 300
```

Convert the Huffman encoded signal and determine its length.

```
binaryComp = de2bi(comp);  
encodedLen = numel(binaryComp)
```

```
encodedLen = 224
```

The Huffman encoded data required 224 bits, which is a 25% savings over the uncoded data.

### Huffman Encoding and Decoding with Alphanumeric Signal

Define an alphanumeric signal in cell array form.

```
sig = {'a2', 44, 'a3', 55, 'a1'}  
  
sig=1x5 cell  
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

Define a dictionary. Codes for signal letters must be numeric.

```
dict = {'a1',0; 'a2',[1,0]; 'a3',[1,1,0]; 44,[1,1,1,0]; 55,[1,1,1,1]}
```

```
dict=5x2 cell
    {'a1'}    {[          0]}
    {'a2'}    {1x2 double}
    {'a3'}    {1x3 double}
    {[44]}    {1x4 double}
    {[55]}    {1x4 double}
```

Encode the alphanumeric symbols.

```
comp = huffmanenco(sig,dict);
```

Decode the data and verify that the decoded data matches the original data.

```
dsig = huffmandeco(comp,dict)
```

```
dsig=1x5 cell
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

```
isequal(sig,dsig)
```

```
ans = logical
     1
```

## **huffmandict**

Generate Huffman code dictionary for source with known probability model

### **Syntax**

```
[dict,avglen] = huffmandict(symbols,p)
[dict,avglen] = huffmandict(symbols,p,N)
[dict,avglen] = huffmandict(symbols,p,N,variance)
```

### **Description**

#### **For All Syntaxes**

The `huffmandict` function generates a Huffman code dictionary corresponding to a source with a known probability model. The required inputs are

- `symbols`, which lists the distinct signal values that the source produces. It can have the form of a numeric vector, numeric cell array, or alphanumeric cell array. If it is a cell array, it must be either a row or a column.
- `p`, a probability vector whose  $k$ th element is the probability with which the source produces the  $k$ th element of `symbols`. The length of `p` must equal the length of `symbols`.

The outputs of `huffmandict` are

- `dict`, a two-column cell array in which the first column lists the distinct signal values from `symbols` and the second column lists the corresponding Huffman codewords. In the second column, each Huffman codeword is represented as a numeric row vector.
- `avglen`, the average length among all codewords in the dictionary, weighted according to the probabilities in the vector `p`.

## For Specific Syntaxes

`[dict,avglen] = huffmandict(symbols,p)` generates a binary Huffman code dictionary using the maximum variance algorithm.

`[dict,avglen] = huffmandict(symbols,p,N)` generates an N-ary Huffman code dictionary using the maximum variance algorithm. N is an integer between 2 and 10 that must not exceed the number of source symbols whose probabilities appear in the vector p.

`[dict,avglen] = huffmandict(symbols,p,N,variance)` generates an N-ary Huffman code dictionary with the minimum variance if *variance* is 'min' and the maximum variance if *variance* is 'max'. N is an integer between 2 and 10 that must not exceed the length of the vector p.

## Examples

### Generate Huffman Code and View Return Values

Generate a binary Huffman code dictionary. Assign the second output to return the average code length.

Specify symbol alphabet and probability vectors.

```
symbols = (1:5); % Alphabet vector
prob = [.3 .3 .2 .1 .1]; % Symbol probability vector
```

Generate binary Huffman code. View the average code length and the cell array containing the codeword dictionary.

```
[dict, avglen] = huffmandict(symbols,prob);
avglen
```

```
avglen = 2.2000
```

```
dict
```

```
dict=5x2 cell
```

```
{[1]} {1x2 double}
{[2]} {1x2 double}
{[3]} {1x2 double}
{[4]} {1x3 double}
```

```
{[5]}    {1x3 double}
```

View the fifth codeword from the dictionary.

```
samplecode = dict{5,2} % Codeword for fifth signal value
```

```
samplecode = 1x3
```

```
    1    1    0
```

### Generate Ternary Huffman Codes

Use the code dictionary generator for Huffman coder function to generate binary and ternary Huffman codes.

Specify symbol alphabet and probability vectors

```
symbols = (1:5); % Alphabet vector  
prob = [.3 .3 .2 .1 .1]; % Symbol probability vector
```

Generate binary Huffman code.

```
[dict, avglen] = huffmandict(symbols, prob);  
dict(:, 2) = cellfun(@num2str, dict(:, 2), 'UniformOutput', false)
```

```
dict=5x2 cell  
    {[1]}    {'0 1' }  
    {[2]}    {'0 0' }  
    {[3]}    {'1 0' }  
    {[4]}    {'1 1 1'}  
    {[5]}    {'1 1 0'}
```

Generate ternary Huffman code

```
[dict, avglen] = huffmandict(symbols, prob, 3);  
dict(:, 2) = cellfun(@num2str, dict(:, 2), 'UniformOutput', false)
```

```
dict=5x2 cell  
    {[1]}    {'2'  }  
    {[2]}    {'1'  }  
    {[3]}    {'0 0'}  
    {[4]}    {'0 2'}
```

```
{[5]} {'0 1'}
```

## **huffmanenco**

Huffman encoder

### **Syntax**

```
comp = huffmanenco(sig,dict)
```

### **Description**

`comp = huffmanenco(sig,dict)` encodes the signal `sig` using the Huffman codes described by the code dictionary `dict`. The argument `sig` can have the form of a numeric vector, numeric cell array, or alphanumeric cell array. If `sig` is a cell array, it must be either a row or a column. `dict` is an N-by-2 cell array, where N is the number of distinct possible symbols to be encoded. The first column of `dict` represents the distinct symbols and the second column represents the corresponding codewords. Each codeword is represented as a numeric row vector, and no codeword in `dict` can be the prefix of any other codeword in `dict`. You can generate `dict` using the `huffmandict` function.

### **Examples**

#### **Huffman Encoding and Decoding**

Create unique symbols, and assign probabilities of occurrence to them.

```
symbols = 1:6;  
p = [.5 .125 .125 .125 .0625 .0625];
```

Create a Huffman dictionary based on the symbols and their probabilities.

```
dict = huffmandict(symbols,p);
```

Generate a vector of random symbols.

```
sig = randsrc(100,1,[symbols; p]);
```

Encode the random symbols.

```
comp = huffmanenco(sig,dict);
```

Decode the data. Verify that the decoded data matches the original data.

```
dsig = huffmandeco(comp,dict);
isequal(sig,dsig)
```

```
ans = logical
      1
```

Convert the original signal to binary, and determine its length.

```
binarySig = de2bi(sig);
seqLen = numel(binarySig)
```

```
seqLen = 300
```

Convert the Huffman encoded signal and determine its length.

```
binaryComp = de2bi(comp);
encodedLen = numel(binaryComp)
```

```
encodedLen = 224
```

The Huffman encoded data required 224 bits, which is a 25% savings over the uncoded data.

## Huffman Encoding and Decoding with Alphanumeric Signal

Define an alphanumeric signal in cell array form.

```
sig = {'a2', 44, 'a3', 55, 'a1'}
sig=1x5 cell
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

Define a dictionary. Codes for signal letters must be numeric.

```
dict = {'a1',0; 'a2',[1,0]; 'a3',[1,1,0]; 44,[1,1,1,0]; 55,[1,1,1,1]}
```

```
dict=5x2 cell
    {'a1'}    {[      0]}
    {'a2'}    {1x2 double}
    {'a3'}    {1x3 double}
    {[44]}    {1x4 double}
    {[55]}    {1x4 double}
```

Encode the alphanumeric symbols.

```
comp = huffmanenco(sig,dict);
```

Decode the data and verify that the decoded data matches the original data.

```
dsig = huffmandeco(comp,dict)
```

```
dsig=1x5 cell
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

```
isequal(sig,dsig)
```

```
ans = logical
     1
```

# ifft

Inverse discrete Fourier transform

## Syntax

`ifft(x)`

## Description

`ifft(x)` is the inverse discrete Fourier transform (DFT) of the Galois vector  $x$ . If  $x$  is in the Galois field  $GF(2^m)$ , the length of  $x$  must be  $2^m-1$ .

## Examples

For an example using `ifft`, see the reference page for `fft`.

## Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words,  $x$  must be in the Galois field  $GF(2^m)$ , where  $m$  is an integer between 1 and 8.

## Algorithms

If  $x$  is a column vector, `ifft` applies `dftmtx` to the multiplicative inverse of the primitive element of the Galois field and multiplies the resulting matrix by  $x$ .

# intdump

Integrate and dump

## Syntax

```
y = intdump(x,nsamp)
```

## Description

`y = intdump(x,nsamp)` integrates the signal `x` for one symbol period, then outputs the averaged one value into `Y`. `nsamp` is the number of samples per symbol. For two-dimensional signals, the function treats each column as one channel.

## Examples

An example in “Combine Pulse Shaping and Filtering with Modulation” uses this function in conjunction with modulation.

Processes two independent channels, each of which contain three symbols of data made up of four samples.

```
s = rng;
rng(68521);
nsamp = 4; % Number of samples per symbol
ch1 = randi([0 1],3*nsamp,1); % Random binary channel
ch2 = rectpulse([1 2 3]',nsamp); % Rectangular pulses
x = [ch1 ch2]; % Two-channel signal
y = intdump(x,nsamp)
rng(s);
```

The output is below. Each column corresponds to one channel, and each row corresponds to one symbol.

y =

```
0.5000    1.0000
```

0.5000    2.0000  
1.0000    3.0000

## **See Also**

# intrlv

Reorder sequence of symbols

## Syntax

```
intrlvd = intrlv(data,elements)
```

## Description

`intrlvd = intrlv(data,elements)` rearranges the elements of `data` without repeating or omitting any elements. If `data` is a length-N vector or an N-row matrix, `elements` is a length-N vector that permutes the integers from 1 to N. The sequence in `elements` is the sequence in which elements from `data` or its columns appear in `intrlvd`. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

## Examples

The command below rearranges the elements of a vector. Your output might differ because the permutation vector is random in this example.

```
p = randperm(10); % Permutation vector  
a = intrlv(10:10:100,p)
```

The output is below.

```
a =  
  
    10    90    60    30    50    80   100    20    70    40
```

The command below rearranges each of two columns of a matrix.

```
b = intrlv([.1 .2 .3 .4 .5; .2 .4 .6 .8 1]',[2 4 3 5 1])  
b =  
  
    0.2000    0.4000
```

0.4000	0.8000
0.3000	0.6000
0.5000	1.0000
0.1000	0.2000

# isVisible

**Package:** comm

Determine visibility of scope window

## Syntax

```
visibility = isVisible(scope)
```

## Description

`visibility = isVisible(scope)` returns a logical to verify in the System object scope is open. `visibility` is 1 if the scope window is open and 0 otherwise.

## Examples

### Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

### **Hide and Show Constellation Diagram**

Generate a 16-QAM reference constellation and a signal to display.

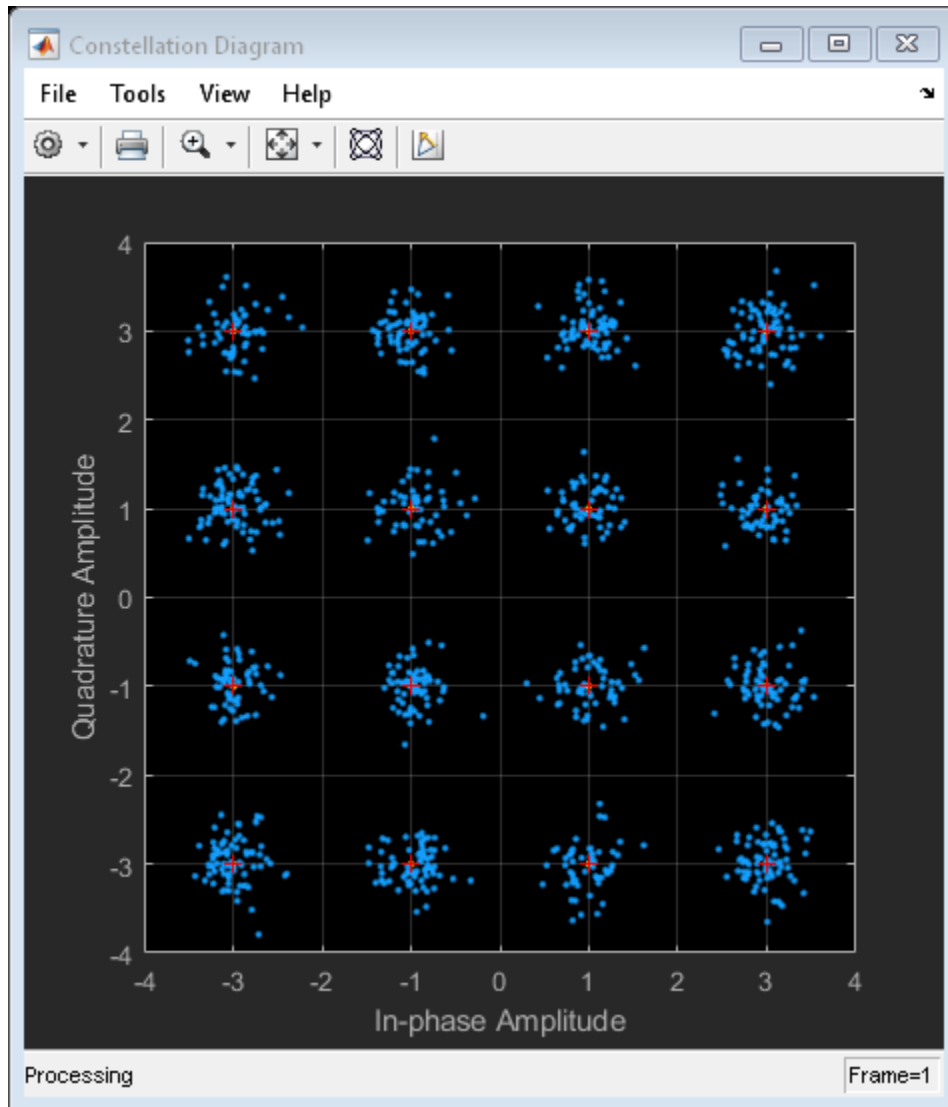

```
M = 16;
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4], 'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20, 'measured');
scope([sym rcv]);
```

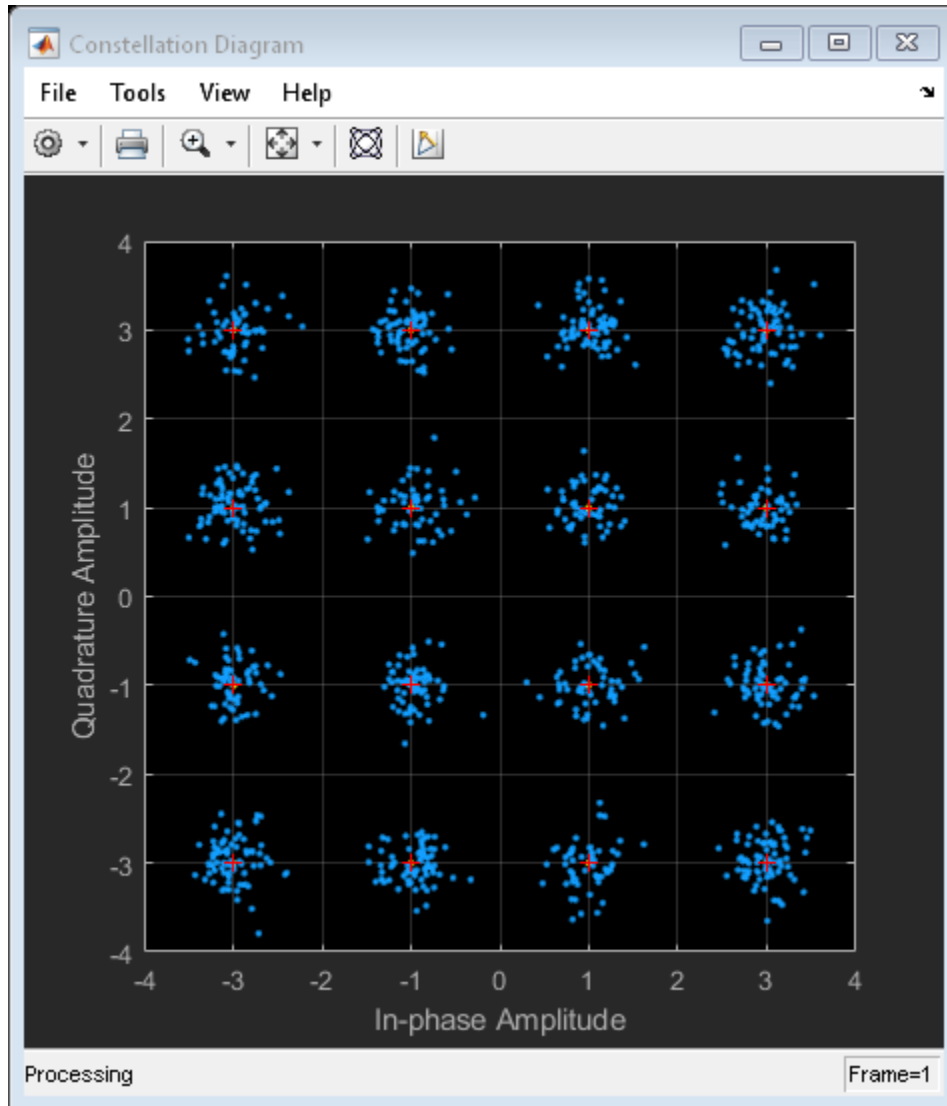

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

## Input Arguments

**scope** — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` or `comm.EyeDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

## iqcoef2imbal

Convert compensator coefficient to amplitude and phase imbalance

### Syntax

```
[A,P] = iqcoef2imbal(C)
```

### Description

`[A,P] = iqcoef2imbal(C)` converts compensator coefficient `C` to its equivalent amplitude and phase imbalance.

### Examples

#### Estimate I/Q Imbalance from Compensator Coefficient

Use `iqcoef2imbal` to estimate the amplitude and phase imbalance for a given complex coefficient. The coefficients are an output from the `step` function of the `IQImbalanceCompensator`.

Create a raised cosine transmit filter to generate a 64-QAM signal.

```
M = 64;  
txFilt = comm.RaisedCosineTransmitFilter;
```

Modulate and filter random 64-ary symbols.

```
data = randi([0 M-1],100000,1);  
dataMod = qammod(data,M);  
txSig = step(txFilt,dataMod);
```

Specify amplitude and phase imbalance.

```
ampImb = 2; % dB  
phImb = 15; % degrees
```

Apply the specified I/Q imbalance.

```
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Normalize the power of the received signal

```
rxSig = rxSig/std(rxSig);
```

Remove the I/Q imbalance using the `comm.IQImbalanceCompensator` System object. Set the compensator object such that the complex coefficients are made available as an output argument.

```
hIQComp = comm.IQImbalanceCompensator('CoefficientOutputPort',true);
[compSig,coef] = step(hIQComp,rxSig);
```

Estimate the imbalance from the last value of the compensator coefficient.

```
[ampImbEst,phImbEst] = iqcoef2imbal(coef(end));
```

Compare the estimated imbalance values with the specified ones. Notice that there is good agreement.

```
[ampImb phImb; ampImbEst phImbEst]
```

```
ans = 2×2
```

```
2.0000    15.0000
2.0178    14.5740
```

## Input Arguments

### **C** — Compensator coefficient

complex-valued scalar or vector

Coefficient used to compensate for an I/Q imbalance, specified as a complex-valued vector.

Example: `0.4+0.6i`

Example: `[0.1+0.2i; 0.3+0.5i]`

Data Types: `single` | `double`

## Output Arguments

### **A — Amplitude imbalance**

real-valued vector

Amplitude imbalance in dB, returned as a real-valued vector with the same dimensions as `C`.

### **P — Phase imbalance**

real-valued vector

Phase imbalance in degrees, returned as a real-valued vector with the same dimensions as `C`.

## More About

### I/Q Imbalance Compensation

The function `iqcoef2imbal` is a supporting function for the `comm.IQImbalanceCompensator` System object.

Given a scaling and rotation factor,  $G$ , compensator coefficient,  $C$ , and received signal,  $x$ , the compensated signal,  $y$ , has the form

$$y = G[x + C\text{conj}(x)] .$$

In matrix form, this can be rewritten as

$$\mathbf{Y} = \mathbf{R}\mathbf{X} ,$$

where  $\mathbf{X}$  is a 2-by-1 vector representing the imbalanced signal  $[X_I, X_Q]$  and  $\mathbf{Y}$  is a 2-by-1 vector representing the compensator output  $[Y_I, Y_Q]$ .

The matrix  $\mathbf{R}$  is expressed as

$$\mathbf{R} = \begin{bmatrix} 1 + \operatorname{Re}\{C\} & \operatorname{Im}\{C\} \\ \operatorname{Im}\{C\} & 1 - \operatorname{Re}\{C\} \end{bmatrix}$$

For the compensator to perfectly remove the I/Q imbalance,  $\mathbf{R} = \mathbf{K}^{-1}$  because  $\mathbf{X} = \mathbf{K}\mathbf{S}$ , where  $\mathbf{K}$  is a 2-by-2 matrix whose values are determined by the amplitude and phase imbalance and  $\mathbf{S}$  is the ideal signal. Define a matrix  $\mathbf{M}$  with the form

$$\mathbf{M} = \begin{bmatrix} 1 & -\alpha \\ \alpha & 1 \end{bmatrix}$$

Both  $\mathbf{M}$  and  $\mathbf{M}^{-1}$  can be thought of as scaling and rotation matrices that correspond to the factor  $G$ . Because  $\mathbf{K} = \mathbf{R}^{-1}$ , the product  $\mathbf{M}^{-1}\mathbf{R}\mathbf{K}\mathbf{M}$  is the identity matrix, where  $\mathbf{M}^{-1}\mathbf{R}$  represents the compensator output and  $\mathbf{K}\mathbf{M}$  represents the I/Q imbalance. The coefficient  $\alpha$  is chosen such that

$$\mathbf{K}\mathbf{M} = L \begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\cos(\theta_Q) \\ I_{gain}\sin(\theta_I) & Q_{gain}\sin(\theta_Q) \end{bmatrix}$$

where  $L$  is a constant. From this form, we can obtain  $I_{gain}$ ,  $Q_{gain}$ ,  $\theta_I$ , and  $\theta_Q$ . For a given phase imbalance,  $\Phi_{Imb}$ , the in-phase and quadrature angles can be expressed as

$$\begin{aligned} \theta_I &= -(\pi/2)(\Phi_{Imb}/180) \\ \theta_Q &= \pi/2 + (\pi/2)(\Phi_{Imb}/180) \end{aligned}$$

Hence,  $\cos(\theta_Q) = \sin(\theta_I)$  and  $\sin(\theta_Q) = \cos(\theta_I)$  so that

$$L \begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\cos(\theta_Q) \\ I_{gain}\sin(\theta_I) & Q_{gain}\sin(\theta_Q) \end{bmatrix} = L \begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\sin(\theta_I) \\ I_{gain}\sin(\theta_I) & Q_{gain}\cos(\theta_I) \end{bmatrix}$$

The I/Q imbalance can be expressed as

$$\begin{aligned} \mathbf{K}\mathbf{M} &= \begin{bmatrix} K_{11} + \alpha K_{12} & -\alpha K_{11} + K_{12} \\ K_{21} + \alpha K_{22} & -\alpha K_{21} + K_{22} \end{bmatrix} \\ &= L \begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\sin(\theta_I) \\ I_{gain}\sin(\theta_I) & Q_{gain}\cos(\theta_I) \end{bmatrix} \end{aligned}$$

Therefore,

$$(K_{21} + \alpha K_{22})/(K_{11} + \alpha K_{12}) = (-\alpha K_{11} + K_{12})/(-\alpha K_{21} + K_{22}) = \sin(\theta_I)/\cos(\theta_I)$$

The equation can be written as a quadratic equation to solve for the variable  $\alpha$ , that is  $D_1\alpha^2 + D_2\alpha + D_3 = 0$ , where

$$\begin{aligned} D_1 &= -K_{11}K_{12} + K_{22}K_{21} \\ D_2 &= K_{12}^2 + K_{21}^2 - K_{11}^2 - K_{22}^2 \\ D_3 &= K_{11}K_{12} - K_{21}K_{22} \end{aligned}$$

When  $|C| \leq 1$ , the quadratic equation has the following solution:

$$\alpha = \frac{-D_2 - \sqrt{D_2^2 - 4D_1D_3}}{2D_1}$$

Otherwise, when  $|C| > 1$ , the solution has the following form:

$$\alpha = \frac{-D_2 + \sqrt{D_2^2 - 4D_1D_3}}{2D_1}$$

Finally, the amplitude imbalance,  $A_{Imb}$ , and the phase imbalance,  $\Phi_{Imb}$ , are obtained.

$$\begin{aligned} \mathbf{K}' &= \mathbf{K} \begin{bmatrix} 1 & -\alpha \\ \alpha & 1 \end{bmatrix} \\ A_{Imb} &= 20\log_{10}(K'_{11}/K'_{22}) \\ \Phi_{Imb} &= -2\tan^{-1}(K'_{21}/K'_{11})(180/\pi) \end{aligned}$$

---

**Note**

- If  $C$  is real and  $|C| \leq 1$ , the phase imbalance is 0 and the amplitude imbalance is  $20\log_{10}((1-C)/(1+C))$
  - If  $C$  is real and  $|C| > 1$ , the phase imbalance is  $180^\circ$  and the amplitude imbalance is  $20\log_{10}((C+1)/(C-1))$ .
  - If  $C$  is imaginary,  $A_{Imb} = 0$ .
-

## **Extended Capabilities**

## iqimbal2coef

Convert I/Q imbalance to compensator coefficient

### Syntax

```
C = iqimbal2coef(A,P)
```

### Description

`C = iqimbal2coef(A,P)` converts an I/Q amplitude and phase imbalance to its equivalent compensator coefficient.

### Examples

#### Generate Coefficients for I/Q Imbalance Compensation

Generate coefficients for the I/Q imbalance compensator System object™ using `iqimbal2coef`. The compensator corrects for an I/Q imbalance using the generated coefficients.

Create a raised cosine transmit filter System object.

```
txRCosFilt = comm.RaisedCosineTransmitFilter;
```

Modulate and filter random 64-ary symbols.

```
M= 64;  
data = randi([0 M-1],100000,1);  
dataMod = qammod(data,M);  
txSig = txRCosFilt(dataMod);
```

Specify amplitude and phase imbalance.

```
ampImb = 2; % dB  
phImb = 15; % degrees
```

Apply the specified I/Q imbalance.

```
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Normalize the power of the received signal.

```
rxSig = rxSig/std(rxSig);
```

Remove the I/Q imbalance by creating and applying a `comm.IQImbalanceCompensator` object. Set the compensator such that the complex coefficients are made available as an output argument.

```
iqComp = comm.IQImbalanceCompensator('CoefficientOutputPort',true);
[compSig,coef] = iqComp(rxSig);
```

Compare the final compensator coefficient to the coefficient generated by the `iqimbal2coef` function. Observe that there is good agreement.

```
idealcoef = iqimbal2coef(ampImb,phImb);
[coef(end); idealcoef]
```

```
ans = 2×1 complex
```

```
-0.1137 + 0.1296i
-0.1126 + 0.1334i
```

## Input Arguments

### A — Amplitude imbalance

real-valued scalar or vector

Amplitude imbalance in dB, specified as a real-valued row or column vector.

Example: 3

Example: [0; 5]

Data Types: single | double

### **P — Phase imbalance**

real-valued scalar or vector

Phase imbalance in degrees, specified as a real-valued row or column vector.

Example: 10

Example: [15; 45]

Data Types: `single` | `double`

## Output Arguments

### **C — Compensator coefficient**

complex-valued vector

Coefficient that perfectly compensates for the I/Q imbalance, returned as a complex-valued vector having the same dimensions as *A* and *P*.

## More About

### **I/Q Imbalance Compensation**

The function `iqimbal2coef` is a supporting function for the `comm.IQImbalanceCompensator` System object.

Define **S** and **X** as 2-by-1 vectors representing the I and Q components of the ideal and I/Q imbalanced signals, respectively.

$$\mathbf{X} = \mathbf{K} \cdot \mathbf{S}$$

where **K** is a 2-by-2 matrix whose values are determined by the amplitude imbalance, *A*, and phase imbalance, *P*. *A* is expressed in dB and *P* is expressed in degrees.

The imbalance can be expressed as:

$$I_{gain} = 10^{0.5A/20}$$

$$Q_{gain} = 10^{-0.5A/20}$$

$$\theta_i = -\left(\frac{P}{2}\right)\left(\frac{\pi}{180}\right)$$

$$\theta_q = \frac{\pi}{2} + \left(\frac{P}{2}\right)\left(\frac{\pi}{180}\right)$$

Then  $\mathbf{K}$  has the form:

$$\mathbf{K} = \begin{bmatrix} I_{gain}\cos(\theta_i) & Q_{gain}\cos(\theta_q) \\ I_{gain}\sin(\theta_i) & Q_{gain}\sin(\theta_q) \end{bmatrix}$$

The vector  $\mathbf{Y}$  is defined as the I/Q imbalance compensator output.

$$\mathbf{Y} = \mathbf{R} \cdot \mathbf{X}$$

For the compensator to perfectly remove the I/Q imbalance,  $\mathbf{R}$  must be the matrix inversion of  $\mathbf{K}$ , namely:

$$\mathbf{R} = \mathbf{K}^{-1}$$

Using complex notation, the vector  $\mathbf{Y}$  can be rewritten as:

$$y = w_1x + w_2\text{conj}(x)$$

$$= w_1\left(x + \left(\frac{w_2}{w_1}\right)\text{conj}(x)\right)$$

where,

$$\text{Re}\{w_1\} = (R_{11} + R_{22})/2$$

$$\text{Im}\{w_1\} = (R_{21} - R_{12})/2$$

$$\text{Re}\{w_2\} = (R_{11} - R_{22})/2$$

$$\text{Im}\{w_2\} = (R_{21} + R_{12})/2$$

The output of the function is  $w_2/w_1$ . To exactly obtain the original signal, the compensator output needs to be scaled and rotated by the complex number  $w_1$ .

---

**Note** There are cases for which the output of `iqimbal2coef` is unreliable.

- If the phase imbalance is  $\pm 90^\circ$ , the in-phase and quadrature components will become co-linear; consequently, the I/Q imbalance cannot be compensated.
  - If the amplitude imbalance is 0 dB and the phase imbalance is  $180^\circ$ ,  $w_1 = 0$  and  $w_2 = 1i$ ; therefore, the compensator takes the form of  $y = 1i*\text{conj}(x)$ .
-

# iqimbal

Apply I/Q imbalance to input signal

## Syntax

```
y = iqimbal(x,A)  
y = iqimbal(x,A,P)
```

## Description

`y = iqimbal(x,A)` applies I/Q amplitude imbalance `A` to input signal `x`.

`y = iqimbal(x,A,P)` applies I/Q amplitude imbalance `A` and phase imbalance `P` to input signal `x`.

## Examples

### Apply Amplitude Imbalance to 16-QAM

Generate a 16-QAM signal. Display the scatter plot.

```
x = qammod(randi([0 15],1000,1),16);  
h = scatterplot(x);  
hold on
```

Apply a 10 dB amplitude imbalance. A positive amplitude imbalance causes horizontal stretching of the constellation.

```
y = iqimbal(x,10);  
scatterplot(y,1,0,'ro',h)
```

Apply a -10 dB amplitude imbalance. A negative amplitude imbalance causes vertical stretching of the constellation.

```
z = iqimbal(x, -10);  
scatterplot(z, 1, 0, 'k*', h)  
hold off
```

### Apply Phase and Amplitude Imbalance to 16-QAM Signal

Generate a 16-QAM signal having two channels.

```
x = qammod(randi([0 15],1000,2),16);
```

Apply a 3 dB amplitude imbalance and a 10 degree phase imbalance to the first channel.  
Apply a -5 dB amplitude imbalance and a -15 degree phase imbalance to the second channel.

```
y = iqimbal(x,[3 -5],[10 -15]);
```

Plot the constellation diagram of both channels of the impaired signal.

```
h = scatterplot(y(:,1),1,0,'b*');  
hold on  
scatterplot(y(:,2),1,0,'ro',h)  
hold off
```

The first channel is stretched horizontally, and the second channel is stretched vertically.

### Apply I/Q Imbalance and DC Offset to QPSK

Apply a 1 dB, 5 degree I/Q imbalance to a QPSK signal. Then apply a DC offset. Visualize the offset using a spectrum analyzer.

Generate a QPSK sequence.

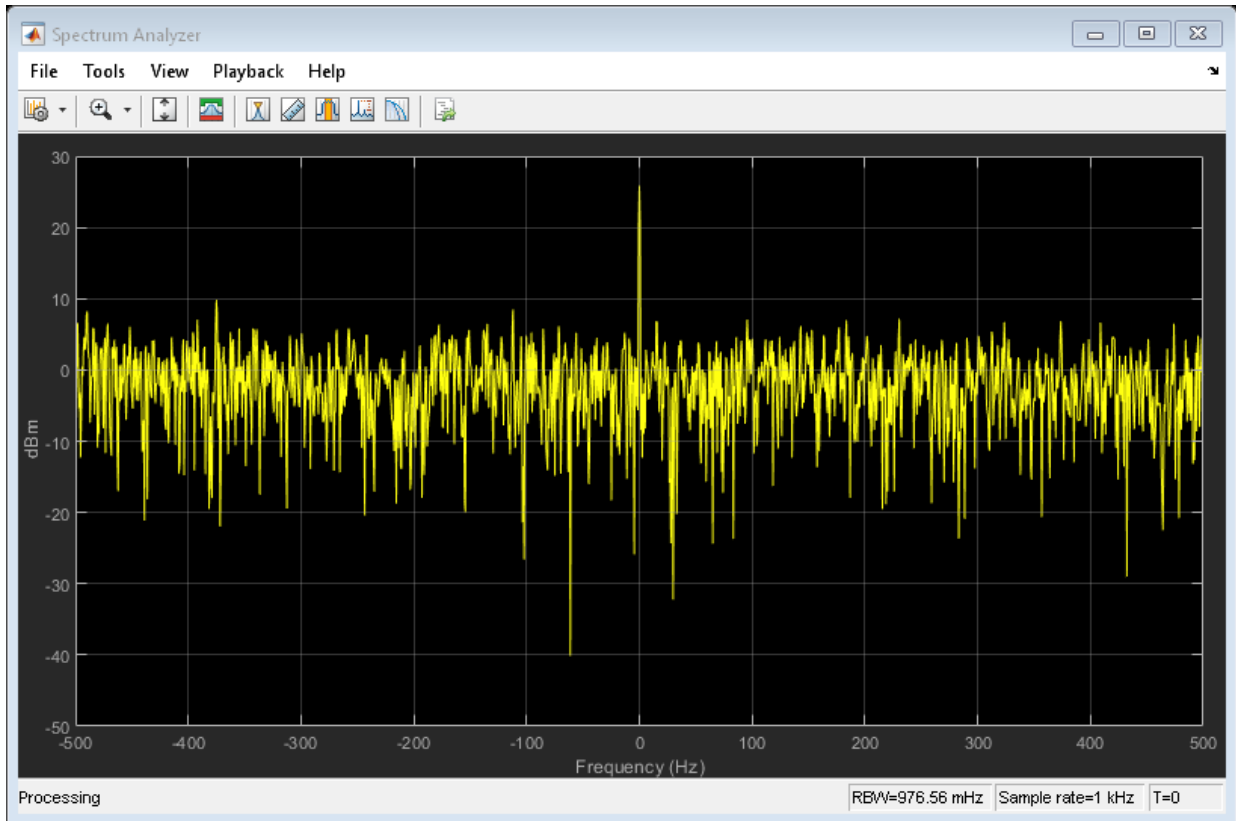

```
x = pskmod(randi([0 3],1e4,1),4,pi/4);
```

Apply a 1 dB amplitude imbalance and 5 degree phase imbalance to a QPSK signal. Apply a  $0.5 + 0.3i$  DC offset.

```
y = iqimbal(x,1,5);  
z = y + complex(0.5,0.3);
```

Plot the spectrum of the impaired signal.

```
sa = dsp.SpectrumAnalyzer('SampleRate',1000,'YLimits',[-50 30]);  
sa(z)
```

Display the corresponding scatter plot.

```
scatterplot(z)  
grid
```

The effect of the I/Q imbalance and the DC offset is observable.

### Correct I/Q Imbalance on Noisy 8-PSK Signal

Generate random data and apply 8-PSK modulation.

```
data = randi([0 7],2000,1);  
txSig = pskmod(data,8,pi/8);
```

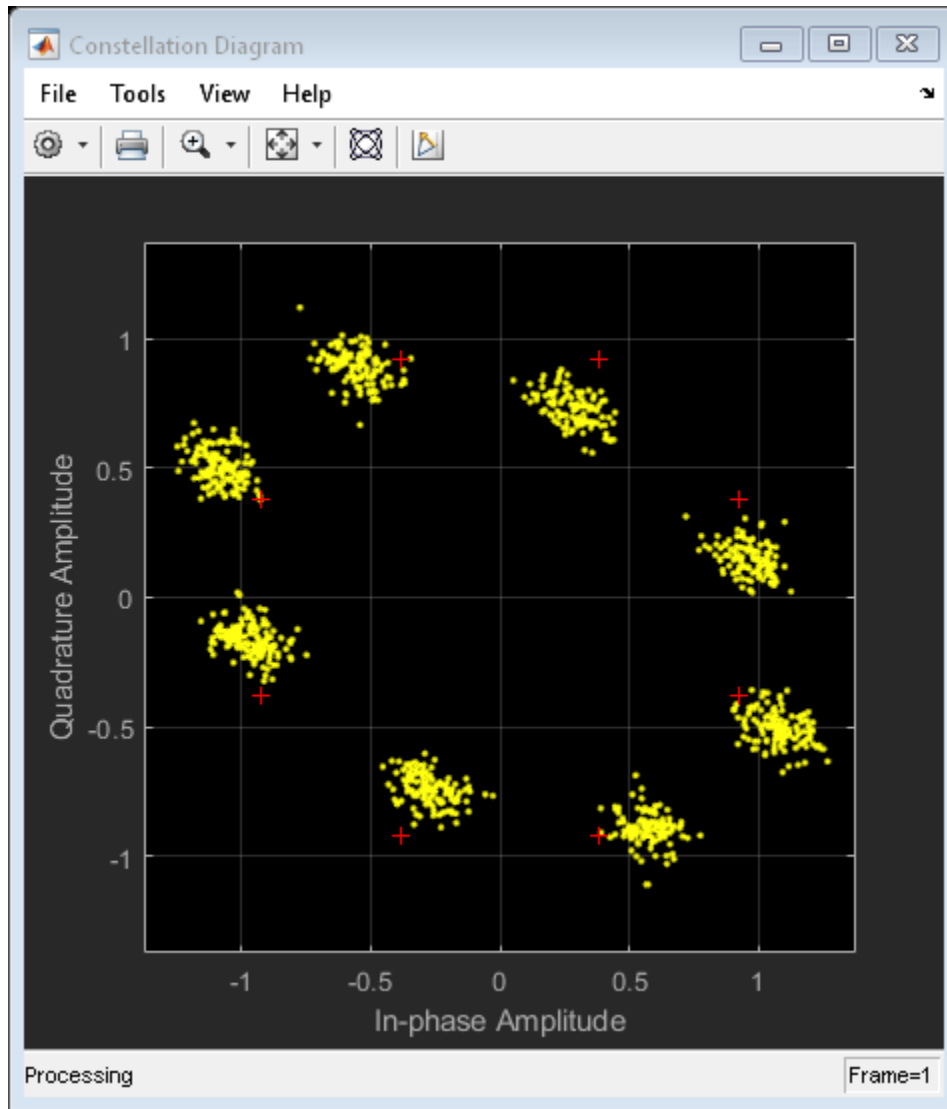

Pass the transmitted signal through an AWGN channel. Apply an I/Q imbalance.

```
noisySig = awgn(txSig,20);  
rxSig = iqimbal(noisySig,2,20);
```

Create a constellation diagram object that displays only the last 1000 symbols. Plot the constellation diagram of the impaired signal.

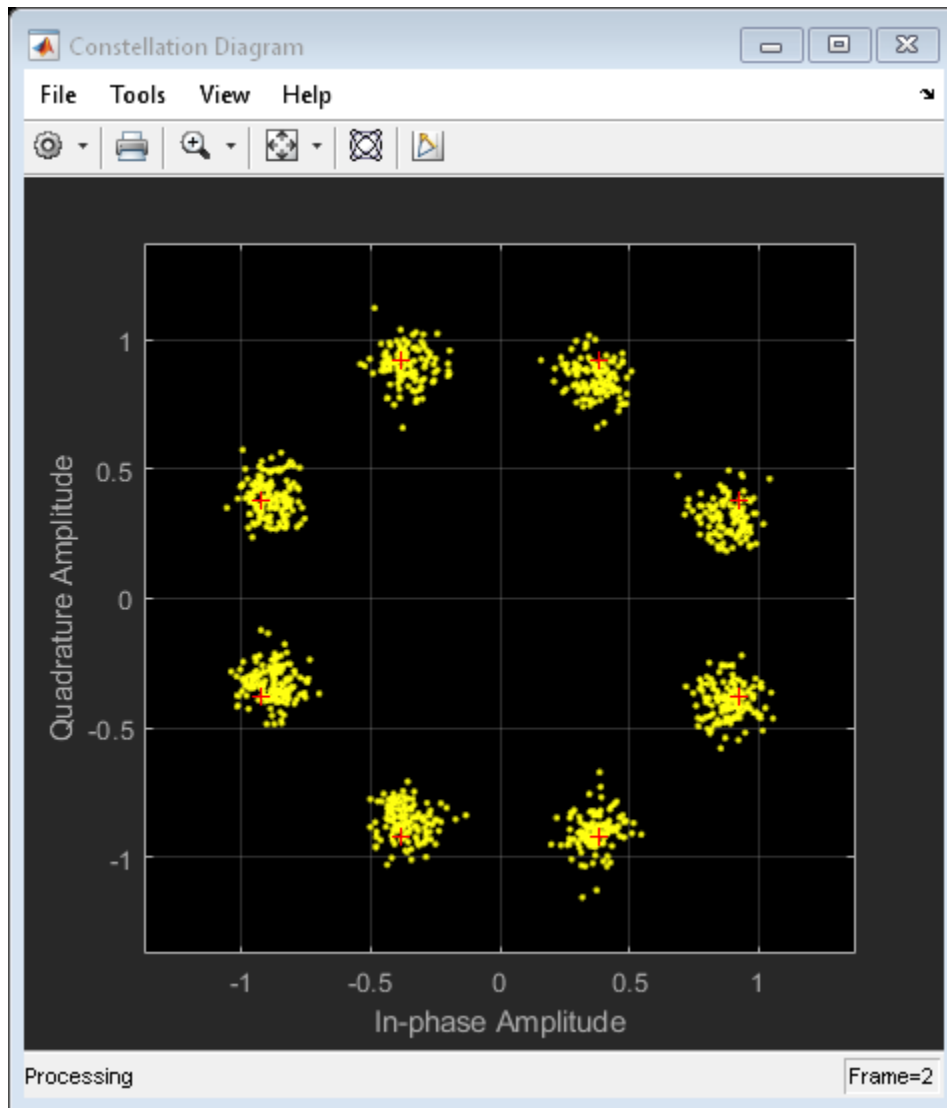

```
cd = comm.ConstellationDiagram('ReferenceConstellation',pskmod(0:7,8,pi/8), ...  
    'SymbolsToDisplaySource','Property','SymbolsToDisplay',1000);  
cd(rxSig)
```

Correct for the I/Q imbalance by using a `comm.IQImbalanceCompensator` object. Plot the constellation diagram of the signal after compensation.

```
iqComp = comm.IQImbalanceCompensator('StepSize',1e-3);  
compSig = iqComp(rxSig);
```

```
cd(compSig)
```

The compensator removes the I/Q imbalance.

## Input Arguments

### **x — Input signal**

column vector | matrix

Input signal, specified as a column vector or matrix. The function supports multichannel operations, where the number of columns corresponds to the number of channels.

Example: `pskmod(randi([0 3],100,1),4,pi/4)`

Data Types: `single` | `double`

### **A — Amplitude imbalance**

real scalar | row vector

Amplitude imbalance in dB, specified as a real scalar or row vector.

- If **A** is a scalar, the function applies the same amplitude imbalance to each channel.
- If **A** is a vector, then each element specifies the amplitude imbalance that is applied to the corresponding column (channel) of the input signal. The number of elements in **A** must equal the number of columns in **x**.

Example: `3`

Example: `[0 5]`

Data Types: `single` | `double`

### **P — Phase imbalance**

0 (default) | real scalar | row vector

Phase imbalance in degrees, specified as a real scalar or row vector.

- If **P** is omitted, a phase imbalance of zero degrees is used.
- If **P** is a scalar, the function applies the same phase imbalance to each channel.
- If **P** is a vector, then each element specifies the phase imbalance that is applied to the corresponding column (channel) of the input signal. The number of elements in **P** must equal the number of columns in **x**.

Example: `10`

Example: [2.5 7]

Data Types: single | double

## Output Arguments

### **y** — Output signal

vector | matrix

Output signal, returned as a vector or matrix having the same dimensions as  $x$ . The number of columns in  $y$  corresponds to the number of channels.

Data Types: single | double

## Algorithms

The `iqimbal` function applies an I/Q amplitude and phase imbalance to an input signal.

Given amplitude imbalance  $I_a$  in dB, the gain,  $g$ , resulting from the imbalance is defined as

$$g \triangleq g_r + ig_i = \left[ 10^{0.5 \frac{I_a}{20}} \right] + i \left[ 10^{-0.5 \frac{I_a}{20}} \right].$$

Applying the I/Q imbalance to input signal  $x$  results in output signal  $y$  such that

$$y = \text{Re}(x) \cdot g_r e^{-i0.5 I_p (\pi/180)} + i \text{Im}(x) \cdot g_i e^{i0.5 I_p (\pi/180)},$$

where  $g$  is the imbalance gain and  $I_p$  is the phase imbalance in degrees.

# iscatastrophic

True for trellis corresponding to catastrophic convolutional code

## Syntax

```
iscatastrophic(s)
```

## Description

`iscatastrophic(s)` returns `true` if the trellis `s` corresponds to a convolutional code that causes catastrophic error propagation. Otherwise, it returns `false`.

## Examples

### Determine if a Convolutional Code is Catastrophic

Determine if a convolutional code causes catastrophic error propagation.

Create the trellis for the standard, rate 1/2, constraint length 7 convolutional code.

```
t = poly2trellis(7,[171 133]);
```

Verify that the code is not catastrophic.

```
iscatastrophic(t)
```

```
ans = logical  
     0
```

Create a trellis for a different convolutional code using the `poly2trellis` function.

```
u = poly2trellis(7,[161 143]);
```

Verify that the code is catastrophic.

```
iscatastrophic(u)
```

```
ans = logical  
     1
```

# isprimitive

True for primitive polynomial for Galois field

## Syntax

```
isprimitive(a)
```

## Description

`isprimitive(a)` returns 1 if the polynomial that `a` represents is primitive for the Galois field  $GF(2^m)$ , and 0 otherwise. The input `a` can represent the polynomial using one of these formats:

- A nonnegative integer less than  $2^{17}$ . The binary representation of this integer indicates the coefficients of the polynomial. In this case, `m` is `floor(log2(a))`.
- A Galois row vector in  $GF(2)$ , listing the coefficients of the polynomial in order of descending powers. In this case, `m` is the order of the polynomial represented by `a`.

## Examples

The example below finds all primitive polynomials for  $GF(8)$  and then checks using `isprimitive` whether specific polynomials are primitive.

```
a = primpoly(3, 'all', 'nodisplay'); % All primitive polys for GF(8)
```

```
isp1 = isprimitive(13) % 13 represents a primitive polynomial.
```

```
isp2 = isprimitive(14) % 14 represents a nonprimitive polynomial.
```

The output is below. If you examine the vector `a`, notice that `isp1` is true because 13 is an element in `a`, while `isp2` is false because 14 is not an element in `a`.

```
isp1 =
```

```
1
```

isp2 =

0

# istrellis

True for valid trellis structure

## Syntax

```
[isok,status] = istrellis(s)
```

## Description

`[isok,status] = istrellis(s)` checks if the input `s` is a valid trellis structure. If the input is a valid trellis structure, `isok` is 1 and `status` is an empty character vector. Otherwise, `isok` is 0 and `status` indicates why `s` is not a valid trellis structure.

A valid trellis structure is a MATLAB structure whose fields are as in the table below.

### Fields of a Valid Trellis Structure for a Rate k/n Code

Field in Trellis Structure	Dimensions	Meaning
<code>numInputSymbols</code>	Scalar	Number of input symbols to the encoder: $2^k$
<code>numOutputSymbols</code>	Scalar	Number of output symbols from the encoder: $2^n$
<code>numStates</code>	Scalar	Number of states in the encoder
<code>nextStates</code>	<code>numStates</code> -by- $2^k$ matrix	Next states for all combinations of current state and current input
<code>outputs</code>	<code>numStates</code> -by- $2^k$ matrix	Outputs (in octal) for all combinations of current state and current input

In the `nextStates` matrix, each entry is an integer between 0 and `numStates`-1. The element in the `s`th row and `u`th column denotes the next state when the starting state is `s`-1 and the input bits have decimal representation `u`-1. To convert the input bits to a

decimal value, use the first input bit as the most significant bit (MSB). For example, the second column of the `nextStates` matrix stores the next states when the current set of input values is  $\{0, \dots, 0, 1\}$ .

To convert the state to a decimal value, use this rule: If  $k$  exceeds 1, the shift register that receives the first input stream in the encoder provides the least significant bits in the state number, and the shift register that receives the last input stream in the encoder provides the most significant bits in the state number.

In the `outputs` matrix, the element in the  $s$ th row and  $u$ th column denotes the encoder's output when the starting state is  $s-1$  and the input bits have decimal representation  $u-1$ . To convert to decimal value, use the first output bit as the MSB.

## Examples

These commands assemble the fields into a very simple trellis structure, and then verify the validity of the trellis structure.

```
trellis.numInputSymbols = 2;
trellis.numOutputSymbols = 2;
trellis.numStates = 2;
trellis.nextStates = [0 1;0 1];
trellis.outputs = [0 0;1 1];
[isok,status] = istrellis(trellis)
```

The output is below.

```
isok =
```

```
    1
```

```
status =
```

```
    ''
```

Another example of a trellis is in “Trellis Description of a Convolutional Code”.

## legacychannelsim

(To be removed) Toggles random number generation mode for channel objects

### Syntax

```
b = legacychannelsim
legacychannelsim(true)
legacychannelsim(false)
oldmode = legacychannelsim(newmode)
```

---

**Note** `legacychannelsim` will be removed in a future release. Use `comm.RayleighChannel` or `comm.RicianChannel` instead.

---

### Description

`b = legacychannelsim` returns `FALSE` if the code you are running uses the R2009b (or later) version of the random number generator for `rayleighchan` or `ricianchan`. (By default, these use the 2009b random number generator.) It returns `TRUE` if pre-R2009b versions are used. See Version 4.4. (R2009b) Communications Toolbox Release Notes for more information.

`legacychannelsim(true)` reverts the random number generation mode for channel objects to pre-2009b version.

---

**Note** `legacychannelsim(true)` will support the `reset(chan, randstate)` functionality.

---

`legacychannelsim(false)` sets the random number generation mode for channel objects to 2009b and later versions.

`oldmode = legacychannelsim(newmode)` sets the random number generation mode for channel objects to `newmode` and returns the previous mode, `oldmode`.

**Introduced in R2009b**

## lineareq

(To be removed) Construct linear equalizer object

---

**Note** will be removed in a future release. Use `comm.LinearEqualizer` instead.

---

### Syntax

```
eqobj = lineareq(nweights,alg)
eqobj = lineareq(nweights,alg,sigconst)
eqobj = lineareq(nweights,alg,sigconst,nsamp)
```

### Description

The `lineareq` function creates an equalizer object that you can use with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`eqobj = lineareq(nweights,alg)` constructs a symbol-spaced linear equalizer object. The equalizer has `nweights` complex weights, which are initially all zeros. `alg` describes the adaptive algorithm that the equalizer uses; you should create `alg` using any of these functions: `lms`, `signlms`, `normlms`, `varlms`, `rls`, or `cma`. The signal constellation of the desired output is `[-1 1]`, which corresponds to binary phase shift keying (BPSK).

`eqobj = lineareq(nweights,alg,sigconst)` specifies the signal constellation vector of the desired output.

`eqobj = lineareq(nweights,alg,sigconst,nsamp)` constructs a fractionally spaced linear equalizer object. The equalizer has `nweights` complex weights spaced at  $T/nsamp$ , where  $T$  is the symbol period and `nsamp` is a positive integer. `nsamp = 1` corresponds to a symbol-spaced equalizer.

## Properties

The table below describes the properties of the linear equalizer object. To learn how to view or change the values of a linear equalizer object, see “Equalization”.

---

**Tip** To initialize or reset the equalizer object `eqobj`, enter `reset(eqobj)`.

---

Property	Description
<code>EqType</code>	Fixed value, 'Linear Equalizer'
<code>AlgType</code>	Name of the adaptive algorithm represented by <code>alg</code>
<code>nWeights</code>	Number of weights
<code>nSampPerSym</code>	Number of input samples per symbol (equivalent to <code>nsamp</code> input argument). This value relates to both the equalizer structure (see the use of <code>K</code> in “Equalization”) and an assumption about the signal to be equalized.
<code>RefTap</code> (except for CMA equalizers)	Reference tap index, between 1 and <code>nWeights</code> . Setting this to a value greater than 1 effectively delays the reference signal and the output signal by <code>RefTap - 1</code> with respect to the equalizer's input signal.
<code>SigConst</code>	Signal constellation, a vector whose length is typically a power of 2
<code>Weights</code>	Vector of complex coefficients. This is the set of $w_i$ values in the schematic in “Equalization”.
<code>WeightInputs</code>	Vector of tap weight inputs. This is the set of $u_i$ values in the schematic in “Equalization”.

Property	Description
ResetBeforeFiltering	If 1, each call to <code>equalize</code> resets the state of <code>eqobj</code> before equalizing. If 0, the equalization process maintains continuity from one call to the next.
NumSamplesProcessed	Number of samples the equalizer processed since the last reset. When you create or reset <code>eqobj</code> , this property value is 0.
Properties specific to the adaptive algorithm represented by <code>alg</code>	See reference page for the adaptive algorithm function that created <code>alg</code> : <code>lms</code> , <code>signlms</code> , <code>normlms</code> , <code>varlms</code> , <code>rls</code> , or <code>cma</code> .

## Relationships Among Properties

If you change `nWeights`, MATLAB maintains consistency in the equalizer object by adjusting the values of the properties listed below.

Property	Adjusted Value
Weights	<code>zeros(1,nWeights)</code>
WeightInputs	<code>zeros(1,nWeights)</code>
StepSize (Variable-step-size LMS equalizers)	<code>InitStep*ones(1,nWeights)</code>
InvCorrMatrix (RLS equalizers)	<code>InvCorrInit*eye(nWeights)</code>

## Examples

### Equalize Using a Training Sequence

You can equalize a signal by using the `equalize` function to apply an adaptive equalizer object to the signal. The `equalize` function also updates the equalizer.

In typical applications, an equalizer begins by using a known sequence of transmitted symbols when adapting the equalizer weights. The known sequence, called a *training sequence*, enables the equalizer to gather information about the channel characteristics. After the equalizer finishes processing the training sequence, it adapts the equalizer

weights in decision-directed mode using a detected version of the output signal. To use a training sequence when invoking the `equalize` function, include the symbols of the training sequence as an input vector.

Note as an exception, that CMA equalizers do not use a training sequence. If an equalizer object is based on CMA, you should not include a training sequence as an input vector.

This code illustrates how to use `equalize` with a training sequence. The training sequence in this case is just the beginning of the transmitted message.

### Set up parameters and signals.

```
M = 4; % Alphabet size for modulation
msg = randi([0 M-1],1500,1); % Random message
qpskMod = comm.QPSKModulator('PhaseOffset',0);
modmsg = qpskMod(msg); % Modulate using QPSK.
trainlen = 500; % Length of training sequence
chan = [.986; .845; .237; .123+.31i]; % Channel coefficients
filtmsg = filter(chan,1,modmsg); % Introduce channel distortion.
```

### Equalize the received signal.

```
eq1 = lineareq(8, lms(0.01)); % Create an equalizer object.
eq1.SigConst = qpskMod((0:M-1)'); % Set signal constellation.
[symbolest,yd] = equalize(eq1,filtmsg,modmsg(1:trainlen)); % Equalize.
```

### Compute error rates with and without equalization

Determine the number of errors that occurred in trying to recover the modulated message with and without the equalizer. The symbol error rates show that the equalizer improves the performance significantly.

```
qpskDemod = comm.QPSKDemodulator('PhaseOffset',0);
demodmsg_noeq = qpskDemod(filtmsg); % Demodulate unequalized signal.
demodmsg = qpskDemod(yd); % Demodulate detected signal from equalizer.
errorCalc = comm.ErrorRate; % ErrorRate calculator
ser_noEq = errorCalc(msg(trainlen+1:end), demodmsg_noeq(trainlen+1:end));
reset(errorCalc)
ser_Eq = errorCalc(msg(trainlen+1:end),demodmsg(trainlen+1:end));
disp('Symbol error rates with and without equalizer:')
```

```
Symbol error rates with and without equalizer:
```

```
disp([ser_Eq(1) ser_noEq(1)])
```

0 0.3230

### Plot the signals

Create a scatter plot showing the signal before and after equalization, as well as the reference signal constellation for QPSK modulation. The points of the equalized signal are clustered more closely around the points of the reference signal constellation, indicating the signal improvement from equalization.

```
h = scatterplot(filtmsg,1,trainlen,'bx'); hold on;  
scatterplot(symbolst,1,trainlen,'g.',h);  
scatterplot(eq1.SigConst,1,0,'k*',h);  
legend('Filtered signal','Equalized signal',...  
       'Ideal signal constellation');  
hold off;
```

For more examples that use training sequences, see “Adaptive Equalization”.

### Equalizing Multiple Times Varying Mode

If you invoke `equalize` multiple times with the same equalizer object to equalize a series of signal vectors, you might use a training sequence the first time you call the function and omit the training sequence in subsequent calls. Each iteration of the `equalize` function after the first one operates completely in decision-directed mode. However, because the `ResetBeforeFiltering` property of the equalizer object is set to `0`, the `equalize` function uses the existing state information in the equalizer object when

starting equalization operation for each iteration. As a result, the training affects all equalization operations, not just the first.

Notice in this code that the first call to `equalize` uses a training sequence as an input argument, and the second call to `equalize` omits a training sequence.

### Set up the signal transmission

Create a signal, QPSK modulate it, then filter it through a distortion channel.

```
M = 4; % Alphabet size for modulation
msg = randi([0 M-1],1500,1); % Random message
qpskMod = comm.QPSKModulator('PhaseOffset',0);
modmsg = qpskMod(msg); % Modulate using QPSK
```

```
chan = [.986; .845; .237; .123+.31i]; % Channel coefficients
filtmsg = filter(chan,1,modmsg); % Introduce channel distortion
```

### Set up equalizer

Specify equalizer parameters and create an lms equalizer object

```
trainlen = 500; % Length of training sequence
eqlms = lineareq(8, lms(0.01)); % Create an equalizer object
eqlms.SigConst = qpskMod((0:M-1)'); % Set signal constellation parameter in the equalizer
```

Maintain continuity between calls to `equalize`.

```
eqlms.ResetBeforeFiltering = 0;
```

### Equalize the received signal in pieces

Process the training sequence.

```
s1 = equalize(eqlms,filtmsg(1:trainlen),modmsg(1:trainlen));
```

Process some of the data in decision-directed mode.

```
s2 = equalize(eqlms,filtmsg(trainlen+1:800));
```

Process the rest of the data in decision-directed mode.

```
s3 = equalize(eqlms,filtmsg(801:end));
```

Concatenate the signal segments to get the full output of equalizer.

```
s = [s1; s2; s3];
```

## Compatibility Considerations

## lloyds

Optimize quantization parameters using Lloyd algorithm

### Syntax

```
[partition,codebook] = lloyds(training_set,initcodebook)
[partition,codebook] = lloyds(training_set,len)
[partition,codebook] = lloyds(training_set,...,tol)
[partition,codebook,distor] = lloyds(...)
[partition,codebook,distor,relldistor] = lloyds(...)
```

### Description

`[partition,codebook] = lloyds(training_set,initcodebook)` optimizes the scalar quantization parameters `partition` and `codebook` for the training data in the vector `training_set`. `initcodebook`, a vector of length at least 2, is the initial guess of the codebook values. The output `codebook` is a vector of the same length as `initcodebook`. The output `partition` is a vector whose length is one less than the length of `codebook`.

See “Represent Partitions”, “Represent Codebooks”, or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

---

**Note** `lloyds` optimizes for the data in `training_set`. For best results, `training_set` should be similar to the data that you plan to quantize.

---

`[partition,codebook] = lloyds(training_set,len)` is the same as the first syntax, except that the scalar argument `len` indicates the size of the vector `codebook`. This syntax does not include an initial codebook guess.

`[partition,codebook] = lloyds(training_set,...,tol)` is the same as the two syntaxes above, except that `tol` replaces  $10^{-7}$  in condition 1 of the algorithm description below.

`[partition,codebook,distor] = lloyds(...)` returns the final mean square distortion in the variable `distor`.

`[partition,codebook,distor,relldistor] = lloyds(...)` returns a value `relldistor` that is related to the algorithm's termination. In condition 1 of the algorithm below, `relldistor` is the relative change in distortion between the last two iterations. In condition 2, `relldistor` is the same as `distor`.

## Examples

The code below optimizes the quantization parameters for a sinusoidal transmission via a three-bit channel. Because the typical data is sinusoidal, `training_set` is a sampled sine wave. Because the channel can transmit three bits at a time, `lloyds` prepares a codebook of length  $2^3$ .

```
% Generate a complete period of a sinusoidal signal.
x = sin([0:1000]*pi/500);
[partition,codebook] = lloyds(x,2^3)
```

The output is below.

```
partition =
```

```
Columns 1 through 6
```

```
-0.8540   -0.5973   -0.3017    0.0031    0.3077    0.6023
```

```
Column 7
```

```
0.8572
```

```
codebook =
```

```
Columns 1 through 6
```

```
-0.9504   -0.7330   -0.4519   -0.1481    0.1558    0.4575
```

```
Columns 7 through 8
```

```
0.7372    0.9515
```

### Algorithms

`lloyd`s uses an iterative process to try to minimize the mean square distortion. The optimization processing ends when either

- The relative change in distortion between iterations is less than  $10^{-7}$ .
- The distortion is less than `eps*max(training_set)`, where `eps` is the MATLAB floating-point relative accuracy.

# lms

(To be removed) Construct least mean square (LMS) adaptive algorithm object

---

**Note** will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedbackEqualizer` instead.

---

## Syntax

```
alg = lms(stepsize)
alg = lms(stepsize,leakagefactor)
```

## Description

The `lms` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfc` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = lms(stepsize)` constructs an adaptive algorithm object based on the least mean square (LMS) algorithm with a step size of `stepsize`.

`alg = lms(stepsize,leakagefactor)` sets the leakage factor of the LMS algorithm. `leakagefactor` must be between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Properties

The table below describes the properties of the LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
<code>AlgType</code>	Fixed value, 'LMS'

Property	Description
StepSize	LMS step size parameter, a nonnegative real number
LeakageFactor	LMS leakage factor, a real number between 0 and 1

## Examples

### Equalize Using a Training Sequence

You can equalize a signal by using the `equalize` function to apply an adaptive equalizer object to the signal. The `equalize` function also updates the equalizer.

In typical applications, an equalizer begins by using a known sequence of transmitted symbols when adapting the equalizer weights. The known sequence, called a *training sequence*, enables the equalizer to gather information about the channel characteristics. After the equalizer finishes processing the training sequence, it adapts the equalizer weights in decision-directed mode using a detected version of the output signal. To use a training sequence when invoking the `equalize` function, include the symbols of the training sequence as an input vector.

Note as an exception, that CMA equalizers do not use a training sequence. If an equalizer object is based on CMA, you should not include a training sequence as an input vector.

This code illustrates how to use `equalize` with a training sequence. The training sequence in this case is just the beginning of the transmitted message.

#### Set up parameters and signals.

```
M = 4; % Alphabet size for modulation
msg = randi([0 M-1],1500,1); % Random message
qpskMod = comm.QPSKModulator('PhaseOffset',0);
modmsg = qpskMod(msg); % Modulate using QPSK.
trainlen = 500; % Length of training sequence
chan = [.986; .845; .237; .123+.31i]; % Channel coefficients
filtmsg = filter(chan,1,modmsg); % Introduce channel distortion.
```

### Equalize the received signal.

```
eq1 = lineareq(8, lms(0.01)); % Create an equalizer object.
eq1.SigConst = qpskMod((0:M-1)'); % Set signal constellation.
[symbolest,yd] = equalize(eq1,filtmsg,modmsg(1:trainlen)); % Equalize.
```

### Compute error rates with and without equalization

Determine the number of errors that occurred in trying to recover the modulated message with and without the equalizer. The symbol error rates show that the equalizer improves the performance significantly.

```
qpskDemod = comm.QPSKDemodulator('PhaseOffset',0);
demodmsg_noeq = qpskDemod(filtmsg); % Demodulate unequalized signal.
demodmsg = qpskDemod(yd); % Demodulate detected signal from equalizer.
errorCalc = comm.ErrorRate; % ErrorRate calculator
ser_noEq = errorCalc(msg(trainlen+1:end), demodmsg_noeq(trainlen+1:end));
reset(errorCalc)
ser_Eq = errorCalc(msg(trainlen+1:end),demodmsg(trainlen+1:end));
disp('Symbol error rates with and without equalizer:')
```

Symbol error rates with and without equalizer:

```
disp([ser_Eq(1) ser_noEq(1)])
```

```
0    0.3230
```

### Plot the signals

Create a scatter plot showing the signal before and after equalization, as well as the reference signal constellation for QPSK modulation. The points of the equalized signal are clustered more closely around the points of the reference signal constellation, indicating the signal improvement from equalization.

```
h = scatterplot(filtmsg,1,trainlen,'bx'); hold on;
scatterplot(symbolest,1,trainlen,'g.',h);
scatterplot(eq1.SigConst,1,0,'k*',h);
legend('Filtered signal','Equalized signal',...
'Ideal signal constellation');
hold off;
```

For more examples that use training sequences, see “Adaptive Equalization”.

### Equalizing Multiple Times Varying Mode

If you invoke `equalize` multiple times with the same equalizer object to equalize a series of signal vectors, you might use a training sequence the first time you call the function and omit the training sequence in subsequent calls. Each iteration of the `equalize` function after the first one operates completely in decision-directed mode. However, because the `ResetBeforeFiltering` property of the equalizer object is set to `0`, the `equalize` function uses the existing state information in the equalizer object when

starting equalization operation for each iteration. As a result, the training affects all equalization operations, not just the first.

Notice in this code that the first call to `equalize` uses a training sequence as an input argument, and the second call to `equalize` omits a training sequence.

### Set up the signal transmission

Create a signal, QPSK modulate it, then filter it through a distortion channel.

```
M = 4; % Alphabet size for modulation
msg = randi([0 M-1],1500,1); % Random message
qpskMod = comm.QPSKModulator('PhaseOffset',0);
modmsg = qpskMod(msg); % Modulate using QPSK
```

```
chan = [.986; .845; .237; .123+.31i]; % Channel coefficients
filtmsg = filter(chan,1,modmsg); % Introduce channel distortion
```

### Set up equalizer

Specify equalizer parameters and create an lms equalizer object

```
trainlen = 500; % Length of training sequence
eqlms = lineareq(8, lms(0.01)); % Create an equalizer object
eqlms.SigConst = qpskMod((0:M-1)'); % Set signal constellation parameter in the equalizer
```

Maintain continuity between calls to `equalize`.

```
eqlms.ResetBeforeFiltering = 0;
```

### Equalize the received signal in pieces

Process the training sequence.

```
s1 = equalize(eqlms,filtmsg(1:trainlen),modmsg(1:trainlen));
```

Process some of the data in decision-directed mode.

```
s2 = equalize(eqlms,filtmsg(trainlen+1:800));
```

Process the rest of the data in decision-directed mode.

```
s3 = equalize(eqlms,filtmsg(801:end));
```

Concatenate the signal segments to get the full output of equalizer.

```
s = [s1; s2; s3];
```

## Algorithms

Referring to the schematics presented in “Equalization”, define  $w$  as the vector of all weights  $w_i$  and define  $u$  as the vector of all inputs  $u_i$ . Based on the current set of weights,  $w$ , this adaptive algorithm creates the new set of weights given by

$$w = w - (\text{LeakageFactor}) \cdot w + (\text{StepSize}) \cdot u^*e$$

where the  $*$  operator denotes the complex conjugate.

## Compatibility Considerations

### **lms will be removed**

*Not recommended starting in R2019a*

`lms` will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

## log

Logarithm in Galois field

### Syntax

```
y = log(x)
```

### Description

`y = log(x)` computes the logarithm of each element in the Galois array `x`. `y` is an integer array that solves the equation  $A.^y = x$ , where `A` is the primitive element used to represent elements in `x`. More explicitly, the base `A` of the logarithm is `gf(2,x.m)` or `gf(2,x.m,x.prim_poly)`. All elements in `x` must be nonzero because the logarithm of zero is undefined.

### Examples

The code below illustrates how the logarithm operation inverts exponentiation.

```
m = 4; x = gf([8 1 6; 3 5 7; 4 9 2],m);  
y = log(x);  
primel = gf(2,m); % Primitive element in the field  
z = primel .^ y; % This is now the same as x.  
ck = isequal(x,z)
```

The output is

```
ck =  
  
    1
```

The code below shows that the logarithm of 1 is 0 and that the logarithm of the base (`primel`) is 1.

```
m = 4; primel = gf(2,m);  
yy = log([1, primel])
```

The output is

yy =

0 1

## marcumq

Generalized Marcum Q function

### Syntax

$Q = \text{marcumq}(a, b)$

$Q = \text{marcumq}(a, b, m)$

### Description

$Q = \text{marcumq}(a, b)$  computes the Marcum Q function of  $a$  and  $b$ , defined by

$$Q(a, b) = \int_b^{\infty} x \exp\left(-\frac{x^2 + a^2}{2}\right) I_0(ax) dx$$

where  $a$  and  $b$  are nonnegative real numbers. In this expression,  $I_0$  is the modified Bessel function of the first kind of zero order.

$Q = \text{marcumq}(a, b, m)$  computes the generalized Marcum Q, defined by

$$Q(a, b) = \frac{1}{a^{m-1}} \int_b^{\infty} x^m \exp\left(-\frac{x^2 + a^2}{2}\right) I_{m-1}(ax) dx$$

where  $a$  and  $b$  are nonnegative real numbers, and  $m$  is a positive integer. In this expression,  $I_{m-1}$  is the modified Bessel function of the first kind of order  $m-1$ .

If any of the inputs is a scalar, it is expanded to the size of the other inputs.

### Examples

**Generate and Plot Marcum Q Function Data**

This example shows how to use the marcumq function.

Create an input vector, x.

```
x = (0:0.1:10)';
```

Generate two output vectors for a=0 and a=2.

```
Q1 = marcumq(0,x);
```

```
Q2 = marcumq(2,x);
```

Plot the resultant Marcum Q functions.

```
plot(x,[Q1 Q2])
```

## mask2shift

Convert mask vector to shift for shift register configuration

### Syntax

```
shift = mask2shift(prpoly,mask)
```

### Description

`shift = mask2shift(prpoly,mask)` returns the shift that is equivalent to a mask, for a linear feedback shift register whose connections are specified by the primitive polynomial `prpoly`. The `prpoly` input can have one of these formats:

- A polynomial character vector
- A binary vector that lists the coefficients of the primitive polynomial in order of descending powers
- An integer scalar whose binary representation gives the coefficients of the primitive polynomial, where the least significant bit is the constant term

The mask input is a binary vector whose length is the degree of the primitive polynomial.

---

**Note** To save time, `mask2shift` does not check that `prpoly` is primitive. If it is not primitive, the output is not meaningful. To find primitive polynomials, use `primpoly` or see [2].

---

For more information about how masks and shifts are related to pseudonoise sequence generators, see `shift2mask`.

### Definition of Equivalent Shift

If  $A$  is a root of the primitive polynomial and  $m(A)$  is the mask polynomial evaluated at  $A$ , the equivalent shift  $s$  solves the equation  $A^s = m(A)$ . To interpret the vector `mask` as a polynomial, treat `mask` as a list of coefficients in order of descending powers.

## Examples

### Convert Mask to Shift

Convert masks into shifts for a linear feedback shift register.

Convert a mask of  $x^3 + 1$  into an equivalent shift for the linear feedback shift register whose connections are specified by the primitive polynomial  $x^4 + x^3 + 1$ .

```
s1 = mask2shift([1 1 0 0 1],[1 0 0 1])
```

```
s1 = 4
```

Convert a mask of 1 to a shift. The mask is equivalent to a shift of 0.

```
s2 = mask2shift([1 1 0 0 1],[0 0 0 1])
```

```
s2 = 0
```

Convert a mask of  $x^2$  into an equivalent shift for the primitive polynomial  $x^3 + x + 1$ .

```
s3 = mask2shift('x3+x+1','x2')
```

```
s3 = 2
```

## matdeintrlv

Restore ordering of symbols by filling matrix by columns and emptying it by rows

### Syntax

```
deintrlvd = matdeintrlv(data,Nrows,Ncols)
```

### Description

`deintrlvd = matdeintrlv(data,Nrows,Ncols)` rearranges the elements in `data` by filling a temporary matrix with the elements column by column and then sending the matrix contents, row by row, to the output. `Nrows` and `Ncols` are the dimensions of the temporary matrix. If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

To use this function as an inverse of the `matintrlv` function, use the same `Nrows` and `Ncols` inputs in both functions. In that case, the two functions are inverses in the sense that applying `matintrlv` followed by `matdeintrlv` leaves data unchanged.

### Examples

The code below illustrates the inverse relationship between `matintrlv` and `matdeintrlv`.

```
Nrows = 2; Ncols = 3;
data = [1 2 3 4 5 6; 2 4 6 8 10 12]';
a = matintrlv(data,Nrows,Ncols); % Interleave.
b = matdeintrlv(a,Nrows,Ncols) % Deinterleave.
```

The output below shows that `b` is the same as `data`.

```
b =
     1     2
     2     4
```

2	4
3	6
4	8
5	10
6	12

## matintrlv

Reorder symbols by filling matrix by rows and emptying it by columns

### Syntax

```
intrlvd = matintrlv(data,Nrows,Ncols)
```

### Description

`intrlvd = matintrlv(data,Nrows,Ncols)` rearranges the elements in `data` by filling a temporary matrix with the elements row by row and then sending the matrix contents, column by column, to the output. `Nrows` and `Ncols` are the dimensions of the temporary matrix. If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

### Examples

The command below rearranges each of two columns of a matrix.

```
b = matintrlv([1 2 3 4 5 6; 2 4 6 8 10 12]',2,3)
b =
```

```
1     2
4     8
2     4
5    10
3     6
6    12
```

To form the first column of the output, the function creates the temporary 2-by-3 matrix `[1 2 3; 4 5 6]`. Then the function reads down each column of the temporary matrix to get `[1 4 2 5 3 6]`.

# mil188qamdemod

MIL-STD-188-110 B/C standard-specific quadrature amplitude demodulation

## Syntax

```
z = mil188qamdemod(y,M)
z = mil188qamdemod(y,M,Name,Value)
```

## Description

`z = mil188qamdemod(y,M)` performs QAM demodulation on an input signal, `y`, that was modulated in accordance with MIL-STD-188-110 and the modulation order, `M`. For a description of MIL-STD-188-110 QAM demodulation, see “MIL-STD-188-110 QAM Hard Demodulation” on page 2-838 and “MIL-STD-188-110 QAM Soft Demodulation” on page 2-838.

`z = mil188qamdemod(y,M,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

## Examples

### Demodulate MIL-STD-188-110B Specific 16-QAM Signal

Demodulate a 16-QAM signal that was modulated as specified in MIL-STD-188-110B. Plot the received constellation and verify that the output matches the input.

Set the modulation order and generate random data.

```
M = 16;
numSym = 20000;
x = randi([0 M-1],numSym,1);
```

Modulate the data and pass through a noisy channel.

```
txSig = mil188qammod(x,M);  
rxSig = awgn(txSig,25,'measured');
```

Plot the transmitted and received signal.

```
plot(rxSig,'b*')  
hold on; grid  
plot(txSig,'r*')  
xlim([-1.5 1.5]);  
ylim([-1.5 1.5])  
xlabel('In-Phase')  
ylabel('Quadrature')  
legend('Received constellation','Reference constellation')
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = mil188qamdemod(rxSig,M);  
isequal(x,z)  
  
ans = logical  
     1
```

### Demodulate MIL-STD-188-110C Specific 64-QAM Signal

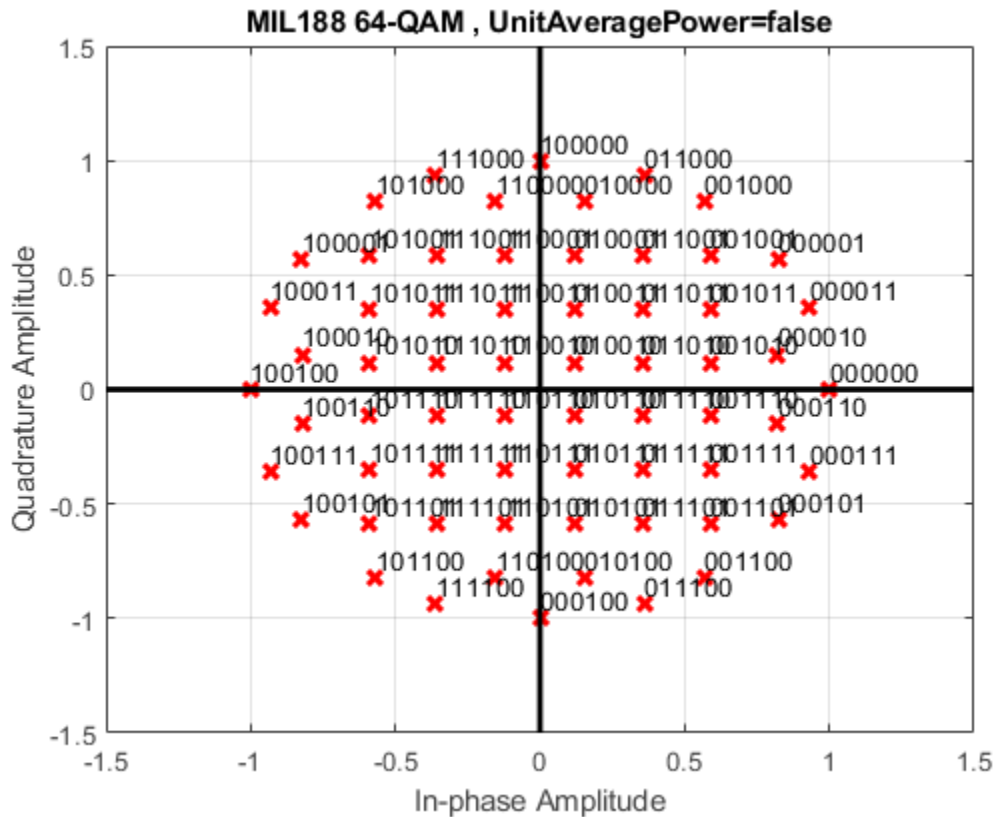

Demodulate a 64-QAM signal that was modulated as specified in MIL-STD-188-110C. Compute hard decision bit output and that verify the output matches the input.

Set the modulation order and generate random bit data.

```
M = 64;  
numBitsPerSym = log2(M);  
x = randi([0 1],1000*numBitsPerSym,1);
```

Modulate the data. Use name-value pairs to specify bit input data and to plot the constellation.

```
txSig = mil188qammod(x,M,'InputType','bit','PlotConstellation',true);
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = mil188qamdemod(txSig,M, 'OutputType', 'bit');
isequal(z,x)
```

```
ans = logical
     1
```

**Soft Bit Demodulate MIL-STD-188-110 Specific 32-QAM Signal**

Demodulate a 32-QAM signal and calculate soft bits.

Set the modulation order and generate a random bit sequence.

```
M = 32;
numSym = 20000;
numBitsPerSym = log2(M);
x = randi([0 1], numSym*numBitsPerSym,1);
```

Modulate the data. Use name-value pairs to specify bit input data and unit average power, and to plot the constellation.

```
txSig = mil188qammod(x,M,'InputType','bit','UnitAveragePower',true, ...
    'PlotConstellation',true);
```

Pass the transmitted data through white Gaussian noise.

```
rxSig = awgn(txSig,10,'measured');
```

View the constellation using a scatter plot.

```
scatterplot(rxSig)
```

Demodulate the signal, computing soft bits using the approximate LLR algorithm.

```
z = mil188qamdemod(rxSig,M,'OutputType','approxllr', ...  
    'NoiseVariance',10^(-1));
```

## Input Arguments

### **y — Modulated signal**

scalar | vector | matrix

Modulated signal, specified as a complex scalar, vector, or matrix. When **y** is a matrix, each column is treated as an independent channel.

**y** must be modulated in accordance with MIL-STD-188-110 [1].

Data Types: `single` | `double`

Complex Number Support: Yes

### **M — Modulation order**

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Example: 16

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `y =`

```
mil188qamdemod(x,M,'OutputType','bit','OutputDataType','single');
```

### **OutputType — Output type**

'integer' (default) | 'bit' | 'llr' | 'approxllr'

Output type, specified as the comma-separated pair consisting of **OutputType** and 'integer', 'bit', 'llr', or 'approxllr'.

Data Types: `char` | `string`

### **OutputDataType — Output data type**

'double' (default) | ...

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and one of the indicated data types. Acceptable values for `OutputDataType` depend on the `OutputType` value.

OutputType Value	Acceptable OutputDataType Values
'integer'	'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', or 'uint32'
'bit'	'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', 'uint32', or 'logical'

**Dependencies**

This name-value pair argument applies only when `OutputType` is set to 'integer' or 'bit'.

Data Types: char | string

**UnitAveragePower — Unit average power flag**

false (default) | true

Unit average power flag, specified as the comma-separated pair consisting of `UnitAveragePower` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1].

Data Types: logical

**NoiseVariance — Noise variance**

1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of `NoiseVariance` and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “MIL-STD-188-110 QAM Soft Demodulation” on page 2-838 for algorithm selection considerations.

**Dependencies**

This name-value pair argument applies only when `OutputType` is set to `'llr'` or `'approxllr'`.

Data Types: double

**PlotConstellation — Option to plot constellation**

false (default) | true

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to true.

Data Types: logical

**Output Arguments****z — Demodulated signal**

scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of `z` depend on the specified `OutputType` value.

<b>OutputType Value</b>	<b>Return Value of mil188qamdemod</b>	<b>Dimensions of z</b>
<code>'integer'</code>	Demodulated integer values from 0 to $(M - 1)$	<code>z</code> has the same dimensions as input <code>y</code> .
<code>'bit'</code>	Demodulated bits	The number of rows in <code>z</code> is $\log_2(\text{sum}(M))$ times the number of rows in <code>y</code> . Each demodulated symbol is mapped to a group of $\log_2(\text{sum}(M))$ elements in a column,
<code>'llr'</code>	Log-likelihood ratio value for each bit	where the first element represents the MSB and the last element represents the LSB.
<code>'approxllr'</code>	Approximate log-likelihood ratio value for each bit	

## More About

### MIL-STD-188-110 QAM Hard Demodulation

The hard demodulation algorithm uses optimum decision region-based demodulation. Since all the constellation points are equally probable, maximum a posteriori probability (MAP) detection reduces to a maximum likelihood (ML) detection. The ML detection rule is equivalent to choosing the closest constellation point to the received symbol. The decision region for each constellation point is designed by drawing perpendicular bisectors between adjacent points. A received symbol is mapped to the proper constellation point based on which decision region it lies in.

Since all MIL-STD constellations are quadrant-based symmetric, for each symbol the optimum decision region-based demodulation:

- Maps the received symbol into the first quadrant
- Chooses the decision region for the symbol
- Maps the constellation point back to its original quadrant using the sign of real and imaginary parts of the received symbol

### MIL-STD-188-110 QAM Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

---

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or -Inf if the noise variance is a very large value

- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

## mil188qammod

MIL-STD-188-110 B/C standard-specific quadrature amplitude modulation (QAM)

### Syntax

```
y = mil188qammod(x,M)
y = mil188qammod(x,M,Name,Value)
```

### Description

`y = mil188qammod(x,M)` performs QAM modulation on the input signal, `x`, in accordance with MIL-STD-188-110 and the modulation order, `M`. For more information, see “MIL-STD-188-110” on page 2-847.

`y = mil188qammod(x,M,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

### Examples

#### Apply 32-QAM to Data Per MIL-STD-188-110C

Modulate data using 32-QAM as specified in the MIL-188-110C standard. Display the result using a scatter plot.

Set `M` to 32 and create a data vector containing all possible symbols.

```
M = 32;
x = (0:M-1);
```

Modulate the data using QAM as specified in MIL-STD-188-110C.

```
y = mil188qammod(x,M);
```

Display the constellation as a scatter plot.

```
scatterplot(y)
```

### Normalize 16-QAM Modulated MIL-STD-188-110B Signal by Average Power

Modulate data using 16-QAM as specified in the MIL-STD-188-110B standard. Normalize the modulator output so that it has an average signal power of 1 W.

Set M and generate random data.

```
M = 16;  
x = randi([0 M-1],1e5,1);
```

Modulate the data applying 16-QAM as specified in MIL-STD-188-110B. Using name-value pairs, set the unit average power to `true` and enable the constellation plot.

```
y = mil188qammod(x,M,'UnitAveragePower',true,'PlotConstellation',true);
```

Verify that the signal has approximately unit average power.

```
avgPow = mean(abs(y).^2)
```

```
avgPow = 1.0012
```

**Apply 64-QAM MIL-STD-188-110B Modulation to Bit Data**

Modulate a sequence of bits using 64-QAM as specified by MIL-STD188-110B. Display the constellation.

Set the modulation order and generate a sequence of random bits.

```
M = 64;  
numBitsPerSym = log2(M);  
data = randi([0 1],1000*numBitsPerSym,1);
```

Modulate the data applying 64-QAM as specified by MIL-STD-188-110B, and output constellation symbols of single data type.

```
y = mil188qammod(data,M, 'InputType', 'bit', 'OutputDataType', 'single');
```

Plot the result constellation using a scatter plot.

```
scatterplot(y)
```

## Input Arguments

### **x** — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of **x** must be binary values or integers that range from 0 to  $(M - 1)$ , where  $M$  is the modulation order.

---

**Note** To process input signal as binary elements, set the 'InputType' value to 'bit'. For binary inputs, the number of rows must be an integer multiple of  $\log_2(M)$ . Groups of

$\log_2(M)$  bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

---

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical

### **M — Modulation order**

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Example: 16

Data Types: double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `y = mil188qammod(data,M,'InputType','bit','OutputDataType','single');`

### **InputType — Input type**

'integer' (default) | 'bit'

Input type, specified as the comma-separated pair consisting of 'InputType' and either 'integer' or 'bit'. If you specify 'integer', the input signal must consist of integers from 0 to  $M - 1$ . If you specify 'bit', the input signal must contain binary values, and the number of rows must be an integer multiple of  $\log_2(M)$ .

Data Types: char | string

### **OutputDataType — Output data type**

'double' (default) | 'single'

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and 'double' or 'single'.

Data Types: char | string

**UnitAveragePower — Unit average power flag**

false (default) | true

Unit average power flag, specified as the comma-separated pair consisting of 'UnitAveragePower' and a logical scalar. When this flag is true, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is false, the function scales the constellation based on specifications in the relevant standard, as described in [1].

Data Types: logical

**PlotConstellation — Option to plot constellation**

false (default) | true

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the constellation, set PlotConstellation to true.

Data Types: logical

## Output Arguments

**y — Modulated signal**

scalar | vector | matrix

Modulated signal, returned as a complex scalar, vector, or matrix. The dimension of the output depends on the specified InputType value.

InputType	Dimensions of Output
'integer'	y has the same dimensions as input x.
'bit'	The number of rows in y equals the number of rows in x divided by $\log_2(M)$ .

Data Types: double | single

## More About

### MIL-STD-188-110

MIL-STD-188-110 is a US Department of Defense standard for HF communications using serial PSK mode of both data and voice signals.

The standard specifies physical layer modulation schemes for tactical and long-haul communications. The modulation scheme specified by the standard is a mix of QAM and APSK. For a detailed description of the modulation scheme, see [1].

## minpol

Find minimal polynomial of Galois field element

### Syntax

```
p1 = minpol(x)
```

### Description

`p1 = minpol(x)` finds the minimal polynomial of each element in the Galois column vector, `x`. The output `p1` is an array in  $GF(2)$ . The  $k$ th row of `p1` lists the coefficients, in order of descending powers, of the minimal polynomial of the  $k$ th element of `x`.

---

**Note** The output is in  $GF(2)$  even if the input is in a different Galois field.

---

### Examples

The code below uses  $m = 4$  and finds that the minimal polynomial of `gf(2,m)` is just the primitive polynomial used for the field  $GF(2^m)$ . This is true for any value of  $m$ , not just the value used in the example.

```
m = 4;  
A = gf(2,m)  
p1 = minpol(A)
```

The output is below. Notice that the row vector `[1 0 0 1 1]` represents the polynomial  $D^4 + D + 1$ .

`A = GF(2^4) array. Primitive polynomial = D^4+D+1 (19 decimal)`

Array elements =

2

pl = GF(2) array.

Array elements =

1 0 0 1 1

Another example is in “Minimal Polynomials”.

## **mldivide**

Matrix left division  $\backslash$  of Galois arrays

### **Syntax**

$x = A \backslash B$

### **Description**

$x = A \backslash B$  divides the Galois array  $A$  into  $B$  to produce a particular solution of the linear equation  $A * x = B$ . In the special case when  $A$  is a nonsingular square matrix,  $x$  is the unique solution,  $\text{inv}(A) * B$ , to the equation.

### **Examples**

The code below shows that  $A \backslash \text{eye}(\text{size}(A))$  is the inverse of the nonsingular square matrix  $A$ .

```
m = 4; A = gf([8 1 6; 3 5 7; 4 9 2],m);  
Id = gf(eye(size(A)),m);  
X = A \ Id;  
ck1 = isequal(X*A, Id)  
ck2 = isequal(A*X, Id)
```

The output is below.

```
ck1 =
```

```
1
```

```
ck2 =
```

```
1
```

Other examples are in “Solving Linear Equations”.

## Limitations

The matrix  $A$  must be one of these types:

- A nonsingular square matrix
- A matrix, in which there are more rows than columns, such that  $A' * A$  is nonsingular
- A matrix, in which there are more columns than rows, such that  $A * A'$  is nonsingular

## Algorithms

If  $A$  is an  $M$ -by- $N$  matrix where  $M > N$ ,  $A \setminus B$  is the same as  $(A' * A) \setminus (A' * B)$ .

If  $A$  is an  $M$ -by- $N$  matrix where  $M < N$ ,  $A \setminus B$  is the same as  $A' * ((A * A') \setminus B)$ . This solution is not unique.

## mlseeq

Equalize linearly modulated signal using MLSE

### Syntax

```
y = mlseeq(x, chcffs, const, tbleen, opmode)
```

```
y = mlseeq( ____, nsamp)
```

```
y = mlseeq( ____, nsamp, preamble, postamble)
```

```
y = mlseeq( ____, nsamp, init_metric, init_states, init_inputs)
```

```
[y, final_metric, final_states, final_inputs] = mlseeq( ____,
```

### Description

`y = mlseeq(x, chcffs, const, tbleen, opmode)` equalizes the baseband signal vector `x` using the maximum likelihood sequence estimation (MLSE). `chcffs` provides estimated channel coefficients. `const` provides the ideal signal constellation points. `tbleen` specifies the traceback depth. `opmode` specifies the operation mode of the equalizer. MLSE is implemented using the “Viterbi Algorithm” on page 2-861.

`y = mlseeq( ____, nsamp)` specifies the number of samples per symbol in `x`, in addition to arguments in the previous syntax.

`y = mlseeq( ____, nsamp, preamble, postamble)` specifies the number of samples per symbol in `x`, `preamble`, and `postamble`, in addition to arguments in the first syntax. This syntax applies when `opmode` is 'rst' only. For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-861.

`y = mlseeq( ____, nsamp, init_metric, init_states, init_inputs)` specifies the number of samples per symbol in `x`, initial likelihood state metrics, initial traceback states, and initial traceback inputs for the equalizer, in addition to arguments in the first syntax. These three inputs are typically the `final_metric`, `final_states`, and `final_inputs` outputs from a previous call to this function. This syntax applies when `opmode` is 'cont' only. For more information, see “Initialization in Continuous Operation Mode” on page 2-862.

`[y,final_metric,final_states,final_inputs] = mlseqq( ___ )` returns the normalized final likelihood state metrics, final traceback states, and final traceback inputs at the end of the traceback decoding process, using any of the previous input argument syntaxes. This syntax applies when `opmode` is 'cont' only. For more information, see "Initialization in Continuous Operation Mode" on page 2-862.

## Examples

### Using MLSE Equalizer Reset Operating Mode

Use the reset operating mode of the `mlseqq` equalizer. Demodulate the signal and check the bit error rate.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, and message length.

```
M = 2;
tblen = 10;
nsamp = 2;
msgLen = 1000;
```

Generate the reference constellation.

```
const = pammod([0:M-1],M);
```

Generate a message with random data. Modulate and upsample the signal.

```
msgData = randi([0 M-1],msgLen,1);
msgSym = pammod(msgData,M);
msgSymUp = upsample(msgSym,nsamp);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chanest = [0.986; 0.845; 0.237; 0.12345+0.31i];
msgFilt = filter(chanest,1,msgSymUp);
msgRx = awgn(msgFilt,5,'measured');
```

Equalize and then demodulate the signal to recover the message. To initialize the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, number of samples per symbol, and set the operating mode to reset. Check the message bit error rate. Your results might vary because this example uses random numbers.

```
eqSym = mlseeq(msgRx,chanest,const,tblen,'rst',nsamp);
eqMsg = pandemod(eqSym,M);

[nerrs ber] = biterr(msgData, eqMsg)

nerrs = 1
ber = 1.0000e-03
```

### Recover Message Containing Preamble

Recover a message that includes a preamble, equalize the signal, and check the symbol error rate.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, preamble, and message length.

```
M = 4;
tblen = 16;
nsamp = 1;
preamble = [3;1];
msgLen = 500;
```

Generate the reference constellation.

```
const = pskmod(0:3,4);
```

Generate a message by using random data and prepend the preamble to the message. Modulate the random data.

```
msgData = randi([0 M-1],msgLen,1);
msgData = [preamble; msgData];
msgSym = pskmod(msgData,M);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chcoeffs = [0.623; 0.489+0.234i; 0.398i; 0.21];
chanest = chcoeffs;
msgFilt = filter(chcoeffs,1,msgSym);
msgRx = awgn(msgFilt,9,'measured');
```

Equalize the received signal. To configure the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, operating mode, number of samples

per symbol, and preamble. The same preamble symbols appear at the beginning of the message vector and in the syntax for `mlseeq`. Because the system does not use a postamble, an empty vector is specified as the last input argument in this `mlseeq` syntax.

Check the symbol error rate of the equalized signal. Run-to-run results vary due to use of random numbers.

```
eqSym = mlseeq(msgRx,chanest,const,tblen,'rst',nsamp,preamble,[]);
[nsymerrs,ser] = symerr(msgSym,eqSym)

nsymerrs = 8
ser = 0.0159
```

### Using MLSE Equalizer Continuous Operating Mode

Use the continuous operating mode of the `mlseeq` equalizer. Demodulate received signal packets and check the symbol error statistics.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, message length, and number of packets to process.

```
M = 4;
tblen = 10;
nsamp = 1;
msgLen = 1000;
numPkts = 25;
```

Generate the reference constellation.

```
const = pskmod(0:M-1,M);
```

Set the initial input parameters for the metric, states, and inputs of the equalizer to empty vectors. These initial assignments represent the parameters for the first packet transmitted.

```
eq_metric = [];
eq_states = [];
eq_inputs = [];
```

Assign variables for symbol error statistics.

```
t1SymbErrs = 0;  
aggrPktSER = 0;
```

Send and receive multiple message packets in a simulation loop. Between the packet transmission and reception filter each packet through a distortion channel and add Gaussian noise.

```
for jj = 1:numPkts
```

Generate a message with random data. Modulate the signal.

```
msgData = randi([0 M-1],msgLen,1);  
msgMod = pskmod(msgData,M);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chanest = [.986; .845; .237; .12345+.31i];  
msgFilt = filter(chanest,1,msgMod);  
msgRx = awgn(msgFilt,10,'measured');
```

Equalize the received symbols. To configure the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, operating mode, number of samples per symbol, and the equalizer initialization information. Continuous operating mode is specified for the equalizer. In continuous operating mode, the equalizer initialization information (metric, states, and inputs) are returned and used as inputs in the next iteration of the `for` loop.

```
[eqSym,eq_metric,eq_states,eq_inputs] = ...  
mlseq(msgRx,chanest,const,tblen,'cont',nsamp, ...  
eq_metric,eq_states,eq_inputs);
```

Save the symbol error statistics. Update the symbol error statistics with the aggregate results. Display the total number of errors. Your results might vary because this example uses random numbers.

```
[nsymmerrs,ser] = symerr(msgMod(1:end-tblen),eqSym(tblen+1:end));  
t1SymbErrs = t1SymbErrs + nsymmerrs;  
aggrPktSER = aggrPktSER + ser;  
end  
printT1Err = 'A total of %d symbol errors over the %d packets received.\n';  
fprintf(printT1Err,t1SymbErrs,numPkts);
```

A total of 155 symbol errors over the 25 packets received.

Display the aggregate symbol error rate.

```
printAggrSER = 'The aggregate symbol error rate was %6.5d.\n';  
fprintf(printAggrSER,aggrPktSER/numPkts);
```

The aggregate symbol error rate was 6.26263e-03.

## Input Arguments

### **x** — Input signal

vector

Input signal, specified as a vector of modulated symbols. The vector length of **x** must be an integer multiple of **nsamp**.

Data Types: `double`

Complex Number Support: Yes

### **chcffs** — Channel coefficients

vector

Channel coefficients, specified as a vector. The channel coefficients provide an estimate of the channel response. When **nsamp** > 1, the **chcffs** input specifies the oversampled channel coefficients.

Data Types: `double`

Complex Number Support: Yes

### **const** — Reference constellation

vector

Reference constellation, specified as a vector with *M* elements. *M* is the modulation order. **const** lists the ideal signal constellation points in the sequence used by the modulator.

Data Types: `double`

Complex Number Support: Yes

### **tblen** — Traceback depth

positive integer

Traceback depth, specified as a positive integer. The equalizer traces back from the likelihood state with the maximum metric.

Data Types: `double`

**opmode — Operation mode**

'rst' | 'cont'

Operation mode, specified as 'rst' or 'cont'.

Value	Usage
'rst'	Run equalizer using reset operating mode. Enables you to specify a <b>preamble</b> and <b>postamble</b> that accompany the input signal. The function processes the input signal, $x$ , independently of the input signal from any other invocations of this function. This operating mode does not incur an output delay. For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-861.
'cont'	Run equalizer using continuous operating mode. Enables you to save the internal state information of the equalizer for use in a subsequent invocation of this function. Continuous operating mode is useful if the input signal is partitioned into a stream of packets processed within a loop. This operating mode incurs an output delay of $tblen$ symbols. For more information, see “Initialization in Continuous Operation Mode” on page 2-862.

Data Types: char

**nsamp — Number of samples per symbol**

1 (default) | positive integer

Number of samples per symbol, specified as a positive integer.  $nsamp$  is the oversampling factor.

**Dependencies**

The input signal,  $x$ , must be an integer multiple of  $nsamp$ .

Data Types: double

**preamble — Input signal preamble**

vector of integers

Input signal preamble, specified as a vector of integers between 0 and  $M-1$ , where  $M$  is the modulation order. To omit a preamble, specify `[]`.

For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-861.

### **Dependencies**

This input argument applies only when `opmode` is set to `'rst'`.

Data Types: `double`

### **postamble — Input signal postamble**

vector of integers

Input signal postamble, specified as a vector of integers between 0 and  $M-1$ , where  $M$  is the modulation order. To omit a postamble, specify `[]`.

For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-861.

### **Dependencies**

This input argument applies only when `opmode` is set to `'rst'`.

Data Types: `double`

### **init\_metric — Initial state metrics**

`[]` (default) | column vector

Initial state metrics, specified as a column vector with  $N_{\text{states}}$  elements. For the description of  $N_{\text{states}}$ , see “Number of Likelihood States” on page 2-863.

For more information, see “Initialization in Continuous Operation Mode” on page 2-862.

### **Dependencies**

This input argument applies only when `opmode` is set to `'cont'`. If specifying `[]` for `init_metric`, you must also specify `[]` for `init_states` and `init_inputs`.

Data Types: `double`

### **init\_states — Initial traceback states**

`[]` (default) | matrix of integers

Initial traceback states, specified as an  $N_{\text{states}}$ -by-`tblen` matrix of integers with values between 0 and  $N_{\text{states}}-1$ . For the description of  $N_{\text{states}}$ , see “Number of Likelihood States” on page 2-863.

For more information, see “Initialization in Continuous Operation Mode” on page 2-862.

### **Dependencies**

This input argument applies only when `opmode` is set to 'cont'. If specifying [] for `init_states`, you must also specify [] for `init_metric` and `init_inputs`.

Data Types: double

### **init\_inputs — Initial traceback inputs**

[] (default) | matrix of integers

Initial traceback inputs, specified as an  $N_{\text{states}}$ -by-`tblen` matrix of integers with values between 0 and  $M-1$ . For the description of  $N_{\text{states}}$ , see “Number of Likelihood States” on page 2-863.

For more information, see “Initialization in Continuous Operation Mode” on page 2-862.

### **Dependencies**

This input argument applies only when `opmode` is set to 'cont'. If specifying [] for `init_inputs`, you must also specify [] for `init_metric` and `init_states`.

Data Types: double

## **Output Arguments**

### **y — Output signal**

vector

Output signal, returned as a vector of modulated symbols.

### **final\_metric — Final normalized state metrics**

vector

Final normalized state metrics, returned as a vector with  $N_{\text{states}}$  elements. `final_metric` corresponds to the final state metrics at the end of the traceback decoding process. For the description of  $N_{\text{states}}$ , see “Number of Likelihood States” on page 2-863.

For more information, see “Initialization in Continuous Operation Mode” on page 2-862.

### **final\_states — Final traceback states**

vector

Final traceback states, returned as a  $N_{\text{states}}$ -by-`tblen` matrix of integers with values between 0 and  $N_{\text{states}}-1$ . `final_states` corresponds to the final traceback states at the end of the traceback decoding process. For the description of  $N_{\text{states}}$ , see “Number of Likelihood States” on page 2-863.

For more information, see “Initialization in Continuous Operation Mode” on page 2-862.

### **final\_inputs — Final traceback inputs**

vector

Final traceback inputs, returned as an  $N_{\text{states}}$ -by-`tblen` matrix of integers with values between 0 and  $M-1$ . `final_inputs` corresponds to the final traceback inputs at the end of the traceback decoding process.  $M$  is the order of the modulation. For the description of  $N_{\text{states}}$ , see “Number of Likelihood States” on page 2-863.

For more information, see “Initialization in Continuous Operation Mode” on page 2-862.

## **More About**

### **Viterbi Algorithm**

The Viterbi algorithm is a sequential trellis search algorithm used to perform maximum likelihood sequence detection.

The MLSE equalizer uses the Viterbi algorithm to recursively search for the sequences that maximize the likelihood function. Using the Viterbi algorithm reduces the number of sequences in the trellis search by eliminating sequences as new data is received. The metric used to determine the maximum likelihood sequence is the correlation between the received signal and an estimated signal for each received symbol over the “Number of Likelihood States” on page 2-863.

For more information, see [1] and [2].

### **Preamble and Postamble in Reset Operation Mode**

When operating the MLSE equalizer in reset mode, you can specify a preamble and postamble as input arguments. Specify `preamble` and `postamble` as vectors equal to the preamble and postamble that are prepended and appended, respectively, to the input signal. The `preamble` and `postamble` vectors consist of integers between 0 and  $M-1$ ,

where  $M$  is the number of elements in `const`. To omit the `preamble` or `postamble` input argument, specify `[]`.

When the function applies the Viterbi algorithm, it initializes state metrics in a way that depends on whether you specify a `preamble`, a `postamble`, or both:

- If `preamble` is nonempty, the function decodes the preamble and assigns a metric of 0 to the decoded state. If the preamble does not decode to a unique state (that is, if the length of the preamble is less than the channel memory), the decoder assigns a metric of 0 to all states that are represented by the preamble. The traceback path ends at one of the states represented by the preamble.
- If `preamble` is `[]`, the decoder initializes the metrics of all states to 0.
- If `postamble` is nonempty, the traceback path begins at the smallest of all possible decoded states that are represented by the `postamble`.
- If `postamble` is `[]`, the traceback path starts at the state with the smallest metric.

## Initialization in Continuous Operation Mode

When operating the MLSE equalizer in continuous mode, you can initialize the equalization based on values returned in the previous call of the function.

At the end of the traceback decoding process, the function returns `final_metric`, `final_states`, and `final_inputs`. When `opmode` is `'cont'`, assign these outputs to `init_metric`, `init_states`, and `init_inputs`, respectively for the next call of the function. These assignments initialize the equalizer to start with the final state metrics, final traceback states, and final traceback inputs from the previous call of the function.

Each real number in `init_metric` represents the starting state metric of the corresponding state. `init_states` and `init_inputs` jointly specify the initial traceback memory of the equalizer.

Output Argument	Input Argument	Meaning	Matrix Size	Range of Values
<code>final_metric</code>	<code>init_metric</code>	State metrics	1-by- $N_{\text{states}}$	Real numbers
<code>final_states</code>	<code>init_states</code>	Traceback states	$N_{\text{states}}$ -by- <code>tblen</code>	Integers between 0 and $N_{\text{states}}-1$
<code>final_inputs</code>	<code>init_inputs</code>	Traceback inputs	$N_{\text{states}}$ -by- <code>tblen</code>	Integers between 0 and $M-1$

To use default values for `init_metric`, `init_states`, and `init_inputs`, specify each as `[]`. For the description of  $N_{\text{states}}$ , see “Number of Likelihood States” on page 2-863.

## Number of Likelihood States

The number of likelihood states,  $N_{\text{states}}$ , is the number of correlative phase states in the trellis.  $N_{\text{states}}$  is equal to  $M^{L-1}$ , where  $M$  is the number of elements in `const` and  $L$  is the number of symbols in the nonoversampled impulse response of the channel.

## modnorm

Scaling factor for normalizing modulation output

### Syntax

```
normfactor = modnorm(refconst,type,power)
```

### Description

`normfactor = modnorm(refconst,type,power)` returns a scale factor for normalizing a PAM or QAM modulator output using the specified reference constellation, normalization type, and output power.

### Examples

#### Normalize Power of QAM Signal

Generate a 16-QAM reference constellation.

```
refconst = qammod(0:15,16);
```

Generate random symbols and apply 16-QAM modulation.

```
x = randi([0 15],1000,1);  
y = qammod(x,16);
```

Plot the constellation.

```
h = scatterplot(y);
```

Compute the normalization factor so that the output signal has a peak power of 1 W.

```
nf = modnorm(refconst, 'peakpow', 1);  
z = nf*y;
```

Confirm that no element of the normalized signal has a power greater than 1 W.

```
max(z.*conj(z))
```

```
ans = 1.0000
```

Plot the scatter plot of the normalized constellation.

```
hold on
scatterplot(z,1,0,'r+',h)
hold off
```

## Input Arguments

### **refconst** — Reference constellation

vector

Reference constellation, specified as a vector of complex elements that comprise the reference constellation points.

Example: `qammod(0:15,16)`

Data Types: `double` | `single`

Complex Number Support: Yes

### **type — Normalization type**

`'avpow'` | `'peakpow'`

Normalization type, specified as either `'avpow'` or `'peakpow'`.

- If `type` is `'avpow'`, the normalization factor is calculated based on average power.
- If `type` is `'peakpow'`, the normalization factor is calculated based on peak power.

Data Types: `char`

### **power — Target power**

scalar

Target power, specified as a real scalar. The target power is the intended power of the modulated signal multiplied by `normfactor`.

Data Types: `double` | `single`

## **Output Arguments**

### **normfactor — Normalization factor**

scalar

Normalization factor, returned as a real scalar. When a modulated signal is multiplied by the normalization factor, its average or peak power matches the target power. The function assumes that the signal you want to normalize has a minimum distance of 2.

Data Types: `double` | `single`

## mskdemod

Minimum shift keying demodulation

### Syntax

```
z = mskdemod(y, nsamp)
z = mskdemod(y, nsamp, dataenc)
z = mskdemod(y, nsamp, dataenc, ini_phase)
z = mskdemod(y, nsamp, dataenc, ini_phase, ini_state)
[z, phaseout] = mskdemod(...)
[z, phaseout, stateout] = mskdemod(...)
```

### Description

`z = mskdemod(y, nsamp)` demodulates the complex envelope `y` of a signal using the differentially encoded minimum shift keying (MSK) method. `nsamp` denotes the number of samples per symbol and must be a positive integer. The initial phase of the demodulator is 0. If `y` is a matrix with multiple rows and columns, the function treats the columns as independent channels and processes them independently.

`z = mskdemod(y, nsamp, dataenc)` specifies the method of encoding data for MSK. `dataenc` can be either 'diff' for differentially encoded MSK or 'nondiff' for nondifferentially encoded MSK.

`z = mskdemod(y, nsamp, dataenc, ini_phase)` specifies the initial phase of the demodulator. `ini_phase` is a row vector whose length is the number of channels in `y` and whose values are integer multiples of  $\pi/2$ . To avoid overriding the default value of `dataenc`, set `dataenc` to `[]`.

`z = mskdemod(y, nsamp, dataenc, ini_phase, ini_state)` specifies the initial state of the demodulator. `ini_state` contains the last half symbol of the previously received signal. `ini_state` is an `nsamp`-by-`C` matrix, where `C` is the number of channels in `y`.

`[z, phaseout] = mskdemod(...)` returns the final phase of `y`, which is important for demodulating a future signal. The output `phaseout` has the same dimensions as the `ini_phase` input, and assumes the values 0,  $\pi/2$ ,  $\pi$ , and  $3\pi/2$ .

`[z, phaseout, stateout] = mskdemod(...)` returns the final `nsamp` values of `y`, which is useful for demodulating the first symbol of a future signal. `stateout` has the same dimensions as the `ini_state` input.

## Examples

### MSK Demodulation

Modulate and demodulate a noisy MSK signal. Display the number of received errors.

Define the number of samples per symbol for the MSK signal.

```
nsamp = 16;
```

Initialize the simulation parameters.

```
numerrs = 0;
modPhase = zeros(1,2);
demodPhase = zeros(1,2);
demodState = complex(zeros(nsamp,2));
```

The main processing loop includes these steps:

- Generate binary data.
- MSK modulate the data.
- Pass the signal through an AWGN channel.
- Demodulate the MSK signal.
- Determine the number of bit errors.

```
for iRuns = 1:20
    txData = randi([0 1],100,2);
    [modSig,modPhase] = mskmod(txData,nsamp,[],modPhase);
    rxSig = awgn(modSig,20,'measured');
    [rxData,demodPhase,demodState] = mskdemod(rxSig,nsamp,[],demodPhase,demodState);
    numerrs = numerrs + biterr(txData,rxData);
end
```

Display the number of bit errors.

```
numerrs
```

```
numerrs = 0
```

# mskmod

Minimum shift keying modulation

## Syntax

```
y = mskmod(x, nsamp)
y = mskmod(x, nsamp, dataenc)
y = mskmod(x, nsamp, dataenc, ini_phase)
[y, phaseout] = mskmod(...)
```

## Description

`y = mskmod(x, nsamp)` outputs the complex envelope `y` of the modulation of the message signal `x` using differentially encoded minimum shift keying (MSK) modulation. The elements of `x` must be 0 or 1. `nsamp` denotes the number of samples per symbol in `y` and must be a positive integer. The initial phase of the MSK modulator is 0. If `x` is a matrix with multiple rows and columns, the function treats the columns as independent channels and processes them independently.

`y = mskmod(x, nsamp, dataenc)` specifies the method of encoding data for MSK. `dataenc` can be either 'diff' for differentially encoded MSK or 'nondiff' for nondifferentially encoded MSK.

`y = mskmod(x, nsamp, dataenc, ini_phase)` specifies the initial phase of the MSK modulator. `ini_phase` is a row vector whose length is the number of channels in `y` and whose values are integer multiples of  $\pi/2$ . To avoid overriding the default value of `dataenc`, set `dataenc` to `[]`.

`[y, phaseout] = mskmod(...)` returns the final phase of `y`. This is useful for maintaining phase continuity when you are modulating a future bit stream with differentially encoded MSK. `phaseout` has the same dimensions as the `ini_phase` input, and assumes the values  $0$ ,  $\pi/2$ ,  $\pi$ , and  $3\pi/2$ .

## Examples

### Eye Diagram of MSK Signal

Generate a random binary signal.

```
x = randi([0 1],100,1);
```

MSK modulate the data.

```
y = mskmod(x,8,[],pi/2);
```

Pass the signal through an AWGN channel. Display the eye diagram.

```
z = awgn(y,30,'measured');  
eyediagram(z,16);
```

## muxdeintrlv

Restore ordering of symbols using specified shift registers

### Syntax

```
deintrlved = muxdeintrlv(data,delay)
[deintrlved,state] = muxdeintrlv(data,delay)
[deintrlved,state] = muxdeintrlv(data,delay,init_state)
```

### Description

`deintrlved = muxdeintrlv(data,delay)` restores the ordering of elements in `data` by using a set of internal shift registers, each with its own delay value. `delay` is a vector whose entries indicate how many symbols each shift register can hold. The length of `delay` is the number of shift registers. Before the function begins to process `data`, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[deintrlved,state] = muxdeintrlv(data,delay)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[deintrlved,state] = muxdeintrlv(data,delay,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver.

### Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `muxintrlv` function, use the same `delay` input in both functions. In that case, the two functions are inverses in the sense that applying `muxintrlv` followed by `muxdeintrlv` leaves `data` unchanged, after you take their combined delay of `length(delay)*max(delay)` into account. To learn more about delays of convolutional interleavers, see “Delays of Convolutional Interleavers”.

### Examples

The example below illustrates how to use the state input and output when invoking `muxdeintrlv` repeatedly. Notice that `[deintrlvd1; deintrlvd2]` is the same as `deintrlvd`.

```
delay = [0 4 8 12]; % Delays in shift registers
symbols = 100; % Number of symbols to process
% Interleave random data.
intrlvd = muxintrlv(randi([0 1],symbols,1),delay);

% Deinterleave some of the data, recording state for later use.
[deintrlvd1,state] = muxdeintrlv(intrlvd(1:symbols/2),delay);
% Deinterleave the rest of the data, using state as an input argument.
deintrlvd2 = muxdeintrlv(intrlvd(symbols/2+1:symbols),delay,state);

% Deinterleave all data in one step.
deintrlvd = muxdeintrlv(intrlvd,delay);

isequal(deintrlvd,[deintrlvd1; deintrlvd2])
```

The output is below.

```
ans =
     1
```

Another example using this function is in “Convolutional Interleaving and Deinterleaving Using a Sequence of Consecutive Integers in MATLAB”.

## **muxintrlv**

Permute symbols using shift registers with specified delays

### **Syntax**

```
intrlv = muxintrlv(data, delay)
[intrlv, state] = muxintrlv(data, delay)
[intrlv, state] = muxintrlv(data, delay, init_state)
```

### **Description**

`intrlv = muxintrlv(data, delay)` permutes the elements in `data` by using internal shift registers, each with its own delay value. `delay` is a vector whose entries indicate how many symbols each shift register can hold. The length of `delay` is the number of shift registers. Before the function begins to process `data`, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[intrlv, state] = muxintrlv(data, delay)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[intrlv, state] = muxintrlv(data, delay, init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding deinterleaver.

### **Examples**

The examples in “Convolutional Interleaving and Deinterleaving Using a Sequence of Consecutive Integers in MATLAB” and on the reference page for the `convintrlv` function use `muxintrlv`.

The example on the reference page for `muxdeintrlv` illustrates how to use the `state` output and `init_state` input with that function; the process is analogous for this function.

## noisebw

Equivalent noise bandwidth of filter

### Syntax

```
bw = noisebw(num, den, numsamp, Fs)
```

### Description

`bw = noisebw(num, den, numsamp, Fs)` returns the two-sided equivalent noise bandwidth, in Hz, of a digital lowpass filter given in descending powers of  $z$  by numerator vector `num` and denominator vector `den`. The bandwidth is calculated over `numsamp` samples of the impulse response. `Fs` is the sampling rate of the signal that the filter would process; this is used as a scaling factor to convert a normalized unitless quantity into a bandwidth in Hz.

### Examples

#### Noise Equivalent Bandwidth of Butterworth Filter

Computes the equivalent noise bandwidth of a Butterworth filter over 100 samples of the impulse response.

Set the sampling rate, Nyquist frequency, and carrier frequency.

```
fs = 16;  
fNyq = fs/2;  
fc = 0.5;
```

Generate the Butterworth filter.

```
[num,den] = butter(2,fc/fNyq);
```

Determine the noise bandwidth.

```
bw = noisebw(num,den,100,fs)
```

```
bw = 1.1049
```

## Algorithms

The two-sided equivalent noise bandwidth is

$$\frac{F_s \sum_{i=1}^N |h(i)|^2}{\left| \sum_{i=1}^N h(i) \right|^2}$$

where  $h$  is the impulse response of the filter described by `num` and `den`, and  $N$  is `numsamp`.

# normlms

(To be removed) Construct normalized least mean square (LMS) adaptive algorithm object

---

**Note** will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

---

## Syntax

```
alg = normlms(stepsize)
alg = normlms(stepsize,bias)
```

## Description

The `normlms` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = normlms(stepsize)` constructs an adaptive algorithm object based on the normalized least mean square (LMS) algorithm with a step size of `stepsize` and a bias parameter of zero.

`alg = normlms(stepsize,bias)` sets the bias parameter of the normalized LMS algorithm. `bias` must be between 0 and 1. The algorithm uses the bias parameter to overcome difficulties when the algorithm's input signal is small.

## Properties

The table below describes the properties of the normalized LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
AlgType	Fixed value, 'Normalized LMS'
StepSize	LMS step size parameter, a nonnegative real number
LeakageFactor	LMS leakage factor, a real number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.
Bias	Normalized LMS bias parameter, a nonnegative real number

## Examples

### Delays from Equalization

For proper equalization using adaptive algorithms other than CMA, you should set the reference tap so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay between the modulator output and the equalizer output is equal to  $(\text{RefTap} - 1) / \text{nSampPerSym}$  symbols. Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap in a linear equalizer, or the center tap of the forward filter in a decision-feedback equalizer.

For CMA equalizers, the expression above does not apply because a CMA equalizer has no reference tap. If you need to know the delay, you can find it empirically after the equalizer weights have converged. Use the `xcorr` function to examine cross-correlations of the modulator output and the equalizer output.

### Techniques for Working with Delays

Here are some typical ways to take a delay of  $D$  into account by padding or truncating data:

- Pad your original data with  $D$  extra symbols at the end. Before comparing the original data with the received data, omit the first  $D$  symbols of the received data. In this approach, all the original data (not including the padding) is accounted for in the received data.

- Before comparing the original data with the received data, omit the last  $D$  symbols of the original data and the first  $D$  symbols of the received data. In this approach, some of the original symbols are not accounted for in the received data.

This example illustrates the second approach by omitting the last  $D$  symbols to account for the delay. For an example that illustrates both approaches in the context of interleavers, see “Delays of Convolutional Interleavers”.

Create a random signal and BPSK modulate it. Assign a portion of the signal as a training signal.

```
M = 2; % Use BPSK modulation
msg = randi([0 M-1],1000,1); % Random data
bpskMod = comm.BPSKModulator('PhaseOffset',0);
modmsg = bpskMod(msg); % Modulate
trainlen = 100; % Length of training sequence
trainsig = modmsg(1:trainlen); % Training sequence
```

Define an equalizer and equalize the received signal.

```
eqlin = lineareq(3,normlms(.0005,.0001),pskmod(0:M-1,M));
eqlin.RefTap = 2; % Set reference tap of equalizer.
[eqsig,detsym] = equalize(eqlin,modmsg,trainsig); % Equalize.
```

Demodulate the detected signal.

```
bpskDemod = comm.BPSKDemodulator('PhaseOffset',0);
detmsg = bpskDemod(detsym);
```

Compute bit error rate while compensating for delay introduced by RefTap and ignoring training sequence.

```
D = (eqlin.RefTap-1)/eqlin.nSampPerSym;
hErrorCalc = comm.ErrorRate('ReceiveDelay',D);
berVec = step(hErrorCalc, msg(trainlen+1:end), detmsg(trainlen+1:end));
ber = berVec(1)
```

```
ber = 0
```

```
numerrs = berVec(2)
```

```
numerrs = 0
```

## Algorithms

Referring to the schematics presented in “Equalization”, define  $w$  as the vector of all weights  $w_i$  and define  $u$  as the vector of all inputs  $u_i$ . Based on the current set of weights,  $w$ , this adaptive algorithm creates the new set of weights given by

$$(\text{LeakageFactor})w + \frac{(\text{StepSize})u^*e}{u^H u + \text{Bias}}$$

where the  $*$  operator denotes the complex conjugate and  $H$  denotes the Hermitian transpose.

## Compatibility Considerations

### **normlms will be removed**

*Not recommended starting in R2019a*

normlms will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

## oct2dec

Convert octal to decimal numbers

### Syntax

```
d = oct2dec(c)
```

### Description

`d = oct2dec(c)` converts an octal matrix `c` to a decimal matrix `d`, element by element. In both octal and decimal representations, the rightmost digit is the least significant.

### Examples

#### Convert Octal Matrix to Decimal Equivalent

Convert a 2-by-2 octal matrix its decimal equivalent.

```
d = oct2dec([12 144;0 25])
```

```
d = 2×2
```

```
    10    100  
     0     21
```

The octal number 144 is equivalent to 100 because  $144 = 1(8^2) + 4(8^1) + 4(8^0) = 100$ .

# ofdm demod

Demodulate time-domain signal using orthogonal frequency division multiplexing (OFDM)

## Syntax

```
outSym = ofdm demod(ofdmSig,nfft,cplen)
outSym = ofdm demod(ofdmSig,nfft,cplen,symOffset)
outSym = ofdm demod(ofdmSig,nfft,cplen,symOffset,nullidx)
[outSym,pilots] = ofdm demod(ofdmSig,nfft,cplen,symOffset,nullidx,
pilotidx)
```

## Description

`outSym = ofdm demod(ofdmSig,nfft,cplen)` performs OFDM demodulation on the input time domain signal specified in `ofdmSig`, using an FFT size specified by `nfft` and cyclic prefix length specified by `cplen`. For information, see “OFDM Demodulation” on page 2-896.

`outSym = ofdm demod(ofdmSig,nfft,cplen,symOffset)` applies the symbol sampling offset, `symOffset`, for each OFDM symbol before demodulation of the input.

`outSym = ofdm demod(ofdmSig,nfft,cplen,symOffset,nullidx)` removes null subcarriers from the locations specified in `nullidx`. For this syntax, the symbol sampling offset is applied to each OFDM symbol and the number of rows in the output is `nfft - length(nullidx)`, which accounts for the removal of null subcarriers. Use null subcarriers to account for guard bands and DC subcarriers. For information, see “Subcarrier Allocation and Guard Bands” on page 2-897.

`[outSym,pilots] = ofdm demod(ofdmSig,nfft,cplen,symOffset,nullidx,pilotidx)` returns pilot subcarriers for the pilot indices specified in `pilotidx`. For this syntax, the symbol sampling offset is applied to each OFDM symbol and number of rows in the output is `nfft - length(nullidx) - length(pilotidx)`, which accounts for the removal of null and pilot subcarriers. The function assumes that pilot subcarrier locations are the same across each OFDM symbol and transmit antenna.

## Examples

### OFDM Demodulation with Different CP Lengths

OFDM-demodulate a signal with different CP lengths for different symbols.

Initialize input parameters defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
nfft = 64;
cplen = [16 32];
nSym = 2;
dataIn = complex(randn(nfft,nSym),randn(nfft,nSym));
y1 = ofdmmod(dataIn,nfft,cplen);
```

Demodulate the OFDM symbols. Compare the results to the original input data. The difference between the signals is negligible.

```
x1 = ofdmdemod(y1,nfft,cplen);
max(x1-dataIn)
```

```
ans = 1×2 complex
10-15 ×
```

```
0.2220 - 0.7772i    0.2498 - 0.8882i
```

### OFDM Mod-Demod SISO link

Apply OFDM multiplexing to a 16-QAM signal SISO link with Rayleigh fading.

```
s1 = RandStream('mt19937ar','Seed',12345);
nFFT = 64;
cplLen = 16;
nullIdx = [1:6 33 64-4:64].';
numTones = nFFT-length(nullIdx);

modOrd = 4;
qam = comm.RectangularQAMModulator('ModulationOrder',2^modOrd, ...
```

```

    'BitInput',true,'NormalizationMethod','Average power');

maxDopp = 1;
pathDelays = [0 4e-3 8e-3];
pathGains = [0 -2 -3];
sRate = 1000;
sampIdx = round(pathDelays/(1/sRate)) + 1;

chan = comm.RayleighChannel('PathGainsOutputPort',true, ...
    'MaximumDopplerShift',maxDopp,'PathDelays',pathDelays, ...
    'AveragePathGains',pathGains,'SampleRate',sRate, ...
    'RandomStream','mt19937ar with seed');

data = randi(s1,[0 1],modOrd*numTones,1);
modOut = qam(data);

```

Apply OFDM modulation and pass the signal through the channel.

```

y = ofdmmod(modOut,nFFT,cpLen,nullIdx);
[fadSig, pg] = chan(y);

```

Determine symbol sampling offset. OFDM demodulate the received signal.

```

symOffset = min(max(sampIdx),cpLen)
x = ofdmmod(fadSig,nFFT,cpLen,symOffset,nullIdx); % with a time shift

```

```

symOffset =

```

```

    9

```

Convert path gains, pg, to scalar taps gains. Use the tap gains for equalization during signal recovery.

```

hImp = complex(zeros(1,nFFT));
hImp(:,sampIdx) = mean(pg,1);
hall = fftshift(fft(hImp.',1);
dataIdx = double(setdiff((1:nFFT)',nullIdx));
h = hall(dataIdx);

```

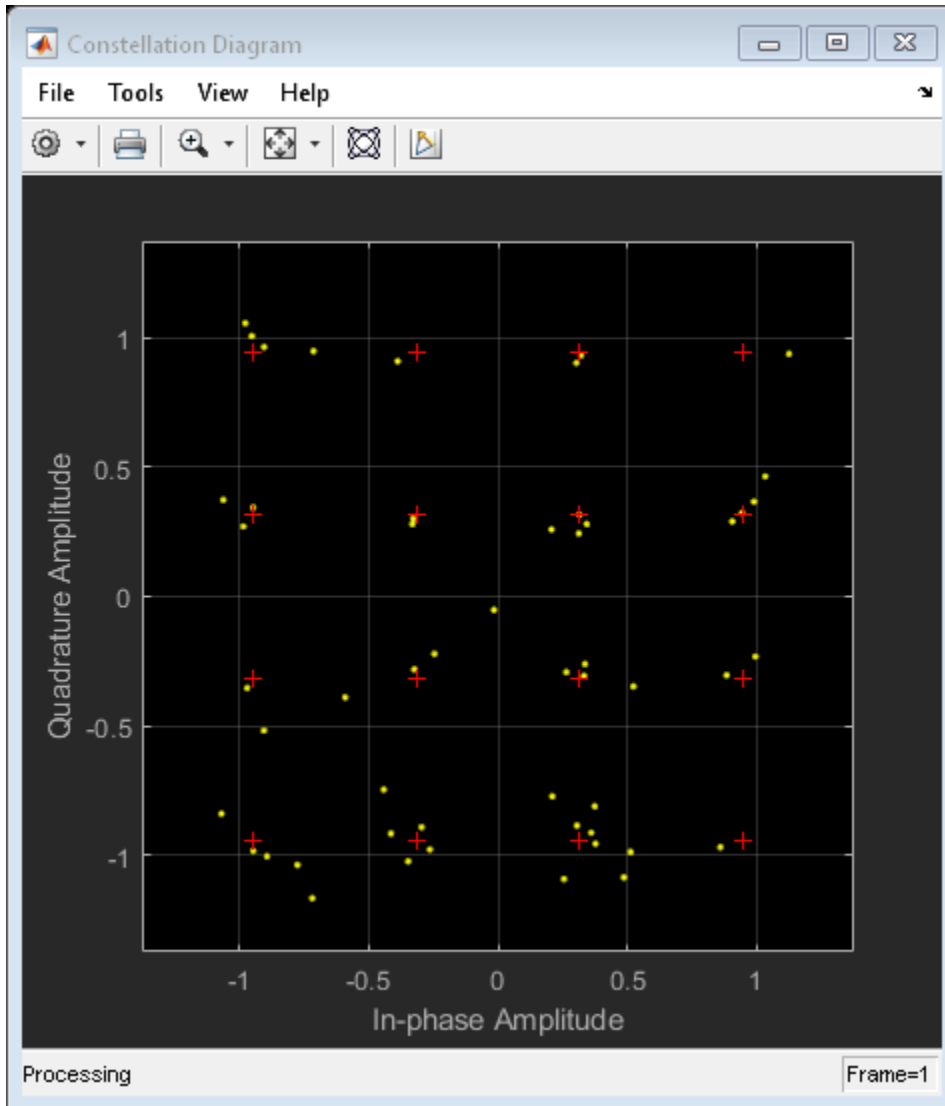

Equalize the signal.

```

eqH = conj(h)./(conj(h).*h);
eqSig = eqH.*x;

```

```
cdScope = comm.ConstellationDiagram('ShowReferenceConstellation',true, ...  
    'ReferenceConstellation',constellation(qam));  
cdScope(eqSig);
```

Demodulate the 16-QAM symbols to recover the signal. Compute the bit error rate.

```
qamdem = comm.RectangularQAMDemodulator('ModulationOrder',2^modOrd, ...
    'BitOutput',true,'NormalizationMethod','Average power');
rxBits = qamdem(eqSig);

numErr = biterr(data,rxBits);
disp(['Number of bit errors: ' num2str(numErr) ' out of ' num2str(length(data)) ' bits

Number of bit errors: 3 out of 208 bits.
```

## OFDM Demodulation with Null and Pilot Packing

OFDM-demodulate data input that includes null and pilot packing.

Initialize input parameters, defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
nfft      = 64;
cplen     = 16;
nSym      = 10;
nullIdx   = [1:6 33 64-4:64]';
pilotIdx  = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
dataIn    = complex(randn(numDataCarrs,nSym),randn(numDataCarrs,nSym));
pilots    = repmat(pskmod((0:3)'.',4),1,nSym);
y2        = ofdmmod(dataIn,nfft,cplen,nullIdx,pilotIdx,pilots);
```

Demodulate the OFDM symbols. Compare the results to the original input data to show that there is negligible difference between the demodulated signal and the original data and pilot signals.

```
symOffset = cplen;
[x2,rxPilots] = ofdm demod(y2,nfft,cplen,symOffset,nullIdx,pilotIdx);
max(x2-dataIn)
```

```
ans = 1×10 complex
10-15 ×
```

```
0.5551 + 0.2220i    0.2220 + 0.4441i    0.4441 - 0.2220i    0.4718 - 0.3331i    -0.1665
```

```
max(rxPilots-pilots)
```

```
ans = 1×10 complex  
10-15 ×
```

```
0.0000 + 0.3331i 0.1837 - 0.2220i -0.4441 - 0.2776i 0.2220 + 0.2220i 0.2220
```

## Input Arguments

### **ofdmSig** — Modulated OFDM symbols

2-D array of complex symbols

Modulated OFDM symbols, specified as a 2-D array of complex symbols.

- If `cplen` is a scalar, the array size is  $((nfft + cplen) \times N_{Sym})$ -by- $N_R$ .
- If `cplen` is a row vector, the array size is  $((nfft \times N_{Sym}) + \text{sum}(cplen))$ -by- $N_R$ .

$N_{Sym}$  is the number of symbols per antenna and  $N_R$  is the number of receive antennas.

Data Types: `double` | `single`  
Complex Number Support: Yes

### **nfft** — FFT length

integer greater than or equal to 8

FFT length, specified as an integer greater than or equal to 8. `nfft` is equivalent to the number of subcarriers used in the demodulation process.

Data Types: `double`

### **cplen** — Cyclic prefix length

scalar | row vector of length  $N_{Sym}$

Cyclic prefix length, specified as a scalar or as a row vector of length  $N_{Sym}$ .

- When you specify `cplen` as a scalar, the cyclic prefix length is the same for all symbols through all antennas.
- When you specify `cplen` as a row vector of length  $N_{Sym}$ , the cyclic prefix length can vary across symbols but remains the same length through all antennas.

Data Types: `double`

**symOffset — Symbol sampling offset**

cplen (default) | scalar | row vector

Symbol sampling offset, specified as values from 0 to cplen.

- If you do not specify `symOffset`, the default value is an offset equal to `cplen`.
- If you specify `symOffset` as a scalar, the same offset is used for all symbols.
- If you specify `symOffset` as a row vector, the offset value can be different for each symbol.

For information, see “Windowing and Symbol Offset” on page 2-898.

Data Types: double

**nullidx — Indices of null subcarrier locations**

column vector

Indices of null subcarrier locations, specified as a column vector with element values from 1 to `nfft`. If you specify `nullidx`, the number of rows in `outSym` is `(nfft - length(nullidx))`. For information, see “Subcarrier Allocation and Guard Bands” on page 2-897.

Data Types: double

**pilotidx — Indices of pilot subcarrier locations**

column vector

Indices of pilot subcarrier locations, specified as a column vector with element values from 1 to `nfft`. If you specify `pilotidx`, the number of rows in `outSym` is `(nfft - length(nullidx) - length(pilotidx))`. For information, see “Subcarrier Allocation and Guard Bands” on page 2-897.

Data Types: double

## Output Arguments

**outSym — Output demodulated symbols**

numeric 3-D array

Output demodulated symbols, returned as an  $N_D$ -by- $N_{\text{Sym}}$ -by- $N_R$  numeric array of symbols.  $N_D$  must equal `nfft - length(nullidx) - length(pilotidx)`.  $N_{\text{Sym}}$  is the number of

OFDM symbols per antenna.  $N_R$  is the number of receive antennas. For information, see “OFDM Demodulation” on page 2-896.

### **pilots — Pilot subcarriers**

numeric 3-D array

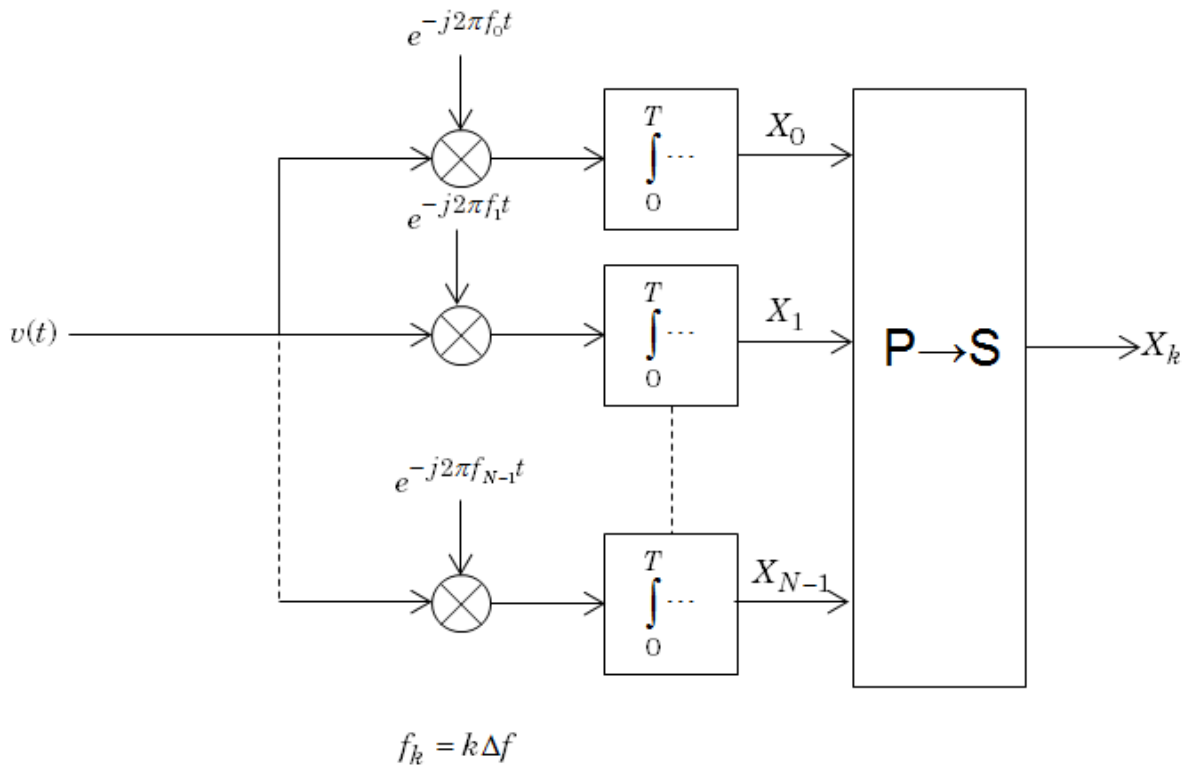

Pilot subcarriers, returned as an  $N_{\text{Pilot}}$ -by- $N_{\text{Sym}}$ -by- $N_R$  numeric array of symbols.  $N_{\text{Pilot}}$  must equal the length of `pilotIdx`.  $N_{\text{Sym}}$  is the number of OFDM symbols per antenna.  $N_R$  is the number of receive antennas. The function assumes that the pilot subcarrier locations are the same across each OFDM symbol and transmit antenna. Use the `comm.OFDMDemodulator` to vary pilot subcarrier locations across OFDM symbols or antennas.

## **More About**

### **OFDM Demodulation**

An OFDM demodulator demultiplexes a multi-subcarrier time-domain signal using orthogonal frequency division modulation.

The OFDM demodulation uses an FFT operation that results in  $N$  parallel data streams. An OFDM demodulator consists of a bank of  $N$  correlators, with one correlator assigned to each OFDM subcarrier, followed by a parallel-to-serial conversion.

## Subcarrier Allocation and Guard Bands

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.

As shown here, subcarriers are designated as data, DC, pilot, or guard band subcarriers.

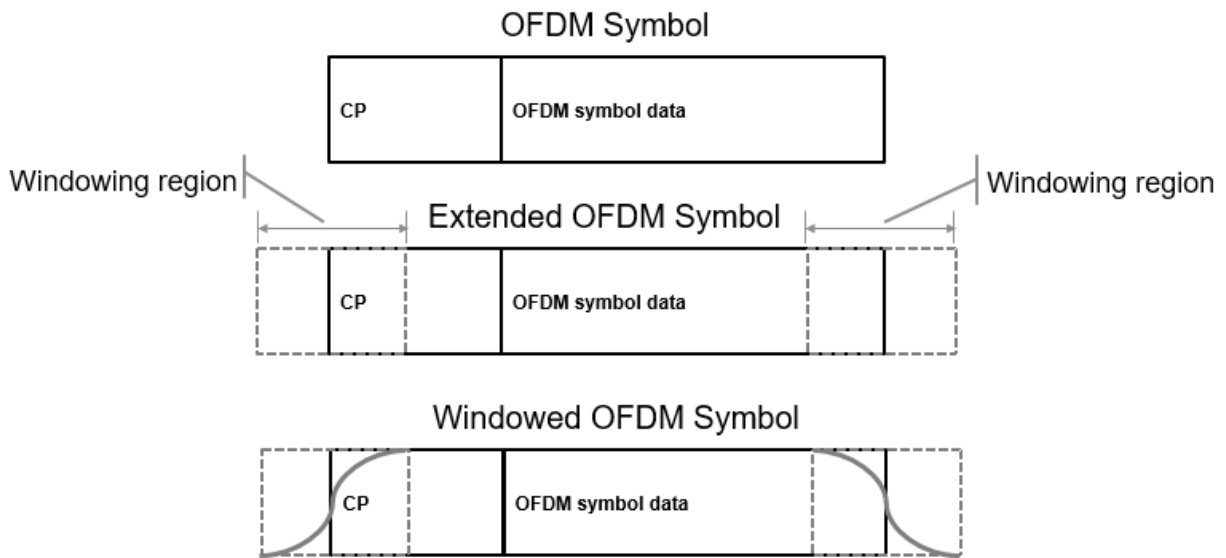

- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.
  - The null DC subcarrier is the center of the frequency band with an index value of  $(nfft/2 + 1)$  if  $nfft$  is even, or  $(nfft + 1) / 2$  if  $nfft$  is odd.
  - The guard bands provide buffers between consecutive OFDM symbols to protect the integrity of transmitted signals by reducing intersymbol interference.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

### Windowing and Symbol Offset

To reduce intersymbol interference (ISI) introduced by signal windowing applied at the transmitter, the function applies a fractional symbol offset before demodulation of each OFDM symbol. Signal windowing is often applied to transmitted OFDM symbols to smooth the discontinuity between consecutive OFDM symbols. Windowing reduces intersymbol out-of-band emissions but increases ISI.

The windowed OFDM symbol consists of the cyclic prefix (CP), OFDM symbol data, plus windowing regions at the beginning and end of the symbol. The leading and trailing windowing shoulders have tails as shown in the figure.

To reduce ISI, you can align signal sample timing by specifying a symbol sampling offset that gets applied before OFDM symbol demodulation.

Specify the symbol sampling offset as a value from 0 to  $L_{CP}$ .

- When the symbol sampling offset is a scalar from 0 to  $L_{CP}$ , the FFT window begins at the  $X+1$  sample of the CP length.

- When the symbol sampling offset is zero, no offset is applied and the FFT window starts at the first sample of the symbol.
- When the symbol sampling offset is the cyclic prefix length,  $L_{CP}$ , the FFT window begins after the last CP sample. This offset is the default setting if symbol sampling offset is not specified.

# ofdmmod

Modulate frequency-domain signal using orthogonal frequency division multiplexing (OFDM)

## Syntax

```
ofdmSig = ofdmmod(inSym,nfft,cplen)
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx)
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx,pilotidx,pilots)
```

## Description

`ofdmSig = ofdmmod(inSym,nfft,cplen)` performs OFDM modulation on the frequency-domain input data subcarriers, `inSym`, using an FFT size specified by `nfft` and cyclic prefix length specified by `cplen`. For information, see “OFDM Modulation” on page 2-906.

`ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx)` inserts null subcarriers into the frequency domain input data signal prior to performing OFDM modulation. The null subcarriers are inserted at index locations from 1 to `nfft`, as specified by `nullidx`. For this syntax, the number of rows in the input `inSym` must be `nfft - length(nullidx)`. Use null carriers to account for guard bands and DC subcarriers. For information, see “Subcarrier Allocation and Guard Bands” on page 2-907.

`ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx,pilotidx,pilots)` inserts null and pilot subcarriers into the frequency domain input data symbols prior to performing OFDM modulation. The null subcarriers are inserted at the index locations specified by `nullidx`. The pilot subcarriers, `pilots`, are inserted at the index locations specified by `pilotidx`. For this syntax, the number of rows in the input `inSym` must be `nfft - length(nullidx) - length(pilotidx)`. The function assumes pilot subcarrier locations are the same across each OFDM symbol and transmit antenna.

## Examples

### OFDM Modulation Over Two Antennas

OFDM-modulate a fully packed input over two transmit antennas.

Initialize input parameters, generate random data, and perform OFDM modulation.

```
nfft = 128;
cplen = 16;
nSym = 5;
nt = 2;
dataIn = complex(randn(nfft,nSym,nt),randn(nfft,nSym,nt));

y1 = ofdmmod(dataIn,nfft,cplen);
```

### Apply OFDM Assigning Null Subcarriers

Apply OFDM modulation assigning null subcarriers.

Initialize input parameters and generate random data.

```
M = 16; % Modulation order for 16QAM
nfft = 64;
cplen = 16;
nSym = 10;
nullIdx = [1:6 33 64-4:64]';
numDataCarrs = nfft-length(nullIdx);
inSig = randi([0 M-1],numDataCarrs,nSym);
```

QAM modulate data. Perform OFDM modulation.

```
qamSym = qammod(inSig,M,'UnitAveragePower',true);
outSig = ofdmmod(qamSym,nfft,cplen,nullIdx);
```

### Perform OFDM Modulation Varying Cyclic Prefix per Symbol

Perform OFDM modulation to input frequency domain data signal varying cyclic prefix length applied to each symbol.

Initialize input parameters and generate random data.

```

M = 16; % Modulation order for 16QAM
nfft = 64;
cplen = [4 8 10 7 2 2 4 11 16 3];
nSym = 10;
nullIdx = [1:6 33 64-4:64]';
numDataCarrs = nfft-length(nullIdx);
inSig = randi([0 M-1],numDataCarrs,nSym);

```

QAM modulate data. Perform OFDM modulation.

```

qamSym = qammod(inSig,M,'UnitAveragePower',true);
outSig = ofdmmod(qamSym,nfft,cplen,nullIdx);

```

### Apply OFDM to QPSK Signal Spatially Multiplexed Over Two Antennas

Apply OFDM modulation to a QPSK signal that is spatially multiplexed over two transmit antennas.

Initialize input parameters and generate random data for each antenna.

```

M = 4; % Modulation order for QPSK
nfft = 64;
cplen = 16;
nSym = 5;
nt = 2;
nullIdx = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
pilots = repmat(pskmod((0:M-1).',M),1,nSym,2);

ant1 = randi([0 M-1],numDataCarrs,nSym);
ant2 = randi([0 M-1],numDataCarrs,nSym);

```

QPSK modulate data individually for each antenna. Perform OFDM modulation.

```

qpskSym(:,:,1) = pskmod(ant1,M);
qpskSym(:,:,2) = pskmod(ant2,M);
y1 = ofdmmod(qpskSym,nfft,cplen,nullIdx,pilotIdx,pilots);

```

## OFDM Modulation with Null and Pilot Packing

OFDM-modulate data input, specifying null and pilot packing.

Initialize input parameters, defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
nfft      = 64;
cplen    = 16;
nSym     = 10;

nullIdx  = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';

numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
dataIn = complex(randn(numDataCarrs,nSym),randn(numDataCarrs,nSym));
pilots = repmat(pskmod((0:3)'.',4),1,nSym);

y2 = ofdmmod(dataIn,nfft,cplen,nullIdx,pilotIdx,pilots);
```

## Input Arguments

### **inSym** — Input data subcarriers

numeric 3-D array

Input data subcarriers, specified as an  $N_D$ -by- $N_{\text{Sym}}$ -by- $N_T$  numeric array of symbols. The number of data subcarriers,  $N_D$ , must equal `nfft - length(nullidx) - length(pilotidx)`.  $N_{\text{Sym}}$  is the number of OFDM symbols per transmit antenna,  $N_T$  is the number of transmit antennas.

Input data symbols to an OFDM modulator are typically created with a baseband digital modulator, such as `qammod`.

Data Types: `double` | `single`  
Complex Number Support: Yes

### **nfft** — FFT length

integer greater than or equal to 8

FFT length, specified as an integer greater than or equal to 8. `nfft` is equivalent to the number of subcarriers used in the modulation process.

Data Types: double

### **cpLen — Cyclic prefix length**

scalar | row vector of length  $N_{\text{Sym}}$

Cyclic prefix length, specified as a scalar or as a row vector of length  $N_{\text{Sym}}$ .

- When you specify `cpLen` as a scalar, the cyclic prefix length is the same for all symbols through all antennas.
- When you specify `cpLen` as a row vector of length  $N_{\text{Sym}}$ , the cyclic prefix length can vary across symbols but remains the same length through all antennas.

For more information, see “Guard Intervals” on page 2-908.

Data Types: double

### **nullIdx — Indices of null subcarrier locations**

column vector

Indices of null subcarrier locations, specified as a column vector with element values from 1 to `nfft`.

Data Types: double

### **pilotIdx — Indices of pilot subcarrier locations**

column vector

Indices of pilot subcarrier locations, specified as a column vector with element values from 1 to `nfft`.

Data Types: double

### **pilots — Pilot subcarriers**

numeric 3-D array

Pilot subcarriers, specified as an  $N_{\text{Pilot}}$ -by- $N_{\text{Sym}}$ -by- $N_{\text{T}}$  numeric array of symbols.  $N_{\text{Pilot}}$  must equal the length of `pilotIdx`.  $N_{\text{Sym}}$  is the number of OFDM symbols per transmit antenna.  $N_{\text{T}}$  is the number of transmit antennas. The function assumes pilot subcarrier locations are the same across each OFDM symbol and transmit antenna. Use the `comm.OFDMModulator` to vary pilot subcarrier locations across OFDM symbols or antennas.

Data Types: double | single

## Output Arguments

### ofdmSig — Modulated OFDM symbols

2-D array of complex symbols

Modulated OFDM symbols, returned as a 2-D array of complex symbols.

- If `cplen` is a scalar, the array size is  $((nfft + cplen) \times N_{\text{Sym}})$ -by- $N_T$ .
- If `cplen` is a row vector, the array size is  $((nfft \times N_{\text{Sym}}) + \text{sum}(cplen))$ -by- $N_T$ .

$N_{\text{Sym}}$  is the number of symbols per transmit antenna and  $N_T$  is the number of transmit antennas.

## More About

### OFDM Modulation

An OFDM modulator multiplexes a frequency-domain input signal over multiple subcarriers using orthogonal frequency division modulation.

The OFDM operation divides a high-rate transmit data stream into  $N$  lower data rate substreams. The individual substreams are sent over  $N$  parallel and orthogonal subchannels. Using an inverse fast Fourier transform (IFFT) to process the transmission data, OFDM can be transmitted with a single radio. Intersymbol interference (ISI) is reduced because the lower data rate substreams have symbol durations larger than the channel delay spread.

The output is a baseband representation of the modulated signal:

$$v(t) = \sum_{k=0}^{N-1} X_k e^{j2\pi k \Delta f t}, \quad 0 \leq t \leq T,$$

where  $\{X_k\}$  are data symbols,  $N$  is the number of subcarriers, and  $T$  is the OFDM symbol time. Using a subcarrier spacing of  $\Delta f = 1/T$ , the subcarriers are orthogonal over each symbol period, as expressed in this equation:

$$\frac{1}{T} \int_0^T (e^{j2\pi m \Delta f t})^* (e^{j2\pi n \Delta f t}) dt = \frac{1}{T} \int_0^T e^{j2\pi(m-n)\Delta f t} dt = 0 \quad \text{for } m \neq n.$$

The data symbols,  $X_k$ , are typically complex and can be from any digital modulation alphabet (for example, QPSK, 16-QAM, 64-QAM).

An OFDM modulator consists of a serial-to-parallel conversion followed by a bank of  $N$  complex modulators, individually corresponding to each OFDM subcarrier.

## Subcarrier Allocation and Guard Bands

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.

As shown here, subcarriers are designated as data, DC, pilot, or guard band subcarriers.

- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.
  - The null DC subcarrier is the center of the frequency band with an index value of  $(nfft/2 + 1)$  if  $nfft$  is even, or  $((nfft + 1) / 2)$  if  $nfft$  is odd.
  - The guard bands provide buffers between consecutive OFDM symbols to protect the integrity of transmitted signals by reducing intersymbol interference.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

### Guard Intervals

Similar to guard bands, guard intervals are used in OFDM to protect the integrity of transmitted signals by reducing intersymbol interference.

Assignment of guard intervals is analogous to the assignment of guard bands. You can model guard intervals to provide temporal separation between OFDM symbols. The guard intervals help preserve intersymbol orthogonality after the signal passes through time-dispersive channels. Guard intervals are created by using cyclic prefixes. Cyclic prefix insertion copies the last part of an OFDM symbol as the first part of the OFDM symbol.

As long as the span of the time dispersion does not exceed the duration of the cyclic prefix, the benefit of cyclic prefix insertion is maintained.

Inserting a cyclic prefix results in a fractional reduction of user data throughput because the cyclic prefix occupies bandwidth that could be used for data transmission.

comm.GeneralQAMModulator | comm.OFDMModulator | comm.OQPSKModulator

**Introduced in R2018a**

# oqpskdemod

(Removed) Offset quadrature phase shift keying demodulation

---

**Note** oqpskdemod has been removed. Use `comm.OQPSKDemodulator` instead.

---

## Syntax

```
z = oqpskdemod(y)
z = oqpskdemod(y,ini_phase)
```

## Description

`z = oqpskdemod(y)` demodulates the complex envelope of an OQPSK modulated signal. The function upsamples by a factor of 2, because OQPSK does not permit an odd number of samples per symbol.

`z = oqpskdemod(y,ini_phase)` specifies the initial phase of the modulated signal.

## Examples

### Modulate and Demodulate OQPSK Signal in AWGN

Generate random 4-ary data. Create modulator and demodulator objects.

```
dataIn = randi([0 3],100,1);
oqpskmod = comm.OQPSKModulator;
oqpskdemod = comm.OQPSKDemodulator;
```

OQPSK modulate the data, and pass it through an AWGN channel.

```
txSig = oqpskmod(dataIn);
rxSig = awgn(txSig,10);
```

OQPSK demodulate the received signal. Determine the number of symbol errors.

```
dataOut = oqpskdemod(rxSig);  
numErrs = symerr(dataIn,dataOut)  
  
numErrs = 79
```

## Input Arguments

### **y** — OQPSK-modulated input signal

vector | matrix

OQPSK-modulated input signal, specified as a complex vector or matrix. If *y* is a matrix, the function processes the columns independently.

Data Types: `single` | `double`

Complex Number Support: Yes

### **ini\_phase** — Initial phase

0 (default) | scalar

Initial phase of the OQPSK modulation, specified in radians as a real scalar.

Example: `pi/4`

Data Types: `double` | `single`

## Output Arguments

### **z** — OQPSK-demodulated output signal

vector | matrix

OQPSK-demodulated output signal, returned as a vector or matrix having the same number of columns as input signal *y*.

Data Types: `double` | `single`

## Compatibility Considerations

### **opskdemod** has been removed

*Errors starting in R2019b*

oqpskdemod has been removed. Use `comm.OQPSKModulator` instead.

# oqpskmod

(Removed) Offset quadrature phase shift keying modulation

---

**Note** `oqpskmod` has been removed. Use `comm.OQPSKModulator` instead.

---

## Syntax

```
y = oqpskmod(x)
y = oqpskmod(x, ini_phase)
```

## Description

`y = oqpskmod(x)` modulates the input signal, `x`, using offset quadrature phase shift keying (OQPSK). The function upsamples by a factor of 2, because OQPSK does not permit an odd number of samples per symbol.

`y = oqpskmod(x, ini_phase)` specifies the initial phase of the modulated signal.

## Examples

### Modulate and Demodulate OQPSK Signal in AWGN

Generate random 4-ary data. Create modulator and demodulator objects.

```
dataIn = randi([0 3],100,1);
oqpskmod = comm.OQPSKModulator;
oqpskdemod = comm.OQPSKDemodulator;
```

OQPSK modulate the data, and pass it through an AWGN channel.

```
txSig = oqpskmod(dataIn);
rxSig = awgn(txSig,10);
```

OQPSK demodulate the received signal. Determine the number of symbol errors.

```
dataOut = oqpskdemod(rxSig);  
numErrs = symerr(dataIn,dataOut)  
  
numErrs = 79
```

## Input Arguments

### **x** — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. The elements of **x** must have values in the range of [0, 3].

Data Types: double | single

### **ini\_phase** — Initial phase

0 (default) | scalar

Initial phase of the OQPSK modulation, specified in radians as a real scalar.

Example:  $\pi/4$

Data Types: double | single

## Output Arguments

### **y** — OQPSK-modulated output signal

vector | matrix

Complex baseband representation of an OQPSK-modulated output signal, returned as a vector or matrix. The columns of **y** represent independent channels.

Data Types: double | single

## Compatibility Considerations

“Phase Modulation”

**Introduced before R2006a**

# pamdemod

Pulse amplitude demodulation

## Syntax

```
z = pamdemod(y,M)
z = pamdemod(y,M,ini_phase)
z = pamdemod(y,M,ini_phase,symbol_order)
```

## Description

`z = pamdemod(y,M)` demodulates the complex envelope `y` of a pulse amplitude modulated signal. `M` is the alphabet size. The ideal modulated signal should have a minimum Euclidean distance of 2.

`z = pamdemod(y,M,ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = pamdemod(y,M,ini_phase,symbol_order)` specifies how the function assigns binary words to corresponding integers. If `symbol_order` is set to 'bin' (default), the function uses a natural binary-coded ordering. If `symbol_order` is set to 'gray', it uses a Gray-coded ordering.

## Examples

### Demodulate PAM Signal

Modulate and demodulate random integers using pulse amplitude modulation. Verify that the output data matches the original data.

Set the modulation order and generate 100 M-ary data symbols.

```
M = 12;
dataIn = randi([0 M-1],100,1);
```

Perform modulation and demodulation operations.

```
modData = pammod(dataIn,M);  
dataOut = pamdemod(modData,M);
```

Compare the first five symbols.

```
[dataIn(1:5) dataOut(1:5)]
```

```
ans = 5x2
```

```
     9     9  
    10    10  
     1     1  
    10    10  
     7     7
```

Verify that there are no symbol errors in the entire sequence.

```
symErrors = symerr(dataIn,dataOut)
```

```
symErrors = 0
```

# pammod

Pulse amplitude modulation

## Syntax

```
y = pammod(x,M)
y = pammod(x,M,ini_phase)
y = pammod(x,M,ini_phase,symbol_order)
```

## Description

`y = pammod(x,M)` outputs the complex envelope `y` of the modulation of the message signal `x` using pulse amplitude modulation. `M` is the alphabet size. The message signal must consist of integers between 0 and `M-1`. The modulated signal has a minimum Euclidean distance of 2. If `x` is a matrix with multiple rows, the function processes the columns independently.

`y = pammod(x,M,ini_phase)` specifies the initial phase of the modulated signal in radians.

`y = pammod(x,M,ini_phase,symbol_order)` specifies how the function assigns binary words to corresponding integers. If `symbol_order` is set to 'bin' (default), the function uses a natural binary-coded ordering. If `symbol_order` is set to 'gray', it uses a Gray constellation ordering.

## Examples

### Modulate Data Symbols with PAM

Generate random data symbols and apply pulse amplitude modulation.

Set the modulation order.

```
M = 8;
```

Generate random integers and apply PAM modulation having an initial phase of  $\pi/4$ .

```
data = randi([0 M-1],100,1);  
modData = pammod(data,M,pi/4);
```

Display the PAM constellation diagram.

```
scatterplot(modData)
```

## plot (channel)

(To be removed) Plot channel characteristics with channel visualization tool

### Syntax

```
plot(h)
```

---

**Note** This function will be removed in a future release. Use function associated with `comm.RicianChannel` or `comm.RayleighChannel` instead.

---

### Description

`plot(h)`, where `h` is a channel object, launches the channel visualization tool. This GUI tool allows you to plot channel characteristics in various ways. See Channel Visualization for details.

### Examples Visualize RF Impairments

Apply various RF impairments to a QAM signal. Observe the effects by using constellation diagrams, time-varying error vector magnitude (EVM) plots, and spectrum plots. Estimate the equivalent signal-to-noise ratio (SNR).

#### Initialization

Set the sample rate, modulation order, and SNR. Calculate the reference constellation points.

```
fs = 1000;  
M = 16;  
snrdB = 30;  
refConst = qammod(0:M-1,M, 'UnitAveragePower', true);
```

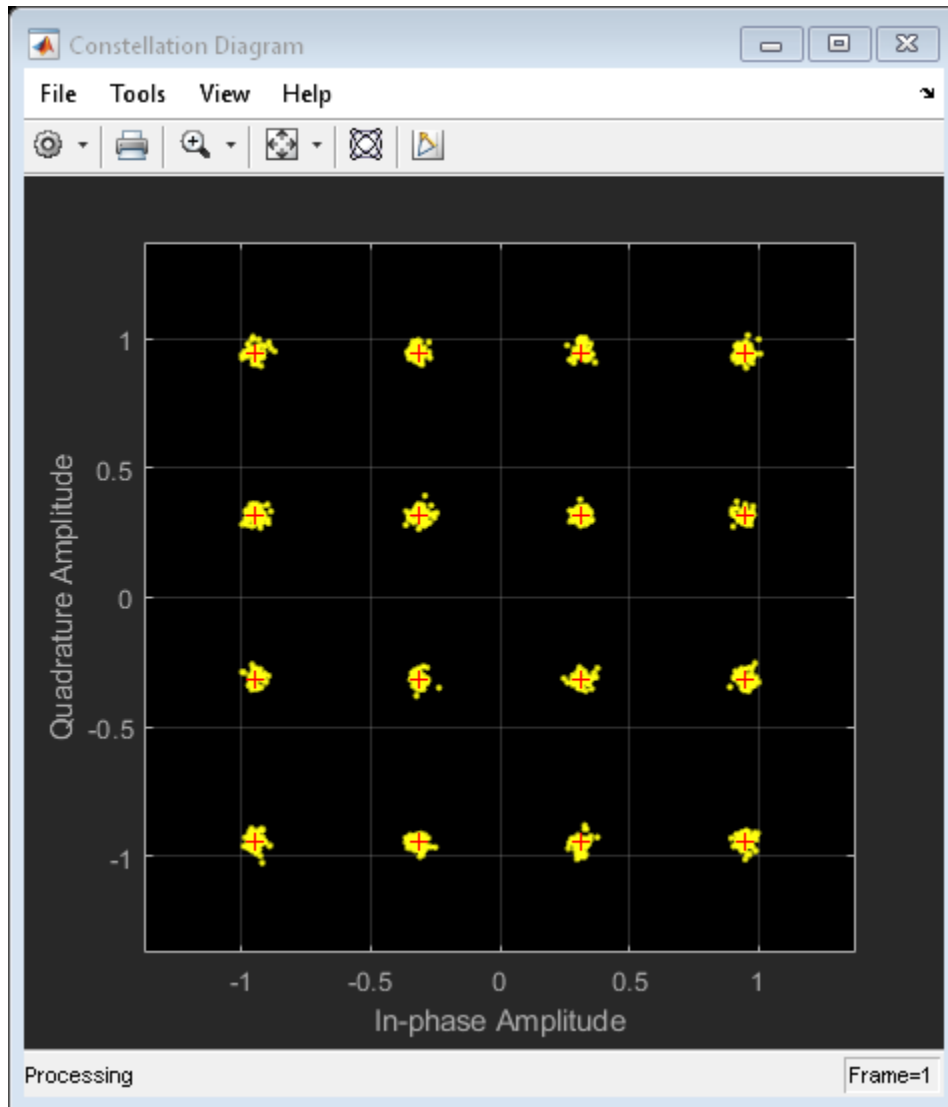

Create constellation diagram and time scope objects to visualize the impairment effects.

```
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);  
timeScope = dsp.TimeScope('YLimits',[0 40],'SampleRate',fs,'TimeSpan',1, ...  
    'ShowGrid',true,'YLabel','EVM (%)');
```

### White Noise

Generate a 16-QAM signal, and pass it through an AWGN channel. Plot its constellation.

```
data = randi([0 M-1],1000,1);  
modSig = qammod(data,M,'UnitAveragePower',true);  
noisySig = awgn(modSig,snrdB);  
  
constDiagram(noisySig)
```

Estimate the EVM of the noisy signal from the reference constellation points.

```
evm = comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst, ...
    'Normalization','Average constellation power');
```

```
rmsEVM = evm(noisySig)
```

```
rmsEVM =  
    3.1768
```

The modulation error rate (MER) closely corresponds to the SNR. Create an MER object, and estimate the SNR.

```
mer = comm.MER('ReferenceSignalSource','Estimated from reference constellation', ...  
    'ReferenceConstellation',refConst);  
snrEst = mer(noisySig)
```

```
snrEst =  
    30.1071
```

The estimate is quite close to the specified SNR of 30 dB.

### **Amplifier Distortion**

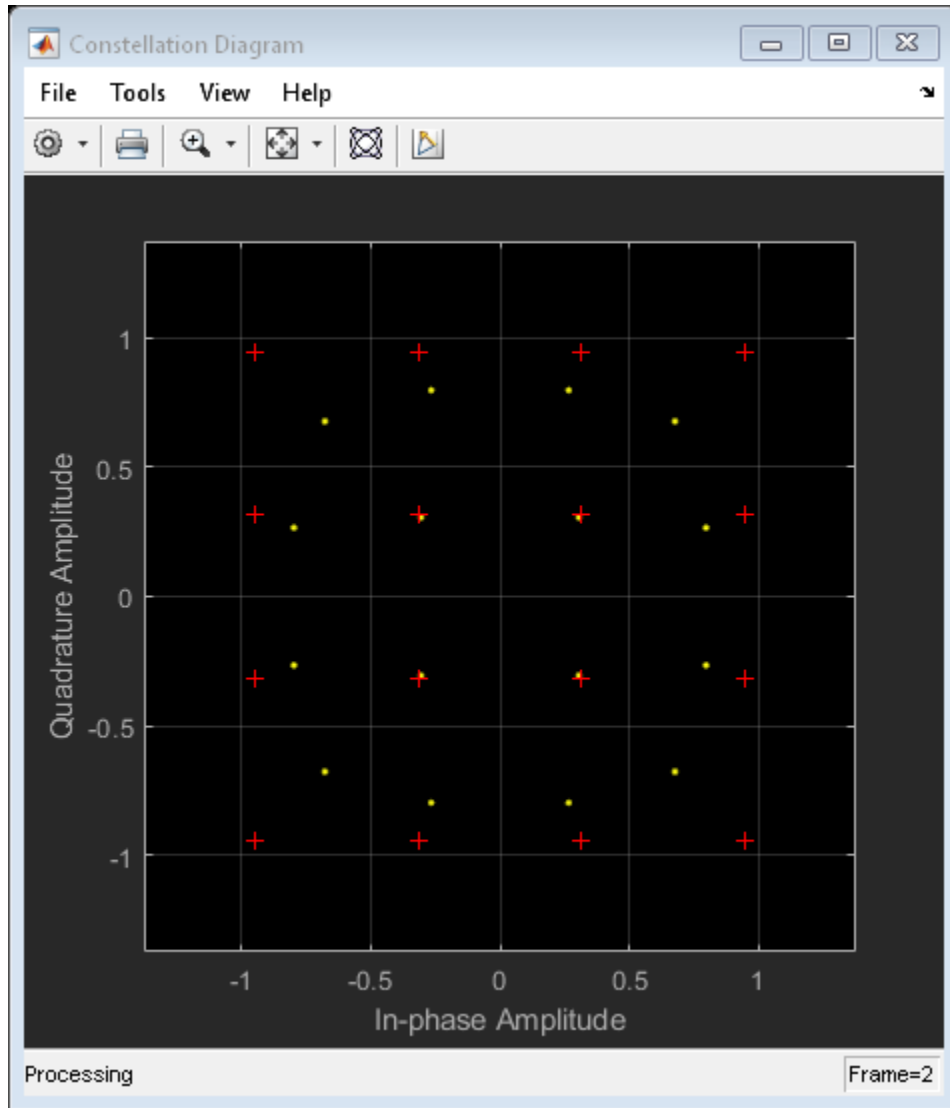

Create an amplifier using the memoryless nonlinearity object.

```
amp = comm.MemorylessNonlinearity('IIP3',38,'AMPMConversion',0);
```

Pass the modulated signal through the nonlinear amplifier, and plot its constellation diagram.

```
txSig = amp(modSig);  
constDiagram(txSig)
```

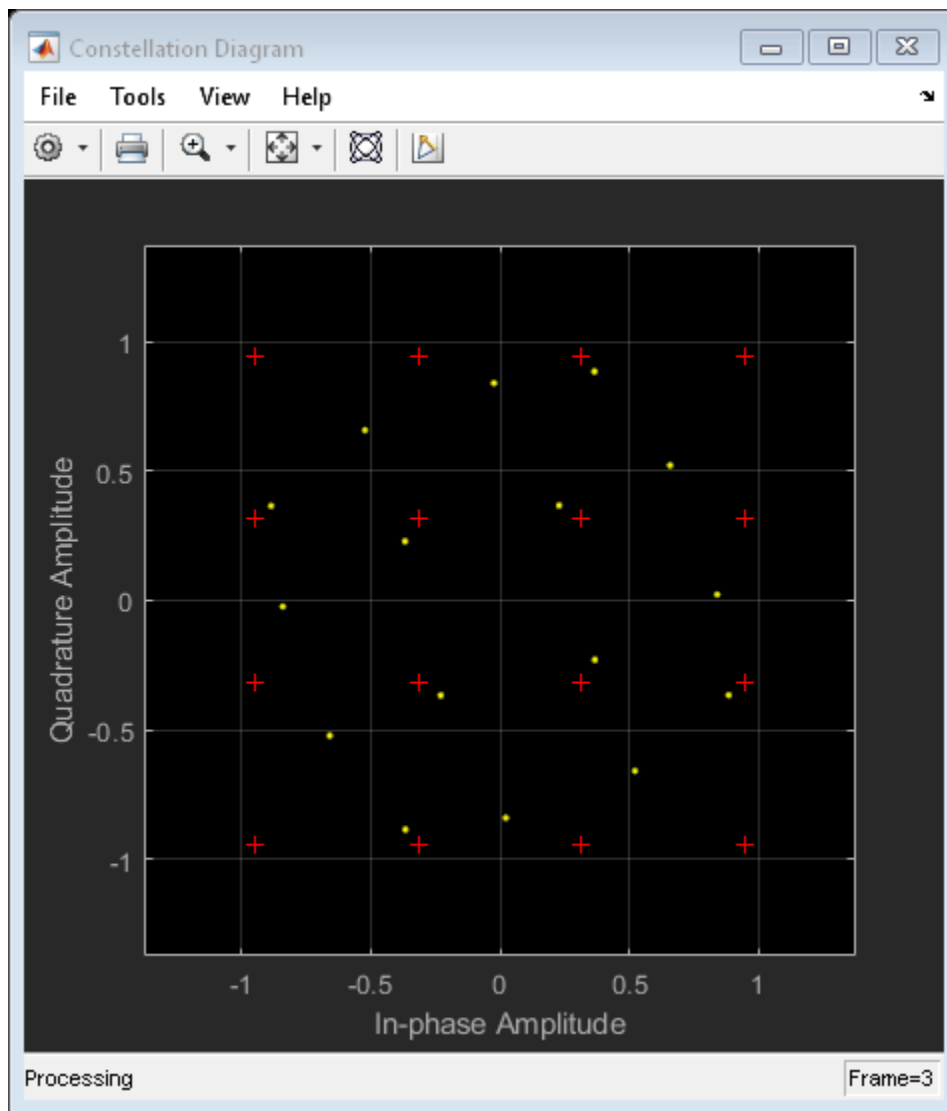

The corner points of the constellation have moved toward the origin due to amplifier gain compression.

Introduce a small AM/PM conversion, and display the received signal constellation.

```
amp.AMPMConversion = 1;  
txSig = amp(modSig);  
constDiagram(txSig)
```

The constellation has rotated due to the AM/PM conversion. To compute the time-varying EVM, release the EVM object and set the `AveragingDimensions` property to 2. To estimate the EVM against an input signal, omit the `ReferenceSignalSource` property definition. This method produces more accurate results.

```
evm = comm.EVM('AveragingDimensions',2);  
evmTime = evm(modSig,txSig);
```

Plot the time-varying EVM of the distorted signal.

```
timeScope(evmTime)
```

Compute the RMS EVM.

```
evmRMS = sqrt(mean(evmTime.^2))
```

```
evmRMS =
```

35.5919

Compute the MER.

```
mer = comm.MER;
snrEst = mer(modSig,txSig)
```

```
snrEst =
```

8.1392

The SNR ( $\approx 8$  dB) is reduced from its initial value ( $\infty$ ) due to amplifier distortion.

Specify input power levels ranging from 0 to 40 dBm. Convert those levels to their linear equivalent in W. Initialize the output power vector.

```
powerIn = 0:40;
pin = 10.^((powerIn-30)/10);
powerOut = zeros(length(powerIn),1);
```

Measure the amplifier output power for the range of input power levels.

```
for k = 1:length(powerIn)
    data = randi([0 15],1000,1);
    txSig = qammod(data,16,'UnitAveragePower',true)*sqrt(pin(k));
    ampSig = amp(txSig);
    powerOut(k) = 10*log10(var(ampSig))+30;
end
```

Plot the power output versus power input curve.

```
figure
plot(powerIn,powerOut,powerIn,powerIn,'--')
legend('Amplifier Output','Ideal Output','location','se')
xlabel('Power In (dBm)')
ylabel('Power Out (dBm)')
grid
```

The output power levels off at 30 dBm. The amplifier exhibits nonlinear behavior for input power levels greater than 25 dBm.

### I/Q Imbalance

Apply an amplitude and phase imbalance to the modulated signal.

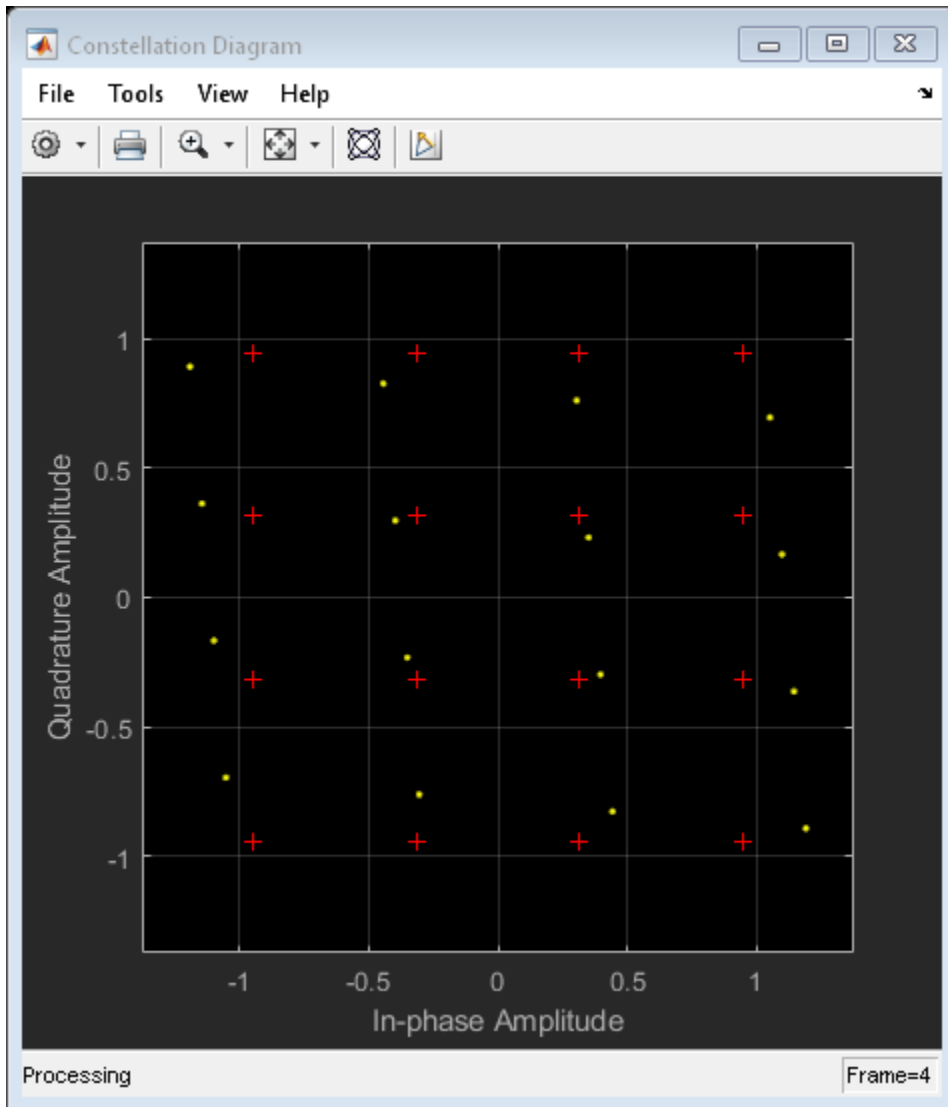

```

ampImb = 3;
phImb = 10;
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(modSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(modSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;

```

Plot the received constellation.

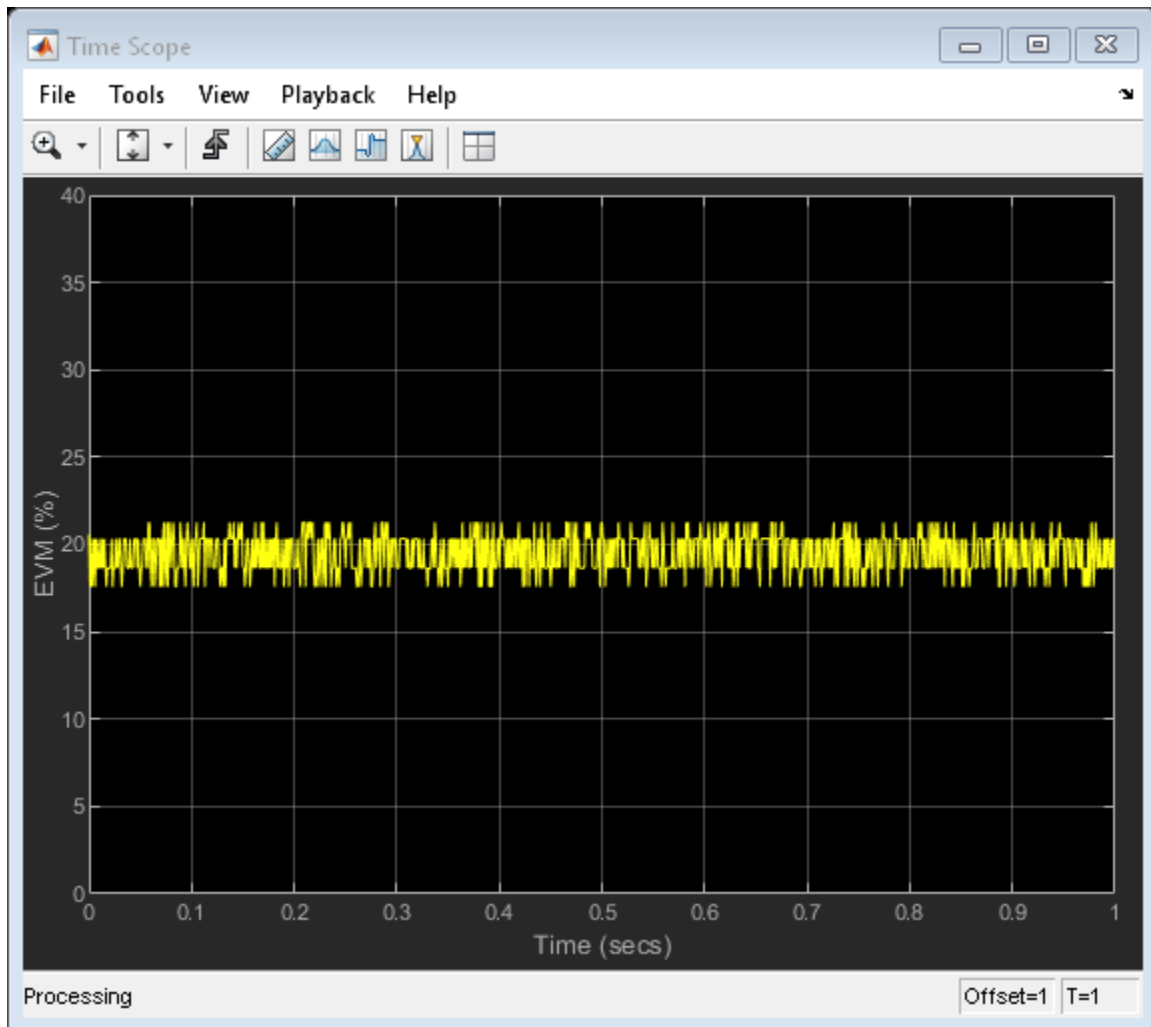

```
constDiagram(rxSig)
```

The magnitude and phase of the constellation has changed as a result of the I/Q imbalance.

Calculate and plot the time-varying EVM.

```
evmTime = evm(modSig,rxSig);  
timeScope(evmTime)
```

The EVM exhibits a behavior that is similar to that experienced with a nonlinear amplifier though the variance is smaller.

Create a 100 Hz sine wave having a 1000 Hz sample rate.

```
sinewave = dsp.SinWave('Frequency',100,'SampleRate',1000, ...  
    'SamplesPerFrame',1e4,'ComplexOutput',true);
```

```
x = sinewave();
```

Apply the same 3 dB and 10 degree I/Q imbalance.

```
ampImb = 3;  
phImb = 10;  
gainI = 10.^(0.5*ampImb/20);  
gainQ = 10.^(-0.5*ampImb/20);  
imbI = real(x)*gainI*exp(-0.5i*phImb*pi/180);  
imbQ = imag(x)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));  
y = imbI + imbQ;
```

Plot the spectrum of the imbalanced signal.

```
spectrum = dsp.SpectrumAnalyzer('SampleRate',1000,'PowerUnits','dBW');
```

```
spectrum(y)
```

The I/Q imbalance introduces a second tone at -100 Hz, which is the inverse of the input tone.

### Phase Noise

Apply phase noise to the transmitted signal. Plot the resulting constellation diagram.

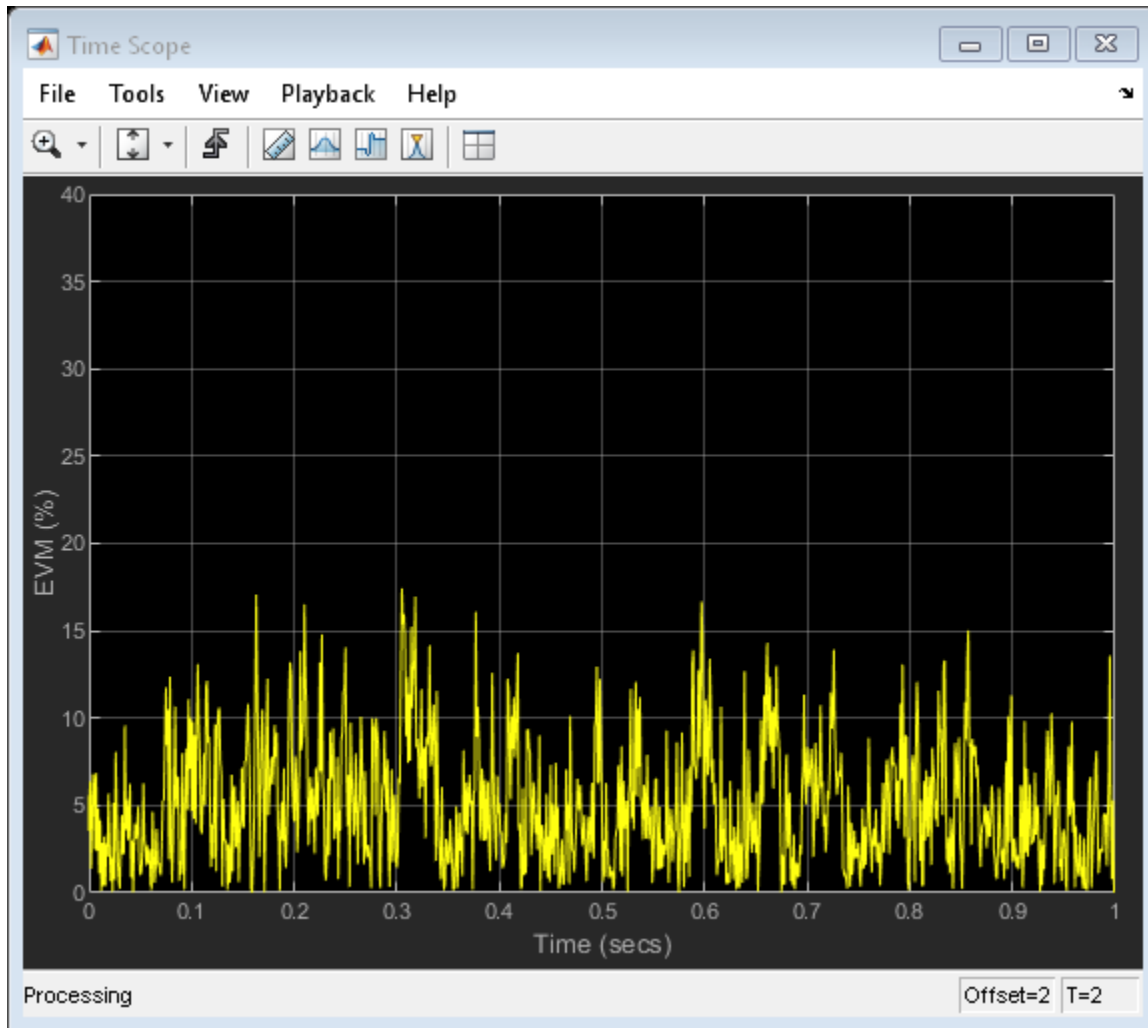

```
pnoise = comm.PhaseNoise('Level',-50,'FrequencyOffset',20,'SampleRate',fs);  
pnoiseSig = pnoise(modSig);  
constDiagram(pnoiseSig)
```

The phase noise introduces a rotational jitter.

Compute and plot the EVM of the received signal.

```
evmTime = evm(modSig,pnoiseSig);  
timeScope(evmTime)
```

Determine the RMS EVM.

```
evmRMS = sqrt(mean(evmTime.^2))
```

```
evmRMS =
    6.1989
```

## Filter Effects

Specify the samples per symbol parameter. Create a pair of raised cosine matched filters.

```
sps = 4;
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.2,'FilterSpanInSymbols',8,
    'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));

rxfilter = comm.RaisedCosineReceiveFilter('RolloffFactor',0.2,'FilterSpanInSymbols',8,
    'InputSamplesPerSymbol',sps,'Gain',1/sqrt(sps), ...
    'DecimationFactor',sps);
```

Determine the delay through the matched filters.

```
fltDelay = 0.5*(txfilter.FilterSpanInSymbols + rxfilter.FilterSpanInSymbols);
```

Pass the modulated signal through the matched filters.

```
filtSig = txfilter(modSig);
rxSig = rxfilter(filtSig);
```

To account for the delay through the filters, discard the first fltDelay samples.

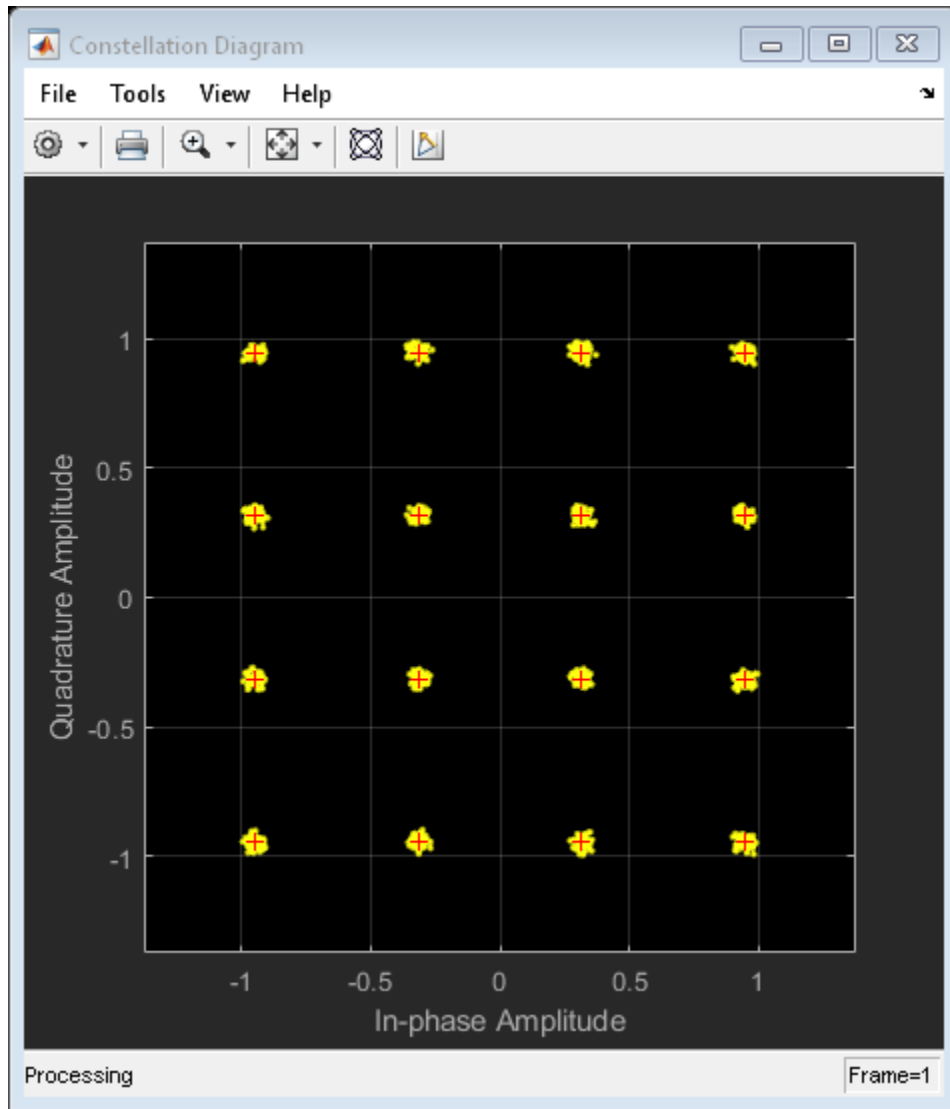

```
rxSig = rxSig(fltDelay+1:end);
```

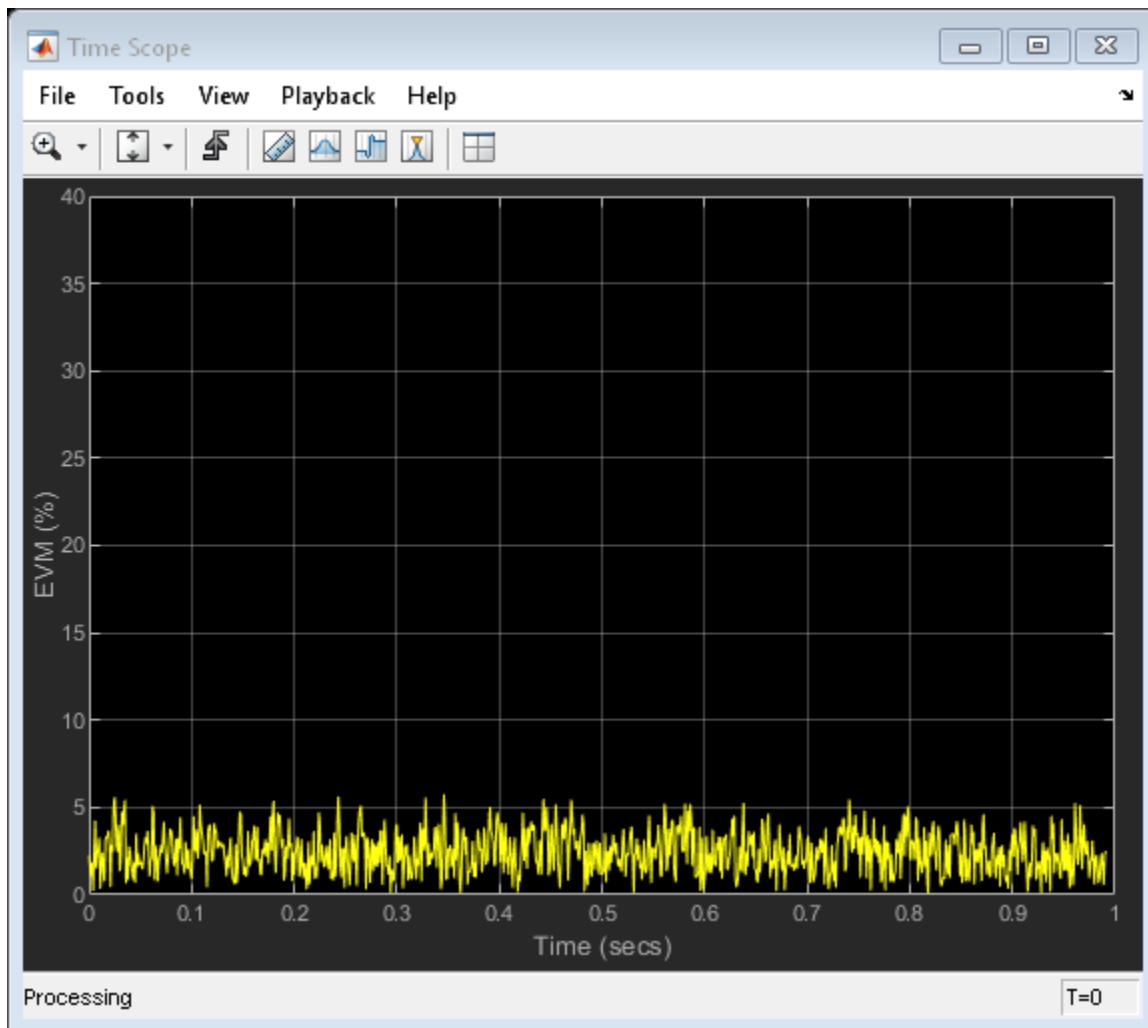

To accommodate the change in the number of received signal samples, create new constellation diagram and time scope objects.

```
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);
timeScope = dsp.TimeScope('YLimits',[0 40],'SampleRate',fs,'TimeSpan',1, ...
    'ShowGrid',true,'YLabel','EVM (%)');
```

Estimate EVM. Plot the received signal constellation diagram and the time-varying EVM.

```
evm = comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst, ...
    'Normalization','Average constellation power','AveragingDimensions',2);
evmTime = evm(rxSig);
constDiagram(rxSig)
timeScope(evmTime)
```

Determine the RMS EVM.

```
evmRMS = sqrt(mean(evmTime.^2))
```

```
evmRMS =
```

2.7199

Determine the equivalent SNR.

```
mer = comm.MER;  
snrEst = mer(modSig(1:end-fltDelay),rxSig)
```

```
snrEst =  
  
31.4603
```

### Combined Effects

Combine the effects of the filters, nonlinear amplifier, AWGN, and phase noise. Display the constellation and EVM diagrams.

Create EVM, time scope and constellation diagram objects.

```
evm = comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ...  
              'ReferenceConstellation',refConst, ...  
              'Normalization','Average constellation power','AveragingDimensions',2);  
timeScope = dsp.TimeScope('YLimits',[0 40],'SampleRate',fs,'TimeSpan',1, ...  
                           'ShowGrid',true,'YLabel','EVM (%)');  
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);
```

Specify the nonlinear amplifier and phase noise objects.

```
amp = comm.MemorylessNonlinearity('IIP3',45,'AMPMConversion',0);  
pnoise = comm.PhaseNoise('Level',-55,'FrequencyOffset',20,'SampleRate',fs);
```

Filter and then amplify the modulated signal.

```
txfiltOut = txfilter(modSig);  
txSig = amp(txfiltOut);
```

Add phase noise. Pass the impaired signal through the AWGN channel. Plot the constellation diagram.

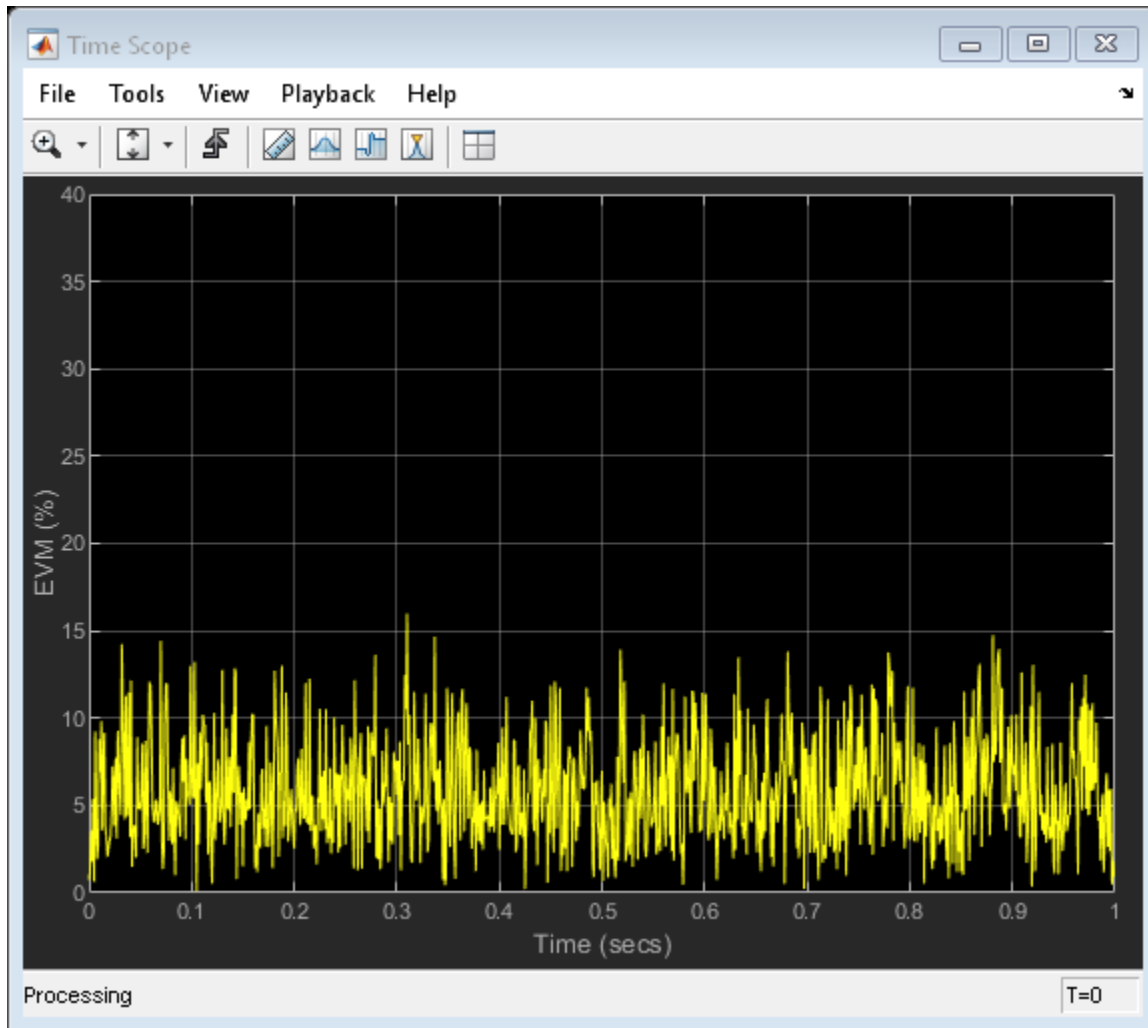

```
rxSig = awgn(txSig,snrdB);  
pnoiseSig = pnoise(rxSig);  
rxfiltOut = rxfilter(pnoiseSig);  
constDiagram(rxfiltOut)
```

Calculate the time-varying EVM. Plot the result.

```
evmTime = evm(rxfiltOut);  
timeScope(evmTime)
```

Determine the RMS EVM.

```
evmRMS = sqrt(mean(evmTime.^2))
```

```
evmRMS =
```

6.6444

Estimate the SNR.

```
mer = comm.MER('ReferenceSignalSource', 'Estimated from reference constellation', ...
    'ReferenceConstellation', refConst);
snrEst = mer(rxfiltOut)
```

snrEst =

23.6978

This value is approximately 6 dB worse than the specified value of 30 dB, which means that the effects of the other impairments are significant and will degrade the bit error rate performance.

## More About

### Use the Channel Visualization Tool

You can use a graphical plotting function that helps you visualize the characteristics of a fading channel. For example, the following code opens the channel visualization tool showing a three-path Rayleigh channel through which a random signal is passed:

```
% Three-Path Rayleigh channel
h = rayleighchan(1/100000, 130, [0 1.5e-5 3.2e-5], [0, -3, -3]);
tx = randi([0 1],500,1);           % Random bit stream
hmod = comm.DBPSKModulator;       % Create DBPSKModulator
dpskSig = step(hmod,tx);          % DPSK signal
h.StoreHistory = true;           % Allow states to be stored
y = filter(h, dpskSig);          % Run signal through channel
plot(h);                          % Call Channel Visualization Tool
```

See “Fading Channels” for a description of fading channels and objects.

# pmdemod

Phase demodulation

## Syntax

```
z = pmdemod(y, Fc, Fs, phasedev)
z = pmdemod(y, Fc, Fs, phasedev, ini_phase)
```

## Description

`z = pmdemod(y, Fc, Fs, phasedev)` demodulates the phase-modulated signal `y` at the carrier frequency `Fc` (hertz). `z` and the carrier signal have sampling rate `Fs` (hertz), where `Fs` must be at least  $2 \cdot Fc$ . The `phasedev` argument is the phase deviation of the modulated signal, in radians.

`z = pmdemod(y, Fc, Fs, phasedev, ini_phase)` specifies the initial phase of the modulated signal, in radians.

## Examples

### Recover Phase Modulated Signal from AWGN Channel

Set the sample rate. To plot the signals, create a time vector.

```
fs = 50;
t = (0:2*fs+1)'/fs;
```

Create a sinusoidal input signal.

```
x = sin(2*pi*t) + sin(4*pi*t);
```

Set the carrier frequency and phase deviation.

```
fc = 10;
phasedev = pi/2;
```

Modulate the input signal.

```
tx = pmmod(x,fc,fs,phasedev);
```

Pass the signal through an AWGN channel.

```
rx = awgn(tx,10,'measured');
```

Demodulate the noisy signal.

```
y = pmdemod(rx,fc,fs,phasedev);
```

Plot the original and recovered signals.

```
figure; plot(t,[x y]);  
legend('Original signal','Recovered signal');  
xlabel('Time (s)')  
ylabel('Amplitude (V)')
```

# pmmmod

Phase modulation

## Syntax

```
y = pmmmod(x, Fc, Fs, phasedev)
y = pmmmod(x, Fc, Fs, phasedev, ini_phase)
```

## Description

`y = pmmmod(x, Fc, Fs, phasedev)` modulates the message signal `x` using phase modulation. The carrier signal has frequency `Fc` (hertz) and sampling rate `Fs` (hertz), where `Fs` must be at least  $2 \cdot Fc$ . The `phasedev` argument is the phase deviation of the modulated signal in radians.

`y = pmmmod(x, Fc, Fs, phasedev, ini_phase)` specifies the initial phase of the modulated signal in radians.

## Examples

### Recover Phase Modulated Signal from AWGN Channel

Set the sample rate. To plot the signals, create a time vector.

```
fs = 50;
t = (0:2*fs+1)'/fs;
```

Create a sinusoidal input signal.

```
x = sin(2*pi*t) + sin(4*pi*t);
```

Set the carrier frequency and phase deviation.

```
fc = 10;
phasedev = pi/2;
```

Modulate the input signal.

```
tx = pmmod(x,fc,fs,phasedev);
```

Pass the signal through an AWGN channel.

```
rx = awgn(tx,10,'measured');
```

Demodulate the noisy signal.

```
y = pmdemod(rx,fc,fs,phasedev);
```

Plot the original and recovered signals.

# poly2trellis

Convert convolutional code polynomials to trellis description

## Syntax

```
trellis = poly2trellis(ConstraintLength,CodeGenerator)
trellis = poly2trellis(ConstraintLength,CodeGenerator,
FeedbackConnection)
```

## Description

`trellis = poly2trellis(ConstraintLength,CodeGenerator)` returns the trellis structure description corresponding to the conversion for a rate  $K / N$  feedforward encoder.  $K$  is the number of input bit streams to the encoder, and  $N$  is the number of output connections. `ConstraintLength` specifies the delay for the input bit streams to the encoder. `CodeGenerator` specifies the output connections for the input bit streams to the encoder.

The `poly2trellis` function accepts a polynomial description of a convolutional encoder and returns the corresponding trellis structure description. This output can be used as an input to the `convenc` and `vitdec` functions. It can also be used as a mask parameter value for the Convolutional Encoder, Viterbi Decoder, and APP Decoder blocks.

---

**Note** When used with a feedback polynomial, `poly2trellis` makes a feedback connection to the input of the trellis.

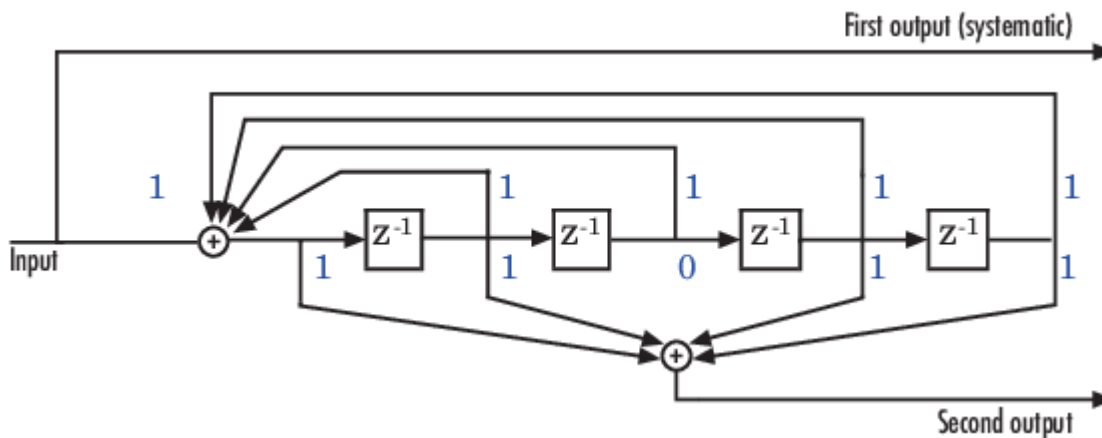

---

`trellis = poly2trellis(ConstraintLength,CodeGenerator, FeedbackConnection)` returns the trellis structure description corresponding to the conversion for a rate  $K / N$  feedback encoder.  $K$  is the number of input bit streams to the encoder, and  $N$  is the number of output connections. `ConstraintLength` specifies the delay for the input bit streams to the encoder. `CodeGenerator` specifies the output connections for the input bit streams to the encoder. `FeedbackConnection` specifies the feedback connection for each of the  $K$  input bit streams to the encoder.

## Examples

### Trellis Structure for 1/2 Feedback Convolutional Encoder

Create a trellis structure for the rate 1/2 systematic convolutional encoder with feedback that is shown. Use the trellis to encode and decode a random bit stream.

This encoder has a constraint length of 5, a generator polynomial matrix of  $[37 \ 33]$ , and a feedback connection polynomial of 37.

The first generator polynomial matches the feedback connection polynomial because the first output corresponds to the systematic bits. The feedback polynomial is represented by the binary vector  $[1 \ 1 \ 1 \ 1 \ 1]$ , corresponding to the upper row of binary digits in the diagram. These digits indicate connections from the outputs of the registers to the adder. The initial 1 corresponds to the input bit. The octal representation of the binary number 11111 is 37.

The second generator polynomial is represented by the binary vector  $[1 \ 1 \ 0 \ 1 \ 1]$ , corresponding to the lower row of binary digits in the diagram. The octal number corresponding to the binary number 11011 is 33.

Use `poly2trellis` to convert the polynomial to a trellis structure. When used with a feedback polynomial, `poly2trellis` makes a feedback connection to the input of the trellis.

```
trellis = poly2trellis(5, [37 33], 37)
```

```
trellis = struct with fields:
    numInputSymbols: 2
    numOutputSymbols: 4
    numStates: 16
    nextStates: [16x2 double]
    outputs: [16x2 double]
```

Generate random binary data, convolutionally encode the data, and decode the data using the Viterbi algorithm.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
decodedData = vitdec(codedData,trellis,34,'trunc','hard');
```

Verify the decoded data has no bit errors.

```
biterr(data,decodedData)
```

```
ans = 0
```

### **Trellis Structure for 2/3 Feedforward Convolutional Encoder**

Create a trellis structure for a rate 2/3 feedforward convolutional code and display a portion of the next states of the trellis. See `convenc` for an example using this encoder.

The diagram shows a rate 2/3 encoder with two input streams, three output streams, and seven shift registers.

Create a trellis structure. Set the constraint length of the upper path to 5 and the constraint length of the lower path to 4. The octal representation of the code generator matrix corresponds to the taps from the upper and lower shift registers.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
```

```
trellis = struct with fields:
    numInputSymbols: 4
    numOutputSymbols: 8
    numStates: 128
    nextStates: [128x4 double]
    outputs: [128x4 double]
```

The structure field `numInputSymbols` equals 4 because two bit streams can produce four different input symbols. The structure field `numOutputSymbols` equals 8 because three bit streams produce eight different output symbols. Because the encoder has seven total shift registers, the number of possible states is  $2^7 = 128$ , as shown by the `nextStates` field.

Display the first five rows of the 128-by-4 `trellis.nextStates` matrix.

```
trellis.nextStates(1:5,:)
```

```
ans = 5x4
      0    64     8    72
      0    64     8    72
      1    65     9    73
      1    65     9    73
      2    66    10    74
```

### Trellis Structure for 1/2 Feedforward Convolutional Encoder

Create a trellis structure for a rate 1/2 feedforward convolutional code. Use the trellis to encode and decode a random bit stream.

Create a trellis structure. Set the constraint length to 7 and specify the code generator as a cell array of polynomial character vectors.

```
trellis = poly2trellis(7,{'1 + x^3 + x^4 + x^5 + x^6', ...
    '1 + x + x^3 + x^4 + x^6'})

trellis = struct with fields:
    numInputSymbols: 2
    numOutputSymbols: 4
    numStates: 64
    nextStates: [64x2 double]
    outputs: [64x2 double]
```

Generate random binary data, convolutionally encode the data, and decode the data using the Viterbi algorithm.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
decodedData = vitdec(codedData,trellis,34,'trunc','hard');
```

Verify the decoded data has no bit errors.

```
biterr(data,decodedData)

ans = 0
```

### Create User Defined Trellis Structure

This example demonstrates creation of a nonstandard trellis structure for a convolutional encoder with uncoded bits and feedback. The encoder cannot be created using `poly2trellis` because the peculiar specifications for the encoder do not match the input requirements of `poly2trellis`.

Even though `poly2trellis` is not used to create the trellis structure, you can manually create the structure, then use that trellis structure as the input trellis structure for an encoder and decoder. The Convolutional Encoder and Viterbi Decoder blocks used in the “Convolutional Encoder with Uncoded Bits and Feedback” model load the trellis structure created here using a `PreLoadFcn` callback.

### Convolutional Encoder

Create a rate 3/4 convolutional encoder with feedback connection whose MSB bit remains uncoded.

Declare variables according to the specifications.

```
k = 3;
n = 4;
constraintLength = 4;
```

### Create trellis structure

A trellis is represented by a structure with the following fields:

- `numInputSymbols` - Number of input symbols
- `numOutputSymbols` - Number of output symbols
- `numStates` - Number of states
- `nextStates` - Next state matrix
- `outputs` - Output matrix

For more information about these structure fields, see `istrellis`.

Reset any previous occurrence of `myTrellis` structure.

```
clear myTrellis;
```

Define the trellis structure fields.

```
myTrellis.numInputSymbols = 2^k;
myTrellis.numOutputSymbols = 2^n;
myTrellis.numStates = 2^(constraintLength-1);
```

### Create nextStates Matrix

The `nextStates` matrix is a [`numStates` x `numInputSymbols`] matrix. The  $(i,j)$  element of the next state matrix is the resulting final state index that corresponds to a transition from the initial state  $i$  for an input equal to  $j$ .

```
myTrellis.nextStates = [0 1 2 3 0 1 2 3; ...
                       6 7 4 5 6 7 4 5; ...
                       1 0 3 2 1 0 3 2; ...
                       7 6 5 4 7 6 5 4; ...
                       2 3 0 1 2 3 0 1; ...
                       4 5 6 7 4 5 6 7; ...
                       3 2 1 0 3 2 1 0; ...
                       5 4 7 6 5 4 7 6]
```

```
myTrellis = struct with fields:
    numInputSymbols: 8
    numOutputSymbols: 16
    numStates: 8
    nextStates: [8x8 double]
```

### Plot nextStates Matrix

Use the `comcnv_plotnextstates` helper function to plot the `nextStates` matrix to illustrate the branch transitions between different states for a given input.

```
comcnv_plotnextstates(myTrellis.nextStates);
```

### Create outputs Matrix

The `outputs` matrix is a `[numStates x numInputSymbols]` matrix. The  $(i,j)$  element of the output matrix is the output symbol in octal format given a current state  $i$  for an input equal to  $j$ .

```
outputs = [0  2  4  6  10 12 14 16; ...
           1  3  5  7  11 13 15 17; ...
```

```

0  2  4  6 10 12 14 16; ...
1  3  5  7 11 13 15 17; ...
0  2  4  6 10 12 14 16; ...
1  3  5  7 11 13 15 17; ...
0  2  4  6 10 12 14 16; ...
1  3  5  7 11 13 15 17]

```

```
outputs = 8x8
```

```

0     2     4     6     10    12    14    16
1     3     5     7     11    13    15    17
0     2     4     6     10    12    14    16
1     3     5     7     11    13    15    17
0     2     4     6     10    12    14    16
1     3     5     7     11    13    15    17
0     2     4     6     10    12    14    16
1     3     5     7     11    13    15    17

```

Use `oct2dec` to display these values in decimal format.

```
outputs_dec = oct2dec(outputs)
```

```
outputs_dec = 8x8
```

```

0     2     4     6     8     10    12    14
1     3     5     7     9     11    13    15
0     2     4     6     8     10    12    14
1     3     5     7     9     11    13    15
0     2     4     6     8     10    12    14
1     3     5     7     9     11    13    15
0     2     4     6     8     10    12    14
1     3     5     7     9     11    13    15

```

Copy `outputs` matrix into the `myTrellis` structure.

```
myTrellis.outputs = outputs
```

```
myTrellis = struct with fields:
  numInputSymbols: 8
  numOutputSymbols: 16
  numStates: 8
  nextStates: [8x8 double]
  outputs: [8x8 double]

```

### Plot outputs Matrix

Use the `comcnv_plotoutputs` helper function to plot the outputs matrix to illustrate the possible output symbols for a given state depending on the input symbol.

```
comcnv_plotoutputs(myTrellis.outputs, myTrellis.numOutputSymbols);
```

### Check Resulting Trellis Structure

```
istrellis(myTrellis)
```

```
ans = logical
      1
```

A return value of 1 confirms the trellis structure is valid.

### Implement Soft-Decision Decoding

Decode with 3-bit soft decisions partitioned so that values near 0 map to 0, and values near 1 map to 7. If your application requires better decoding performance, refine the partition to obtain finer quantization.

The example decodes the code and computes the bit error rate. When comparing the decoded data with the original message, the example must take the decoding delay into account. The continuous operation mode of the Viterbi decoder causes a delay equal to the traceback length, so `msg(1)` corresponds to `decoded(tblen+1)` rather than to `decoded(1)`.

### System Setup

Initialize runtime variables for the message data, trellis, bit error rate computations, and traceback length.

```
stream = RandStream.create('mt19937ar', 'seed', 94384);
prevStream = RandStream.setGlobalStream(stream);
msg = randi([0 1], 4000, 1); % Random data

trellis = poly2trellis(7, [171 133]); % Define trellis

ber = zeros(3, 1); % Store BER values
tblen = 48; % Traceback length
```

Create an AWGN channel System object, a Viterbi decoder System object, and an error rate calculator System object. Account for the receive delay caused by the traceback length of the Viterbi decoder.

```
awgnChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)', 'SNR', 6);
vitDec = comm.ViterbiDecoder(trellis, 'InputFormat', 'Soft', ...
    'SoftInputWordLength', 3, 'TracebackDepth', tblen, 'TerminationMethod', 'Continuous');
errorCalc = comm.ErrorRate('ReceiveDelay', tblen);
```

### Run Coding and Decoding

Convolutionally code the message, pass in through an AWGN filter, quantize the noisy message for soft-decision decoding. Perform Viterbi decoding using the trellis generated using `poly2trellis`.

```
code = convenc(msg,trellis);  
awgnChan.SignalPower = (code'*code)/length(code);  
ncode = awgnChan(code);
```

Use `quantiz` to map the noisy data values to appropriate decision-value integers between 0 and 7. The second argument in `quantiz` is a partition vector that determines which data values map to 0, 1, 2, etc.

```
qcode = quantiz(ncode,[0.001,0.1,0.3,0.5,0.7,0.9,0.999]);  
decoded = vitDec(qcode);
```

Compute bit error rate.

```
ber = errorCalc(msg,decoded);  
ratio = ber(1)
```

```
ratio = 0.0013
```

```
number = ber(2)
```

```
number = 5
```

```
RandStream.setGlobalStream(prevStream);
```

## Input Arguments

### **ConstraintLength** — Constraint length

row vector

Constraint length, specified as a 1-by- $K$  row vector defining the delay for each of the  $K$  input bit streams to the encoder.

Data Types: `double`

### **CodeGenerator** — Code generator

matrix | cell array of character vector | string array

Code generator, specified as a  $K$ -by- $N$  matrix of octal numbers, a  $K$ -by- $N$  cell array of polynomial character vectors, or a  $K$ -by- $N$  string array. `CodeGenerator` specifies the  $N$  output connections for each of the  $K$  input bit streams to the encoder.

For more information, see “Character Representation of Polynomials”.

Data Types: `double` | `char` | `string`

**FeedbackConnection — Feedback connection**

row vector

Feedback connection, specified as a 1-by- $K$  row vector of octal numbers defining the feedback connection for each of the  $K$  input bit streams to the encoder.

Data Types: double

## Output Arguments

**trellis — Trellis description**

structure

Trellis description, returned as a structure with these fields. For more about this structure, see the `istrellis` function.

**Trellis Structure Fields for Rate  $K/N$  Code****numInputSymbols — Number of input symbols**

scalar

Number of input symbols, returned as a scalar with a value of  $2^K$ . This value represents the number of input symbols to the encoder.

**numOutputSymbols — Number of output symbols**

scalar

Number of output symbols, returned as a scalar with a value of  $2^N$ . This value represents the number of output symbols from the encoder.

**numStates — Number of states**

scalar

Number of states in the encoder, returned as a scalar.

**nextStates — Next states**

matrix

Next states for all combinations of current states and current inputs, returned as a  $\text{numStates}$ -by- $2^K$  matrix.

### **outputs — Outputs**

matrix

Outputs for all combinations of current states and current inputs, returned as a numStates-by- $2^K$  matrix. The elements of this matrix are octal numbers.

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Inputs must be constants, of which there can be at most 3 (ConstraintLength, CodeGenerator, FeedbackConnection).

# primpoly

Find primitive polynomials for Galois field

## Syntax

```
pr = primpoly(m)
pr = primpoly(m,opt)
pr = primpoly(m..., 'nodisplay')
```

## Description

`pr = primpoly(m)` returns the primitive polynomial for  $GF(2^m)$ , where  $m$  is an integer between 2 and 16. The Command Window displays the polynomial using "D" as an indeterminate quantity. The output argument `pr` is an integer whose binary representation indicates the coefficients of the polynomial.

`pr = primpoly(m,opt)` returns one or more primitive polynomials for  $GF(2^m)$ . The output `pol` depends on the argument `opt` as shown in the table below. Each element of the output argument `pr` is an integer whose binary representation indicates the coefficients of the corresponding polynomial. If no primitive polynomial satisfies the constraints, `pr` is empty.

<b>opt</b>	<b>Meaning of pr</b>
'min'	One primitive polynomial for $GF(2^m)$ having the smallest possible number of nonzero terms
'max'	One primitive polynomial for $GF(2^m)$ having the greatest possible number of nonzero terms
'all'	All primitive polynomials for $GF(2^m)$
Positive integer k	All primitive polynomials for $GF(2^m)$ that have k nonzero terms

`pr = primpoly(m..., 'nodisplay')` prevents the function from displaying the result as polynomials in "D" in the Command Window. The output argument `pr` is unaffected by the `'nodisplay'` option.

## Examples

The first example below illustrates the formats that `primpoly` uses in the Command Window and in the output argument `pr`. The subsequent examples illustrate the display options and the use of the *opt* argument.

```
pr = primpoly(4)
pr1 = primpoly(5, 'max', 'nodisplay')
pr2 = primpoly(5, 'min')
pr3 = primpoly(5, 2)
pr4 = primpoly(5, 3);
```

The output is below.

```
Primitive polynomial(s) =
```

```
D^4+D^1+1
```

```
pr =
```

```
    19
```

```
pr1 =
```

```
    61
```

```
Primitive polynomial(s) =
```

```
D^5+D^2+1
```

```
pr2 =
```

37

No primitive polynomial satisfies the given constraints.

pr3 =

[]

Primitive polynomial(s) =

$D^5+D^2+1$

$D^5+D^3+1$

## pskdemod

Phase shift keying demodulation

### Syntax

```
z = pskdemod(y,M)
z = pskdemod(y,M,ini_phase)
z = pskdemod(y,M,ini_phase,symorder)
```

### Description

`z = pskdemod(y,M)` demodulates the complex envelope, `y`, of a PSK-modulated signal having modulation order `M`.

`z = pskdemod(y,M,ini_phase)` specifies the initial phase of the PSK-modulated signal.

`z = pskdemod(y,M,ini_phase,symorder)` specifies the symbol order of the PSK-modulated signal.

### Examples

#### Compare Phase Noise Effects on PSK and PAM Signals

Compare PSK and PAM modulation schemes to demonstrate that PSK is more sensitive to phase noise. This is the expected result because the PSK constellation is circular while the PAM constellation is linear.

Specify the number of symbols and the modulation order parameters. Generate random data symbols.

```
len = 10000;
M = 16;
msg = randi([0 M-1],len,1);
```

Modulate msg using both PSK and PAM to compare the two methods.

```
txpsk = pskmod(msg,M);  
txpam = pammod(msg,M);
```

Perturb the phase of the modulated signals by applying a random phase rotation.

```
phasenoise = randn(len,1)*.015;  
rxpsk = txpsk.*exp(2i*pi*phasenoise);  
rxpam = txpam.*exp(2i*pi*phasenoise);
```

Create scatter plots of the received signals.

```
scatterplot(rxpsk);  
title('Noisy PSK Scatter Plot')
```

```
scatterplot(rxpsk);  
title('Noisy PSK Scatter Plot')
```

Demodulate the received signals.

```
recovpsk = pskdemod(rxpsk,M);  
recovpam = pamdemod(rxpsk,M);
```

Compute the number of symbol errors for each modulation scheme. The PSK signal experiences a much greater number of symbol errors.

```
numerrs_psk = symerr(msg,recovpsk);  
numerrs_pam = symerr(msg,recovpam);  
[numerrs_psk numerrs_pam]
```

```
ans = 1x2  
      343      1
```

## Modulate and Demodulate QPSK Signal in AWGN

Generate random symbols.

```
dataIn = randi([0 3],1000,1);
```

QPSK modulate the data.

```
txSig = pskmod(dataIn,4,pi/4);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,10);
```

Demodulate the received signal and compute the number of symbol errors.

```
dataOut = pskdemod(rxSig,4,pi/4);  
numErrs = symerr(dataIn,dataOut)
```

```
numErrs = 2
```

## Input Arguments

### **y** — PSK-modulated input signal

vector | matrix

PSK-modulated input signal, specified as a real or complex vector or matrix. If *y* is a matrix, the function processes the columns independently.

Data Types: `single` | `double`

Complex Number Support: Yes

### **M** — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: double | single

### **ini\_phase — Initial phase**

0 (default) | scalar | []

Initial phase of the PSK modulation, specified in radians as a real scalar.

If `ini_phase` is empty, then `pskdemod` uses an initial phase of 0.

Example: `pi/4`

Data Types: double | single

### **symorder — Symbol order**

'bin' (default) | 'gray'

Symbol order, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is 'bin', the function uses a natural binary-coded ordering.
- If `symorder` is 'gray', the function uses a Gray-coded ordering.

Data Types: char

## Output Arguments

### **z — PSK-demodulated output signal**

vector | matrix

PSK-demodulated output signal, returned as a vector or matrix having the same number of columns as input signal `y`.

Data Types: double | single

## See Also

## **Topics**

“Phase Modulation”

**Introduced before R2006a**

## pskmod

Phase shift keying modulation

### Syntax

```
y = pskmod(x,M)
y = pskmod(x,M,ini_phase)
y = pskmod(x,M,ini_phase,symorder)
```

### Description

`y = pskmod(x,M)` modulates the input signal, `x`, using phase shift keying (PSK) with modulation order `M`.

`y = pskmod(x,M,ini_phase)` specifies the initial phase of the PSK-modulated signal.

`y = pskmod(x,M,ini_phase,symorder)` specifies the symbol order of the PSK-modulated signal.

### Examples

#### Modulate PSK Signal

Modulate and plot the constellations of QPSK and 16-PSK signals.

#### QPSK

Set the modulation order to 4.

```
M = 4;
```

Generate random data symbols.

```
data = randi([0 M-1],1000,1);
```

Modulate the data symbols.

```
txSig = pskmod(data,M,pi/M);
```

Pass the signal through white noise and plot its constellation.

```
rxSig = awgn(txSig,20);  
scatterplot(rxSig)
```

### 16-PSK

Change the modulation order from 4 to 16.

```
M = 16;
```

Generate random data symbols.

```
data = randi([0 M-1],1000,1);
```

Modulate the data symbols.

```
txSig = pskmod(data,M,pi/M);
```

Pass the signal through white noise and plot its constellation.

```
rxSig = awgn(txSig,20);  
scatterplot(rxSig)
```

## Modulate and Demodulate QPSK Signal in AWGN

Generate random symbols.

```
dataIn = randi([0 3],1000,1);
```

QPSK modulate the data.

```
txSig = pskmod(dataIn,4,pi/4);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,10);
```

Demodulate the received signal and compute the number of symbol errors.

```
dataOut = pskdemod(rxSig,4,pi/4);
```

```
numErrs = symerr(dataIn,dataOut)
```

```
numErrs = 2
```

## Input Arguments

### **x** — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. The elements of **x** must have values in the range of  $[0, M - 1]$ .

Example: `randi([0 3],100,1)`

Data Types: `double` | `single`

### **M** — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: `2` | `4` | `16`

Data Types: `double` | `single`

### **ini\_phase** — Initial phase

0 (default) | scalar | []

Initial phase of the PSK modulation, specified in radians as a real scalar.

If you specify `ini_phase` as empty, then `pskmod` uses an initial phase of 0.

Example: `pi/4`

Data Types: `double` | `single`

### **symorder — Symbol order**

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

## Output Arguments

### **y — PSK-modulated output signal**

`vector` | `matrix`

Complex baseband representation of a PSK-modulated signal, returned as vector or matrix. The columns of `y` represent independent channels.

Data Types: `double` | `single`

## See Also

## Topics

“Phase Modulation”

**Introduced before R2006a**

# qamdemod

Quadrature amplitude demodulation

## Syntax

```
z = qamdemod(y,M)
z = qamdemod(y,M,symOrder)
z = qamdemod( ____,Name,Value)
```

## Description

`z = qamdemod(y,M)` returns a demodulated signal, `z`, given quadrature amplitude modulated (QAM) signal `y` of modulation order `M`.

`z = qamdemod(y,M,symOrder)` returns a demodulated signal and specifies the symbol order.

`z = qamdemod( ____,Name,Value)` specifies demodulation behavior using `Name,Value` pairs and any of the previous syntaxes.

## Input Arguments

### **y** — Input signal

scalar | vector | matrix | 3-D array

Input signal resulting from quadrature amplitude modulation, specified as a complex scalar, vector, matrix, or 3-D array. Each column is treated as an independent channel.

Data Types: `double` | `single` | `fi`

### **M** — Modulation order

scalar integer

Modulation order, specified as a power-of-two scalar integer. The modulation order specifies the number of points in the signal constellation.

Example: 16

Data Types: double

### **symOrder** — Symbol order

'gray' (default) | 'bin' | vector

Symbol order, specified as 'gray', 'bin', or a vector.

- 'gray' — Use “Gray Code” on page 2-992 ordering
- 'bin' — Use natural binary-coded ordering
- Vector — Use custom symbol ordering

Vectors must use unique elements whose values range from 0 to  $M - 1$ . The first element corresponds to the upper-left point of the constellation, with subsequent elements running down column-wise from left to right.

Example: [0 3 1 2]

Data Types: char | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **UnitAveragePower** — Unit average power flag

false (default) | true

Unit average power flag, specified as the comma-separated pair consisting of `UnitAveragePower` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation so that the QAM constellation points are separated by a minimum distance of 2.

Data Types: logical

### **OutputType** — Output type

'integer' (default) | 'bit' | 'llr' | 'approxllr'

Output type, specified as the comma-separated pair consisting of `OutputType` and one of the following: 'integer', 'bit', 'llr', or 'approxllr'.

Data Types: char

### NoiseVariance — Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of elements in the last dimension of the input signal. Each element of the vector specifies noise variance for all the elements of the input along the corresponding last dimension.

---

**Tip** When `OutputType` = 'llr', if the demodulation computation outputs `Inf` or `-Inf` values, it is likely because the specified noise variance values are significantly smaller than the SNR. Since the LLR algorithm computes exponentials using finite precision arithmetic, computation of exponentials with very large or very small numbers can yield positive or negative infinity.

Try using `OutputType` = 'approxllr' instead, because the approximate LLR algorithm does not compute exponentials.

---

### Dependencies

This input argument applies only when 'OutputType' is set to 'llr' or 'approxllr'.

Data Types: double

### PlotConstellation — Option to plot constellation

false (default) | true

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the QAM constellation, set `PlotConstellation` to true.

Data Types: logical

## Output Arguments

### **z** — Demodulated output signal

scalar | vector | matrix | 3-D array

Demodulated output signal, returned as a scalar, vector, matrix, or 3-D array. The data type is the same as that of the input signal, *y*. The dimensions of the output vary depending on the specified `OutputType` value.

'OutputType'	Return Value of <code>qamdmod</code>	Dimensions of Output
'integer'	Demodulated integer values from 0 to $M - 1$	<i>z</i> has the same dimensions as input <i>y</i> .
'bit'	Demodulated bits	The number of rows in <i>z</i> is $\log_2(M)$ times the number of rows in <i>y</i> . Each demodulated symbol is mapped to a group of $\log_2(M)$ bits, where the first bit represents the MSB and the last bit represents the LSB.
'llr'	Log-likelihood ratio value for each bit	
'approxllr'	Approximate log-likelihood ratio value for each bit	

## Examples

### Demodulate 8-QAM Signal

Demodulate an 8-QAM signal and plot the points corresponding to symbols 0 and 3.

Generate random 8-ary data symbols.

```
data = randi([0 7],1000,1);
```

Apply 8-QAM.

```
txSig = qammod(data,8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,18,'measured');
```

Demodulate the received signal using an initial phase of  $\pi/8$ .

```
rxData = qamdemod(rxSig.*exp(-1i*pi/8),8);
```

Generate the reference constellation points.

```
refpts = qammod((0:7)',8) .* exp(1i*pi/8);
```

Plot the received signal points corresponding to symbols 0 and 3 and overlay the reference constellation. Only the received data corresponding to those symbols is displayed.

```
plot(rxSig(rxData==0), 'g. ');  
hold on  
plot(rxSig(rxData==3), 'c. ');  
plot(refpts, 'r*')  
text(real(refpts)+0.1, imag(refpts), num2str((0:7)'))  
xlabel('In-Phase')  
ylabel('Quadrature')  
legend('Points corresponding to 0', 'Points corresponding to 3', ...  
       'Reference constellation', 'location', 'nw');
```

### QAM Demodulation with WLAN Symbol Mapping

Modulate and demodulate random data by using 16-QAM with WLAN symbol mapping. Verify that the input data symbols match the demodulated symbols.

Generate a 3-D array of random symbols.

```
x = randi([0,15],20,4,2);
```

Create a custom symbol mapping for the 16-QAM constellation based on WLAN standards.

```
wlanSymMap = [2 3 1 0 6 7 5 4 14 15 13 12 10 11 9 8];
```

Modulate the data, and set the constellation to have unit average signal power. Plot the constellation.

```
y = qammod(x,16,wlanSymMap,'UnitAveragePower', true,'PlotConstellation',true);
```

Demodulate the received signal.

```
z = qamdemod(y,16,wlanSymMap,'UnitAveragePower', true);
```

Verify that the demodulated signal is equal to the original data.

```
isequal(x,z)
```

```
ans = logical  
    1
```

### Demodulate QAM Fixed-Point Signal

Demodulate a fixed-point QAM signal and verify that the data is recovered correctly.

Set the modulation order, and determine the number of bits per symbol.

```
M = 64;  
bitsPerSym = log2(M);
```

Generate random bits. When operating in bit mode, the length of the input data must be an integer multiple of the number of bits per symbol.

```
x = randi([0 1],10*bitsPerSym,1);
```

Modulate the input data using a binary symbol mapping. Set the modulator to output fixed-point data. The numeric data type is signed with a 16-bit word length and a 10-bit fraction length.

```
y = qammod(x,M,'bin','InputType','bit','OutputDataType',...  
    numericity(1,16,10));
```

Demodulate the 64-QAM signal. Verify that the demodulated data matches the input data.

```
z = qamdemod(y,M,'bin','OutputType','bit');  
s = isequal(x,double(z))
```

```
s = logical  
    1
```

### Estimate BER for Hard and Soft Decision Viterbi Decoding

Estimate bit error rate (BER) performance for hard-decision and soft-decision Viterbi decoders in AWGN. Compare the performance to that of an uncoded 64-QAM link.

Set the simulation parameters.

```

clear; close all
rng default
M = 64;           % Modulation order
k = log2(M);     % Bits per symbol
EbNoVec = (4:10)'; % Eb/No values (dB)
numSymPerFrame = 1000; % Number of QAM symbols per frame

```

Initialize the BER results vectors.

```

berEstSoft = zeros(size(EbNoVec));
berEstHard = zeros(size(EbNoVec));

```

Set the trellis structure and traceback length for a rate 1/2, constraint length 7, convolutional code.

```

trellis = poly2trellis(7,[171 133]);
tbl = 32;
rate = 1/2;

```

The main processing loops performs these steps:

- Generate binary data.
- Convolutionally encode the data.
- Apply QAM modulation to the data symbols. Specify unit average power for the transmitted signal.
- Pass the modulated signal through an AWGN channel.
- Demodulate the received signal using hard decision and approximate LLR methods. Specify unit average power for the received signal.
- Viterbi decode the signals using hard and unquantized methods.
- Calculate the number of bit errors.

The while loop continues to process data until either 100 errors are encountered or  $1e7$  bits are transmitted.

```

for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
    snrdB = EbNoVec(n) + 10*log10(k*rate);
    % Noise variance calculation for unity average signal power.
    noiseVar = 10.^(-snrdB/10);
    % Reset the error and bit counters
    [numErrsSoft,numErrsHard,numBits] = deal(0);

```

```
while numErrsSoft < 100 && numBits < 1e7
    % Generate binary data and convert to symbols
    dataIn = randi([0 1],numSymPerFrame*k,1);

    % Convolutionally encode the data
    dataEnc = convenc(dataIn,trellis);

    % QAM modulate
    txSig = qammod(dataEnc,M,'InputType','bit','UnitAveragePower',true);

    % Pass through AWGN channel
    rxSig = awgn(txSig,snrdB,'measured');

    % Demodulate the noisy signal using hard decision (bit) and
    % soft decision (approximate LLR) approaches.
    rxDataHard = qamdemod(rxSig,M,'OutputType','bit','UnitAveragePower',true);
    rxDataSoft = qamdemod(rxSig,M,'OutputType','approxllr', ...
        'UnitAveragePower',true,'NoiseVariance',noiseVar);

    % Viterbi decode the demodulated data
    dataHard = vitdec(rxDataHard,trellis,tbl,'cont','hard');
    dataSoft = vitdec(rxDataSoft,trellis,tbl,'cont','unquant');

    % Calculate the number of bit errors in the frame. Adjust for the
    % decoding delay, which is equal to the traceback depth.
    numErrsInFrameHard = biterr(dataIn(1:end-tbl),dataHard(tbl+1:end));
    numErrsInFrameSoft = biterr(dataIn(1:end-tbl),dataSoft(tbl+1:end));

    % Increment the error and bit counters
    numErrsHard = numErrsHard + numErrsInFrameHard;
    numErrsSoft = numErrsSoft + numErrsInFrameSoft;
    numBits = numBits + numSymPerFrame*k;

end

% Estimate the BER for both methods
berEstSoft(n) = numErrsSoft/numBits;
berEstHard(n) = numErrsHard/numBits;
end

Plot the estimated hard and soft BER data. Plot the theoretical performance for an
uncoded 64-QAM channel.

semilogy(EbNoVec,[berEstSoft berEstHard],'-*')
hold on
```

```

semilogy(EbNoVec,berawgn(EbNoVec,'qam',M))
legend('Soft','Hard','Uncoded','location','best')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')

```

As expected, the soft decision decoding produces the best results.

### Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Create an OQPSK modulated signal and add noise to the signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);

impairedSig = awgn(oqpskSig,15);
```

### Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align I and Q. Apply matched filtering to the received OQPSK signal.

```
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end)));

halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps, halfSinePulse, 'DecimationOffset', sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping,'OutputType','llr');
```

## More About

### Gray Code

A Gray code, also known as a reflected binary code, is a system where the bit patterns in adjacent constellation points differ by only one bit.

## Compatibility Considerations

### Initial Phase Input Removed

*Errors starting in R2018b*

Starting in R2018b, you can no longer offset the initial phase for the QAM constellation using the `qamdemod` function.

Instead use `genqamdemod` to offset the initial phase of the QAM data being demodulated or you can multiply the modulated input to `qamdemod` by the desired initial phase:

```
z = qamdemod(y .* exp(-1i*initPhase,M))
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

# qammod

Quadrature amplitude modulation

## Syntax

```
y = qammod(x,M)
y = qammod(x,M,symOrder)
y = qammod( ____,Name,Value)
```

## Description

`y = qammod(x,M)` returns a baseband quadrature amplitude modulated (QAM) signal given input signal `x` and modulation order `M`.

`y = qammod(x,M,symOrder)` returns a modulated signal and specifies the symbol order.

`y = qammod( ____,Name,Value)` specifies modulation behavior using `Name,Value` pairs and any of the previous syntaxes.

## Input Arguments

### **x** — Input signal

scalar | vector | matrix | 3-D array

Input signal, specified as a scalar, vector, matrix, or 3-D array. The elements of `x` must be binary values or integers that range from 0 to  $(M - 1)$ , where `M` is the modulation order.

---

**Note** To process input signal as binary elements, set the 'InputType' name-value pair to 'bit'. For binary inputs, the number of rows must be an integer multiple of  $\log_2(M)$ . Groups of  $\log_2(M)$  bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

---

Data Types: `double` | `single` | `fi` | `int8` | `int16` | `uint8` | `uint16`

### **M — Modulation order**

scalar integer

Modulation order, specified as a power-of-two scalar integer. The modulation order specifies the number of points in the signal constellation.

Example: 16

Data Types: `double`

### **symOrder — Symbol order**

'gray' (default) | 'bin' | vector

Symbol order, specified as 'gray', 'bin', or a vector.

- 'gray' — Use “Gray Code” on page 2-1006 ordering
- 'bin' — Use natural binary-coded ordering
- Vector — Use custom symbol ordering

Vectors must use unique elements whose values range from 0 to  $M - 1$ . The first element corresponds to the upper-left point of the constellation, with subsequent elements running down column-wise from left to right.

Example: [0 3 1 2]

Data Types: `char` | `double`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **InputType — Input type**

'integer' (default) | 'bit'

Input type, specified as the comma-separated pair consisting of 'InputType' and either 'integer' or 'bit'. If you specify 'integer', the input signal must consist of integers from 0 to  $M - 1$ . If you specify 'bit', the input signal must contain binary values, and the number of rows must be an integer multiple of  $\log_2(M)$ .

Data Types: `char`

### **UnitAveragePower — Unit average power flag**

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `UnitAveragePower` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation so that the QAM constellation points are separated by a minimum distance of 2.

Data Types: `logical`

### **OutputDataType — Output data type**

numeric type object

Output data type, specified as the comma-separated pair consisting of `'OutputDataType'` and a numeric type object. See `numeric type` for more information on constructing these objects. If `OutputDataType` is omitted, the output data type is `double` for `double` or built-in integer inputs, and `single` for `single` inputs.

### **PlotConstellation — Option to plot constellation**

`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the QAM constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

## **Output Arguments**

### **y — Modulated signal**

`scalar` | `vector` | `matrix` | 3-D array

Modulated signal, returned as a complex scalar, vector, matrix, or 3-D array. For integer inputs, output `y` has the same dimensions as input signal `x`. For bit inputs, the number of rows in `y` is the number of rows in `x` divided by  $\log_2(M)$ .

Data Types: `double` | `single`

## Examples

### Modulate Data Using QAM

Modulate data using QAM and display the result in a scatter plot.

Set the modulation order to 16 and create a data vector containing each of the possible symbols.

```
M = 16;  
x = (0:M-1)';
```

Modulate the data using the `qammod` function.

```
y = qammod(x,M);
```

Display the modulated signal constellation using the `scatterplot` function.

```
scatterplot(y)
```

Set the modulation order to 256, and display the scatter plot of the modulated signal.

```
M = 256;  
x = (0:M-1)';  
y = qammod(x,M);  
scatterplot(y)
```

### Normalize QAM Signal by Average Power

Modulate random data symbols using QAM. Normalize the modulator output so that it has an average signal power of 1 W.

Set the modulation order and generate random data.

```
M = 64;  
x = randi([0 M-1],1000,1);
```

Modulate the data. Use the 'UnitAveragePower' name-value pair to set the output signal to have an average power of 1 W.

```
y = qammod(x,M, 'UnitAveragePower',true);
```

Confirm that the signal has unit average power.

```
avgPower = mean(abs(y).^2)
```

```
avgPower = 1.0070
```

Plot the resulting constellation.

```
scatterplot(y)  
title('64-QAM, Average Power = 1 W')
```

## QAM Symbol Ordering

Plot QAM constellations for Gray, binary, and custom symbol mappings.

Set the modulation order, and create a random data sequence.

```
M = 16;  
d = randi([0 M-1],1000,1);
```

Modulate the data, and plot its constellation.

```
y = qammod(d,M,'PlotConstellation',true);
```

The default symbol mapping uses Gray ordering. The ordering of the points is not sequential.

Repeat the modulation process with binary symbol mapping.

```
z = qammod(d,M,'bin','PlotConstellation',true);
```

The symbol mapping follows a natural binary order and is sequential.

Create a custom symbol mapping.

```
smap = randperm(16)-1;
```

Modulate and plot the constellation.

```
w = qammod(d,M,smap,'PlotConstellation',true);
```

### Quadrature Amplitude Modulation with Bit Inputs

Modulate a sequence of bits using 64-QAM. Pass the signal through a noisy channel. Display the resultant constellation diagram.

Set the modulation order, and determine the number of bits per symbol.

```
M = 64;
k = log2(M);
```

Create a binary data sequence. When using binary inputs, the number of rows in the input must be an integer multiple of the number of bits per symbol.

```
data = randi([0 1],1000*k,1);
```

Modulate the signal using bit inputs, and set it to have unit average power.

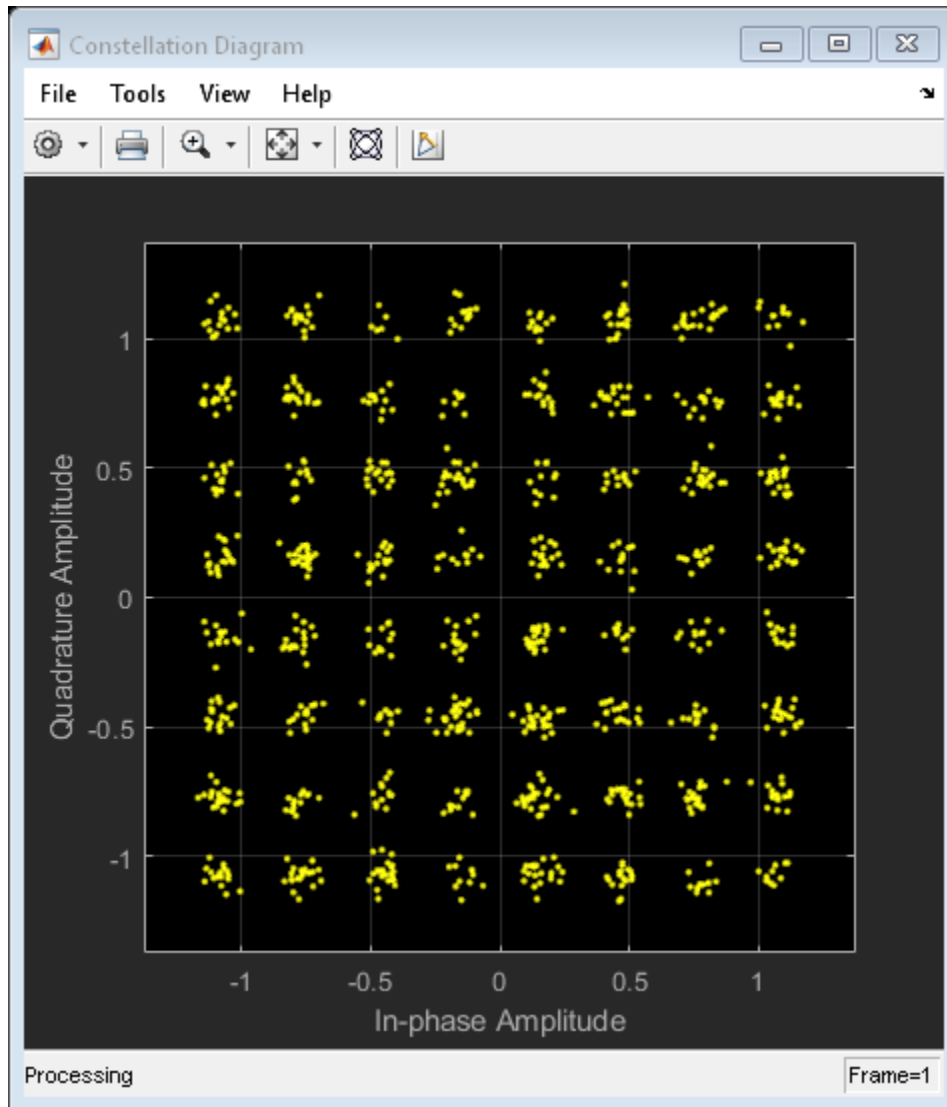

```
txSig = qammod(data,M,'InputType','bit','UnitAveragePower',true);
```

Pass the signal through a noisy channel.

```
rxSig = awgn(txSig,25);
```

Plot the constellation diagram.

```
cd = comm.ConstellationDiagram('ShowReferenceConstellation',false);  
step(cd,rxSig)
```

### Demodulate QAM Fixed-Point Signal

Demodulate a fixed-point QAM signal and verify that the data is recovered correctly.

Set the modulation order, and determine the number of bits per symbol.

```
M = 64;  
bitsPerSym = log2(M);
```

Generate random bits. When operating in bit mode, the length of the input data must be an integer multiple of the number of bits per symbol.

```
x = randi([0 1],10*bitsPerSym,1);
```

Modulate the input data using a binary symbol mapping. Set the modulator to output fixed-point data. The numeric data type is signed with a 16-bit word length and a 10-bit fraction length.

```
y = qammod(x,M,'bin','InputType','bit','OutputDataType',...  
    numericity(1,16,10));
```

Demodulate the 64-QAM signal. Verify that the demodulated data matches the input data.

```
z = qamdemod(y,M,'bin','OutputType','bit');  
s = isequal(x,double(z))
```

```
s = logical  
    1
```

## More About

### Gray Code

A Gray code, also known as a reflected binary code, is a system where the bit patterns in adjacent constellation points differ by only one bit.

## Compatibility Considerations

### Initial Phase Input Removed

*Errors starting in R2018b*

Starting in R2018b, you can no longer offset the initial phase for the QAM constellation using the `qammod` function.

Instead use `genqammod` to offset the initial phase of the data being modulated, or you can multiply the `qammod` output by the desired initial phase:

```
y = qammod(x,M) .* exp(1i*initPhase)
```

to adjust the initial phase of the QAM data.

# qfunc

Q function

## Syntax

`y = qfunc(x)`

## Description

`y = qfunc(x)` returns the output of the Q function for each element of the real array `x`. The Q function is one minus the cumulative distribution function of the standardized normal random variable.

## Input Arguments

### **x** — Input

scalar | vector | matrix | N-D array

Input, specified as a real scalar or array.

## Output Arguments

### **y** — Q function output

scalar | vector | matrix | N-D array

Q function output, returned as a real scalar or array having the same dimensions as input `x`.

## Examples

## Q Function Results and Plot

Determine the values of the Q function for an input vector.

```
x = -4:0.1:4;  
y = qfunc(x);
```

Plot the results.

```
plot(x,y)  
grid
```

### Calculate QPSK Error Probability Using Q Function

Convert an input Eb/No in dB to its linear equivalent.

```
ebnodB = 7;  
ebno = 10^(ebnodB/10);
```

Determine the QPSK error probability,  $P_b$ , given that:

$$P_b = Q\left(\sqrt{2\frac{Eb}{No}}\right).$$

```
Pb = qfunc(sqrt(2*ebno))
```

```
Pb = 7.7267e-04
```

## Algorithms

For a scalar  $x$ , the formula is

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} \exp(-t^2/2) dt$$

The Q function is related to the complementary error function, `erfc`, according to

$$Q(x) = \frac{1}{2} \operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

## See Also

`erf` | `erfc` | `erfcinv` | `erfcx` | `erfinv` | `qfuncinv`

**Introduced before R2006a**

# qfuncinv

Inverse Q function

## Syntax

```
y = qfuncinv(x)
```

## Description

`y = qfuncinv(x)` returns the argument of the Q function at which the Q function's value is `x`. The input `x` must be a real array with elements between 0 and 1, inclusive.

For a scalar `x`, the Q function is one minus the cumulative distribution function of the standardized normal random variable, evaluated at `x`. The Q function is defined as

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} \exp(-t^2/2) dt$$

The Q function is related to the complementary error function, `erfc`, according to

$$Q(x) = \frac{1}{2} \operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

## Examples

The example below illustrates the inverse relationship between `qfunc` and `qfuncinv`.

```
x1 = [0 1 2; 3 4 5];  
y1 = qfuncinv(qfunc(x1)) % Invert qfunc to recover x1.  
x2 = 0:.2:1;  
y2 = qfunc(qfuncinv(x2)) % Invert qfuncinv to recover x2.
```

The output is below.

y1 =

0	1	2
3	4	5

y2 =

0	0.2000	0.4000	0.6000	0.8000	1.0000
---	--------	--------	--------	--------	--------

# quantiz

Produce quantization index and quantized output value

## Syntax

```
index = quantiz(sig,partition)
[index,quants] = quantiz(sig,partition,codebook)
[index,quants,distor] = quantiz(sig,partition,codebook)
```

## Description

`index = quantiz(sig,partition)` returns the quantization levels in the real vector signal `sig` using the parameter `partition`. `partition` is a real vector whose entries are in strictly ascending order. If `partition` has length `n`, `index` is a vector whose `k`th entry is

- 0 if  $\text{sig}(k) \leq \text{partition}(1)$
- `m` if  $\text{partition}(m) < \text{sig}(k) \leq \text{partition}(m+1)$
- `n` if  $\text{partition}(n) < \text{sig}(k)$

`[index,quants] = quantiz(sig,partition,codebook)` is the same as the syntax above, except that `codebook` prescribes a value for each partition in the quantization and `quants` contains the quantization of `sig` based on the quantization levels and prescribed values. `codebook` is a vector whose length exceeds the length of `partition` by one. `quants` is a row vector whose length is the same as the length of `sig`. `quants` is related to `codebook` and `index` by

```
quants(ii) = codebook(index(ii)+1);
```

where `ii` is an integer between 1 and `length(sig)`.

`[index,quants,distor] = quantiz(sig,partition,codebook)` is the same as the syntax above, except that `distor` estimates the mean square distortion of this quantization data set.

### Examples

The command below rounds several numbers between 1 and 100 up to the nearest multiple of 10. `quants` contains the rounded numbers, and `index` tells which quantization level each number is in.

```
[index,quants] = quantiz([3 34 84 40 23],10:10:90,10:10:100)
```

The output is below.

```
index =
```

```
    0    3    8    3    2
```

```
quants =
```

```
    10    40    90    40    30
```

## randdeintrlv

Restore ordering of symbols using random permutation

### Syntax

```
deintrlvd = randdeintrlv(data,state)
```

### Description

`deintrlvd = randdeintrlv(data,state)` restores the original ordering of the elements in `data` by inverting a random permutation. The `state` parameter initializes the random number generator that the function uses to determine the permutation. `state` is either a scalar or a 35x1 vector, and is described in the `rand` function, which is used in `randintrlv`. The function is predictable for a given state, but different states produce different permutations. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

To use this function as an inverse of the `randintrlv` function, use the same `state` input in both functions. In that case, the two functions are inverses in the sense that applying `randintrlv` followed by `randdeintrlv` leaves `data` unchanged.

This function uses, by default, the Mersenne Twister algorithm by Nishimura and Matsumoto.

---

**Note** Using the `state` parameter causes this function to switch random generators to use the 'state' algorithm of the `rand` function.

See `rand` for details on the generator algorithm.

---

### Examples

For an example using random interleaving and deinterleaving, see “Improve Error Rate Using Block Interleaving in MATLAB”.

# randerr

Generate bit error patterns

## Syntax

```
out = randerr(m)
out = randerr(m,n)
out = randerr(m,n,errors)
out = randerr(m,n,errors,seed)
out = randerr(m,n,errors,streamhandle)
```

## Description

For all syntaxes, `randerr` treats each row of `out` independently.

`out = randerr(m)` generates an  $m$ -by- $m$  binary matrix, where each row has exactly one nonzero entry in a random position. Each allowable configuration has an equal probability.

`out = randerr(m,n)` generates an  $m$ -by- $n$  binary matrix, where each row has exactly one nonzero entry in a random position. Each allowable configuration has an equal probability.

`out = randerr(m,n,errors)` uses the `errors` input to determine the number of nonzero entries in each row of the output  $m$ -by- $n$  binary matrix.

- If `errors` is a scalar, it is the number of nonzero entries in each row.
- If `errors` is a row vector, it lists the possible number of nonzero entries in each row.
- If `errors` is a matrix having two rows, the first row lists the possible number of nonzero entries in each row and the second row lists the probabilities that correspond to the possible error counts. The elements in the second row of `errors` must sum to one.

Once `randerr` determines the number of nonzero entries in a given row, each configuration of that number of nonzero entries has equal probability.

`out = randerr(m,n,errors,seed)` accepts a seed value for initializing the uniform random number generator `rand`.

`out = randerr(m,n,errors,streamhandle)` accepts a random stream handle to generate uniform random noise samples by using `rand`. Providing a random stream handle or using the `reset` function on the default random stream object enables you to generate repeatable noise samples. If you want to generate repeatable noise samples, then either reset the random stream input before calling `randerr` or use the same seed input. For more information, see `RandStream`.

## Examples

### Generate Random Error Matrix

Generate an 8-by-7 binary matrix in which each row is equally likely to have either zero or two nonzero elements.

```
out = randerr(8,7,[0 2])
```

```
out = 8×7
```

```
0    1    0    0    0    1    0
0    1    0    0    0    1    0
0    0    0    0    0    0    0
0    0    0    0    0    1    1
0    0    0    0    0    0    0
0    0    0    0    0    0    0
0    0    1    0    0    0    1
0    0    1    0    1    0    0
```

Now generate a matrix in which it is three times more likely that a row will have two nonzero elements.

```
out = randerr(8,7,[0 2; 0.25 0.75])
```

```
out = 8×7
```

```
0    0    0    0    1    0    1
0    1    0    0    0    0    1
0    0    1    0    0    1    0
```

0	1	0	0	1	0	0
1	0	0	0	1	0	0
0	0	0	0	0	0	0
0	0	0	0	0	0	0
0	0	0	0	0	0	0

**Introduced before R2006a**

# randintrlv

Reorder symbols using random permutation

## Syntax

```
intrlvd = randintrlv(data,state)
```

## Description

`intrlvd = randintrlv(data,state)` rearranges the elements in `data` using a random permutation. The `state` parameter initializes the random number generator that the function uses to determine the permutation. `state` is either a scalar or a 35x1 vector, and is described in the `rand` function, which is used in `randintrlv`. The function is predictable and invertible for a given state, but different states produce different permutations. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

This function uses, by default, the Mersenne Twister algorithm by Nishimura and Matsumoto.

---

**Note** Using the `state` parameter causes this function to switch random generators to use the 'state' algorithm of the `rand` function.

See `rand` for details on the generator algorithm.

---

## Examples

For an example using random interleaving and deinterleaving, see “Improve Error Rate Using Block Interleaving in MATLAB”.

`rand` | `randdeintrlv`

## **Topics**

“Interleaving”

**Introduced before R2006a**

# randseed

(To be removed) Generate prime numbers for use as random number seeds

## Compatibility

randseed will be removed in a future release. Use `rng(N)` or `rng('shuffle')` instead. For more information, see “Compatibility Considerations” on page 2-1023.

## Syntax

```
out = randseed
out = randseed(state)
out = randseed(state,m)
out = randseed(state,m,n)
out = randseed(state,m,n,rmin)
out = randseed(state,m,n,rmin,rmax)
```

## Description

The `randseed` function produces random prime numbers that work well as seeds for random source blocks or noisy channel blocks in Communications Toolbox software.

---

**Note** The `randseed` function uses a local stream of numbers that is independent from the global stream of numbers in the MATLAB software. Use of this function does not affect the state of the global random number stream.

---

`out = randseed` generates a random prime number between 31 and  $2^{17}-1$ , using the MATLAB function `rand`.

`out = randseed(state)` generates a random prime number after setting the state of `rand` to the positive integer `state`. This syntax produces the same output for a particular value of `state`.

`out = randseed(state,m)` generates a column vector of  $m$  random primes.

`out = randseed(state,m,n)` generates an  $m$ -by- $n$  matrix of random primes.

`out = randseed(state,m,n,rmin)` generates an  $m$ -by- $n$  matrix of random primes between  $rmin$  and  $2^{17}-1$ .

`out = randseed(state,m,n,rmin,rmax)` generates an  $m$ -by- $n$  matrix of random primes between  $rmin$  and  $rmax$ .

## Examples

To generate a two-element sample-based row vector of random bits using the Bernoulli Random Binary Generator block, you can set **Probability of a zero** to `[0.1 0.5]` and set **Initial seed** to `randseed(391,1,2)`.

To generate three streams of random data from three different blocks in a single model, you can define `out = randseed(93,3)` in the MATLAB workspace and then set the three blocks' **Initial seed** parameters to `out(1)`, `out(2)`, and `out(3)`, respectively.

## Compatibility Considerations

### randseed will be removed

*Warns starting in R2019a*

The functionality provided by `randseed` is no longer necessary for controlling random number generation. Instead, use `rng(seed)`, where `seed` specifies a nonnegative integer seed for the random number generator, or use `rng('shuffle')` to seed the random number generator based on the current time.

### See Also

`primes` | `rand` | `rng`

**Introduced before R2006a**

## **randsrc**

Generate random matrix using prescribed alphabet

### **Syntax**

```
out = randsrc
out = randsrc(m)
out = randsrc(m,n)
out = randsrc(m,n,alphabet)
out = randsrc(m,n,[alphabet; prob])
out = randsrc(m,n, ___, seed)
out = randsrc(m,n, ___, streamhandle)
```

### **Description**

`out = randsrc` generates a random scalar that is either `-1` or `1`, with equal probability.

`out = randsrc(m)` generates an `m`-by-`m` random bipolar matrix. Each entry independently takes the value `-1` or `1` with equal probability.

`out = randsrc(m,n)` generates an `m`-by-`n` random bipolar matrix. Each entry independently takes the value `-1` or `1` with equal probability.

`out = randsrc(m,n,alphabet)` generates an `m`-by-`n` matrix, with each entry independently chosen from the entries in the row vector `alphabet`. Each entry in `alphabet` occurs in `out` with equal probability. Duplicate values in `alphabet` are ignored.

`out = randsrc(m,n,[alphabet; prob])` generates an `m`-by-`n` matrix, with each entry independently chosen from the entries in the row vector `alphabet`. Duplicate values in `alphabet` are ignored. The row vector `prob` lists corresponding probabilities, so that the symbol `alphabet(k)` occurs with probability `prob(k)`, where `k` is any integer between one and the number of columns of `alphabet`. The elements of `prob` must add up to `1`.

`out = randsrc(m,n, ___, seed)` accepts input combinations from prior syntaxes and a seed value, for initializing the uniform random number generator, `rand`.

`out = randsrc(m,n, ___, streamhandle)` accepts input combinations from prior syntaxes and a random stream handle to generate uniform random noise samples by using `rand`. Providing a random stream handle or using the `reset` function on the default random stream object enables you to generate repeatable noise samples. If you want to generate repeatable noise samples, then either reset the random stream input before calling `randsrc` or use the same seed input. For more information, see `RandStream`.

## Examples

### Generate Random Matrix from Prescribed Alphabet

Generate a 10-by-10 matrix from the set of `{-3,-1,1,3}`.

```
out = randsrc(10,10,[-3 -1 1 3])
```

```
out = 10×10
```

```
 3   -3   1   1   -1  -1   3   3   -1  -3
 3   3   -3  -3  -1   1  -1  -1   3  -3
-3   3   3   -1   3   1   1   3   1   1
 3   -1   3  -3   3  -3   1  -3   1   3
 1   3   1  -3  -3  -3   3   3   3   3
-3  -3   3   3  -1  -1   3  -1  -1  -3
-1  -1   1   1  -1   3   1  -3   3   1
 1   3  -1  -1   1  -1  -3  -1   3  -1
 3   3   1   3   1   1  -3   1  -1  -3
 3   3  -3  -3   3  -3  -1  -1   1  -1
```

Plot the histogram. Each of the four possible element values occur with equal probability. Your values might differ.

```
histogram(out,[-4 -2 0 2 4])
```

Generate a matrix in which the likelihood of a -1 or 1 is four times higher than the likelihood of a -3 or 3.

```
out = randsrc(10,10,[-3 -1 1 3; 0.1 0.4 0.4 0.1])
```

```
out = 10x10
```

```
-1  -1  -1  -1  1  -1  1  -1  1  3
 1  -3  3  3  1  -3  -1  -1  -1  1
-1  -1  -3  -1  -1  3  -1  1  1  -1
 1  3  1  -1  1  3  -1  -3  -1  -1
-1  -1  1  -1  -1  -1  -3  -3  1  -1
 1  1  1  -1  -3  -1  -1  -1  -1  -1
-1  1  -3  1  -1  -1  3  1  -1  1
```

```
1    3   -1    1   -1    3    3    1    1    1
1   -3   -1    1   -1   -1    1    1    1    1
1   -1    1   -1   -1   -1   -3   -1   -3    1
```

Plot the histogram. Values of -1 and 1 are more likely.

```
histogram(out,[-4 -2 0 2 4])
```

# rayleighchan

(To be removed) Construct Rayleigh fading channel object

## Syntax

```
chan = rayleighchan(ts,fd)
chan = rayleighchan(ts,fd,tau,pdb)
chan = rayleighchan
```

---

**Note** rayleighchan will be removed in a future release. Use `comm.RayleighChannel` instead.

---

## Description

`chan = rayleighchan(ts,fd)` constructs a frequency-flat ("single path") Rayleigh fading channel object. `ts` is the sample time of the input signal, in seconds. `fd` is the maximum Doppler shift, in hertz. You can model the effect of the channel on a signal `x` by using the syntax `y = filter(chan,x)`.

`chan = rayleighchan(ts,fd,tau,pdb)` constructs a frequency-selective ("multiple path") fading channel object that models each discrete path as an independent Rayleigh fading process. `tau` is a vector of path delays, each specified in seconds. `pdb` is a vector of average path gains, each specified in dB.

With the above two syntaxes, a smaller `fd` (a few hertz to a fraction of a hertz) leads to slower variations, and a larger `fd` (a couple hundred hertz) to faster variations.

`chan = rayleighchan` constructs a frequency-flat Rayleigh channel object with no Doppler shift. This is a static channel. The sample time of the input signal is irrelevant for frequency-flat static channels.

## Properties

The tables below describe the properties of the channel object, `chan`, that you can set and that MATLAB technical computing software sets automatically. To learn how to view

or change the values of a channel object, see “Displaying and Changing Object Properties”.

**Writeable Properties**

<b>Property</b>	<b>Description</b>
InputSamplePeriod	Sample period of the signal on which the channel acts, measured in seconds.
DopplerSpectrum	Doppler spectrum object(s). The default is a Jakes Doppler object.
MaxDopplerShift	Maximum Doppler shift of the channel, in hertz (applies to all paths of a channel).
PathDelays	Vector listing the delays of the discrete paths, in seconds.
AvgPathGaindB	Vector listing the average gain of the discrete paths, in decibels.
NormalizePathGains	If 1, the Rayleigh fading process is normalized such that the expected value of the path gains' total power is 1.
StoreHistory	If this value is 1, channel state information needed by the channel visualization tool is stored as the channel filter function processes the signal. The default value is 0.
StorePathGains	If set to 1, the complex path gain vector is stored as the channel filter function processes the signal. The default value is 0.
ResetBeforeFiltering	If 1, each call to <code>filter</code> resets the state of <code>chan</code> before filtering. If 0, the fading process maintains continuity from one call to the next.

## Read-Only Properties

Property	Description	When MATLAB Sets or Updates Value
ChannelType	Fixed value, 'Rayleigh'	When you create object
PathGains	Complex vector listing the current gains of the discrete paths. When you create or reset chan, PathGains is a random vector influenced by AvgPathGaindB and NormalizePathGains.	When you create object, reset object, or use it to filter a signal
ChannelFilterDelay	Delay of the channel filter, measured in samples.  The ChannelFilterDelay property returns a delay value that is valid only if the first value of the PathGain is the biggest path gain. In other words, main channel energy is in the first path.	When you create object or change ratio of InputSamplePeriod to PathDelays
NumSamplesProcessed	Number of samples the channel processed since the last reset. When you create or reset chan, this property value is 0.	When you create object, reset object, or use it to filter a signal

## Relationships Among Properties

The PathDelays and AvgPathGaindB properties of the channel object must always have the same vector length, because this length equals the number of discrete paths of the channel. The DopplerSpectrum property must either be a single Doppler object or a vector of Doppler objects with the same length as PathDelays.

If you change the length of PathDelays, MATLAB truncates or zero-pads the value of AvgPathGaindB if necessary to adjust its vector length (MATLAB may also change the values of read-only properties such as PathGains and ChannelFilterDelay). If DopplerSpectrum is a vector of Doppler objects, and you increase or decrease the

length of `PathDelays`, MATLAB will add Jakes Doppler objects or remove elements from `DopplerSpectrum`, respectively, to make it the same length as `PathDelays`.

If `StoreHistory` is set to 1 (the default is 0), the object stores channel state information as the channel filter function processes the signal. You can then visualize this state information through a GUI using the `plot (channel)` method.

---

**Note** Setting `StoreHistory` to 1 will result in a slower simulation. If you do not want to visualize channel state information using `plot (channel)`, but want to access the complex path gains, then set `StorePathGains` to 1, while keeping `StoreHistory` as 0.

---

## Visualization of Channel

The characteristics of a channel can be plotted using the channel visualization tool, `plot (channel)`. You can use the channel visualization tool in Normal mode and Accelerator mode.

## Examples

The example below illustrates that when you change the value of `PathDelays`, MATLAB automatically changes the values of other properties to make their vector lengths consistent with that of the new value of `PathDelays`.

```
c1 = rayleighchan(1e-5,130) % Create object.  
c1.PathDelays = [0 1e-6] % Change the number of delays.
```

MATLAB automatically changes the size of `c1.AvgPathGaindB`, `c1.PathGains`, and `c1.ChannelFilterDelay`. The output below displays all the properties of the channel object before and after the change in the value of the `PathDelays` property. In the second listing of properties, the `AvgPathGaindB`, `PathGains`, and `ChannelFilterDelay` properties all have different values compared to the first listing of properties.

```
c1 =  
  
    ChannelType: 'Rayleigh'  
InputSamplePeriod: 1.0000e-005  
    DopplerSpectrum: [1x1 doppler.jakes]  
    MaxDopplerShift: 130
```

```

        PathDelays: 0
        AvgPathGaindB: 0
    NormalizePathGains: 1
        StoreHistory: 0
        PathGains: 0.2035 + 0.1014i
    ChannelFilterDelay: 0
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0

```

c1 =

```

        ChannelType: 'Rayleigh'
    InputSamplePeriod: 1.0000e-005
        DopplerSpectrum: [1x1 doppler.jakes]
        MaxDopplerShift: 130
            PathDelays: [0 1.0000e-006]
            AvgPathGaindB: [0 0]
    NormalizePathGains: 1
        StoreHistory: 0
        PathGains: [0.6108 - 0.4688i 0.1639 - 0.0027i]
    ChannelFilterDelay: 4
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0

```

## Algorithms

The methodology used to simulate fading channels is described in “Methodology for Simulating Multipath Fading Channels”. The properties of the channel object are related to the quantities of the latter section as follows:

- The `InputSamplePeriod` property contains the value of  $T_s$ .
- The `PathDelays` vector property contains the values of  $\{\tau_k\}$ , where  $1 \leq k \leq K$ .
- The `PathGains` read-only property contains the values of  $\{a_k\}$ , where  $1 \leq k \leq K$ .
- The `AvgPathGaindB` vector property contains the values of  $10\log_{10}\{E[|a_k|^2]\}$ , where  $1 \leq k \leq K$ , and  $E[\cdot]$  denotes statistical expectation.
- The `ChannelFilterDelay` read-only property contains the value of  $N_1$ .

# rectpulse

Rectangular pulse shaping

## Syntax

```
y = rectpulse(x,nsamp)
```

## Description

`y = rectpulse(x,nsamp)` applies rectangular pulse shaping to `x` to produce an output signal having `nsamp` samples per symbol. Rectangular pulse shaping means that each symbol from `x` is repeated `nsamp` times to form the output `y`. If `x` is a matrix with multiple rows, the function treats each column as a channel and processes the columns independently.

---

**Note** To insert zeros between successive samples of `x` instead of repeating the samples of `x`, use the `upsample` function instead.

---

## Examples

An example in “Combine Pulse Shaping and Filtering with Modulation” uses this function in conjunction with modulation.

The code below processes two independent channels, each containing three symbols of data. In the pulse-shaped matrix `y`, each symbol contains four samples.

```
nsamp = 4; % Number of samples per symbol
nsymb = 3; % Number of symbols
s = RandStream('mt19937ar', 'Seed', 0);
ch1 = randi(s, [0 1], nsymb, 1); % Random binary channel
ch2 = [1:nsymb]';
x = [ch1 ch2] % Two-channel signal
y = rectpulse(x,nsamp)
```

The output is below. In  $y$ , each column corresponds to one channel and each row corresponds to one sample. Also, the first four rows of  $y$  correspond to the first symbol, the next four rows of  $y$  correspond to the second symbol, and the last four rows of  $y$  correspond to the last symbol.

$x =$

```
1 1
1 2
0 3
```

$y =$

```
1 1
1 1
1 1
1 1
1 2
1 2

## reset (channel)

(To be removed) Reset channel object

### Syntax

```
reset(chan)  
reset(chan, randstate)
```

---

**Note** This function will be removed in a future release. Use function associated with `comm.RicianChannel` or `comm.RayleighChannel` instead.

---

### Description

`reset(chan)` resets the channel object `chan`, initializing the `PathGains` and `NumSamplesProcessed` properties as well as internal filter states. This syntax is useful when you want the effect of creating a new channel.

`reset(chan, randstate)` resets the channel object `chan` and initializes the state of the random number generator that the channel uses. `randstate` is a two-element column vector. This syntax is useful when you want to repeat previous numerical results that started from a particular state.

---

**Note** `reset(chan, randstate)` will not support `randstate` in a future release. See the `legacychannelsim` function for more information.

---

### Examples

The example below shows how to obtain repeatable results. The example chooses a state for the random number generator immediately after defining the channel object and later resets the random number generator to that state.

```
%% Set up channel.
```

```
% Assume you want to maintain continuity
% from one filtering operation to the next, except
% when you explicitly reset the channel.
c = rayleighchan(1e-4,100);
c.ResetBeforeFiltering = 0;

% Filter all ones.
sig = ones(100,1);
y1 = [filter(c,sig(1:50)); filter(c,sig(51:end))];

% Reset the channel and filter all ones.
reset(c);
% Generate an independent channel
y2 = [filter(c,sig(1:50)); filter(c,sig(51:end))];

% Plot the magnitude of the channel output
plot(abs([y1; y2]),'*')
grid on
```

This example generates a plot similar to this figure.

# ricianchan

(To be removed) Construct Rician fading channel object

## Syntax

```
chan = ricianchan(ts,fd,k)
chan = ricianchan(ts,fd,k,tau,pdb)
chan = ricianchan(ts,fd,k,tau,pdb,fdlos)
chan = ricianchan
```

---

**Note** `ricianchan` will be removed in a future release. Use `comm.RicianChannel` instead.

---

## Description

`chan = ricianchan(ts,fd,k)` constructs a frequency-flat (single path) Rician fading-channel object. `ts` is the sample time of the input signal, in seconds. `fd` is the maximum Doppler shift, in hertz. `k` is the Rician K-factor in linear scale. You can model the effect of the channel `chan` on a signal `x` by using the syntax `y = filter(chan,x)`.

`chan = ricianchan(ts,fd,k,tau,pdb)` constructs a frequency-selective (multiple paths) fading-channel object. If `k` is a scalar, then the first discrete path is a Rician fading process (it contains a line-of-sight component) with a K-factor of `k`, while the remaining discrete paths are independent Rayleigh fading processes (no line-of-sight component). If `k` is a vector of the same size as `tau`, then each discrete path is a Rician fading process with a K-factor given by the corresponding element of the vector `k`. `tau` is a vector of path delays, each specified in seconds. `pdb` is a vector of average path gains, each specified in dB.

`chan = ricianchan(ts,fd,k,tau,pdb,fdlos)` specifies `fdlos` as the Doppler shift(s) of the line-of-sight component(s) of the discrete path(s), in hertz. `fdlos` must be the same size as `k`. If `k` and `fdlos` are scalars, the line-of-sight component of the first discrete path has a Doppler shift of `fdlos`, while the remaining discrete paths are independent Rayleigh fading processes. If `fdlos` is a vector of the same size as `k`, the line-of-sight component of each discrete path has a Doppler shift given by the

corresponding element of the vector `fdlos`. By default, `fdlos` is `0`. The initial phase(s) of the line-of-sight component(s) can be set through the property `DirectPathInitPhase`.

`chan = ricianchan` sets the maximum Doppler shift to `0`, the Rician K-factor to `1`, and the Doppler shift and initial phase of the line-of-sight component to `0`. This syntax models a static frequency-flat channel, and, in this trivial case, the sample time of the signal is unimportant.

### Properties

The following tables describe the properties of the channel object, `chan`, that you can set and that MATLAB technical computing software sets automatically. To learn how to view or change the values of a channel object, see “Displaying and Changing Object Properties”.

**Writeable Properties**

<b>Property</b>	<b>Description</b>
InputSamplePeriod	Sample period of the signal on which the channel acts, measured in seconds.
DopplerSpectrum	Doppler spectrum object(s). The default is a Jakes doppler object.
MaxDopplerShift	Maximum Doppler shift of the channel, in hertz (applies to all paths of a channel).
KFactor	Rician K-factor (scalar or vector). The default value is 1 (line-of-sight component on the first path only).
PathDelays	Vector listing the delays of the discrete paths, in seconds.
AvgPathGaindB	Vector listing the average gain of the discrete paths, in decibels.
DirectPathDopplerShift	Doppler shift(s) of the line-of-sight component(s) in hertz. The default value is 0.
DirectPathInitPhase	Initial phase(s) of line-of-sight component(s) in radians. The default value is 0.
NormalizePathGains	If this value is 1, the Rayleigh fading process is normalized such that the expected value of the path gains' total power is 1.
StoreHistory	If this value is 1, channel state information needed by the channel visualization tool is stored as the channel filter function processes the signal. The default value is 0.
StorePathGains	If this value is 1, the complex path gain vector is stored as the channel filter function processes the signal. The default value is 0.

Property	Description
ResetBeforeFiltering	If this value is 1, each call to <code>filter</code> resets the state of <code>chan</code> before filtering. If it is 0, the fading process maintains continuity from one call to the next.

### Read-Only Properties

Property	Description	When MATLAB Sets or Updates Value
ChannelType	Fixed value, 'Rician'.	When you create object.
PathGains	Complex vector listing the current gains of the discrete paths. When you create or reset <code>chan</code> , <code>PathGains</code> is a random vector influenced by <code>AvgPathGaindB</code> and <code>NormalizePathGains</code> .	When you create object, reset object, or use it to filter a signal.
ChannelFilterDelay	Delay of the channel filter, measured in samples.  The <code>ChannelFilterDelay</code> property returns a delay value that is valid only if the first value of the <code>PathGain</code> is the biggest path gain. In other words, main channel energy is in the first path.	When you create object or change ratio of <code>InputSamplePeriod</code> to <code>PathDelays</code> .
NumSamplesProcessed	Number of samples the channel processed since the last reset. When you create or reset <code>chan</code> , this property value is 0.	When you create object, reset object, or use it to filter a signal.

### Relationships Among Properties

Changing the length of `PathDelays` also changes the length of `AvgPathGaindB`, the length of `KFactor` if `KFactor` is a vector (no change if it is a scalar), and the length of `DopplerSpectrum` if `DopplerSpectrum` is a vector (no change if it is a single object).

`DirectPathDopplerShift` and `DirectPathInitPhase` both follow changes in `KFactor`.

The `PathDelays` and `AvgPathGaindB` properties of the channel object must always have the same vector length, because this length equals the number of discrete paths of the channel. The `DopplerSpectrum` property must either be a single Doppler object or a vector of Doppler objects with the same length as `PathDelays`.

If you change the length of `PathDelays`, MATLAB truncates or zero-pads the value of `AvgPathGaindB` if necessary to adjust its vector length (MATLAB may also change the values of read-only properties such as `PathGains` and `ChannelFilterDelay`). If `DopplerSpectrum` is a vector of Doppler objects, and you increase or decrease the length of `PathDelays`, MATLAB will add Jakes Doppler objects or remove elements from `DopplerSpectrum`, respectively, to make it the same length as `PathDelays`.

If `StoreHistory` is set to 1 (the default is 0), the object stores channel state information as the channel filter function processes the signal. You can then visualize this state information through a GUI using the `plot (channel)` method.

---

**Note** Setting `StoreHistory` to 1 will result in a slower simulation. If you do not want to visualize channel state information using `plot (channel)`, but want to access the complex path gains, then set `StorePathGains` to 1, while keeping `StoreHistory` as 0.

---

## Reset Method

If `MaxDopplerShift` is set to 0 (the default), the channel object, `chan`, models a static channel.

Use the syntax `reset (chan)` to generate a new channel realization.

## Algorithm

The methodology used to simulate fading channels is described in “Methodology for Simulating Multipath Fading Channels”, where the properties specific to the Rician channel object are related to the quantities of this section as follows:

- The `Kfactor` property contains the value of  $K_r$  (if it’s a scalar) or  $\{K_{r,k}\}$ ,  $1 \leq k \leq K$  (if it’s a vector).

- The `DirectPathDopplerShift` property contains the value of  $f_{d,LOS}$  (if it's a scalar) or  $\{f_{d,LOS,k}\}$ ,  $1 \leq k \leq K$  (if it's a vector).
- The `DirectPathInitPhase` property contains the value of  $\theta_{LOS}$  (if it's a scalar) or  $\{\theta_{LOS,k}\}$ ,  $1 \leq k \leq K$  (if it's a vector).

The `rayleighchan` reference page includes descriptions for properties common to both Rayleigh and Rician channel objects.

## Channel Visualization

The characteristics of a channel can be plotted using the channel visualization tool, `plot(channel)`. You can use the channel visualization tool in Normal mode and Accelerator mode.

## rls

(To be removed) Construct recursive least squares (RLS) adaptive algorithm object

---

**Note** will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

---

## Syntax

```
alg = rls(forgetfactor)
alg = rls(forgetfactor, invcorr0)
```

## Description

The `rls` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see .

`alg = rls(forgetfactor)` constructs an adaptive algorithm object based on the recursive least squares (RLS) algorithm. The forgetting factor is `forgetfactor`, a real number between 0 and 1. The inverse correlation matrix is initialized to a scalar value.

`alg = rls(forgetfactor, invcorr0)` sets the initialization parameter for the inverse correlation matrix. This scalar value is used to initialize or reset the diagonal elements of the inverse correlation matrix.

## Properties

The table below describes the properties of the RLS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
<code>AlgType</code>	Fixed value, 'RLS'

Property	Description
ForgetFactor	Forgetting factor
InvCorrInit	Scalar value used to initialize or reset the diagonal elements of the inverse correlation matrix

Also, when you use this adaptive algorithm object to create an equalizer object (via the `lineareq` function or `dfc` function), the equalizer object has an `InvCorrMatrix` property that represents the inverse correlation matrix for the RLS algorithm. The initial value of `InvCorrMatrix` is `InvCorrInit*eye(N)`, where `N` is the total number of equalizer weights.

## Examples

### Defining an Equalizer Object

The code creates equalizer objects for these configurations:

- A symbol-spaced linear RLS equalizer with 10 weights.
- A fractionally spaced linear RLS equalizer with 10 weights, a BPSK constellation, and two samples per symbol.
- A decision-feedback RLS equalizer with three weights in the feedforward filter and two weights in the feedback filter.

All three equalizer objects specify the RLS adaptive algorithm with a forgetting factor of 0.3.

Create equalizer objects of different types. The default settings are used for properties not set using 'Name, Value' pairs.

```
eqlin = comm.LinearEqualizer('Algorithm','RLS','NumTaps',10,'ForgettingFactor',0.3)
eqlin =
    comm.LinearEqualizer with properties:
        Algorithm: 'RLS'
        NumTaps: 10
        ForgettingFactor: 0.3000
```

```
InitialInverseCorrelationMatrix: 0.1000
      Constellation: [1x4 double]
      ReferenceTap: 3
      InputDelay: 0
InputSamplesPerSymbol: 1
TrainingFlagInputPort: false
      AdaptAfterTraining: true
      InitialWeightsSource: 'Auto'
      WeightUpdatePeriod: 1

eqfrac = comm.LinearEqualizer('Algorithm','RLS','NumTaps',10,'ForgettingFactor',0.3, .
      'Constellation',[-1 1],'InputSamplesPerSymbol',2)

eqfrac =
comm.LinearEqualizer with properties:
      Algorithm: 'RLS'
      NumTaps: 10
      ForgettingFactor: 0.3000
InitialInverseCorrelationMatrix: 0.1000
      Constellation: [-1 1]
      ReferenceTap: 3
      InputDelay: 0
InputSamplesPerSymbol: 2
TrainingFlagInputPort: false
      AdaptAfterTraining: true
      InitialWeightsSource: 'Auto'
      WeightUpdatePeriod: 1

eqdfe = comm.DecisionFeedbackEqualizer('Algorithm','RLS','NumForwardTaps',3, ...
      'NumFeedbackTaps',2,'ForgettingFactor',0.3)

eqdfe =
comm.DecisionFeedbackEqualizer with properties:
      Algorithm: 'RLS'
      NumForwardTaps: 3
      NumFeedbackTaps: 2
      ForgettingFactor: 0.3000
InitialInverseCorrelationMatrix: 0.1000
      Constellation: [1x4 double]
      ReferenceTap: 3
      InputDelay: 0
```

```
InputSamplesPerSymbol: 1
TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

## Algorithms

Referring to the schematics presented in “Equalization”, define  $w$  as the vector of all weights  $w_i$  and define  $u$  as the vector of all inputs  $u_i$ . Based on the current set of inputs,  $u$ , and the current inverse correlation matrix,  $P$ , this adaptive algorithm first computes the Kalman gain vector,  $K$

where  $H$  denotes the Hermitian transpose.

Then the new inverse correlation matrix is given by

$$(\text{ForgetFactor})^{-1}(P - Ku^H P)$$

and the new set of weights is given by

$$w + K^* e$$

where the  $*$  operator denotes the complex conjugate.

## Compatibility Considerations

### rls will be removed

*Not recommended starting in R2019a*

rls will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

## rsdec

Reed-Solomon decoder

### Syntax

```
decoded = rsdec(code,n,k)
decoded = rsdec(code,n,k,genpoly)
decoded = rsdec(...,paritypos)
[decoded,cnumerr] = rsdec(...)
[decoded,cnumerr,ccode] = rsdec(...)
```

### Description

`decoded = rsdec(code,n,k)` attempts to decode the received signal in `code` using an  $[n,k]$  Reed-Solomon decoding process with the narrow-sense generator polynomial. `code` is a Galois array of symbols having  $m$  bits each. Each  $n$ -element row of `code` represents a corrupted systematic codeword, where the parity symbols are at the end and the leftmost symbol is the most significant symbol.  $n$  is at most  $2^m-1$ . If  $n$  is not exactly  $2^m-1$ , `rsdec` assumes that `code` is a corrupted version of a shortened code.

In the Galois array `decoded`, each row represents the attempt at decoding the corresponding row in `code`. A *decoding failure* occurs if `rsdec` detects more than  $(n-k)/2$  errors in a row of `code`. In this case, `rsdec` forms the corresponding row of `decoded` by merely removing  $n-k$  symbols from the end of the row of `code`.

`decoded = rsdec(code,n,k,genpoly)` is the same as the syntax above, except that a nonempty value of `genpoly` specifies the generator polynomial for the code. In this case, `genpoly` is a Galois row vector that lists the coefficients, in order of descending powers, of the generator polynomial. The generator polynomial must have degree  $n-k$ . To use the default narrow-sense generator polynomial, set `genpoly` to `[]`.

`decoded = rsdec(...,paritypos)` specifies whether the parity symbols in `code` were appended or prepended to the message in the coding operation. `paritypos` can be either 'end' or 'beginning'. The default is 'end'. If `paritypos` is 'beginning', a decoding failure causes `rsdec` to remove  $n-k$  symbols from the beginning rather than the end of the row.

`[decoded, cnumerr] = rsdec(...)` returns a column vector `cnumerr`, each element of which is the number of corrected errors in the corresponding row of code. A value of -1 in `cnumerr` indicates a decoding failure in that row in code.

`[decoded, cnumerr, ccode] = rsdec(...)` returns `ccode`, the corrected version of code. The Galois array `ccode` has the same format as `code`. If a decoding failure occurs in a certain row of code, the corresponding row in `ccode` contains that row unchanged.

## Examples

### Reed-Solomon Decoding

Set the RS code parameters.

```
m = 3;           % Number of bits per symbol
n = 2^m-1;      % Codeword length
k = 3;          % Message length
```

Generate three codewords composed of 3-bit symbols. Encode the message with a (7,3) RS code.

```
msg = gf([2 7 3; 4 0 6; 5 1 1],m);
code = rsenc(msg,n,k);
```

Introduce one error on the first codeword, two errors on the second codeword, and three errors on the third codeword.

```
errors = gf([2 0 0 0 0 0 0; 3 4 0 0 0 0 0; 5 6 7 0 0 0 0],m);
noisycode = code + errors;
```

Decode the corrupted codeword.

```
[rxcode, cnumerr] = rsdec(noisycode,n,k);
```

Observe that the number of corrected errors matches the introduced errors for the first two rows. In row three, the number of corrected errors is -1 because a (7,3) RS code cannot correct more than two errors.

```
cnumerr
cnumerr = 3x1
```

1  
2  
-1

### Limitations

$n$  and  $k$  must differ by an even integer.  $n$  must be between 3 and 65535.

### Algorithms

`rsdec` uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see the works listed in “References” on page 2-1054 below.

## rsenc

Reed-Solomon encoder

### Syntax

```
code = rsenc(msg,n,k)
code = rsenc(msg,n,k,genpoly)
code = rsenc(...,paritypos)
```

### Description

`code = rsenc(msg,n,k)` encodes the message in `msg` using an  $[n,k]$  Reed-Solomon code with the narrow-sense generator polynomial. `msg` is a Galois array of symbols having  $m$  bits each. Each  $k$ -element row of `msg` represents a message word, where the leftmost symbol is the most significant symbol.  $n$  is at most  $2^m-1$ . If  $n$  is not exactly  $2^m-1$ , `rsenc` uses a shortened Reed-Solomon code. Parity symbols are at the end of each word in the output Galois array `code`.

`code = rsenc(msg,n,k,genpoly)` is the same as the syntax above, except that a nonempty value of `genpoly` specifies the generator polynomial for the code. In this case, `genpoly` is a Galois row vector that lists the coefficients, in order of descending powers, of the generator polynomial. The generator polynomial must have degree  $n-k$ . To use the default narrow-sense generator polynomial, set `genpoly` to `[]`.

`code = rsenc(...,paritypos)` specifies whether `rsenc` appends or prepends the parity symbols to the input message to form `code`. `paritypos` can be either 'end' or 'beginning'. The default is 'end'.

## Examples

### Reed-Solomon Code Generation

Set the code parameters.

```
m = 3;           % Number of bits per symbol
n = 2^m - 1;    % Codeword length
k = 3;         % Message length
```

Create two messages based on GF(8).

```
msg = gf([2 7 3; 4 0 6],m)
```

```
msg = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =
```

```
 2  7  3
 4  0  6
```

Generate RS (7,3) codewords.

```
code = rsenc(msg,n,k)
```

```
code = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =
```

```
 2  7  3  3  6  7  6
 4  0  6  4  2  2  0
```

The codes are systematic so the first three symbols of each row match the rows of msg.

## Limitations

n and k must differ by an integer. n between 7 and 65535.

## rsgenpoly

Generator polynomial of Reed-Solomon code

### Syntax

```
genpoly = rsgenpoly(N,K)
genpoly = rsgenpoly(N,K,prim_poly)
genpoly = rsgenpoly(N,K,prim_poly,B)
genpoly = rsgenpoly(N,K,prim_poly,B,outputFormat)
[genpoly,T] = rsgenpoly( ___ )
```

### Description

`genpoly = rsgenpoly(N,K)` returns the narrow-sense generator polynomial of an  $[N,K]$  Reed-Solomon code. The output `genpoly` is a Galois field array that represents the coefficients of the generator polynomial in order of descending powers. The narrow-sense generator polynomial is  $(X - \alpha^1)(X - \alpha^2)\dots(X - \alpha^{N-K})$ , where  $\alpha$  is a root of the default primitive polynomial for the field  $GF(N+1)$ . For additional information, see Narrow-Sense BCH Codes and “Reed-Solomon Codes”.

`genpoly = rsgenpoly(N,K,prim_poly)` also specifies the primitive polynomial, `prim_poly`, for  $GF(N+1)$  that has  $\alpha$  as a root.

`genpoly = rsgenpoly(N,K,prim_poly,B)` returns the generator polynomial,  $(X - \alpha^B)(X - \alpha^{B+1})\dots(X - \alpha^{B+N-K-1})$ , where  $B$  is an integer.

`genpoly = rsgenpoly(N,K,prim_poly,B,outputFormat)` specifies the output format of `genpoly` as a Galois field array or double-precision array.

`[genpoly,T] = rsgenpoly( ___ )` also returns the error-correction capability of the  $[N,K]$  Reed-Solomon code, `T`, using any of the preceding input argument syntaxes.

### Examples

### Create Narrow-Sense Generator Polynomial

Specify the codeword length,  $n$ , and message length,  $k$ .

```
n = 7;
k = 3;
```

Create the narrow-sense generator polynomial for the  $[n,k]$  Reed-Solomon code. `genpoly` is a Galois field array, by default, that represents the coefficients of this generator polynomial in order of descending powers.

```
genpoly = rsgenpoly(n,k)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =
```

```
    1    3    1    2    3
```

### Create Narrow-Sense Generator Polynomial Specifying Primitive Polynomial

Create the narrow-sense generator polynomial of a Reed-Solomon code with respect to the primitive polynomial  $D^3 + D^2 + 1$ .

Specify the codeword length,  $n$ , message length,  $k$ , and primitive polynomial  $D^3 + D^2 + 1$  represented in decimal form.

```
n = 7;
k = 3;
prim_poly = 13;
```

Create the narrow-sense generator polynomial for the  $[n,k]$  Reed-Solomon code with respect to primitive polynomial  $D^3 + D^2 + 1$  for GF(8). `genpoly` is a Galois field array, by default, that represent the coefficients of this generator polynomial in order of descending powers.

```
genpoly = rsgenpoly(n,k,prim_poly)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D^2+1 (13 decimal)
```

```
Array elements =  
    1  4  5  1  5
```

### Create Narrow-Sense Generator Polynomial for Specified B

Create the narrow-sense generator polynomial of a Reed-Solomon code with respect to the default primitive polynomial.

Specify the codeword length,  $n$ , message length,  $k$ , and exponent of  $\alpha$ ,  $b$ .

```
n = 7;  
k = 3;  
b = 4;
```

Create the narrow-sense generator polynomial  $(X - \alpha^4)(X - \alpha^5)(X - \alpha^6)(X - \alpha^7)$ , with respect to the default primitive polynomial. `genpoly` is a Galois field array, by default, that represents the coefficients of this generator polynomial in order of descending powers. Display the error-correcting capability of the code.

```
[genpoly,t] = rsgenpoly(n,k,[],b)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =  
    1  5  5  3  2  
t = 2
```

### Create Narrow-Sense Generator Polynomial for DVB-S and WiMAX

Create the narrow-sense generator polynomial of a Reed-Solomon code with respect to the primitive polynomial  $D^8 + D^4 + D^3 + D^2 + 1$ .

Specify the codeword length,  $n$ , message length,  $k$ , the primitive polynomial represented in decimal form, and the exponent of  $\alpha$ ,  $b$ .

```
n = 255;
k = 239;
prim_poly = 285;
b = 0;
```

Create the narrow-sense generator polynomial for the  $[n,k]$  Reed-Solomon code. `genpoly` is a Galois field array, by default, that represents a generator polynomial and is compliant with DVB-S and WiMAX.

```
genpoly = rsgenpoly(n,k,prim_poly,b)
```

`genpoly` = GF(2<sup>8</sup>) array. Primitive polynomial =  $D^8+D^4+D^3+D^2+1$  (285 decimal)

Array elements =

Columns 1 through 13

```
1    59    13   104   189    68   209    30    8   163    65   41   229
```

Columns 14 through 17

```
98    50    36    59
```

### Create Narrow-Sense Generator Polynomial with Output Format Double

Create the narrow-sense generator polynomial of a Reed-Solomon code. Specify the output data type as a double-precision array.

Specify the codeword length,  $n$ , and message length,  $k$ .

```
n = 7;
k = 3;
```

Create the narrow-sense generator polynomial for the  $[n,k]$  Reed-Solomon code. `genpoly` is a double-precision array, that represents the coefficients of this generator polynomial in order of descending powers. Specify default values for the primitive polynomial and exponent of  $\alpha$  inputs by assigning `[]` for them.

```
genpoly = rsgenpoly(n,k,[],[], 'double')
```

```
genpoly = 1x5
```

1 3 1 2 3

## Input Arguments

### **N — Codeword length**

positive odd integer

Codeword length, specified as an integer of the form  $N = 2^M - 1$ , where  $M$  is in the range [3,16]. For more information, see “Limitations” on page 2-1063.

Example: Set  $N$  to 15 for  $M=4$ .

### **K — Message length**

positive integer

Message length, specified as a positive integer. For more information, see “Limitations” on page 2-1063.

### **prim\_poly — Primitive polynomial**

GF(N+1) (default) | positive integer

Primitive polynomial, specified as a positive integer. `prim_poly` is an integer whose binary representation indicates the coefficients of the primitive polynomial. To use the default primitive polynomial GF(N+1), set `prim_poly` to []. For more information, see “Default Primitive Polynomials” on page 2-1063.

Example: 19 specifies the primitive polynomial  $D^4+D+1$  because its binary representation is 10011.

### **B — Exponent of $\alpha$**

positive integer

Exponent of  $\alpha$ , specified as a positive integer.  $\alpha$  is a root of `prim_poly`.

### **outputFormat — Output format**

'gf' (default) | 'double'

Output format of `genpoly`, specified as:

- 'gf' — to output a Galois field array.

- 'double' — to output a double-precision array of the Galois field values.

For more information, see “Working with Galois Fields”.

## Output Arguments

### **genpoly** — Generator polynomial coefficients

Galois field array | double-precision array

Generator polynomial coefficients in descending order, returned as a Galois field array or double-precision array. `genpoly` is a row vector that represents the coefficients of the narrow-sense generator polynomial of an [N,K] Reed-Solomon code in order of descending powers.

### **T** — Error-correction capability

positive integer

Error-correction capability of the code, returned as a positive integer equal to  $\lfloor (N - K)/2 \rfloor$ .

## Limitations

- Valid values for  $N = 2^M - 1$ , where  $M$  is an integer in the range [3,16]. The maximum allowable value of  $N = 2^{16} - 1 = 65,535$ .
- Valid values for  $K = [1, N - 1]$ .

## More About

### Default Primitive Polynomials

This table lists the default primitive polynomial used for each Galois field array  $GF(2^M)$ . To use a different primitive polynomial, specify `prim_poly` as an input argument. `prim_poly` must be in the range  $[(2^M+1), (2^{(M+1)}-1)]$  and must indicate an irreducible polynomial. For more information, see “Specifying the Primitive Polynomial”.

<b>M</b>	<b>Default Primitive Polynomial</b>	<b>Integer Representation</b>
1	$D + 1$	3
2	$D^2 + D + 1$	7
3	$D^3 + D + 1$	11
4	$D^4 + D + 1$	19
5	$D^5 + D^2 + 1$	37
6	$D^6 + D + 1$	67
7	$D^7 + D^3 + 1$	137
8	$D^8 + D^4 + D^3 + D^2 + 1$	285
9	$D^9 + D^4 + 1$	529
10	$D^{10} + D^3 + 1$	1033
11	$D^{11} + D^2 + 1$	2053
12	$D^{12} + D^6 + D^4 + D + 1$	4179
13	$D^{13} + D^4 + D^3 + D + 1$	8219
14	$D^{14} + D^{10} + D^6 + D + 1$	17475
15	$D^{15} + D + 1$	32771
16	$D^{16} + D^{12} + D^3 + D + 1$	69643

## Extended Capabilities

# rsgenpolycoeffs

Generator polynomial coefficients of Reed-Solomon code

## Syntax

```
x = rsgenpolycoeffs(...)  
[x,t] = rsgenpolycoeffs(...)
```

## Description

`x = rsgenpolycoeffs(...)` returns the coefficients for the generator polynomial of the Reed-Solomon code. The output is identical to `genpoly = rsgenpoly(...); x = genpoly.x`.

`[x,t] = rsgenpolycoeffs(...)` returns `t`, the error-correction capability of the code.

## Examples

### Generate Polynomial Coefficients for a Reed-Solomon Code

This example shows how to generate polynomial coefficients for a (15,11) Reed-Solomon code.

Generate the coefficients using `rsgenpolycoeffs`.

```
genpoly = rsgenpolycoeffs(15,11)
```

```
genpoly = 1x5 uint32 row vector
```

```
    1    13    12     8     7
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

For C/C++ code generation, these usage notes and limitations apply:

All inputs must be constants. Expressions or variables are allowed if their values do not change.

### See Also

**Introduced in R2010b**

## scatterplot

Generate scatter plot

### Syntax

```
scatterplot(x)
scatterplot(x,n)
scatterplot(x,n,offset)
scatterplot(x,n,offset,plotstring)
scatterplot(x,n,offset,plotstring,h)
h = scatterplot(...)
```

### Description

`scatterplot(x)` produces a scatter plot for the signal `x`. The interpretation of `x` depends on its shape and complexity:

- If `x` is a real two-column matrix, `scatterplot` interprets the first column as in-phase components and the second column as quadrature components.
- If `x` is a complex vector, `scatterplot` interprets the real part as in-phase components and the imaginary part as quadrature components.
- If `x` is a real vector, `scatterplot` interprets it as a real signal.

`scatterplot(x,n)` is the same as the first syntax, except that the function plots every `n`th value of the signal, starting from the first value. That is, the function decimates `x` by a factor of `n` before plotting.

`scatterplot(x,n,offset)` is the same as the first syntax, except that the function plots every `n`th value of the signal, starting from the `(offset+1)`st value in `x`.

`scatterplot(x,n,offset,plotstring)` is the same as the syntax above, except that `plotstring` determines the plotting symbol, line type, and color for the plot. `plotstring` is a character vector whose format and meaning are the same as in the `plot` function.

`scatterplot(x,n,offset,plotstring,h)` is the same as the syntax above, except that the scatter plot is in the figure whose handle is `h`, rather than a new figure. `h` must be a handle to a figure that `scatterplot` previously generated. To plot multiple signals in the same figure, use `hold on`.

`h = scatterplot(...)` is the same as the earlier syntaxes, except that `h` is the handle to the figure that contains the scatter plot.

## Examples

### Generate Scatter Plot of 64-QAM Signal

Create a 64-QAM signal in which each constellation point is used.

```
d = (0:63)';  
s = qammod(d,64);
```

Display the scatter plot of the constellation.

```
scatterplot(s)
```

### Tips

Use `comm.ConstellationDiagram` when these are required:

- Measurements
- Basic reference constellations
- Signal trajectory plots
- Maintaining state between calls

Use `scatterplot` when:

- A simple snapshot of the signal constellation is needed.

## semianalytic

Calculate bit error rate (BER) using semianalytic technique

### Syntax

```
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,num,den)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,EbNo)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,num,den,EbNo)
[ber,avgampl,avgpower] = semianalytic(...)
```

### Description

`ber = semianalytic(txsig,rxsig,modtype,M,Nsamp)` returns the bit error rate (BER) of a system that transmits the complex baseband vector signal `txsig` and receives the noiseless complex baseband vector signal `rxsig`. Each of these signals has `Nsamp` samples per symbol. `Nsamp` is also the sampling rate of `txsig` and `rxsig`, in Hz. The function assumes that `rxsig` is the input to the receiver filter, and the function filters `rxsig` with an ideal integrator. `modtype` is the modulation type of the signal and `M` is the alphabet size. The table below lists the valid values for `modtype` and `M`.

Modulation Scheme	Value of <i>modtype</i>	Valid Values of <i>M</i>
Differential phase shift keying (DPSK)	'dpsk'	2, 4
Minimum shift keying (MSK) with differential encoding	'msk/diff'	2
Minimum shift keying (MSK) with nondifferential encoding	'msk/nondiff'	2
Phase shift keying (PSK) with differential encoding, where the phase offset of the constellation is 0	'psk/diff'	2, 4

Modulation Scheme	Value of <i>modtype</i>	Valid Values of <i>M</i>
Phase shift keying (PSK) with nondifferential encoding, where the phase offset of the constellation is 0	'psk/nondiff'	2, 4, 8, 16, 32, or 64
Offset quadrature phase shift keying (OQPSK)	'oqpsk'	4
Quadrature amplitude modulation (QAM)	'qam'	4, 8, 16, 32, 64, 128, 256, 512, 1024

'msk/diff' is equivalent to conventional MSK (setting the 'Precoding' property of the MSK object to 'off'), while 'msk/nondiff' is equivalent to precoded MSK (setting the 'Precoding' property of the MSK object to 'on').

---

**Note** The output *ber* is an *upper bound* on the BER in these cases:

- DQPSK (*modtype* = 'dpsk', *M* = 4)
  - Cross QAM (*modtype* = 'qam', *M* not a perfect square). In this case, note that the upper bound used here is slightly tighter than the upper bound used for cross QAM in the *berawgn* function.
- 

When the function computes the BER, it assumes that symbols are Gray-coded. The function calculates the BER for values of  $E_b/N_0$  in the range of [0:20] dB and returns a vector of length 21 whose elements correspond to the different  $E_b/N_0$  levels.

---

**Note** You must use a sufficiently long vector *txsig*, or else the calculated BER will be inaccurate. If the system's impulse response is *L* symbols long, the length of *txsig* should be at least  $M^L$ . A common approach is to start with an augmented binary pseudonoise (PN) sequence of total length  $(\log_2 M)^L$ . An *augmented* PN sequence is a PN sequence with an extra zero appended, which makes the distribution of ones and zeros equal.

---

*ber* = *semianalytic*(*txsig*, *rxsig*, *modtype*, *M*, *Nsamp*, *num*, *den*) is the same as the previous syntax, except that the function filters *rxsig* with a receiver filter instead of

an ideal integrator. The transfer function of the receiver filter is given in descending powers of  $z$  by the vectors `num` and `den`.

`ber = semianalytic(txsig, rxsig, modtype, M, Nsamp, EbNo)` is the same as the first syntax, except that `EbNo` represents  $E_b/N_0$ , the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, then the output `ber` is a vector of the same size, whose elements correspond to the different  $E_b/N_0$  levels.

`ber = semianalytic(txsig, rxsig, modtype, M, Nsamp, num, den, EbNo)` combines the functionality of the previous two syntaxes.

`[ber, avgampl, avgpower] = semianalytic(...)` returns the mean complex signal amplitude and the mean power of `rxsig` after filtering it by the receiver filter and sampling it at the symbol rate.

## Examples

A typical procedure for implementing the semianalytic technique is in “Procedure for the Semianalytic Technique”. Sample code is in “Using Semianalytic Technique”.

## Limitations

The function makes several important assumptions about the communication system. See “When to Use the Semianalytic Technique” to find out whether your communication system is suitable for the semianalytic technique and the `semianalytic` function.

## Alternatives

As an alternative to the `semianalytic` function, invoke the BERTool GUI (`bertool`) and use the **Semianalytic** tab.

# shift2mask

Convert shift to mask vector for shift register configuration

## Syntax

```
mask = shift2mask(prpoly,shift)
```

## Description

`mask = shift2mask(prpoly,shift)` returns the mask that is equivalent to the shift (or offset) specified by `shift`, for a linear feedback shift register whose connections are specified by the primitive polynomial `prpoly`. The `prpoly` input can have one of these formats:

- A polynomial character vector
- A binary vector that lists the coefficients of the primitive polynomial in order of descending powers
- An integer scalar whose binary representation gives the coefficients of the primitive polynomial, where the least significant bit is the constant term

The `shift` input is an integer scalar.

---

**Note** To save time, `shift2mask` does not check that `prpoly` is primitive. If it is not primitive, the output is not meaningful. To find primitive polynomials, use `primpoly` or see [2].

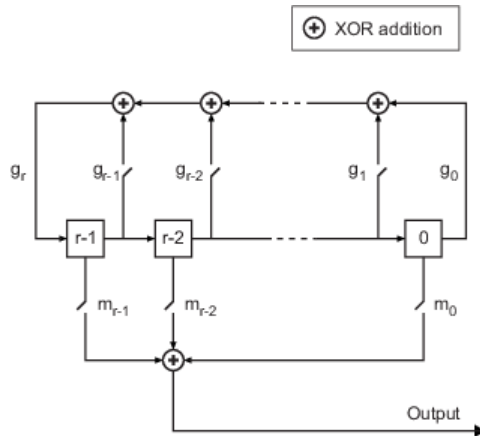

---

## Definition of Equivalent Mask

The equivalent mask for the shift  $s$  is the remainder after dividing the polynomial  $x^s$  by the primitive polynomial. The vector `mask` represents the remainder polynomial by listing the coefficients in order of descending powers.

## Shifts, Masks, and Pseudonoise Sequence Generators

Linear feedback shift registers are part of an implementation of a pseudonoise sequence generator. Below is a schematic diagram of a pseudonoise sequence generator. All adders perform addition modulo 2.

The primitive polynomial determines the state of each switch labeled  $g_k$ , and the mask determines the state of each switch labeled  $m_k$ . The lower half of the diagram shows the implementation of the shift, which delays the starting point of the output sequence. If the shift is zero, the  $m_0$  switch is closed while all other  $m_k$  switches are open. The table below indicates how the shift affects the shift register's output.

	<b>T = 0</b>	<b>T = 1</b>	<b>T = 2</b>	...	<b>T = s</b>	<b>T = s+1</b>
<b>Shift = 0</b>	$X_0$	$X_1$	$X_2$	...	$X_s$	$X_{s+1}$
<b>Shift = s &gt; 0</b>	$X_s$	$X_{s+1}$	$X_{s+2}$	...	$X_{2s}$	$X_{2s+1}$

If you have Communications Toolbox software and want to generate a pseudonoise sequence in a Simulink model, see the PN Sequence Generator block reference page.

## Examples

### Convert Shift to Mask

Convert a shift in a linear feedback shift register into an equivalent mask.

Convert a shift of 5 into the equivalent mask  $x^3 + x + 1$  for the linear feedback shift register whose connections are specified by the primitive polynomial  $x^4 + x^3 + 1$ . The length of the mask is equal to the degree of the primitive polynomial, 4.

```
mk = shift2mask([1 1 0 0 1],5)
```

```
mk = 1×4
```

```
    1    0    1    1
```

Convert a shift of 7 to a mask of  $x^4 + x^2$  for the primitive polynomial  $x^5 + x^2 + 1$ .

```
mk2 = shift2mask('x5+x2+1',7)
```

```
mk2 = 1×5
```

```
    1    0    1    0    0
```

# show

**Package:** comm

Show scope window

## Syntax

```
show(scope)
```

## Description

show(scope) shows the window of the System object scope.

## Examples

### Hide and Show Scope

Create a comm.ConstellationDiagram object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

### Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

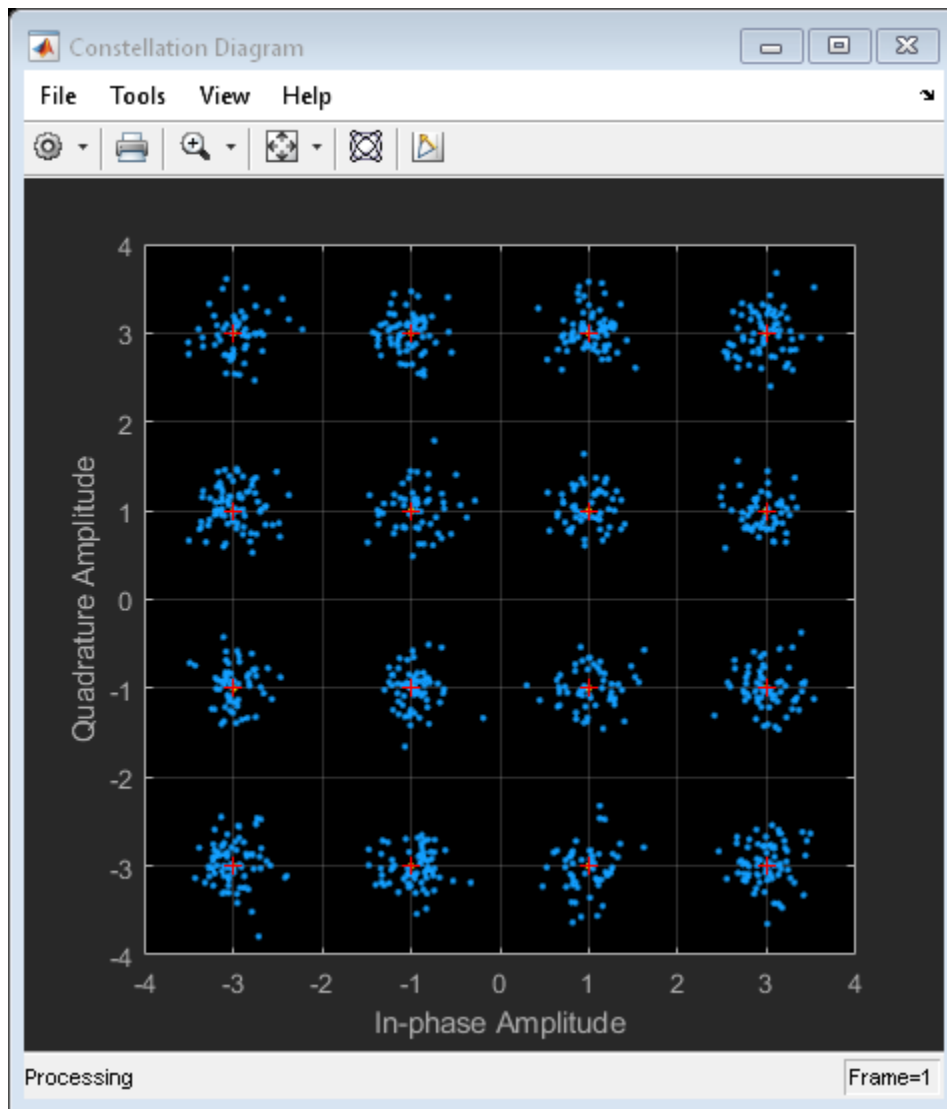

```
M = 16;
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4], 'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20, 'measured');
scope([sym rcv]);
```

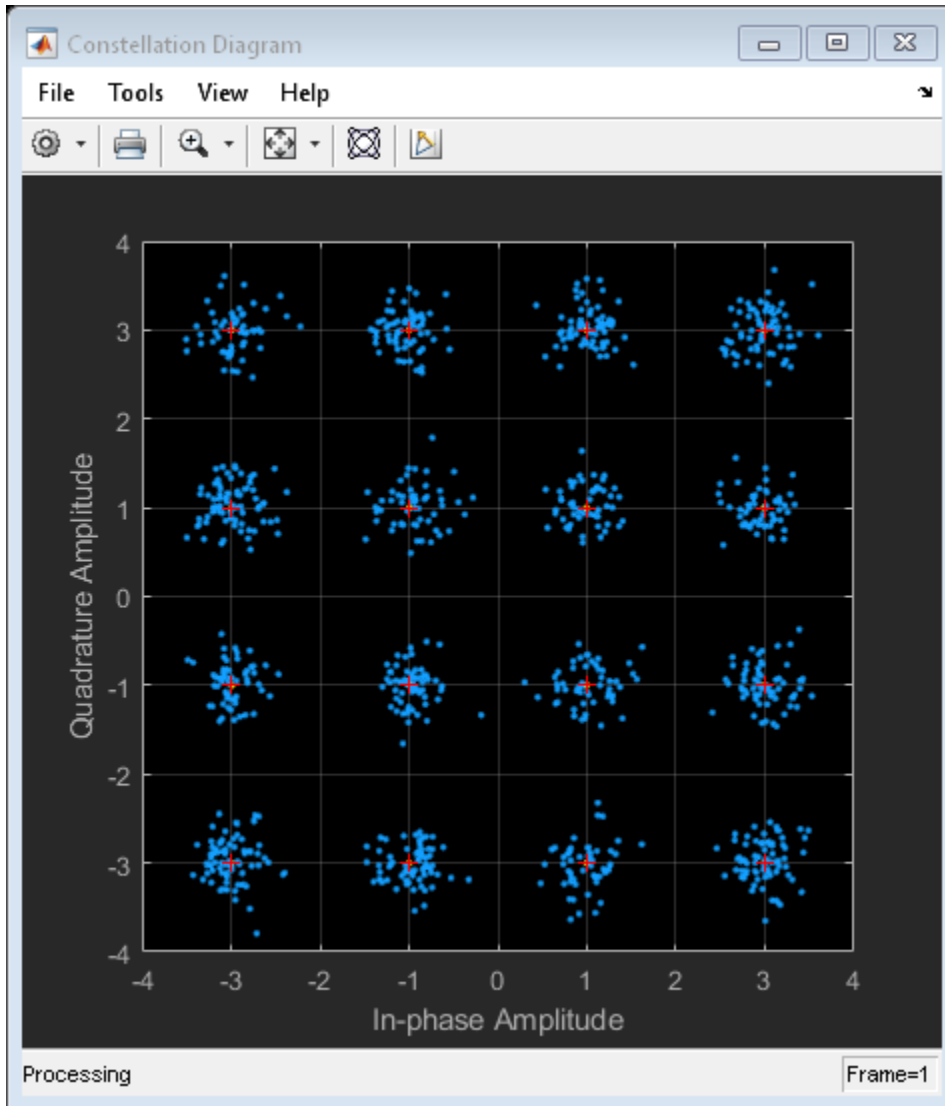

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

## Input Arguments

### **scope** — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` or `comm.EyeDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

# showcommblockdatatypetable

Communications Toolbox block characteristics

## Syntax

```
showcommblockdatatypetable
```

## Description

`showcommblockdatatypetable` shows a table of characteristics for the Communications Toolbox blocks. The table lists capabilities and limitations about code generation, variable size, and supported data types for each block. If a cell includes an "X", the corresponding block supports the capability indicated by the column heading. Descriptions for numbered footnotes, "(#)", follow the table.

## Examples

### Show Communications Toolbox Block Characteristics

Show a table of Communications Toolbox block characteristics. The table opens in a separate window.

```
showcommblockdatatypetable
```

```
Loading Communications Toolbox Library.
```

## signlms

(To be removed) Construct signed least mean square (LMS) adaptive algorithm object

---

**Note** will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

---

## Syntax

```
alg = signlms(stepsize)
alg = signlms(stepsize,algtype)
```

## Description

The `signlms` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = signlms(stepsize)` constructs an adaptive algorithm object based on the signed least mean square (LMS) algorithm with a step size of `stepsize`.

`alg = signlms(stepsize,algtype)` constructs an adaptive algorithm object of type `algtype` from the family of signed LMS algorithms. The table below lists the possible values of `algtype`.

Value of <code>algtype</code>	Type of Signed LMS Algorithm
'Sign LMS'	Sign LMS (default)
'Signed Regressor LMS'	Signed regressor LMS
'Sign Sign LMS'	Sign-sign LMS

## Properties

The table below describes the properties of the signed LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
AlgType	Type of signed LMS algorithm, corresponding to the <i>algtype</i> input argument. You cannot change the value of this property after creating the object.
StepSize	LMS step size parameter, a nonnegative real number
LeakageFactor	LMS leakage factor, a real number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.

## Examples

### Create a Linear Equalizer using Signed LMS Algorithm

This example shows to use a signed least mean square (LMS) algorithm to create an adaptive equalizer object.

Set the number of weights and the step size for the equalizer.

```
nWeights = 2;
stepSize = 0.05;
```

Create the adaptive algorithm object using the signed regressor LMS algorithm type.

```
alg = signlms(stepSize, 'Signed Regressor LMS');
```

Construct a linear equalizer using the algorithm object.

```
eqObj = lineareq(nWeights, alg)
```

```
eqObj =  
  
    EqType: 'Linear Equalizer'  
    AlgType: 'Signed Regressor LMS'  
    nWeights: 2  
    nSampPerSym: 1  
    RefTap: 1  
    SigConst: [-1 1]  
    StepSize: 0.0500  
    LeakageFactor: 1  
    Weights: [0 0]  
    WeightInputs: [0 0]  
    ResetBeforeFiltering: 1  
    NumSamplesProcessed: 0
```

## Algorithms

Referring to the schematics presented in “Equalization”, define  $w$  as the vector of all weights  $w_i$  and define  $u$  as the vector of all inputs  $u_i$ . Based on the current set of weights,  $w$ , this adaptive algorithm creates the new set of weights given by

- $(\text{LeakageFactor}) w + (\text{StepSize}) u^* \text{sgn}(\text{Re}(e))$ , for sign LMS
- $(\text{LeakageFactor}) w + (\text{StepSize}) \text{sgn}(\text{Re}(u)) \text{Re}(e)$ , for signed regressor LMS
- $(\text{LeakageFactor}) w + (\text{StepSize}) \text{sgn}(\text{Re}(u)) \text{sgn}(\text{Re}(e))$ , for sign-sign LMS

where the  $*$  operator denotes the complex conjugate and  $\text{sgn}$  denotes the signum function (`sign` in MATLAB technical computing software).

## Compatibility Considerations

### **signlms will be removed**

*Not recommended starting in R2019a*

`signlms` will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

# ssbdemod

Single sideband amplitude demodulation

## Syntax

```
z = ssbdemod(y,Fc,Fs)
z = ssbdemod(y,Fc,Fs,ini_phase)
z = ssbdemod(y,Fc,Fs,ini_phase,num,den)
```

## Description

### For All Syntaxes

`z = ssbdemod(y,Fc,Fs)` demodulates the single sideband amplitude modulated signal `y` from the carrier signal having frequency `Fc` (Hz). The carrier signal and `y` have sampling rate `Fs` (Hz). The modulated signal has zero initial phase, and can be an upper- or lower-sideband signal. The demodulation process uses the lowpass filter specified by `[num,den] = butter(5,Fc*2/Fs)`.

---

**Note** The `Fc` and `Fs` arguments must satisfy  $Fs > 2(Fc + BW)$ , where `BW` is the bandwidth of the original signal that was modulated.

---

`z = ssbdemod(y,Fc,Fs,ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = ssbdemod(y,Fc,Fs,ini_phase,num,den)` specifies the numerator and denominator of the lowpass filter used in the demodulation.

## Examples

## Demodulate Sideband Signal

Define the sampling frequency and original signal.

```
fs = 270000;  
t = (0:1/fs:0.01)';  
signal = sin(2*pi*300.*t)+2*sin(2*pi*600.*t);
```

Convert the original signal to upper-sideband and lower-sideband modulated signals using `ssbmod`. Use a cutoff frequency of 12000 and an initial phase of 0.

```
fc = 12000;  
initialPhase = 0;  
lowerSidebandSignal = ssbmod(signal,fc,fs,initialPhase);  
upperSidebandSignal = ssbmod(signal,fc,fs,initialPhase,'upper');
```

Demodulate the lower and upper sideband signals.

```
s1 = ssbdemod(lowerSidebandSignal,fc,fs);  
s2 = ssbdemod(upperSidebandSignal,fc,fs);
```

Compare processed signals with original and verify reconstruction.

```
plot(t,signal,'k',t,s1,'r:',t,s2,'g-.');  
legend('Original Signal','Demodulation of Lower Sideband','Demodulation of Upper Sideband');
```

## See Also

amdemod | ssbmod

## Topics

“Digital Modulation”

Introduced before R2006a

## ssbmod

Single sideband amplitude modulation

### Syntax

```
y = ssbmod(x,Fc,Fs)
y = ssbmod(x,Fc,Fs,ini_phase)
y = ssbmod(x,fc,fs,ini_phase,'upper')
```

### Description

`y = ssbmod(x,Fc,Fs)` uses the message signal `x` to modulate a carrier signal with frequency `Fc` (Hz) using single sideband amplitude modulation in which the lower sideband is the desired sideband. The generated output `y` is a single side band signal with a suppressed carrier. The carrier signal and `x` have sample frequency `Fs` (Hz). The modulated signal has zero initial phase.

`y = ssbmod(x,Fc,Fs,ini_phase)` specifies the initial phase of the modulated signal in radians.

`y = ssbmod(x,fc,fs,ini_phase,'upper')` uses the upper sideband as the desired sideband.

### Examples

#### Compare Double-Sideband and Single-Sideband Amplitude Modulation

Set the sample rate to 100 Hz. Create a time vector 100 seconds long.

```
fs = 100;
t = (0:1/fs:100)';
```

Set the carrier frequency to 10 Hz. Generate a sinusoidal signal.

```
fc = 10;  
x = sin(2*pi*t);
```

Modulate  $x$  using single- and double-sideband AM.

```
ydouble = ammod(x,fc,fs);  
ysingle = ssbmod(x,fc,fs);
```

Create a spectrum analyzer object to plot the spectra of the two signals. Plot the spectrum of the double-sideband signal.

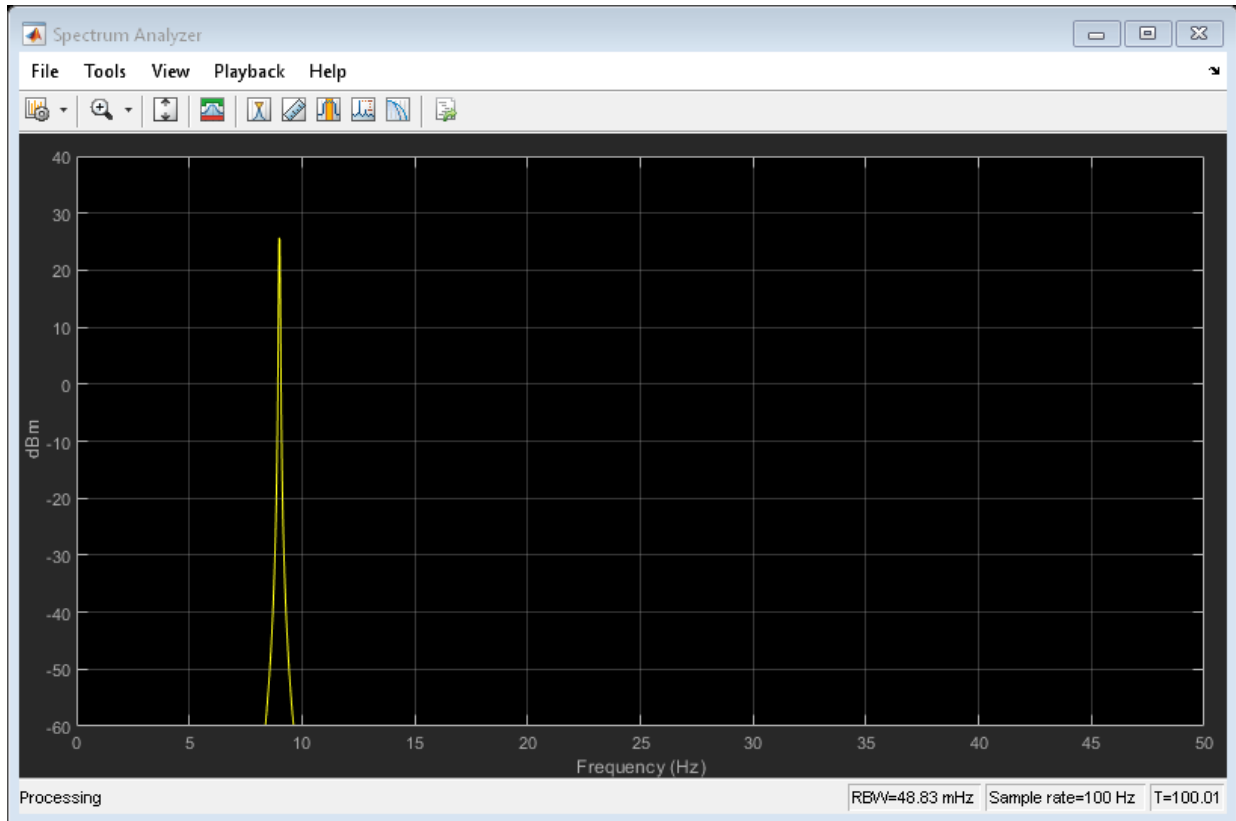

```
sa = dsp.SpectrumAnalyzer('SampleRate',fs, ...  
    'PlotAsTwoSidedSpectrum',false, ...  
    'YLimits',[-60 40]);  
step(sa,ydouble)
```

Plot the single-sideband spectrum.

```
step(sa,ysingle)
```

# stdchan

Construct channel System object from set of standardized channel models

## Syntax

```
chan = stdchan(chantype,rs,fd)
```

## Description

`chan = stdchan(chantype,rs,fd)` constructs a fading channel object `chan` according to the specified `chantype`. `chantype` is chosen from the channel models listed in “Supported Standards” on page 2-1105. `rs` is the sampling rate of the input signal and `fd` is the maximum Doppler shift.

## Examples

### Filter Signal Through CDMA Channel

Set the sample rate and the maximum Doppler shift.

```
rs = 20e6;  
fd = 3;
```

Create a CDMA Typical Urban channel model (TUx) channel object and turn on frequency response visualization.

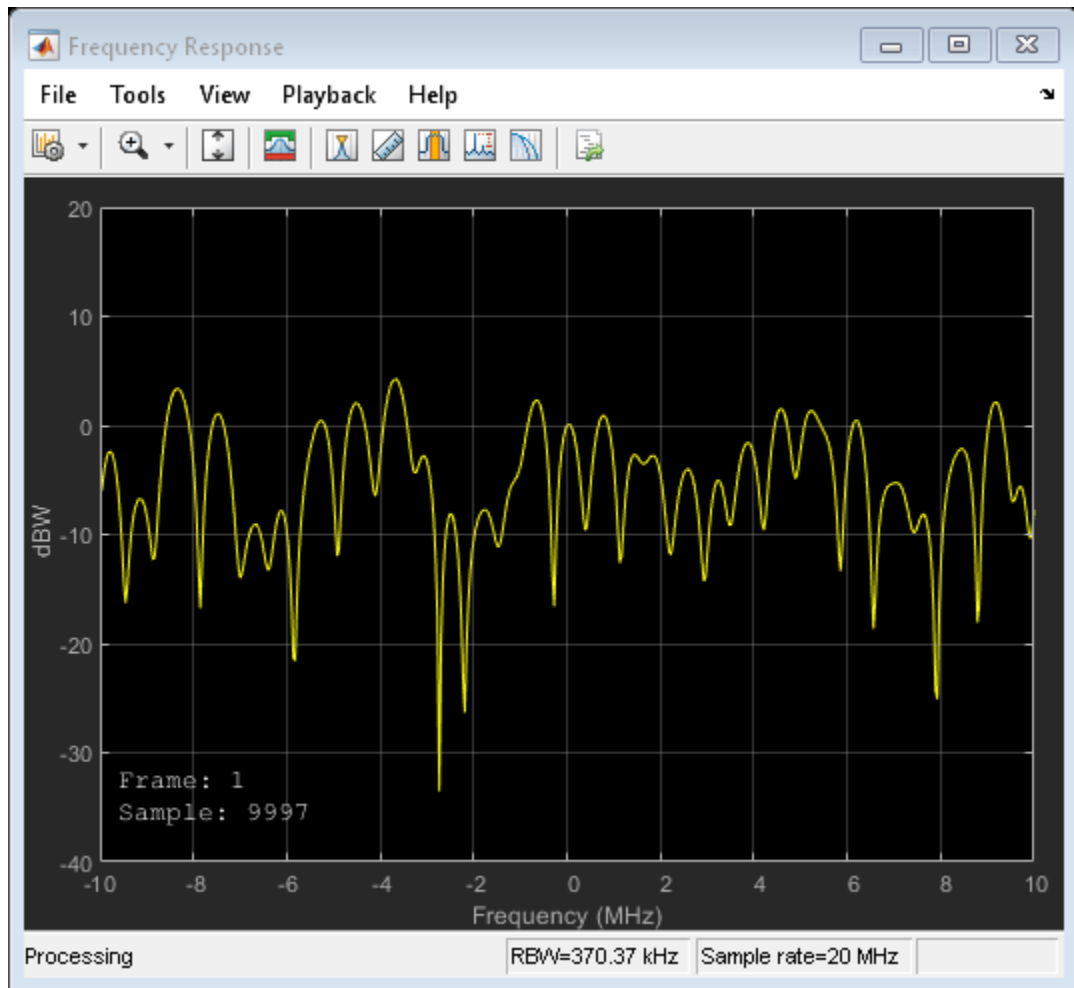

```
chan = stdchan('cdmaTUx',rs,fd);  
chan.Visualization = 'Frequency response';
```

Generate random data and apply QPSK modulation.

```
data = randi([0 3],10000,1);  
txSig = pskmod(data,4,pi/4);
```

Filter the QPSK signal through the CDMA channel.

```
y = chan(txSig);
```

### GSM and EDGE Channel Model

Create a channel model useful for GSM and EDGE simulations. Experiment with low speed and high speed conditions.

### Configure parameters and System objects

Frame configuration.

```
M = 8; % Modulation order, 8-PSK
Rbit = 9600; % Input bit rate
Rs = Rbit / log2(M); % Symbol rate
Nsamples = 5e2; % Number of samples per frame
Nframes = 10; % Number of frames
```

Speed and channel configuration.

```
v = 10 * 1e3/3600; % Mobile speed (m/s)
fc = 1800e6; % Carrier frequency
c = physconst('LightSpeed'); % Speed of light in free space
fd = v*fc/c; % Maximum Doppler shift of diffuse component
```

Create System objects for modulator and channel.

```
modulator = comm.PSKModulator(M,'PhaseOffset',0);

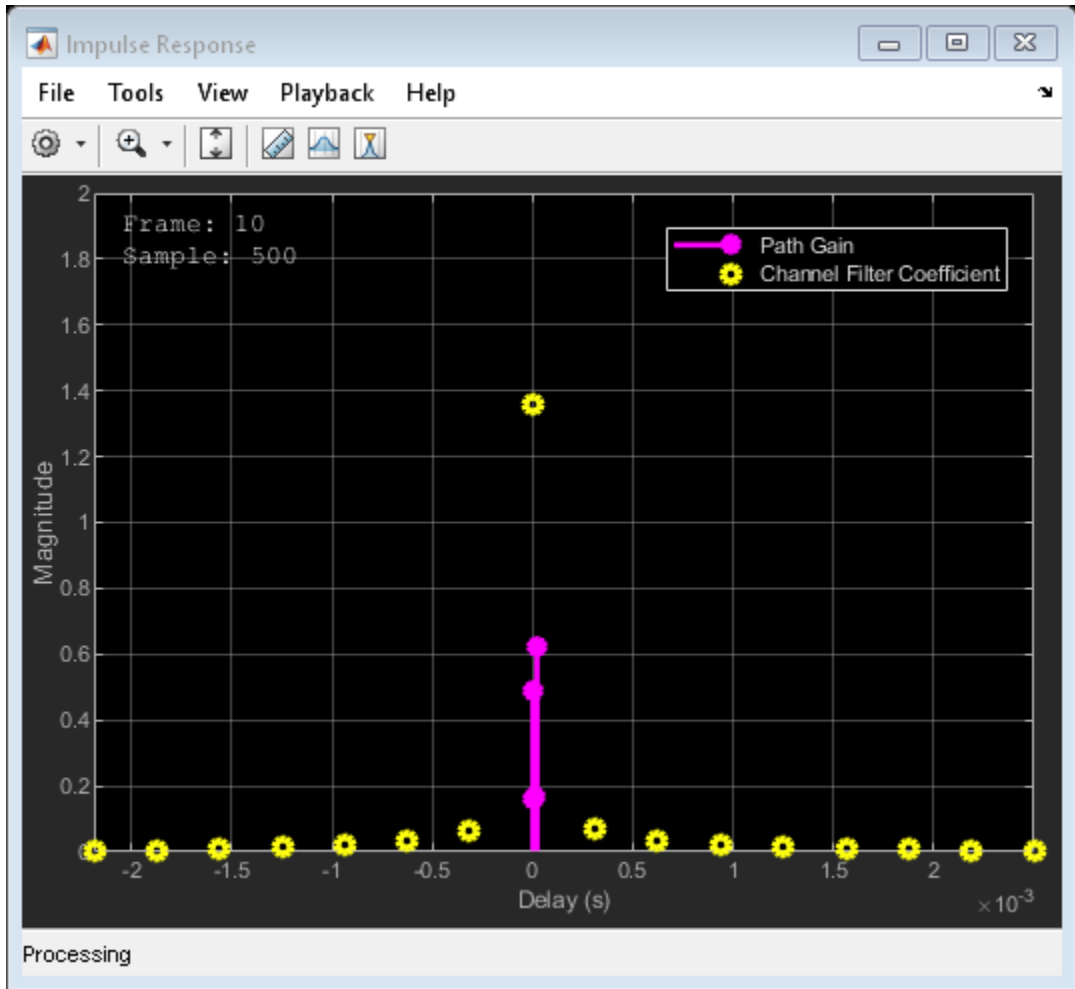

channel = stdchan('gsmeqx6',Rs,fd);
channel.RandomStream = 'mt19937ar with seed'; % set for reproducibility
channel.Visualization = 'Impulse and frequency responses';
channel.SamplesToDisplay = '100%';

refC = constellation(modulator);
constDiagram = comm.ConstellationDiagram( ...
    'ReferenceConstellation',refC, ...
    'XLimits',[-3 3],'YLimits',[-3 3]);
```

### Simulate at low speed

```
for iFrames = 1:Nframes
    msg = randi([0 M-1], Nsamples, 1);
    modSignal = modulator(msg);
    chanOut = channel(modSignal);
    constDiagram(chanOut);
end
```

### Simulate at high speed

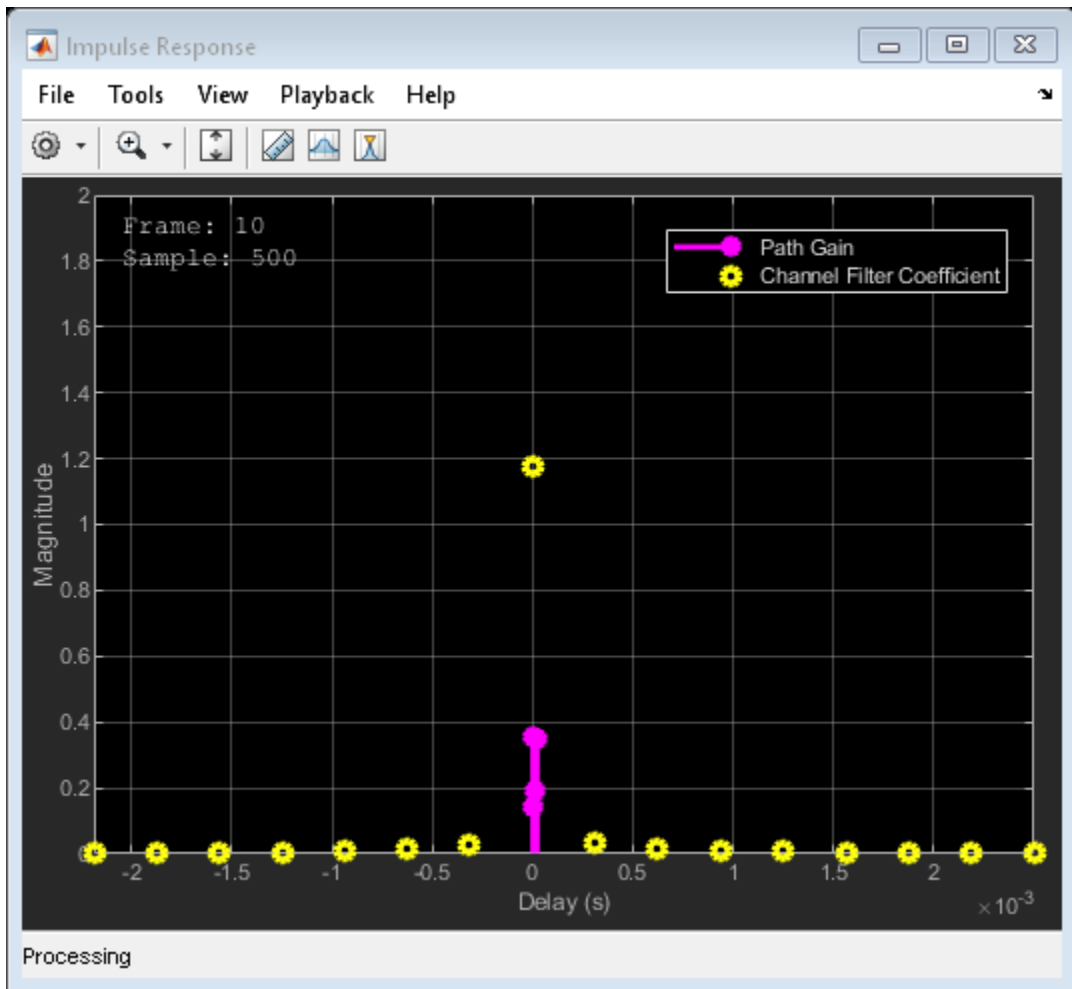

Release and reconfigure objects.

```
release(constDiagram);  
release(channel);
```

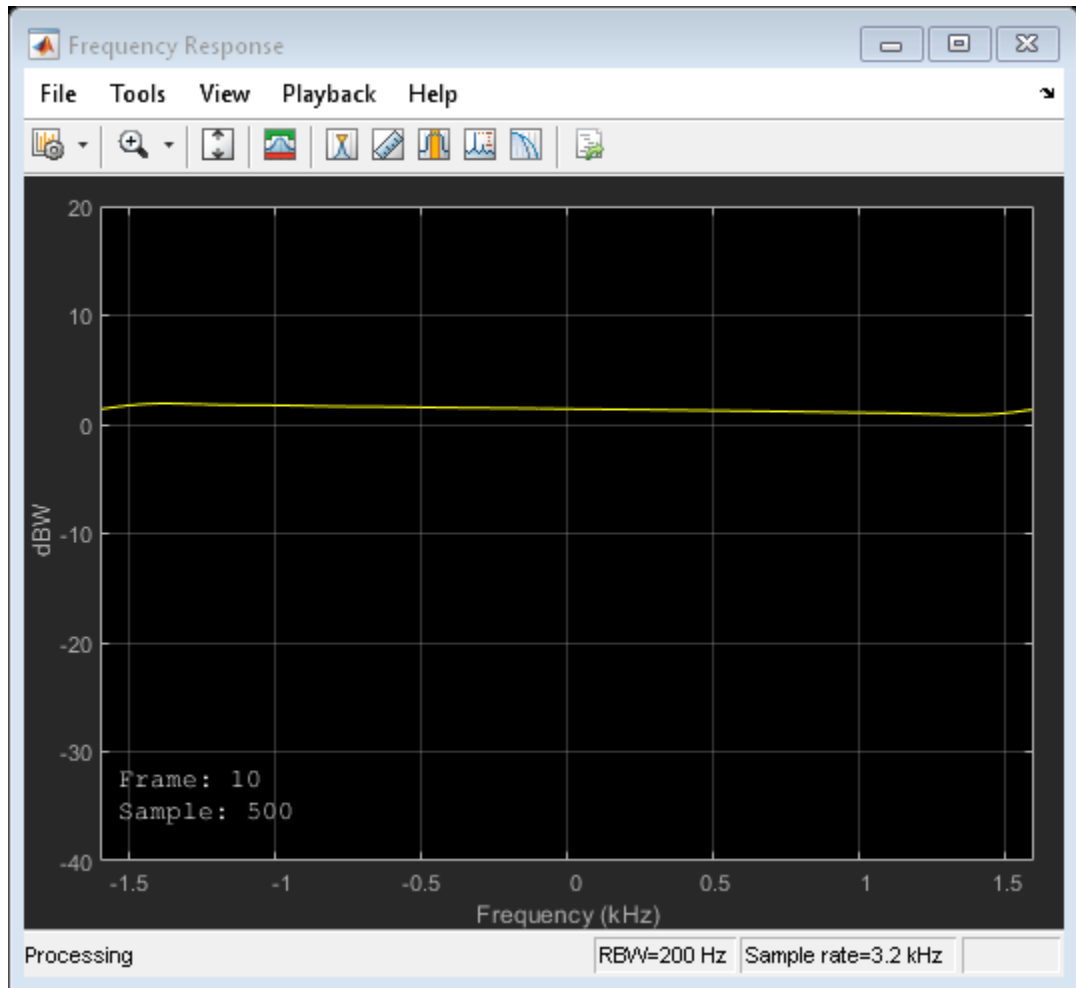

```
v = 120 * 1e3 / 3600; % Mobile speed (m/s)  
fd = v*fc/c; % Maximum Doppler shift of diffuse component
```

```
channel.MaximumDopplerShift = fd; % Adjust maximum doppler shift

for iFrames = 1:Nframes
    msg = randi([0 M-1], Nsamples, 1);
    modSignal = modulator(msg);
    chanOut = channel(modSignal);
    constDiagram(chanOut);
end
```

## Input Arguments

**chantype** — Channel type

string | character vector

Channel type, specified as a string or character vector. Valid options are listed in “Supported Standards” on page 2-1105.

Example: `stdchan('gsmRAx6c1', rs, fd)`, configures a channel model for the GSM typical case for rural area (RAx), 6 taps, case 1, with a sample rate `rs`, and maximum Doppler shift `fd`

Data Types: `char` | `string`

### **rs — Sample rate**

scalar

Sample rate in Hertz, specified as a scalar.

Data Types: `double`

### **fd — Maximum Doppler shift**

scalar

Maximum Doppler shift in Hertz, specified as a scalar.

Data Types: `double`

## **Output Arguments**

### **chan — Channel object**

System object

Channel object, returned as a `comm.RayleighChannel` or `comm.RicianChannel` System object.

## **More About**

### **Supported Standards**

For GSM, CDMA, and ITU-R HF standards, call `stdchan` to return a `comm.RayleighChannel` or `comm.RicianChannel` System object modeling one of these profiles.

GSM/EDGE channel models (3GPP TS 45.005 V7.9.0 (2007-2), 3GPP TS 05.05 V8.20.0 (2005-11)):

<b>Channel model</b>	<b>Profile</b>
gsmRAx6c1	Typical case for rural area (RAx), 6 taps, case 1
gsmRAx4c2	Typical case for rural area (RAx), 4 taps, case 2

## symerr

Compute number of symbol errors and symbol error rate

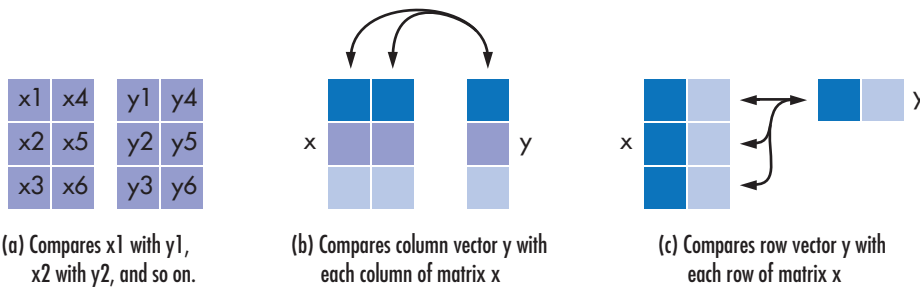

### Syntax

```
[number,ratio] = symerr(x,y)
[number,ratio] = symerr(x,y,flg)
[number,ratio,loc] = symerr(...)
```

### Description

#### For All Syntaxes

The `symerr` function compares binary representations of elements in `x` with those in `y`. The schematics below illustrate how the shapes of `x` and `y` determine which elements `symerr` compares.

The output number is a scalar or vector that indicates the number of elements that differ. The size of number is determined by the optional input `flg` and by the dimensions of `x` and `y`. The output ratio equals number divided by the total number of elements in the smaller input.

## For Specific Syntaxes

`[number, ratio] = symerr(x, y)` compares the elements in `x` and `y`. The sizes of `x` and `y` determine which elements are compared:

- If `x` and `y` are matrices of the same dimensions, then `symerr` compares `x` and `y` element by element. `number` is a scalar. See schematic (a) in the figure.
- If one is a row (respectively, column) vector and the other is a two-dimensional matrix, then `symerr` compares the vector element by element with *each row (resp., column)* of the matrix. The length of the vector must equal the number of columns (resp., rows) in the matrix. `number` is a column (resp., row) vector whose `m`th entry indicates the number of elements that differ when comparing the vector with the `m`th row (resp., column) of the matrix. See schematics (b) and (c) in the figure.

`[number, ratio] = symerr(x, y, flg)` is similar to the previous syntax, except that `flg` can override the defaults that govern which elements `symerr` compares and how `symerr` computes the outputs. The values of `flg` are 'overall', 'column-wise', and 'row-wise'. The table below describes the differences that result from various combinations of inputs. In all cases, `ratio` is `number` divided by the total number of elements in `y`.

**Comparing a Two-Dimensional Matrix  $x$  with Another Input  $y$**

Shape of $y$	flag	Type of Comparison	number
Two-dim. matrix	'overall' (default)	Element by element	Total number of symbol errors
	'column-wise'	mth column of $x$ vs. mth column of $y$	Row vector whose entries count symbol errors in each column
	'row-wise'	mth row of $x$ vs. mth row of $y$	Column vector whose entries count symbol errors in each row
Column vector	'overall'	$y$ vs. each column of $x$	Total number of symbol errors
	'column-wise' (default)	$y$ vs. each column of $x$	Row vector whose entries count symbol errors in each column of $x$
Row vector	'overall'	$y$ vs. each row of $x$	Total number of symbol errors
	'row-wise' (default)	$y$ vs. each row of $x$	Column vector whose entries count symbol errors in each row of $x$

`[number, ratio, loc] = symerr(...)` returns a binary matrix `loc` that indicates which elements of  $x$  and  $y$  differ. An element of `loc` is zero if the corresponding comparison yields no discrepancy, and one otherwise.

**Examples**

On the reference page for `biterr`, the last example uses `symerr`.

## Compare Elements of Matrix

### Compare Elements of Matrix with Another Matrix

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3x4
```

```

1     1     3     1
3     2     2     2
3     3     8     3
```

```
aMatrix = [1,1,1,1;2,2,2,2;3,3,3,3]
```

```
aMatrix = 3x4
```

```

1     1     1     1
2     2     2     2
3     3     3     3
```

```
[number1,ratio1] = symerr(x,aMatrix)
```

```
number1 = 3
```

```
ratio1 = 0.2500
```

### Compare Elements of Matrix with Row Vector

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3x4
```

```

1     1     3     1
3     2     2     2
3     3     8     3
```

```
aRowVector = [1,2,3,1]
```

```
aRowVector = 1x4
```

```

1     2     3     1
```

```
[number2, ratio2] = symerr(x, aRowVector)
```

```
number2 = 3×1
```

```
1  
3  
4
```

```
ratio2 = 3×1
```

```
0.2500  
0.7500  
1.0000
```

### Compare Elements of Matrix with Column Vector

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3×4
```

```
1    1    3    1  
3    2    2    2  
3    3    8    3
```

```
aColumnVector = [1;2;3]
```

```
aColumnVector = 3×1
```

```
1  
2  
3
```

```
[number3, ratio3] = symerr(x, aColumnVector)
```

```
number3 = 1×4
```

```
1    0    2    0
```

```
ratio3 = 1×4
```

```
0.3333      0      0.6667      0
```

## Use Alternative Type of Comparison

You can specify alternative comparison methods used by `symerr`. In this example, you use a flag to override the default row-by-row comparison. Notice that `number` and `ratio` are scalars.

```
format rat;  
[number,ratio,loc] = symerr([1 2; 3 4],[1 3], 'overall')
```

```
number =  
      3
```

```
ratio =  
      3/4
```

```
loc =  
      0      1  
      1      1
```

# syndtable

Produce syndrome decoding table

## Syntax

```
t = syndtable(h)
```

## Description

`t = syndtable(h)` returns a decoding table for an error-correcting binary code having codeword length  $n$  and message length  $k$ .  $h$  is an  $(n-k)$ -by- $n$  parity-check matrix for the code.  $t$  is a  $2^{n-k}$ -by- $n$  binary matrix. The  $r$ th row of  $t$  is an error pattern for a received binary codeword whose syndrome has decimal integer value  $r-1$ . (The syndrome of a received codeword is its product with the transpose of the parity-check matrix.) In other words, the rows of  $t$  represent the coset leaders from the code's standard array.

When converting between binary and decimal values, the leftmost column is interpreted as the *most* significant digit. This differs from the default convention in the `bi2de` and `de2bi` commands.

## Examples

An example is in “Decoding Table”.

## testconsole.Results

(To be removed) Gets results from test console simulations

### Compatibility

testconsole.Results will be removed in a future release. Use `comm.ErrorRate` or `bertool` instead. For more information, see “Compatibility Considerations” on page 2-1135.

### Description

The `getResults` method of the Error Rate Test Console returns an instance of a `testconsole.Results` object containing simulation results data. You use methods of the results object to retrieve and plot simulations results data.

### Properties

A `testconsole.Results` object has the properties shown in the following table. All properties are writable except for the ones explicitly noted otherwise.

Property	Description
TestConsoleName	Error Rate Test Console. This property is not writable.
System Under Test Name	Name of the system under test for which the Error Rate Test Console obtained results. This property is not writable.
IterationMode	Iteration mode the Error Rate Test Console used for obtaining results. This property is not writable.

Property	Description
TestPoint	Specify the name of the registered test point for which the results object parses results. The <code>getData</code> , <code>plot</code> , and <code>semilogy</code> methods of the Results object return data or create a plot for the test point that the TestPoint property specifies.
Metric	Specify the name of the test metric for which the results object parses results. The <code>getData</code> , <code>plot</code> , and <code>semilogy</code> methods of the Results object returns data or creates a plot for the metric that the Metric property specifies.
TestParameter1	Specifies the name of the first independent variable for which the results object parses results.
TestParameter2	Specifies the name of the second independent variable for which the results object parses results.

## Methods

A `testconsole.Results` object has the following methods.

### **getData**

`d = getData(r)` returns results data matrix,  $d$ , available in the results object  $r$ . The returned results correspond to the test point currently specified in the `TestPoint` property of  $r$ , and to the test metric currently specified in the `Metric` property of  $r$ .

If `IterationMode` is 'Combinatorial' then  $d$  is a matrix containing results for all the sweep values available in the test parameters specified in the `TestParameter1` and `TestParameter2` properties. The rows of the matrix correspond to results for all the sweep values available in `TestParameter1`. The columns of the matrix correspond to results for all sweep values available in `TestParameter2`. If more than two test parameters are registered to the Error Rate Test Console,  $d$  contains results

corresponding to the first value in the sweep vector of all parameters that are not `TestParameter1` or `TestParameter2`.

If `IterationMode` is 'Indexed', then  $d$  is a vector of results corresponding to each indexed combination of all the test parameter values registered to the Error Rate Test Console.

### **plot**

`plot(r)` creates a plot for the results available in the results object  $r$ . The plot corresponds to the test point and test metric, specified by the `TestPoint` and `Metric` properties of  $r$

If `IterationMode` is 'Combinatorial' then the plot contains a set of curves. The sweep values in `TestParameter1` control the x-axis and the number of sweep values for `TestParameter2` specifies how many curves the plot contains. If more than two test parameters are registered to the Error Rate Test Console, the curves correspond to results obtained with the first value in the sweep vector of all parameters that are not `TestParameter1`, or `TestParameter2`.

No plots are available when 'IterationMode' is 'Indexed'.

### **semilogy**

`semilogy(...)` is the same as `plot(...)`, except that the Y-Axis uses a logarithmic (base 10) scale.

### **surf**

`surf(r)` creates a 3-D, color, surface plot for the results available in the results object,  $r$ . The surface plot corresponds to following items:

- The test point you specify using the `TestPoint` property of the results object
- The test metric currently you specify in the `Metric` property of the results object

You can specify parameter/value pairs for the results object, which establishes additional properties of the surface plot.

When you select 'Combinatorial' for the `IterationMode`, the sweep values available in the test parameter you specify for the `TestParameter1` property control the x-axis of the

surface plot. The sweep values available in the test parameter you specify for the `TestParameter2` property control the y-axis.

If more than two test parameters are registered to the test console, the surface plot corresponds to the results obtained with the parameter sweep values previously specified with the `setParsingValues` method of the results object.

You display the current parsing values by calling the `getParsingValues` method of the results object. The parsing values default to the first value in the sweep vector of each test parameter. By default, the surf method ignores the parsing values for any parameters currently set as `TestParameter1` or `TestParameter2`.

No surface plots are available if the `IterationMode` is 'Indexed', when less than two registered test parameters exist, or `TestParameter2` is set to 'None'.

## **setParsingValues**

`setParsingValues(R, 'ParameterName1', 'Value1', ... 'ParameterName2', 'Value2', ...)` sets the parsing values to the values you specify using the parameter-value pairs. Parameter name inputs must correspond to names of registered test parameters, and value inputs must correspond to a valid test parameter sweep value.

You use this method for specifying single sweep values for test parameters that differ from the values for `TestParameter1` and `TestParameter2`. When you define this method, the results object returns the data values or plots corresponding to the sweep values you set for the `setParsingValues` method. The parsing values default to the first value in the sweep vector of each test parameter.

You display the current parsing values by calling the `getParsingValues` method of the results object. You may set parsing values for parameters in `TestParameter1` and `TestParameter2`, but the results object ignores the values when getting data or returning plots.

Parsing values are irrelevant when `IterationMode` is 'Indexed'.

## **getParsingValues**

`getParsingValues` displays the current parsing values for the Error Rate Test Console.

`s = getParsingValues(r)` returns a structure, `s`, with field names equal to the registered test parameter names and with values corresponding to the current parsing values.

Parsing values are irrelevant when `IterationMode` is 'Indexed'.

## Examples

### Error Rate Simulation Sweeps

The `commtest.ErrorRate` and `testconsole.Results` object packages will be removed in a future release. They can be used to perform parameter sweeps to analyze communication system performance. This example demonstrates a workflow that uses them and along with recommended alternate workflows.

### Multiple Parameter Sweep and Parallel Run using `commtest.ErrorRate`

Obtain bit error rate and symbol error rate of an M-PSK system for different modulation orders and `EbNo` values. System under test is `commtest.MPSKSystem`.

```
% Create an M-ary PSK system
systemUnderTest = commtest.MPSKSystem;
```

```
% Instantiate an Error Rate Test Console and attach the system
errorRateTester = commtest.ErrorRate(systemUnderTest);
```

Warning: `commtest.ErrorRate` will be removed in the future. Use `comm.ErrorRate` or `bertool`.

```
errorRateTester.SimulationLimitOption = 'Number of errors or transmissions';
errorRateTester.MaxNumTransmissions = 1e5;
```

```
% Set sweep values for simulation test parameters
setTestParameterSweepValues(errorRateTester, 'M', 2.^[1 2 3 4], 'EbNo', (-5:10))
```

```
% Register a test point
registerTestPoint(errorRateTester, 'MPSK_BER', 'TxInputBits', 'RxOutputBits')
```

```
% Get information about the simulation settings
info(errorRateTester)
```

```
Test console name:      commtest.ErrorRate
System under test name: commtest.MPSKSystem
```

```
Available test inputs:      NumTransmissions, RandomIntegerSource
Registered test inputs:    NumTransmissions
Registered test parameters: EbNo, M

### Multiple Parameter Sweep and Parallel Run using nested for loops and comm.ErrorRate

Run an error rate simulation over  $M=2.^{(1:4)}$  and  $E_b/N_0=-5:10$ . Use `comm.ErrorRate` to collect both bit error rate (BER) and symbol error rate (SER) data. Run the simulations to collect a minimum of 100 symbol errors or for a maximum of  $1e5$  symbols.

```
% Set the M sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester, 'M')
```

```
ans = 1x4
```

```
     2     4     8    16
```

```
MSweep = 2.^[1 2 3 4];

% Set EbNo sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester, 'EbNo')

ans = 1x16

    -5    -4    -3    -2    -1     0     1     2     3     4     5     6     7     8

EbNoSweep = -5:10;

% Set minimum number of errors same as the commtest.ErrorRate object
errorRateTester.MinNumErrors

ans = 100

minNumErrors = 100;

% Set maximum number of transmissions same as the commtest.ErrorRate
% object. In this example a transmission is a symbol.
errorRateTester.MaxNumTransmissions

ans = 100000

MaxNumTransmissions = 1e5;

% Set frame length same as the commtest.ErrorRate object
errorRateTester.FrameLength

ans = 500

frameLength = 500;

% Find out if there is a parallel pool and how many workers are available

```

### Multiple Variable Sweeps using BERTool

BERTool computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB® functions and Simulink® models or with theoretical closed-form expressions for selected types of communication systems. The `bertool` function opens the BERTool. Here BERTool is configured to call the simulation defined in the function `mpsksim` included below.

```
function [ber,numBits] = mpsksim(EbNo,minNumErrs,maxNumBits)
% Import the Java class for BERTool, so that you will be able to stop the simulation us
import com.mathworks.toolbox.comm.BERTool;
```

```
frameLength = 500;
```

```

M = 16; % Can be 2, 4, 8, 16
bitsPerSymbol = log2(M);

maxNumSymbols = maxNumBits/bitsPerSymbol;

SNR = EbNo + 10*log10(bitsPerSymbol);

% Initialize variables related to exit criteria.
numBitErrors = 0;
numSymbols = 0;

while (numBitErrors < minNumErrs) || (numSymbols < maxNumSymbols)

    % Check if the user clicked the Stop button of BERTool.
    if (BERTool.getSimulationStop)
        break;
    end

    % Generate frameLength source outputs
    txMsg = randi([0 M-1],frameLength,1);
    numSymbols = numSymbols+frameLength;

    % Modulate the data
    txOutput = pskmod(txMsg,M,0,'gray');
    % Pass data through an AWGN channel with current SNR value
    chnlOutput = awgn(txOutput,SNR,'measured',[],'dB');
    % Demodulate the data
    rxOutput = pskdemod(chnlOutput,M,0,'gray');

    % Convert symbol streams to bit streams
    bTx = de2bi(txMsg,bitsPerSymbol,'left-msb');
    bTx = bTx(:);
    bRx = de2bi(rxOutput,bitsPerSymbol,'left-msb');
    bRx = bRx(:);

    % Calculate number of bit errors
    numBitErrors = numBitErrors+sum(bTx~=bRx);
end

% Assign values to the output variables.
numBits = numSymbols*bitsPerSymbol;
ber = numBitErrors/numBits;

```

Configure BERTool as follows.

The screenshot shows the Bit Error Rate Analysis Tool window. The title bar reads "Bit Error Rate Analysis Tool". The menu bar includes "File", "Edit", "Window", and "Help". Below the menu bar is a table with the following columns: "Confidence Level", "Fit", "Plot", "BER Data Set",  $E_b/N_0$  (dB), BER, and # of Bits. The main area of the tool is divided into three tabs: "Theoretical", "Semianalytic", and "Monte Carlo". The "Monte Carlo" tab is selected. In this tab, there are several input fields and buttons:

- $E_b/N_0$  range:  dB
- Simulation MATLAB file or Simulink model:  - BER variable name:
- Simulation limits:
  - Number of errors:
  - or
  - Number of bits:
- At the bottom right, there are two buttons:  and .

Set  $M=2$  in the `mpsksim` function and click Run. Set the **BER Data Set** name to 'M=2'.

### Parallel SNR Sweep using BERTool

Using `parfor`, run each simulation point in parallel by configuring your simulation function similar to the `mpsksim_parfor` function included below. Since `parfor` cannot work with the Java class for BERTool, you will not be able to stop the simulation using the **Stop** button.

```
function [ber,numBits] = mpsksim_parfor(EbNo,minNumErrs,maxNumBits)

% Find out if there is a parallel pool and how many workers are available
if license('test','Distrib_Computing_Toolbox')
    p = gcp;

## Compatibility Considerations

### testconsole.Results will be removed

*Warns starting in R2019b*

testconsole.Results will be removed in a future release. Use `comm.ErrorRate` or `bertool` instead. The “Error Rate Simulation Sweeps” on page 2-1120 example demonstrates alternate workflows using `comm.ErrorRate` and `bertool`.

## tpcdec

Turbo product code (TPC) decoder

### Syntax

```

decoded = tpcdec(llr,N,K)
decoded = tpcdec(llr,N,K,S)
decoded = tpcdec(llr,N,K,S,maxnumiter)
decoded = tpcdec(llr,N,K,S,maxnumiter,earlyterm)
[decoded,actualnumiter] = tpcdec( ___ )

```

### Description

`decoded = tpcdec(llr,N,K)` performs 2-D TPC decoding on input log likelihood ratios, `llr`, using two linear block codes specified by codeword length `N` and message length `K`. For a description of 2-D TPC decoding, see “Algorithms” on page 2-1144.

`decoded = tpcdec(llr,N,K,S)` performs 2-D TPC decoding on the shortened `llr` using a 2-D TPC decoder specified by codeword length  $(N-K+S)$  and message length `S`.

`decoded = tpcdec(llr,N,K,S,maxnumiter)` performs 2-D TPC decoding for `maxnumiter` iterations. To use `maxnumiter` with full-length messages, specify `S` as empty, `[]`.

`decoded = tpcdec(llr,N,K,S,maxnumiter,earlyterm)` performs 2-D TPC decoding and terminates early if the calculated syndrome or parity-check of the component code evaluates to zero before `maxnumiter` decoding iterations. To use `maxnumiter` and `earlyterm` with full-length messages, specify `S` as empty, `[]`.

`[decoded,actualnumiter] = tpcdec( ___ )` also returns the actual number of decoding iterations after performing 2-D TPC decoding using any of the prior syntaxes.

### Examples

### Decode Using Full-Length TPC Codes

Decode an approximate log-likelihood ratio output signal from 16-QAM demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify the (N,K) code pairs to use for TPC encoding.

```
N = [32;16];  
K = [21;11];
```

Generate a column vector of random message bits and TPC-encode the message. Specify the message bits as a vector with length equal to the product of the elements in K.

```
msg = randi([0 1],prod(K),1);  
code = tpcenc(msg,N,K);
```

Apply 16-QAM modulation. Add AWGN to the signal. Demodulate the signal, outputting approximate LLRs.

```
M = 16;  
snr = 10;
```

```
txsig = qammod(code,M,'InputType','bit', ...  
    'UnitAveragePower',true);
```

```
rxsig = awgn(txsig,snr,'measured');
```

```
llr = qamdemod(rxsig,M,'OutputType','approxllr', ...  
    'UnitAveragePower',true,'NoiseVariance',10.^(-snr/10));
```

Perform TPC decoding using three iterations. Because the demodulator output is negative bipolar mapped and TPC decoder expects positive bipolar mapped input, the demodulated signal output must be negated at the decoder input. Check the number of bit errors in the decoded signal.

```
iterations = 3;  
decoded = tpcdec(-llr,N,K,[],iterations);
```

```
numerr = biterr(msg,decoded)
```

```
numerr = 0
```

## Decode Using Shortened TPC Codes

Decode a shortened TPC code. Apply QPSK modulation and output the approximate log-likelihood ratio signal obtained from QPSK demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify (N,K) code pairs and S for TPC encoding.

```
N = [32;32];
K = [21;26];
S = [19;24];
```

Generate a column vector of random message bits and TPC-encode the message. Specify the shortened message bits as a vector with length equal to the product of the elements in S.

```
msg = randi([0 1],prod(S),1);
code = tpcenc(msg,N,K,S);
```

Apply QPSK modulation. Add AWGN to the signal. Demodulate the signal and output approximate LLRs.

```
M = 4;
snr = 3;
```

```
txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);
```

```
rxsig = awgn(txsig,snr,'measured');
```

```
llr = qamdemod(rxsig,M,'OutputType','approxllr', ...
    'UnitAveragePower',true,'NoiseVariance',10.^(-snr/10));
```

Perform TPC decoding using two iterations. Because the demodulator output is negative bipolar mapped and TPC decoder expects positive bipolar mapped input, the demodulated signal output must be negated at the decoder input. Check the bit error rate of the decoded signal.

```
iterations = 2;
decoded = tpcdec(-llr,N,K,S,iterations);
```

```
[~,ber] = biterr(msg,decoded)
ber = 0.0066
```

### TPC Decoding with Shortening and Early Termination

Decode a shortened TPC code and specify early termination of decoding. Apply QPSK modulation and output the approximate log-likelihood ratio signal obtained from QPSK demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes. Specify (N,K) code pairs and S for TPC encoding, and a maximum of 10 decoding iterations. Perform QPSK modulation on the signal.

```
n = [64; 32];
k = [51; 26];
s = [49; 24];
maxnumiter = 10;
M = 4;

msg = randi([0 1],prod(s),1); % Random bits
code = tpcenc(msg,n,k,s);

txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);
```

Add noise to the transmitted signal.

```
snr = 5;
rxsig = awgn(txsig,snr,'measured');
```

Demodulate the received signal using approximate LLR demapping.

```
llr = qamdemod(rxsig,M,'OutputType', ...
    'approxllr','UnitAveragePower',true, ...
    'NoiseVariance',10.^(-snr/10));
```

Specify the maximum number of TPC decoding iterations and return the actual number of iterations performed. Early termination of the TPC decoding is on by default. Display the number of errors and the number of iterations performed.

```
[decoded,actualNumIter] = tpcdec(-llr,n,k,s,maxnumiter);
numErr = biterr(msg,decoded);
disp(['Terminated after ' num2str(actualNumIter) ' iterations.' ...
      ' Number of errors = ' num2str(numErr) '.']);
```

Terminated after 4 iterations. Number of errors = 0.

## Input Arguments

### **llr** — Log likelihood ratios

column vector

Log likelihood ratios, specified as a column vector.

- For full-length codes, the length of the input column vector is the product of the elements in  $N$ .
- For shortened codes, the length of the input column vector is the product of the elements in  $(N-K+S)$ .

Data Types: double | single

### **N** — Codeword length

two-element integer vector

Codeword length, specified as a two-element integer vector,  $[N_R; N_C]$ .  $N_R$  represents the number of rows in the product code matrix.  $N_C$  represents the number of columns in the product code matrix. For more information about  $N_R$  and  $N_C$ , see “Algorithms” on page 2-1144. For a list of valid  $(N(i), K(i))$  code pairs, see “More About” on page 2-1143.

Data Types: double

### **K** — Message length

two-element integer vector

Message length, specified as a two-element integer vector,  $[K_R; K_C]$ . For a full-length message, the input column vector containing the input LLRs is arranged into a  $K_R$ -by- $K_C$  matrix.  $K_R$  represents the number of rows in the message matrix.  $K_C$  represents the number of columns in the message matrix. For more information about  $K_R$  and  $K_C$ , see “Algorithms” on page 2-1144. For a list of valid  $(N(i), K(i))$  code pairs, see “More About” on page 2-1143.

Data Types: double

### **S — Shortened message length**

two-element integer vector

Shortened message length, specified as a two-element integer vector,  $[S_R; S_C]$ . For a shortened message, the input column vector containing the input LLRs is arranged into an  $S_R$ -by- $S_C$  matrix.  $S_R$  represents the number of rows in the matrix.  $S_C$  represents the number of columns in the matrix. For more information about  $S_R$  and  $S_C$ , see “Algorithms” on page 2-1144.

When you specify this parameter, specify  $N$  and  $K$  vectors for the full-length TPC codes that are shortened to  $(N(i) - K(i) + S(i), S(i))$  codes.

Data Types: double

### **maxnumiter — Maximum number of decoding iterations**

4 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: double

### **earlyterm — Enable early termination**

true (default) | false

Enable early termination of decoding, specified as a logical. When `earlyterm` is `true` the decoding terminates early if the calculated syndrome or parity-check of the component code evaluates to zero before `maxnumiter` decoding iterations.

Data Types: double

## **Output Arguments**

### **decoded — TPC decoded message**

column vector

TPC decoded message, returned as a column vector.

- For full-length codes, the length of the returned column vector is the product of the elements in  $K$ .

- For shortened codes, the length of the returned column vector is the product of the elements in  $S$ .

Data Types: logical

### **actualnumiter** – Actual number of decoding iterations

positive integer

Actual number of decoding iterations performed, returned as a positive integer.

Data Types: double

## More About

### Component Codes

This table lists the supported component code pairs for the row ( $N_R, K_R$ ) and column ( $N_C, K_C$ ) parameters.

- $N_R$  and  $K_R$  represent the number of rows in the product code matrix and message matrix, respectively.
- $N_C$  and  $K_C$  represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

Code type	Component Code Pairs( $N_R, K_R$ ) and ( $N_C, K_C$ )	Error-Correction Capability ( $T$ )

## Algorithms

Turbo product codes (TPC) are a form of concatenated codes used as forward error correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. For a detailed description, see [1] and [2]. This decoder implements an iterative soft input, soft output 2-D product code decoding, as

described in [2], using two “Linear Block Codes”. The decoder expects the soft bit log likelihood ratios (LLRs) obtained from digital demodulation as the input signal.

---

**Note** The TPC decoder expects a positive bipolar mapped input, specifically -1 mapped to 0 and +1 mapped to 1. The output from demodulators in the Communications Toolbox is negative bipolar mapping, specifically +1 mapped to 0 and -1 mapped to +1. Therefore, the LLR output from demodulators must be negated to provide the positive bipolar mapped input expected by the TPC decoder.

---

### TPC Decoding Full-Length Messages

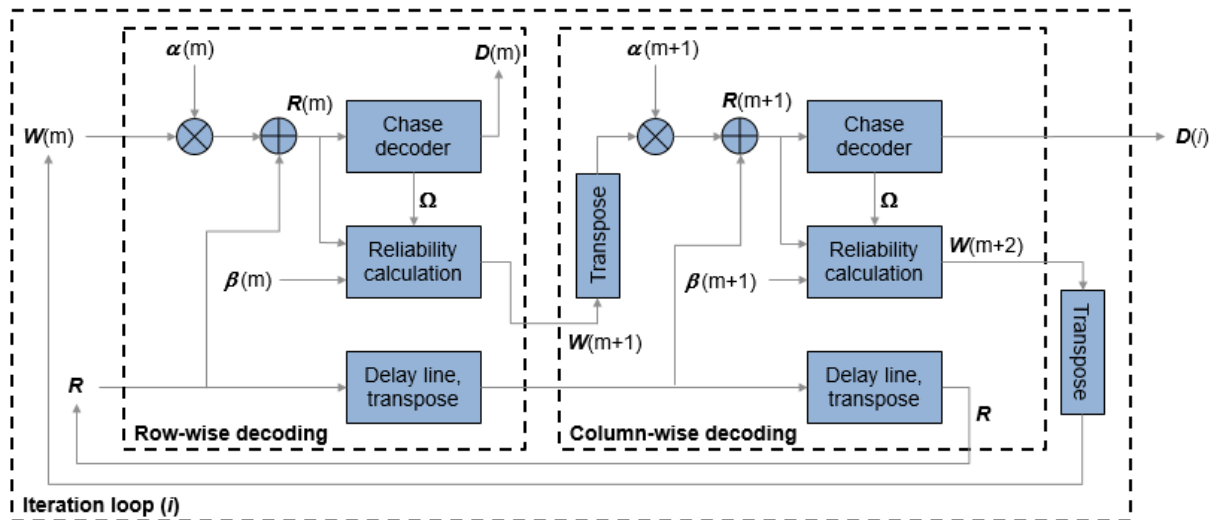

TPC encoded full-length input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the  $(N_C, K_C)$  code pair and column-wise decoding uses the  $(N_R, K_R)$  code pair. The input vector length must be  $N_R \times N_C$ . To perform the 2-D TPC decoding, the column vector of the input LLRs, composed of the message and parity bits, is arranged into an  $N_R$ -by- $N_C$  matrix.

The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. Chase decoding forms a set of possible codewords for each row or column. The Pyndiah algorithm calculates soft information required for the next decoding step.

### Iterative Soft Input, Soft Output Decoder

The iterative soft input, soft output decoding, as shown in the block diagram, carries out two decoding steps for each iteration.

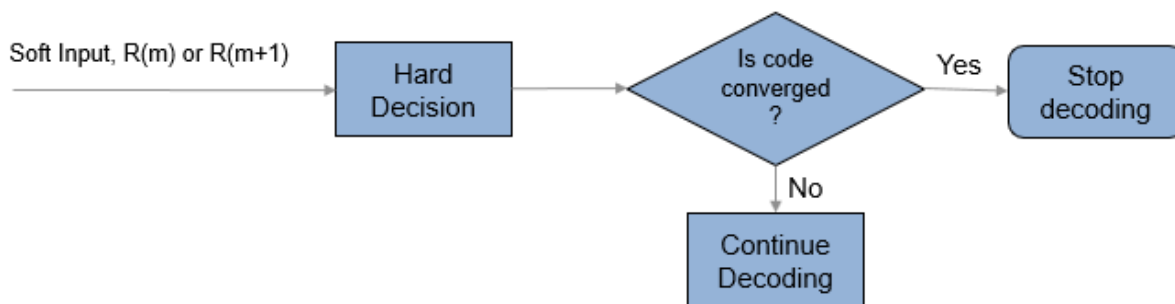

The soft inputs for decoding are  $\mathbf{R}(m) = \mathbf{R} + \alpha(m)\mathbf{W}(m)$ .

- Iteration loop counter  $i$  increments from  $i = 1$  to the specified number of iterations.
- $m = 2i - 1$  is the decoding step index.
- $\mathbf{R}$  is the received LLR matrix.
- $\mathbf{R}(m)$  is the soft input for the  $m$ th decoding step.
- $\mathbf{W}(m)$  is the input extrinsic information for the  $m$ th decoding step.
- $\alpha(m) = [0, 0.2, 0.3, 0.5, 0.7, 0.9, 1, 1, \dots]$ , where  $\alpha$  is a weighting factor applied based on the decoding step index. For higher decoding steps,  $\alpha = 1$ .
- $\beta(m) = [0.2, 0.4, 0.6, 0.8, 1, 1, \dots]$ , where  $\beta$  is a reliability factor applied based on the decoding step index. For higher decoding steps,  $\beta = 1$ .
- $\mathbf{D}$  contains the decoded message bits. The output message bits are formed from  $\mathbf{D}$  by mapping  $-1$  to  $0$  and  $+1$  to  $1$ , then reshaping the message block into a column vector.

The output message bits are formed after iterating through the specified number of iterations, or, if early termination is enabled, after code convergence.

### Early Termination of TPC Decoding

If early termination is enabled, a code convergence check is performed on the hard decision of the soft input in each row-wise and column-wise decoding step. Early termination can be triggered after either the row-wise decoding or column-wise decoding converges.

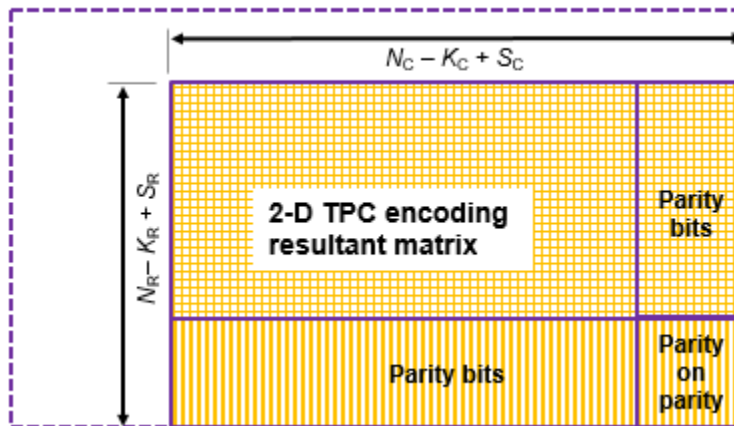

The code is converged if, for all rows or all columns,

- The syndrome evaluates to zero in the codes (Hamming codes, Extended Hamming codes, BCH codes, or Extended BCH codes).
- The parity check is evaluated to zero in parity check codes.

The reported number of iterations evaluates to the iteration value that is currently in progress. For example, if the code convergence check is satisfied after row-wise decoding in the third iteration (after 2.5 decoding steps), then the number of iteration returned is 3.

### TPC Decoding Shortened Messages

TPC encoded shortened input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the  $(N_C - K_C + S_C, S_C)$  code pair and column-wise decoding uses the  $(N_R - K_R + S_R, S_R)$  code pair. The input vector length must be  $(N_R - K_R + S_R) \times (N_C - K_C + S_C)$ . To perform the 2-D TPC decoding of shortened messages, the column vector of the input LLRs, composed of the shortened message and parity bits, is arranged into an  $(N_R - K_R + S_R)$ -by- $(N_C - K_C + S_C)$  matrix.

The TPC decoder processes the received shortened message LLRs similar to full length codes, with these exceptions:

- The shortened bit positions in the received codeword are set to -1.
- The Chase algorithm does not consider the shortened bit positions while choosing the least reliable bits.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- TPC parameters N, K, and S must be constant values. If the value used for each of these parameters does not change, then you can assign them by expression or variable.

### Blocks

TPC Decoder

**Introduced in R2018a**

# tpcenc

Turbo product code (TPC) encoder

## Syntax

```
code = tpcenc(msg,N,K)
code = tpcenc(msg,N,K,S)
```

## Description

`code = tpcenc(msg,N,K)` performs 2-D TPC encoding of the input message, `msg`, using two linear block codes specified by codeword length `N` and message length `K`. For a description of 2-D TPC encoding, see “Algorithms” on page 2-1155.

`code = tpcenc(msg,N,K,S)` performs 2-D TPC encoding on the shortened input message of length `S`, using a 2-D TPC encoder specified by codeword length  $(N-K+S)$  and message length `S`.

## Examples

### Encode Using Full-Length TPC Codes

Encode a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify  $(N,K)$  code pairs for TPC encoding.

```
N = [32;64];
K = [21;57];
```

Generate a column vector of random message bits. The desired length for the message bits is the product of elements in `K`.

```
msg = randi([0 1],prod(K),1);
```

TPC-encode the message.

```
code = tpcenc(msg,N,K);
```

Verify that the length of the encoded codeword is the product of elements in N.

```
size(code)
```

```
ans = 1×2
```

```
    2048         1
```

```
prod(N)
```

```
ans = 2048
```

### Encode Shortened Message Using Turbo Product Coding

Encode a random bit vector using 2-D turbo product coding (TPC), applying message shortening.

Specify (N,K) code pairs and S for TPC encoding.

```
N = [32;64];
```

```
K = [21;57];
```

```
S = [19;24];
```

Generate a column vector of random message bits. The desired length for the shortened message bits is the product of the elements in S.

```
msg = randi([0 1],prod(S),1);
```

TPC-encode the shortened message.

```
code = tpcenc(msg,N,K,S);
```

Verify that the length of the encoded codeword is the product of elements in (N-K+S).

```
size(code)
```

```
ans = 1×2
```

```
930      1
```

```
prod(N-K+S)
```

```
ans = 930
```

## Input Arguments

### **msg** — Input message bits to encode

column vector

Input message bits to encode, specified as a column vector.

- For a full-length input messages, the length of the column vector must be the product of the elements in  $K$ .
- For a shortened input messages, the length of the column vector must be the product of the elements in  $S$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

### **N** — Codeword length

two-element integer vector

Codeword length, specified as a two-element integer vector,  $[N_R; N_C]$ .  $N_R$  represents the number of rows in the product code matrix.  $N_C$  represents the number of columns in the product code matrix. For more information about  $N_R$  and  $N_C$ , see “Algorithms” on page 2-1155. For a list of valid  $(N(i),K(i))$  code pairs, see “Component Codes” on page 2-1153.

Data Types: `double`

### **K** — Message length

two-element integer vector

Message length, specified as a two-element integer vector,  $[K_R; K_C]$ . For a full-length message, the input column vector containing the message bits to encode is arranged into a  $K_R$ -by- $K_C$  matrix.  $K_R$  represents the number of rows in the message matrix.  $K_C$  represents the number of columns in the message matrix. For more information about  $K_R$  and  $K_C$ , see “Algorithms” on page 2-1155. For a list of valid  $(N(i),K(i))$  code pairs, see “Component Codes” on page 2-1153.

Data Types: double

### **S — Shortened message length**

two-element integer vector

Shortened message length, specified as a two-element integer vector,  $[S_R; S_C]$ . For a shortened message, the input column vector containing the message bits to encode is arranged into an  $S_R$ -by- $S_C$  matrix.  $S_R$  represents the number of rows in the matrix.  $S_C$  represents the number of columns in the matrix. For more information about  $S_R$  and  $S_C$ , see “Algorithms” on page 2-1155.

When you specify this parameter, specify  $N$  and  $K$  vectors for the full-length TPC codes that are shortened to  $(N(i)-K(i)+S(i), S(i))$  codes.

Data Types: double

## **Output Arguments**

### **code — TPC-encoded message**

column vector

TPC-encoded message, returned as a column vector with the same data type as the input message bits.

- For full-length input messages, the length of the returned column vector is the product of the elements in  $N$ .
- For shortened input messages, the length of the returned column vector is the product of the elements in  $(N-K+S)$ .

## **More About**

### **Component Codes**

This table lists the supported component code pairs for the row  $(N_R, K_R)$  and column  $(N_C, K_C)$  parameters.

- $N_R$  and  $K_R$  represent the number of rows in the product code matrix and message matrix, respectively.

- $N_C$  and  $K_C$  represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

## Algorithms

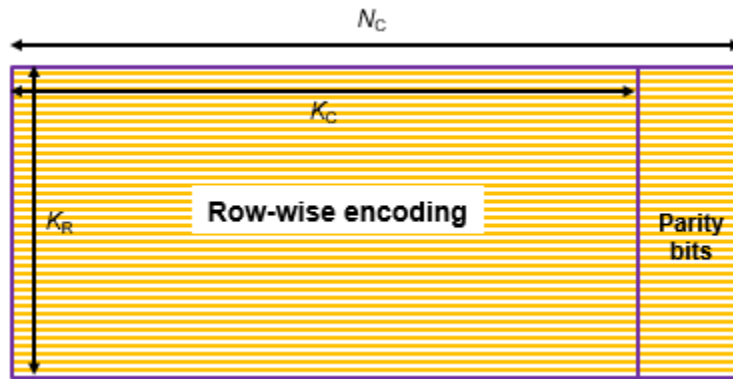

Turbo product codes (TPC) are a form of concatenated codes used as forward error-correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. This encoder implements 2-D product code encoding, as described in [1], using two “Linear Block Codes”.

### Construction of Full-Length Message Product Codes

Full-length input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the  $(N_C, K_C)$  code pair and column-wise encoding uses the  $(N_R, K_R)$  code pair. The input vector length must be  $K_R \cdot K_C$ . The input message bits vector is arranged into a  $K_R$ -by- $K_C$  matrix.

Row-wise encoding uses an  $(N_C, K_C)$  systematic linear block encoder with  $K_C$  bits per row. The row-wise encoding results in a  $K_R$ -by- $N_C$  matrix that includes parity bits added to each row.

Next, column-wise encoding uses an  $(N_R, K_R)$  systematic linear block encoder on each of the  $N_C$  columns. Applying this 2-D TPC encoding to the initial  $K_R$ -by- $K_C$  matrix results in an  $N_R$ -by- $N_C$  matrix that includes parity bits added to each row and column.

The 2-D TPC full-code matrix is reshaped into a column vector of length  $N_R \cdot N_C$  and returned as the TPC-encoded output.

### Construction of Shortened Message Product Codes

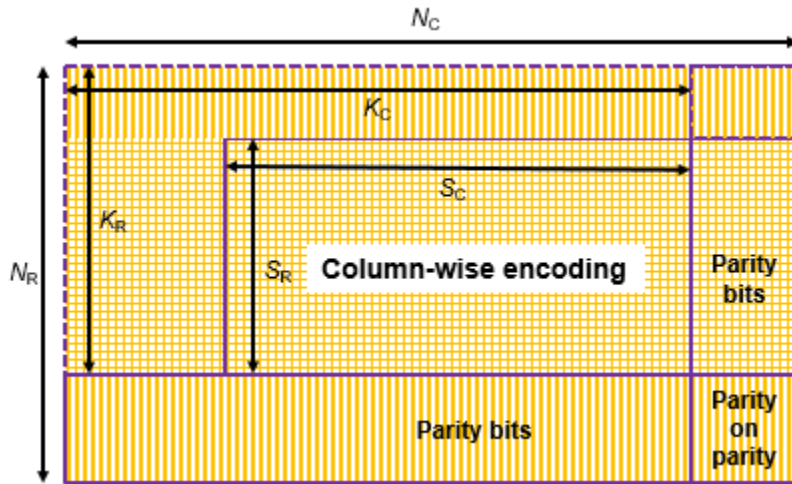

Shortened input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the  $(N_C, K_C)$  code pair and column-wise encoding uses an  $(N_R, K_R)$  code pair. The input vector length must be  $S_R \cdot S_C$ . The input shortened message bits vector is arranged into an  $S_R$ -by- $S_C$  matrix. The shortened message matrix prepends two dimensions by padding the beginning of the message matrix with zeros. The resulting matrix is a  $K_R$ -by- $K_C$  matrix.

Row-wise encoding uses an  $(N_C, K_C)$  systematic linear block encoder with  $K_C$  bits per row. The row-wise encoding results in a  $K_R$ -by- $N_C$  matrix that includes parity bits added to each row.

Next, the column-wise encoding uses an  $(N_R, K_R)$  systematic linear block encoder on each of the  $N_C$  columns.

Applying this 2-D TPC encoding to the initial  $K_R$ -by- $K_C$  matrix and excluding the zero-padded bits from the output results in an  $(N_R - K_R + S_R)$ -by- $(N_C - K_C + S_C)$  matrix. This matrix includes parity bits added to each row and column.

The 2-D TPC shortened-code matrix is reshaped into a column vector of length  $(N_R - K_R + S_R) \cdot (N_C - K_C + S_C)$  and returned as the TPC-encoded output.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- TPC parameters N, K, and S must be constant values. If the value used for each of these parameters does not change, then you can assign them by expression or variable.

TPC Encoder

**Introduced in R2018a**

## varlms

(To be removed) Construct variable-step-size least mean square (LMS) adaptive algorithm object

---

**Note** will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

---

## Syntax

```
alg = varlms(initstep,incstep,minstep,maxstep)
```

## Description

The `varlms` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = varlms(initstep,incstep,minstep,maxstep)` constructs an adaptive algorithm object based on the variable-step-size least mean square (LMS) algorithm. `initstep` is the initial value of the step size parameter. `incstep` is the increment by which the step size changes from iteration to iteration. `minstep` and `maxstep` are the limits between which the step size can vary.

## Properties

The table below describes the properties of the variable-step-size LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
<code>AlgType</code>	Fixed value, 'Variable Step Size LMS'

Property	Description
LeakageFactor	LMS leakage factor, a real number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.
InitStep	Initial value of step size when the algorithm starts
IncStep	Increment by which the step size changes from iteration to iteration
MinStep	Minimum value of step size
MaxStep	Maximum value of step size

Also, when you use this adaptive algorithm object to create an equalizer object (via the `lineareq` or `dfe` function), the equalizer object has a `StepSize` property. The property value is a vector that lists the current step size for each weight in the equalizer.

## Algorithms

Referring to the schematics presented in “Equalization”, define  $w$  as the vector of all current weights  $w_i$  and define  $u$  as the vector of all inputs  $u_i$ . Based on the current step size,  $\mu$ , this adaptive algorithm first computes the quantity

$$\mu_0 = \mu + (\text{IncStep}) \text{Re}(g g_{\text{prev}})$$

where  $g = u e^*$ ,  $g_{\text{prev}}$  is the analogous expression from the previous iteration, and the  $*$  operator denotes the complex conjugate.

Then the new step size is given by

- $\mu_0$ , if it is between `MinStep` and `MaxStep`
- `MinStep`, if  $\mu_0 < \text{MinStep}$
- `MaxStep`, if  $\mu_0 > \text{MaxStep}$

The new set of weights is given by

$$(\text{LeakageFactor}) w + 2 \mu g^*$$

## Compatibility Considerations

### **varlms will be removed**

*Not recommended starting in R2019a*

varlms will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

# vec2mat

Convert vector to matrix

## Syntax

```
mat = vec2mat(vec,matcol)
mat = vec2mat(vec,matcol,padding)
[mat,padded] = vec2mat( ___ )
```

## Description

`mat = vec2mat(vec,matcol)` converts vector `vec` to matrix `mat` with `matcol` columns. The function creates the matrix one row at a time, filling the rows with elements from `vec` in order. If the length of `vec` is not a multiple of `matcol`, then the function pads the last row of `mat` with zeros until the row contains `matcol` elements.

`mat = vec2mat(vec,matcol,padding)` specifies values for the function to use to pad the last row of `mat`. The function uses the value from `padding` in order.

`[mat,padded] = vec2mat( ___ )` also returns `padded`, the number of padded elements in the last row of `mat`. You can specify any of the input argument combinations from previous syntaxes.

---

**Note** `vec2mat` is similar to the MATLAB function `reshape`. However, given a vector input, `reshape` creates its corresponding matrix one column at a time (instead of one row at a time). Also, `reshape` requires its input and output arrays to have the same number of elements, whereas `vec2mat` pads its output matrix if necessary.

---

## Examples

### Convert Vector to Matrix

Create a five-element numeric vector.

```
vec = [1,2,3,4,5];
```

Convert the vector to two-column matrix. Repeat the conversion for a three-column and a four-column matrix respectively. Display each resulting matrix.

```
twoColumnMatrix = vec2mat(vec,2)
```

```
twoColumnMatrix = 3×2
```

```
1    2
3    4
5    0
```

```
threeColumnMatrix = vec2mat(vec,3)
```

```
threeColumnMatrix = 2×3
```

```
1    2    3
4    5    0
```

```
fourColumnMatrix = vec2mat(vec,4)
```

```
fourColumnMatrix = 2×4
```

```
1    2    3    4
5    0    0    0
```

### Convert Vector to Matrix with Nonzero Padding

Create a five-element numeric vector.

```
vec = 1:5;
```

Specify a nonzero padding value. Convert the vector to a four-column matrix, specifying the nonzero padding value.

```
paddingValue = NaN;
mat = vec2mat(vec,4,paddingValue)
```

```
mat = 2×4
```

```

1     2     3     4
5   NaN   NaN   NaN

```

Specify another nonzero padding value.

```
paddingValue = [10,8,6;9,7,5]
```

```
paddingValue = 2×3
```

```

10     8     6
 9     7     5

```

Convert the vector to a three-column and a four-column matrix respectively, specifying the nonzero padding values.

```
mat2 = vec2mat(vec,3,paddingValue)
```

```
mat2 = 2×3
```

```

1     2     3
4     5    10

```

```
mat3 = vec2mat(vec,4,paddingValue)
```

```
mat3 = 2×4
```

```

1     2     3     4
5    10     9     8

```

### Return Number of Padded Elements from Output Matrix

Create a five-element numeric vector and a matrix of padding values.

```
vec = [1;2;3;4;5];
padding = [2,4;6,4];
```

Convert the vector to a two-column matrix, specifying the padding values and returning the number of padded elements. Repeat the conversion for a three-column and a four-column matrix, respectively. Display each resulting matrix.

```
[mat2,numPadded2] = vec2mat(vec,2,padding)
```

```
mat2 = 3×2
```

```
    1    2  
    3    4  
    5    2
```

```
numPadded2 = 1
```

```
[mat3,numPadded3] = vec2mat(vec,3,padding)
```

```
mat3 = 2×3
```

```
    1    2    3  
    4    5    2
```

```
numPadded3 = 1
```

```
[mat4,numPadded4] = vec2mat(vec,4,padding)
```

```
mat4 = 2×4
```

```
    1    2    3    4  
    5    2    6    4
```

```
numPadded4 = 3
```

## Input Arguments

### **vec** — Input array

vector

Input array, specified as a vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Complex Number Support: Yes

### **matcol** — Number of columns

positive integer

Number of columns for the output matrix `mat`, specified as a positive integer. If the length of `vec` is not a multiple of `matcol`, then the function pads the last row of `mat` with zeros until the row contains `matcol` elements.

Data Types: `double`

### **padding** — Padding values

`vector` | `matrix`

Padding values for the last row of `mat`, specified as a vector or matrix. The `padding` input inherits the data type of the `vec` input. The function uses the values from `padding` in order. If `padding` has fewer elements than what the function needs to complete the last row of `mat`, then the function repeats the last element of `padding` until `mat` is full.

## Output Arguments

### **mat** — Output array

`matrix`

Output array, returned as a matrix with elements from `vec` and having `matcol` columns. The output inherits the data type of the input. The number of rows is equal to `ceil(length(vec)/matcol)`.

### **padded** — Number of padded elements

`positive integer`

Number of padded elements in the last row of `mat`, returned as a positive integer.

## vitdec

Convolutionally decode binary data using Viterbi algorithm

### Syntax

```
decoded = vitdec(code,trellis,tblen,opmode,dectype)
decoded = vitdec(code,trellis,tblen,opmode,'soft',nsdec)
decoded = ...
vitdec(code,trellis,tblen,opmode,dectype,puncpat)
decoded = ...
vitdec(code,trellis,tblen,opmode,dectype,puncpat,eraspat)
decoded = ...
vitdec(...,'cont',...,initmetric,initstates,initinputs)
[decoded,finalmetric,finalstates,finalinputs] = ...
vitdec(...,'cont',...)
```

### Description

`decoded = vitdec(code,trellis,tblen,opmode,dectype)` decodes the vector `code` using the Viterbi algorithm. The MATLAB structure `trellis` specifies the convolutional encoder that produced `code`; the format of `trellis` is described in “Trellis Description of a Convolutional Code” and the reference page for the `istrellis` function. `code` contains one or more symbols, each of which consists of  $\log_2(\text{trellis.numOutputSymbols})$  bits. Each symbol in the vector `decoded` consists of  $\log_2(\text{trellis.numInputSymbols})$  bits. `tblen` is a positive integer scalar that specifies the traceback depth. If the code rate is 1/2, a typical value for `tblen` is about five times the constraint length of the code.

`opmode` indicates the decoder's operation mode and its assumptions about the corresponding encoder's operation. Choices are in the table below.

### Values of `opmode` Input

Value	Meaning
'cont'	The encoder is assumed to have started at the all-zeros state. The decoder traces back from the state with the best metric. A delay equal to <code>tblen</code> symbols elapses before the first decoded symbol appears in the output. This mode is appropriate when you invoke this function repeatedly and want to preserve continuity between successive invocations. See the continuous operation mode syntaxes on page 2-1170 below.
'term'	The encoder is assumed to have both started and ended at the all-zeros state, which is true for the default syntax of the <code>convenc</code> function. The decoder traces back from the all-zeros state. This mode incurs no delay. This mode is appropriate when the uncoded message (that is, the input to <code>convenc</code> ) has enough zeros at the end to fill all memory registers of the encoder. If the encoder has <code>k</code> input streams and constraint length vector <code>constr</code> (using the polynomial description of the encoder), “enough” means $k * \max(\text{constr} - 1)$ .
'trunc'	The encoder is assumed to have started at the all-zeros state. The decoder traces back from the state with the best metric. This mode incurs no delay. This mode is appropriate when you cannot assume the encoder ended at the all-zeros state and when you do not want to preserve continuity between successive invocations of this function.

For the 'term' and 'trunc' mode, the traceback depth (`tblen`) must be a positive integer scalar value, not greater than the number of input symbols in `code`.

`dectype` indicates the type of decision that the decoder makes, and influences the type of data the decoder expects in `code`. Choices are in the table below.

### Values of dectype Input

Value	Meaning
'unquant'	code contains real input values, where 1 represents a logical zero and -1 represents a logical one.
'hard'	code contains binary input values.
'soft'	For soft-decision decoding, use the syntax below. nsdec is required for soft-decision decoding.

### Syntax for Soft Decision Decoding

`decoded = vitdec(code,trellis,tblen,opmode,'soft',nsdec)` decodes the vector `code` using soft-decision decoding. `code` consists of integers between 0 and  $2^{nsdec}-1$ , where 0 represents the most confident 0 and  $2^{nsdec}-1$  represents the most confident 1. The existing implementation of the functionality supports up to 13 bits of quantization, meaning `nsdec` can be set up to 13. For reference, 3 bits of quantization is about 2 db better than hard decision decoding.

### Syntax for Punctures and Erasures

`decoded = ... vitdec(code,trellis,tblen,opmode,dectype,puncpat)` denotes the input punctured code, where `puncpat` is the puncture pattern vector, and where 0s indicate punctured bits in the input code.

`decoded = ... vitdec(code,trellis,tblen,opmode,dectype,puncpat,eraspat)` allows an erasure pattern vector, `eraspat`, to be specified for the input code, where the 1s indicate the corresponding erasures. `eraspat` and `code` must be of the same length. If puncturing is not used, specify `puncpat` to be `[]`. In the `eraspat` vector, 1s indicate erasures in the input code.

### Additional Syntaxes for Continuous Operation Mode

Continuous operation mode enables you to save the decoder's internal state information for use in a subsequent invocation of this function. Repeated calls to this function are

useful if your data is partitioned into a series of smaller vectors that you process within a loop, for example.

```
decoded = ...
vitdec(..., 'cont', ..., initmetric, initstates, initinputs)
```

is the same as the earlier syntaxes, except that the decoder starts with its state metrics, traceback states, and traceback inputs specified by `initmetric`, `initstates`, and `initinputs`, respectively. Each real number in `initmetric` represents the starting state metric of the corresponding state. `initstates` and `initinputs` jointly specify the initial traceback memory of the decoder; both are `trellis.numStates-by-tblen` matrices. `initstates` consists of integers between 0 and `trellis.numStates-1`. If the encoder schematic has more than one input stream, the shift register that receives the first input stream provides the least significant bits in `initstates`, while the shift register that receives the last input stream provides the most significant bits in `initstates`. The vector `initinputs` consists of integers between 0 and `trellis.numInputSymbols-1`. To use default values for all of the last three arguments, specify them as `[]`, `[]`, `[]`.

```
[decoded, finalmetric, finalstates, finalinputs] = ...
vitdec(..., 'cont', ...)
```

is the same as the earlier syntaxes, except that the final three output arguments return the state metrics, traceback states, and traceback inputs, respectively, at the end of the decoding process. `finalmetric` is a vector with `trellis.numStates` elements that correspond to the final state metrics. `finalstates` and `finalinputs` are both matrices of size `trellis.numStates-by-tblen`. The elements of `finalstates` have the same format as those of `initstates`.

## Traceback Matrices

The  $t^{\text{th}}$  column of  $P_1$  shows the  $t-1^{\text{th}}$  time step states given the inputs listed in the input matrix. For example, the value in the  $i^{\text{th}}$  row shows the state at time  $t-1$  that transitions to the  $i-1$  state at time  $t$ . The input required for this state transition is given in the  $i^{\text{th}}$  row of the  $t^{\text{th}}$  column of the input matrix.

The  $P_1$  output is the states of the traceback matrix. It is a [number of states x traceback length] matrix. The following example uses a (7,5), rate 1/2 code. This code is easy to follow:

```
t = poly2trellis(3,[7 5]);
k = log2(t.numInputSymbols);
msg = [1 1 0 0 1 1 0 0 1 1 0 0 1 1 0 0 1 1 0 0 1 1 0 0 1 1 0 0 1 1 0 0];
code = convenc(msg,t); tblen = 15; [d1 m1 p1 in1]=vitdec(code(1:end/2),t,tblen,'cont','hard')
```

m1 =

0 3 2 3

p1 =

0	1	1	0	0	1	1	0	0	1	1	0	0	1
2	3	3	2	2	3	3	2	2	3	3	2	2	3
0	1	1	0	0	1	1	0	0	1	1	0	0	1
2	3	3	2	2	3	3	2	2	3	3	2	2	3

in1 =

0	0	0	0	0	0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0	0	0	0	0	0
1	1	1	1	1	1	1	1	1	1	1	1	1	1
1	1	1	1	1	1	1	1	1	1	1	1	1	1

In this example, the message makes the encoder states follow the following sequence:

0 2 3 1 / 0 2 3 1 / ...

Since the best state is 0 (column index of smallest metric in  $m_1 - 1$ ), the traceback matrix starts from state 0, looking at the first row (0<sup>th</sup> state) of the last column of  $P_1$ , ([1; 3; 1; 3]), which is 1. This indicates 1 for the previous state.

Next, the traceback matrix checks in1 ([0; 0; 1; 1]), which indicates 0 for the input. The second row (1st state) of the 14<sup>th</sup> column of  $P_1$  ([1; 3; 1; 3]) is 3. This indicates 3 for the previous state.

The traceback matrix checks in1 ([0; 0; 1; 1]), which indicates that the input was 0. The fourth row (3rd state) of the 13th column of  $P_1$  ([0; 2; 0; 2]), is 2. This indicates 2 for the previous state.

The traceback matrix checks in1 ([0; 0; 1; 1]), which indicates the input was 1. The third row (2nd state) of the 12th column of  $P_1$  ([0; 2; 0; 2]), is 0. This indicates 0 for the previous state.

The traceback matrix checks in1 ([0; 0; 1; 1]), which indicates the input was 1. The first row (0th state) of the 11th column of  $P_1$  ([1; 3; 1; 3]), is 1. This indicates 1 for the previous state. Then, the matrix checks in1 ([0; 0; 1; 1]), which indicates 0 for the input.

To determine the best state for a given time, use  $m_1$ . The smallest number in  $m_1$  represents the best state.

## Examples

### Create Convolutional Code

This example shows how to create a convolutional code using the `convenc` function and how to decode it using `vitdec`.

#### Encoding

Define a trellis.

```
t = poly2trellis([4 3],[4 5 17;7 4 2]);
```

Encode a vector of ones.

```
x = ones(100,1);  
code = convenc(x,t);
```

#### Decoding

Define a trellis.

```
t = poly2trellis([4 3],[4 5 17;7 4 2]);
```

Encode a vector of ones.

```
code = convenc(ones(100,1),t);
```

Set the traceback length for decoding and decode using `vitdec`.

```
tb = 2;  
decoded = vitdec(code,t,tb,'trunc','hard');
```

Verify that the decoded data is a vector of 100 ones.

```
isequal(decoded,ones(100,1))
```

```
ans = logical  
     1
```

### Estimate BER for Rate 2/3 Convolutional Code

This example performs a bit error rate simulation for a link that uses 16-QAM modulation a rate 2/3 convolutional code.

Set the modulation order, and compute the number of bits per symbol.

```
M = 16;  
k = log2(M);
```

Generate random binary data.

```
dataIn = randi([0 1],100000,1);
```

Define a convolutional coding trellis for a rate 2/3 code.

```
tPoly = poly2trellis([5 4],[23 35 0; 0 5 13]);  
codeRate = 2/3;
```

Convolutionally encode the input data.

```
codeword = convenc(dataIn,tPoly);
```

Reshape the encoded column vector into a matrix having k columns. Then, convert the binary matrix into an integer column vector.

```
codewordMat = reshape(codeword,length(codeword)/k,k);  
txSym = bi2de(codewordMat);
```

Apply 16-QAM modulation to the encoded symbols.

```
txSig = qammod(txSym,M);
```

Convert a 10 dB Eb/No to an equivalent signal-to-noise ratio. Pass the signal through an AWGN channel.

```
EbNo = 10;  
snr = EbNo + 10*log10(k*codeRate);  
rxSig = awgn(txSig,snr,'measured');
```

Demodulate the received signal.

```
demodSig = qamdemod(rxSig,M);
```

Convert the output of the demodulator into a binary column vector.

```
demodSigMat = de2bi(demodSig,k);
demodSigBinary = demodSigMat(:);
```

Set the traceback depth of the Viterbi decoder.

```
traceBack = 16;
```

Decode the binary demodulated signal by using a Viterbi decoder operating in a continuous termination mode.

```
dataOut = vitdec(demodSigBinary,tPoly,traceBack,'cont','hard');
```

Calculate the delay through the decoder, and compute the bit error statistics.

```
decDelay = 2*traceBack;
[numErrors,ber] = biterr(dataIn(1:end-decDelay),dataOut(decDelay+1:end))
```

```
numErrors = 26
```

```
ber = 2.6008e-04
```

Compare the BER with the uncoded BER.

```
berUncoded = berawgn(EbNo,'qam',M);
berUncoded/ber
```

```
ans = 6.7446
```

The convolutional code reduces the BER by approximately a factor of 4.

### Estimate BER for Hard and Soft Decision Viterbi Decoding

Estimate bit error rate (BER) performance for hard-decision and soft-decision Viterbi decoders in AWGN. Compare the performance to that of an uncoded 64-QAM link.

Set the simulation parameters.

```
clear; close all
rng default
M = 64; % Modulation order
k = log2(M); % Bits per symbol
EbNoVec = (4:10)'; % Eb/No values (dB)
numSymPerFrame = 1000; % Number of QAM symbols per frame
```

Initialize the BER results vectors.

```
berEstSoft = zeros(size(EbNoVec));
berEstHard = zeros(size(EbNoVec));
```

Set the trellis structure and traceback length for a rate 1/2, constraint length 7, convolutional code.

```
trellis = poly2trellis(7,[171 133]);
tbl = 32;
rate = 1/2;
```

The main processing loops performs these steps:

- Generate binary data.
- Convolutionally encode the data.
- Apply QAM modulation to the data symbols. Specify unit average power for the transmitted signal.
- Pass the modulated signal through an AWGN channel.
- Demodulate the received signal using hard decision and approximate LLR methods. Specify unit average power for the received signal.
- Viterbi decode the signals using hard and unquantized methods.
- Calculate the number of bit errors.

The while loop continues to process data until either 100 errors are encountered or  $1e7$  bits are transmitted.

```
for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
    snrdb = EbNoVec(n) + 10*log10(k*rate);
    % Noise variance calculation for unity average signal power.
    noiseVar = 10.^(-snrdb/10);
    % Reset the error and bit counters
    [numErrsSoft,numErrsHard,numBits] = deal(0);
```

```

while numErrsSoft < 100 && numBits < 1e7
    % Generate binary data and convert to symbols
    dataIn = randi([0 1],numSymPerFrame*k,1);

    % Convolutionally encode the data
    dataEnc = convenc(dataIn,trellis);

    % QAM modulate
    txSig = qammod(dataEnc,M,'InputType','bit','UnitAveragePower',true);

    % Pass through AWGN channel
    rxSig = awgn(txSig,snrdB,'measured');

    % Demodulate the noisy signal using hard decision (bit) and
    % soft decision (approximate LLR) approaches.
    rxDataHard = qamdemod(rxSig,M,'OutputType','bit','UnitAveragePower',true);
    rxDataSoft = qamdemod(rxSig,M,'OutputType','approxllr', ...
        'UnitAveragePower',true,'NoiseVariance',noiseVar);

    % Viterbi decode the demodulated data
    dataHard = vitdec(rxDataHard,trellis,tbl,'cont','hard');
    dataSoft = vitdec(rxDataSoft,trellis,tbl,'cont','unquant');

    % Calculate the number of bit errors in the frame. Adjust for the
    % decoding delay, which is equal to the traceback depth.
    numErrsInFrameHard = biterr(dataIn(1:end-tbl),dataHard(tbl+1:end));
    numErrsInFrameSoft = biterr(dataIn(1:end-tbl),dataSoft(tbl+1:end));

    % Increment the error and bit counters
    numErrsHard = numErrsHard + numErrsInFrameHard;
    numErrsSoft = numErrsSoft + numErrsInFrameSoft;
    numBits = numBits + numSymPerFrame*k;

end

% Estimate the BER for both methods
berEstSoft(n) = numErrsSoft/numBits;
berEstHard(n) = numErrsHard/numBits;
end

Plot the estimated hard and soft BER data. Plot the theoretical performance for an
uncoded 64-QAM channel.

semilogy(EbNoVec,[berEstSoft berEstHard],'-*')
hold on

```

```
semilogy(EbNoVec,berawgn(EbNoVec,'qam',M))
legend('Soft','Hard','Uncoded','location','best')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
```

As expected, the soft decision decoding produces the best results.

## Limitations

In order to improve performance of C/C++ code generated by MATLAB, integrity and responsiveness checks should be disabled before running the codegen function. See

“MATLAB Code Design Considerations for Code Generation” (Simulink) for more information.

For example, given the following function:

```
function y = vitdec_hard(x,t,tb)
%# codegen

y = vitdec(x,t,tb,'trunc','hard');
```

Execute these commands for optimal performance.

```
cf = coder.config;
cf.IntegrityChecks = false;
cf.ResponsivenessChecks = false;
codegen('vitdec_hard', '-args', {x,coder.Constant(t),tb})
```

The coded data,  $x$ , the trellis structure,  $t$ , and the traceback length,  $tb$ , must be defined in the base workspace.

## wgn

Generate white Gaussian noise samples

### Syntax

```
noise = wgn(m,n,power)
noise = wgn(m,n,power,imp)
noise = wgn(m,n,power,imp,randobject)
noise = wgn(m,n,power,imp,seed)
```

```
noise = wgn( ____,powertype)
noise = wgn( ____,outputtype)
```

### Description

`noise = wgn(m,n,power)` generates an m-by-n matrix of white Gaussian noise samples in volts. `power` specifies the power of noise in dBW.

`noise = wgn(m,n,power,imp)` specifies the load impedance in ohms.

`noise = wgn(m,n,power,imp,randobject)` specifies a random number stream object to use when generating the matrix of white Gaussian noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-1184.

`noise = wgn(m,n,power,imp,seed)` specifies a seed value for initializing the normal random number generator that is used when generating the matrix of white Gaussian noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-1184.

`noise = wgn( ____,powertype)` specifies the units of power as 'dBW', 'dBm', or 'linear' in addition to the input arguments in any of the previous syntaxes.

`noise = wgn( ____,outputtype)` specifies the output type as 'real' or 'complex' in addition to the input arguments in any of the previous syntaxes.

## Examples

### Generate White Gaussian Noise

Generate real and complex white Gaussian noise (WGN) samples. Check the power of output WGN matrices.

Generate a 1000-element column vector of real WGN samples and confirm that the power is approximately 1 watt, which is 0 dBW.

```
y1 = wgn(1000,1,0);  
var(y1)
```

```
ans = 0.9979
```

Generate a 1000-element column vector of complex WGN samples and confirm that the power is approximately 0.25 watts, which is -6 dBW.

```
y2 = wgn(1000,1,-6,'complex');  
var(y2)
```

```
ans = 0.2522
```

## Input Arguments

### **m** — Number of white Gaussian noise samples

positive integer

Number of white Gaussian noise samples desired per channel, specified as a positive integer.

Data Types: double

### **n** — Number of channels

positive integer

Number of channels of white Gaussian noise samples desired, specified as a positive integer.

Data Types: double

**power — Power of noise samples**

scalar

Power of noise samples, specified as a scalar. The default units for power is dBW. Use `powertype` to change the units of power.

Data Types: double

**imp — Load impedance**

1 (default) | scalar

Load impedance in ohms, specified as a scalar.

Data Types: double

**randobject — Random number stream object**

RandStream object

Random number stream object, specified as a RandStream object. The state of the random stream object determines the sequence of numbers produced by the `randn` function. Configure the random stream object using the `reset` function and its properties.

wgn generates normal random noise samples using `randn`. The `randn` function uses one or more uniform values from the RandStream object to generate each normal value.

For information about producing repeatable noise samples, see “Tips” on page 2-1184.

**seed — Random number generator seed**

nonnegative integer

Random number generator seed, specified as a nonnegative integer. For more information on the random number generator, see `randn`.

**powertype — Signal power unit**

'dBW' (default) | 'dBm' | 'linear'

Signal power unit, specified as 'dBW', 'dBm', or 'linear'. Linear power is in watts.

**outputtype — Output type**

'real' (default) | 'complex'

Output type, specified as 'real' or 'complex'. If `outputtype` is 'complex', then the real and imaginary parts of noise each have a noise power of  $(\text{power} / 2)$ .

## Output Arguments

### **noise** — Output white Gaussian noise samples

scalar | vector | array

Output white Gaussian noise samples in volts, returned as an m-by-n matrix.

---

**Note** Unless the default impedance for `imp` is changed, a load of 1 ohm is used for power calculations.

---

## Tips

- To generate repeatable white Gaussian noise samples, use one of these tips:
  - Provide a static `seed` value as an input to `wgn`.
  - Use the `reset` function on the `randobject` before passing it as an input to `wgn`.
  - Provide `randobject` in a known state as an input to `wgn`. For more information, see `RandStream`.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation supported, except for syntaxes that include a `RandStream` object.

## winner2.AntennaArray

Create antenna array

### Syntax

```
antArray = winner2.AntennaArray  
antArray = winner2.AntennaArray(Name,Value)
```

### Description

**Download Required:** To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons” (MATLAB).

`antArray = winner2.AntennaArray` returns a structure representing an antenna array with one isotropic antenna element. Both the antenna array and the single element have no rotation and are located at the origin, [0;0;0].

`antArray = winner2.AntennaArray(Name,Value)` returns a structure representing an antenna array defined using one or more `Name,Value` pair arguments.

For more information, see “Antenna Array Model” on page 2-1192.

### Examples

#### Create WINNER2 Eight Element Uniform Circular Array

Use the `winner2.AntennaArray` function to create an eight element uniform circular array (UCA-8) with a 1 cm radius.

```
UCA8 = winner2.AntennaArray('UCA',8,0.01);
```

Plot element positions

```
pos = {UCA8.Element(:).Pos};  
plot(cellfun(@(x) x(1),pos),cellfun(@(x) x(2),pos),'+');  
xlim([-0.02 0.02]);  
ylim([-0.02 0.02]);  
title('UCA-8 Element Positions');
```

## Create WINNER2 Two Element Uniform Linear Array

Use the `winner2.AntennaArray` function to create a two element uniform linear array (ULA-2) with 50 cm spacing and the dipole elements slanted at +45 and -45 degrees.

```
az = -180:179; % 1-degree spacing
pattern = cat(1,shiftdim(winner2.dipole(az,45),-1), ...
    shiftdim(winner2.dipole(az,-45),-1));
ULA2 = winner2.AntennaArray('ULA',2,0.5, ...
    'FP-ECS',pattern,'Azimuth',az);
```

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Pos',[1 0 0; 0 1 0],'Rot',[0 0 0; 0 pi() 0]` indicates the coordinates and rotation angles for two antenna elements.

#### **Pos** — Position of each antenna element

0 (default) | column vector | matrix

Position of each antenna element, specified as the comma-separated pair consisting of `'Pos'` and a column vector or an  $N_E$ -by-3 matrix. The three columns represent the x-, y-, and z-coordinates in meters from the origin.  $N_E$  indicates the number of elements in the antenna array. The elements have no rotation. When there is more than one element, the `'Element'` field of `antArray` is a row vector of structures representing all the elements.

Example: `'Pos',[63.1 10.2 11.5; 62 11 12]` indicates the coordinates for two antenna elements.

Data Types: double

#### **Rot** — Rotation angle of each antenna element

0 (default) | column vector | matrix | optional

Rotation angle of each antenna element, specified as the comma-separated pair consisting of `'Rot'` and a column vector or an  $N_E$ -by-3 matrix. The three columns represent the

$Rot_x$ ,  $Rot_y$ , and  $Rot_z$  rotation angles of each antenna element in radians.  $N_E$  indicates the number of elements in the antenna array. Rot only applies when Pos is specified. If not specified with Pos, the rotation angle is 0.

Example: 'Rot', [2 1.5 0; 0 pi() 0] indicates the rotation angles for two antenna elements.

Data Types: double

### **UCA — Uniform circular antenna array**

N, 1 (default) | N, Rad

Uniform circular antenna array, specified as the comma-separated pair consisting of 'UCA' and N, Rad. In this argument, N indicates the number of elements ( $N_E$ ) and Rad indicates the radius in meters. If Rad is not specified, the default radius is 1 meter.

Example: 'UCA', 8, 0.5 indicates an eight element uniform circular array with 0.5 meter radius.

Data Types: double

### **ULA — Uniform linear antenna array**

N, 1/N (default) | N, Spacing

Uniform linear antenna array, specified as the comma-separated pair consisting of 'ULA' and N, Spacing. In this argument, N indicates the number of elements ( $N_E$ ) and Spacing indicates the separation between adjacent elements in meters. If Spacing is not specified, the default separation is 1/N meters.

ULA elements are placed along  $x$ -axis with the center of the array at [0;0;0]. For an even number of elements, there is no antenna element at [0;0;0].

Example: 'ULA', 3, 0.25 indicates a three element uniform linear array with 0.25 meter spacing between adjacent elements.

Data Types: double

### **FP-ECS — Field pattern of element coordinate system**

4-D array

Field pattern of element coordinate system, specified as the comma-separated pair consisting of 'FP-ECS' and a  $P$ -by-2-by1-by- $N_{AZ}$  array.

- The first dimension,  $P$ , can be either 1 or any number greater than or equal to the number of elements in the antenna array ( $N_E$ ). When  $P = 1$ , the same pattern applies to all elements. When  $P > N_E$ , the first  $N_E$  rows apply.
- The second dimension, 2, indicates that two polarizations characterize the field pattern. The first dimension in the field pattern stores vertical polarization, and the second one stores horizontal polarization.
- The third dimension, 1, indicates that one elevation angle characterizes the field pattern.
- The fourth dimension,  $N_{AZ}$ , is the number of field pattern samples taken between -180 and 180 degrees.  $N_{AZ}$  equals the number of elements specified in `Azimuth` or when `Azimuth` is not present it equals the number of equidistant field pattern samples taken over azimuth angle.

Data Types: double

### **FP-ACS — Field pattern array coordinate system**

4-D array

Field pattern array coordinate system, specified as the comma-separated pair consisting of 'FP-ACS' and a  $P$ -by-2-by1-by- $N_{AZ}$  array. Array format is the same as the FP-ECS syntax, except that the field pattern is specified in the array-coordinate-system (ACS).

- The first dimension,  $P$ , can be either 1 or any number greater than or equal to the number of elements in the antenna array ( $N_E$ ). When  $P = 1$ , the same pattern applies to all elements. When  $P > N_E$ , the first  $N_E$  rows apply.
- The second dimension, 2, indicates that two polarizations characterize the field pattern. The first dimension in the field pattern stores vertical polarization, and the second one stores horizontal polarization. Missing polarization dimensions of the field pattern are substituted with zeros.
- The third dimension, 1, indicates that one elevation angle characterizes the field pattern.
- The fourth dimension,  $N_{AZ}$ , is the number of field pattern samples taken between -180 and 180 degrees.  $N_{AZ}$  equals the number of elements specified in `Azimuth` or when `Azimuth` is not present it equals the number of equidistant field pattern samples taken over azimuth angle.

Data Types: double

### **Azimuth — Azimuth angles for 'FP-ACS' or 'FP-ECS' field patterns**

row vector

Azimuth angles for FP-ACS or FP-ECS field patterns in degrees, specified as the comma-separated pair consisting of 'Azimuth' and an 1-by- $N_{AZ}$  row vector. The values in the row vector indicate azimuth angles for elements in the field patterns.

---

**Note** Azimuth applies only when FP-ACS or FP-ECS are defined. If Azimuth is not specified, uniform spacing is used for elements in the field pattern.

---

Example: 'Azimuth',[0 10 20 90 180 270 340 350]

Data Types: double

## Output Arguments

### **antArray** — Antenna array definition

structure

Antenna array definition, returned as a structure containing these fields.

### **Name** — Antenna array name

character vector

Antenna array name, returned as a character vector.

### **Pos** — Antenna array position

vector

Antenna array position, returned as a 3-by-1 vector, representing the x-, y-, and z-coordinates in meters from the origin.

### **Rot** — Antenna array rotation

vector

Antenna array rotation, returned as a 3-by-1 vector, representing the  $Rot_x$ ,  $Rot_y$ , and  $Rot_z$  rotation angles of each antenna element in radians.

### **Element** — Element definition

row vector of structures

Element definition, returned as a row vector of structures, with each structure representing one element and containing these fields.

### **Pos — Antenna array position**

vector

Antenna array position, returned as a 3-by-1 vector, representing the x-, y-, and z-coordinates in meters from the origin.

### **Rot — Antenna array rotation**

vector

Antenna array rotation, returned as a 3-by-1 vector, representing the  $Rot_x$ ,  $Rot_y$ , and  $Rot_z$  rotation angles of each antenna element in radians.

### **Aperture — Aperture definition**

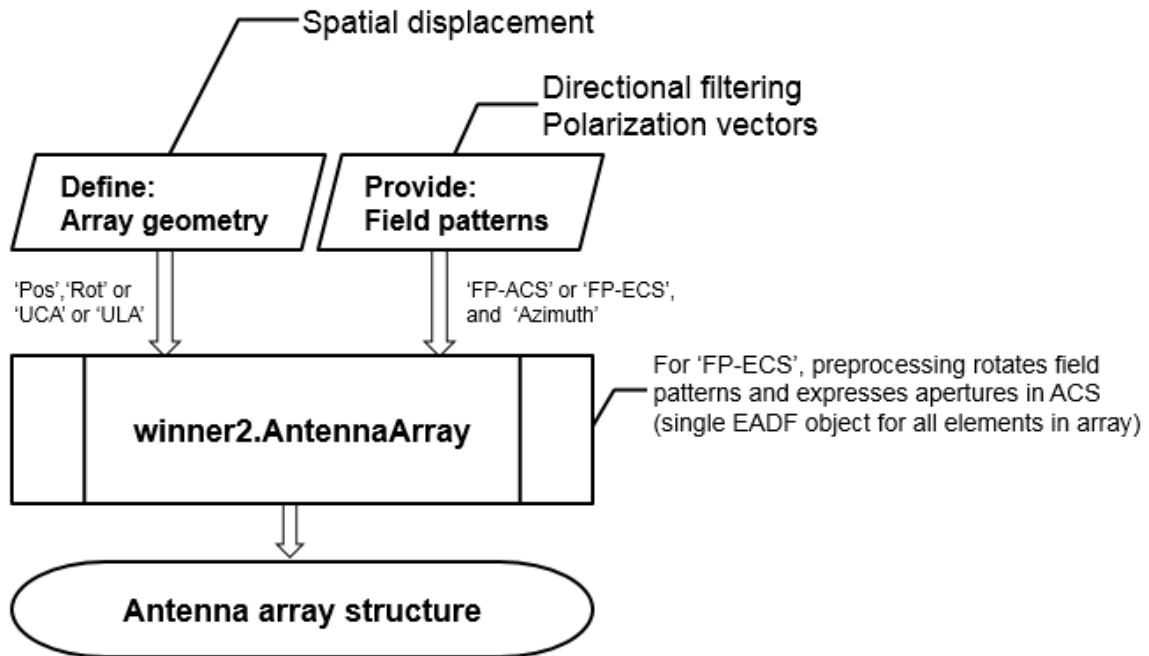

structure

Aperture definition, returned as a structure representing the antenna aperture.

## **More About**

### **Antenna Array Model**

To create an antenna array model, you must define the geometry of array elements (positions and rotation) and the element field patterns. The arguments provided to `winner2.AntennaArray` are always processed such that the array geometry is created first, and then the field patterns are assigned.

For a detailed description of the antenna array specification for the WINNER channel model, see WINNER II Channel Models [1], Section 4.1.

`winner2.dipole` | `winner2.layoutparset`

**Introduced in R2017a**

## winner2.dipole

Calculate field pattern of half-wavelength dipole

### Syntax

```
pat = winner2.dipole(az)
pat = winner2.dipole(az,slant)
```

### Description

**Download Required:** To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons” (MATLAB).

`pat = winner2.dipole(az)` returns the azimuth field pattern of a 0-degree slanted dipole at the azimuth angles specified in `az`.

`pat = winner2.dipole(az,slant)` returns the azimuth field pattern of a slanted dipole at the azimuth angles specified in `az`.

### Examples

#### Create 45 and 90 Degree Slanted Dipoles

```
az = -180:179; % 1 degree spacing
pattern45 = squeeze(winner2.dipole(az, 45));
pattern90 = squeeze(winner2.dipole(az, 90));

fh = figure;
set(fh, 'Position', [100 100 1000 500]);
fh.Name = 'Dipole Pattern Plots';

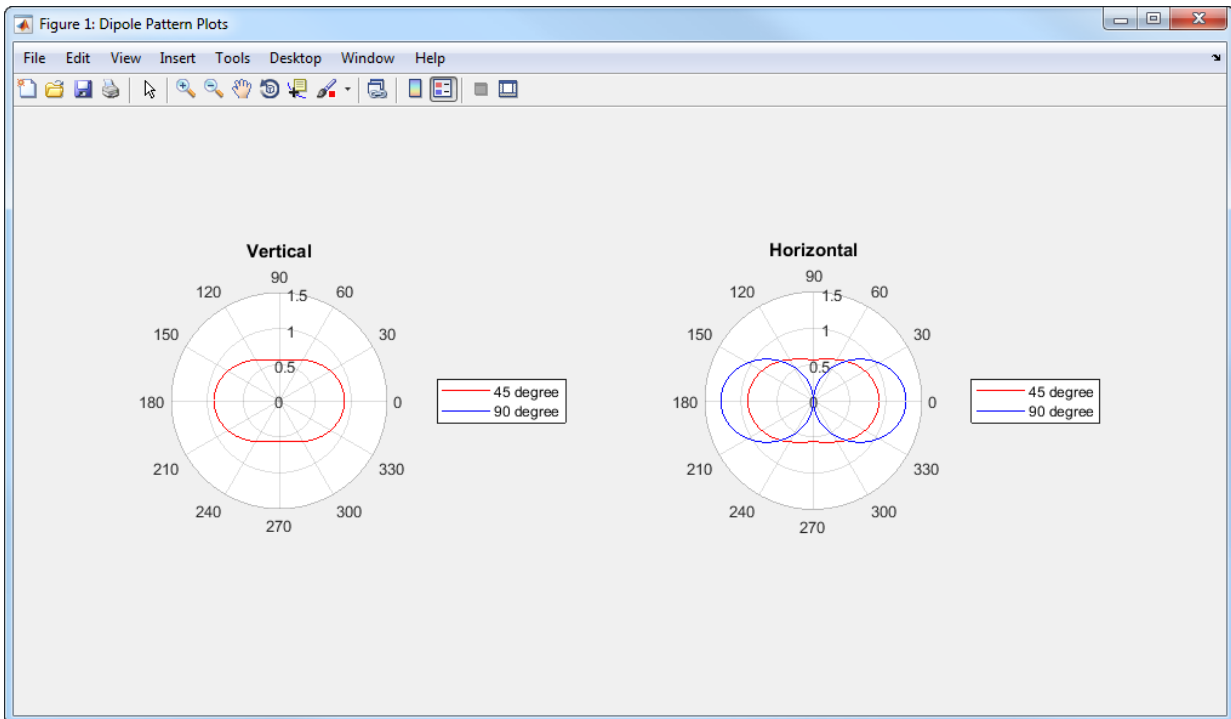

subplot(1,2,1);
polarplot(az/180*pi, pattern45(1,:), 'r');
hold on;
```

```

polarplot(az/180*pi, pattern90(1,:), 'b');
rlim([0 1.5]);
legend('45 degree', '90 degree');
title('Vertical');

subplot(1,2,2);
polarplot(az/180*pi, pattern45(2,:), 'r');
hold on;
polarplot(az/180*pi, pattern90(2,:), 'b');
rlim([0 1.5]);
legend('45 degree', '90 degree');
title('Horizontal');

```

## Input Arguments

**az** — Azimuth angles

vector

Azimuth angles, specified as a vector indicating the azimuth angles to compute the field pattern gain. Units are in degrees.

Data Types: double

### **slant** — Slant angle

scalar

Slant angle, specified as a scalar representing the counterclockwise angle seen from the front of the dipole. Units are in degrees.

Data Types: double

## Output Arguments

### **pat** — Field pattern

3-D array

Field pattern, returned as a 2-by-1-by- $N_{AZ}$  array representing the vertical and horizontal field pattern, where  $N_{AZ}$  is the number of elements in the `az` input vector.

## See Also

`winner2.AntennaArray` | `winner2.layoutparset`

**Introduced in R2017a**

# winner2.layoutparset

WINNER II layout parameter configuration

## Syntax

```
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays)
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax)
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax,seed)
```

## Description

**Download Required:** To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons” (MATLAB).

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays)` returns a structure of randomly generated WINNER II network layout parameters given mobile station (MS) indices, base station (BS) indices, BS to MS links, and antenna array configurations.

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax)` additionally specifies the maximum layout range used when generating MS and BS positions.

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax,seed)` additionally specifies a seed value for repeatability. To assign seed when not assigning `rmax`, specify `rmax` as `[ ]`.

## Examples

### Create Two MS to One BS WINNER 2 System Layout

Create a WINNER 2 system layout with two mobile stations (MS) connecting to the same base station (BS).

Define antenna arrays for one BS and two MS.

```
BSAA = winner2.AntennaArray('UCA', 8, 0.02); % UCA-8 array for BS
MSAA1 = winner2.AntennaArray('ULA', 2, 0.01); % ULA-2 array for MS
MSAA2 = winner2.AntennaArray('ULA', 4, 0.005); % ULA-4 array for MS
```

Create system layout.

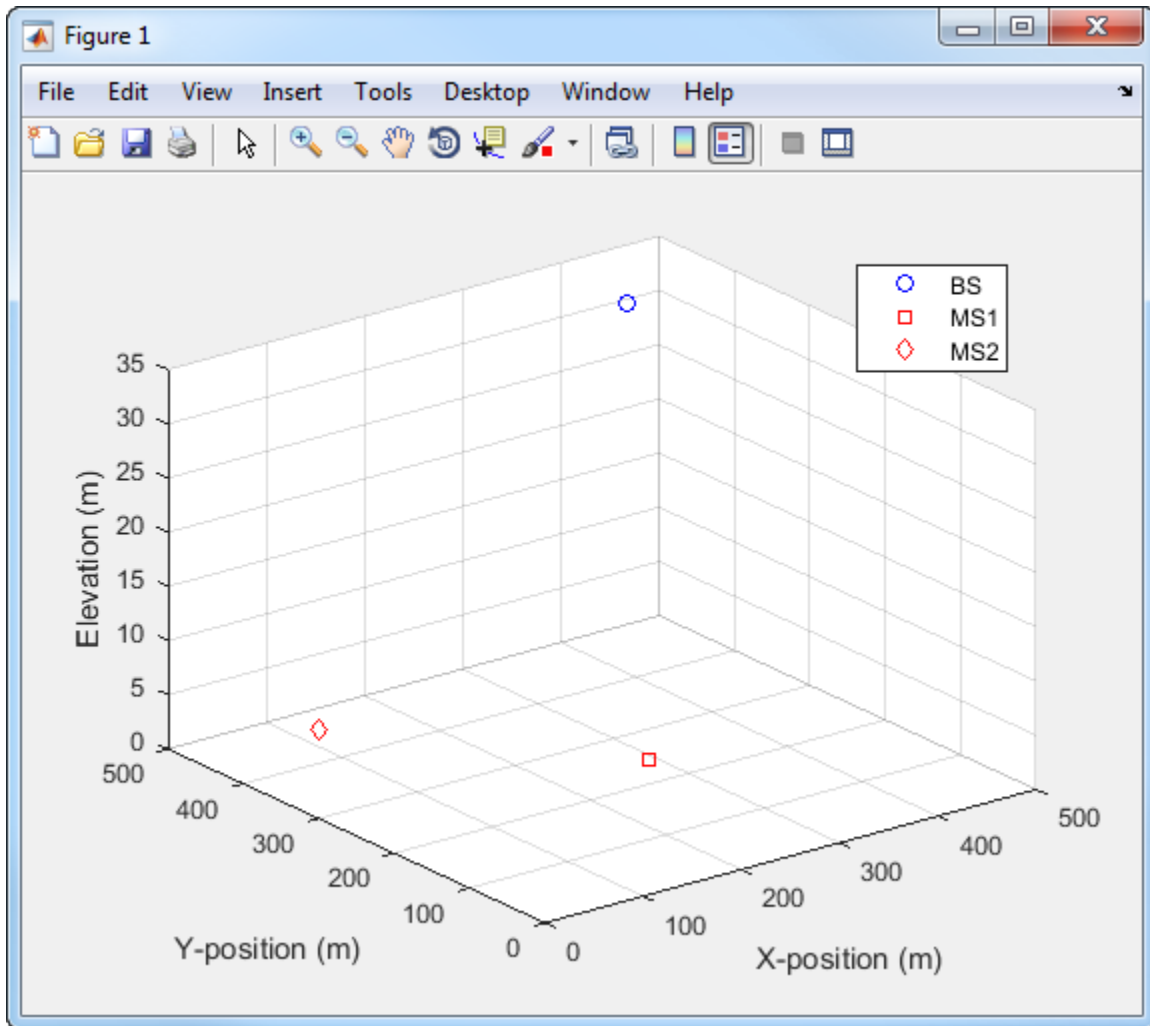

```
MSIdx = [2 3];
BSIdx = {1};
K = 2;
rndSeed = 5;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx, ...
    K,[BSAA,MSAA1,MSAA2],[],rndSeed);
```

Visualize BS and MS positions.

```
BSPos = cfgLayout.Stations(cfgLayout.Pairing(1,1)).Pos;
MS1Pos = cfgLayout.Stations(cfgLayout.Pairing(2,1)).Pos;
MS2Pos = cfgLayout.Stations(cfgLayout.Pairing(2,2)).Pos;

plot3(BSPos(1),BSPos(2),BSPos(3),'bo', ...
    MS1Pos(1),MS1Pos(2),MS1Pos(3),'rs', ...
    MS2Pos(1),MS2Pos(2),MS2Pos(3),'rd');
grid on;
xlim([0 500]);
ylim([0 500]);
zlim([0 35]);
xlabel('X-position (m)');
ylabel('Y-position (m)');
zlabel('Elevation (m)');
legend('BS','MS1','MS2','Location','northeast');
```

## Input Arguments

**msIdx** – Mobile station index  
row vector

Mobile station index, specified as a row vector indicating the indices in arrays to serve as mobile stations.

Data Types: double

### **bsIdx — Base station index**

column cell array

Base station index, specified as a column cell array, with each element representing one base station. Each cell element is an integer-valued row vector to indicate the indices in arrays to serve as different sectors of that base station.

Data Types: double

### **K — Number of links**

scalar

Number of links, specified as a scalar representing the number of BS-MS links to be formulated.

Data Types: double

### **arrays — Antenna array configurations**

vector of structures

Antenna array configurations, specified as a vector of structures defining all available arrays. All MS and BS sectors are chosen from this vector. The array of elements is typically created using the `winner2.AntennaArray` function.

Data Types: double

### **rmax — Maximum layout range**

500 (default) | scalar

Maximum layout range, specified as a scalar representing the maximum layout range in meters used to randomly generate the MS and BS positions.

Data Types: double

### **seed — Seed value**

integer

Seed value used to provide repeatability, specified as an integer. When `seed` is not specified, the global random number generator is used. To assign `seed` when not assigning `rmax`, specify `rmax` as `[]`.

Data Types: double

## Output Arguments

### **cfgLayout** — Configuration layout

structure

Configuration layout, returned as a structure containing these fields, which represent the location and orientation parameters for all simulated stations.

### **Stations** — Active stations

row vector of structures

Active stations, returned as a row vector of structures describing the antenna arrays for active stations. `Stations` is created from the `arrays` input and adds an additional `Velocity` field. The row ordering specifies base station (BS) sectors first, followed by the mobile stations (MS). The BS sector and MS positions are randomly assigned. The BS sectors have no velocity. Each MS has a velocity of about 1.42 m/s with a randomly assigned direction.

### **NofSect** — Number of sectors

vector

Number of sectors, returned as a vector indicating the number of sectors in each BS.

### **Pairing** — BS to MS pairing

matrix

BS to MS pairing, returned as a 2-by- $N_L$  matrix, where  $N_L$  specifies the number of links to be modeled. See `Stations` for BS and MS row ordering.

### **ScenarioVector** — Spatial scenario

1 (default) | vector

Spatial scenario, returned as a 1-by- $N_L$  vector of scenario numbers. The default is 1, which specifies scenario A1.

The scenarios numbers map as {1=A1, 2=A2, 3=B1, 4=B2, 5=B3, 6=B4, 10=C1, 11=C2, 12=C3, 13=C4, 14=D1, 15=D2a}.

For more information, see WINNER II Channel Models [1], Section 2.3.

### **PropagConditionVector — Propagation condition**

1 (default) | vector

Propagation condition, returned as a 1-by- $N_L$  vector of propagation conditions (LOS = 1 and NLOS = 0) for each link. The default is 1.

### **StreetWidth — Street width**

20 (default) | vector

Street width, returned as a 1-by- $N_L$  vector of identical values that specify the average width (in meters) of the streets. `StreetWidth` is used for the path loss model of the B1 and B2 scenarios. See `ScenarioVector` for the scenario number mapping. All elements must have the same value. `StreetWidth` applies only when the `PathLossModelUsed` field from `winner2.wimparset` is set to 'yes'.

### **Dist1 — Distances from BS to the last LOS point**

NaN (default) | vector

Distances from BS to the last LOS point, returned as a 1-by- $N_L$  vector. `Dist1` is used for the path loss model of the B1 and B2 scenarios. The default value of NaN indicates that the distance is randomly determined in path loss function. See `ScenarioVector` for the scenario number mapping. `Dist1` applies only when the `PathLossModelUsed` field from `winner2.wimparset` is set to 'yes'.

For more information, see WINNER II Channel Models [1], Figure 4-3.

### **NumFloors — Floor numbers**

1 (default) | vector

Floor numbers, returned as a 1-by- $N_L$  vector indicating the floor number where the indoor BS or MS is located. The `NumFloors` property is used for the path loss model of the A2 and B4 scenarios only. See `ScenarioVector` for the scenario number mapping. `NumFloors` applies only when the `PathLossModelUsed` field from `winner2.wimparset` is set to 'yes'.

### **NumPenetratedFloors — Number of floors penetrated**

0 (default) | vector

Number of floors penetrated, returned as a 1-by- $N_L$  vector indicating the number of penetrated floors between BS and MS. The `NumPenetratedFloors` property is used for the NLOS path loss model of the A1 scenario. See `ScenarioVector` for the scenario

number mapping. NumPenetratedFloors applies only when the PathLossModelUsed field from winner2.wimparset is set to 'yes'.

For more information, see WINNER II Channel Models [1], Table 4-4.

**Introduced in R2017a**

## winner2.wim

Generate channel coefficients using WINNER II channel model

### Syntax

```
chanCoef = winner2.wim(cfgWim, cfgLayout)
[chanCoef, pathDelays] = winner2.wim(cfgWim, cfgLayout)
[chanCoef, pathDelays, finalCond] = winner2.wim(cfgWim, cfgLayout)
[chanCoef, pathDelays, finalCond] = winner2.wim(cfgWim, cfgLayout,
initCond)
```

### Description

**Download Required:** To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons” (MATLAB).

`chanCoef = winner2.wim(cfgWim, cfgLayout)` returns channel coefficients based on the WINNER II model parameters for all links defined in the WINNER II network layout.

`[chanCoef, pathDelays] = winner2.wim(cfgWim, cfgLayout)` also returns the path delays for all links.

`[chanCoef, pathDelays, finalCond] = winner2.wim(cfgWim, cfgLayout)` also returns the final condition of the system after generating the channel coefficients.

`[chanCoef, pathDelays, finalCond] = winner2.wim(cfgWim, cfgLayout, initCond)` generates the channel coefficients by using the initial system conditions rather than of performing random initialization. `initCond` is of the same form as `finalCond` and is typically the `finalCond` output from the prior call of this function. Use this syntax to repeatedly generate channel coefficients for continuous time samples.

### Examples

## Continuously Generate WINNER 2 Channel Coefficients

Continuously generate channel coefficients for each link in a two-link system layout.

Configure model parameters.

```
cfgWim = winner2.wimparset;
cfgWim.SampleDensity = 20;
cfgWim.RandomSeed = 10; % For repeatability
```

Configure layout parameters.

```
BSAA = winner2.AntennaArray('UCA',8,0.02); % UCA-8 array for BS
MSAA1 = winner2.AntennaArray('ULA',2,0.01); % ULA-2 array for MS1
MSAA2 = winner2.AntennaArray('ULA',4,0.005); % ULA-4 array for MS2
MSIdx = [2,3];
BSIdx = {1};
NL = 2;
rndSeed = 5;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL,[BSAA,MSAA1,MSAA2],[],rndSeed);
```

Generate channel coefficients for the first time.

```
[H1,~,finalCond] = winner2.wim(cfgWim,cfgLayout);
```

Generate a second set of channel coefficients.

```
[H2,~,finalCond] = winner2.wim(cfgWim,cfgLayout,finalCond);
```

Concatenate H1 and H2 in time domain.

```
H = cellfun(@(x,y) cat(4,x,y), H1, H2, 'UniformOutput', false);
```

Plot H for the first link, 1st Tx, 1st Rx, and 1st path.

```
figure;
Ts = finalCond.delta_t(1); % Sample time for the 1st link
plot(Ts*(0:2*cfgWim.NumTimeSamples-1)', ...
     abs(squeeze(H{1}(1,1,1,:))));
xlabel('Time (s)');
ylabel('Amplitude');
title('First Path Coefficient of 1st Link, 1st Tx, and 1st Rx');
```

The image shows the channel continuity over the two outputs from the `winner2.wim` function.

## Input Arguments

### **cfgWim** — Configuration layout

structure

Configuration model, specified as a structure containing these fields. `cfgWim` is typically created using the `winner2.wimparset` function.

**NumTimeSamples — Number of time samples**

100 (default) | scalar

Number of time samples, specified as a scalar.

**FixedPdpUsed — Use predefined path delays and powers for specific scenarios**

'no' (default) | 'yes'

Use predefined path delays and powers for specific scenarios, specified as 'no' or 'yes'.

**FixedAnglesUsed — Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios**

'no' (default) | 'yes'

Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as 'yes' or 'no'.

**IntraClusterDsUsed — Divide each of the two strongest clusters into three subclusters per link**

'yes' (default) | 'no'

Divide each of the two strongest clusters into three subclusters per link, specified as 'yes' or 'no'.

**PolarisedArrays — Use dual-polarized arrays**

'yes' (default) | 'no'

Use dual-polarized arrays, specified as 'yes' or 'no'.

**UseManualPropCondition — Use manually defined propagation conditions**

'yes' (default) | 'no'

Use manually defined propagation conditions, specified as 'yes' or 'no'. Set to 'yes' to enforce the use of manually defined propagation conditions (LOS/NLOS) in the PropagConditionVector structure field returned by winner2.layoutparset. Set to 'no' to draw propagation conditions from pre-defined LOS probabilities.

**CenterFrequency — Carrier frequency**

5.25e9 (default) | scalar

Carrier frequency in Hz, specified as a scalar.

### **UniformTimeSampling — Enforce uniform time sampling**

'no' (default) | 'yes'

Enforce all links to be sampled at the same time instants, specified as 'no' or 'yes'.

### **SampleDensity — Number of time samples per half wavelength**

2e6 (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

### **DelaySamplingInterval — Sampling interval**

5e-9 (default) | scalar

Sampling interval, specified as a scalar indicating the input signal sample time in seconds. `DelaySamplingInterval` defines the sampling grid to which the path delays are rounded. A value of 0 seconds indicates no rounding on path delays.

### **ShadowingModelUsed — Use shadow fading**

'no' (default) | 'yes'

Use shadow fading, specified as 'no' or 'yes'.

### **PathLossModelUsed — Use path loss model**

'no' (default) | 'yes'

Use path loss model, specified as 'no' or 'yes'.

### **PathLossModel — Path loss model**

'pathloss' (default) | character vector

Path loss model, specified as a character vector representing a valid function name. `PathLossModel` applies only when `PathLossModelUsed` is set to 'yes'.

### **PathLossOption — Wall material**

'CR\_light' (default) | 'CR\_heavy' | 'RR\_light' | 'RR\_heavy'

Wall material, specified as 'CR\_light', 'CR\_heavy', 'RR\_light', or 'RR\_heavy', indicating the wall material for the A1 scenario NLOS path loss calculation. `PathLossOption` applies only when `PathLossModelUsed` is set to 'yes'.

### **RandomSeed — Seed for random number generators**

[] (default) | scalar

Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, [], indicate that the global random stream is used.

### **cfgLayout — Configuration layout**

structure

Configuration layout, specified as a structure containing these fields, which represent the location and orientation parameters for all simulated stations. `cfgLayout` is typically created using the `winner2.layoutparset` function.

### **Stations — Active stations**

row vector of structures

Active stations, specified as a row vector of structures describing the antenna arrays for active stations. `Stations` is created from the `arrays` input of `winner2.layoutparset` and adds an additional `Velocity` field. The row ordering specifies base station (BS) sectors first, followed by the mobile stations (MS). The BS sector and MS positions are randomly assigned. The BS sectors have no velocity. Each MS has a velocity of about 1.42 m/s with a randomly assigned direction.

### **NofSect — Number of sectors**

vector

Number of sectors, specified as a vector indicating the number of sectors in each BS.

### **Pairing — BS to MS pairing**

matrix

BS to MS pairing, specified as a 2-by- $N_L$  matrix, where  $N_L$  specifies the number of links to be modeled. See `Stations` for BS and MS row ordering.

### **ScenarioVector — Spatial scenario**

1 (default) | vector

Spatial scenario, specified as a 1-by- $N_L$  vector of scenario numbers. The default is 1, which specifies scenario A1.

The scenarios numbers map as {1=A1, 2=A2, 3=B1, 4=B2, 5=B3, 6=B4, 10=C1, 11=C2, 12=C3, 13=C4, 14=D1, 15=D2a}.

For more information, see WINNER II Channel Models [1], Section 2.3.

### **PropagConditionVector — Propagation condition**

1 (default) | vector

Propagation condition, specified as a 1-by- $N_L$  vector of propagation conditions (LOS = 1 and NLOS = 0) for each link.

### **StreetWidth — Street width**

20 (default) | vector

Street width, specified as a 1-by- $N_L$  vector of identical values that specify the average width (in meters) of the streets. `StreetWidth` is used for the path loss model of the B1 and B2 scenarios. See `ScenarioVector` for the scenario number mapping. All elements must have the same value. `StreetWidth` applies only when `cfgWim.PathLossModelUsed` is set to 'yes'.

### **Dist1 — Distances from BS to the last LOS point**

NaN (default) | vector

Distances from BS to the last LOS point, specified as a 1-by- $N_L$  vector. `Dist1` is used for the path loss model of the B1 and B2 scenarios. The default value of NaN indicates that the distance is randomly determined in path loss function. See `ScenarioVector` for the scenario number mapping. `Dist1` applies only when `cfgWim.PathLossModelUsed` is set to 'yes'.

For more information, see WINNER II Channel Models [1], Figure 4-3.

### **NumFloors — Floor numbers**

1 (default) | vector

Floor numbers, specified as a 1-by- $N_L$  vector indicating the floor number where the indoor BS or MS is located. The default value is 1. The `NumFloors` field is used for the path loss model of the A2 and B4 scenarios only. See `ScenarioVector` for the scenario number mapping. `NumFloors` applies only when `cfgWim.PathLossModelUsed` is set to 'yes'.

### **NumPenetratedFloors — Number of floors penetrated**

0 (default) | vector

Number of floors penetrated, specified as a 1-by- $N_L$  vector indicating the number of penetrated floors between BS and MS. The default value is 0. The `NumPenetratedFloors` is used for the NLOS path loss model of the A1 scenario. See `ScenarioVector` for the scenario number mapping. `NumPenetratedFloors` field applies only when `cfgWim.PathLossModelUsed` is set to 'yes'.

For more information, see WINNER II Channel Models [1], Table 4-4.

### **initCond — Initial system condition**

structure | optional

Initial system condition, specified as a structure. `initCond` is of the same form as `finalCond` and is typically the `finalCond` output from the prior call of `winner2.wim`.

Data Types: `struct`

## **Output Arguments**

### **chanCoef — Channel coefficients**

cell array containing 4-D arrays of complex values

Channel coefficients, returned as an  $N_L$ -by-1 cell array.  $N_L$  is the number of links in the system. The  $i$ th element of `chanCoef` is an  $N_R(i)$ -by- $N_T(i)$ -by- $N_P(i)$ -by- $N_S$  array.  $N_R$ ,  $N_T$ , and  $N_P$  are link specific.  $N_S$  is the same for all the links.

- $N_R(i)$  is the number of receive antenna elements at MS for the  $i$ th link.
- $N_T(i)$  is the number of transmit antenna elements at BS for the  $i$ th link.
- $N_P(i)$  is the number of paths for the  $i$ th link.
- $N_S$  is the number of time samples given by `cfgWim.NumTimeSamples`.

For more information, see “Channel Power” on page 2-1212.

Data Types: `cell`

### **pathDelays — Path delays**

matrix

Path delays, returned as an  $N_L$ -by- $maxN_P$  matrix.  $N_L$  is the number of links in the system and  $maxN_P$  is the maximum number of paths among all links. Each row of the matrix applies to each link. When a link has fewer than  $maxN_P$  paths, the corresponding row in `pathDelays` is NaN padded.

Data Types: `double`

### **finalCond — Final system condition**

structure

Final system condition, returned as a structure. When generating channel coefficients for continuous time samples, use `finalCond` as the `initCond` input for the next call to `winner2.wim`.

For more information, see WINNER II Channel Models [1], Section 5.2.

Data Types: `struct`

## More About

### Channel Power

When path loss and shadowing are off, path gains of the computed WINNER channel are normalized. Specifically, path gains are normalized when the `ShadowingModelUsed` and `PathLossModelUsed` parameters are set to 'no'.

# winner2.wimparset

WINNER II model parameter configuration

## Syntax

```
cfgWim = winner2.wimparset
```

## Description

**Download Required:** To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons” (MATLAB).

`cfgWim = winner2.wimparset` returns a structure of WINNER II model parameters with their default values.

## Examples

### Create a WINNER II model parameter set

```
cfgWim = winner2.wimparset;
```

Adjust default settings.

```
cfgWim.RandomSeed = 31; % set the rng seed for repeatability  
cfgWim.NumTimeSamples = 250;  
cfgWim.CenterFrequency = 4e9;
```

## Output Arguments

**cfgWim** — Configuration layout  
structure

Configuration model, returned as a structure containing these fields.

### **NumTimeSamples — Number of time samples**

100 (default) | scalar

Number of time samples, specified as a scalar.

### **FixedPdpUsed — Use predefined path delays and powers for specific scenarios**

'no' (default) | 'yes'

Use predefined path delays and powers for specific scenarios, specified as 'no' or 'yes'.

### **FixedAnglesUsed — Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios**

'no' (default) | 'yes'

Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as 'yes' or 'no'.

### **IntraClusterDsUsed — Divide each of the two strongest clusters into three subclusters per link**

'yes' (default) | 'no'

Divide each of the two strongest clusters into three subclusters per link, specified as 'yes' or 'no'.

### **PolarisedArrays — Use dual-polarized arrays**

'yes' (default) | 'no'

Use dual-polarized arrays, specified as 'yes' or 'no'.

### **UseManualPropCondition — Use manually defined propagation conditions**

'yes' (default) | 'no'

Use manually defined propagation conditions, specified as 'yes' or 'no'. Set to 'yes' to enforce the use of manually defined propagation conditions (LOS/NLOS) in the PropagConditionVector structure field returned by winner2.layoutparset. Set to 'no' to draw propagation conditions from pre-defined LOS probabilities.

### **CenterFrequency — Carrier frequency**

5.25e9 (default) | scalar

Carrier frequency in Hz, specified as a scalar.

**UniformTimeSampling — Enforce uniform time sampling**

'no' (default) | 'yes'

Enforce all links to be sampled at the same time instants, specified as 'no' or 'yes'.

**SampleDensity — Number of time samples per half wavelength**

2e6 (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

**DelaySamplingInterval — Sampling interval**

5e-9 (default) | scalar

Sampling interval, specified as a scalar indicating the input signal sample time in seconds. `DelaySamplingInterval` defines the sampling grid to which the path delays are rounded. A value of 0 seconds indicates no rounding on path delays.

**ShadowingModelUsed — Use shadow fading**

'no' (default) | 'yes'

Use shadow fading, specified as 'no' or 'yes'.

**PathLossModelUsed — Use path loss model**

'no' (default) | 'yes'

Use path loss model, specified as 'no' or 'yes'.

**PathLossModel — Path loss model**

'pathloss' (default) | character vector

Path loss model, specified as a character vector representing a valid function name. `PathLossModel` applies only when `PathLossModelUsed` is set to 'yes'.

**PathLossOption — Wall material**

'CR\_light' (default) | 'CR\_heavy' | 'RR\_light' | 'RR\_heavy'

Wall material, specified as 'CR\_light', 'CR\_heavy', 'RR\_light', or 'RR\_heavy', indicating the wall material for the A1 scenario NLOS path loss calculation. `PathLossOption` applies only when `PathLossModelUsed` is set to 'yes'.

### **RandomSeed — Seed for random number generators**

[ ] (default) | scalar

Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, [ ], indicate that the global random stream is used.

# zadoffChuSeq

Generate root Zadoff-Chu sequence

## Syntax

```
seq = zadoffChuSeq(R,N)
```

## Description

`seq = zadoffChuSeq(R,N)` generates the Rth root Zadoff-Chu sequence with length N, as defined in 3GPP TS 36.211.

The function generates the sequence using the algorithm given by

$$seq(m+1) = \exp(-j \cdot \pi \cdot R \cdot m \cdot (m+1)/N), \text{ for } m = 0, \dots, N-1.$$

The function uses a negative polarity on the argument of the exponent, that is, a clockwise sequence of phases.

## Examples

### Examine Correlation Properties of Root Zadoff-Chu Sequence

Generate the 25th root Zadoff-Chu sequence with a length of 139.

Plot the absolute values of the output sequence.

```
seq = zadoffChuSeq(25,139);  
plot(abs(xcorr(seq)./length(seq)))
```

## Input Arguments

### **R** — Root of Zadoff-Chu sequence

positive integer

Root of the Zadoff-Chu sequence, specified as a positive integer.

Example: 25

Data Types: double

**N — Length of Zadoff-Chu sequence**

odd positive integer

Length of the Zadoff-Chu sequence, specified as an odd positive integer.

Example: 139

Data Types: double

## Output Arguments

**seq — Rth root Zadoff-Chu sequence**

column vector of complex values

Rth root Zadoff-Chu sequence, returned as an N-by-1 vector of complex values.

## Compatibility Considerations

**lteZadoffChuSeq was renamed to zadoffChuSeq***Behavior changed in R2019a*

In release R2019a, the lteZadoffChuSeq function was renamed to zadoffChuSeq.

# addCustomBasemap

Add custom basemap

## Syntax

```
addCustomBasemap(basemapName,URL)
addCustomBasemap( ____,Name,Value)
```

## Description

`addCustomBasemap(basemapName,URL)` adds the custom basemap specified by URL to the list of basemaps available for use with mapping functions. `basemapName` is the name you choose to call the custom basemap. Added basemaps remain available for use in future MATLAB sessions.

`addCustomBasemap( ____,Name,Value)` specifies name-value pairs that set additional parameters of the basemap.

## Examples

### Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from `siteviewer`.

Initialize simulation variables to:

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.

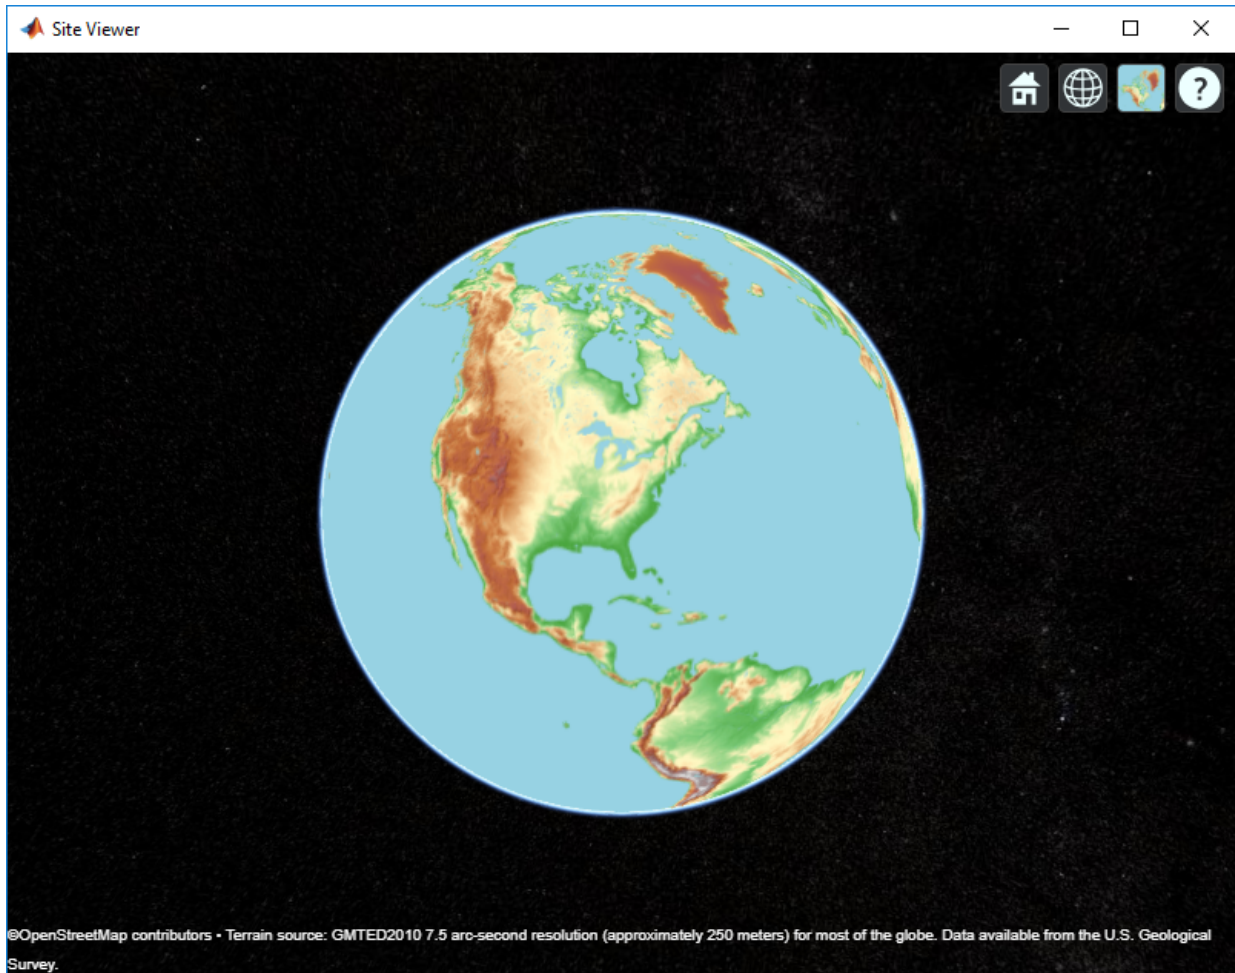

- Define a display name for the custom map.

```
name = 'opentopomap';  
url = 'a.tile.opentopomap.org';  
copyright = char(uint8(169));  
attribution = copyright + "OpenStreetMap contributors";  
displayName = 'Open Topo Map';
```

Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

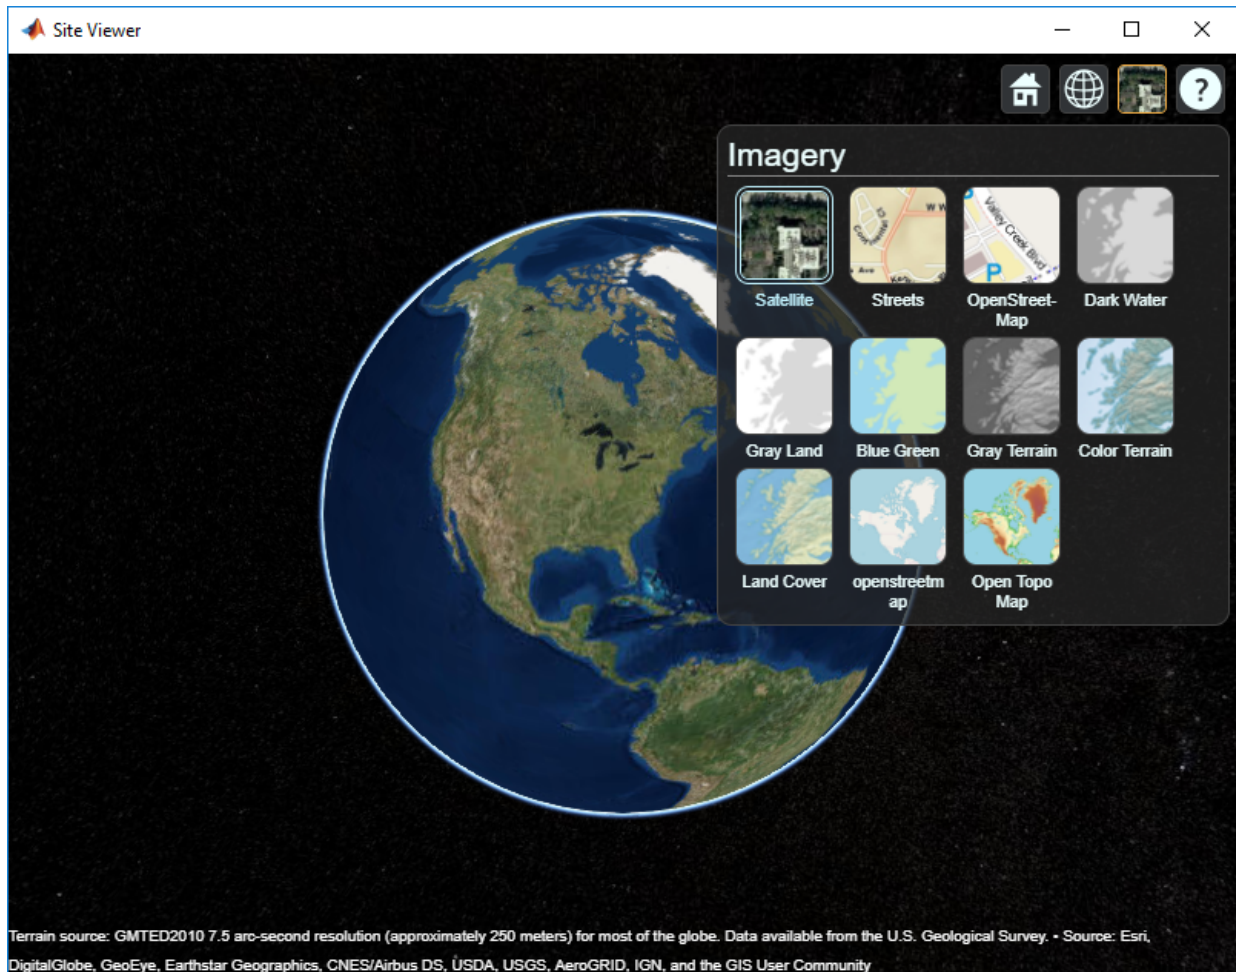

```
addCustomBasemap(name,url,'Attribution',attribution,'DisplayName',displayName)  
viewer = siteviewer('Basemap',name);
```

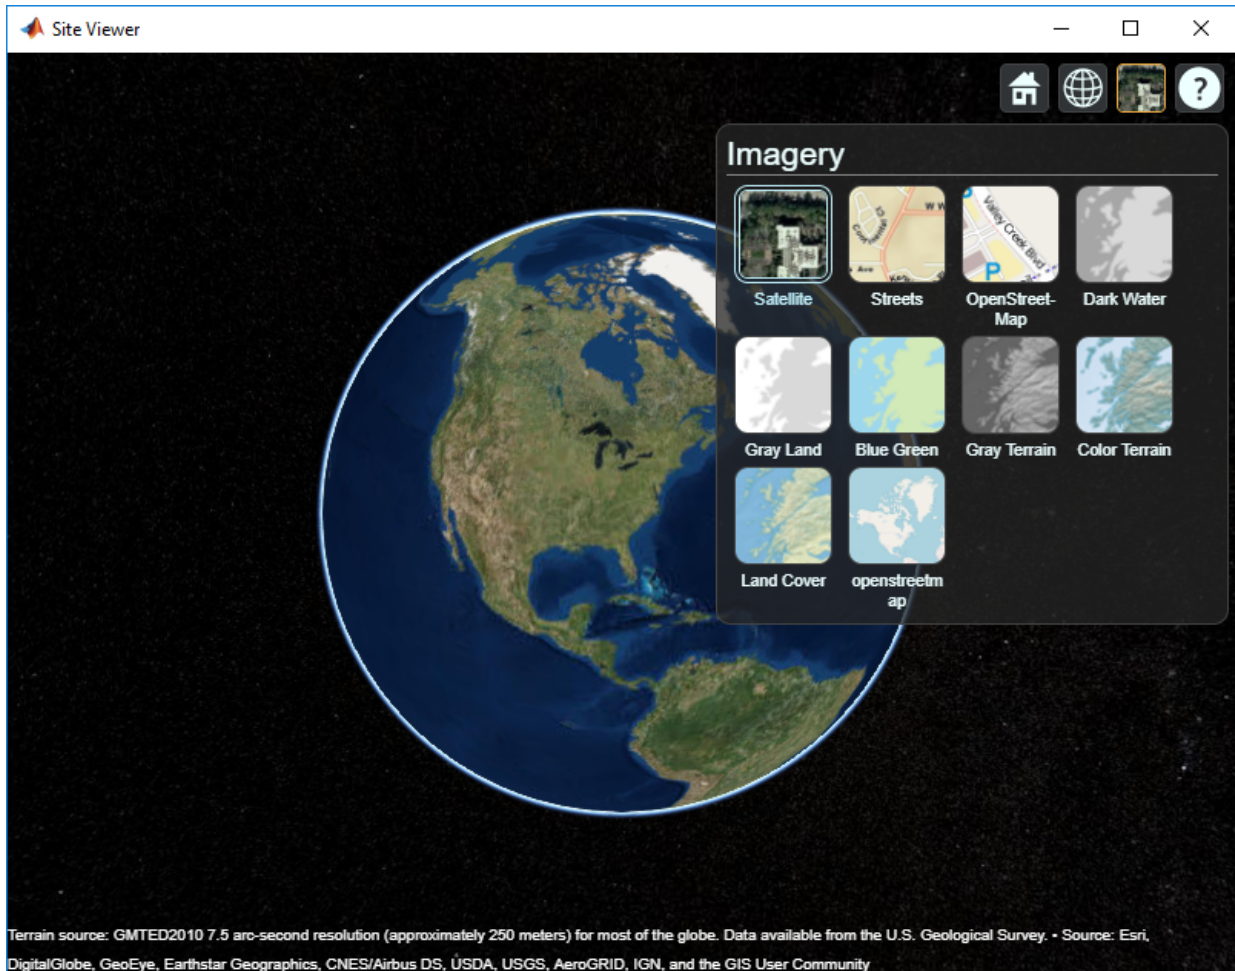

After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the 'Open Topo Map' icon in the Imagery tab.

```
siteviewer;
```

Use `removeCustomBasemap` to remove the custom basemap from future calls to `siteviewer`. Note the 'Open Topo Map' icon is no longer available in the Imagery tab.

```
removeCustomBasemap(name)  
siteviewer;
```

## Input Arguments

**basemapName** — Name used to identify basemap programmatically

string scalar | character vector

Name used to identify basemap programmatically, specified as a string scalar or character vector.

Example: 'openstreetmap'

Data Types: string | char

### URL — Parameterized map URL

string scalar | character vector

Parameterized map URL, specified as a string scalar or character vector. A parameterized URL is an index of the map tiles, formatted as  $\${z}/\${x}/\${y}.png$  or  $\{z}/\{x}/\{y}.png$ , where:

- $\${z}$  or  $\{z}$  is the tile zoom level.
- $\${x}$  or  $\{x}$  is the tile column index.
- $\${y}$  or  $\{y}$  is the tile row index.

Example: 'https://hostname/\${z}/\${x}/\${y}.png'

Data Types: string | char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `addCustomBasemap(basemapName, URL, 'Attribution', attribution)`

### Attribution — Attribution of custom basemap

'Tiles courtesy of *DOMAIN\_NAME\_OF\_URL*' (default) | string scalar | string array | character vector | cell array of character vectors

Attribution of custom basemap, specified as the comma-separated pair consisting of 'Attribution' and a string scalar, string array, character vector, or cell array of character vectors. If the host is 'localhost', or if URL contains only IP numbers, specify an empty value (''). To create a multiline attribution, specify a string array or nonscalar cell array of character vectors.

If you do not specify an attribution, the default attribution is 'Tiles courtesy of *DOMAIN\_NAME\_OF\_URL*', where the `addCustomBasemap` function obtains the domain name from the URL input argument.

Example: 'Credit: U.S. Geological Survey'

Data Types: string | char | cell

### **DisplayName** — Display name of custom basemap

string scalar | character vector

Display name of the custom basemap, specified as the comma-separated pair consisting of 'DisplayName' and a string scalar or character vector.

Example: 'OpenStreetMap'

Data Types: string | char

### **MaxZoomLevel** — Maximum zoom level of basemap

18 (default) | integer in the range [0, 25]

Maximum zoom level of the basemap, specified as the comma-separated pair consisting of 'MaxZoomLevel' and an integer in the range [0, 25].

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **IsDeployable** — Map is deployable using MATLAB Compiler™

false (default) | true

Map is deployable using MATLAB Compiler, specified as the comma-separated pair consisting of 'IsDeployable' and false or true.

Data Types: logical

## Tips

- You can find tiled web maps from various vendors, such as OpenStreetMap®, the USGS National Map, Mapbox, DigitalGlobe, Esri® ArcGIS Online, the Geospatial Information Authority of Japan (GSI), and HERE Technologies. Abide by the map vendors terms-of-service agreement and include accurate attribution with the maps you use.
- To access a list of available basemaps, press **Tab** before specifying the basemap in your plotting function.

```
geobubble (lat, lon, 'Basemap', '
```

### See Also

# removeCustomBasemap

Remove custom basemap

## Syntax

```
removeCustomBasemap(basemapName)
```

## Description

`removeCustomBasemap(basemapName)` removes the custom basemap specified by `basemapName` from the list of available basemaps.

## Examples

### Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from siteviewer.

Initialize simulation variables to:

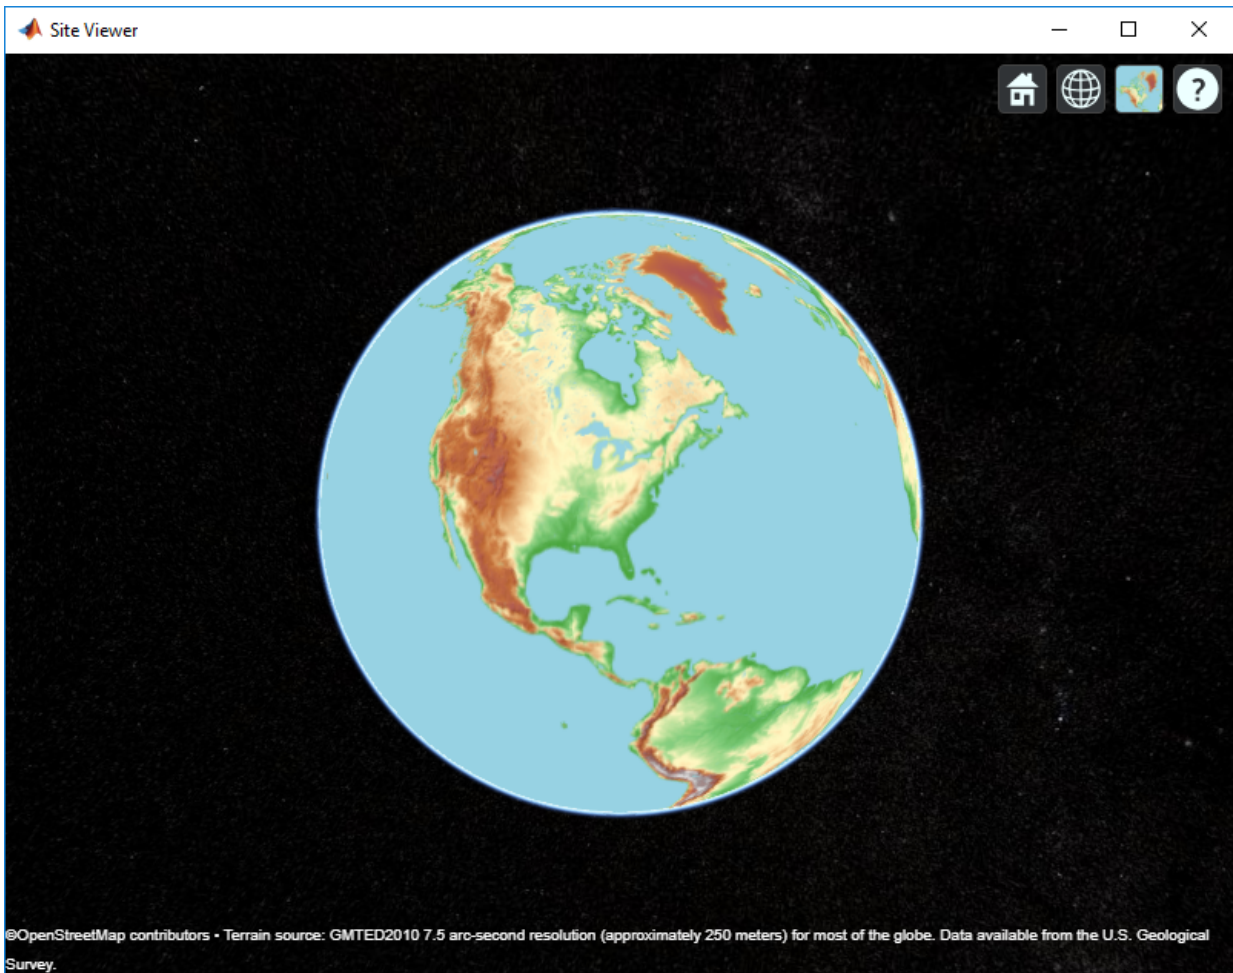

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';  
url = 'a.tile.opentopomap.org';  
copyright = char(uint8(169));
```

```
attribution = copyright + "OpenStreetMap contributors";  
displayName = 'Open Topo Map';
```

Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

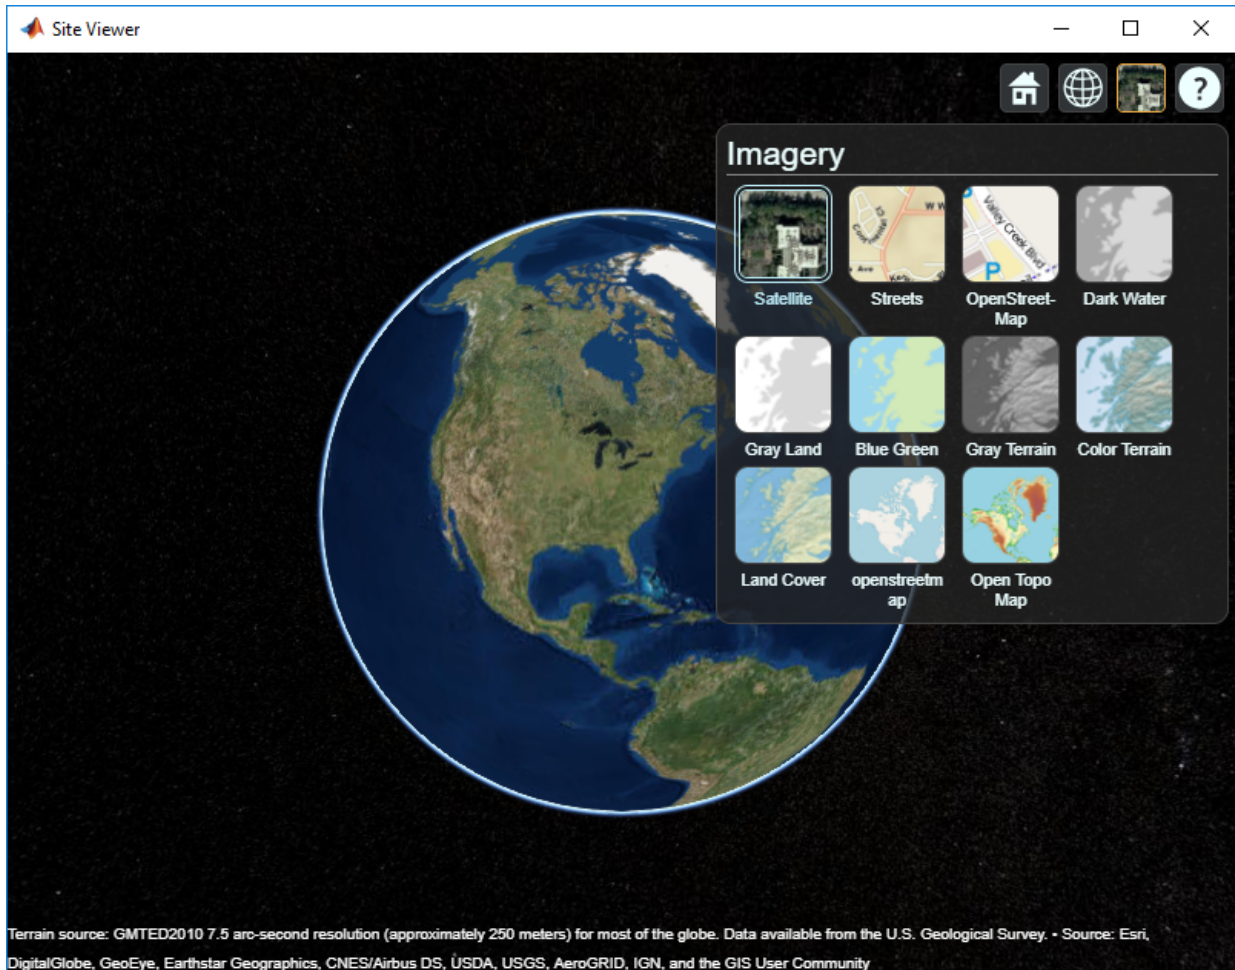

```
addCustomBasemap(name,url,'Attribution',attribution,'DisplayName',displayName)  
viewer = siteviewer('Basemap',name);
```

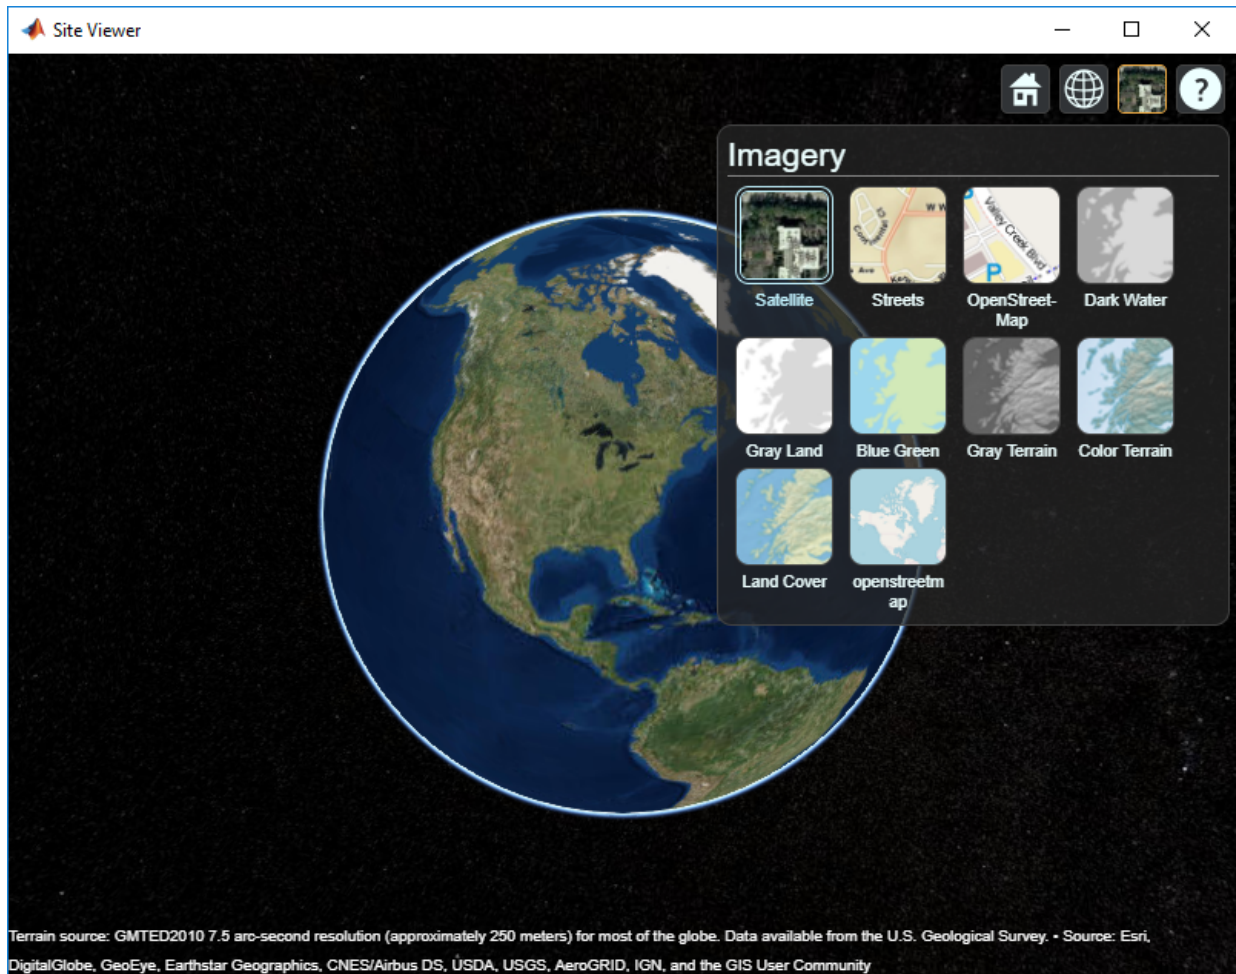

After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the 'Open Topo Map' icon in the Imagery tab.

```
siteviewer;
```

Use `removeCustomBasemap` to remove the custom basemap from future calls to `siteviewer`. Note the 'Open Topo Map' icon is no longer available in the Imagery tab.

```
removeCustomBasemap(name)  
siteviewer;
```

## Input Arguments

**basemapName** — Name of custom basemap  
string scalar | character vector

Name of the custom basemap to remove, specified as a string scalar or character vector. You define the basemap name when you add the basemap using the `addCustomBasemap` function.

Data Types: `string` | `char`

# fogpl

RF signal attenuation due to fog and clouds

## Syntax

`L = fogpl(R, freq, T, den)`

## Description

`L = fogpl(R, freq, T, den)` returns attenuation, `L`, when signals propagate in fog or clouds. `R` represents the signal path length. `freq` represents the signal carrier frequency, `T` is the ambient temperature, and `den` specifies the liquid water density in the fog or cloud.

The `fogpl` function applies the International Telecommunication Union (ITU) cloud and fog attenuation model to calculate path loss of signals propagating through clouds and fog [1]. Fog and clouds are the same atmospheric phenomenon, differing only by height above ground. Both environments are parameterized by their liquid water density. Other model parameters include signal frequency and temperature. This function applies when the signal path is contained entirely in a uniform fog or cloud environment. The liquid water density does not vary along the signal path. The attenuation model applies only for frequencies at 10-1000 GHz.

## Examples

### Attenuation in Cumulus Clouds

Compute the attenuation of signals propagating through a cloud that is 1 km long at 1000 meters altitude. Compute the attenuation for frequencies from 15 to 1000 GHz. A typical value for the cloud liquid water density is  $0.5 \text{ g/m}^3$ . Assume the atmospheric temperature at 1000 meters is  $20^\circ\text{C}$ .

```
R = 1000.0;  
freq = [15:5:1000]*1e9;
```

```
T = 20.0;  
lwd = 0.5;  
L = fogpl(R, freq, T, lwd);
```

Plot the specific attenuation as a function of frequency. Specific attenuation is the attenuation or loss per kilometer.

```
loglog(freq/1e9, L)  
grid  
xlabel('Frequency (GHz)')  
ylabel('Specific Attenuation (dB/km)')
```

## Input Arguments

### **R — Signal path length**

positive real-valued scalar |  $M$ -by-1 nonnegative real-valued vector | 1-by- $M$  nonnegative real-valued vector

Signal path length, specified as a scalar or as an  $M$ -by-1 or 1-by- $M$  vector of nonnegative real-values. Total attenuation is the specific attenuation multiplied by the path length. Units are meters.

Example: [1300.0, 1400.0]

### **freq — Signal frequency**

positive real-valued scalar |  $N$ -by-1 nonnegative real-valued column vector | 1-by- $N$  nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar or as an  $N$ -by-1 nonnegative real-valued vector or 1-by- $N$  nonnegative real-valued vector. Frequencies must lie in the range 10-1000 GHz.

Example: [14.0e9, 15.0e9]

### **T — Ambient temperature**

real-valued scalar

Ambient temperature in fog or cloud, specified as a real-valued scalar. Units are in degrees Celsius.

Example: -10.0

### **den — Liquid water density**

nonnegative real-valued scalar

Liquid water density, specified as a nonnegative real-valued scalar. Units are  $\text{g}/\text{m}^3$ . Typical values for liquid water density in fog range from approximately  $0.05 \text{ g}/\text{m}^3$  for medium fog to approximately  $0.5 \text{ g}/\text{m}^3$  for thick fog. For medium fog, visibility is about 300 meters. For heavy fog, visibility is about 50 meters. Cumulus cloud liquid water density is typically  $0.5 \text{ g}/\text{m}^3$ .

Example: 0.01

## Output Arguments

### L — Signal attenuation

real-valued  $M$ -by- $N$  matrix

Signal attenuation, returned as a real-valued  $M$ -by- $N$  matrix. Each matrix row represents a different path where  $M$  is the number of paths. Each column represents a different frequency where  $N$  is the number of frequencies. Units are in dB.

## More About

### Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where  $M$  is the liquid water density in  $\text{gm}/\text{m}^3$ . The quantity  $K_l(f)$  is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are  $(\text{dB}/\text{km})/(\text{g}/\text{m}^3)$ .

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length  $R$ . Total attenuation is  $L_c = R\gamma_c$ .

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

# fspl

Free space path loss

## Syntax

$L = \text{fspl}(R, \lambda)$

## Description

$L = \text{fspl}(R, \lambda)$  returns the free space path loss in decibels for a waveform with wavelength  $\lambda$  propagated over a distance of  $R$  meters. The minimum value of  $L$  is zero, indicating no path loss.

## Input Arguments

### **R**

real-valued 1-by- $M$  or  $M$ -by-1 vector

Propagation distance of signal. Units are in meters.

### **lambda**

real-valued 1-by- $N$  or  $N$ -by-1 vector

The wavelength is the speed of propagation divided by the signal frequency. Wavelength units are meters.

## Output Arguments

### **L**

Path loss in decibels.  $M$ -by- $N$  nonnegative matrix. A value of zero signifies no path loss. When  $\lambda$  is a scalar,  $L$  has the same dimensions as  $R$ .

# Examples

## Calculate Free-Space Path Loss

Calculate the free-space path loss (in dB) of a 10 GHz radar signal over a distance of 10 km.

```
fc = 10.0e9;  
lambda = physconst('LightSpeed')/fc;  
R = 10e3;  
L = fspl(R, lambda)  
  
L = 132.4478
```

# More About

## Free Space Path Loss

The free-space path loss,  $L$ , in decibels is:

$$L = 20\log_{10}\left(\frac{4\pi R}{\lambda}\right)$$

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in a loss smaller than 0 dB, equivalent to a signal gain. For this reason, the loss is set to 0 dB for range values  $R \leq \lambda/4\pi$ .

# gaspl

RF signal attenuation due to atmospheric gases

## Syntax

`L = gaspl(range, freq, T, P, den)`

## Description

`L = gaspl(range, freq, T, P, den)` returns the attenuation, `L`, when signals propagate through the atmosphere. `range` represents the signal path length, and `freq` represents the signal carrier frequency. `T` represents the ambient temperature, `P` represents the atmospheric pressure, and `den` represents the atmospheric water vapor density.

The `gaspl` function applies the International Telecommunication Union (ITU) atmospheric gas attenuation model [1] to calculate path loss for signals primarily due to oxygen and water vapor. The model computes attenuation as a function of ambient temperature, pressure, water vapor density, and signal frequency. The function requires that the signal path is contained entirely in a uniform environment. Atmospheric parameters do not vary along the signal path. The attenuation model applies only for frequencies at 1-1000 GHz.

## Examples

### Atmospheric Gas Attenuation Spectrum

Compute the attenuation spectrum from 1 to 1000 GHz for an atmospheric pressure of 101.300 kPa and a temperature of 15°C. Plot the spectrum for a water vapor density of  $7.5 \text{ g/m}^3$  and then plot the spectrum for dry air (zero water vapor density).

Set the attenuation frequencies.

```
freq = [1:1000]*1e9;
```

Assume a 1 km path distance.

```
R = 1000.0;
```

Compute the attenuation for air containing water vapor.

```
T = 15;
```

```
P = 101300.0;
```

```
W = 7.5;
```

```
L = gaspl(R, freq, T, P, W);
```

Compute the attenuation for dry air.

```
L0 = gaspl(R, freq, T, P, 0.0);
```

Plot the attenuations.

```
semilogy(freq/1e9, L)
```

```
hold on
```

```
semilogy(freq/1e9, L0)
```

```
grid
```

```
xlabel('Frequency (GHz)')
```

```
ylabel('Specific Attenuation (dB)')
```

```
hold off
```

### Plot Attenuation Due to Atmospheric Gases and Free Space

First, plot the specific attenuation of atmospheric gases for frequencies from 1 GHz to 1000 GHz. Assume a sea-level dry air pressure of  $101.325 \times 10^5$  kPa and a water vapor density of  $7.5 \text{ g/m}^3$ . The air temperature is  $20^\circ\text{C}$ . Specific attenuation is defined as dB loss per kilometer. Then, plot the actual attenuation at 10 GHz for a span of ranges.

### Plot Specific Atmospheric Gas Attenuation

Set the atmosphere temperature, pressure, water vapor density.

```
T = 20.0;  
Patm = 101.325e3;  
rho_wv = 7.5;
```

Set the propagation distance, speed of light, and frequencies.

```
km = 1000.0;  
c = physconst('LightSpeed');  
freqs = [1:1000]*1e9;
```

Compute and plot the atmospheric gas loss.

```
loss = gaspl(km,freqs,T,Patm,rho_wv);  
semilogy(freqs/1e9,loss)  
grid on  
xlabel('Frequency (GHz)')  
ylabel('Specific Attenuation (dB/km)')
```

### Plot Actual Atmospheric and Free Space Attenuation

Compute both free space loss and atmospheric gas loss at 10 GHz for ranges from 1 to 100 km. The frequency corresponds to an X-band radar. Then, plot the free space loss and the total (atmospheric + free space) loss.

```

ranges = [1:100]*1000;
freq_xband = 10e9;
loss_gas = gaspl(ranges, freq_xband, T, Patm, rho_wv);
lambda = c/freq_xband;
loss_fsp = fspl(ranges, lambda);
semilogx(ranges/1000, loss_gas + loss_fsp.', ranges/1000, loss_fsp)
legend('Atmospheric + Free Space Loss', 'Free Space Loss', 'Location', 'SouthEast')

```

```
xlabel('Range (km)')  
ylabel('Loss (dB)')
```

## Input Arguments

### **range** — Signal path length

nonnegative real-valued scalar |  $M$ -by-1 nonnegative real-valued column vector | 1-by- $M$  nonnegative real-valued row vector

Signal path length used to compute attenuation, specified as a nonnegative real-valued scalar or vector. You can specify multiple path lengths simultaneously. Units are in meters.

Example: [13000.0, 14000.0]

### **f req** — Signal frequency

positive real-valued scalar |  $N$ -by-1 nonnegative real-valued column vector | 1-by- $N$  nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar, or as an  $N$ -by-1 nonnegative real-valued vector or 1-by- $N$  nonnegative real-valued vector. You can specify multiple frequencies simultaneously. Frequencies must lie in the range 1-1000 GHz. Units are in hertz.

Example: [1.4e9, 2.0e9]

### **T** — Ambient temperature

real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: -10.0

### **P** — Dry air pressure

positive real-valued scalar

Dry air pressure, specified as a positive real-valued scalar. Units are in Pa. One standard atmosphere at sea level is 101325 Pa.

Example: 101300.0

### **den** — Water vapor density

nonnegative real-valued scalar

Water vapor density or absolute humidity, specified as a nonnegative real-valued scalar. Units are  $\text{g}/\text{m}^3$ . The maximum water vapor density of air at 30° C is approximately 30.0  $\text{g}/\text{m}^3$ . The maximum water vapor density of air at 0°C is approximately 5.0  $\text{g}/\text{m}^3$ .

Example: 4.0

## Output Arguments

### **L** — Signal attenuation

real-valued  $M$ -by- $N$  matrix

Signal attenuation, returned as a real-valued  $M$ -by- $N$  matrix. Each matrix row represents a different path where  $M$  is the number of paths. Each column represents a different frequency where  $N$  is the number of frequencies. Units are in dB.

## More About

### Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1-1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820fN''(f).$$

The quantity  $N''()$  is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function,  $F(f)_i$ , multiplied by a spectral line strength,  $S_i$ . For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left( \frac{300}{T} \right)^3 \exp \left[ a_2 \left( 1 - \left( \frac{300}{T} \right) \right) \right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left( \frac{300}{T} \right)^{3.5} \exp \left[ b_2 \left( 1 - \left( \frac{300}{T} \right) \right) \right] W.$$

$P$  is the dry air pressure,  $W$  is the water vapor partial pressure, and  $T$  is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure,  $W$ , is related to the water vapor density,  $\rho$ , by

$$W = \frac{\rho T}{216.7}.$$

The total atmospheric pressure is  $P + W$ .

For each oxygen line,  $S_i$  depends on two parameters,  $a_1$  and  $a_2$ . Similarly, each water vapor line depends on two parameters,  $b_1$  and  $b_2$ . The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions  $F_i(f)$  are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length,  $R$ . Then, the total attenuation is  $L_g = R(\gamma_o + \gamma_w)$ .

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

# rainpl

RF signal attenuation due to rainfall

## Syntax

```
L = rainpl(range, freq, rainrate)
L = rainpl(range, freq, rainrate, elev)
L = rainpl(range, freq, rainrate, elev, tau)
```

## Description

`L = rainpl(range, freq, rainrate)` returns the signal attenuation, `L`, due to rainfall. In this syntax, attenuation is a function of signal path length, `range`, signal frequency, `freq`, and rain rate, `rainrate`. The path elevation angle and polarization tilt angles are assumed to zero.

The `rainpl` function applies the International Telecommunication Union (ITU) rainfall attenuation model to calculate path loss of signals propagating in a region of rainfall [1]. The function applies when the signal path is contained entirely in a uniform rainfall environment. Rain rate does not vary along the signal path. The attenuation model applies only for frequencies at 1-1000 GHz.

`L = rainpl(range, freq, rainrate, elev)` specifies the elevation angle, `elev`, of the propagation path.

`L = rainpl(range, freq, rainrate, elev, tau)` specifies the polarization tilt angle, `tau`, of the signal.

## Examples

### Signal Attenuation Due to Rainfall

Compute the signal attenuation due to rainfall for a 20 GHz signal over a distance of 10 km in light and heavy rain.

Propagate the signal in a light rainfall of 1 mm/hr.

```
rr = 1.0;
L = rainpl(10000,20.0e9,rr)

L = 0.7104

L = 0.7104

L = 0.7104
```

Propagate the signal in a heavy rainfall of 10 mm/hr.

```
rr = 10.0;
L = rainpl(10000,20.0e9,rr)

L = 7.8413

L = 7.8413

L = 7.8413
```

### Signal Attenuation Due to Rainfall as Function of Frequency

Plot the signal attenuation due to moderate rainfall for signals in the frequency range from 1 to 1000 GHz. The path distance is 10 km.

Set the rain rate value for moderate rainfall to 3 mm/hr.

```
rr = 3.0;
freq = [1:1000]*1e9;
L = rainpl(10000,freq,rr);
loglog(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')
```

### Signal Attenuation Due to Rainfall as Function of Elevation Angle

Compute the signal attenuation due to heavy rain as a function of elevation angle. Elevation angles vary from 0 to 90 degrees. Assume a path distance of 100 km and a signal frequency of 100 GHz.

Set the rain rate to 10 mm/hr.

`rr = 10.0;`

Set the elevation angles, frequency, range.

```
elev = [0:1:90];  
freq = 100.0e9;  
rng = 100000.0*ones(size(elev));
```

Compute and plot the loss.

```
L = rainpl(rng,freq,rr,elev);  
plot(elev,L)  
grid  
xlabel('Path Elevation (degrees)')  
ylabel('Attenuation (dB)')
```

**Signal Attenuation Due to Rainfall as Function of Polarization**

Compute the signal attenuation due to heavy rainfall as a function of the polarization tilt angle. Assume a path distance of 100 km, a signal frequency of 100 GHz signal, and a path elevation angle of 0 degrees. Set the rainfall rate to 10 mm/hour. Plot the signal attenuation versus polarization tilt angle.

Set the polarization tilt angle to vary from -90 to 90 degrees.

```
tau = -90:90;
```

Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;  
freq = 100.0e9;  
rng = 100e3*ones(size(tau));  
rr = 10.0;
```

Compute and plot the attenuation.

```
L = rainpl(rng,freq,rr,elev,tau);  
plot(tau,L)  
grid  
xlabel('Tilt Angle (degrees)')  
ylabel('Attenuation (dB)')
```

## Input Arguments

### range — Signal path length

nonnegative real-valued scalar | nonnegative real-valued  $M$ -by-1 column vector |  
nonnegative real-valued 1-by- $M$  row vector

Signal path length, specified as a nonnegative real-valued scalar, or as a  $M$ -by-1 or 1-by- $M$  vector. Units are in meters.

Example: [13000.0, 14000.0]

### **freq** — Signal frequency

positive real-valued scalar | nonnegative real-valued  $N$ -by-1 column vector | nonnegative real-valued 1-by- $N$  row vector

Signal frequency, specified as a positive real-valued scalar, or as a nonnegative  $N$ -by-1 or 1-by- $N$  vector. Frequencies must lie in the range 1-1000 GHz.

Example: [1400.0e6,2.0e9]

### **rainrate** — Rain rate

nonnegative real-valued scalar

Rain rate, specified as a nonnegative real-valued scalar. Units are in mm/hr.

Example: 1.5

### **elev** — Signal path elevation angle

0.0 (default) | real-valued scalar | real-valued  $M$ -by-1 column vector | real-valued 1-by- $M$  row vector

Signal path elevation angle, specified as a real-valued scalar, or as an  $M$ -by-1 or 1-by- $M$  vector. Units are in degrees between  $-90^\circ$  and  $90^\circ$ . If `elev` is a scalar, all propagation paths have the same elevation angle. If `elev` is a vector, its length must match the dimension of `range` and each element in `elev` corresponds to a propagation range in `range`.

Example: [0,45]

### **tau** — Tilt angle of polarization ellipse

0.0 (default) | real-valued scalar | real-valued  $M$ -by-1 column vector | real-valued 1-by- $M$  row vector

Tilt angle of the signal polarization ellipse, specified as a real-valued scalar, or as an  $M$ -by-1 or 1-by- $M$  vector. Units are in degrees between  $-90^\circ$  and  $90^\circ$ . If `tau` is a scalar, all signals have the same tilt angle. If `tau` is a vector, its length must match the dimension of `range`. In that case, each element in `tau` corresponds to a propagation path in `range`.

The tilt angle is defined as the angle between the semimajor axis of the polarization ellipse and the  $x$ -axis. Because the ellipse is symmetrical, a tilt angle of  $100^\circ$  corresponds to the same polarization state as a tilt angle of  $-80^\circ$ . Thus, the tilt angle need only be specified between  $\pm 90^\circ$ .

Example: [45,30]

## Output Arguments

### L — Signal attenuation

real-valued  $M$ -by- $N$  matrix

Signal attenuation, returned as a real-valued  $M$ -by- $N$  matrix. Each matrix row represents a different path where  $M$  is the number of paths. Each column represents a different frequency where  $N$  is the number of frequencies. Units are in dB.

## More About

### Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^\alpha,$$

where  $r$  is the rain rate in mm/hr. The parameter  $k$  and exponent  $\alpha$  depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1-1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance,  $R$ . Then, total attenuation is  $L_r = R\gamma_r$ . Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

**Introduced in R2016a**

# rangeangle

Range and angle calculation

## Syntax

```
[rng,ang] = rangeangle(pos)
[rng,ang] = rangeangle(pos,refpos)
[rng,ang] = rangeangle(pos,refpos,refaxes)
[rng,ang] = rangeangle( ____,model)
```

## Description

The function `rangeangle` determines the propagation path length and path direction of a signal from a source point or set of source points to a reference point. The function supports two propagation models - the *free space* model and the *two-ray* model. The *free space* model is a single line-of-sight path from a source point to a reference point. The *two-ray* multipath model generates two paths. The first path follows the free-space path. The second path is a reflected path off a boundary plane at  $z = 0$ . Path directions are defined with respect to either the global coordinate system at the reference point or a local coordinate system at the reference point. Distances and angles at the reference point do not depend upon which direction the signal is travelling along the path.

`[rng,ang] = rangeangle(pos)` returns the propagation path length, `rng`, and direction angles, `ang`, of a signal path from a source point or set of source points, `pos`, to the origin of the global coordinate system. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the origin. Signals follow a line-of-sight path from the source point to the origin. The line-of-sight path corresponds to the geometric straight line between the points.

`[rng,ang] = rangeangle(pos,refpos)` also specifies a reference point or set of reference points, `refpos`. `rng` now contains the propagation path length from the source points to the reference points. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the reference points. You can specify multiple points and multiple reference points.

`[rng,ang] = rangeangle(pos,refpos,refaxes)` also specifies local coordinate system axes, `refaxes`, at the reference points. Direction angles are the azimuth and elevation with respect to the local coordinate axes centered at `refpos`.

`[rng,ang] = rangeangle(____,model)`, also specifies a propagation model. When `model` is set to `'reespace'`, the signal propagates along a line-of-sight path from source point to reception point. When `model` is set to `'two-ray'`, the signal propagates along two paths from source point to reception point. The first path is the line-of-sight path. The second path is the reflecting path. In this case, the function returns the distances and angles for two paths for each source point and corresponding reference point.

## Input Arguments

### **pos**

Source point position, specified as a real-valued 3-by-1 vector or a real-valued 3-by- $N$  matrix. A matrix represents multiple source points. The columns contain the Cartesian coordinates of  $N$  points in the form  $[x;y;z]$ .

When `pos` is a 3-by- $N$  matrix, you must specify `refpos` as a 3-by- $N$  matrix for  $N$  reference positions. If all the reference points are identical, you can specify `refpos` by a single 3-by-1 vector.

Position units are meters.

### **refpos**

Reference point position, specified as a real-valued 3-by-1 vector or a real-valued 3-by- $N$  matrix. A matrix represents multiple reference points. The columns contain the Cartesian coordinates of  $N$  points in the form  $[x;y;z]$ .

When `refpos` is a 3-by- $N$  matrix, you must specify `pos` as a 3-by- $N$  matrix for  $N$  source positions. If all the source points are identical, you can specify `pos` by a single 3-by-1 vector.

Position units are meters.

**Default:** `[0;0;0]`

**refaxes**

Local coordinate system axes, specified as a real-valued 3-by-3 matrix or a 3-by-3-by- $N$  array. For an array, each page corresponds to a local coordinate axes at each reference point. The columns in `refaxes` specify the direction of the coordinate axes for the local coordinate system in Cartesian coordinates.  $N$  must match the number of columns in `pos` or `refpos` when these dimensions are greater than one.

**Default:** [1 0 0;0 1 0;0 0 1]

**model**

Propagation model, specified as 'freespace' or 'two-ray'. Choosing 'freespace' invokes the free space propagation model. Choosing 'two-ray' invokes the two-ray propagation model.

**Default:** 'freespace'

## Output Arguments

**rng**

Propagation range, returned as a real-valued 1-by- $N$  vector or real-valued 1-by- $2N$  vector.

When `model` is set to 'freespace', the size of `rng` is 1-by- $N$ . The propagation range is the length of the direct path from the position defined in `pos` to the corresponding reference position defined in `refpos`.

When `model` is set to 'two-ray', `rng` contains the ranges for the direct path and the reflected path. Alternate columns of `rng` refer to the line-of-sight path and reflected path, respectively for the same source-reference point pair. Position units are meters.

**ang**

Azimuth and elevation angles, returned as a 2-by- $N$  matrix or 2-by- $2N$  matrix. Each column represents a direction angle in the form [azimuth;elevation].

When `model` is set to 'freespace', `ang` is a 2-by- $N$  matrix and represents the angle of the path from a source point to a reference point.

When `model` is set to 'two-ray', `ang` is a 2-by-2*N* matrix. Alternate columns of `ang` refer to the line-of-sight path and reflected path, respectively.

Angle units are in degrees.

## Examples

### Range and Angle Computation

Compute the range and angle of a target located at (1000,2000,50) meters from the origin.

```
TargetLoc = [1000;2000;50];  
[tgtrng,tgtang] = rangeangle(TargetLoc)
```

```
tgtrng = 2.2366e+03
```

```
tgtang = 2×1
```

```
63.4349  
1.2810
```

### Range and Angle With Respect to Local Origin

Compute the range and angle of a target located at (1000,2000,50) meters with respect to a local origin at (100,100,10) meters.

```
TargetLoc = [1000;2000;50];  
Origin = [100;100;10];  
[tgtrng,tgtang] = rangeangle(TargetLoc,Origin)
```

```
tgtrng = 2.1028e+03
```

```
tgtang = 2×1
```

```
64.6538  
1.0900
```

## Range and Angle With Respect to Local Coordinates

Compute the range and angle of a target located at  $(1000,2000,50)$  meters but with respect to a local coordinate system origin at  $(100,100,10)$  meters. Choose a local coordinate reference frame that is rotated about the z-axis by  $45^\circ$  from the global coordinate axes.

```
targetpos = [1000;2000;50];
origin = [100;100;10];
refaxes = [1/sqrt(2) -1/sqrt(2) 0; 1/sqrt(2) 1/sqrt(2) 0; 0 0 1];
[tgtrng,tgtang] = rangeangle(targetpos,origin,refaxes)
```

```
tgtrng = 2.1028e+03
```

```
tgtang = 2×1
```

```
19.6538
1.0900
```

## More About

### Angles in Local and Global Coordinate Systems

The `rangeangle` function returns the path distance and path angles in either the global or local coordinate systems. By default, the `rangeangle` function determines the angle a signal path makes with respect to global coordinates. If you add the `refaxes` argument, you can compute the angles with respect to local coordinates. As an illustration, this figure shows a 5-by-5 uniform rectangular array (URA) rotated from the global coordinates  $(xyz)$  using `refaxes`. The  $x'$  axis of the local coordinate system  $(x'y'z')$  is aligned with the main axis of the array and moves as the array moves. The path length is independent of orientation. The global coordinate system defines the azimuth and elevations angles  $(\Phi,\theta)$  and the local coordinate system defines the azimuth and elevations angles  $(\Phi',\theta')$ .

### Local and Global Coordinate Axes

## Free Space Propagation Model

The free-space signal propagation model states that a signal propagating from one point to another in a homogeneous, isotropic medium travels in a straight line, called the *line-of-sight* or *direct path*. The straight line is defined by the geometric vector from the radiation source to the destination.

## Two-Ray Propagation Model

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at  $z = 0$ . There are at most two rays propagating

from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel. The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection, the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The figure illustrates two propagation paths. From the source position,  $s_s$ , and the receiver position,  $s_r$ , you can compute the arrival angles of both paths,  $\theta'_{los}$  and  $\theta'_{rp}$ . The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles,  $\theta_{los}$  and  $\theta_{rp}$ . In the global coordinates, the angle of reflection at the boundary is the same as the angles  $\theta_{rp}$  and  $\theta'_{rp}$ . The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by  $R_{los}$  which is equal to the geometric distance between source and receiver. The total path length for the reflected path is  $R_{rp} = R_1 + R_2$ . The quantity  $L$  is the ground range between source and receiver.

You can easily derive exact formulas for path lengths and angles in terms of the ground range and object heights in the global coordinate system.

$$\begin{aligned}\vec{R} &= \vec{x}_s - \vec{x}_r \\ R_{los} &= |\vec{R}| = \sqrt{(z_r - z_s)^2 + L^2} \\ R_1 &= \frac{z_r}{z_r + z_s} \sqrt{(z_r + z_s)^2 + L^2} \\ R_2 &= \frac{z_s}{z_s + z_r} \sqrt{(z_r + z_s)^2 + L^2} \\ R_{rp} &= R_1 + R_2 = \sqrt{(z_r + z_s)^2 + L^2} \\ \tan\theta_{los} &= \frac{(z_s - z_r)}{L} \\ \tan\theta_{rp} &= -\frac{(z_s + z_r)}{L} \\ \theta'_{los} &= -\theta_{los} \\ \theta'_{rp} &= \theta_{rp}\end{aligned}$$

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Does not support variable-size inputs.

### See Also

**Introduced in R2011a**

## addCustomTerrain

Add custom terrain data

### Syntax

```
addCustomTerrain(name,files)
addCustomTerrain( ____,Name,Value)
```

### Description

`addCustomTerrain(name,files)` adds the terrain data specified with a user-defined name and files. You can use this function to add custom terrain data in Site Viewer and other RF propagation functions. You can access the custom terrain data in the current and future sessions of MATLAB until you call `removeCustomTerrain`.

`addCustomTerrain( ____,Name,Value)` adds custom terrain data with additional options specified by one or more name-value pairs.

### Examples

#### Site Viewer Maps Using Custom Terrain

Add a custom terrain using `n44_w072_3arc_v1.dt1` DTED file.

```
addCustomTerrain('mydted5','n44_w072_3arc_v1.dt1')
```

Use the custom terrain name in Site Viewer.

```
viewer = siteviewer('Terrain','mydted5');
```

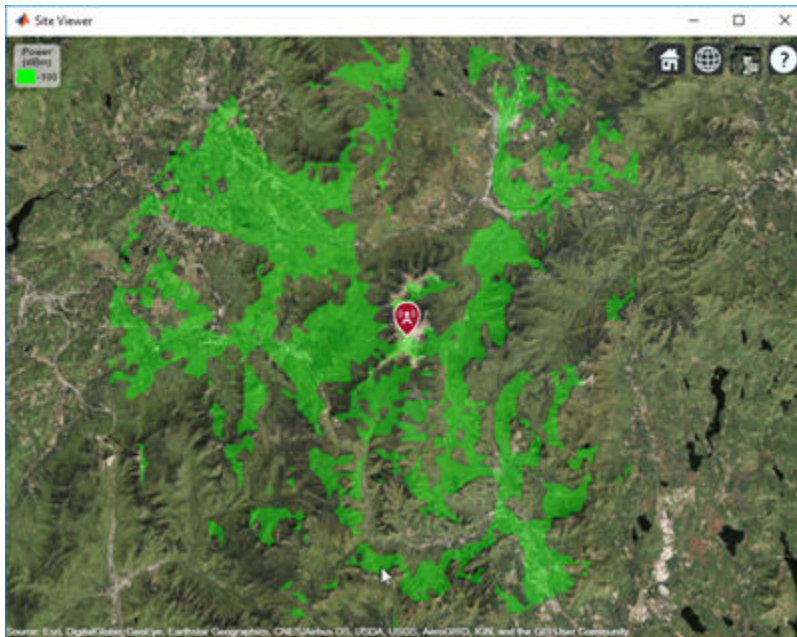

Create a site with the terrain region.

```
mtwash = txsite('Name', 'Mt Washington', ...  
               'Latitude', 44.2706, ...  
               'Longitude', -71.3033, ...  
               'AntennaHeight', 30);  
show(mtwash)
```

Create a coverage map.

coverage(mtwash)

Remove the custom terrain.

```
close(viewer)
removeCustomTerrain("mydted5")
```

## Input Arguments

**name** — User-defined identifier for terrain data

string scalar | character vector

User-defined identifier for terrain data, specified as a string scalar or a character vector.

Data Types: char | string

**files** — List of DTED files

string scalar | character vector | cell array of character vectors

List of DTED files, specified as a string scalar, a character vector or a cell array of character vectors.

**Note** If you specify multiple files, they must combine to define a complete rectangular geographic region. If not, you must set the name-value pair 'FillMissing' to 'true'.

Data Types: `char` | `string`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'FillMissing', true`

#### **Attribution — Attribution of custom terrain data**

`character vector` | `string scalar`

Attribution of custom terrain data, specified as a character vector or a string scalar. The attribution is displayed on the Site Viewer map. By default, the value is empty.

Data Types: `char` | `string`

#### **FillMissing — Fill data of missing files with value 0**

`false` (default) | `true`

Fill data of missing files with value 0, specified as `true` or `false`. Missing file values are required to complete a rectangular geographic region with the input files.

Data Types: `logical`

#### **WriteLocation — Name of folder to write extracted terrain files to**

`character vector` | `string scalar`

Name of folder to write extracted terrain files to, specified as a character vector or a string scalar. The folder must exist and have write permissions. The default value is a folder name generated using `tempname`.

Data Types: `char` | `string`

### See Also

`removeCustomTerrain` | `siteviewer`

# angle

Angle between sites

## Syntax

```
[az,el] = angle(site1,site2)
[az,el] = angle(site1,site2,path)
[az,el] = angle( ____,Name,Value)
```

## Description

`[az,el] = angle(site1,site2)` returns the azimuth and elevation angles between site 1 and site

`[az,el] = angle(site1,site2,path)` returns the angles using a specified path type, either Euclidean or geodesic.

`[az,el] = angle( ____,Name,Value)` returns the azimuth and elevation angles with additional options specified by name-value pairs.

## Examples

### Angle Between Sites

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx)
az = 14.0142
```

```
el = -0.2816
```

Get the azimuth angle between sites in degrees clockwise from north.

```
azFromEast = angle(tx,rx); % Unit: degrees counter-clockwise from east  
azFromNorth = -azFromEast + 90 % Convert angle to clockwise from north  
  
azFromNorth = 75.9858
```

## Angle Between Sites When Path is Geodesic

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);  
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx,'geodesic')  
  
az = 14.0142  
  
el = 0
```

## Input Arguments

### **site1,site2** — Transmitter or receiver site

txsite or rxsite object

Transmitter or receiver site, specified as a txsite or rxsite object. You can use array inputs to specify multiple sites.

### **path** — Measurement path type

'euclidean' or 'geodesic'

Measurement path type, specified as one of the following:

- 'euclidean': Uses the shortest path through space connecting the antenna center positions of the site 1 and site 2.

- `'geodesic'`: Uses the shortest path on the surface of the earth connecting the latitude and longitude locations of site 1 and site 2. This path uses Earth ellipsoid model WGS-84.

Data Types: `char`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Map', 'siteviewer1'`

#### Map — Map for surface data

`siteviewer` object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or `'gmted2010'`, if none is open.

Data Types: `char` | `string`

### Output Arguments

#### az — Azimuth angle between site 1 and site 2

*M*-by-*N* arrays

Azimuth angle between site 1 and site 2, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in sites 2 and *N* is the number of sites in sites 1. The values range from -180 to 180.

#### e1 — Elevation angle between site 1 and site 2

*M*-by-*N* arrays

Elevation angle between site 1 and site 2, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in sites 2 and *N* is the number of sites in sites 1. The values range from -90 to 90.

When the path type specified is 'geodesic', elevation angle is always zero.

## **See Also**

distance

**Introduced in R2017b**

# clearMap

Clear map visualizations

## Syntax

```
clearMap(viewer)
```

## Description

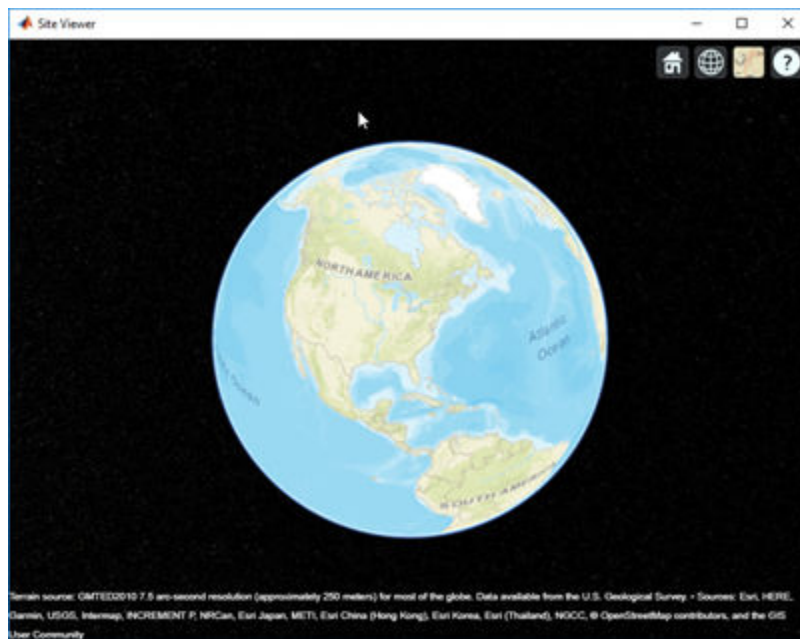

`clearMap(viewer)` removes all visualizations from the map.

## Examples

### View Transmitter Site On Site Viewer

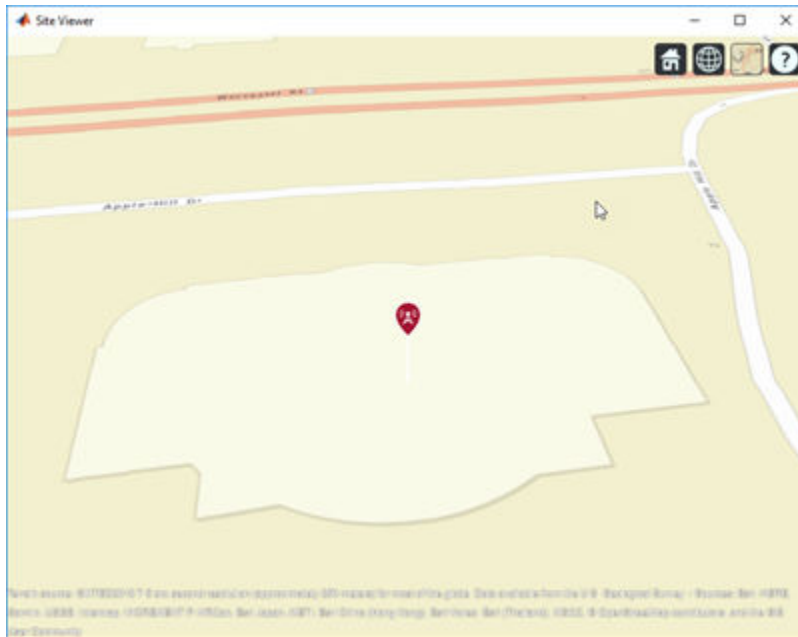

Launch a Site Viewer with streets basemap.

```
viewer = siteviewer("Basemap", "streets");
```

View a transmitter site on this map.

```
tx = txsite;  
show(tx)
```

Clear the map.

```
t = timer('TimerFcn',@(~,~)disp('Fired.'), 'StartDelay',3);
start(t)
wait(t)
clearMap(viewer)
```

## Input Arguments

**viewer** — Map viewer for visualizing transmitter or receiver sites  
`siteviewer` object

Map viewer for visualizing transmitter or receiver sites, specified as a `siteviewer` object.

## See Also

`close` | `siteviewer`

**Introduced in R2019a**

# close

Close map viewer window

## Syntax

```
close(viewer)
```

## Description

`close(viewer)` closes the map viewer window and deletes the handle

## Examples

### Compare Coverage Maps

Launch two Site Viewer windows.

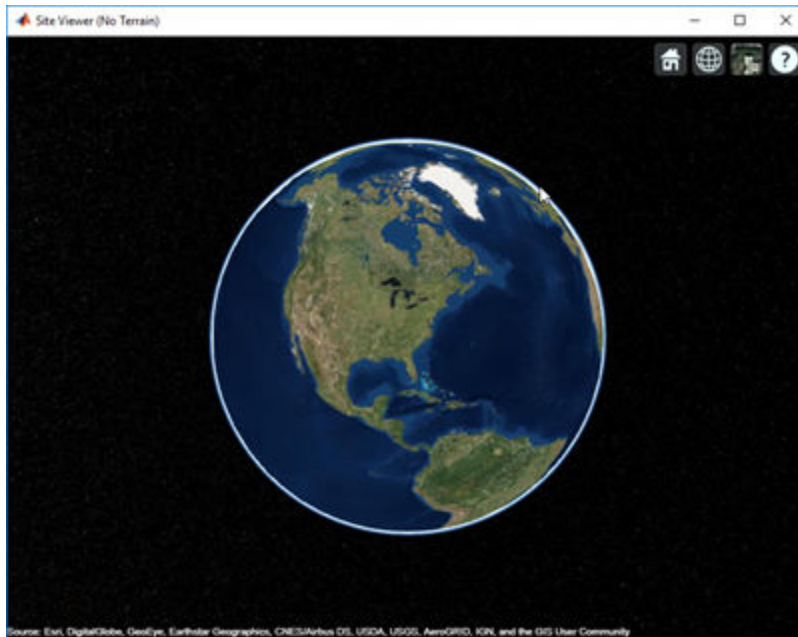

One Site Viewer window uses the terrain model.

```
viewer1 = siteviewer("Terrain", "gmted2010", "Name", "Site Viewer (Using Terrain)");
```

The second Site Viewer window does not use the terrain model.

```
viewer2 = siteviewer("Terrain", "none", "Name", "Site Viewer (No Terrain)");
```

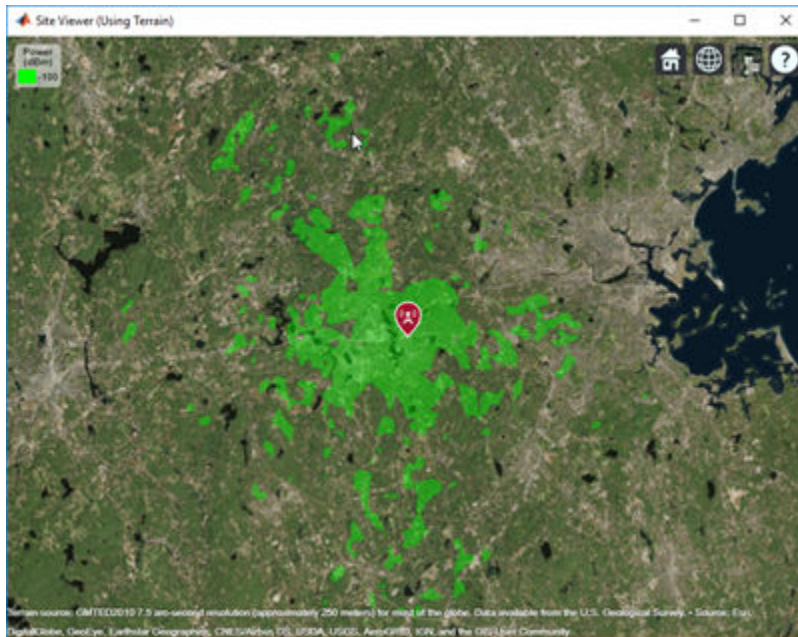

Create a transmitter site.

```
tx = txsite;
```

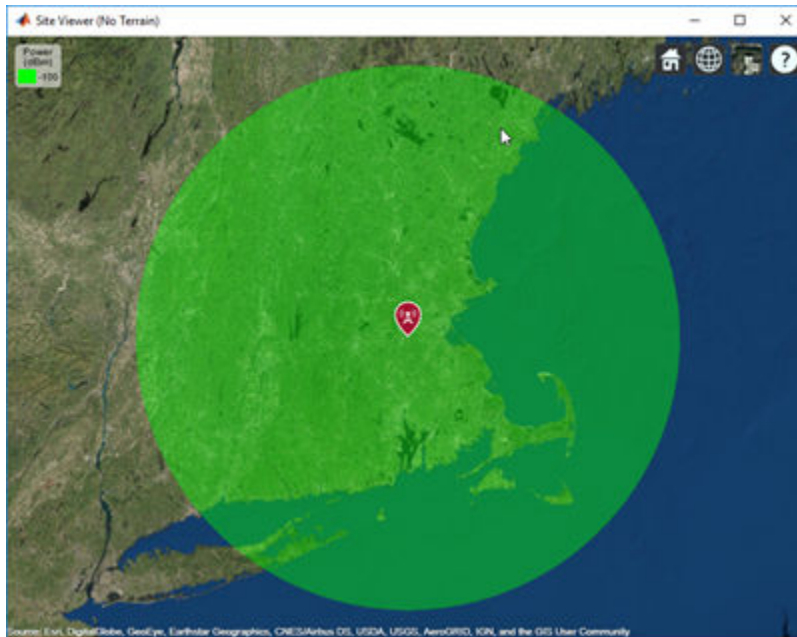

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.

```
coverage(tx, "Map", viewer1)
```

The map without terrain uses the free-space model by default.  
coverage(tx, "Map", viewer2)

Close the maps.

```
close(viewer1)  
close(viewer2)
```

## Input Arguments

**viewer** — Map viewer for visualizing transmitter or receiver sites

siteviewer object

Map viewer for visualizing transmitter or receiver sites, specified as a siteviewer object.

## See Also

clearMap | siteviewer

**Introduced in R2019a**

# coverage

Display coverage map

## Syntax

```
coverage(tx)  
coverage(tx,propmodel)  
coverage(tx,rx)  
coverage(tx,rx,propmodel)  
coverage( ____,Name,Value, ____ )
```

## Description

`coverage(tx)` displays the coverage map for the transmitter site. Each colored contour of the map defines an area where the corresponding signal strength is transmitted to the mobile receiver.

`coverage(tx,propmodel)` displays the coverage map based on the specified propagation model.

`coverage(tx,rx)` displays the coverage map based on the receiver site properties.

`coverage(tx,rx,propmodel)` displays the coverage map based on the receiver site properties and specified propagation model.

`coverage( ____,Name,Value, ____ )` displays the coverage map using additional options specified by the `Name,Value` pairs.

## Examples

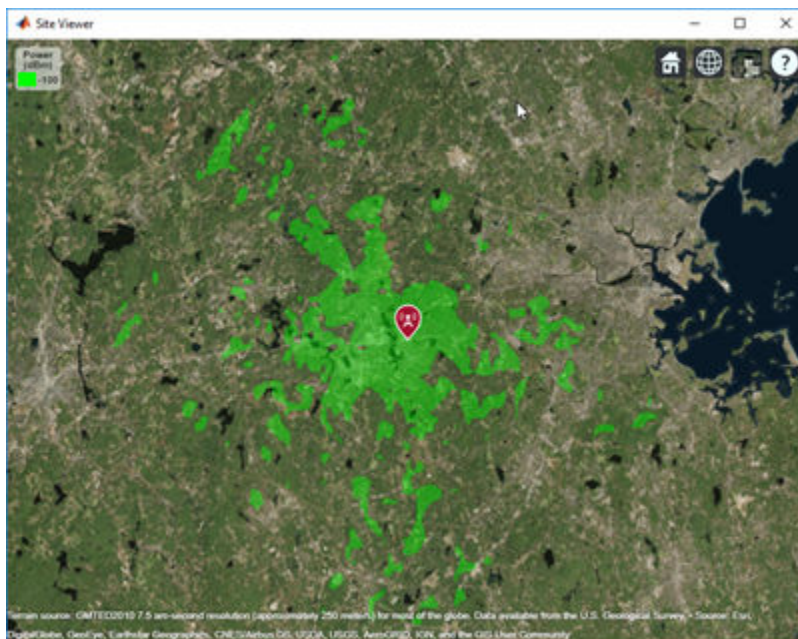

### Coverage Map of Transmitter

Create a transmitter site at MathWorks headquarters.

```
tx = txsite('Name','MathWorks', ...  
           'Latitude', 42.3001, ...  
           'Longitude', -71.3503);
```

Show the coverage map.

```
coverage(tx)
```

## Coverage Map Using Transmitter and Receiver

Create a transmitter site at MathWorks headquarters.

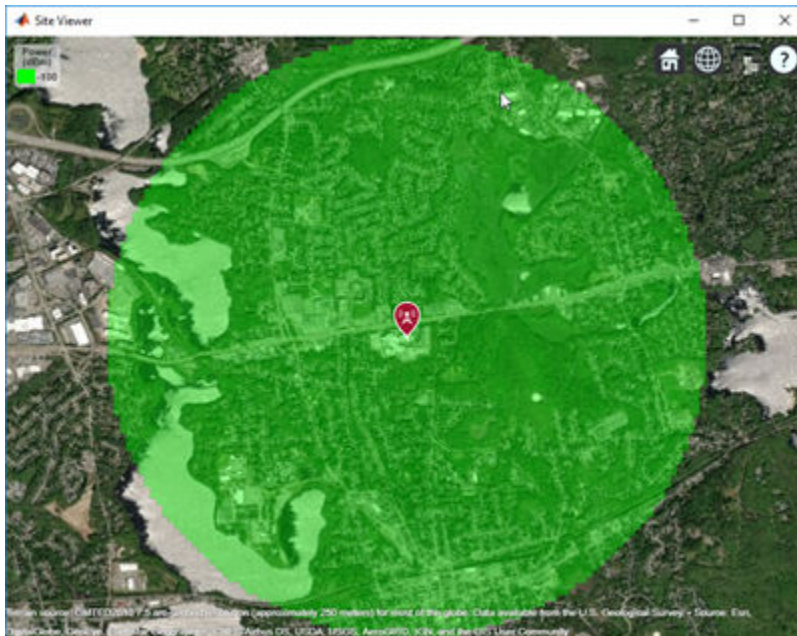

```
tx = txsite('Name','MathWorks', ...  
           'Latitude', 42.3001, ...  
           'Longitude', -71.3503);
```

Create a receiver site at Fenway Park with an antenna height of 1.2 m and system loss of 10 dB.

```
rx = rxsite('Name','Fenway Park', ...  
           'Latitude',42.3467, ...  
           'Longitude',-71.0972,'AntennaHeight',1.2,'SystemLoss',10);
```

Calculate the coverage area of the transmitter using a close-in propagation model.

```
coverage(tx,rx,'PropagationModel','closein')
```

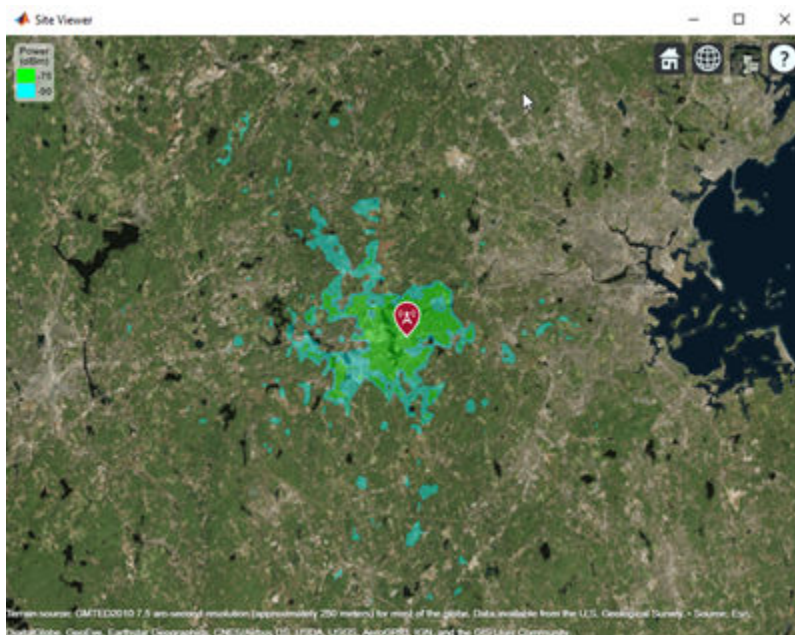

### Coverage Map for Strong and Weak Signals

Define strong and weak signal strengths with corresponding colors.

```
strongSignal = -75;  
strongSignalColor = "green";  
weakSignal = -90;  
weakSignalColor = "cyan";
```

Create a transmitter site and display the coverage map.

```
tx = txsite('Name','MathWorks','Latitude', 42.3001,'Longitude', -71.3503);
coverage(tx,'SignalStrengths',[strongSignal,weakSignal], ...
         'Colors', [strongSignalColor,weakSignalColor])
```

## Combined Coverage Map of Multiple Transmitters

Define the names and the locations of sites around Boston.

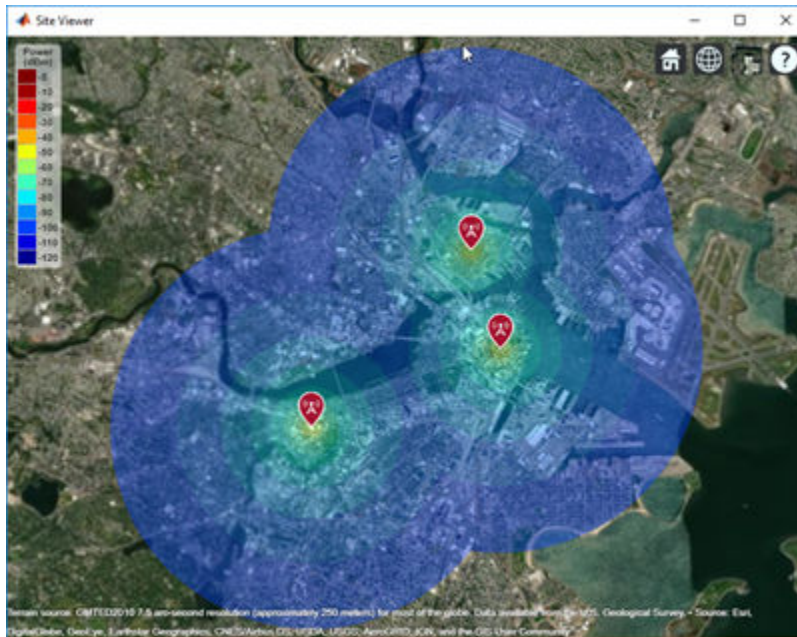

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create the transmitter site array.

```
txs = txsite('Name', names,...
            'Latitude',lats,...
            'Longitude',lons, ...
            'TransmitterFrequency',2.5e9);
```

Display the combined coverage map for multiple signal strengths, using close-in propagation model.

```
coverage(txs, 'close-in', 'SignalStrengths', -100:5:-60)
```

## Input Arguments

### **tx — Transmitter site**

txsite object | array of txsite objects

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

### **rx — Receiver site**

rxsite object

Receiver site, specified as an rxsite object. You can also use the name-value pairs 'ReceiverGain' and 'ReceiverAntennaHeight' to specify the receiver values.

**propmodel — Propagation model**

character vector | string

Propagation model, specified as a character vector or string. You can also use the name-value pair 'PropagationModel' to specify this parameter. You can also use the `propagationModel` function to define this input. The default propagation model is 'longley-ricc' when terrain is enabled and 'freespace' when terrain is disabled.

Data Types: char | string

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Type', 'power'

**Type — Type of signal strength to compute**

'power' (default) | 'efield'

Type of signal strength to compute, specified as 'power' or 'efield'.

Power is expressed in power units (dBm) of the signal at the receiver input. E-field is expressed in electric field strength units (dB $\mu$ V/m) of signal wave incident on the antenna.

Data Types: char

**SignalStrengths — Signal strengths to display on coverage map**

numeric vector

Signal strengths to display on coverage map, specified as a numeric vector.

Each strength uses different colored filled contour on the map. The default value is -100 dBm if the 'Type' name-value pair is 'power' and 40 dB $\mu$ V/m if 'Type' is 'efield'.

Data Types: | bus | char

**PropagationModel — Propagation model to use for path loss calculations**

'longley-ricc' (default) | 'freespace' | 'close-in' | 'rain' | 'gas' | 'fog' | propagation model object

Propagation model to use for the path loss calculations, specified as 'freespace', 'close-in', 'rain', 'gas', 'fog', 'longley-ricc', or as an object created using the `propagationModel` function. The default propagation model is 'longley-ricc' when terrain is enabled and 'freespace' when terrain is disabled.

Data Types: char

### **MaxRange — Maximum range of coverage map from each transmitter site**

numeric scalar

Maximum range of the coverage map from each transmitter site, specified as a numeric scalar in meters representing a great circular distance. This property defines the region of interest on the map to plot. If the 'Map' is a siteviewer object with 'Buildings' specified, the default value is the distance to the farthest building. If using a terrain propagation model, the default value is 30000 m or 30 km. If using non-terrain propagation model, the default value is computed to include all `SignalStrengths` in the coverage map region.

---

**Note** When using terrain, the `MaxRange` limit is 300000 m.

---

Data Types: double

### **Resolution — Resolution of coverage map**

'auto' (default) | numeric scalar

Resolution of coverage map, specified as a numeric scalar in meters.

The resolution of 'auto' computes the maximum value scaled to 'MaxRange'. Decreasing the resolution increases the quality of the coverage map and the time required to create it.

Data Types: char | double

### **ReceiverGain — Mobile receiver gain**

2.1 (default) | numeric scalar

Mobile receiver gain, specified as a numeric scalar in dB. The receiver gain value includes the mobile receiver antenna gain and system loss.

The receiver gain computes received signal strength when the 'Type' is 'power'.

If receiver site argument `rx` is passed to `coverage`, the default value is the maximum gain of the receiver antenna with the system loss subtracted. Otherwise the default value is 2.1.

Data Types: `char` | `double`

### **ReceiverAntennaHeight — Mobile receiver antenna height above ground elevation**

1 (default) | numeric scalar

Mobile receiver antenna height above ground elevation, specified as a numeric scalar in meters.

If receiver site argument `rx` is passed to `coverage`, the default value is the `AntennaHeight` of the receiver. Otherwise the default value is 1.

Data Types: `double`

### **Colors — Colors of filled contours on coverage map**

*M*-by-3 array of RGB triplets | array of strings | cell array of character vectors

Filled contours color of coverage map, specified as an *M*-by-3 array of RGB triplets, an array of strings, or a cell array of character vectors.

Colors are assigned element-wise to `'SignalStrengths'` values for coloring the corresponding filled contours.

`'Colors'` cannot be used with `'ColorLimits'` or `'ColorMap'`.

For more information, see `ColorSpec` (Color Specification).

Data Types: `char` | `string` | `double`

### **ColorLimits — Color limits for colormap**

two-element vector

Color limits for colormap, specified as a two-element vector of type `[min max]`.

The color limits indicate the signal level values that map to the first and last colors on the colormap.

The default value is `[-120 -5]` if the `'Type'` name-value pair is `'power'` and `[20 135]` if `'Type'` is `'efields'`.

'ColorLimits' cannot be used with 'Color'.

Data Types: double

### **ColorMap — Colormap filled contours for coverage map**

'jet' (default) | predefined color map |  $M$ -by-3 array of RGB triplets

Colormap filled contours on coverage map, specified as a predefined colormap or  $M$ -by-3 array of RGB triplets, where  $M$  defines individual colors.

'ColorMap' cannot be used with 'Colors'.

Data Types: char | double

### **Transparency — Transparency of coverage map**

0.4 (default) | numeric scalar

Transparency of coverage map, specified as a numeric scalar in the range 0 to 1. 0 is transparent and 1 is opaque.

Data Types: double

### **Map — Map for surface data**

siteviewer object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or 'gmted2010', if none is open.

Data Types: char | string

# distance

Distance between sites

## Syntax

```
d = distance(site1,site2)
d = distance(site1,site2,path)
d = distance( ____,Name,Value)
```

## Description

`d = distance(site1,site2)` returns the distance in meters between site1 and site2.

`d = distance(site1,site2,path)` returns the distance using a specified path type, either Euclidean or geodesic.

`d = distance( ____,Name,Value)` returns the distance with additional options specified by name-value pairs.

## Examples

### Distance Between Transmitter and Receiver Site

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the Euclidean distance in km between the sites.

```
dme = distance(tx,rx)
```

```
dme = 2.1504e+04
```

```
dkm = dme / 1000
```

```
dkm = 21.5038
```

Get the geodesic distance between the two sites.

```
dmg = distance(tx,rx, 'geodesic')
```

```
dmg = 2.1504e+04
```

## Input Arguments

### **site1,site2** — Transmitter or receiver site

txsite or rxsite object

Transmitter or receiver site, specified as a txsite or rxsite. You can use array inputs to specify multiple sites.

### **path** — Measurement path type

'euclidean' | 'geodesic'

Measurement path type, specified as one of the following:

- 'euclidean': Uses the shortest path through space that connects the antenna center positions of the site 1 and site 2.
- 'geodesic': Uses the shortest path on the surface of the earth that connects the latitude and longitude locations of site 1 and site 2. This path uses Earth ellipsoid model WGS-84.

Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Map', 'siteviewer1'

### **Map** — Map for surface data

siteviewer object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or 'gmted2010', if none is open.

Data Types: `char` | `string`

## Output Arguments

### **d** — Distance between sites

*M*-by-*N* numeric array

Distance between sites, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in site 2 and *N* is the number of sites in site 1.

## See Also

`angle`

**Introduced in R2017b**

# elevation

Elevation of site

## Syntax

```
z = elevation(site)
z = elevation( ____,Name,Value)
```

## Description

`z = elevation(site)` returns the ground or building surface elevation of antenna site in meters. Elevation is measured relative to mean sea level using earth gravitational model, EGM-96. If the site coincides with a building, elevation is measured at the top of the building. Otherwise, elevation is measured at the ground.

---

**Note** Enable terrain data to use this function.

---

`z = elevation( ____,Name,Value)` returns the ground elevation of the antenna in meters with additional options specified by name-value pairs.

## Examples

### Elevation at Mount Washington

Compute and display the elevation at Mount Washington in meters.

```
mtwash = txsite('Name','Mt Washington','Latitude',44.2706, ...
               'Longitude',-71.3033);
z = elevation(mtwash)

z = 1.8675e+03
```

## Input Arguments

### **site — Transmitter or receiver site**

`txsite` or `rxsite` object | array of `txsite` or `rxsite` objects

Transmitter or receiver site, specified as a `txsite` or `rxsite` object or an array of `txsite` or `rxsite` objects.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Map', 'siteviewer1'`

### **Map — Map for surface data**

`siteviewer` object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or `'gmted2010'`, if none is open.

Data Types: `char` | `string`

## Output Arguments

### **z — Ground or building surface elevation of antenna site**

$M$ -by-1 matrix

Ground or building surface elevation of the antenna site, returned as an  $M$ -by-1 matrix with each element unit in meters.  $M$  is the number of sites in `site`.

## See Also

`angle` | `distance` | `rxsite` | `txsite`

**Introduced in R2018b**

# hide

Hide site location on map

## Syntax

```
hide(site)
hide( ____,Name,Value)
```

## Description

hide(site) hides the site location of the antenna site on a map.

hide( \_\_\_\_,Name,Value) hides the site location with additional specified by one or more name-value pairs.

## Examples

### Show and Hide Transmitter Site

Create a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...
           'Latitude',42.3001, ...
           'Longitude',-71.3504);
```

Show the transmitter site.

```
show(tx)
```

## 2 Functions — Alphabetical List

---

Hide the transmitter site.

`hide(tx)`

## Input Arguments

### **site** — Transmitter or receiver site

`txsite` or `rxsite` object | array of `txsite` or `rxsite` objects

Transmitter or receiver site, specified as a `txsite` or `rxsite` object or an array of `txsite` or `rxsite` objects.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Map', 'siteviewer1'`

### **Map — Map for surface data**

`siteviewer` object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or `'gmted2010'`, if none is open.

Data Types: `char` | `string`

## **See Also**

`show`

**Introduced in R2017b**

# link

Display communication link on map

## Syntax

```
link(rx,tx)
link(rx,tx,propmodel)
link( ____,Name,Value)
status = link( ____)
```

## Description

`link(rx,tx)` plots a one-way point-to-point communication link between a receiver site and transmitter site. The plot is color coded to identify the link success status.

`link(rx,tx,propmodel)` plots the communication link based on the specified propagation model.

`link( ____,Name,Value)` plots a communication link using additional options specified by `Name,Value` pairs.

`status = link( ____)` returns the success status of the communication link as `true` or `false`.

## Examples

### Communication Link Between Transmitter and Receiver

Create a transmitter site.

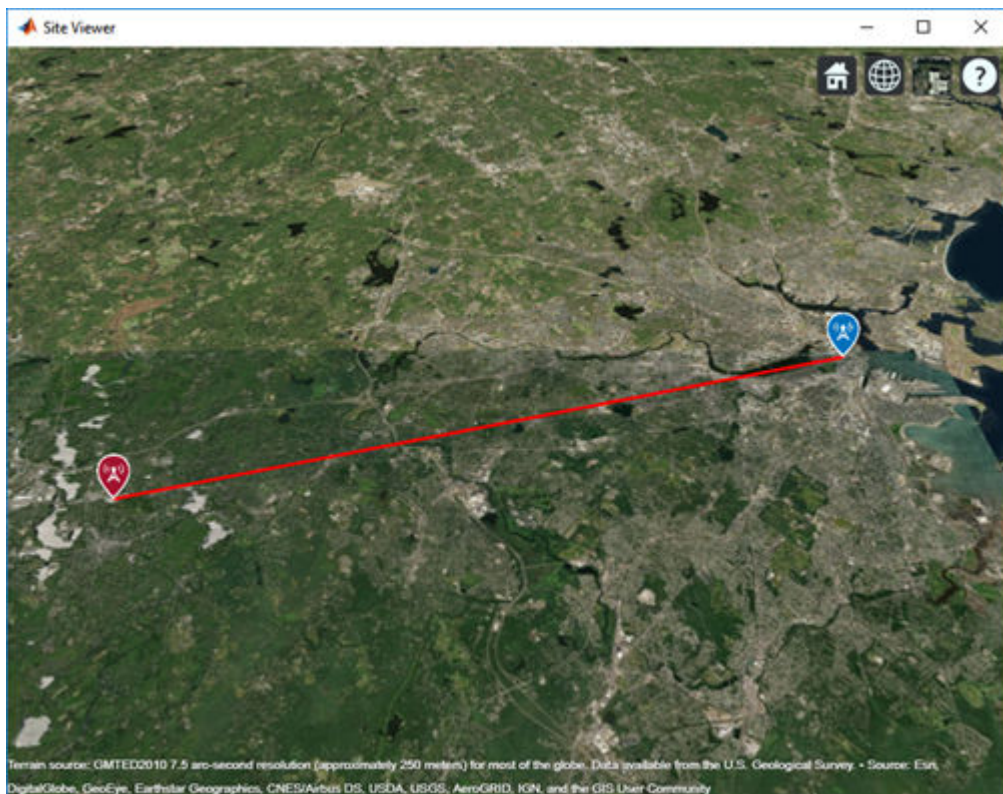

```
tx = txsite('Name','MathWorks', ...
           'Latitude', 42.3001, ...
           'Longitude', -71.3503);
```

Create a receiver site with sensitivity defined in dBm.

```
rx = rxsite('Name', 'Boston', ...  
           'Latitude', 42.3601, ...  
           'Longitude', -71.0589, ...  
           'ReceiverSensitivity', -90);
```

Plot the communication link between the transmitter and the receiver.

```
link(rx,tx)
```

---

## Input Arguments

### **rx — Receiver site**

rxsite object | array of rxsite objects

Receiver site, specified as a rxsite object. You can use array inputs to specify multiple sites.

### **tx — Transmitter site**

txsite object | array of txsite objects

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

### **propmodel — Propagation model**

character vector | string

Propagation model, specified as a character vector or string. You can also use the name-value pair 'PropagationModel' to specify this parameter.

Data Types: char | string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Type', 'power'

### **PropagationModel — Propagation model to use for path loss calculations**

'freespace' (default) | 'close-in' | 'rain' | 'gas' | 'fog' | propagation model object

Propagation model to use for path loss calculations, specified as 'freespace', 'close-in', 'rain', 'gas', 'fog', or as an object created using the propagationModel function.

Data Types: char

### **SuccessColor — Color of successful links**

'green' (default) | RGB triplet | character vector

Color of successful links, specified as an RGB triplet or character vector. For more information, see `ColorSpec` (Color Specification).

Data Types: `char` | `double`

### **FailColor — Color of unsuccessful links**

'red' (default) | RGB triplet | character vector

Color of unsuccessful links, specified as RGB triplet or character vector. For more information, see `ColorSpec` (Color Specification).

Data Types: `char` | `double`

### **Map — Map for surface data**

`siteviewer` object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or 'gmted2010', if none is open.

Data Types: `char` | `string`

## **Output Arguments**

### **status — Success status of communication link**

*M*-by-*N* array

Success status of communication links, returned as an *M*-by-*N* arrays. *M* is the number of transmitter sites and *N* is the number of receiver sites.

## **See Also**

# location

Location coordinates at a given distance and angle from site

## Syntax

```
sitelocation = location(site)
[lat,lon] = location(site)
[ ___ ] = location(site,distance,azimuth)
```

## Description

`sitelocation = location(site)` returns the site location of the antenna.

`[lat,lon] = location(site)` returns the latitude and longitude of the antenna site.

`[ ___ ] = location(site,distance,azimuth)` returns the new location achieved by moving the antenna site by the distance specified in the direction of the azimuth angle. The location is calculated by moving along the surface of the earth, using Earth ellipsoid model WGS-84.

## Examples

### Location of Antenna Site

Create a site 1 km north of a given site.

Create the first transmitter site.

```
tx = txsite('Name','MathWorks',...
           'Latitude',42.3001, ...
           'Longitude',-71.3504);
```

Calculate the location 1 km north of the first site.

```
[lat,lon] = location(tx,1000,90)
```

```
lat = 42.3091
```

```
lon = -71.3504
```

Create a second transmitter site at the location specified by `lat` and `lon`.

```
tx2 = txsite('Name','Second transmitter', ...  
            'Latitude',lat, ...  
            'Longitude',lon);
```

Show the two transmitter sites.

```
show([tx,tx2])
```

---

## Input Arguments

### **site** — Antenna site

scalar | array

Antenna site, specified as a scalar or an array. It is either a `txsite` or a `rxsite` object. For more information, see `txsite`, and `rxsite`

---

**Note** If `distance` or `azimuth` is a vector, then `site` must be a scalar.

---

### **distance** — Distance to move antenna site

scalar | vector

Distance to move antenna site, specified as a scalar or vector in meters.

### **azimuth** — Azimuth angle

scalar | vector

Azimuth angle, specified as a scalar or vector in degrees. Azimuth angle is measured counterclockwise from due east.

## Output Arguments

### **siteLocation** — Location of antenna site

$M$ -by-2 matrix

Location of antenna site, returned as an  $M$ -by-2 matrix with each element unit in degrees.  $M$  is the number of sites in `sites`. The location value includes the latitude and longitude of the antenna site.

### **lat** — Latitude of one or more antenna sites

$M$ -by-1 vector

Latitude of one or more antenna sites, returned as an  $M$ -by-1 vector with each element unit in degrees.  $M$  is the number of sites in `site`.

### **lon** — Longitude of one or more antenna sites

$M$ -by-1 matrix

Longitude of one or more antenna sites, returned as an  $M$ -by-1 matrix with each element unit in degrees.  $M$  is the number of sites in `site`. The output is wrapped so that the values are in the range `[-180 180]`.

### **See Also**

`angle` | `distance` | `rxsite` | `txsite`

# los

Plot or compute the line-of-sight (LOS) visibility between sites on a map

## Syntax

```
los(site1,site2)
los(site1,site2,Name,Value)
vis = los(site1,site2,Name,Value)
```

## Description

`los(site1,site2)` plots the LOS from site 1 to site 2. The plot is color coded to identify the visibility of the points along the LOS.

`los(site1,site2,Name,Value)` sets properties using one or more name-value pairs. For example, `los(site1,site2,'ObstructedColor','red')` plots the LOS using red to show blocked visibility.

`vis = los(site1,site2,Name,Value)` returns the status of the LOS visibility.

## Examples

### LOS from a Transmitter Site to a Receiver Site

Plot the LOS from the MathWorks Apple Hill campus to the MathWorks Lakeside campus.

Create a transmitter site with an antenna of height 30 m.

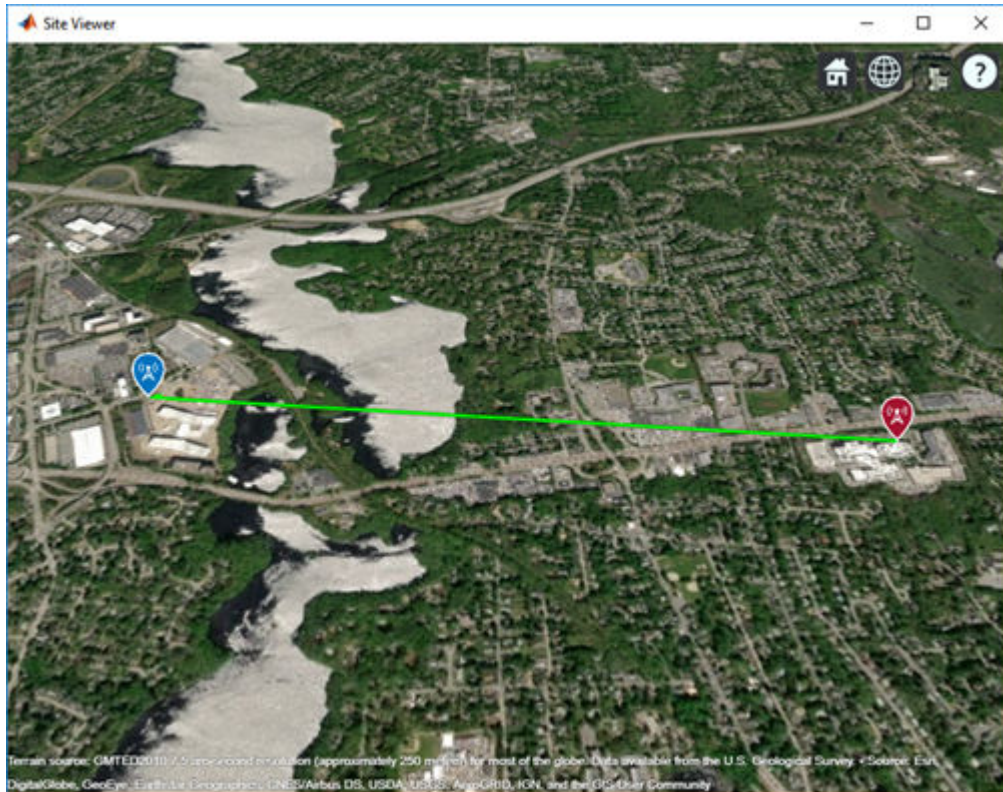

```
tx = txsite('Name','MathWorks Apple Hill',...
           'Latitude',42.3001,'Longitude',-71.3504,'AntennaHeight',30);
```

Create a receiver site with an antenna at ground level.

```
rx = rxsite('Name','MathWorks Lakeside', ...
           'Latitude',42.3021,'Longitude',-71.3764);
```

Plot the LOS between the two sites.

```
los(tx, rx);
```

### LOS from a Transmitter Site to Two Receiver Sites

Create a transmitter site with an antenna of height 30 m.

```
tx = txsite('Name', 'MathWorks Apple Hill', ...  
           'Latitude', 42.3001, 'Longitude', -71.3504, 'AntennaHeight', 30);
```

Create two receiver sites with antennas at ground level.

```
names = ["Fenway Park", "Bunker Hill Monument"];  
lats = [42.3467, 42.3763];  
lons = [-71.0972, -71.0611];
```

Create the receiver site array.

```
rxs = rxsite('Name', names, ...  
            'Latitude', lats, ...  
            'Longitude', lons);
```

Plot the lines of sight to the receiver sites. The red portion of the LOS represents obstructed visibility.

```
los(tx, rxs);
```

### Input Arguments

#### **site1 — Source antenna site**

txsite object | rxsite object

Source antenna site, specified as a txsite object or a rxsite object. Site 1 must be a single site object.

#### **site2 — Target antenna site**

txsite object | rxsite object | vector of txsite or rxsite objects

Target antenna site, specified as a txsite object or a rxsite object. Site 2 can be a single site object or a vector of multiple site objects.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'ObstructedColor', 'blue'

#### **VisibleColor — Plot color for successful visibility**

'green' (default) | RGB triplet | character vector | color name string

Plot color for successful visibility, specified as an RGB triplet, a character vector, or a color name specified as a string. For more information, see ColorSpec (Color Specification).

#### **ObstructedColor — Plot color for blocked visibility**

'red' (default) | RGB triplet | character vector | color name string

Plot color for blocked visibility, specified as an RGB triplet, a character vector, or a color name specified as a string. For more information, see ColorSpec (Color Specification).

#### **Resolution — Sampling distance between two sites**

'auto' (default) | numeric scalar

Resolution of sample locations used to compute line-of-sight visibility, specified as 'auto' or a numeric scalar expressed in meters. Resolution defines the distance between

samples on the geodesic path between sites, using Earth ellipsoid model WGS-84. If Resolution is 'auto', the function computes a value based on the distance between the sites.

### Map — Map for surface data

siteviewer object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or 'gmted2010', if none is open.

Data Types: char | string

## Output Arguments

### vis — Status of LOS visibility

'true' | 'false' | *n*-by-1 logical array

Status of LOS visibility, returned as 'true' or 'false'. If there are multiple target sites, the function returns a logical array of *n*-by-1.

## See Also

angle | distance | link

## Topics

ColorSpec (Color Specification)

**Introduced in R2018a**

# pathloss

Path loss of radio wave propagation

## Syntax

```
pl = pathloss(propmodel,rx,tx)
```

## Description

`pl = pathloss(propmodel,rx,tx)` returns the path loss of radio wave propagation at the receiver site from the transmitter site.

## Examples

### Path Loss of Receiver In Heavy Rain

Specify the transmitter and the receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...  
           'Latitude',42.3001, ...  
           'Longitude',-71.3504, ...  
           'TransmitterFrequency', 2.5e9);
```

```
rx = rxsite('Name','Fenway Park',...  
           'Latitude',42.3467, ...  
           'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm =  
Rain with properties:
```

```
    RainRate: 50
```

```
Tilt: 0
```

Calculate the pathloss at the receiver using the rain propagation model.

```
pl = pathloss(pm,rx,tx)
```

```
pl = 127.1559
```

## Input Arguments

### **propmodel** — Propagation model

character vector or string

Propagation model, specified as a character vector or string.

Data Types: char

### **rx** — Receiver site

rxsite object

Receiver site, specified as a rxsite object. You can use array inputs to specify multiple sites.

Data Types: char

### **tx** — Transmitter site

txsite object

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

Data Types: char

## Output Arguments

### **pl** — Path loss

scalar |  $M$ -by- $N$  arrays

Path loss, returned as a scalar or  $M$ -by- $N$  arrays with each element in decibels.  $M$  is the number of TX sites and  $N$  is the number of RX sites.

Path loss is computed along the shortest path through space connecting the transmitter and receiver antenna centers.

For terrain propagation models, path loss is computed using terrain elevation profile that is computed at sample locations on the great circle path between the transmitter and the receiver. If `Map` is a `siteviewer` object with buildings specified, the terrain elevation is adjusted to include the height of the buildings.

### **See Also**

`propagationModel` | `range`

**Introduced in R2017b**

# propagationModel

Create RF propagation model

## Syntax

```
pm = propagationModel(modelname)
pm = propagationModel( ____,Name,Value)
```

## Description

`pm = propagationModel(modelname)` creates an RF propagation model for the specified model.

`pm = propagationModel( ____,Name,Value)` sets properties using one or more name-value pairs. For example, `pm = propagationModel('rain','RainRate',96)` creates a rain propagation model with a rain rate of 96 mm/h. Enclose each property name in quotes.

## Examples

### Signal Strength of Receiver in Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504, ...
    'TransmitterFrequency', 2.5e9);

rx = rxsite('Name','Fenway Park',...
    'Latitude',42.3467, ...
    'Longitude',-71.0972);
```

Create the propagation model for a heavy rainfall rate.

```
pm = propagationModel('rain', 'RainRate', 50)
```

```
pm =  
  Rain with properties:  
  
    RainRate: 50  
    Tilt: 0
```

Calculate the signal strength at the receiver using the rain propagation model.

```
ss = sigstrength(rx,tx,pm)  
ss = -87.1559
```

### Longley-Rice Propagation Model

Create a transmitter site.

```
tx = txsite  
tx =  
  txsite with properties:  
  
        Name: 'Site 9'  
    Latitude: 42.3001  
    Longitude: -71.3504  
    Antenna: 'isotropic'  
    AntennaAngle: 0  
    AntennaHeight: 10  
    SystemLoss: 0  
    TransmitterFrequency: 1.9000e+09  
    TransmitterPower: 10
```

Create a Longley-Rice propagation model using the `propagationModel` function.

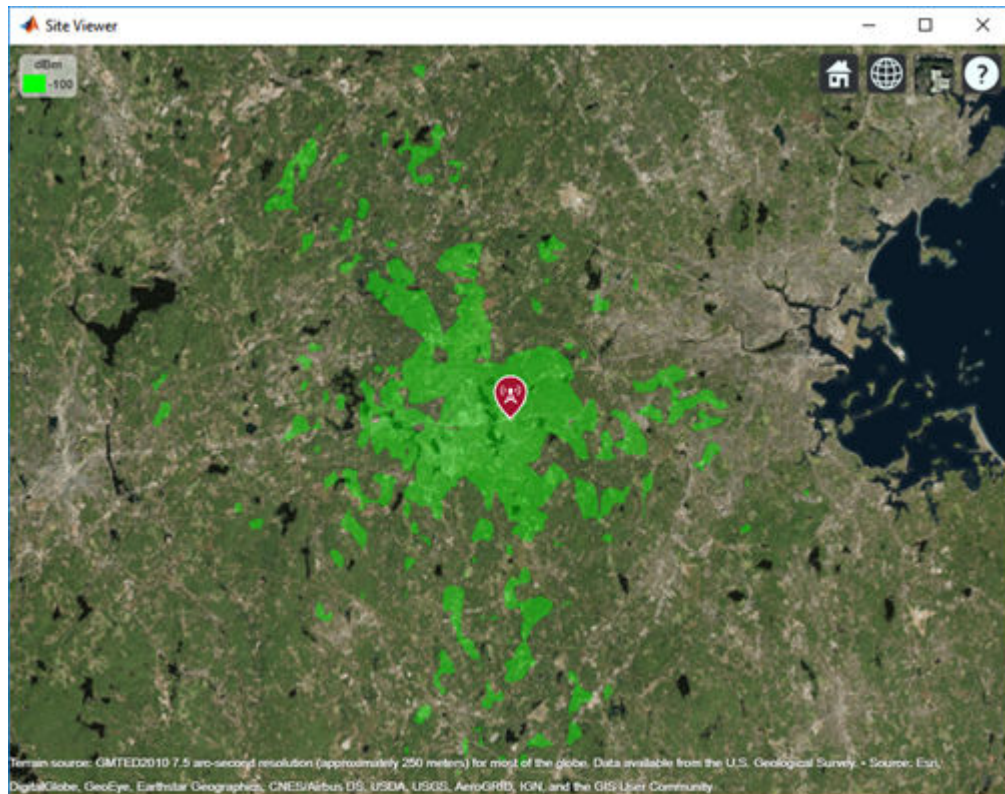

```
pm = propagationModel('longley-rice', 'TimeVariabilityTolerance', 0.7)  
pm =  
  LongleyRice with properties:  
  
    AntennaPolarization: 'horizontal'
```

```
GroundConductivity: 0.0050
GroundPermittivity: 15
AtmosphericRefractivity: 301
ClimateZone: 'continental-temperate'
TimeVariabilityTolerance: 0.7000
SituationVariabilityTolerance: 0.5000
```

Find the coverage of the transmitter site using the defined propagation model.

coverage(tx, 'PropagationModel', pm)

# Input Arguments

### modelName — Type of propagation model

'freespace' | 'rain' | 'gas' | 'fog' | 'close-in' | 'longley-rice'

Type of propagation model:

- 'freespace' - Free space propagation model
- 'rain' - Rain propagation model. For more information, see [3].
- 'gas' - Gas propagation model
- 'fog' - Fog propagation model. For more information, see [2] (Antenna Toolbox).
- 'close-in' - Close-in propagation model typically used in urban macro cell scenarios. For more information, see [1].

---

**Note** The close-in model implements a statistical path loss model and can be configured for different scenarios. The default values correspond to an urban macro-cell scenario in a non-line-of-sight (NLOS) environment.

---

- 'longley-rice' - Longley-Rice propagation model. This model is also known as Irregular Terrain Model (ITM). You can use this model to calculate point-to-point path loss between sites over irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. For more information and list of limitations, see [4].

---

**Note** The Longley-Rice model implements the point-to-point mode of the model, which uses terrain data to predict the loss between two points.

---

- 'tirem' -- Terrain Integrated Rough Earth Model™ (TIREM™). You can use this model to calculate point-to-point path loss between sites over irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. The model needs access to an external TIREM library. The actual model is valid from 1 MHz to 1000 GHz. But with Antenna Toolbox™ elements and arrays the frequency range is limited at 200 GHz.

You can use the following functions on RF propagation models:

- **range** - Calculate the range of the radio wave under different propagation scenarios. **range** function does not support Longley-Rice or TIREM propagation models. This function does not support the TIREM propagation model.
- **pathloss** - Calculate the path loss of radio wave propagation between the transmitter and receiver sites under different propagation scenarios.

### Dependencies

To specify 'tirem', requires the Antenna Toolbox.

Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1, Value1, . . . , NameN, ValueN**.

Example: 'RainRate', 50

### Rain

#### **RainRate** — Rain rate

16 (default) | positive scalar

Rain rate, specified as a positive scalar in millimeters per hour (mm/h).

### Dependencies

To specify 'RainRate', you must specify 'rain' propagation model.

Data Types: double

#### **Tilt** — Polarization tilt angle of the signal

0 (default) | scalar

Polarization tilt angle of the signal, specified as scalar in degrees.

### Dependencies

To specify 'Tilt', you must specify 'rain' propagation model.

Data Types: double

### Gas

#### **Temperature — Air temperature**

15 (default) | scalar

Air temperature, specified as a scalar in Celsius (C).

#### **Dependencies**

To specify 'Temperature', you must specify 'gas' propagation model.

Data Types: double

#### **AirPressure — Dry air pressure**

101300 (default) | scalar

Dry air pressure, specified as a scalar in pascals (Pa).

#### **Dependencies**

To specify 'AirPressure', you must specify 'gas' propagation model.

Data Types: double

#### **WaterDensity — Water vapor density**

7.5 (default) | scalar

Water vapor density, specified as a scalar in grams per cubic meter (g/m<sup>3</sup>).

#### **Dependencies**

To specify 'WaterDensity', you must specify 'gas' propagation model.

Data Types: double

### Fog

#### **Temperature — Air temperature**

15 (default) | scalar

Air temperature, specified as a scalar in Celsius (C).

#### **Dependencies**

To specify 'Temperature', you must specify 'fog' propagation model.

Data Types: double

**WaterDensity — Liquid water density**

0.5 (default) | scalar

Liquid water density, specified as a scalar in grams per cubic meter (g/m<sup>3</sup>).

**Dependencies**

To specify 'WaterDensity', you must specify 'fog' propagation model.

Data Types: double

**Close-In****ReferenceDistance — Free-space reference distance**

1 (default) | scalar

Free-space reference distance, specified as a scalar in meters.

**Dependencies**

To specify 'ReferenceDistance', you must specify the 'close-in' propagation model.

Data Types: double

**PathLossExponent — Path loss exponent**

2.9 (default) | scalar

Path loss exponent, specified as a scalar.

**Dependencies**

To specify 'PathLossExponent', you must specify 'close-in' propagation model.

Data Types: double

**Sigma — Standard deviation**

5.7 (default) | scalar

Standard deviation of the zero-mean Gaussian random variable, specified as a scalar in decibels (dB).

**Dependencies**

To specify 'Sigma', you must specify 'close-in' propagation model.

Data Types: double

### **NumDataPoints — Number of data points**

1869 (default) | integer

Number of data points of zero-mean Gaussian random variable, specified as an integer.

#### **Dependencies**

To specify 'NumPoints', you must specify 'close-in' propagation model.

Data Types: double

---

**Note** The close-in model is valid for distances greater than or equal to the 'ReferenceDistance' property. If a distance less than the 'ReferenceDistance' is used, path loss is  $\theta$ .

---

### **Longley-Rice**

#### **AntennaPolarization — Polarization of transmitter and receiver antennas**

'horizontal' (default) | 'vertical'

Polarization of transmitter and receiver antennas, specified as 'horizontal' or 'vertical'. Both antennas are assumed to have the same polarization. This value is used to calculate path loss due to ground reflection.

#### **Dependencies**

To specify 'AntennaPolarization', you must specify 'longley-rice' propagation model.

Data Types: char | string

#### **GroundConductivity — Conductivity of ground**

0.005 (default) | scalar

Conductivity of the ground, specified as a scalar in Siemens per meter (S/m). This value is used to calculate path loss due to ground reflection. The default value corresponds to average ground.

#### **Dependencies**

To specify 'GroundConductivity', you must specify 'longley-rice' propagation model.

Data Types: double

### **GroundPermittivity — Relative permittivity of ground**

15 (default) | scalar

Relative permittivity of the ground, specified as a scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate the path loss due to ground reflection. The default value corresponds to average ground.

#### **Dependencies**

To specify 'GroundPermittivity', you must specify 'longley-rice' propagation model.

Data Types: double

### **AtmosphericRefractivity — Atmospheric refractivity near ground**

301 (default) | scalar

Atmospheric refractivity near the ground, specified as a scalar in N-units. This value is used to calculate the path loss due to refraction through the atmosphere and tropospheric scatter. The default value corresponds to average atmospheric conditions.

#### **Dependencies**

To specify 'AtmosphericRefractivity', you must specify 'longley-rice' propagation model.

Data Types: double

### **ClimateZone — Radio climate zone**

'continental-temperate' (default) | 'equatorial' | 'continental-subtropical' | 'maritime-subtropical' | 'desert' | 'maritime-over-land' | 'maritime-over-sea'

Radio climate zone. This value is used to calculate the variability due to changing atmospheric conditions. The default value corresponds to average atmospheric conditions in a particular climate zone.

#### **Dependencies**

To specify 'ClimateZone', you must specify 'longley-rice' propagation model.

Data Types: char | string

### **TimeVariabilityTolerance — Time variability tolerance level**

0.5 (default) | scalar

Time variability tolerance level of the path loss, specified as a scalar between [0.001, 0.999]. Time variability occurs due to changing atmospheric conditions. This value gives the required system reliability or the fraction of time during which the actual path loss is expected to be less than or equal to model prediction. For more information, see [5].

#### **Dependencies**

To specify 'TimeVariabilityTolerance', you must specify 'longley-rice' propagation model.

Data Types: double

### **SituationVariabilityTolerance — Situation variability tolerance level**

0.5 (default) | scalar

Situation variability tolerance level of the path loss, specified as a scalar in between [0.001, 0.999]. Situation variability occurs due to uncontrolled or hidden random variables. This value gives the required system confidence or the fraction of similar situations for which the actual path loss is expected to be less than or equal to the model prediction. For more information, see [5].

#### **Dependencies**

To specify 'SituationVariabilityTolerance', you must specify 'longley-rice' propagation model.

Data Types: double

### **TIREM**

#### **AntennaPolarization — Polarization of transmitter and receiver antennas**

'horizontal' (default) | 'vertical'

Polarization of transmitter and receiver antennas, specified as 'horizontal' or 'vertical'. Both antennas are assumed to have the same polarization. This value is used to calculate path loss due to ground reflection.

#### **Dependencies**

To specify 'AntennaPolarization', you must specify 'tirem' propagation model.

Data Types: char | string

**GroundConductivity – Conductivity of ground**

0.005 (default) | numeric scalar

Conductivity of the ground, specified as a numeric scalar in Siemens per meter (S/m) in the range of 0.0005 to 100. This value is used to calculate path loss due to ground reflection. The default value corresponds to average ground.

**Dependencies**

To specify 'GroundConductivity', you must specify 'tirem' propagation model.

Data Types: double

**GroundPermittivity – Relative permittivity of ground**

15 (default) | numeric scalar

Relative permittivity of the ground, specified as a numeric scalar in the range of 1 to 100. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate the path loss due to ground reflection. The default value corresponds to average ground.

**Dependencies**

To specify 'GroundPermittivity', you must specify 'tirem' propagation model.

Data Types: double

**AtmosphericRefractivity – Atmospheric refractivity near ground**

301 (default) | scalar

Atmospheric refractivity near the ground, specified as a numeric scalar in N-units in the range of 250 to 400. This value is used to calculate the path loss due to refraction through the atmosphere and tropospheric scatter. The default value corresponds to average atmospheric conditions.

**Dependencies**

To specify 'AtmosphericRefractivity', you must specify 'tirem' propagation model.

Data Types: double

**Humidity – Absolute air humidity near ground**

'9' (default) | numeric scalar

Absolute air humidity near ground, specified as a numeric scalar in  $\text{g}/\text{m}^3$  units in the range of 0 to 110. You can use this value to calculate path loss due to atmospheric absorption. The default value corresponds to the absolute humidity of air at 15 degrees Celsius and 70 percent relative humidity.

### Dependencies

To specify 'Humidity', you must specify 'tirem' propagation model.

Data Types: double

## More About

### Propagation models

Basic propagation models predict path loss as a function of distance between sites and assume line-of-sight (LOS) conditions, disregarding the curvature of the Earth, terrain, or other obstacles. Urban propagation models also predict path loss as a function of distance but use empirical models that are derived from measurements in non-line-of-sight (NLOS) conditions. Terrain propagation models predict path loss as a function of the terrain elevation profile between sites including buildings, which may be used to compute whether LOS or NLOS conditions apply.

### N-Units

The refractive index of air  $n$  is related to the dielectric constants of the gas constituents of an air mixture. The numerical value of  $n$  is only slightly larger than one. To make the calculation more convenient, you can use  $N$  units which are given by the formula:

$$N = (n - 1) \times 10^6$$

**Introduced in R2017b**

# range

Range of radio wave propagation

## Syntax

```
r = range(propmodel,tx,pl)
```

## Description

`r = range(propmodel,tx,pl)` returns the range of radio wave propagation from the transmitter site.

## Examples

### Range of Transmitter In Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...  
           'Latitude',42.3001, ...  
           'Longitude',-71.3504, ...  
           'TransmitterFrequency', 2.5e9);
```

```
rx = rxsite('Name','Fenway Park',...  
           'Latitude',42.3467, ...  
           'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm =  
Rain with properties:
```

```
    RainRate: 50
```

```
Tilt: 0
```

Calculate the range of transmitter using the rain propagation model and a path loss of 127 dB.

```
r = range(pm,tx,127)
```

```
r = 2.1123e+04
```

## Input Arguments

### **propmodel** — Propagation model

character vector or string

Propagation model, specified as a character vector or string.

Data Types: char

### **tx** — Transmitter site

txsite object

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

Data Types: char

### **pl** — Path loss

scalar

Path loss, specified as a scalar in decibels.

Data Types: double

## Output Arguments

### **r** — range

scalar |  $M$ -by-1 arrays

Range, returned as a scalar or  $M$ -by-1 array with each element in meters.  $M$  is the number of TX sites.

Range is the maximum distance for which the path loss does not exceed the value of specified `pl`.

### **See Also**

`pathloss` | `propagationModel`

**Introduced in R2017b**

# raytrace

Plot propagation paths between sites

## Syntax

```
raytrace(tx, rx)  
raytrace( ____, Name, Value)
```

## Description

`raytrace(tx, rx)` plots the propagation paths from the transmitter site (tx) to the receiver site (rx). The propagation paths are found using ray tracing with the terrain and buildings data defined in the Site Viewer map. Each propagation path is color-coded according to the received power (dBm) or path loss (dB) along the path, assuming unpolarized rays.

---

### Note

- The ray tracing analysis includes surface reflections but does not include effects from refraction, diffraction, or scattering.
  - Path loss and received power values do not include reflection loss due to material or antenna polarization properties.
- 

`raytrace( ____, Name, Value)` plots propagation paths with additional options specified by one or more name-value pairs.

## Examples

### Reflected Propagation Paths

Launch Site Viewer with buildings in Chicago.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building.

```
tx = txsite('Latitude',41.8800, ...  
           'Longitude',-87.6295, ...  
           'TransmitterFrequency',2.5e9);
```

Create a receiver site on another building.

```
rx = rxsite('Latitude',41.881352, ...  
           'Longitude',-87.629771, ...  
           'AntennaHeight',30);
```

Show the obstruction to line of sight.

```
los(tx,rx)
```

Show a reflected propagation path using ray tracing.

```
raytrace(tx, rx)
```

Show multiple propagation paths, including first-order and second-order reflections.

```
raytrace(tx, rx, 'NumReflections', [1 2])
```

## Input Arguments

### rx — Receiver site

`rxsite` object | array of `rxsite` objects

Receiver site, specified as a `rxsite` object or an array of `rxsite` objects. If the transmitter sites are specified as arrays, then the propagation paths are plotted from each transmitter to each receiver site.

### tx — Transmitter site

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object or an array of `txsite` objects. If the receiver sites are specified as arrays, then the propagation paths are plotted from each transmitter to each receiver site.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Type', 'power'`

#### **Type** — Type of quantity to plot

`'power'` (default) | `'pathloss'`

Type of quantity to plot, specified as the comma-separated pair consisting of `'Type'` and `'power'` in dBm or `'pathloss'` in dB.

When you specify `'power'`, each path is color-coded according to the received power along the path. When you specify `'pathloss'`, each path is color-coded according to the path loss along the path.

Data Types: `char`

#### **NumReflections** — Number of reflections to search for in propagation paths

`[0 1]` (default) | numeric row vector

Number of reflections to search for in propagation paths using ray tracing, specified as the comma-separated pair consisting of `'NumReflections'` and a numeric row vector whose elements are 0, 1, or 2.

The default value results in the search for a line-of-sight propagation path along with propagation paths that each contain a single reflection.

Data Types: `double`

#### **Colormap** — Color map for coloring propagation paths

`'jet'` (default) | predefined color map name |  $M$ -by-3 array of RGB

Color map for coloring propagation paths, specified as the comma-separated pair consisting of `'Colormap'` and a predefined color map name or an  $M$ -by-3 array of RGB (red, blue, green) triplets that define  $M$  individual colors.

Data Types: char | double

### **ColorLimits — Color limits for colormap**

two-element numeric row vector

Color limits for colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element numeric row vector of the form [min max]. The units and default values of the color limits depend on the value of the 'Type' parameter:

- 'power' - Units are in dBm, and the default value is [-120 -5].
- 'pathloss' - Units are in dB, and the default value is [45 160].

The color limits indicate the values that map to the first and last colors in the colormap. Propagation paths with values below the minimum color limit are not plotted.

Data Types: double

### **ShowLegend — Show color legend on map**

true (default) | false

Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend' and true or false.

Data Types: logical

### **Map — Map for visualization and surface data**

siteviewer object

Map for visualization and surface data, specified as a siteviewer object. The default value is the current Site Viewer.

Data Types: char | string

## **See Also**

los | siteviewer

**Introduced in R2019b**

# removeCustomTerrain

Remove custom terrain data

## Syntax

```
removeCustomTerrain(name)
```

## Description

`removeCustomTerrain(name)` removes the custom terrain data specified by the user-defined name. You can use this function to remove terrain data that is no longer needed. The terrain data to be removed must have been previously added using `addCustomTerrain`.

## Examples

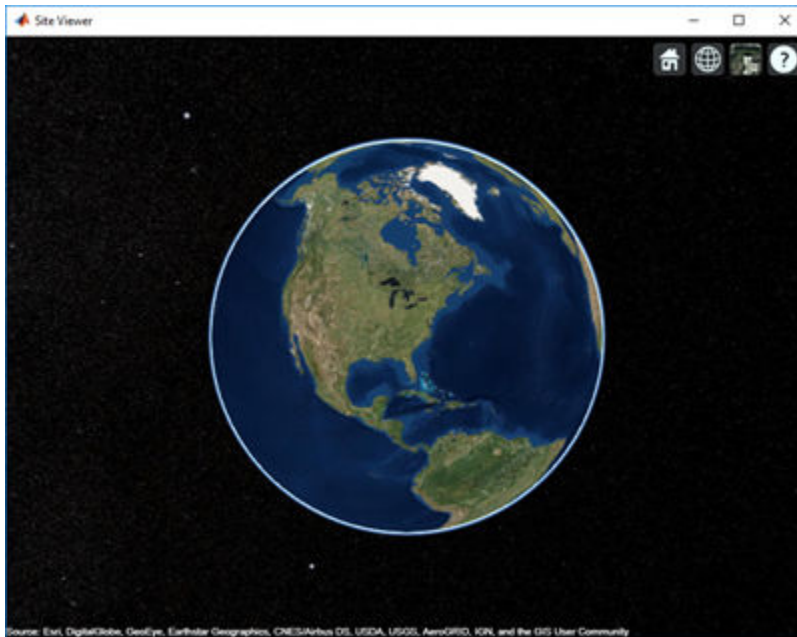

### Site Viewer Maps Using Custom Terrain

Add a custom terrain using `n44_w072_3arc_v1.dt1` DTED file.

```
addCustomTerrain('mydted5', 'n44_w072_3arc_v1.dt1')
```

Use the custom terrain name in Site Viewer.

```
viewer = siteviewer('Terrain', 'mydted5');
```

Create a site with the terrain region.

```
mtwash = txsite('Name', 'Mt Washington', ...  
               'Latitude', 44.2706, ...  
               'Longitude', -71.3033, ...  
               'AntennaHeight', 30);  
show(mtwash)
```

Create a coverage map.

coverage(mtwash)

Remove the custom terrain.

```
close(viewer)
removeCustomTerrain("mydted5")
```

## Input Arguments

**name** — User-defined identifier for terrain data

string scalar | character vector

User-defined identifier for terrain data previously added using `addCustomTerrain`, specified as a string scalar or a character vector.

Data Types: `char` | `string`

## See Also

`addCustomTerrain` | `siteviewer`

**Introduced in R2019a**

# pattern

Plot antenna radiation pattern on map

## Syntax

```
pattern(tx)
pattern(rx, frequency)
pattern( ____, Name, Value)
```

## Description

`pattern(tx)` plots the 3-D antenna radiation pattern for the transmitter site, `txsite`. Signal gain value (dBi) in a particular direction determines the color of the pattern.

`pattern(rx, frequency)` plots the 3-D radiation pattern for the receiver site, `rxsite` for the specified `frequency`.

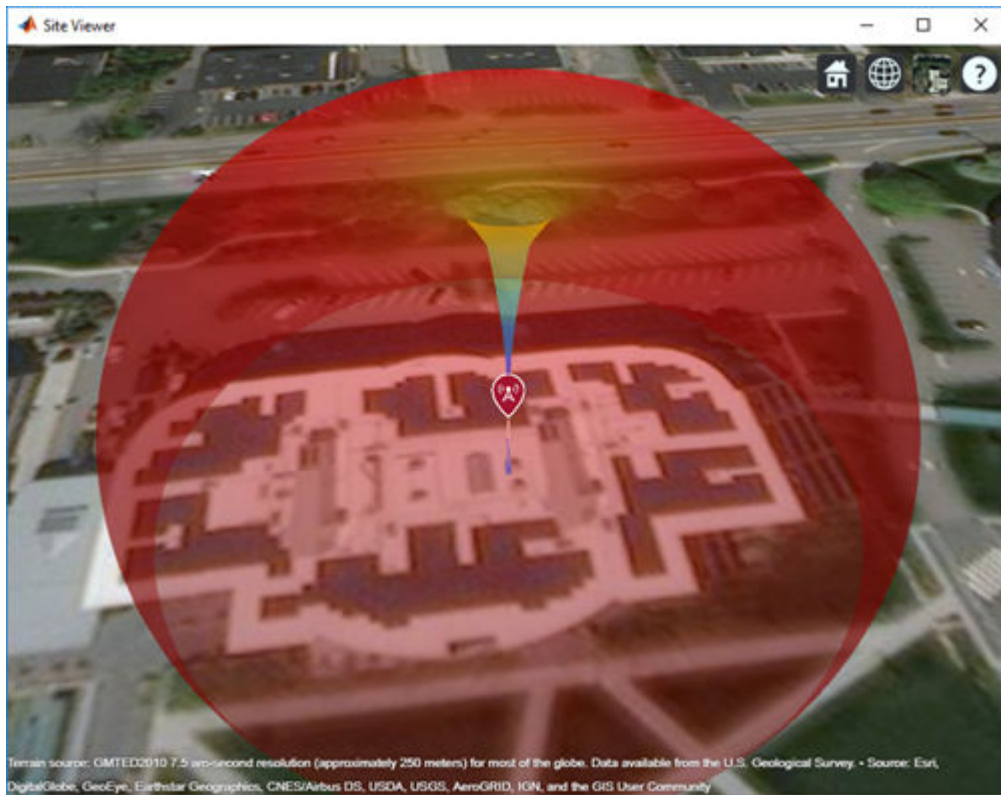

`pattern( ____, Name, Value)` plots the 3-D radiation pattern with additional options specified by name-value pair arguments.

## Examples

### Single Transmitter Site Pattern

Define and visualize the radiation pattern of a single transmitter site.

```
tx = txsite;
pattern(tx)
```

## Input Arguments

### **tx — Transmitter site**

txsite object

Transmitter site, specified as a txsite object.

### **rx — Receiver site**

rxsite object

Receiver site, specified as a rxsite object.

**frequency — Frequency to calculate radiation pattern**

positive scalar

Frequency to calculate radiation pattern, specified as a positive scalar.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Size', 2`

**Size — Size of pattern plot**

50 (default) | numerical scalar

Size of the pattern plot, specified as a numerical scalar in meters. This parameter represents the distance between the antenna position and the point on the plot with the highest gain.

Data Types: double

**Transparency — Transparency of pattern plot**

0.4 (default) | real number in the range of [0,1]

Transparency of the pattern plot, specified as a real number in the range of [0,1], where 0 is completely transparent and 1 is completely opaque.

Data Types: double

**Colormap — Colormap for coloring of pattern plot**'jet(256)' (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for coloring of the pattern plot, specified as a predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors.

Data Types: double

**Map — Map for surface data**

siteviewer object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using

`addCustomTerrain`. The default value is the current Site Viewer or 'gmted2010', if none is open.

Data Types: `char` | `string`

### **See Also**

`coverage`

**Introduced in R2018b**

## show

Show site location on map

## Syntax

```
show(site)
show(site,Name,Value)
```

## Description

`show(site)` displays the location of transmitter or receiver site on a map using a marker.

`show(site,Name,Value)` uses `icon` displays the site map using additional options specified by the `Name,Value` pairs.

## Examples

### Default Receiver Site

Create and show the default receiver site.

```
rx = rxsite
```

```
rx =
```

```
  rxsite with properties:
```

```
      Name: 'Site 2'
      Latitude: 42.3021
      Longitude: -71.3764
      Antenna: 'isotropic'
      AntennaAngle: 0
      AntennaHeight: 1
      SystemLoss: 0
```

ReceiverSensitivity: -100

show(rx)

### Show and Hide Transmitter Site

Create a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...  
           'Latitude',42.3001, ...  
           'Longitude',-71.3504);
```

Show the transmitter site.

```
show(tx)
```

Hide the transmitter site.

hide(tx)

## Input Arguments

### **site** — Transmitter or receiver site

`txsite` or `rxsite` object | array of `txsite` or `rxsite` objects

Transmitter or receiver site, specified as a `txsite` or `rxsite` object or an array of `txsite` or `rxsite` objects.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'ClusterMarkers', true`

### **Icon — Image file**

character vector

Image file, specified as a character vector.

Data Types: `char`

### **IconSize — Width and height of icon**

36-by-36 (default) | 1-by-2 vector of positive numeric values

Width and height of the icon, specified as a 1-by-2 vector of positive numeric values in pixels.

### **IconAlignment — Vertical position of icon relative to site**

'top' (default) | 'center' | 'bottom'

Vertical position of icon relative to site, specified as:

- 'bottom' - Aligns the icon below the site antenna position.
- 'center' - Aligns the center of the icon to the site antenna position.
- 'top' - Aligns the icon above the site antenna position.

### **ClusterMarkers — Combine nearby markers into groups or clusters**

true | false

Combine nearby markers into groups or clusters, specified as true or false.

Data Types: `char`

### **Map — Map for surface data**

siteviewer object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or 'gmted2010', if none is open.

Data Types: `char` | `string`

## **See Also**

hide

**Introduced in R2017b**

# sigstrength

Signal strength due to transmitter

## Syntax

```
ss = sigstrength(rx,tx)
ss = sigstrength(rx,tx,propmodel)
ss = sigstrength( ____,Name,Value)
```

## Description

`ss = sigstrength(rx,tx)` returns the signal strength at the receiver site due to the transmitter site.

`ss = sigstrength(rx,tx,propmodel)` returns the signal strength at the receiver site using the specified propagation model. Specifying propagation model is same as specifying the 'PropagationModel' name-value pair.

`ss = sigstrength( ____,Name,Value)` returns the signal strength using additional options specified by Name,Value pairs and either of the previous syntaxes.

## Examples

### Received Power and Link Margin at Receiver

Create a transmitter site.

```
tx = txsite('Name','MathWorks', ...
           'Latitude', 42.3001, ...
           'Longitude', -71.3503);
```

Create a receiver site with sensitivity defined (in dBm).

```
rx = rxsite('Name','Boston', ...
           'Latitude', 42.3601, ...
```

```
'Longitude', -71.0589, ...  
'ReceiverSensitivity', -90);
```

Calculate the received power and link margin. Link margin is the difference between the receiver's sensitivity and the received power.

```
ss = sigstrength(rx,tx)  
ss = -144.4685  
margin = abs(rx.ReceiverSensitivity - ss)  
margin = 54.4685
```

## Input Arguments

### **rx — Receiver site**

rxsite object | array of rxsite objects

Receiver site, specified as a rxsite object. You can use array inputs to specify multiple sites.

### **tx — Transmitter site**

txsite object | array of txsite objects

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

### **propmodel — Propagation model**

character vector | string

Propagation model, specified as a character vector or string. You can also use the name-value pair 'PropagationModel' to specify this parameter. You can also use the propagationModel function to define this input.

Data Types: char | string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Type', 'power'`

### **Type — Type of signal strength to compute**

`'power'` (default) | `'efield'`

Type of signal strength to compute, specified as `'power'` or `'efield'`.

Power is expressed in power units (dBm) of signal at receiver input. E-Field is expressed in electric field strength units (dBuV/m) of signal wave incident on antenna.

Data Types: `char` | `string`

### **PropagationModel — Propagation model to use for path loss calculations**

`'freespace'` (default) | `'close-in'` | `'rain'` | `'gas'` | `'fog'` | propagation model object

Propagation model to use for path loss calculations, specified as `'freespace'`, `'close-in'`, `'rain'`, `'gas'`, `'fog'`, or as an object created using the `propagationModel` function.

Data Types: `char` | `string`

### **Map — Map for surface data**

`siteviewer` object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or `'gmted2010'`, if none is open.

Data Types: `char` | `string`

## **Output Arguments**

### **ss — Signal strength**

*M*-by-*N* array

Signal strength, returned as *M*-by-*N* array in dBm. *M* is the number of TX sites and *N* is the number of RX sites.

## **See Also**

`link` | `propagationModel` | `sinr`

**Introduced in R2017b**

## sinr

Display signal-to-interference-plus-noise ratio (SINR) map

### Syntax

```
sinr(txs)
sinr(txs,propmodel)
sinr( ____,Name,Value)
r = sinr(rxs,txs, ____)
```

### Description

`sinr(txs)` displays the signal-to-interference-plus-noise ratio (SINR) for transmitter sites, `txs`. Each colored contour of the map defines the areas where the corresponding SINR is available to a mobile receiver. For each location, the signal source is the transmitter site in `txs` with the greatest signal strength. The remaining transmitter sites in `txs` act as interference. If `txs` is scalar, or there are no sources of interference, the resultant map displays signal-to-noise ratio (SNR).

`sinr(txs,propmodel)` displays the SINR map with the propagation model set to the value in `propmodel`.

`sinr( ____,Name,Value)` sets properties using one or more name-value pairs, in addition to the input arguments in previous syntaxes. For example, `sinr(txs,'MaxRange',8000)` sets the range from the site location at 8000 meters to include in the SINR map region.

`r = sinr(rxs,txs, ____)` returns the `sinr` computed at the receiver sites due to the transmitter sites.

### Examples

### SINR Map for Multiple Transmitters

Define names and location of sites in Boston.

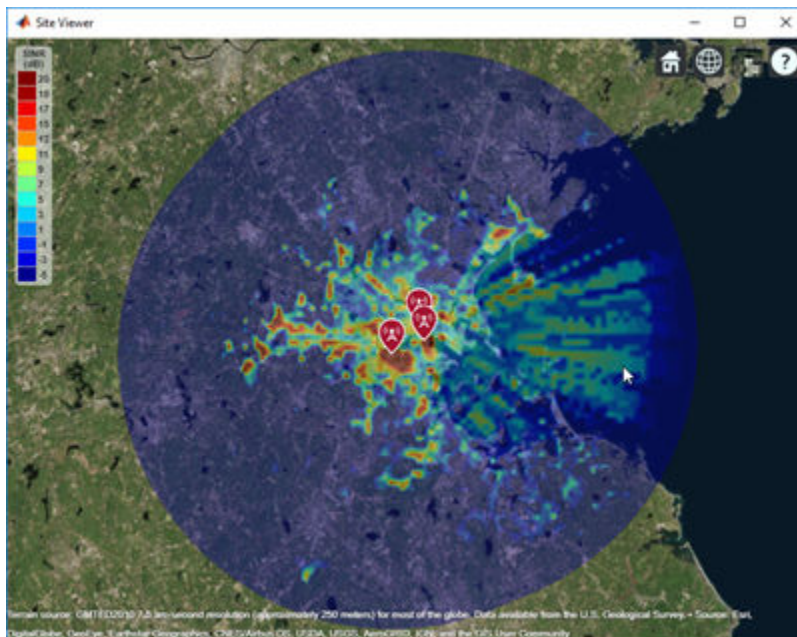

```
names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"];  
lats = [42.3467, 42.3598, 42.3763];  
lons = [-71.0972, -71.0545, -71.0611];
```

Create a transmitter site array.

```
txs = txsite('Name', names, ...  
            'Latitude', lats, ...  
            'Longitude', lons, ...  
            'TransmitterFrequency', 2.5e9);
```

Display the SINR map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sinr(txs)
```

## Input Arguments

### **txs — Transmitter sites**

txsite object | array of txsite objects

Transmitter site, specified as a txsite object. Use array inputs to specify multiple sites.

### **rxs — Receiver sites**

rxsite object | array of rxsite objects

Receiver site, specified as a rxsite object. Use array inputs to specify multiple sites.

### **propmodel — Propagation model**

character vector | string

Propagation model, specified as a character vector or string. You can use the `propagationModel` function to define this input.

You can also use the name-value pair `'PropagationModel'` to specify this parameter.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'MaxRange', 8000`

### **General**

### **SignalSource — Signal source of interest**

`'strongest'` (default) | transmitter site object

Signal source of interest, specified as `'strongest'` or as a transmitter site object. When the signal source of interest is `'strongest'`, the transmitter with the greatest signal strength is chosen as the signal source of interest for that location. When computing `sinr`, `SignalSource` can be a `txsite` array with equal number of elements `rxs` where each transmitter site element defines the signal source for the corresponding receiver site.

### **PropagationModel — Propagation model to use for path loss calculations**

'freespace' (default) | 'close-in' | 'rain' | 'gas' | 'fog' | 'longley-rice' | propagation model object

Propagation model to use for path loss calculations, specified as 'freespace', 'close-in', 'rain', 'gas', 'fog', 'longley-rice', or as an object created using the `PropagationModel` function.

### **ReceiverNoisePower — Total noise power at receiver**

-107 (default) | scalar

Total noise power at receiver, specified as a scalar in dBm. The default value assumes that the receiver bandwidth is 1 MHz and receiver noise figure is 7 dB.

$$N = -174 + 10 * \log(B) + F$$

where,

- $N$  = Receiver noise in dBm
- $B$  = Receiver bandwidth in Hz
- $F$  = Noise figure in dB

### **ReceiverGain — Receiver gain**

2.1 (default) | scalar

Mobile receiver gain, specified as a scalar in dB. The receiver gain values include the antenna gain and the system loss. If you call the function using an output argument, the default value is computed using `rxs`.

### **ReceiverAntennaHeight — Receiver antenna height**

1 (default) | scalar

Receiver antenna height above the ground, specified as a scalar in meters. If you call the function using an output argument, the default value is computed using `rxs`.

### **Map — Map for surface data**

siteviewer object | terrain name

Map for surface data, specified as a `siteviewer` object or a terrain name. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using `addCustomTerrain`. The default value is the current Site Viewer or 'gmted2010', if none is open.

Data Types: char | string

### For Plotting SINR

#### Values — Values of SINR for display

`[-5:20]` (default) | numeric vector

Values of SINR for display, specified as numeric vector. Each value is displayed as a different colored, filled on the contour map. The contour colors are derived using `Colormap` and `ColorLimits`.

#### MaxRange — Maximum range of SINR map from each transmitter site

positive numeric scalar

Maximum range of the SINR map from each transmitter site, specified as a positive numeric scalar in meters representing a great circle distance. This property defines the region of interest on the map to plot. If the `'Map'` is a siteviewer object with `'Buildings'` specified, the default value is the distance to the farthest building. Otherwise, the default value is 30000 m or 30 km.

---

**Note** When using terrain, the `MaxRange` limit is 300,000 m.

---

Data Types: double

#### Resolution — Resolution of receiver site locations used to compute SINR values

`'auto'` (default) | numeric scalar

Resolution of receiver site locations used to compute SINR values, specified as `'auto'` or a numeric scalar in meters. The resolution defines the maximum distance between the locations. If the resolution is `'auto'`, `sinr` computes a value scaled to `MaxRange`. Decreasing the resolution increases the quality of the SINR map and the time required to create it.

#### Colormap — Colormap for coloring filled contours

`'jet'` (default) |  $M$ -by-3 array of RGB triplets

Colormap for coloring filled contours, specified as an  $M$ -by-3 array of RGB triplets, where  $M$  is the number of individual colors.

#### ColorLimits — Color limits for color maps

`[-5 20]` (default) | two-element vector

Color limits for color maps, specified as a two-element vector of the form [min max]. The color limits indicate the SINR values that map to the first and last colors in the colormap.

### **ShowLegend — Show signal strength color legend on map**

'true' (default) | 'false'

Show signal strength color legend on map, specified as 'true' or 'false'.

### **Transparency — Transparency of SINR map**

0.4 (default) | numeric scalar

Transparency of SINR map, specified as a numeric scalar in the range 0-1. If the value is zero, the map is completely transparent. If the value is one, the map is completely opaque.

## **Output Arguments**

### **r — Signal to interference plus noise ratio at the receiver**

numeric vector (default)

Signal to interference plus noise ratio at the receiver due to the transmitter sites, returned as a numeric vector. The vector length is equal to the number of receiver sites.

Data Types: double

## A-Law Compressor

Implement A-law compressor for source coding

## Library

Source Coding

## Description

The A-Law Compressor block implements an A-law compressor for the input signal. The formula for the A-law compressor is

$$y = \begin{cases} \frac{A|x|}{1 + \log A} \operatorname{sgn}(x) & \text{for } 0 \leq |x| \leq \frac{V}{A} \\ \frac{V(1 + \log(A|x|/V))}{1 + \log A} \operatorname{sgn}(x) & \text{for } \frac{V}{A} < |x| \leq V \end{cases}$$

where  $A$  is the A-law parameter of the compressor,  $V$  is the peak signal magnitude for  $x$ ,  $\log$  is the natural logarithm, and  $\operatorname{sgn}$  is the `sign` function.

The most commonly used  $A$  value is 87.6.

The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

### A value

The A-law parameter of the compressor.

**Peak signal magnitude**

The peak value of the input signal. This is also the peak value of the output signal.

**Supported Data Type**

## A-Law Expander

Implement A-law expander for source coding

## Library

Source Coding

## Description

The A-Law Expander block recovers data that the A-Law Compressor block compressed. The formula for the A-law expander, shown below, is the inverse of the compressor function.

$$x = \begin{cases} \frac{y(1 + \log A)}{A} & \text{for } 0 \leq |y| \leq \frac{V}{1 + \log A} \\ \exp(|y|(1 + \log A)/V - 1) \frac{V}{A} \operatorname{sgn}(y) & \text{for } \frac{V}{1 + \log A} < |y| \leq V \end{cases}$$

The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

### A value

The A-law parameter of the compressor.

### Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.

Match these parameters to the ones in the corresponding A-Law Compressor block.

## Algebraic Deinterleaver

Restore ordering of input symbols using algebraically derived permutation

## Library

Block sublibrary of Interleaving

## Description

The Algebraic Deinterleaver block restores the original ordering of a sequence that was interleaved using the Algebraic Interleaver block. In typical usage, the parameters in the two blocks have the same values.

The **Number of elements** parameter,  $N$ , indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

The **Type** parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are `Takeshita-Costello` and `Welch-Costas`. Each of these methods has parameters and restrictions that are specific to it; these are described on the reference page for the Algebraic Interleaver block.

## Parameters

### Type

The type of permutation table that the block uses for deinterleaving. Choices are `Takeshita-Costello` and `Welch-Costas`.

**Number of elements**

The number of elements,  $N$ , in the input vector.

**Multiplicative factor**

The factor the block uses to compute the corresponding interleaver's cycle vector. This field appears only when you set **Type** to Takeshita-Costello.

**Cyclic shift**

The amount by which the block shifts indices when creating the corresponding interleaver's permutation table. This field appears only when you set **Type** to Takeshita-Costello.

**Primitive element**

An element of order  $N$  in the finite field  $GF(N+1)$ . This field appears only if **Type** is set to Welch-Costas.

# Algebraic Interleaver

Reorder input symbols using algebraically derived permutation table

## Library

Block sublibrary of Interleaving

## Description

The Algebraic Interleaver block rearranges the elements of its input vector using a permutation that is algebraically derived. The **Number of elements** parameter,  $N$ , indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

The **Type** parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are `Takehita-Costello` and `Welch-Costas`. Each of these methods has parameters and restrictions that are specific to it:

- If you set **Type** to `Welch-Costas`, then  $N + 1$  must be prime. The **Primitive element** parameter is an integer,  $A$ , between 1 and  $N$  that represents a primitive element of the finite field  $GF(N + 1)$ . This means that every nonzero element of  $GF(N + 1)$  can be expressed as  $A$  raised to some integer power.

In a Welch-Costas interleaver, the permutation maps the integer  $k$  to  $\text{mod}(A^k, N + 1) - 1$ .

- If you set **Type** to `Takehita-Costello`, then  $N$  must be  $2^m$  for some integer  $m$ . The **Multiplicative factor** parameter,  $k$ , must be an odd integer less than  $N$ . The **Cyclic shift** parameter,  $h$ , must be a nonnegative integer less than  $N$ .

A Takeshita-Costello interleaver uses a length- $N$  *cycle vector* whose  $n$ th element is

$$c(n) = \text{mod}\left(k \cdot \frac{n \cdot (n - 1)}{2}, N\right) + 1, n$$

for integers  $n$  between 1 and  $N$ . The intermediate permutation function is obtained by using the following relationship:

$$\Pi(c(n)) = c(n + 1)$$

where

$$n = 1:N$$

The interleaver's actual permutation vector is the result of cyclically shifting the elements of the permutation vector,  $\pi$ , by the **Cyclic shift** parameter,  $h$ .

## Parameters

### Type

The type of permutation table that the block uses for interleaving.

### Number of elements

The number of elements,  $N$ , in the input vector.

### Multiplicative factor

The factor used to compute the interleaver's cycle vector. This field appears only if **Type** is set to Takeshita-Costello.

### Cyclic shift

The amount by which the block shifts indices when creating the permutation table. This field appears only if **Type** is set to Takeshita-Costello.

### Primitive element

An element of order  $N$  in the finite field  $\text{GF}(N+1)$ . This field appears only if **Type** is set to Welch-Costas.

## Align Signals

(To be removed) Align two signals by finding delay between them

## Compatibility

Align Signals Block will be removed in a future release. Use the Find Delay block to find delays and the Delay block to apply delays instead. For more information, see “Compatibility Considerations” on page 3-14.

## Library

Utility Blocks

## Description

The Align Signals block aligns two signals by finding the delay between them. This is useful when you want to compare a transmitted and received signal to determine the bit error rate, but do not know the delay in the received signal. This block accepts a column vector or matrix input signal. For a matrix input, the block aligns each channel independently.

The `s1` input port receives the original signal, while the `s2` input port receives a delayed version. The two input signals must have the same dimensions and sample times. The block calculates the delay between the two signals, and then

- Delays the first signal, `s1`, by the calculated value, and outputs it through the port labeled `s1 del`.
- Outputs the second signal `s2` without change through the port labeled `s2`.
- Outputs the delay value through the port labeled `delay`.

See “Delays” for more information about signal delays.

The block's **Correlation window length** parameter specifies how many samples of the signals the block uses to calculate the cross-correlation. The delay output is a nonnegative integer less than the **Correlation window length**.

As the **Correlation window length** is increased, the reliability of the computed delay also increases. However, the processing time to compute the delay increases as well.

You can make the Align Signals block stop updating the delay after it computes the same delay value for a specified number of samples. To do so, select **Disable recurring updates**, and enter a positive integer in the **Number of constant delay outputs to disable updates** field. For example, if you set **Number of constant delay outputs to disable updates** to 20, the block will stop recalculating and updating the delay after it calculates the same value 20 times in succession. Disabling recurring updates causes the simulation to run faster after the target number of constant delays occurs.

## Tips for Using the Block Effectively

- Set the **Correlation window length** parameter sufficiently large so that the computed delay eventually stabilizes at a constant value. If the computed delay is not constant, you should increase **Correlation window length**. If the increased value of **Correlation window length** exceeds the duration of the simulation, then you should also increase the duration of the simulation accordingly.
- If the cross-correlation between the two signals is broad, then **Correlation window length** should be much larger than the expected delay, or else the algorithm might stabilize at an incorrect value. For example, a CPM signal has a broad autocorrelation, so it has a broad cross-correlation with a delayed version of itself. In this case, the **Correlation window length** value should be much larger than the expected delay.
- If the block calculates a delay that is greater than 75 percent of **Correlation window length**, the signal s1 is probably delayed relative to the signal s2. In this case, you should switch the signal lines leading into the two input ports.
- If you use the Align Signals block with the Error Rate Calculation block, you should set the **Receive delay** parameter of the Error Rate Calculation block to 0 because the Align Signals block compensates for the delay. Also, you might want to set the Error Rate Calculation block's **Computation delay** parameter to a nonzero value to account for the possibility that the Align Signals block takes a nonzero amount of time to stabilize on the correct amount by which to delay one of the signals.

## Parameters

### Correlation window length

The number of samples the block uses to calculate the cross-correlations of the two signals.

### Disable recurring updates

Selecting this option causes the block to stop computing the delay after it computes the same delay value for a specified number of samples.

### Number of constant delay outputs to disable updates

A positive integer specifying how many times the block must compute the same delay before ceasing to update. This field appears only if **Disable recurring updates** is selected.

## Algorithm

The Align Signals block finds the delay by calculating the cross-correlations of the first signal with time-shifted versions of the second signal, and then finding the index at which the cross-correlation is maximized.

## Compatibility Considerations

### Align Signals Block will be removed

*Warns starting in R2019b*

Align Signals Block will be removed in a future release. Use the Find Delay block to find delays and the Delay block to apply delays instead.

See “Delays” for an example that uses the Find Delay block in conjunction with the Error Rate Calculation block.

For an example that illustrates how to set the correlation window length properly, see the section **Setting the Correlation Window Length** on the Find Delay block reference page.

## APP Decoder

Decode convolutional code using a posteriori probability (APP) method

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The APP Decoder block performs a posteriori probability (APP) decoding of a convolutional code.

## Input Signals and Output Signals

The input  $L(u)$  represents the sequence of log-likelihoods of encoder input bits, while the input  $L(c)$  represents the sequence of log-likelihoods of code bits. The outputs  $L(u)$  and  $L(c)$  are updated versions of these sequences, based on information about the encoder.

If the convolutional code uses an alphabet of  $2^n$  possible symbols, this block's  $L(c)$  vectors have length  $Q*n$  for some positive integer  $Q$ . Similarly, if the decoded data uses an alphabet of  $2^k$  possible output symbols, then this block's  $L(u)$  vectors have length  $Q*k$ .

This block accepts a column vector input signal with any positive integer for  $Q$ .

If you only need the input  $L(c)$  and output  $L(u)$ , you can attach a Simulink Ground block to the input  $L(u)$  and a Simulink Terminator block to the output  $L(c)$ .

This block accepts `single` and `double` data types. Both inputs, however, must be of the same type. The output data type is the same as the input data type.

## Specifying the Encoder

To define the convolutional encoder that produced the coded input, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name as the **Trellis structure** parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a `poly2trellis` command within the **Trellis structure** field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

To indicate how the encoder treats the trellis at the beginning and end of each frame, set the **Termination method** parameter to either `Truncated` or `Terminated`. The `Truncated` option indicates that the encoder resets to the all-zeros state at the beginning of each frame. The `Terminated` option indicates that the encoder forces the trellis to end each frame in the all-zeros state. If you use the Convolutional Encoder block with the **Operation mode** parameter set to `Truncated (reset every frame)`, use the `Truncated` option in this block. If you use the Convolutional Encoder block with the **Operation mode** parameter set to `Terminate trellis by appending bits`, use the `Terminated` option in this block.

## Specifying Details of the Algorithm

You can control part of the decoding algorithm using the **Algorithm** parameter. The True APP option implements a posteriori probability decoding as per equations 20–23 in section V of [1]. To gain speed, both the `Max*` and `Max` options approximate expressions like

$$\log \sum_i \exp(a_i)$$

by other quantities. The `Max` option uses  $\max(a_i)$  as the approximation, while the `Max*` option uses  $\max(a_i)$  plus a correction term given by  $\ln(1 + \exp(-|a_i - 1 - a_i|))$  [3].

The Max\* option enables the **Scaling bits** parameter in the dialog box. This parameter is the number of bits by which the block scales the data it processes internally (multiplies the input by  $(2^{\text{numScalingBits}})$  and divides the pre-output by the same factor). Use this parameter to avoid losing precision during the computations.

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

### Termination method

Either Truncated or Terminated. This parameter indicates how the convolutional encoder treats the trellis at the beginning and end of frames.

### Algorithm

Either True APP, Max\*, or Max.

### Number of scaling bits

An integer between 0 and 8 that indicates by how many bits the decoder scales data in order to avoid losing precision. This field is active only when **Algorithm** is set to Max\*.

### Disable L(c) output port

Select this check box to disable the secondary block output, L(c).

## Examples

For an example using this block, see the “Iterative Decoding of a Serially Concatenated Convolutional Code” example.

## AGC Block

Adaptively adjust gain for constant signal-level output

## Library

RF Impairments Correction

## Description

The automatic gain controller (AGC) block adaptively adjusts its gain to achieve a constant signal level at the output.

## Parameters

### Step size

Specify the step size for gain updates as a double-precision or single-precision real positive scalar. The default is `0.01`.

If you increase **Step size**, the AGC responds faster to changes in the input signal level. However, gain pumping also increases.

### Desired output power (W)

Specify the desired output power level as a real positive scalar. The power level is specified in Watts referenced to 1 ohm. The default is `1`.

### Averaging length

Specify the length of the averaging window in samples as a positive integer scalar. The default is `100`.

---

**Note** If you use the AGC with higher order QAM signals, you might need to reduce the variation in the gain during steady-state operation. Inspect the constellation diagram at the output of the AGC and increase the averaging length as needed. An increase in **Averaging length** reduces execution speed.

---

### **Maximum power gain (dB)**

Specify the maximum gain of the AGC in decibels as a positive scalar. The default is 60.

If the AGC input signal power is very small, the AGC gain will be very large. This can cause problems when the input signal power suddenly increases. Use **Maximum power gain (dB)** to avoid this by limiting the gain that the AGC applies to the input signal.

### **Enable output of estimated input power**

Select this check box to provide an input signal power estimate to an output port. By default, the check box is not selected.

### **Simulate using**

Select the simulation mode.

#### **Code generation**

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is **Code generation**, System objects corresponding to the blocks accept a maximum of nine inputs.

#### **Interpreted execution**

Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## **Algorithms**

This block implements the algorithm, inputs, and outputs described on the `comm.AGC` reference page. The object properties correspond to the block parameters.

## Examples

To open these examples, enter the example names at the MATLAB command prompt:

- `doc_agc_received_signal_amplitude` — Adaptively adjusts the received signal power to approximately 1 Watt.
- `doc_agc_plot_step_size` — Plots the effect of step size on AGC performance.
- `doc_agc_plot_max_gain` — Shows how the maximum gain affects the ability of the AGC to reach its target output power.

# AWGN Channel

Add white Gaussian noise to input signal

**Library:** Communications Toolbox / Channels

## Description

The AWGN Channel block adds white Gaussian noise to the input signal. It inherits the sample time from the input signal.

## Ports

### Input

#### In — Input data signal

vector | matrix

Input data signal, specified as an  $N_S$ -by-1 vector or an  $N_S$ -by- $N_C$  matrix.

$N_S$  represents the number of samples in the input signal.  $N_C$  represents the number of channels, as determined by the number of columns in the input signal matrix. Both  $N_S$  and  $N_C$  can be equal to 1.

The block adds frames of length- $N_S$  Gaussian noise to each of the  $N_C$  channels, using a distinct random distribution per channel.

Data Types: double | single

Complex Number Support: Yes

#### Var — Variance of additive white Gaussian noise

positive scalar | vector

Variance of additive white Gaussian noise, specified as a positive scalar or a 1-by- $N_C$  vector.  $N_C$  represents the number of channels, as determined by the number of columns in the input signal matrix. For more information, see “Specifying the Variance Directly or Indirectly” on page 3-28.

**Dependencies**

To enable this port, set Mode to Variance from port.

Data Types: double

**Output****Out — Output data signal**

vector | matrix

Output data signal for the AWGN channel, returned as a vector or matrix. The datatype and dimensions of Out match those of the input signal, In.

**Parameters****Initial seed — Noise generator initial seed**

67 (default) | positive scalar | vector

Noise generator initial seed, specified as a positive scalar or a 1-by- $N_C$  vector.

This block uses the Random Source block to generate noise. Random numbers are generated using the Ziggurat method (V5 RANDN algorithm). The block reuses the same initial seeds every time you rerun the simulation, so that this block outputs the same signal each time you run a simulation.

When the input signal is complex, the block creates random data as:

```
randData = randn(2*NS,NC)  
noise = randData(1:2:end) + 1i(randData(2:2:end))
```

$N_S$  is the number of samples and  $N_C$  is the number of channels.

You can specify different seed values for each DLL build.

**Tunable:** Yes

**Mode — Variance mode**

Signal to noise ratio (Eb/No) (default) | Signal to noise ratio (Es/No) |  
Signal to noise ratio (SNR) | Variance from mask | Variance from port

Variance mode, specified as Signal to noise ratio (Eb/No), Signal to noise ratio (Es/No), Signal to noise ratio (SNR), Variance from mask, or Variance from port. For more information, see “Relationship Among Eb/No, Es/No, and SNR Modes” on page 3-27 and “Specifying the Variance Directly or Indirectly” on page 3-28.

**Eb/No (dB) — Ratio of information bit energy per symbol to noise power spectral density**

10 (default) | scalar | vector

Ratio of information bit energy per symbol to noise power spectral density in decibels, specified as a scalar or vector. The information bit energy is the magnitude without channel coding.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set Mode to Eb/No.

**Es/No (dB) — Ratio of information symbol energy per symbol to noise power spectral density**

10 (default) | scalar | vector

Ratio of information symbol energy per symbol to noise power spectral density in decibels, specified as a scalar or vector. The information bit energy is the magnitude without channel coding.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set Mode to Es/No.

**SNR (dB) — Ratio of signal power to noise power**

10 (default) | scalar | vector

Ratio of signal power to noise power in decibels, specified as a scalar or vector.

**Tunable:** Yes

#### **Dependencies**

To enable this parameter, set Mode to SNR.

#### **Number of bits per symbol — Number of bits in each input symbol**

1 (default) | scalar | vector

Number of bits in each input symbol, specified as a scalar or vector.

#### **Dependencies**

To enable this parameter, set Mode to Eb/No.

#### **Input signal power, referenced to 1 ohm (watts) — Mean square power of input**

1 (default) | scalar | vector

Mean square power of the input in watts, specified as a scalar or vector.

- When Mode is Eb/No or Es/No, the parameter is the mean square power of the input symbols.
- When Mode is SNR, this parameter is the mean square power of the input samples.

**Tunable:** Yes

#### **Dependencies**

To enable this parameter, set Mode to Eb/No, Es/No, or SNR.

#### **Symbol period (s) — Duration of an information channel**

1 (default) | positive scalar | vector

Duration of an information channel symbol in seconds, specified as a positive scalar or vector. The duration of the information channel is measured without channel coding.

#### **Dependencies**

To enable this parameter, set Mode to Eb/No or Es/No.

#### **Variance — Variance of white Gaussian noise**

1 (default) | scalar | vector

Variance of the white Gaussian noise, specified as a scalar or vector. For more information, see “Specifying the Variance Directly or Indirectly” on page 3-28.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set Mode to Variance from mask.

## Block Characteristics

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## Tips

- You can tune parameters in normal mode, accelerator mode, or rapid accelerator mode.
- Unless otherwise indicated, parameters are *nontunable*.
  - For nontunable parameters, when you use the Simulink Coder™ rapid simulation (RSIM) target to build an RSIM executable, you cannot change their values without recompiling the model.
  - If a parameter is *tunable*, you can change its value at any time. This is useful for Monte Carlo simulations in which you run the simulation multiple times (such as on multiple computers) with different amounts of noise.

## Algorithms

### Relationship Among Eb/No, Es/No, and SNR Modes

For uncoded complex input signals, the AWGN Channel block relates  $E_b/N_0$ ,  $E_s/N_0$ , and SNR according to these equations:

$$E_s/N_0 = (T_{\text{sym}}/T_{\text{samp}}) \cdot \text{SNR}$$

$$E_s/N_0 = E_b/N_0 + 10\log_{10}(k) \text{ in dB}$$

- $E_s$  represents the signal energy in joules.
- $E_b$  represents the bit energy in joules.
- $N_0$  represents the noise power spectral density in watts/Hz.
- $T_{\text{sym}}$  represents the Symbol period (s) parameter of the block in  $E_s/N_0$  mode.
- $k$  represents the number of information bits per input symbol, Number of bits per symbol.
- $T_{\text{samp}}$  represents the inherited sample time of the block, in seconds.

For real signal inputs, the AWGN Channel block relates  $E_s/N_0$  and SNR according to this equation:

$$E_s/N_0 = 0.5 (T_{\text{sym}}/T_{\text{samp}}) \cdot \text{SNR}$$

---

#### Note

- All values of power assume a nominal impedance of 1 ohm.
  - The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of  $N_0/2$  watts/Hz for real input signals, versus  $N_0$  watts/Hz for complex signals.
- 

For more information, see “AWGN Channel Noise Level”.

## Specifying the Variance Directly or Indirectly

To directly specify the variance of the noise generated by AWGN Channel, specify the Mode as:

- **Variance from mask**, where you specify the variance in the dialog box. The value must be positive.
- **Variance from port**, where you provide the variance as an input to the block. The variance input must be positive, and its sampling rate must equal that of the input signal.

For **Variance from mask** and **Variance from port** mode:

- If the variance is a scalar, then all signal channels are uncorrelated but share the same variance.
- If the variance is a vector whose length is the number of channels in the input signal, then each element represents the variance of the corresponding signal channel.

---

**Note** If you apply complex input signals to the AWGN Channel block, then it adds complex zero-mean Gaussian noise with the calculated or specified variance. The variance for each quadrature component of the complex noise is half of the calculated or specified value.

---

To specify the variance indirectly, that is, to have the block calculate the variance, specify the Mode as:

- **Signal to noise ratio ( $E_b/N_0$ )**, where the block calculates the variance from these quantities that you specify in the dialog box:
  - $E_b/N_0$  (dB), the ratio of bit energy to noise power spectral density
  - Number of bits per symbol
  - Input signal power, referenced to 1 ohm (watts), the actual power of the symbols at the input of the block
  - Symbol period (s)
- **Signal to noise ratio ( $E_s/N_0$ )**, where the block calculates the variance from these quantities that you specify in the dialog box:
  - $E_s/N_0$  (dB), the ratio of signal energy to noise power spectral density
  - Input signal power, referenced to 1 ohm (watts), the actual power of the symbols at the input of the block
  - Symbol period (s)
- **Signal to noise ratio (SNR)**, where the block calculates the variance from these quantities that you specify in the dialog box:
  - SNR (dB), the ratio of signal power to noise power
  - Input signal power, referenced to 1 ohm (watts), the actual power of the samples at the input of the block

Changing the symbol period in the AWGN Channel block affects the variance of the noise added per sample, which also causes a change in the final error rate.

$$\text{NoiseVariance} = \frac{\text{SignalPower} \times \text{SymbolPeriod}}{\text{SampleTime} \times 10^{\frac{Es/No}{10}}}$$

---

**Tip** Select the symbol period equal to the symbol period of the model. The value depends on what constitutes a symbol and what the oversampling applied to it is. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see “AWGN Channel Noise Level”.

# Barker Code Generator

Generate bipolar Barker Code

**Library:** Communications Toolbox  
 Communications Toolbox / Comm Sources / Sequence  
 Generators

## Description

The Barker Code Generator block generates a bipolar Barker code. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. For more information, see “Barker Codes” on page 3-33.

## Ports

### Output

#### **output — Barker code frame**

column vector

Barker code frame, returned as a column vector. If the frame length exceeds the Barker code length, the block fills the frame by repeating the Barker code.

#### **Dependencies**

Set the data type of the output with the **Output data type** parameter.

## Parameters

#### **Code length — Length of generated code**

7 (default) | 1 | 2 | 3 | 4 | 5 | 11 | 13

Length of the generated code, specified as 1, 2, 3, 4, 5, 7, 11, or 13. For more information, see “Barker Codes” on page 4-90.

Example: 2 outputs the Barker code [-1;1].

Data Types: double

**Sample time — Output sample time**

1 (default) | positive scalar

Output sample time, specified as a positive scalar that represents the time between each sample of the output signal. For information on the relationship between **Sample time** and **Samples per frame**, see “Sample Timing” on page 3-34.

**Samples per frame — Samples per output frame**

1 (default) | positive integer

Samples per output frame, specified as a positive integer. If **Samples per frame** is  $M$ , the block outputs a frame containing  $M$  samples comprised of length  $N$  Barker code sequences.  $N$  is the length of the generated code, which is set by the **Code length** parameter. When  $M$  is not an integer multiple of  $N$ , consecutive frames maintain continuity of the Barker code across frame boundaries.

For information on the relationship between **Sample time** and **Samples per frame**, see “Sample Timing” on page 3-34.

Data Types: double

**Output data type — Output data type**

double (default) | int8

Output data type, specified as double or int8.

Data Types: char | string

**Simulate using — Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the

speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

<b>Data Types</b>	double   integer
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### Barker Codes

Barker codes have a maximum autocorrelation sequence, which has off-peak autocorrelations no larger than 1.

A correlation sidelobe is the correlation of a codeword with a time-shifted version of itself. The correlation sidelobe,  $C_k$ , for a  $k$ -symbol shift of an  $N$ -bit code sequence,  $\{X_j\}$ , is

$$C_k = \sum_{j=1}^{N-k} X_j X_{j+k}$$

For  $j=1, 2, 3, \dots, N$ ,  $X_j$  is an individual code symbol that is equal to +1 or -1. The adjacent symbols are assumed to be 0.

The output code is in a bipolar format with 0 and 1 mapped to 1 and -1. The maximum known Barker code length is 13. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. The Barker code generator outputs the Barker codes listed in this table.

Barker Code Length	Barker Code	Sidelobe Level
1	[-1]	0 dB
2	[-1; 1]	-6 dB
3	[-1; -1; 1]	-9.5 dB
4	[-1; -1; 1; -1]	-12 dB
5	[-1; -1; -1; 1; -1]	-14 dB
7	[-1; -1; -1; 1; 1; -1; 1]	-16.9 dB
11	[-1; -1; -1; 1; 1; 1; -1; 1; 1; -1; 1]	-20.8 dB
13	[-1; -1; -1; -1; -1; 1; 1; -1; -1; 1; -1; 1; -1]	-22.3 dB

## Sample Timing

The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

## Baseband File Reader

Read baseband signals from file

**Library:** Communications Toolbox / Comm Sources

### Description

The Baseband File Reader block reads a signal from a baseband file. A baseband file is a specific type of binary file written by the Baseband File Writer block. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz. The block automatically reads the sample rate, center frequency, number of channels, and any descriptive data.

### Input/Output Ports

#### Output

##### Data — Baseband signal

scalar | vector | matrix

Baseband signal, returned as a scalar, vector, or matrix. The signal is read from the file specified by the **Baseband file name** parameter. The sample time is either inherited from the file or can be set by the **Sample Time (s)** parameter.

Data Types: double

##### EOF — End-of-file indicator

logical scalar

End-of-file indicator, returned as a logical scalar. The output is `true` when the **Repeatedly read the file** parameter is `false` and the entire file has been read. To enable this port, select the **Output end-of-file indicator** parameter.

## Parameters

### Baseband file name — Name of file from which data is read

example.bb (default) | character vector

Specify the name of the baseband file as a character vector.

Click **Browse** to locate the baseband file you want to read. Click **File Info** to display this information:

- File name
- Sample rate
- Center frequency
- Number of samples
- Number of channels
- Data type
- Any metadata fields

Data Types: char

### Inherit sample time from file — Select source of sample time

on (default) | off

Select this check box to inherit the sample time from the file specified by **Baseband file name**.

### Sample time (s) — Block sample time

1 (default) | positive scalar

Specify the block sample time in seconds as a real positive scalar. To enable this parameter, clear the **Inherit sample time from file** check box.

### Samples per frame — Number of samples in one frame

100 (default) | positive integer scalar

Specify the samples per frame as a positive integer scalar.

### Repeatedly read the file — Continuously loop data from file

off (default) | on

Select this check box to repeatedly read the contents of the baseband file. If the end of the file is reached, the block exhibits this behavior:

- Parameter is selected — The block outputs zeros.
- Parameter is not selected — The block outputs samples from the beginning of the file.

**Simulate using — Select simulation mode**

Code generation (default) | Interpreted execution

**Code generation**

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

**Interpreted execution**

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

## Block Characteristics

<b>Data Types</b>	double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

**Introduced in R2016b**

## Baseband File Writer

Write baseband signals to file

**Library:** Communications Toolbox / Comm Sinks

### Description

The Baseband File Writer block writes a baseband signal to a specific type of binary file. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz. Sample rate, which is determined by the input signal sample time and frame size, and center frequency are saved when the signal is written to a file.

### Input/Output Ports

#### Input

**Port\_1 — Baseband signal**

scalar | vector | matrix

This port accepts a baseband signal to be saved under the filename specified by the **Baseband file name** parameter. The saved signal is always complex.

Data Types: single | double

### Parameters

**Baseband file name — Name of file in which data is saved**

untitled.bb (default) | character vector

Specify the name of the baseband file as a character vector.

To specify the location where the file is saved, click **Browse**.

**Center frequency (Hz) — Center frequency of the baseband signal**

1e8 (default) | nonnegative scalar

Specify the center frequency in Hz as a nonnegative scalar.

**Metadata in a structure — Data describing the baseband signal**

struct() (default) | structure

Specify data describing the baseband signal as a structure. If the signal has no descriptive data, this parameter is an empty structure. The structure can contain any number of fields. Field names have no restrictions, but the field values must be numeric, logical, or character data types having any dimension.

**Number of latest samples to write — Number of samples to write**

inf (default) | positive scalar

Specify the number to write. If this parameter is `inf`, all samples are saved. Otherwise, only the last  $N$  samples are saved, where  $N$  is specified by this parameter.

**Simulate using — Select simulation mode**

Code generation (default) | Interpreted execution

**Code generation**

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

**Interpreted execution**

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

## Block Characteristics

<b>Data Types</b>	double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

### Tips

- The Baseband File Writer block writes baseband signals to uncompressed binary files. To share these files, you can compress them to a zip file using the `zip` function. For more information, see “Create and Extract from Zip Archives” (MATLAB).

## Baseband PLL

Implement baseband phase-locked loop

## Library

Components sublibrary of Synchronization

## Description

The Baseband PLL (phase-locked loop) block is a feedback control system that automatically adjusts the phase of a locally generated signal to match the phase of an input signal. Unlike the Phase-Locked Loop block, this block uses a baseband method and does not depend on a carrier frequency.

This PLL has these three components:

- An integrator used as a phase detector.
- A filter. You specify the filter's transfer function using the **Lowpass filter numerator** and **Lowpass filter denominator** parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of  $s$ .

To design a filter, you can use the Signal Processing Toolbox™ functions `cheby1`, and `cheby2`. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

```
[num, den] = cheby2(3,40,100,'s')
```

- A voltage-controlled oscillator (VCO). You specify the sensitivity of the VCO signal to its input using the **VCO input sensitivity** parameter. This parameter, measured in Hertz per volt, is a scale factor that determines how much the VCO shifts from its quiescent frequency.

This block accepts a sample-based scalar signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

This model is nonlinear; for a linearized version, use the Linearized Baseband PLL block.

## Parameters

### Lowpass filter numerator

The numerator of the lowpass filter's transfer function, represented as a vector that lists the coefficients in order of descending powers of  $s$ .

### Lowpass filter denominator

The denominator of the lowpass filter's transfer function, represented as a vector that lists the coefficients in order of descending powers of  $s$ .

### VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the VCO's quiescent frequency.

## BCH Decoder

Decode BCH code to recover binary vector data

**Library:** Communications Toolbox / Error Detection and Correction / Block

### Description

The BCH Decoder block recovers a binary message vector from a binary BCH codeword vector. For proper decoding, the **Codeword length, N** and **Message length, K** parameter values in this block must match the parameters in the corresponding BCH Encoder block. The full-length values of  $N$  and  $K$  must produce a valid narrow-sense BCH code.

If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords. The input and output signal lengths are listed in “Input and Output Signal Length in BCH Blocks” on page 3-51.

See “Tips” on page 3-53 for information about valid  $N$  values, valid  $(N,K)$  pairs, and error-correcting capabilities for a given BCH code.

If decoding fails, the message portion of the decoder input is returned unchanged as the decoder output.

The sample times of all input and output signals are equal.

This icon shows optional ports.

## Ports

### Input

#### In — Encoded message

binary column vector

Encoded message, specified as a binary column vector. The encoded message is a BCH code with message length  $K$  and codeword length ( $N$  - number of punctures).

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

#### Era — Erasure vector

binary column vector

Erasure vector, specified as a binary column vector that is the same length as In. Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased.

#### Dependencies

To enable this port, select **Enable erasures input port**.

Data Types: double | Boolean

### Output

#### Out — Decoded message

binary column vector

Decoded message, returned as a binary column vector input signal with an integer multiple of **Message length, K** elements or **Shortened message length, S** elements if the code is shortened. Each group of input elements represents one codeword to decode. The input and output signal lengths are listed in the "Input and Output Signal Length in BCH Blocks" on page 3-51 table.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

#### Err — Decoding errors

integer vector

Decoding errors, returned as an integer vector that indicates the number of errors detected during decoding of the codeword. A negative integer indicates that the block detected more errors than it could correct by using the coding scheme.

**Dependencies**

To enable this port, select **Output number of corrected errors**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

For more information, see “Supported Data Types” on page 3-53.

## Parameters

**Codeword length, N — Codeword length**

15 (default) | integer

Codeword length, specified as an integer of the form  $N = 2^M - 1$ , where  $M$  is an integer from 3 through 16. For more information, see “Tips” on page 3-53.

**Message length, K — Message length**

5 (default) | integer

Message length, specified as an integer. The  $(N, K)$  pair must produce a narrow-sense BCH code.

**Shortened message length, S — Shortened message length**

5 (default) | integer

Shortened message length, specified as an integer. When you specify this parameter, provide full-length  $N$  and  $K$  values to specify the  $(N, K)$  code that is shortened to an  $(N-K+S, S)$  code.

**Dependencies**

To enable this parameter, select **Specify shortened message length**.

**Generator polynomial — Generator polynomial**

' $X^{10} + X^8 + X^5 + X^4 + X^2 + X + 1$ ' (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector — For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.
- A binary Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: `'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'`, which is equivalent to `bchgenpoly(15,5)`

### Dependencies

To enable this parameter, select **Specify generator polynomial**.

### Primitive polynomial — Primitive polynomial

`'X^4 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. It is a polynomial of order  $M$  that defines the finite Galois field  $GF(2)$ , specified as one of the following:

- A polynomial character vector — For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: `'X^4 + X + 1'`, which is the primitive polynomial used for a (15,5) code, `de2bi(primpoly(4,'nodisplay'),'left-msb')`

### Dependencies

To enable this parameter, select **Specify primitive polynomial**.

### Disable generator polynomial checking — Option to disable generator polynomial checking

on (default) | off

Select this parameter to disable generator polynomial check.

Each time a model initializes, the block performs a polynomial check. This check verifies that  $X^N + 1$  is divisible by the specified generator polynomial, where  $N$  represents the full codeword length. For larger codes, disabling the check speeds up the simulation process.

---

**Tip** Always run the check at least once before disabling this feature.

---

#### **Dependencies**

To enable this parameter, select **Specify generator polynomial**.

#### **Puncture vector — Puncture vector**

`[ones(8,1); zeros(2,1)]` (default) | column vector

Puncture vector, specified as a binary column vector of length  $N-K$ . Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 3-52.

#### **Dependencies**

To enable this parameter, select **Puncture code**.

#### **Enable erasures input port — Option to enable erasures input port**

off (default) | on

Selecting this check box enables the erasures port, Era.

Through the port, you can input a binary column vector that is  $1/M$  times as long as the codeword input.

Erasure values of 1 correspond to erased symbols in the same position in the bit-packed codeword. Values of 0 correspond to nonerased symbols. For more information, see “Puncturing and Erasures” on page 3-52.

#### **Output number of corrected errors — Option to enable port to output number of corrected errors**

off (default) | on

Selecting this check box enables an additional output port, Err, which indicates the number of errors the block corrected in the input codeword.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### Input and Output Signal Length in BCH Blocks

This table shows how to compute the input and output signal lengths for the BCH encoder and decoder blocks.

The notation  $y = c * x$  denotes that  $y$  is an integer multiple of  $x$ .

Specify Shortened Message Length, S	BCH Encoder	BCH Decoder
off	<b>Input Length:</b> $c * K$ <b>Output Length:</b> $c * (N - P)$	<b>Input Length:</b> $c * (N - P)$ <b>Output Length:</b> $c * K$ <b>Erasures Length:</b> $c * (N - P)$

Specify Shortened Message Length, S	BCH Encoder	BCH Decoder
on	<p><b>Input Length:</b> <math>c * S</math></p> <p><b>Output Length:</b> <math>c * (N - K + S - P)</math></p>	<p><b>Input Length:</b> <math>c * (N - K + S - P)</math></p> <p><b>Output Length:</b> <math>c * S</math></p> <p><b>Erasures Length:</b> <math>c * (N - K + S - P)</math></p>

- $N$  is the codeword length
- $K$  is the message length
- $S$  is the shortened message length
- $P$  is the number of punctures value, and is equal to the number of zeros in the puncture vector.

## Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

## Supported Data Types

Port	Supported Data Types
In	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>
Out	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>
Era	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean</li> </ul>
Err	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>

## Pair Block

BCH Encoder — Encodes data using BCH algorithm.

## Tips

- To generate the list of valid (N,K) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.
- Valid values for  $N = 2^M - 1$ , where  $M$  is an integer from 3 through 16. The maximum allowable value of  $N$  is 65,535.

## Algorithms

This block implements the algorithm, inputs, and outputs described in “Algorithms for BCH and RS Errors-only Decoding”.

Create BCH code from binary vector data

**Library:** Communications Toolbox / Error Detection and Correction / Block

### Description

The BCH Encoder block creates a BCH code with message length  $K$  and codeword length ( $N$  - number of punctures).

If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords. The input and output signal lengths are listed in “Input and Output Signal Length in BCH Blocks” on page 3-60.

See “Tips” on page 3-61 for information about valid  $N$  values, valid  $(N,K)$  pairs, and error-correcting capabilities for a given BCH code.

### Ports

#### Input

**In — Message to encode**

binary column vector

Message to encode, specified as a binary column vector input signal with an integer multiple of **Message length, K** elements or **Shortened message length, S** elements if the code is shortened. Each group of input elements represents one message word to encode. The input and output signal lengths are listed in “Input and Output Signal Length in BCH Blocks” on page 3-60.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

## Output

### Out — Encoded message

binary column vector

Encoded message, returned as a binary column vector. The encoded message is a BCH code with message length  $K$  and codeword length ( $N$  - number of punctures).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

For more information, see “Supported Data Types” on page 3-61.

## Parameters

### Codeword length, N — Codeword length

15 (default) | integer

Codeword length, specified as an integer of the form  $N = 2^M - 1$ , where  $M$  is an integer from 3 through 16. For more information, see “Tips” on page 3-61.

### Message length, K — Message length

5 (default) | integer

Message length, specified as an integer. The ( $N$ ,  $K$ ) pair must produce a narrow-sense BCH code.

### Shortened message length, S — Shortened message length

5 (default) | integer

Shortened message length, specified as an integer. When you specify this parameter, provide full-length  $N$  and  $K$  values to specify the ( $N$ ,  $K$ ) code that is shortened to an ( $N-K+S$ ,  $S$ ) code.

### Dependencies

To enable this parameter, select **Specify shortened message length**.

### Generator polynomial — Generator polynomial

' $X^{10} + X^8 + X^5 + X^4 + X^2 + X + 1$ ' (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector — For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.
- A binary Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: `'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'`, which is equivalent to `bchgenpoly(15,5)`

#### **Dependencies**

To enable this parameter, select **Specify generator polynomial**.

#### **Primitive polynomial — Primitive polynomial**

`'X^4 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. It is a polynomial of order  $M$  that defines the finite Galois field  $GF(2)$ , specified as one of the following:

- A polynomial character vector — For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: `'X^4 + X + 1'`, which is the primitive polynomial used for a (15,5) code, `de2bi(primpoly(4, 'nodisplay'), 'left-msb')`

#### **Dependencies**

To enable this parameter, select **Specify primitive polynomial**.

#### **Disable generator polynomial checking — Option to disable generator polynomial checking**

on (default) | off

Select this parameter to disable generator polynomial check.

Each time a model initializes, the block performs a polynomial check. This check verifies that  $X^N + 1$  is divisible by the specified generator polynomial, where  $N$  represents the full codeword length. For larger codes, disabling the check speeds up the simulation process.

---

**Tip** Always run the check at least once before disabling this feature.

---

### Dependencies

To enable this parameter, select **Specify generator polynomial**.

### Puncture vector — Puncture vector

[ones(8,1); zeros(2,1)] (default) | binary column vector

Puncture vector, specified as a binary column vector of length  $N-K$ . Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Shortening, Puncturing, and Erasures”.

---

**Note** 1s and 0s have precisely opposite meanings for the puncture and erasure vectors. For an erasure vector, 1 means that the data symbol is to be replaced with an erasure symbol, and 0 means that the data symbol is passed through the block unaltered. This convention applies to both the encoder and the decoder.

---

### Dependencies

To enable this parameter, select **Puncture code**.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### Input and Output Signal Length in BCH Blocks

This table shows how to compute the input and output signal lengths for the BCH encoder and decoder blocks.

The notation  $y = c * x$  denotes that  $y$  is an integer multiple of  $x$ .

Specify Shortened Message Length, S	BCH Encoder	BCH Decoder
off	<p><b>Input Length:</b> <math>c * K</math></p> <p><b>Output Length:</b> <math>c * (N - P)</math></p>	<p><b>Input Length:</b> <math>c * (N - P)</math></p> <p><b>Output Length:</b> <math>c * K</math></p> <p><b>Erasures Length:</b> <math>c * (N - P)</math></p>
on	<p><b>Input Length:</b> <math>c * S</math></p> <p><b>Output Length:</b> <math>c * (N - K + S - P)</math></p>	<p><b>Input Length:</b> <math>c * (N - K + S - P)</math></p> <p><b>Output Length:</b> <math>c * S</math></p> <p><b>Erasures Length:</b> <math>c * (N - K + S - P)</math></p>

- $N$  is the codeword length
- $K$  is the message length
- $S$  is the shortened message length
- $P$  is the number of punctures value, and is equal to the number of zeros in the puncture vector.

## Supported Data Types

Port	Supported Data Types

Out	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>

## Pair Block

BCH Decoder — Decodes BCH encoded data.

## Tips

- To generate the list of valid (N,K) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.
- Valid values for  $N = 2^M - 1$ , where  $M$  is an integer from 3 through 16. The maximum allowable value of  $N$  is 65,535.

## Algorithms

This block implements the algorithm, inputs, and outputs described in “Algorithms for BCH and RS Errors-only Decoding”.

# Bernoulli Binary Generator

Generate Bernoulli-distributed random binary numbers

## Library

Random Data Sources sublibrary of Comm Sources

## Description

The Bernoulli Binary Generator block generates random binary numbers using a Bernoulli distribution. The Bernoulli distribution with parameter  $p$  produces zero with probability  $p$  and one with probability  $1-p$ . The Bernoulli distribution has mean value  $1-p$  and variance  $p(1-p)$ . The **Probability of a zero** parameter specifies  $p$ , and can be any real number between zero and one.

## Attributes of Output Signal

The output signal can be a column or row vector, a two-dimensional matrix, or a scalar. The number of rows in the output signal corresponds to the number of samples in one frame and is determined by the **Samples per frame** parameter. The number of columns in the output signal corresponds to the number of channels and is determined by the number of elements in the **Probability of a zero** parameter. See “Sources and Sinks” in *Communications Toolbox User’s Guide* for more details.

## Parameters

### Probability of a zero

The probability with which a zero output occurs. Specify the probability as a scalar or row vector whose elements are real numbers between 0 and 1. The number of

elements in the **Probability of a zero** parameter correspond to the number of independent channels output from the block.

#### **Source of initial seed**

The source of the initial seed for the random number generator. Specify the source as either `Auto` or `Parameter`. When set to `Auto`, the block uses the global random number stream.

---

**Note** When **Source of initial seed** is `Auto` in `Code generation` mode, the random number generator uses an initial seed of zero. Therefore, the block generates the same random numbers each time it is started. Use `Interpreted execution` to ensure that the model uses different initial seeds. If `Interpreted execution` is run in `Rapid accelerator` mode, then it behaves the same as `Code generation` mode.

---

#### **Initial seed**

The initial seed value for the random number generator. Specify the seed as a nonnegative integer scalar. **Initial seed** is available when the **Source of initial seed** parameter is set to `Parameter`.

#### **Sample time**

The time between each sample of a column of the output signal.

#### **Samples per frame**

The number of samples per frame in one channel of the output signal. Specify **Samples per frame** as a positive integer scalar.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a binary sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

---

#### **Output data type**

The output type of the block can be specified as a `boolean`, `uint8`, `uint16`, `uint32`, `single`, or `double`. The default is `double`.

## Simulate using

Select the simulation mode.

### Code generation

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is **Code generation**, System objects corresponding to the blocks accept a maximum of nine inputs.

### Interpreted execution

Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

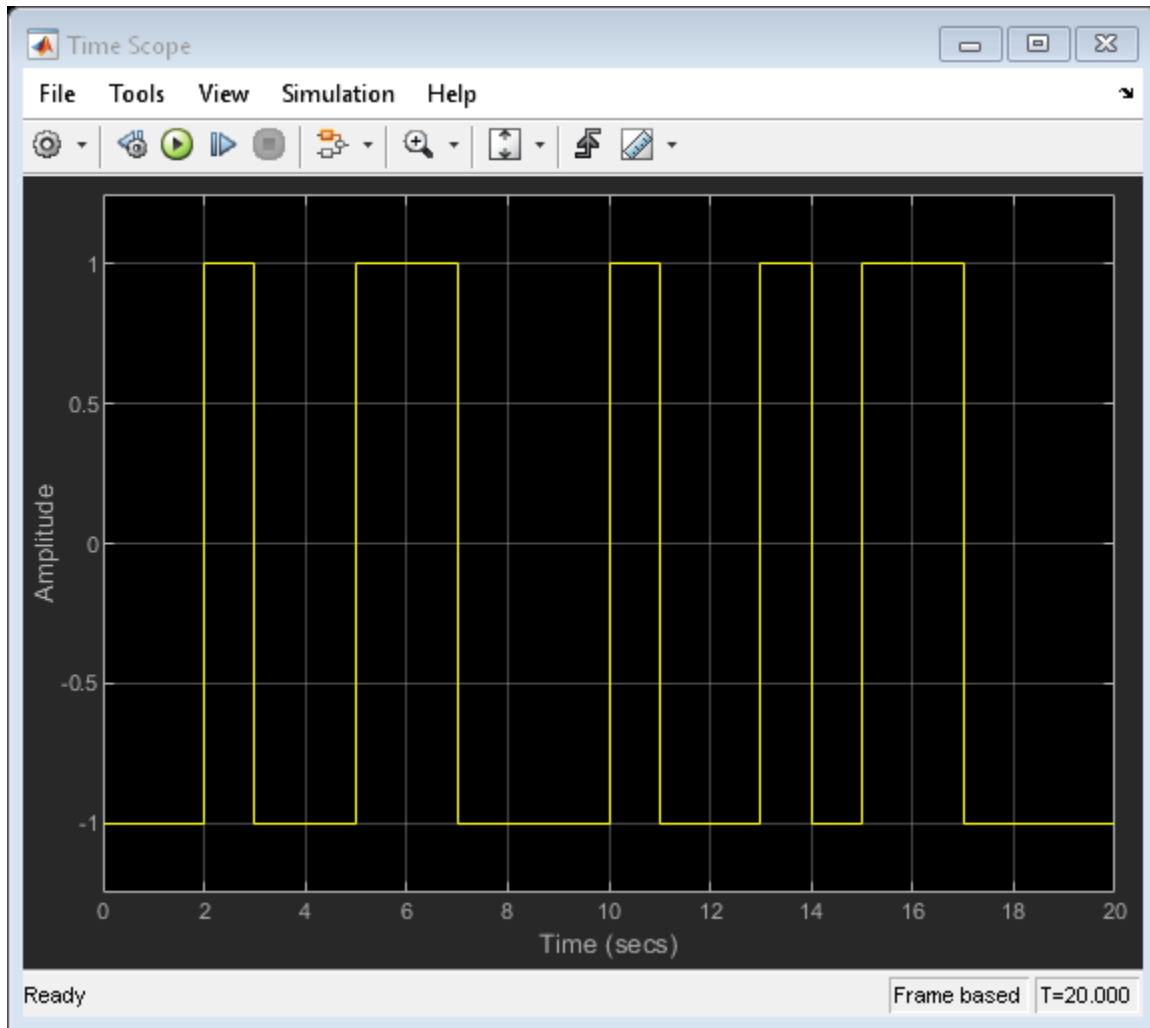

## Examples

### Generate Bernoulli Binary Numbers

Open the Bernoulli generator model. The model generates binary data, applies BPSK modulation, and displays the output.

Run the model.

## Binary Cyclic Decoder

Decode systematic cyclic code to recover binary vector data

### Library

Block sublibrary of Error Detection and Correction

### Description

The Binary Cyclic Decoder block recovers a message vector from a codeword vector of a binary systematic cyclic code. For proper decoding, the parameter values in this block should match those in the corresponding Binary Cyclic Encoder block.

This block accepts a column vector input signal containing  $N$  elements, where  $N$  is the codeword length. The output signal is a column vector containing  $K$  elements, where  $K$  is the message length of the cyclic code.

You can determine the systematic cyclic coding scheme in one of two ways:

- To create an  $[N,K]$  code, enter  $N$  and  $K$  as the first and second dialog parameters, respectively. The block computes an appropriate generator polynomial, namely, `cyclpoly(N,K,'min')`.
- To create a code with codeword length  $N$  and a particular degree- $(N-K)$  binary *generator polynomial*, enter  $N$  as the first parameter and a polynomial character vector or a binary vector as the second parameter. The vector represents the generator polynomial by listing its coefficients in order of ascending exponents. You can create cyclic generator polynomials using the Communications Toolbox `cyclpoly` function.

For information about the data types each block port supports, see the “Supported Data Type” on page 3-69 table on this page.

## Parameters

### Codeword length $N$

The codeword length  $N$ , which is also the input vector length.

### Message length $K$ , or generator polynomial

Either the message length, which is also the input vector length, a polynomial character vector, or a binary vector that represents the generator polynomial for the code.

# Binary Cyclic Encoder

Create systematic cyclic code from binary vector data

## Library

Block sublibrary of Error Detection and Correction

## Description

The Binary Cyclic Encoder block creates a systematic cyclic code with message length  $K$  and codeword length  $N$ .

This block accepts a column vector input signal containing  $K$  elements. The output signal is a column vector containing  $N$  elements.

You can determine the systematic cyclic coding scheme in one of two ways:

- To create an  $[N,K]$  code, enter  $N$  and  $K$  as the first and second dialog parameters, respectively. The block computes an appropriate generator polynomial, namely, `cyclpoly(N,K,'min')`.
- To create a code with codeword length  $N$  and a particular degree- $(N-K)$  binary *generator polynomial*, enter  $N$  as the first parameter and a polynomial character vector or a binary vector as the second parameter. The vector represents the generator polynomial by listing its coefficients in order of ascending exponents. You can create cyclic generator polynomials using the Communications Toolbox `cyclpoly` function.

For information about the data types each block port supports, see the “Supported Data Type” on page 3-72 table on this page.

## Parameters

### Codeword length $N$

The codeword length, which is also the output vector length.

### Message length $K$ , or generator polynomial

Either the message length, which is also the input vector length, a polynomial character vector, or a binary vector that represents the generator polynomial for the code.

## Binary-Input RS Encoder

Create Reed-Solomon code from binary vector data

**Library:** Communications Toolbox / Error Detection and Correction / Block

### Description

The Binary-Input RS Encoder block creates a Reed-Solomon code.

The symbols for the code are binary sequences of length  $M$ , corresponding to elements of the Galois field  $GF(2^M)$ . The first bit in each symbol is the most significant bit.

Suppose  $M = 3$ ,  $N = 2^3 - 1 = 7$ , and  $K = 2$ . Then a message is a vector of length 2 whose entries are integers between 0 and 7. A corresponding codeword is a vector of length 7 whose entries are integers between 0 and 7. The following figure illustrates possible input and output signals to this block when codeword length  $N=7$  and message word length  $K=2$ . Since  $N=2^M-1$ , when  $N=7$ , the symbol length,  $M=3$ .

Each input message word is a binary vector of length 6, that represents 2 three-bit integers. Each corresponding output codeword is a binary vector of length 21 that represents 7 three-bit integers. For more information, see “Input and Output Signal Length in RS Blocks” on page 3-79.

## Ports

### Input

#### In — Message

binary column vector

Message in bits, specified as one of the following:

- When there is no message shortening, a  $(N_C \times K \times M)$ -by-1 binary column vector.
- When there is message shortening, a  $(N_C \times S \times M)$ -by-1 binary column vector.

$N_C$  is the number of message words,  $K$  is the **Message length K (symbols)**,  $M$  is the number of bits per symbol, and  $S$  is the **Shortened message length S (symbols)**.

---

**Note** The number of decoded message words equals the number of codewords.

---

For more information, see “Input and Output Signal Length in RS Blocks” on page 3-79.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

## Output

### **Out — Reed-Solomon codeword**

binary column vector

Reed-Solomon codeword in bits, returned as an  $(N_C \times (N - K + S - P) \times M)$ -by-1 binary column vector.  $N_C$  is the number of codewords,  $N$  is the **Codeword length N (symbols)**,  $K$  is the **Message length K (symbols)**,  $S$  is the **Shortened message length S (symbols)**,  $P$  is the number of punctures per codeword, and  $M$  is the number of bits per symbol.

For more information, see “Input and Output Signal Length in RS Blocks” on page 3-79.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

For more information, see “Supported Data Types” on page 3-82.

## Parameters

### **Codeword length N (symbols) — Codeword length**

7 (default) | integer

Codeword length in symbols, specified as an integer.

For more information, see “Restrictions on the M and the Codeword Length N” on page 3-80 and “Input and Output Signal Length in RS Blocks” on page 3-79.

### **Message length K (symbols) — Message word length**

3 (default) | integer

Message word length in symbols, specified as an integer in the range  $[1, N-2]$ , where  $N$  is the codeword length.

### **Shortened message length S (symbols) – Shortened message word length**

3 (default) | integer

Shortened message word length in symbols, specified as an integer, such that  $S \leq K$ . When **Shortened message length S (symbols) < Message length K (symbols)**, the Reed-Solomon code is shortened.

You still specify  $N$  and  $K$  values for the full-length  $(N, K)$  code but the decoding is shortened to an  $(N-K+S, S)$  code.

#### **Dependencies**

To enable this parameter, select **Specify shortened message length**.

### **Generator polynomial – Generator polynomial**

rsgenpoly(7, 3, [], [], 'double') (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values from 0 to  $2^M-1$ , in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see “Specify the Generator Polynomial” on page 3-81.

Example: [1 3 1 2 3], which is equivalent to rsgenpoly(7,3)

#### **Dependencies**

To enable this parameter, select **Specify generator polynomial**.

### **Primitive polynomial – Primitive polynomial**

'X^3 + X + 1' (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. This polynomial is of order  $M$  and defines the finite Galois field  $GF(2^M)$  corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see “Restrictions on the  $M$  and the Codeword Length  $N$ ” on page 3-80.

Example: `'X^3 + X + 1'`, which is the primitive polynomial used for a (7,3) code, `de2bi(primpoly(3,'nodisplay'),'left-msb')`

#### Dependencies

To enable this parameter, select **Specify primitive polynomial**.

#### Puncture vector — Puncture vector

`[ones(2,1); zeros(2,1)]` (default) | binary column vector

Puncture vector, specified as an  $(N-K)$ -by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 3-81.

#### Dependencies

To enable this parameter, select **Puncture code**.

#### Output data type — Output type of the block

Same as `input` (default) | `boolean` | `double`

Output type of the block, specified as `Same as input`, `boolean`, or `double`.

## Block Characteristics

<b>Data Types</b>	Boolean   double   fixed point <sup>a</sup>   integer   single
<b>Multidimensional Signals</b>	no

<b>Variable-Size Signals</b>	no
------------------------------	----

a. ufix(1) only.

## More About

### Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length,  $K$ , or shortened message word length,  $S$ . The codeword length is  $N - K + S - P$ , where  $N$  is the full codeword length and  $P$  is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to  $N - P$ , because  $K = S$ . If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation  $y = N_C \times x$  denotes that  $y$  is an integer multiple of  $x$ .

	<b>Input, Erasure, and Output Vector Lengths</b>	
<b>RS Block Coder</b>	<b>No Message Shortening Used</b>	<b>Message Shortening Used</b>
Binary-Input RS Encoder	<b>Input Length (bits):</b> $N_C \times K \times M$  <b>Output Length (bits):</b> $N_C \times (N-P) \times M$	<b>Input Length (bits):</b> $N_C \times S \times M$  <b>Output Length (bits):</b> $N_C \times (N-K+S-P) \times M$

	Input, Erasure, and Output Vector Lengths	
RS Block Coder	No Message Shortening Used	Message Shortening Used
Binary-Output RS Decoder	<p><b>Input Length (bits):</b>  <math>N_C \times (N-P) \times M</math></p> <p><b>Erasures Length (symbols):</b>  <math>N_C \times (N-P)</math></p> <p><b>Output Length (bits):</b>  <math>N_C \times K \times M</math></p>	<p><b>Input Length (bits):</b>  <math>N_C \times (N-K+S-P) \times M</math></p> <p><b>Erasures Length (symbols):</b>  <math>N_C \times (N-K+S-P)</math></p> <p><b>Output Length (bits):</b>  <math>N_C \times S \times M</math></p>

- $N$  is the codeword length.
- $K$  is the message word length.
- $S$  is the shortened message word length.
- $N_C$  is the number of codewords (and message words).
- $P$  is the number of punctures per codeword, and is equal to the number of zeros in the puncture vector.
- $M$  is the degree of the primitive polynomial. Each group of  $M$  bits represents an integer between 0 and  $2^M-1$  that belongs to the finite Galois field  $GF(2^M)$ .

For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

Also, see “Restrictions on the M and the Codeword Length N” on page 3-80.

## Restrictions on the M and the Codeword Length N

- If you do not select **Specify primitive polynomial**, valid values for the codeword length,  $N$ , are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree  $M = \text{ceil}(\log_2(N+1))$ . You can display the default primitive polynomial by running `primpoly(ceil(log2(N+1)))`.
- If you select **Specify primitive polynomial**, valid values for the primitive polynomial degree,  $M$ , are from 3 to 16. The valid values for  $N$  in this case are from 7 to  $2^M-1$ .

Selecting **Specify primitive polynomial** enables you to specify the primitive polynomial that defines the finite field  $GF(2^M)$ , which corresponds to the values that form message words and codewords.

## Specify the Generator Polynomial

Select **Specify generator polynomial** to enable the **Generator polynomial** parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to  $2^M-1$ . The vector represents a polynomial, in descending order of powers, whose coefficients are elements of  $GF(2^M)$  represented in integer format. For more information about integer and binary format, see “Integer Format (Reed-Solomon Only)”. The generator polynomial must be equal to a polynomial with this factored form:

$$g(x) = (x + \alpha^b)(x + \alpha^{b+1})(x + \alpha^{b+2}) \dots (x + \alpha^{b+N-K-1})$$

$\alpha$  is the primitive element of the Galois field over which the input message is defined, and  $b$  is an integer.

If you do not select **Specify generator polynomial**, the block uses the default generator polynomial, corresponding to  $b=1$ , for Reed-Solomon encoding. You can display the default generator polynomial by running `rsgenpoly`.

- If you are using the default primitive polynomial (**Specify primitive polynomial** is not selected), the default generator polynomial is `rsgenpoly(N,K)`, where  $N = 2^M - 1$ .
- If you are not using the default primitive polynomial (**Specify primitive polynomial** is selected) and you specify the primitive polynomial as `poly`, the generator polynomial is `rsgenpoly(N,K,poly)`.

---

**Note** The degree of the generator polynomial is  $N - K$ , where  $N$  is the codeword length and  $K$  is the message word length.

---

## Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.

- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

## Binary Linear Decoder

Decode linear block code to recover binary vector data

### Library

Block sublibrary of Error Detection and Correction

### Description

The Binary Linear Decoder block recovers a binary message vector from a binary codeword vector of a linear block code.

The **Generator matrix** parameter is the generator matrix for the block code. For proper decoding, this should match the **Generator matrix** parameter in the corresponding Binary Linear Encoder block. If  $N$  is the codeword length of the code, then **Generator matrix** must have  $N$  columns. If  $K$  is the message length of the code, then the **Generator matrix** parameter must have  $K$  rows.

This block accepts a column vector input signal containing  $N$  elements. This block outputs a column vector with a length of  $K$  elements.

The decoder tries to correct errors, using the **Decoding table** parameter. If **Decoding table** is the scalar 0, then the block defaults to the table produced by the Communications Toolbox function `syndtable`. Otherwise, **Decoding table** must be a  $2^{N-K}$ -by- $N$  binary matrix. The  $r$ th row of this matrix is the correction vector for a received binary codeword whose syndrome has decimal integer value  $r-1$ . The syndrome of a received codeword is its product with the transpose of the parity-check matrix.

For information about the data types each block port supports, see the “Supported Data Type” on page 3-85 table on this page.

## Parameters

### Generator matrix

Generator matrix for the code; same as in Binary Linear Encoder block.

### Decoding table

Either a  $2^{N-K}$ -by- $N$  matrix that lists correction vectors for each codeword's syndrome; or the scalar 0, in which case the block defaults to the table corresponding to the **Generator matrix** parameter.

## Supported Data Type

# Binary Linear Encoder

Create linear block code from binary vector data

## Library

Block sublibrary of Error Detection and Correction

## Description

The Binary Linear Encoder block creates a binary linear block code using a generator matrix that you specify. If  $K$  is the message length of the code, then the **Generator matrix** parameter must have  $K$  rows. If  $N$  is the codeword length of the code, then **Generator matrix** must have  $N$  columns.

This block accepts a column vector input signal containing  $K$  elements. This block outputs a column vector with a length of  $N$  elements. For information about the data types each block port supports, see “Supported Data Type” on page 3-88.

## Parameters

### Generator matrix

A  $K$ -by- $N$  matrix, where  $K$  is the message length and  $N$  is the codeword length.

## Supported Data Type

Port	Supported Data Types
In	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• Fixed-point</li> </ul>
Out	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• Fixed-point</li> </ul>

## Binary-Output RS Decoder

Decode Reed-Solomon code to recover binary vector data

**Library:** Communications Toolbox / Error Detection and Correction / Block

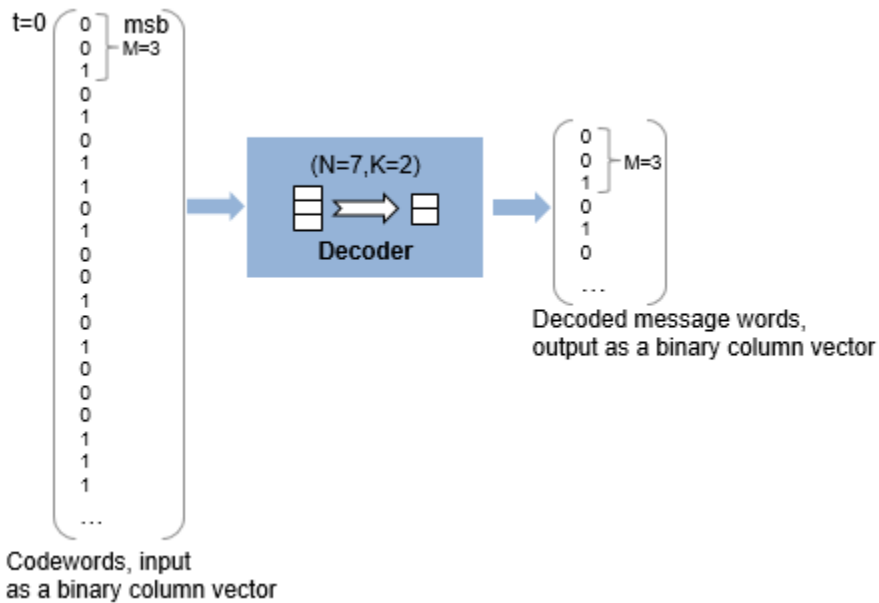

### Description

The Binary-Output RS Decoder block recovers a binary message vector from a binary Reed-Solomon codeword vector. For proper decoding, the parameter values in this block must match parameter values in the corresponding Binary-Input RS Encoder block.

The symbols for the code are binary sequences of length  $M$ , corresponding to elements of the Galois field  $GF(2^M)$ . The first bit in each symbol is the most significant bit.

This figure shows the decoder input-output word length for codeword length  $N=7$  and message word length  $K=2$ . Since  $N=2^M-1$ , when  $N=7$ , the symbol length,  $M=3$ .

Each input codeword is a binary vector of length 21 that represents 7 three-bit integers. Each corresponding output message word is a binary vector of length 6, that represents 2 three-bit integers. For more information, see “Input and Output Signal Length in RS Blocks” on page 3-95.

This icon shows all ports, including optional ones:

## Ports

### Input

**In — Reed-Solomon codeword**

binary column vector

Reed-Solomon codeword in bits, specified as an  $(N_C \times (N - K + S - P) \times M)$ -by-1 binary column vector.  $N_C$  is the number of codewords,  $N$  is the **Codeword length N (symbols)**,  $K$  is the **Message length K (symbols)**,  $S$  is the **Shortened message length S (symbols)**,  $P$  is the number of punctures per codeword, and  $M$  is the number of bits per symbol.

For more information, see “Input and Output Signal Length in RS Blocks” on page 3-95.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | ufix(1)

### Era — Erasure vector

binary column vector

Erasure vector in symbols, specified as an  $(N_C \times (N - K + S - P))$ -by-1 binary column vector.  $N_C$  is the number of codewords,  $N$  is the **Codeword length N (symbols)**,  $K$  is the **Message length K (symbols)**,  $S$  is the **Shortened message length S (symbols)**,  $P$  is the number of punctures per codeword, and  $M$  is the number of bits per symbol.

Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased. For more information, see “Puncturing and Erasures” on page 3-98.

### Dependencies

To enable this port, select **Enable erasures input port**.

Data Types: double | Boolean

## Output

### Out — Decoded message

binary column vector

Decoded message in bits, returned as one of the following:

- When there is no message shortening, a  $(N_C \times K \times M)$ -by-1 binary column vector.
- When there is message shortening, a  $(N_C \times S \times M)$ -by-1 binary column vector.

$N_C$  is the number of message words,  $K$  is the **Message length K (symbols)**,  $M$  is the number of bits per symbol, and  $S$  is the **Shortened message length S (symbols)**.

---

**Note** The number of decoded message words equals the number of codewords.

---

For more information, see “Input and Output Signal Length in RS Blocks” on page 3-95.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

#### **Err — Decoding errors**

integer vector

Symbol decoding errors, returned as an integer vector with  $N_C$  elements, where  $N_C$  is the number of codewords. This port indicates the number of symbol errors detected during decoding of each codeword. A negative integer indicates that the block detected more errors than it could correct by using the specified coding scheme.

---

**Note** An  $(N,K)$  Reed-Solomon code can correct up to  $\text{floor}((N-K)/2)$  symbol errors (not bit errors) in each codeword. When a received codeword contains more than  $(N-K)/2$  symbol errors, a decoding failure occurs.

---

#### **Dependencies**

To enable this port, select **Output number of corrected symbol errors**.

Data Types: `double`

For more information, see “Supported Data Types” on page 3-98.

## **Parameters**

#### **Codeword length N (symbols) — Codeword length**

7 (default) | integer

Codeword length in symbols, specified as an integer.

For more information, see “Restrictions on M and Codeword Length N” on page 3-97 and “Input and Output Signal Length in RS Blocks” on page 3-95.

#### **Message length K (symbols) — Message word length**

3 (default) | integer

Message word length in symbols, specified as an integer in the range  $[1, N-2]$ , where  $N$  is the codeword length.

### **Shortened message length S (symbols) – Shortened message word length**

3 (default) | integer

Shortened message word length in symbols, specified as an integer, such that  $S \leq K$ . When **Shortened message length S (symbols) < Message length K (symbols)**, the Reed-Solomon code is shortened.

You still specify  $N$  and  $K$  values for the full-length  $(N, K)$  code but the decoding is shortened to an  $(N-K+S, S)$  code.

#### **Dependencies**

To enable this parameter, select **Specify shortened message length**.

### **Generator polynomial – Generator polynomial**

`rsgenpoly(7, 3, [], [], 'double')` (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values from 0 to  $2^M-1$ , in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see “Specify the Generator Polynomial” on page 3-97.

Example: `[1 3 1 2 3]`, which is equivalent to `rsgenpoly(7,3)`

#### **Dependencies**

To enable this parameter, select **Specify generator polynomial**.

### **Primitive polynomial – Primitive polynomial**

`'X^3 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. This polynomial is of order  $M$  and defines the finite Galois field  $GF(2^M)$  corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see “Restrictions on  $M$  and Codeword Length  $N$ ” on page 3-97.

Example: `'X^3 + X + 1'`, which is the primitive polynomial used for a (7,3) code, `de2bi(primpoly(3,'nodisplay'),'left-msb')`

#### **Dependencies**

To enable this parameter, select **Specify primitive polynomial**.

#### **Puncture vector — Puncture vector**

`[ones(2,1); zeros(2,1)]` (default) | binary column vector

Puncture vector, specified as an  $(N-K)$ -by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 3-98.

#### **Dependencies**

To enable this parameter, select **Punctured code**.

#### **Enable erasures input port — Enable erasures input port**

off (default) | on

Selecting this check box enables the erasures port, **Era**. For more information, see “Puncturing and Erasures” on page 3-98.

#### **Output number of corrected symbol errors — Enable port to output number of corrected symbol errors**

off (default) | on

Selecting this check box enables an additional output port, **Err**, which indicates the number of symbol errors the block corrected in the input codeword.

#### **Output data type — Output type of the block**

Same as input (default) | boolean | double

Output type of the block, specified as Same as input, boolean, or double.

## Block Characteristics

<b>Variable-Size Signals</b>	no

a. ufix(1) only.

## More About

### Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length,  $K$ , or shortened message word length,  $S$ . The codeword length is  $N - K + S - P$ , where  $N$  is the full codeword length and  $P$  is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to  $N - P$ , because  $K = S$ . If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation  $y = N_C \times x$  denotes that  $y$  is an integer multiple of  $x$ .

	Input, Erasure, and Output Vector Lengths	
RS Block Coder	No Message Shortening Used	Message Shortening Used
Binary-Input RS Encoder	<b>Input Length (bits):</b> $N_C \times K \times M$ <b>Output Length (bits):</b> $N_C \times (N-P) \times M$	<b>Input Length (bits):</b> $N_C \times S \times M$ <b>Output Length (bits):</b> $N_C \times (N-K+S-P) \times M$
Binary-Output RS Decoder	<b>Input Length (bits):</b> $N_C \times (N-P) \times M$ <b>Erasures Length (symbols):</b> $N_C \times (N-P)$ <b>Output Length (bits):</b> $N_C \times K \times M$	<b>Input Length (bits):</b> $N_C \times (N-K+S-P) \times M$ <b>Erasures Length (symbols):</b> $N_C \times (N-K+S-P)$ <b>Output Length (bits):</b> $N_C \times S \times M$

- $N$  is the codeword length.
- $K$  is the message word length.
- $S$  is the shortened message word length.
- $N_C$  is the number of codewords (and message words).
- $P$  is the number of punctures per codeword, and is equal to the number of zeros in the puncture vector.
- $M$  is the degree of the primitive polynomial. Each group of  $M$  bits represents an integer between  $0$  and  $2^M-1$  that belongs to the finite Galois field  $GF(2^M)$ .

For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

Also, see “Restrictions on  $M$  and Codeword Length  $N$ ” on page 3-97.

## Restrictions on M and Codeword Length N

- If you do not select **Specify primitive polynomial**, valid values for the codeword length,  $N$ , are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree  $M = \text{ceil}(\log_2(N+1))$ . You can display the default primitive polynomial by running `primpoly(ceil(log2(N+1)))`.
- If you select **Specify primitive polynomial**, valid values for the primitive polynomial degree,  $M$ , are from 3 to 16. The valid values for  $N$  in this case are from 7 to  $2^M-1$ . Selecting **Specify primitive polynomial** enables you to specify the primitive polynomial that defines the finite field  $GF(2^M)$ , which corresponds to the values that form message words and codewords.

## Specify the Generator Polynomial

Select **Specify generator polynomial** to enable the **Generator polynomial** parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to  $2^M-1$ . The vector represents a polynomial, in descending order of powers, whose coefficients are elements of  $GF(2^M)$  represented in integer format. For more information about integer and binary format, see “Integer Format (Reed-Solomon Only)”. The generator polynomial must be equal to a polynomial with this factored form:

$$g(x) = (x+\alpha^b)(x+\alpha^{b+1})(x+\alpha^{b+2})\dots(x+\alpha^{b+N-K-1})$$

$\alpha$  is the primitive element of the Galois field over which the input message is defined, and  $b$  is an integer.

If you do not select **Specify generator polynomial**, the block uses the default generator polynomial, corresponding to  $b=1$ , for Reed-Solomon encoding. You can display the default generator polynomial by running `rsgenpoly`.

- If you are using the default primitive polynomial (**Specify primitive polynomial** is not selected), the default generator polynomial is `rsgenpoly(N,K)`, where  $N = 2^M-1$ .
- If you are not using the default primitive polynomial (**Specify primitive polynomial** is selected) and you specify the primitive polynomial as `poly`, the generator polynomial is `rsgenpoly(N,K,poly)`.

---

**Note** The degree of the generator polynomial is  $N - K$ , where  $N$  is the codeword length and  $K$  is the message word length.

---

## Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

# Binary Symmetric Channel

Introduce binary errors

**Library:** Communications Toolbox / Channels

## Description

The Binary Symmetric Channel block introduces errors to the input signal transmitted through a binary symmetric channel. The errors are introduced based on the specified Error probability. For more information, see “Tips” on page 3-103.

## Ports

### Input

#### Input — Input signal

column vector | matrix

Input signal, specified as a column vector or an  $N_S$ -by- $N_C$  matrix of Boolean values.  $N_S$  is the number of samples per channel.  $N_C$  is the number of independent data channels. For more information, see “Tips” on page 3-103.

### Output

#### Output — Binary output signal

column vector | matrix

Binary output signal, returned as a column vector or matrix with the same dimensions as Input. The output signal is a version of the input signal that has been modified by introducing random errors based on the specified Error probability. To set the output data type, use Output data type.

### **Err — Error locations**

column vector | matrix

Error locations, returned as a column vector or matrix with the same dimensions as **Input**. Element values in **Err** are 1 or 0, where:

- 1 indicates that the corresponding element in **Output** has an error.
- 0 indicates that the corresponding element in **Output** does not have an error.

The data type of **Err** is the same as **Output**, as set by **Output data type**.

#### **Dependencies**

To enable this port, select **Output error vector**.

## **Parameters**

### **Error probability — Probability of error occurrence**

0.05 (default) | scalar

Probability of error occurrence for the input signal elements, specified as a scalar in the range [0,1]. The probability of error applies independently for each element.

### **Output error vector — Option to output error locations**

on (default) | off

To enable the **Err** output port to the block, select this parameter.

### **Output data type — Output data type**

double (default) | single | boolean

Select the output data type as **double**, **single**, or **boolean**. This parameter sets the output data type for both the **Output** and **Err** ports.

### **Initial seed — Initial seed**

71 (default) | integer

Initial seed value for the random number generator used by the block, specified as an integer. The block uses the `mt19937ar` algorithm to generate uniformly distributed random numbers. For details about the `mt19937ar` algorithm, see “Choosing a Random Number Generator” (MATLAB).

**Simulate using — Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In **Interpreted execution** mode, you can debug the source code of the block.

## Block Characteristics

<b>Data Types</b>	Boolean   double   fixed point   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## Tips

- When the input consists of not Boolean values, Binary Symmetric Channel converts zero-valued elements to 0 and converts nonzero-valued elements to 1.
- The Binary Symmetric Channel block creates and uses an independent `RandStream` to provide a random number stream for probability determination.
- To generate repeatable results, use the same Initial seed value.
- To generate independent probability statistics, set different Initial seed values for multichannel signals, multiple processing chains, or simulation runs.

## Compatibility Considerations

### Random Number Generation

*Behavior changed in R2018b*

To improve statistical properties, the Binary Symmetric Channel block uses the mt19937ar algorithm with RandStream. The Binary Symmetric Channel block accepts a single scalar value for the Initial seed parameter.

# Bipolar to Unipolar Converter

Map bipolar signal into unipolar signal in range [0, M-1]

## Library

Utility Blocks

## Description

The Bipolar to Unipolar Converter block maps the bipolar input signal to a unipolar output signal. If the input consists of integers in the set  $\{-M+1, -M+3, -M+5, \dots, M-1\}$ , where  $M$  is the **M-ary number** parameter, then the output consists of integers between 0 and  $M-1$ . This block is only designed to work when the input value is within the set  $\{-M+1, -M+3, -M+5, \dots, M-1\}$ , where  $M$  is the **M-ary number** parameter. If the input value is outside of this set of integers the output may not be valid.

The table below shows how the block's mapping depends on the **Polarity** parameter.

Polarity Parameter Value	Output Corresponding to Input Value of $k$
Positive	$(M-1+k)/2$
Negative	$(M-1-k)/2$

## Parameters

### M-ary number

The number of symbols in the bipolar or unipolar alphabet.

#### **Polarity**

A value of **Positive** causes the block to maintain the relative ordering of symbols in the alphabets. A value of **Negative** causes the block to reverse the relative ordering of symbols in the alphabets.

#### **Output Data Type**

The type of bipolar signal produced at the block's output.

The block supports the following output data types:

- `Inherit via internal rule`
- `Same as input`
- `double`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`

When the parameter is set to its default setting, `Inherit via internal rule`, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either `single` or `double`), the output data type is the same as the input data type.
- If the input data type is not floating-point:
  - Based on the **M-ary number** parameter, the output data type is the ideal unsigned integer output word length required to contain the range `[0 M-1]` and is computed as follows:

$$\text{ideal word length} = \text{ceil}(\log_2(M))$$

- The block sets the output data type to be an unsigned integer, based on the smallest word length (in bits) that can fit best the computed ideal word length.

---

**Note** The selections in the “Hardware Implementation Pane” (Simulink) pane pertaining to word length constraints do not affect how this block determines output data types.

---

## Examples

If the input is [-3; -1; 1; 3], the **M-ary number** parameter is 4, and the **Polarity** parameter is **Positive**, then the output is [0; 1; 2; 3]. Changing the **Polarity** parameter to **Negative** changes the output to [3; 2; 1; 0].

If the value for the **M-ary number** is  $2^8$  the block gives an output of uint8.

If the value for the **M-ary number** is  $2^8+1$  the block gives an output of uint16.

## Pair Block

## Bit to Integer Converter

Map vector of bits to corresponding vector of integers

## Library

Utility Blocks

## Description

The Bit to Integer Converter block maps groups of bits in the input vector to integers in the output vector.  $M$  defines how many bits are mapped for each output integer.

For unsigned integers, if  $M$  is the **Number of bits per integer**, then the block maps each group of  $M$  bits to an integer between 0 and  $2^M-1$ . As a result, the output vector length is  $1/M$  times the input vector length. For signed integers, if  $M$  is the **Number of bits per integer**, then the block maps each group of  $M$  bits to an integer between  $-2^{M-1}$  and  $2^{M-1}-1$ .

This block accepts a column vector input signal with an integer multiple equal to the value you specify for **Number of bits per integer** parameter. The block accepts double, single, boolean, int8, uint8, int16, uint16, int32, uint32 and ufix1 input data types.

## Dialog Box

### Number of bits per integer

The number of input bits that the block maps to each integer of the output. This parameter must be an integer between 1 and 32.

### Input bit order

Defines whether the first bit of the input signal is the most significant bit (MSB) or the least significant bit (LSB). The default selection is MSB.

### After bit packing, treat resulting integer value as

Indicates if the integer value input ranges should be treated as signed or unsigned. The default setting is Unsigned.

---

**Note** This parameter setting determines which **Output data type** selections are available.

---

#### Output data type

If the input values are unsigned integers, you can choose from the following **Output data type** options:

- `Inherit via internal rule`
- `Smallest integer`
- `Same as input`
- `double`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

If the input values are signed integers, you can choose from the following **Output data type** options:

- `Inherit via internal rule`
- `Smallest integer`
- `double`
- `single`
- `int8`
- `int16`
- `int32`

The default selection for this parameter is `Inherit via internal rule`.

When you set the parameter to `Inherit via internal rule`, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either `double` or `single`), the output data type is the same as the input data type.
- If the input data type is not floating-point, the output data type is determined as if the parameter is set to `Smallest integer`.

When you set the parameter to **Smallest integer**, the software selects the output data type based on the settings used in the “Hardware Implementation Pane” (Simulink) of the Configuration Parameters dialog box.

- If ASIC/FPGA is selected, the output data type is the smallest ideal integer or fixed-point data type, based on the setting for the **Number of bits per integer** parameter.
- For all other selections, the output data type is the smallest available (signed or unsigned) integer word length that is large enough to fit the ideal minimum bit size.

## BPSK Demodulator Baseband

Demodulate BPSK-modulated data

### Library

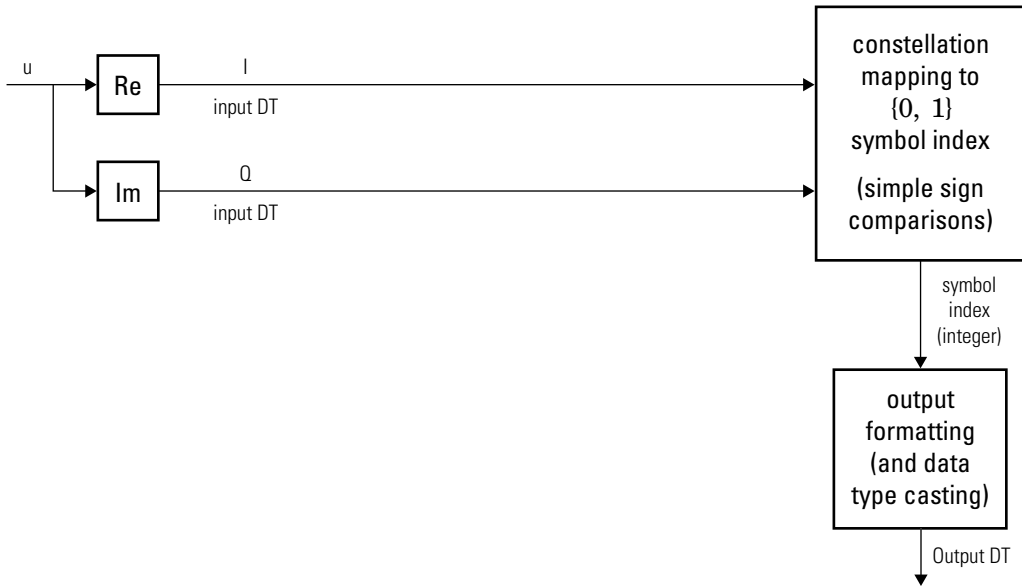

PM, in Digital Baseband sublibrary of Modulation

### Description

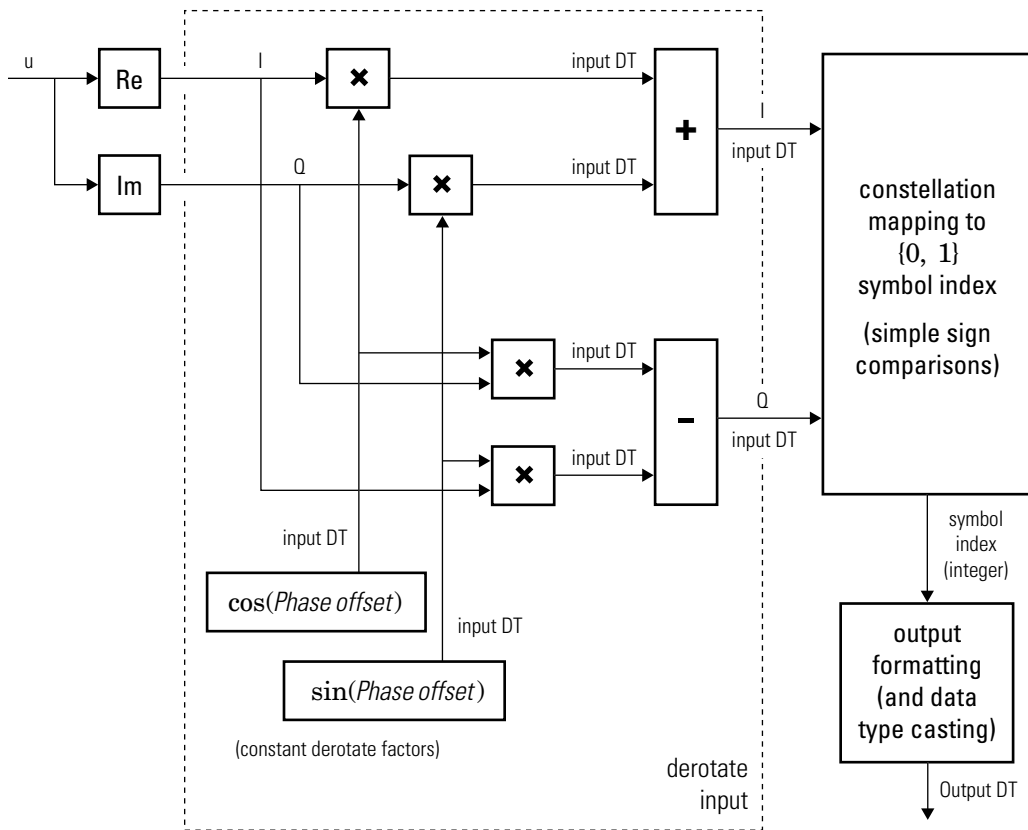

The BPSK Demodulator Baseband block demodulates a signal that was modulated using the binary phase shift keying method. The input is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal. The input signal must be a discrete-time complex signal. The block maps the points  $\exp(j\theta)$  and  $-\exp(j\theta)$  to 0 and 1, respectively, where  $\theta$  is the **Phase offset** parameter.

For information about the data types each block port supports, see “Supported Data Types” on page 3-120.

## Algorithm

**Hard-Decision BPSK Demodulator Signal Diagram for Trivial Phase Offset (multiple of  $\pi/2$ )**

**Hard-Decision BPSK Demodulator Floating-Point Signal Diagram for Nontrivial Phase Offset**

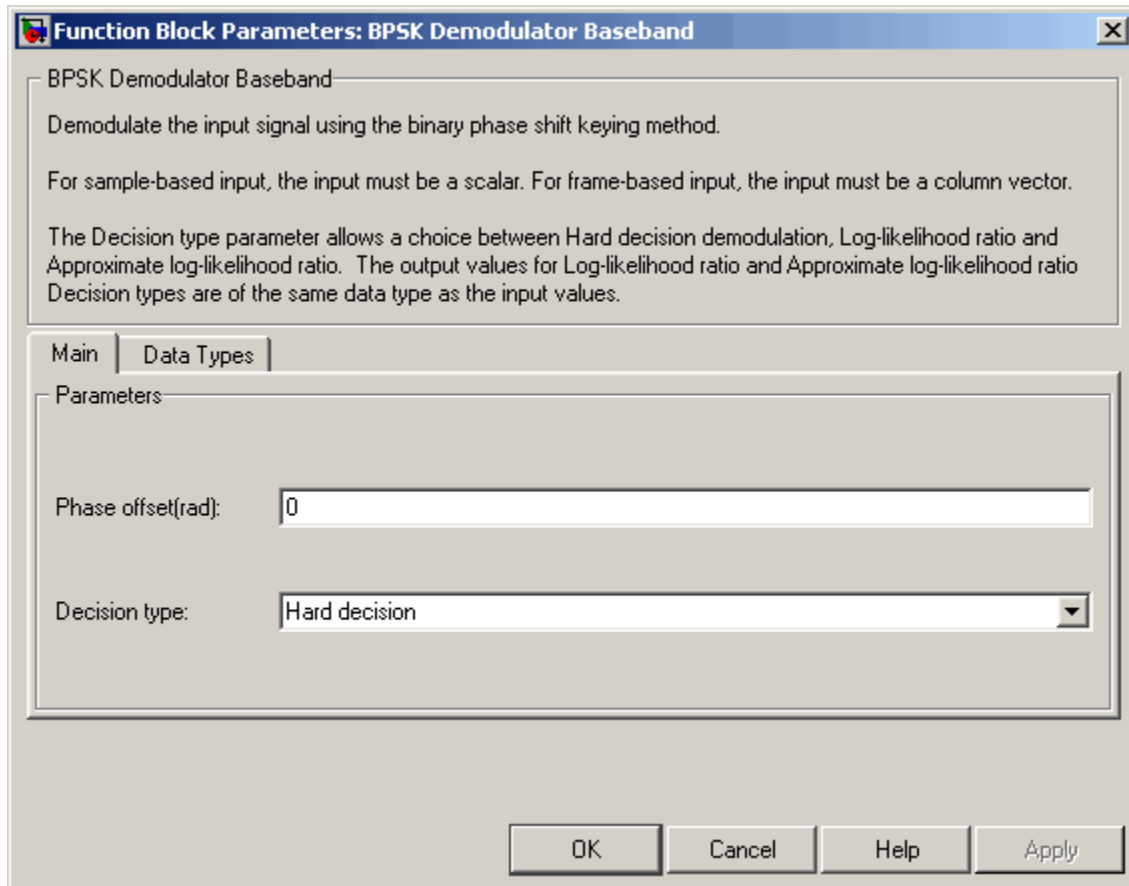

### Hard-Decision BPSK Demodulator Fixed-Point Signal Diagram for Nontrivial Phase Offset

The exact LLR and approximate LLR cases (soft-decision) are described in “Exact LLR Algorithm” and “Approximate LLR Algorithm” in the *Communications Toolbox User's Guide*.

## Dialog Box

### Phase offset (rad)

The phase of the zeroth point of the signal constellation.

### Decision type

Specifies the use of hard decision, LLR, or approximate LLR during demodulation. The output values for Log-likelihood ratio and Approximate log-likelihood ratio are of the same data type as the input values. See “Exact LLR Algorithm” and “Approximate LLR Algorithm” in the *Communications Toolbox User's Guide* for algorithm details.

**Noise variance source**

This field appears when `Approximate log-likelihood ratio` or `Log-likelihood ratio` is selected for **Decision type**.

When set to `Dialog`, the noise variance can be specified in the **Noise variance** field. When set to `Port`, a port appears on the block through which the noise variance can be input.

**Noise variance**

This parameter appears when the **Noise variance source** is set to `Dialog` and specifies the noise variance in the input signal. This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- `Inf` to `-Inf` if **Noise variance** is very high
- `NaN` if **Noise variance** and signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

#### Data Types Pane for Hard-Decision

#### Output

When **Decision type** is set to Hard decision, the output data type can be set to 'Inherit via internal rule', 'Smallest unsigned integer', double, single, int8, uint8, int16, uint16, int32, uint32, or boolean.

When this parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is a floating-point type (single or double). If the input data type is fixed-point, the output data type will work as if this parameter is set to 'Smallest unsigned integer'.

When this parameter is set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the **Hardware Implementation** pane, the output data type is the ideal minimum one-bit size, i.e., `ufix(1)`. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a char (e.g., `uint8`).

### Derotate factor

This parameter only applies when the input is fixed-point and **Phase offset** is not a multiple of  $\pi/2$ .

This can be set to **Same word length as input** or **Specify word length**, in which case a field is enabled for user input.

### Data Types Pane for Soft-Decision

When **Decision type** is set to **Log-likelihood ratio** or **Approximate log-likelihood ratio**, the output data type is inherited from the input (e.g., if the input is of data type **double**, the output is also of data type **double**).

## Supported Data Types

## BPSK Modulator Baseband

Modulate using binary phase shift keying method

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The BPSK Modulator Baseband block modulates using the binary phase shift keying method. The output is a baseband representation of the modulated signal.

This block accepts a column vector input signal. The input must be a discrete-time binary-valued signal. If the input bit is 0 or 1, respectively, then the modulated symbol is  $\exp(j\theta)$  or  $-\exp(j\theta)$ , respectively, where  $\theta$  represents the **Phase offset** parameter.

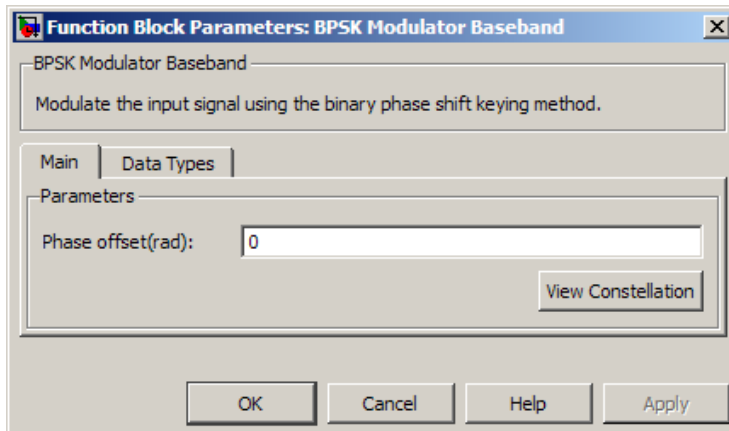

For information about the data types each block port supports, see the “Supported Data Types” on page 3-125 table on this page.

## Constellation Visualization

The BPSK Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the “Constellation Visualization” section of the *Communications Toolbox User's Guide*.

## Dialog Box

### Phase offset (rad)

The phase of the zeroth point of the signal constellation.

### Output data type

The output data type can be set to double, single, Fixed-point, User-defined, or Inherit via back propagation.

Setting this parameter to **Fixed-point** or **User-defined** enables fields in which you can further specify details. Setting this parameter to **Inherit via back propagation**, sets the output data type and scaling to match the following block.

### **Output word length**

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter.

### **Set output fraction length to**

Specify the scaling of the fixed-point output by either of the following two methods:

- Choose **Best precision** to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose **User-defined** to specify the output scaling in the **Output fraction length** parameter.

This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter or when you select **User-defined** and the specified output data type is a fixed-point data type.

### **User-defined data type**

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the `sfix`, `sint`, `sfrac`, and `fixdt` functions from Fixed-Point Designer™. This parameter is only visible when you select **User-defined** for the **Output data type** parameter.

### **Output fraction length**

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select **Fixed-point** or **User-defined** for the **Output data type** parameter and **User-defined** for the **Set output fraction length to** parameter.

## Supported Data Types

**Introduced before R2006a**

# Carrier Synchronizer

Compensate for carrier frequency offset

## Library

Synchronization

## Description

The Carrier Synchronizer block compensates for carrier frequency and phase offsets using a closed-loop approach for BPSK, QPSK, OQPSK, 8-PSK, QAM, and PAM modulation schemes. The block accepts a single input port. To obtain an estimate of the phase error in radians, select the **Estimated phase error output port** check box. The block accepts a sample- or frame-based complex input signal and returns a complex output signal and a real phase estimate. The block outputs have the same dimensions as the input.

### Note

- This block does not resolve phase ambiguities created by the synchronization algorithm. As indicated in this table, the potential phase ambiguity introduced by the synchronizer depends on the modulation type:

Modulation	Phase Ambiguity (degrees)
'BPSK' or 'PAM'	0, 180
'OQPSK', 'QPSK', or 'QAM'	0, 90, 180, 270
'8PSK'	0, 45, 90, 135, 180, 225, 270, 315

- For best results, apply carrier synchronization to non-oversampled signals.

## Parameters

### Modulation

Specify the modulation type as BPSK, QPSK, OQPSK, 8PSK, QAM, or PAM.

### Modulation phase offset

Specify the method used to calculate the modulation phase offset as either Auto or Custom.

- Auto applies the traditional offset for the specified modulation type.

Modulation	Phase Offset (radians)
BPSK, QAM, or PAM	0
QPSK or OQPSK	$\pi/4$
8PSK	$\pi/8$

- Custom enables the **Custom phase offset (radians)** parameter.

### Custom phase offset (radians)

Specify the phase offset in radians as a real scalar. This parameter is available only when **Modulation phase offset** is set to Custom.

### Samples per symbol

Specify the number of samples per symbol as a positive integer scalar.

### Damping factor

Specify the damping factor of the loop as a positive real finite scalar.

### Normalized loop bandwidth

Specify the normalized loop bandwidth as a real scalar between 0 and 1. The bandwidth is normalized by the sample rate of the carrier synchronizer block.

### Estimated phase error output port

Select this check box to provide the estimated phase error to an output port.

### Simulate using

Select the simulation mode.

#### Code generation

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

### Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

## Algorithms

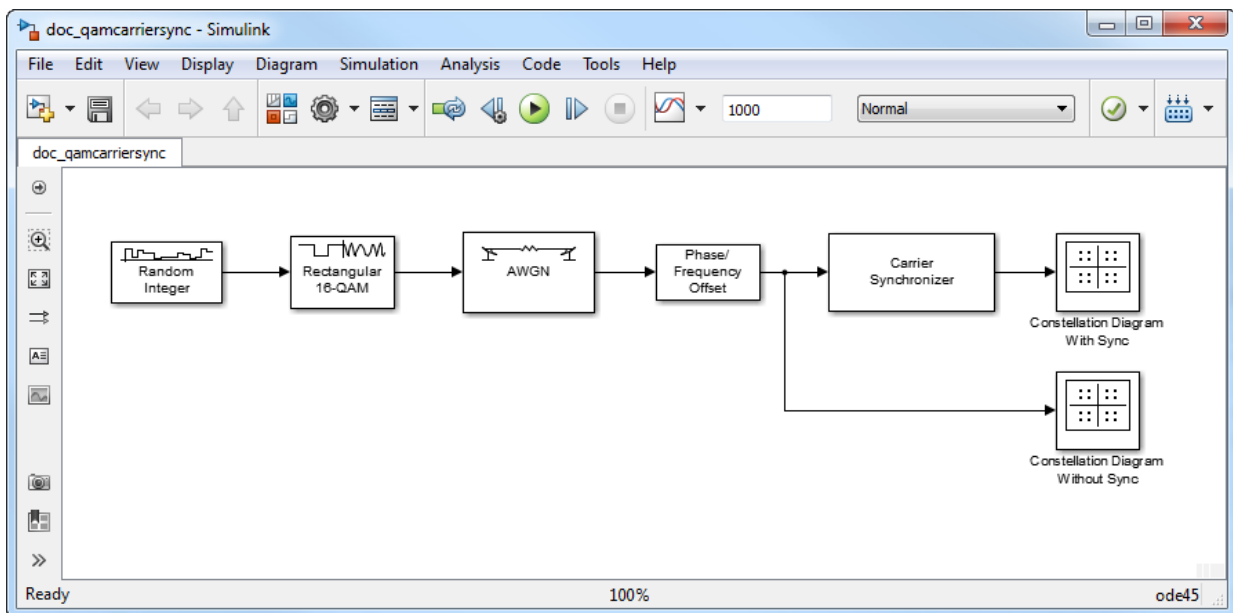

This block implements the algorithm, inputs, and outputs described on the `comm.CarrierSynchronizer` reference page. The object properties correspond to the block parameters.

## Examples

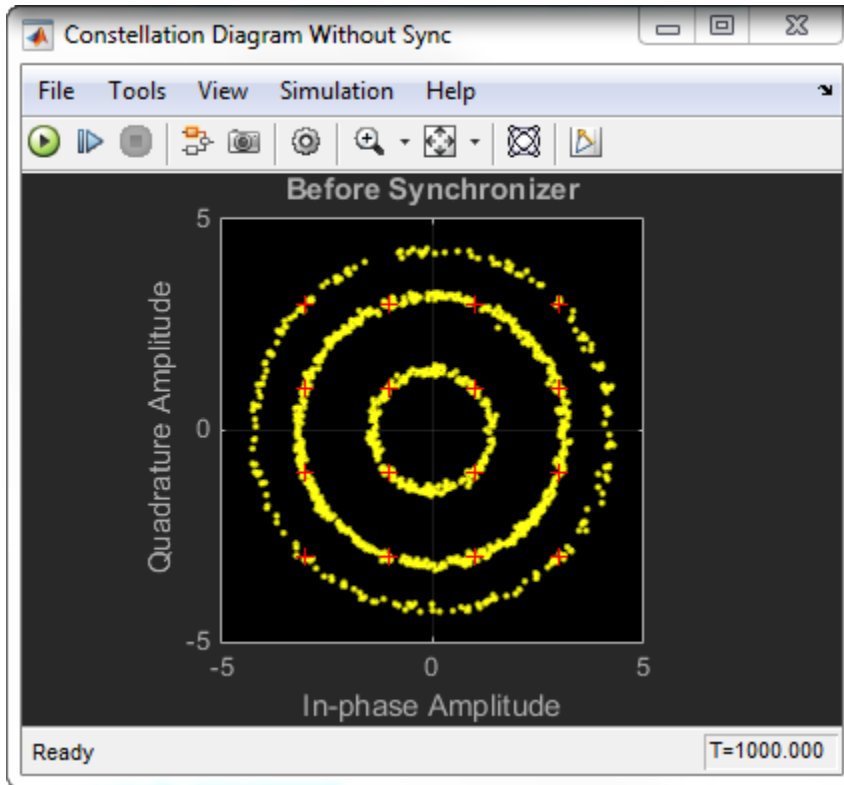

### Correct for Frequency and Phase Offset

Correct for a phase and frequency offset imposed on a noisy 16-QAM channel using the Carrier Synchronizer block.

Open the `doc_qamcarriersync` model.

Run the model. The Constellation Diagram Without Sync block shows a spiral pattern that indicates a phase and frequency offset. After the carrier synchronizer converges to a solution, the data displayed on the Constellation Diagram With Sync block are grouped around the reference constellation.

Experiment with the parameters in the Phase/Frequency Offset and Carrier Synchronizer blocks. By varying these parameters, you can change how quickly the output conforms to an ideal 16-QAM constellation.

If the signal does not converge to the expected constellation, additional measures can be taken to achieve successful recovery. For more information, see the “Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization” on page 4-318 example.

## Supported Data Types

Port	Supported Data Types
Signal Input	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul>
Signal Output	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul>
Phase Error Estimate	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul>

## Charge Pump PLL

Implement charge pump phase-locked loop using digital phase detector

## Library

Components sublibrary of Synchronization

## Description

The Charge Pump PLL (phase-locked loop) block automatically adjusts the phase of a locally generated signal to match the phase of an input signal. It is suitable for use with digital signals.

This PLL has these three components:

- A sequential logic phase detector, also called a digital phase detector or a phase/frequency detector.
- A filter. You specify the filter transfer function using the **Lowpass filter numerator** and **Lowpass filter denominator** parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of  $s$ .

To design a filter, use functions such as `butter`, `cheby1`, and `cheby2` in Signal Processing Toolbox software. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

```
[num, den] = cheby2(3,40,100,'s')
```

- A voltage-controlled oscillator (VCO). You specify characteristics of the VCO using the **VCO input sensitivity**, **VCO quiescent frequency**, **VCO initial phase**, and **VCO output amplitude** parameters.

This block accepts a sample-based scalar input signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

A sequential logic phase detector operates on the zero crossings of the signal waveform. The equilibrium point of the phase difference between the input signal and the VCO signal equals  $\pi$ . The sequential logic detector can compensate for any frequency difference that might exist between a VCO and an incoming signal frequency. Hence, the sequential logic phase detector acts as a frequency detector.

## Parameters

### Lowpass filter numerator

The numerator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of  $s$ .

### Lowpass filter denominator

The denominator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of  $s$ .

### VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the **VCO quiescent frequency** value. The units of **VCO input sensitivity** are Hertz per volt.

### VCO quiescent frequency (Hz)

The frequency of the VCO signal when the voltage applied to it is zero. This should match the frequency of the input signal.

### VCO initial phase (rad)

The initial phase of the VCO signal.

### VCO output amplitude

The amplitude of the VCO signal.

# CMA Equalizer

(To be removed) Equalize using constant modulus algorithm

## Library

Equalizers

---

**Note** will be removed in a future release. Use Linear Equalizer or Decision Feedback Equalizer instead.

---

## Description

The CMA Equalizer block uses a linear equalizer and the constant modulus algorithm (CMA) to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the CMA to update the weights, once per symbol. If the **Number of samples per symbol** parameter is 1, then the block implements a symbol-spaced equalizer; otherwise, the block implements a fractionally spaced equalizer.

When using this block, you should initialize the equalizer weights with a nonzero vector. Typically, CMA is used with differential modulation; otherwise, the initial weights are very important. A typical vector of initial weights has a 1 corresponding to the center tap and zeros elsewhere.

## Input and Output Signals

The Input port accepts a scalar-valued or column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal.

You can configure the block to have one or more of the extra ports listed in the table below.

Port	Meaning	How to Enable
Err output	$y(R -  y ^2)$ , where $y$ is the equalized signal and $R$ is a constant related to the signal constellation	Select <b>Output error</b> .
Wts output	A vector listing the weights after the block has processed either the current input frame or sample.	Select <b>Output weights</b> .

## Algorithms

Referring to the schematics in “Adaptive Equalizers”, define  $w$  as the vector of all weights  $w_i$  and define  $u$  as the vector of all inputs  $u_i$ . Based on the current set of weights,  $w$ , this adaptive algorithm creates the new set of weights given by

$$(\text{LeakageFactor}) \quad w \quad + \quad (\text{StepSize}) \quad u^*e$$

where the  $*$  operator denotes the complex conjugate.

## Equalizer Delay

The delay between the transmitter's modulator output and the CMA equalizer output is typically unknown (unlike the delay for other adaptive equalizers in this product). If you need to determine the delay, you can use the Find Delay block.

## Parameters

### Number of taps

The number of taps in the filter of the equalizer.

### Number of samples per symbol

The number of input samples for each symbol.

When you set this parameter to 1, the filter weights are updated once for each symbol, for a symbol spaced (i.e. T-spaced) equalizer. When you set this parameter to

a value greater than one, the weights are updated once every  $N^{\text{th}}$  sample, for a fractionally spaced (i.e. T/N-spaced) equalizer.

**Signal constellation**

A vector of complex numbers that specifies the constellation for the modulation.

**Step size**

The step size of the CMA.

**Leakage factor**

The leakage factor of the CMA, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

**Initial weights**

A vector that lists the initial weights for the taps.

**Output error**

If you check this box, the block outputs the error signal described in the table above.

**Output weights**

If you check this box, the block outputs the current weights.

# Coarse Frequency Compensator

Compensate for carrier frequency offset for PAM, PSK, or QAM

## Library

Synchronization

## Description

The Coarse Frequency Compensator block compensates for a carrier frequency offset for BPSK, QPSK, OQPSK, 8-PSK, PAM, and QAM modulation schemes. The block accepts a single input signal. To obtain an estimate of the frequency offset in Hz, select the **Estimated frequency offset output port** check box. The block accepts a sample- or frame-based complex input signal and returns a complex output signal and a real frequency offset estimate. The output signal has the same dimensions as the input signal. The frequency offset estimate is a scalar.

## Parameters

### Modulation type of input signal

Specify the modulation type as BPSK, QPSK, OQPSK, 8PSK, PAM, or QAM.

The default setting is QAM.

### Estimation algorithm

Specify the frequency offset estimation algorithm as FFT-based or Correlation-based. This parameter appears when **Modulation type of input signal** is BPSK, QPSK, 8PSK, or PAM.

The table shows the allowable combinations of the modulation type and the estimation algorithm.

Modulation	FFT-Based Algorithm	Correlation-Based Algorithm
BPSK, QPSK, 8PSK, PAM	✓	✓
OQPSK, QAM	✓	

### Frequency resolution (Hz)

Specify the frequency resolution in Hz as a positive real scalar. This option is available when the FFT-based algorithm is used. The default setting is 0.001 Hz.

### Samples per symbol

Specify the number of samples per symbol as a positive integer scalar greater than or equal to 4. The default setting is 4.

### Maximum frequency offset (Hz)

Specify the maximum frequency offset in Hz as a positive real scalar. This option is appears when you set **Estimation algorithm** to Correlation-based. The default setting is 0.05 Hz.

### Estimated frequency offset output port

Select this check box to provide the estimated frequency offset to an output port. The default for this parameter is selected.

### Simulate using

Select the simulation mode.

#### Code generation

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects accept a maximum of nine inputs.

#### Interpreted execution

Simulate your model using all supported MATLAB functions. Choosing this option can slow simulation performance.

The default setting is Code generation.

## Algorithms

This block implements the algorithm, inputs, and outputs described on the `comm.CoarseFrequencyCompensator` reference page. The object properties correspond to the block parameters.

## Examples

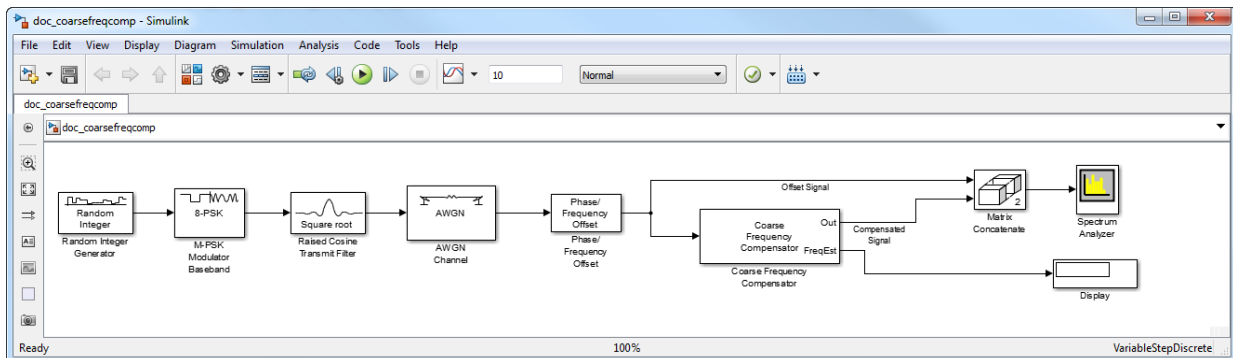

### Correct for Frequency and Phase Offset

Correct for a frequency offset imposed on a noisy 8-PSK channel by using the Coarse Frequency Compensator block.

Open the `doc_coarsefreqcomp` model.

Open the dialog boxes to verify these parameter values:

- Random Integer Generator — **Sample time** is  $1e-4$ , which is equivalent to a 10 ksym/sec symbol rate.
- Raised Cosine Transmit Filter — **Output samples per symbol** is 4.
- AWGN Channel — **Mode** is Signal to noise ratio (SNR) and **SNR (dB)** is 20.
- Phase/Frequency Offset — **Frequency offset (Hz)** is 2000.
- Coarse Frequency Compensator — **Estimation algorithm** is FFT-based and **Frequency resolution (Hz)** is 1.

Run the model. The Spectrum Analyzer block shows both the frequency offset signal and the compensated signal. In addition, the Display block shows the estimate of the frequency offset. Observe that the spectrum plot shows that the Coarse Frequency Compensator correctly centers the signal around 0 Hz. Additionally, the display shows that the estimated frequency offset is 2000 Hz.

Adjust the parameters in the Phase/Frequency Offset and Coarse Frequency Compensator blocks and see their effect on frequency compensation performance.

# Complex Phase Difference

Output phase difference between two complex input signals

## Library

Utility Blocks

## Description

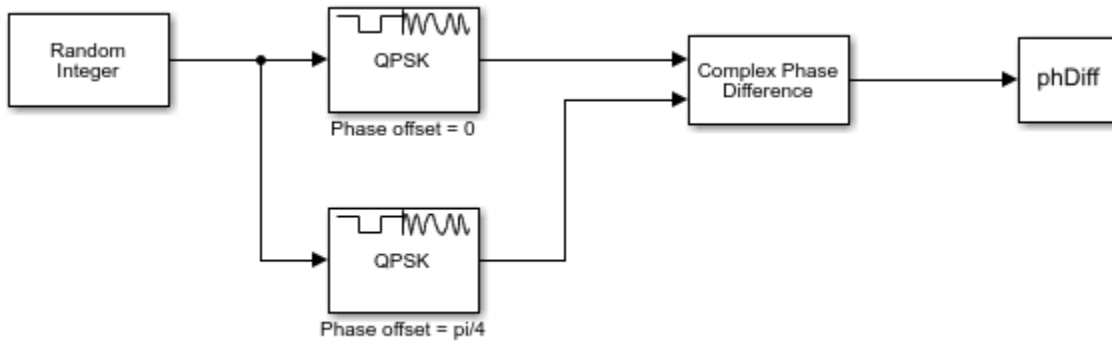

The Complex Phase Difference block accepts two complex input signals that have the same size and frame status. The output is the phase difference from the second to the first, measured in radians. The elements of the output are between  $-\pi$  and  $\pi$ .

The input signals can have any size or frame status. This block processes each pair of elements independently.

## Examples

### Calculate Complex Phase Difference

Open the complex phase difference model. The model generates random integers and applies QPSK modulation. The first QPSK modulator has a phase offset of 0, while the second has a  $\pi/4$  phase offset. The Complex Phase Difference block determines the phase difference. The data is passed to the workspace from the To Workspace block.

Run the model.

Display the phase difference.

```
phDiff =  
-0.7854
```

The phase difference is equal to  $-\pi/4$  as expected.

# Constellation Diagram

Display constellation diagram for input signals

**Library:** Communications Toolbox / Comm Sinks  
Communications Toolbox HDL Support / Comm Sinks

## Description

The Constellation Diagram block displays real and complex-valued floating and fixed-point signals in the I/Q plane. Use this block to perform qualitative and quantitative analysis on modulated single-carrier signals.

In the constellation diagram window you can:

- Input and plot multiple signals on a single constellation diagram. You can define one reference constellation for each input signal. For more information, see **Reference constellation**.
- Choose which channels are displayed by selecting signals in the legend. Use the Show legend parameter to display the legend.
- Display the “EVM / MER Measurements” on page 3-164 panel, which displays calculated error vector magnitude (EVM) and modulation error ratio (MER) measurements. When a multichannel signal is input, use Trace Selection to choose the signal being measured.

## Ports

### Input

**Port\_1** — Signal or signals to visualize  
 column vector | matrix

Connect to the signal or signals you want to visualize as an  $N_{\text{sym}}$ -by-1 column vector or  $N_{\text{sym}}$ -by- $N_{\text{sig}}$  matrix.  $N_{\text{sym}}$  is the number of symbols and  $N_{\text{sig}}$  is the number of input signals.

You can specify up to 20 input signals. Specifically, the maximum number of channels through all the ports is 20. For example, if you create a two-channel signal for every input port, then you can define up to 10 number of input ports.

Example: `[-1 + 1i; -1 - 1i; 1 + 1i; 1 - 1i]` specifies a 4-symbol input signal.

## Parameters

### File

From the Constellation Diagram window, select **File** to view the options available.

#### **Open at Start of Simulation — Open constellation diagram at start of simulation**

on (default) | off

Select to open constellation diagram window at start of simulation. Deselect to prevent constellation diagram window from opening at start of simulation.

#### **Number of input ports — Number of input ports on scope block**

1 (default) | positive integer in the range [1, 20]

Specify the number of input ports on the Scope block, specified as an integer in the range [1, 20].

When multichannel input signals are specified, the maximum number of input ports is limited by the total number of input signals defined. The total number of input signal cannot exceed 20.

### Tools > Axes Scaling Properties

From the Constellation Diagram window, select **Tools > Axes Scaling Properties** to open the Axes Scaling Properties: Constellation Diagram dialog box. In this dialog box, you can customize the graphical properties of the axes.

## Properties

### Axes scaling — Axes scaling options

Manual (default) | Auto | After N Updates

Axes scaling options, specified as:

- **Manual** — Applies the x and y axes limits specified in the Visuals - Constellation Properties: Constellation Diagram dialog box.
- **Auto** — Scales the axes limits as needed during and after simulation.
- **After N Updates** — Scales the axes limits after the specified **Number of updates**.

**Tunable:** Yes

### Number of updates — Number of updates after which to scale the axes

10 (default) | positive integer

Number of updates after which to scale the axes, specified as a positive integer.

**Tunable:** Yes

## Dependencies

This parameter appears when **Axes scaling** is set to After N Updates.

### Scale axes limits at stop — Option to scale axes at end of simulation

off (default) | on

Select to scale axes at end of the simulation to the data range percentage limits specified by **X-axis Data range (%)** and **Y-axis Data range (%)**.

### X-axis Data range (%) — Percentage of x-axis used to display data

80 (default) | scalar from 1 to 100

Percentage of x-axis used to display data.

Example: 100 scales the x-axis range to the maximum value of the in-phase amplitude component of the input signal.

**Tunable:** Yes

### X-axis Align — Align data along x-axis

Center (default) | Left | Right

Align data along x-axis, specified as **Center**, **Left**, or **Right**.

Example: **Right** aligns the maximum value of the in-phase amplitude component of the input signal toward the upper x-axis limit.

**Tunable:** Yes

### **Y-axis Data range (%) — Percentage of y-axis used to display data**

80 (default) | scalar from 1 to 100

Percentage of y-axis used to display data.

Example: 30 scales the y-axis range so that the maximum value of the quadrature amplitude component of the signal occupies 30% of the y-axis range.

**Tunable:** Yes

### **Y-axis Align — Align data along y-axis**

Center (default) | Top | Bottom

Align data along y-axis, specified as **Center**, **Top**, or **Bottom**.

Example: **Bottom** aligns the maximum value of the quadrature amplitude component of the signal toward the lower y-axis limit.

**Tunable:** Yes

## **Tools > Measurements**

From the Constellation Diagram window, select options under **Tools > Measurements** to display the **Trace Selection** and **Signal Quality** panes. By default these panes are docked in the Constellation Diagram window when displayed.

The **Signal Quality** pane contains the **Settings** and **EVM / MER** subpanes. Both subpanes can be independently expanded or collapsed.

For more information about the signal quality measurements, see “EVM / MER Measurements” on page 3-164.

### **Trace Selection — Signal trace used to compute measurements**

list of signals

Select the signal trace used to compute measurements from the list of available signals. This parameter lists the signals input to the block.

**Tunable:** Yes

#### **Dependencies**

To set this parameter, the **Trace Selection** pane must be visible. The **Trace Selection** pane automatically appears when you plot multiple signals on the Constellation Diagram window. To hide or display the **Trace Selection** pane, select **Tools > Measurements > Trace Selection** from the Constellation Diagram window.

#### **EVM / MER Settings Pane**

##### **Measurement interval — Duration of EVM or MER measurement**

Current Display (default) | All displays | positive integer

Duration of the EVM or MER measurement in symbols, specified as **Current Display**, **All displays**, or a positive integer. To specify a positive integer, select and then replace **<user-defined>** with your desired value. The value must be positive and less than or equal to **Symbols to display**. The measurement is computed after the number of input data samples exceeds the measurement interval.

**Tunable:** Yes

##### **EVM normalization — Normalization method used for EVM calculation**

Average constellation power (default) | Peak constellation power

Normalization method used for EVM calculation, specified as **Average constellation power** or **Peak constellation power**. The `comm.EVM System` object computes the EVM.

**Tunable:** Yes

##### **Reference constellation — Reference constellation**

QPSK (default) | BPSK | 8-PSK | 16-QAM | 64-QAM | 256-QAM | vector

Reference constellation, specified as **BPSK**, **QPSK**, **8-PSK**, **16-QAM**, **64-QAM**, **256-QAM**, or a **<user-defined>** vector. To specify a custom value, select **<user-defined>**, then in the **Custom value** property replace the entry with your desired value.

Each input port can have its own reference constellation. For a multichannel input signal, a single reference constellation is applied for all signals in that input port.

To obtain the EVM/MER measurements, you must set **Reference constellation** to a valid value corresponding to the modulation of the input signal.

**Tunable:** Yes

### **Custom value — Input reference constellation**

vector

Input the reference constellation, specified as a vector.

#### **Dependencies**

To enable this parameter, set **Reference constellation** to <user-defined>.

Data Types: double

Complex Number Support: Yes

### **Average reference power — Average power of reference constellation**

1 (default) | positive scalar

Average power of the reference constellation in watts, specified as a positive scalar and referenced to a one-ohm load.

**Tunable:** Yes

### **Reference phase offset (rad) — Phase offset of reference constellation**

pi/4 (default) | scalar

Phase offset of the reference constellation in radians, specified as a scalar.

**Tunable:** Yes

## **View > Configuration Properties**

From the Constellation Diagram window, select **View > Configuration Properties** to open the Visuals - Constellation Properties: Constellation Diagram dialog box. In this dialog box, you can customize the graphical properties of the plotted signals.

#### Main

#### **Number of input ports — Number of input ports on scope block**

1 (default) | positive integer in the range [1, 20]

Specify the number of input ports on the Scope block, specified as an integer in the range [1, 20].

#### **Samples per symbol — Number of samples used to represent each symbol**

1 (default) | positive integer

Number of samples used to represent each symbol, specified as a positive integer. When **Samples per symbol** is greater than 1, the signal is downsampled before it is plotted.

**Tunable:** Yes

#### **Offset (samples) — Number of samples to skip before plotting points**

0 (default) | nonnegative integer

Number of samples to skip before plotting points, specified as a nonnegative integer less than Samples per symbol. This parameter specifies the number of samples to skip when downsampling the input signal.

**Tunable:** Yes

#### **Symbols to display — Maximum number of symbols to display**

Input frame length (default) | positive integer

Maximum number of symbols to display, specified as Input frame length or a positive integer. To specify a positive integer, select and then replace <user-defined> with your desired value.

Use **Symbols to display** to limit the maximum number of symbols displayed when long signals are input. Symbols plotted are the most recent symbols received.

**Tunable:** Yes

#### Display

#### **Show grid — Display plot grid lines**

on (default) | off

Select to display plot grid lines.

**Tunable:** Yes

**Show Legend — Display plot legend**

off (default) | on

Select to display plot legend. The names listed in the legend are the signal names from the model.

From the legend, you can control which signals are plotted. This control is equivalent to changing the visibility in the **View > Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal and hide all other signals, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

**Show signal trajectory — Display signal trajectory**

off (default) | on

Select to display the trajectory between constellation points for the plotted signals.

**Tunable:** Yes

**Color fading — Option to add color fading effect**

off (default) | on

When you select **Color fading**, the points in the display fade as the interval of time after they are first plotted increases. **Color fading** is for animation that resembles an oscilloscope.

**Tunable:** Yes

**X-limits (Minimum) — Minimum x-axis value**

-1.375 (default) | scalar

Minimum x-axis value, specified as a scalar.

**Tunable:** Yes

**X-limits (Maximum) — Maximum x-axis value**

1.375 (default) | scalar

Maximum x-axis value, specified as a scalar.

**Tunable:** Yes

**Y-limits (Minimum) — Minimum y-axis value**

-1.375 (default) | scalar

Minimum y-axis value, specified as a scalar.

**Tunable:** Yes

**Y-limits (Maximum) — Maximum y-axis value**

1.375 (default) | scalar

Maximum y-axis value, specified as a scalar.

**Tunable:** Yes

**Title — Title on plot**

blank (default) | character vector | string

Title on plot, specified as a character vector or string.

**Tunable:** Yes

**X-axis label — x-axis label**

'In-phase Amplitude' (default) | character vector | string

x-axis label, specified as a character vector or string.

**Tunable:** Yes

**Y-axis label — y-axis label**

'Quadrature Amplitude' (default) | character vector | string

y-axis label, specified as a character vector or string.

**Tunable:** Yes

**Reference constellation**

**Show reference constellation — Select to display reference constellation**

on (default) | off

Select to display the reference constellation.

**Tunable:** Yes

**Input — Input port number**

1 (default) | integer

Select the input port number for which you want to view/change the reference constellation and the associated attributes.

**Dependencies**

To enable this parameter, set the **Number of input ports** parameter to a value greater than 1.

**Reference constellation — Reference constellation**

QPSK (default) | BPSK | 8-PSK | 16-QAM | 64-QAM | 256-QAM | vector

Reference constellation, specified as BPSK, QPSK, 8-PSK, 16-QAM, 64-QAM, 256-QAM, or a <user-defined> vector. To specify the value, select and then replace <user-defined> with your desired value. When defined by the user, the reference constellation values can be specified as a vector.

Each input port can have its own reference constellation. For a multichannel input signal, a single reference constellation is applied for all signals in that input port.

To obtain the EVM/MER measurements, you must set **Reference constellation** to a valid value corresponding to the modulation of the input signal.

**Tunable:** Yes

Data Types: double

Complex Number Support: Yes

**Average reference power — Average power of reference constellation**

1 (default) | positive scalar

Average power of the reference constellation in watts, specified as a positive scalar and referenced to a one-ohm load.

**Tunable:** Yes

**Reference phase offset (rad) — Phase offset of reference constellation**

$\pi/4$  (default) | scalar

Phase offset of the reference constellation in radians, specified as a scalar.

**Tunable:** Yes

### View > Style

From the Constellation Diagram window, select **View > Style** to open the Constellation Diagram - Style dialog box. In this dialog box, you can customize the graphical properties of the components in the Constellation Diagram window.

#### Figure color — Select background color

gray (default)

Select the background color within the Constellation Diagram window and outside the scope axes.

#### Axes colors — Select colors of plot and measurement panes

black (default for background) | gray (default for axes)

Select colors of plot and measurement panes. The first color option specifies the background color of the plot figure and the measurement panes. The second option specifies the color of the plot figure axes (ticks, labels, and grid lines) and the text. For more a description of the measurement panes, see in the “Tools > Measurements” on page 3-155.

**Tunable:** Yes

#### Properties for channel — View or change graphical properties of each channel

Channel 1 (default)

Select a channel to view or change its graphical properties.

#### Bring To Front — Bring channel to front

button

Bring the active channel, as indicated by **Properties for channel**, to the front.

#### Show signal and reference constellation — Option to hide channel

on (default) | off

Clear to hide the active channel and its associated reference constellation. Use **Properties for channel** to select the active channel. The setting is synchronized with actions in the interactive legend, see Show legend.

**Symbols — Set properties of symbols**

symbol properties

Set graphical properties of the symbols for the active channel. Adjust style, size, line width, and color of the marker. Use **Properties for channel** to select the active channel.

**Dependencies**

To set marker shape to none, **Show signal trajectory** must be selected.

**Signal trajectory — Select properties of signal trajectory**

no line (default) | trajectory properties

Set graphical properties for the signal trajectory of the active channel. Adjust style, width, and color of the line. Use **Properties for channel** to select the active channel.

**Dependencies**

To adjust signal trajectory properties, **Show signal trajectory** must be selected. When **Show signal trajectory** is selected, the **Signal trajectory** line style cannot be set to no line.

**Reference Constellation****Input — Input port number**

1 (default) | integer

View or change the graphical properties for the symbol of the reference constellation for each port individually.

If none of the input are multichannel signals, then the graphical properties of the reference constellation can be adjusted by selecting the channel from the **Properties for channel** parameter.

**Dependencies**

To enable this parameter, set the **Number of input ports** parameter to a value greater than 1 and specify at least one multichannel input signal.

**Properties — Select properties of reference constellation symbols**

symbol properties

Select the graphical properties for the symbols of the reference constellation. Adjust the style, size, line width, and color of the marker.

**Dependencies**

To adjust reference constellation graphical properties, **Show reference constellation** must be selected.

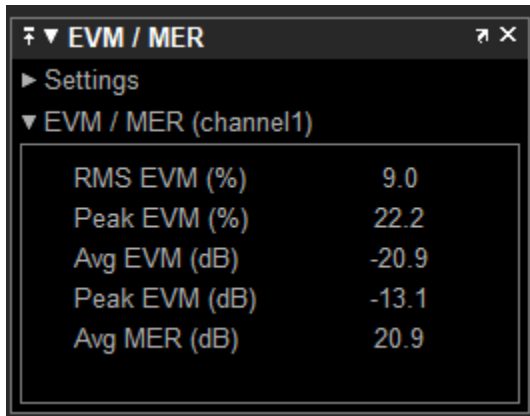

## Block Characteristics

<b>Data Types</b>	Boolean   double   enumerated   fixed point   integer   single
<b>Direct Feedthrough</b>	no
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes
<b>Zero-Crossing Detection</b>	no

## More About

### EVM / MER Measurements

The **EVM / MER** signal quality pane displays the measurement settings, and error vector magnitude (EVM) and modulation error ratio (MER) measurement calculation results for the specified trace selection.

- **EVM** — An error vector is a vector in the IQ plane from the ideal constellation point to the actual point at the receiver. The root mean square error vector magnitude,  $EVM_{\text{RMS}}$ , is measured for the average and peak constellation power.

On the constellation diagram, you can display the  $EVM_{\text{RMS}}$  measurements normalized by either the Average constellation power or Peak constellation power method as computed using these algorithms.

EVM Normalization Method	Algorithm
Average constellation power	<p>Average constellation power normalization:</p> $EVM_k = 100 \sqrt{\frac{e_k}{P_{\text{avg}}}}$ <p><math>EVM_{\text{RMS}}</math>, in percent, for average constellation power normalization:</p> $EVM_{\text{RMS}}(\%) = 100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{\text{avg}}}}$

EVM Normalization Method	Algorithm
Peak constellation power	Peak constellation power normalization  $EVM_k = 100\sqrt{\frac{e_k}{P_{\max}}}$ $EVM_{\text{RMS}}, \text{ in percent, for peak constellation power normalization}$ $EVM_{\text{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{\max}}}$

The **EVM / MER** pane shows the average and peak  $EVM_{\text{RMS}}$  in both percent and decibels for the selected trace. The EVM reported in decibels is computed as  $EVM(\text{dB}) = 10\text{-log}_{10}(EVM_{\text{MS}}) = 20\text{-log}_{10}(EVM_{\text{RMS}})$ , where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- $I_k$  is the in-phase value of the  $k$ th symbol in the input vector.
- $Q_k$  is the quadrature phase value of the  $k$ th symbol in the input vector.
- $I_k$  and  $Q_k$  represent ideal (reference) symbol values.  $\tilde{I}_k$  and  $\tilde{Q}_k$  represent measured (received) symbol values.
- $N$  is the input vector length.
- $P_{\text{avg}}$  is the value for Average constellation power.
- $P_{\text{max}}$  is the value for Peak constellation power.
- $EVM_{\text{RMS}} = \sqrt{EVM_{\text{MS}}}$

The maximum EVM value in a vector is  $EVM_{\text{max}} = \max_{k \in [1, \dots, N]} \{EVM_k\}$ , where  $k$  is the  $k$ th symbol in a vector of length  $N$ .

For more information, see `comm.EVM`.

- **MER** — MER is the ratio of the average power of the transmitted signal to the average power of the error vector. The **EVM / MER** pane indicates average MER measurement result in decibels for the selected trace.

MER is a measure of the SNR in a modulated signal, calculated in dB. The MER over  $N$  symbols is

$$\text{MER} = 10 \cdot \log_{10} \left( \frac{\sum_{n=1}^N (I_k^2 + Q_k^2)}{\sum_{n=1}^N (e_k)} \right) \text{dB},$$

where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- $I_k$  is the in-phase value of the  $k$ th symbol in the input vector.
- $Q_k$  is the quadrature phase value of the  $k$ th symbol in the input vector.
- $I_k$  and  $Q_k$  represent ideal (reference) values.  $\tilde{I}_k$  and  $\tilde{Q}_k$  represent measured (received) symbols.

For more information, see `comm.MER`.

## Programmatic Configuration

You can programmatically configure the scope properties with callbacks or within scripts using a scope configuration object as, described in “Control Scope Blocks Programmatically” (Simulink).

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block is excluded from the generated code when code generation is performed on a system containing this block.

## **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

# Continuous-Time VCO

Implement voltage-controlled oscillator

## Library

Components sublibrary of Synchronization

## Description

The Continuous-Time VCO (voltage-controlled oscillator) block generates a signal with a frequency shift from the **Quiescent frequency** parameter that is proportional to the input signal. The input signal is interpreted as a voltage. If the input signal is  $u(t)$ , then the output signal is

$$y(t) = A_c \cos\left(2\pi f_c t + 2\pi k_c \int^t u(\tau) d\tau + \varphi\right)$$

where  $A_c$  is the **Output amplitude** parameter,  $f_c$  is the **Quiescent frequency** parameter,  $k_c$  is the **Input sensitivity** parameter, and  $\varphi$  is the **Initial phase** parameter.

This block uses a continuous-time integrator to interpret the equation above.

The input and output are both sample-based scalar signals.

## Parameters

### Output amplitude

The amplitude of the output.

**Quiescent frequency**

The frequency of the oscillator output when the input signal is zero.

**Input sensitivity**

This value scales the input voltage and, consequently, the shift from the **Quiescent frequency** value. The units of **Input sensitivity** are Hertz per volt.

**Initial phase**

The initial phase of the oscillator in radians.

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

**Introduced before R2006a**

# Convolutional Deinterleaver

Restore ordering of symbols that were permuted using shift registers

## Library

Convolutional sublibrary of Interleaving

## Description

The Convolutional Deinterleaver block recovers a signal that was interleaved using the Convolutional Interleaver block. Internally, this block uses a set of shift registers. The delay value of the  $k^{\text{th}}$  shift register is  $(N-k)$  times the **Register length step** parameter. The number of shift registers,  $N$ , is the value of the **Rows of shift registers** parameter. The parameters in the two blocks must have the same values.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

This block accepts the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point.

## Parameters

### Rows of shift registers

The number of shift registers that the block uses internally.

### Register length step

The difference in symbol capacity of each successive shift register, where the last register holds zero symbols.

### Initial conditions

Indicates the values that fill each shift register at the beginning of the simulation (except for the last shift register, which has zero delay).

- When you select a scalar value for **Initial conditions**, the value fills all shift registers (except for the last one)
- When you select a column vector with a length equal to the **Rows of shift registers** parameter, each entry fills the corresponding shift register.

The value of the first element of the **Initial conditions** parameter is unimportant, since the last shift register has zero delay.

## Examples

For an example that uses this block, see “Convolutional Interleaving”.

## Pair Block

Convolutional Interleaver

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

#### HDL Architecture

You can generate HDL code for the Convolutional Deinterleaver block using a shift-register-based implementation, or a RAM-based implementation.

The default implementation for the Convolutional Deinterleaver block is shift register-based. To suppress generation of reset logic, set the implementation parameter `ResetType` to 'none'. When you set `ResetType` to 'none', reset is not applied to the shift registers.

When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench errors, determine the number of samples required to fill the shift registers. Set the **Ignore output data checking (number of samples)** option accordingly. (If you are using the command-line interface, you can use the `IgnoreDataChecking` property for this purpose.)

When you select the RAM implementation for a Convolutional Deinterleaver block, HDL Coder uses RAM resources instead of shift registers.

#### HDL Block Properties

<b>ConstrainedOutput Pipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
-----------------------------------	--

<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
<b>ResetType</b>	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also “ResetType” (HDL Coder).

### Restrictions

When you select the RAM implementation:

- Double or single data types are not supported for either input or output signals.
- You must set **Initial conditions** for the block to zero.
- At least two rows of interleaving are required.

**Introduced before R2006a**

# Convolutional Encoder

Create convolutional code from binary data

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The Convolutional Encoder block encodes a sequence of binary input vectors to produce a sequence of binary output vectors. This block can process multiple symbols at a time.

This block can accept inputs that vary in length during simulation. For more information about variable-size signals, see “Variable-Size Signal Basics” (Simulink).

## Input and Output Sizes

If the encoder takes  $k$  input bit streams (that is, it can receive  $2^k$  possible input symbols), the block input vector length is  $L*k$  for some positive integer  $L$ . Similarly, if the encoder produces  $n$  output bit streams (that is, it can produce  $2^n$  possible output symbols), the block output vector length is  $L*n$ .

This block accepts a column vector input signal with any positive integer for  $L$ . For variable-size inputs, the  $L$  can vary during simulation. The operation of the block is governed by the **Operation mode** parameter.

For both its inputs and outputs for the data ports, the block supports **double**, **single**, **boolean**, **int8**, **uint8**, **int16**, **uint16**, **int32**, **uint32**, and **ufix1**. The port data types are inherited from the signals that drive the block. The input reset port supports **double** and **boolean** typed signals.

## Specifying the Encoder

To define the convolutional encoder, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name in the **Trellis structure** parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a `poly2trellis` command in the **Trellis structure** parameter. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

The encoder registers begin in the all-zeros state. Set the **Operation mode** parameter to `Reset on nonzero input via port` to reset all encoder registers to the all-zeros state during the simulation. This selection opens a second input port, labeled `Rst`, which accepts a scalar-valued input signal. When the input signal is nonzero, the block resets before processing the data at the first input port. To reset the block after it processes the data at the first input port, select **Delay reset action to next time step**.

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

### Operation mode

In `Continuous` mode, the block retains the encoder states at the end of each input, for use with the next frame.

In `Truncated (reset every frame)` mode, the block treats each input independently. The encoder states are reset to all-zeros state at the start of each input.

---

**Note** When this block outputs sequences that vary in length during simulation and you set the **Operation mode** to **Truncated (reset every frame)** or **Terminate trellis by appending bits**, the block's state resets at every input time step.

---

In **Terminate trellis by appending bits** mode, the block treats each input independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by  $y = n \cdot (x + s)/k$ , where  $x$  is the number of input bits, and  $s = \text{constraint length} - 1$  (or, in the case of multiple constraint lengths,  $s = \text{sum}(\text{ConstraintLength}(i) - 1)$ ).

---

**Note** This block works for cases  $k \geq 1$ , where it has the same values for constraint lengths in each input stream (e.g., constraint lengths of [2 2] or [7 7] will work, but [5 4] will not).

---

In **Reset on nonzero input via port** mode, the block has an additional input port, labeled **Rst**. When the **Rst** input is nonzero, the encoder resets to the all-zeros state.

#### **Delay reset action to next time step**

When you select **Delay reset action to next time step**, the Convolutional Encoder block resets after computing the encoded data. This check box only appears when you set the **Operation mode** parameter to **Reset on nonzero input via port**.

The delay in the reset action allows the block to support HDL code generation. In order to generate HDL code, you must have an HDL Coder license.

#### **Output final state**

When you select **Output final state**, the second output port signal specifies the output state for the block. The output signal is a scalar, integer value. You can select **Output final state** for all operation modes except **Terminate trellis by appending bits**.

#### **Specify initial state via input port**

When you select **Specify initial state via input port** the second input port signal specifies the starting state for every frame in the block. The input signal must be a scalar, integer value. **Specify initial state via input port** appears only in **Truncated** operation mode.

#### **Puncture code**

Selecting this option opens the field **Puncture vector**.

### **Puncture vector**

Vector used to puncture the encoded data. The puncture vector is a pattern of 1s and 0s where the 0s indicate the punctured bits. This field appears when you select **Punctured code**.

## **Puncture Pattern Examples**

For some commonly used puncture patterns for specific rates and polynomials, see the last three references listed on this page.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

#### HDL Architecture

This block has a single, default HDL architecture.

#### HDL Block Properties

<b>ConstrainedOutput Pipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

#### Restrictions

- Input data requirements:
  - Must be sample-based,
  - Must have a `boolean` or `ufix1` data type.

- HDL Coder supports only the following coding rates:
  - $\frac{1}{2}$  to  $\frac{1}{7}$
  - $\frac{2}{3}$
- The coder supports only constraint lengths for 3 to 9.
- Specify **Trellis structure** by the `poly2trellis` function.
- The coder supports the following **Operation mode** settings:
  - Continuous
  - Reset on nonzero input via port

If you select this mode, you must select the **Delay reset action to next time step** option. When you select this option, the Convolutional Encoder block finishes its current computation before executing a reset.

- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.

**Introduced before R2006a**

# Convolutional Interleaver

Permute input symbols using set of shift registers

## Library

Convolutional sublibrary of Interleaving

## Description

The Convolutional Interleaver block permutes the symbols in the input signal. Internally, it uses a set of shift registers. The delay value of the  $k$ th shift register is  $(k-1)$  times the **Register length step** parameter. The number of shift registers is the value of the **Rows of shift registers** parameter.

The **Initial conditions** parameter indicates the values that fill each shift register at the beginning of the simulation (except for the first shift register, which has zero delay). If **Initial conditions** is a scalar, then its value fills all shift registers except the first; if **Initial conditions** is a column vector whose length is the **Rows of shift registers** parameter, then each entry fills the corresponding shift register. The value of the first element of the **Initial conditions** parameter is unimportant, since the first shift register has zero delay.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

The block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and `fixed-point`. The data type of this output will be the same as that of the input signal.

## Parameters

### Rows of shift registers

The number of shift registers that the block uses internally.

### Register length step

The number of additional symbols that fit in each successive shift register, where the first register holds zero symbols.

### Initial conditions

The values that fill each shift register when the simulation begins.

## Examples

For an example that uses this block, see “Convolutional Interleaving”.

## Pair Block

Convolutional Deinterleaver

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

#### HDL Architecture

You can generate HDL code for the Convolutional Interleaver block using a shift-register-based implementation, or a RAM-based implementation.

The default implementation for the Convolutional Interleaver block is shift register-based. To suppress generation of reset logic, set the implementation parameter `ResetType` to 'none'. When you set `ResetType` to 'none', reset is not applied to the shift registers.

When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench errors, determine the number of samples required to fill the shift registers. Set the **Ignore output data checking (number of samples)** option accordingly. (If you are using the command-line interface, you can use the `IgnoreDataChecking` property for this purpose.)

When you select the RAM implementation for a Convolutional Interleaver block, HDL Coder uses RAM resources instead of shift registers.

#### HDL Block Properties

<b>ConstrainedOutput Pipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
-----------------------------------	--

<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
<b>ResetType</b>	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also “ResetType” (HDL Coder).

### Restrictions

When you select the RAM implementation:

- Double or single data types are not supported for either input or output signals.
- You must set **Initial conditions** for the block to zero.
- At least two rows of interleaving are required.

**Introduced before R2006a**

# CPFSK Demodulator Baseband

Demodulate CPFSK-modulated data

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The CPFSK Demodulator Baseband block demodulates a signal that was modulated using the continuous phase frequency shift keying method. The input to this block is a baseband representation of the modulated signal. The **M-ary number** parameter,  $M$ , is the size of the input alphabet.  $M$  must have the form  $2^K$  for some positive integer  $K$ .

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

## Integer-Valued Signals and Binary-Valued Signals

When you set the **Output type** parameter to **Integer**, then the block produces odd integers between  $-(M-1)$  and  $M-1$ .

When you set the **Output type** parameter to **Bit**, then the block produces groupings of  $K$  bits. Each grouping is called a binary *word*.

In binary output mode, the block first maps each input symbol to an intermediate value as in the integer output mode. The block then maps the odd integer  $k$  to the nonnegative integer  $(k+M-1)/2$ . Finally, the block maps each nonnegative integer to a binary word, using a mapping that depends on whether the **Symbol set ordering** parameter is set to **Binary** or **Gray**.

This block accepts a scalar-valued or column vector input signal with a data type of **single** or **double**.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to `Bit`, the output width is  $K$  times the number of input symbols.
- When you set **Output type** to `Integer`, the output width is the number of input symbols.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to `Bit`, the output width equals the number of bits per symbol.
- When you set **Output type** to `Integer`, the output is a scalar.

## Traceback Depth and Output Delays

Internally, this block creates a trellis description of the modulation scheme and uses the Viterbi algorithm. The **Traceback depth** parameter,  $D$ , in this block is the number of trellis branches that the algorithm uses to construct each traceback path.  $D$  influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When you set the **Rate options** parameter to `Allow multirate processing`, and the model uses a variable-step solver or a fixed-step solver with the **Tasking Mode** parameter set to `SingleTasking`, then the delay consists of  $D+1$  zero symbols.
- When you set the **Rate options** parameter to `Enforce single-rate processing`, then the delay consists of  $D$  zero symbols.

The optimal **Traceback depth** parameter value is dependent on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the “five-times-the-constraint-length” rule, which corresponds to  $5 \cdot \log_2(\text{numStates})$ .

For the definition of the number of states, see CPM Demodulator Baseband Help page.

## Parameters

### M-ary number

The size of the alphabet.

### Output type

Determines whether the output consists of integers or groups of bits.

### Symbol set ordering

Determines how the block maps each integer to a group of output bits. This field is active only when **Output type** is set to **Bit**.

### Modulation index

Specify the modulation index  $\{h_i\}$ . The default is  $0.5$ . The value of this property must be a real, nonnegative scalar or column vector.

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

### Phase offset (rad)

The initial phase of the modulated waveform.

### Samples per symbol

The number of input samples that represent each modulated symbol, which must be a positive integer. For more information, see “Upsample Signals and Rate Changes” in *Communications Toolbox User's Guide*.

### Rate options

Select the rate processing method for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to **Integer**).
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output period is the same as

the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

**Traceback depth**

The number of trellis branches that the CPFSK Demodulator Baseband block uses to construct each traceback path.

**Output datatype**

The output data type can be `boolean`, `int8`, `int16`, `int32`, or `double`.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean (When <b>Output type</b> set to Bit)</li> <li>• 8-, 16-, and 32-bit signed integers (When <b>Output type</b> set to Integer)</li> </ul>

## CPFSK Modulator Baseband

Modulate using continuous phase frequency shift keying method

### Library

CPM, in Digital Baseband sublibrary of Modulation

### Description

The CPFSK Modulator Baseband block modulates a signal using the continuous phase frequency shift keying method. The output is a baseband representation of the modulated signal. The **M-ary number** parameter,  $M$ , represents the size of the input alphabet.  $M$  must have the form  $2^K$  for some positive integer  $K$ .

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

### Integer-Valued Signals and Binary-Valued Signals

When you set the **Input type** parameter to Integer, the block accepts odd integers between  $-(M-1)$  and  $M-1$ .

When you set the **Input type** parameter to Bit, the block accepts groupings of  $K$  bits. Each grouping is called a binary *word*. The input vector length must be an integer multiple of  $K$ .

In binary input mode, the block maps each binary word to an integer between 0 and  $M-1$ , using a mapping scheme that depends on whether you set the **Symbol set ordering** parameter to Binary or Gray. The block then maps the integer  $k$  to the intermediate value  $2k-(M-1)$  and proceeds as if it operates in the integer input mode. For more information, see “Integer-Valued Signals and Binary-Valued Signals”.

This block accepts a scalar-valued or column vector input signal. If you set **Input type** to **Bit**, then the input signal can also be a vector of length  $K$ .

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set **Input type** to **Integer**, the input can be a column vector, the length of which is the number of input symbols.
- When you set **Input type** to **Bit**, the input must be a column vector with a width that is an integer multiple of  $K$ , the number of bits per symbol.

The output width equals the product of the number of input symbols and the **Samples per symbol** parameter value.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to **Integer**, the input must be a scalar.
- When you set **Input type** to **Bit**, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

## Parameters

### M-ary number

The size of the alphabet.

### Input type

Indicates whether the input consists of integers or groups of bits.

#### Symbol set ordering

Determines how the block maps each group of input bits to a corresponding integer. This field is active only when **Input type** is set to **Bit**.

#### Modulation index

Specify the modulation index  $\{h_i\}$ . The default is  $0.5$ . The value of this property must be a real, nonnegative scalar or column vector.

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

#### Phase offset (rad)

The initial phase of the output waveform, measured in radians.

#### Samples per symbol

The number of output samples that the block produces for each integer or binary word in the input, which must be a positive integer. For all non-binary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

#### Rate options

Select the rate processing option for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

#### Output data type

Select the data type of the output signal. The output data type can be **single** or **double**.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Boolean (When <b>Input type</b> set to Bit)</li> <li>• 8-, 16-, and 32-bit signed integers (When <b>Input type</b> set to Integer)</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>

## CPM Demodulator Baseband

Demodulate CPM-modulated data

**Library:** Communications Toolbox / Modulation / Digital Baseband Modulation / CPM

### Description

The CPM Demodulator Baseband block demodulates a signal that was modulated using continuous phase modulation (CPM).

CPM is a modulation method with memory. The block processing includes a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum Euclidean distance path. The block uses the Viterbi algorithm to perform MLSD.

For more information about this demodulation and the filtering applied, see “CPM Demodulation” on page 3-198 and “Pulse Shape Filtering” on page 3-200.

### Ports

#### Input

##### **In — Input signal**

scalar | column vector

Input signal, specified as a scalar or column vector. The length of the input signal must be an integer multiple of the number of samples per symbol specified in the **Samples per symbol** parameter. For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 3-201.

Data Types: double | single

## Output

### Out — Output signal

scalar | column vector

Output signal, returned as a scalar or column vector. For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 3-201.

### Supported Data Types

- Double-precision floating point
- Boolean (when **Output type** is set to Bit)
- 8-, 16-, and 32-bit signed integers (when **Output type** is set to Integer)

Data Types: double | Boolean | int8 | int16 | int32

For more information on the processing rates, see “Single-Rate Processing” on page 3-202, and “Multirate Processing” on page 3-202.

## Parameters

### M-ary number — Modulation order

4 (default) | positive integer

Modulation order indicating the alphabet size, specified as a positive integer that is a nonzero power of two.  $M$  must have the form  $2^K$  for some positive integer  $K$ , where  $K$  is the number of bits per symbol.

### Output type — Determines whether output consists of integers or groups of bits

Integer (default) | Bit

Determines whether the output consists of integers or groups of bits, specified as Integer or Bit.

### Symbol set ordering — Bit mapping

Binary (default) | Gray

Bit mapping, specified as Binary or Gray.

This parameter determines how the block maps each integer to a group of output bits. For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 3-201.

**Dependencies**

To enable this parameter, set **Output type** to Bit.

**Modulation index — Modulation index  $\{h_i\}$** 

0.5 (default) | nonnegative scalar | column vector

Modulation index  $\{h_i\}$ , specified as a nonnegative scalar or column vector.

$\{h\}$  represents a sequence of modulation indices. For more information, see “CPM Demodulation” on page 3-198.

**Frequency pulse shape — Type of pulse shaping**

Rectangular (default) | Raised Cosine | Spectral Raised Cosine | Gaussian | Tamed FM

Type of pulse shaping used to smooth the phase transitions of the modulated signal, specified as Rectangular, Raised Cosine, Spectral Raised Cosine, Gaussian, or Tamed FM. For more information on the filtering options, see “Pulse Shape Filtering” on page 3-200.

**Main lobe pulse duration (symbol intervals) — Number of symbol intervals of largest lobe of the spectral raised cosine pulse**

1 (default) | positive scalar

Number of symbol intervals of the largest lobe of the spectral raised cosine pulse, specified as a positive scalar.

**Dependencies**

To enable this parameter, set **Frequency pulse shape** to Spectral Raised Cosine.

**Rolloff — Rolloff factor of spectral raised cosine pulse shape**

0.2 (default) | nonnegative scalar

Rolloff factor of the spectral raised cosine pulse shape, specified as a scalar from 0 to 1.

**Dependencies**

To enable this parameter, set **Frequency pulse shape** to Spectral Raised Cosine.

**BT product — Product of bandwidth and time**

0.3 (default) | nonnegative scalar

Product of bandwidth and time, specified as a nonnegative scalar. Use **BT product** to reduce the bandwidth, at the expense of increased intersymbol interference.

#### **Dependencies**

To enable this parameter, set **Frequency pulse shape** to `Gaussian`.

#### **Pulse length (symbol intervals) — Frequency pulse length**

1 (default) | positive scalar

Frequency pulse shape length, specified as a positive scalar. Refer to *LT* in “Pulse Shape Filtering” on page 3-200 for more information on the frequency pulse length.

#### **Symbol prehistory — Data symbols used before the start of simulation**

1 (default) | scalar | vector

Data symbols used before the start of simulation in reverse chronological order. If **Symbol prehistory** is a vector, then its length must be one less than the **Pulse length** parameter value.

#### **Phase offset (rad) — Initial phase offset**

0 (default) | scalar

Initial phase offset of output in radians, specified as a scalar.

#### **Samples per symbol — Symbol sampling rate**

8 (default) | positive scalar

Symbol sampling rate, specified as a positive scalar. This parameter represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

#### **Rate options — Block processing rate**

`Enforce single-rate processing` (default) | `Allow multirate processing`

Block processing rate, specified as one of these options:

- `Enforce single-rate processing` — The input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols

(which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to Integer).

- **Allow multirate processing** — The input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

**Traceback depth — Number of trellis branches**

16 (default) | positive integer

Number of trellis branches used to construct each traceback path, specified as a positive integer. For more information, see “Traceback Depth and Output Delays” on page 3-202.

**Output data type — Output data type**

double (default) | boolean | int8 | int16 | int32

Output data type, specified as double, boolean, int8, int16, or int32. For more information, see **Supported Data Types** in Out.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### CPM Demodulation

The CPM demodulation processing consists of a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum Euclidean distance path. When the modulation index is rational ( $h = m/p$ ), there are a finite number of phase states in the symbol. The block uses the Viterbi algorithm to perform MLSD.

$\{h_i\}$  represents a sequence of modulation indices that moves cyclically through a set of indices  $\{h_0, h_1, h_2, \dots, h_{H-1}\}$ .

- $h_i = m_i/p_i$  represents the modulation index in proper rational form.
- $m_i$  represents the numerator of the modulation index.
- $p_i$  represents the denominator of the modulation index.
- $m_i$  and  $p_i$  are relatively prime positive numbers.
- The least common multiple (LCM) of  $\{p_0, p_1, p_2, \dots, p_{H-1}\}$  is denoted as  $p$ .
- $h_i = m'_i / p$

$\{h_i\}$  determines the number of phase states:

$$\text{numPhaseStates} = \begin{cases} p, & \text{for all even } m'_i \\ 2p, & \text{for any odd } m'_i \end{cases}$$

and affects the number of trellis states:

$$\text{numStates} = \text{numPhaseStates} * M^{(L-1)}$$

- $L$  represents the **Pulse length**.
- $M$  represents the **M-ary number**.

## CPM Modulation

The input to the demodulator is a baseband representation of the modulated signal:

$$s(t) = \exp \left[ j 2\pi \sum_{i=0}^n \alpha_i h_i q(t - iT) \right],$$

$$nT < t < (n+1)T$$

where:

- $\{\alpha_i\}$  represents a sequence of  $M$ -ary data symbols selected from the alphabet  $\pm 1, \pm 3, \dots, \pm(M-1)$ .
- $M$  must have the form  $2^K$  for some positive integer  $K$ , where  $M$  is the modulation order and specifies the size of the symbol alphabet.

- $\{h_i\}$  represents a sequence of modulation indices and  $h_i$  moves cyclically through a set of indices  $\{h_0, h_1, h_2, \dots, h_{H-1}\}$ . When  $H=1$ , there is only one modulation index,  $h_0$ , which is denoted as  $h$ .

### Pulse Shape Filtering

Continuous phase modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function  $q(t)$  is the phase response obtained from the frequency

pulse,  $g(t)$ , through this relation:

$$q(t) = \int_{-\infty}^t g(t) dt$$

The specified frequency pulse shape corresponds to these pulse shape expressions,  $g(t)$ .

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$
Raised Cosine	$g(t) = \begin{cases} \frac{1}{2LT} \left[ 1 - \cos\left(\frac{2\pi t}{LT}\right) \right], & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$
Spectral Raised Cosine	$g(t) = \frac{1}{L_{main} T} \frac{\sin\left(\frac{2\pi t}{L_{main} T}\right) \cos\left(\beta \frac{2\pi t}{L_{main} T}\right)}{\frac{2\pi t}{L_{main} T} \left[ 1 - \left(\frac{4\beta}{L_{main} T} t\right)^2 \right]}, \quad 0 \leq \beta \leq 1$
Gaussian	$g(t) = \frac{1}{2T} \left\{ Q \left[ 2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln 2}} \right] - Q \left[ 2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln 2}} \right] \right\}, \text{ where}$ $Q(t) = \int_t^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$

Pulse Shape	Expression
Tamed FM (tamed frequency modulation)	$g(t) = \frac{1}{8} [g_0(t-T) + 2g_0(t) + g_0(t+T)],$ where $g_0(t) \approx \frac{1}{T} \left[ \frac{\sin(\frac{\pi t}{T})}{\frac{\pi t}{T}} - \frac{\pi^2}{24} \frac{2 \sin(\frac{\pi t}{T}) - \frac{2\pi t}{T} \cos(\frac{\pi t}{T}) - (\frac{\pi t}{T})^2 \sin(\frac{\pi t}{T})}{(\frac{\pi t}{T})^3} \right]$

- $L_{\text{main}}$  is the main lobe pulse duration in symbol intervals.
- $\beta$  is the rolloff factor of the spectral raised cosine.
- $B_b$  is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse,  $LT$ , is the pulse length in symbol intervals. As defined by the expressions, the Spectral Raised Cosine, Gaussian, and Tamed FM pulse shapes have infinite length. For all practical purposes,  $LT$  specifies the truncated finite length.

For more information on pulse shape filtering, see [1]

## Integer-Valued and Binary-Valued Output Signals

When the **Output type** parameter is set to Integer:

- The block produces odd integers between  $-(M-1)$  and  $M-1$ . The modulation order,  $M$ , is specified by the **M-ary number** parameter.
- The **Output datatype** parameter cannot be set to boolean.

When the **Output type** parameter is set to Bit:

- The block produces groupings of  $K$  bits. Each grouping is called a binary word.
- The **Output datatype** can only be double or boolean.
- In binary output mode, the block processing follows this procedure:
  - 1 Maps each input symbol to an intermediate value, as in the integer output mode.
  - 2 Maps the odd integer  $k$  to the nonnegative integer  $(k+M-1)/2$ .
  - 3 Maps each nonnegative integer to a binary word, using Binary or Gray mapping, as specified by the **Symbol set ordering** parameter.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to `Bit`, the output width is  $K$  times the number of input symbols.
- When you set **Output type** to `Integer`, the output width is the number of input symbols.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to `Bit`, the output width equals the number of bits per symbol.
- When you set **Output type** to `Integer`, the output is a scalar.

## Traceback Depth and Output Delays

The **Traceback depth** parameter,  $D$ , is the number of trellis branches used to construct each traceback path.  $D$  influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When the **Rate options** parameter is set to `Allow multirate processing`, and the model uses a variable-step solver or a fixed-step solver with the **Tasking Mode** parameter set to `SingleTasking`, then the delay vector consists of  $D+1$  zero-value symbols.
- When the **Rate options** parameter is set to `Enforce single-rate processing`, the delay vector consists of  $D$  zero-value symbols.

The optimal **Traceback depth** parameter value depends on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the five-times-the-constraint-length rule, which corresponds to  $5 \cdot \log_2(\text{numStates})$ .

For a binary raised cosine pulse shape with a pulse length of 3 and  $h=2/3$ , applying this rule  $(5 * \log_2(3 * 2^2) = 18)$  gives a result that is close to the optimum value of 20.

## CPM Modulator Baseband

Modulate using continuous phase modulation

**Library:** Communications Toolbox / Modulation / Digital Baseband Modulation / CPM

### Description

The CPM Modulator Baseband block modulates an input signal using continuous phase modulation (CPM). The output of the modulator is a baseband representation of the modulated signal:

$$s(t) = \exp \left[ j 2\pi \sum_{i=0}^n \alpha_i h_i q(t - iT) \right],$$

$$nT < t < (n+1)T$$

where:

- $\{\alpha_i\}$  represents a sequence of  $M$ -ary data symbols selected from the alphabet  $\pm 1, \pm 3, \dots, \pm(M-1)$ .
- $M$  must have the form  $2^K$  for some positive integer  $K$ , where  $M$  is the modulation order and specifies the size of the symbol alphabet.
- $\{h_i\}$  represents a sequence of modulation indices and  $h_i$  moves cyclically through a set of indices  $\{h_0, h_1, h_2, \dots, h_{H-1}\}$ . When  $H=1$ , there is only one modulation index,  $h_0$ , which is denoted as  $h$ .

For more information about this modulation and the filtering applied, see “CPM Modulation” on page 3-209 and “Pulse Shape Filtering” on page 3-210.

## Ports

### Input

#### In — Input signal

scalar | column vector

Input signal, specified as a scalar or column vector.

When the **Input type** parameter is set to **Integer**, the block accepts odd integers between  $-(M-1)$  and  $M-1$ .  $M$  represents the **M-ary number** parameter.

When the **Input type** parameter is set to **Bit**, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of  $K = \log_2(M)$  bits.  $K$  is the number of bits per symbol and  $M$  is the modulation order. The input vector length must be an integer multiple of  $K$ . The block maps each group of  $K$  bits onto a symbol, as specified by the **Symbol set ordering** parameter. For each group of  $K$  bits, the block outputs one modulated symbol, oversampled by the **Samples per symbol** parameter value.

#### Supported Data Types

- Double-precision floating point
- Boolean (when **Input type** is set to **Bit**)
- 8-, 16-, and 32-bit signed integers (when **Input type** is set to **Integer**)

Data Types: double | Boolean | int8 | int16 | int32

### Output

#### Out — Output signal

scalar | column vector

Output signal, returned as a scalar or column vector.

- When the **Input type** parameter is set to **Integer**, the block outputs one modulated symbol for each input symbol.
- When the **Input type** parameter is set to **Bit**, the block outputs one modulated symbol for each group of  $K$  bits.

In both cases, the modulated symbols are oversampled by the **Samples per symbol** parameter value.

Data Types: `double` | `single`

For more information on the processing rates, see “Single-Rate Processing” on page 3-211, and “Multirate Processing” on page 3-212.

## Parameters

### **M-ary number — Modulation order**

4 (default) | positive integer

Modulation order indicating the alphabet size, specified as a positive integer that is a nonzero power of two.  $M$  must have the form  $2^K$  for some positive integer  $K$ , where  $K$  is the number of bits per symbol.

### **Input type — Integer or group of bits input indicator**

Integer (default) | Bit

Indicates whether the input consists of integers or groups of bits, specified as Integer or Bit.

### **Symbol set ordering — Bit mapping**

Binary (default) | Gray

Bit mapping, specified as Binary or Gray. For more information, see “Symbol Sets” on page 3-211.

### **Dependencies**

To enable this parameter, set **Input type** to Bit.

### **Modulation index — Modulation index $\{h_i\}$**

0.5 (default) | nonnegative scalar | column vector

Modulation index  $\{h_i\}$ , specified as a nonnegative scalar or column vector.

$\{h\}$  represents a sequence of modulation indices. For more information, see “CPM Modulation” on page 3-209.

**Frequency pulse shape — Type of pulse shaping**

Rectangular (default) | Raised Cosine | Spectral Raised Cosine | Gaussian | Tamed FM

Type of pulse shaping used to smooth the phase transitions of the modulated signal, specified as Rectangular, Raised Cosine, Spectral Raised Cosine, Gaussian, or Tamed FM. For more information on the filtering options, see “Pulse Shape Filtering” on page 3-210.

**Main lobe pulse duration (symbol intervals) — Number of symbol intervals of largest lobe of spectral raised cosine pulse**

1 (default) | positive scalar

Number of symbol intervals of the largest lobe of the spectral raised cosine pulse, specified as a positive scalar.

**Dependencies**

To enable this parameter, set **Frequency pulse shape** to Spectral Raised Cosine.

**Rolloff — Rolloff factor of spectral raised cosine pulse shape**

0.2 (default) | nonnegative scalar

Rolloff factor of the spectral raised cosine pulse, specified as a scalar from 0 to 1.

**Dependencies**

To enable this parameter, set **Frequency pulse shape** to Spectral Raised Cosine.

**BT product — Product of bandwidth and time**

0.3 (default) | nonnegative scalar

Product of bandwidth and time, specified as a nonnegative scalar. Use **BT product** to reduce the bandwidth, at the expense of increased intersymbol interference.

**Dependencies**

To enable this parameter, set **Frequency pulse shape** to Gaussian.

**Pulse length (symbol intervals) — Frequency pulse length**

1 (default) | positive scalar

Frequency pulse length, specified as a positive scalar. Refer to *LT* in “Pulse Shape Filtering” on page 3-210 for more information on the frequency pulse length.

#### **Symbol prehistory — Data symbols used before the start of simulation**

1 (default) | scalar | vector

Data symbols used before the start of simulation, specified as a scalar or vector in reverse chronological order. If **Symbol prehistory** is a vector, then its length must be one less than the **Pulse length (symbol intervals)** parameter value.

#### **Phase offset (rad) — Initial phase offset**

0 (default) | scalar

Initial phase offset of output in radians, specified as a scalar.

#### **Samples per symbol — Symbol sampling rate**

8 (default) | positive scalar

Symbol sampling rate, specified as a positive scalar. This parameter represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

#### **Rate options — Block processing rate**

Enforce single-rate processing (default) | Allow multirate processing

Block processing rate, specified as one of these options:

- **Enforce single-rate processing** — The input and output signals have the same sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- **Allow multirate processing** — The input and output signals have different sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

#### **Output data type — Output data type**

double (default) | single

Output data type, specified as double or single.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### CPM Modulation

The output of the modulator is a baseband representation of the modulated signal:

$$s(t) = \exp \left[ j 2\pi \sum_{i=0}^n \alpha_i h_i q(t - iT) \right],$$

$$nT < t < (n+1)T$$

where:

- $\{\alpha_i\}$  represents a sequence of  $M$ -ary data symbols selected from the alphabet  $\pm 1, \pm 3, \dots, \pm(M-1)$ .
- $M$  must have the form  $2^K$  for some positive integer  $K$ , where  $M$  is the modulation order and specifies the size of the symbol alphabet.
- $\{h_i\}$  represents a sequence of modulation indices and  $h_i$  moves cyclically through a set of indices  $\{h_0, h_1, h_2, \dots, h_{H-1}\}$ . When  $H=1$ , there is only one modulation index,  $h_0$ , which is denoted as  $h$ .

$h_i$  specifies the modulation index. When  $h_i$  varies from interval to interval, the block operates in multi- $h$ . To ensure a finite number of phase states,  $h_i$  must be a rational number.

### Pulse Shape Filtering

Continuous phase modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function  $q(t)$  is the phase response obtained from the frequency

pulse,  $g(t)$ , through this relation:

$$q(t) = \int_{-\infty}^t g(t) dt$$

The specified frequency pulse shape corresponds to these pulse shape expressions,  $g(t)$ .

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$
Raised Cosine	$g(t) = \begin{cases} \frac{1}{2LT} \left[ 1 - \cos\left(\frac{2\pi t}{LT}\right) \right], & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$
Spectral Raised Cosine	$g(t) = \frac{1}{L_{main} T} \frac{\sin\left(\frac{2\pi t}{L_{main} T}\right) \cos\left(\beta \frac{2\pi t}{L_{main} T}\right)}{\frac{2\pi t}{L_{main} T} \left[ 1 - \left(\frac{4\beta}{L_{main} T} t\right)^2 \right]}, \quad 0 \leq \beta \leq 1$
Gaussian	$g(t) = \frac{1}{2T} \left\{ Q \left[ 2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln 2}} \right] - Q \left[ 2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln 2}} \right] \right\}, \text{ where}$ $Q(t) = \int_t^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$

Pulse Shape	Expression
Tamed FM (tamed frequency modulation)	$g(t) = \frac{1}{8} [g_0(t-T) + 2g_0(t) + g_0(t+T)],$ where $g_0(t) \approx \frac{1}{T} \left[ \frac{\sin(\frac{\pi t}{T})}{\frac{\pi t}{T}} - \frac{\pi^2}{24} \frac{2 \sin(\frac{\pi t}{T}) - \frac{2\pi t}{T} \cos(\frac{\pi t}{T}) - (\frac{\pi t}{T})^2 \sin(\frac{\pi t}{T})}{(\frac{\pi t}{T})^3} \right]$

- $L_{\text{main}}$  is the main lobe pulse duration in symbol intervals.
- $\beta$  is the rolloff factor of the spectral raised cosine.
- $B_b$  is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse,  $LT$ , is the pulse length in symbol intervals. As defined by the expressions, the Spectral Raised Cosine, Gaussian, and Tamed FM pulse shapes have infinite length. For all practical purposes,  $LT$  specifies the truncated finite length.

For more information on pulse shape filtering, see [1].

## Symbol Sets

In binary input mode, the block processing follows this procedure:

- 1 Maps each binary word to  $k$ , an integer from 0 to  $M-1$ . The binary word mapping options are Binary or Gray, as specified by the **Symbol set ordering** parameter.
- 2 Maps  $k$  to the intermediate value  $2k-(M-1)$
- 3 Proceeds with block processing as in the integer input mode.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. In this mode, the input to the block can be multiple symbols. The block implicitly implements the rate change by making a size change at the output when compared to the input.

- When you set **Input type** to Integer, the input can be a scalar or a column vector with the length equal to the number of input symbols.
- When you set **Input type** to Bit, the input width must be an integer multiple of the number of bits per symbol.

The output width equals  $N_{\text{Sym}} \times N_{\text{SPS}}$ , where  $N_{\text{Sym}}$  is the number of symbols in the frame and  $N_{\text{SPS}}$  is the number of samples per symbol.

### Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to **Integer**, the input must be a scalar.
- When you set **Input type** to **Bit**, the input width must equal the number of bits per symbol.

The output sample time equals  $T_{\text{Sym}} / N_{\text{SPS}}$ , where  $T_{\text{Sym}}$  is the symbol period and  $N_{\text{SPS}}$  is the number of samples per symbol.

“CPM Modulation”

**Introduced before R2006a**

## CPM Phase Recovery

(To be removed) Recover carrier phase using 2P-Power method

---

**Note** CPM Phase Recovery will be removed in a future release. Use the Carrier Synchronizer block instead.

---

### Library

Carrier Phase Recovery sublibrary of Synchronization

### Description

The CPM Phase Recovery block recovers the carrier phase of the input signal using the 2P-Power method. This feedforward, non-data-aided, clock-aided method is suitable for systems that use these types of baseband modulation: continuous phase modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), and Gaussian minimum shift keying (GMSK). This block is suitable for use with blocks in the Baseband Continuous Phase Modulation library.

If you express the modulation index for CPM as a proper fraction,  $h = K / P$ , then P is the number to which the name "2P-Power" refers. The observation interval parameter must be an integer multiple of the input signal vector length.

The 2P-Power method assumes that the carrier phase is constant over a series of consecutive symbols, and returns an estimate of the carrier phase for the series. The **Observation interval** parameter is the number of symbols for which the carrier phase is assumed constant. This number must be an integer multiple of the input signal's vector length.

### Input and Output Signals

This block accepts a scalar or column vector input signal of type `double` or `single`. The input signal represents a baseband signal at the symbol rate, so it must be complex-valued and must contain one sample per symbol.

The outputs are as follows:

- The output port labeled **Sig** gives the result of rotating the input signal counterclockwise, where the amount of rotation equals the carrier phase estimate. The **Sig** output is thus a corrected version of the input signal, and has the same sample time and vector size as the input signal.
- The output port labeled **Ph** outputs the carrier phase estimate, in degrees, for all symbols in the observation interval. The **Ph** output is a scalar signal.

---

**Note** Because the block internally computes the argument of a complex number, the carrier phase estimate has an inherent ambiguity. The carrier phase estimate is between  $-90/P$  and  $90/P$  degrees and might differ from the actual carrier phase by an integer multiple of  $180/P$  degrees.

---

## Delays and Latency

The block's algorithm requires it to collect symbols during a period of length **Observation interval** before computing a single estimate of the carrier phase. Therefore, each estimate is delayed by **Observation interval** symbols and the corrected signal has a latency of **Observation interval** symbols, relative to the input signal.

## Parameters

### P

The denominator of the modulation index for CPM ( $h = K / P$ ) when expressed as a proper fraction.

### Observation interval

The number of symbols for which the carrier phase is assumed constant. The observation interval parameter must be an integer multiple of the input signal vector length.

When this parameter is exactly equal to the vector length of the input signal, then the block always works. When the integer multiple is not equal to 1, select **Simulation > Configuration Parameters > Solver** and clear the **Treat each discrete rate as a separate task** checkbox.

## Algorithm

If the symbols occurring during the observation interval are  $x(1)$ ,  $x(2)$ ,  $x(3)$ , ...,  $x(L)$ , then the resulting carrier phase estimate is

$$\frac{1}{2P} \arg \left\{ \sum_{k=1}^L (x(k))^{2P} \right\}$$

where the arg function returns values between -180 degrees and 180 degrees.

## CRC-N Generator

(Removed) Generate CRC bits according to CRC method and append to input data frames

## Library

CRC sublibrary of Error Detection and Correction

---

**Note** has been removed. Use General CRC Generator instead.

---

## Description

The CRC-N Generator block generates cyclic redundancy code (CRC) bits for each input data frame and appends them to the frame. The input must be a binary column vector. The CRC-N Generator block is a simplified version of the General CRC Generator block. With the CRC-N Generator block, you can select the generator polynomial for the CRC algorithm from a list of commonly used polynomials, given in the **CRC-N method** field in the block's dialog. N is degree of the generator polynomial. The table below lists the options for the generator polynomial.

CRC Method	Generator Polynomial	Number of Bits
CRC-32	$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$	32
CRC-24	$x^{24}+x^{23}+x^{14}+x^{12}+x^8+1$	24
CRC-16	$x^{16}+x^{15}+x^2+1$	16
Reversed CRC-16	$x^{16}+x^{14}+x+1$	16
CRC-8	$x^8+x^7+x^6+x^4+x^2+1$	8
CRC-4	$x^4+x^3+x^2+x+1$	4

You specify the initial state of the internal shift register using the **Initial states** parameter. You specify the number of checksums that the block calculates for each input

frame using the **Checksums per frame** parameter. For more detailed information, see the reference page for the General CRC Generator block.

This block supports `double` and `boolean` data types. The output data type is inherited from the input.

### Signal Attributes

The General CRC Generator block has one input port and one output port. Both ports accept binary column vector input signals.

## Parameters

### CRC-N method

The generator polynomial for the CRC algorithm.

### Initial states

A binary scalar or a binary row vector of length equal to the degree of the generator polynomial, specifying the initial state of the internal shift register.

### Checksums per frame

A positive integer specifying the number of checksums the block calculates for each input frame.

## Algorithm

For a description of the CRC algorithm as implemented by this block, see “CRC Non-Direct Algorithm” in *Communications Toolbox User's Guide*.

## Schematic of the CRC Implementation

The above circuit divides the polynomial  $a(x) = a_{k-1}x^{k-1} + a_{k-2}x^{k-2} + \dots + a_1x + a_0$  by  $g(x) = g_{r-1}x^{r-1} + g_{r-2}x^{r-2} + \dots + g_1x + g_0$ , and returns the remainder  $d(x) = d_{r-1}x^{r-1} + d_{r-2}x^{r-2} + \dots + d_1x + d_0$ .

The input symbols  $\{a_{k-1}, a_{k-2}, \dots, a_2, a_1, a_0\}$  are fed into the shift register one at a time in order of decreasing index. When the last symbol ( $a_0$ ) works its way out of the register (achieved by augmenting the message with  $r$  zeros), the register contains the coefficients of the remainder polynomial  $d(x)$ .

This remainder polynomial is the checksum that is appended to the original message, which is then transmitted.

# CRC-N Syndrome Detector

(Removed) Detect errors in input data frames according to selected CRC method

## Library

CRC sublibrary of Error Detection and Correction

---

**Note** has been removed. Use General CRC Syndrome Detector instead.

---

## Description

The CRC-N Syndrome Detector block computes checksums for its entire input frame. This block has two output ports. The first output port contains the set of message words with the CRC bits removed. The second output port contains the checksum result, which is a vector of a size equal to the number of checksums. A value of 0 indicates no checksum errors. A value of 1 indicates a checksum error occurred.

The CRC-N Syndrome Detector block is a simplified version of the General CRC Syndrome Detector block. You can select the generator polynomial for the CRC algorithm from a list of commonly used polynomials, given in the **CRC-N method** field in the block's dialog. N is the degree of the generator polynomial. The reference page for the CRC-N Generator block contains a list of the options for the generator polynomial.

The parameter settings for the CRC-N Syndrome Detector block should match those of the CRC-N Generator block.

You specify the initial state of the internal shift register by the **Initial states** parameter. You specify the number of checksums that the block calculates for each input frame by the **Checksums per frame** parameter. For more detailed information, see the reference page for the General CRC Syndrome Detector block.

This block supports `double` and `boolean` data types. The output data type is inherited from the input.

### Signal Attributes

The CRC-N Syndrome Detector block has one input port and two output ports. All three ports accept binary column vector signals.

## Parameters

### CRC-N method

The generator polynomial for the CRC algorithm.

### Initial states

A binary scalar or a binary row vector of length equal to the degree of the generator polynomial, specifying the initial state of the internal shift register.

### Checksums per frame

A positive integer specifying the number of checksums the block calculates for each input frame.

## Algorithm

For a description of the CRC algorithm as implemented by this block, see “Cyclic Redundancy Check Codes”.

## Data Mapper

Map integer symbols from one coding scheme to another

**Library:** Communications Toolbox / Utility Blocks

### Description

The Data Mapper block accepts integer inputs and maps them to integer outputs. The mapping types include: binary to Gray coded, Gray coded to binary, and user defined. Additionally, a pass through option is available.

Gray coding is an ordering of binary numbers such that all adjacent numbers differ by only one bit.

### Input/Output Ports

#### Input

##### Port\_1 — Input port

scalar | column vector | matrix

Input signal, specified as a scalar, vector, or matrix of integers. Elements of the input signal must be nonnegative values. The block truncates noninteger values to integer values. When the input is a matrix, the columns are treated as independent channels.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32

#### Output

##### Port\_2 — Output signal

scalar | column vector | matrix

Output signal, returned as a scalar, column vector, or matrix. The dimensions of the output signal match those of the input signal.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

## Parameters

### Mapping mode — Mapping mode

`Binary to Gray (default)` | `Gray to Binary` | `User Defined` | `Straight through`

Mapping mode, specified as one of the four options. The mapping for the `Binary to Gray` and the `Gray to Binary` modes are shown in the following table when the inputs range from 0 to 7.

Binary to Gray Mode		Gray to Binary Mode	
Input	Output	Input	Output
0	0 (000)	0 (000)	0
1	1 (001)	1 (001)	1
2	3 (011)	2 (010)	3
3	2 (010)	3 (011)	2
4	6 (110)	4 (100)	7
5	7 (111)	5 (101)	6
6	5 (101)	6 (110)	4
7	4 (100)	7 (111)	5

When you select the `User Defined` mode, you can use any arbitrary mapping by providing a vector to specify the output ordering. When you select the `Straight Through` mode, the output equals the input.

### Symbol set size (M) — Symbol set size

`8 (default)` | positive integer

Symbol set size, specified as a positive integer. This parameter restricts the inputs and outputs to integers in the range of 0 to M-1.

### Mapping vector — Maps input elements to the output elements

`[0 1 3 2 7 6 4 5]` (default) | vector

Mapping vector, specified as vector of nonnegative integers whose length equals `N`. This parameter defines the relationship between the input and output integers. For example, the vector `[1 5 0 4 2 3]` defines the following mapping:

0 → 1

1 → 5

2 → 0

3 → 4

4 → 2

5 → 3

## DBPSK Demodulator Baseband

Demodulate DBPSK-modulated data

### Library

PM, in Digital Baseband sublibrary of Modulation

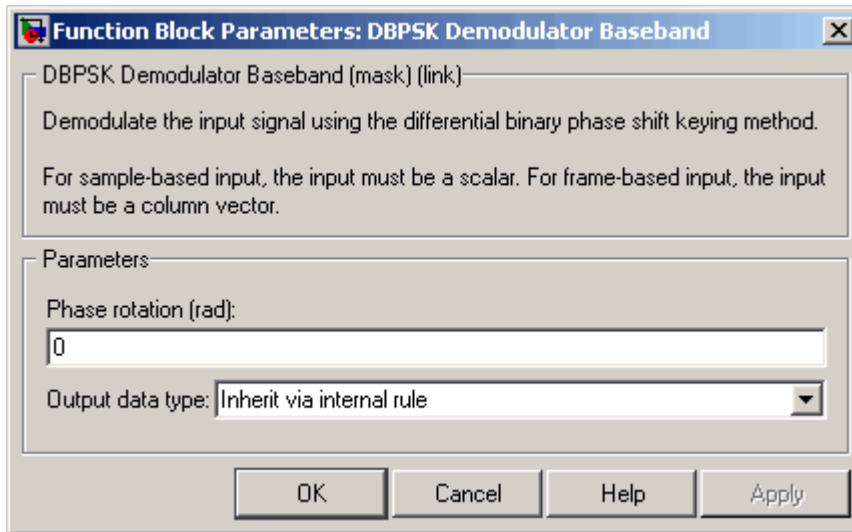

### Description

The DBPSK Demodulator Baseband block demodulates a signal that was modulated using the differential binary phase shift keying method. The input is a baseband representation of the modulated signal.

The input must be a discrete-time complex signal. The block compares the current symbol to the previous symbol. It maps phase differences of  $\theta$  and  $\pi+\theta$ , respectively, to outputs of 0 and 1, respectively, where  $\theta$  is the **Phase rotation** parameter. The first element of the block's output is the initial condition of zero because there is no previous symbol with which to compare the first symbol.

This block accepts a scalar or column vector input signal. The input signal can be of data types `single` and `double`. For information about the data types each block port supports, see “Supported Data Types” on page 3-229.

## Dialog Box

### Phase rotation (rad)

This phase difference between the current and previous modulated symbols results in an output of zero.

### Output data type

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type `single` or `double`.

For additional information, see “Supported Data Types” on page 3-229.

## Supported Data Types

# DBPSK Modulator Baseband

Modulate using differential binary phase shift keying method

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

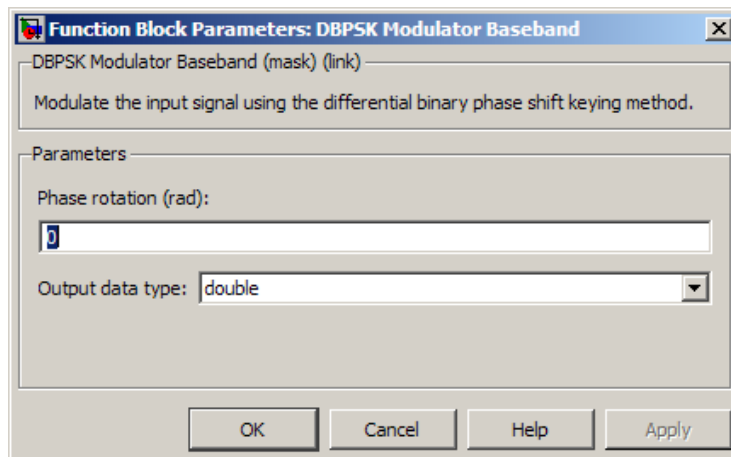

The DBPSK Modulator Baseband block modulates using the differential binary phase shift keying method. The output is a baseband representation of the modulated signal.

This block accepts a scalar or column vector input signal. The input must be a discrete-time binary-valued signal. For information about the data types each block port supports, see “Supported Data Types” on page 3-232.

The following rules govern this modulation method when the **Phase rotation** parameter is  $\theta$ :

- If the first input bit is 0 or 1, respectively, then the first modulated symbol is  $\exp(j\theta)$  or  $-\exp(j\theta)$ , respectively.
- If a successive input bit is 0 or 1, respectively, then the modulated symbol is the previous modulated symbol multiplied by  $\exp(j\theta)$  or  $-\exp(j\theta)$ , respectively.

## Dialog Box

### Phase rotation (rad)

The phase difference between the previous and current modulated symbols when the input is zero.

### Output Data type

The output data type can be either `single` or `double`. By default, the block sets this to `double`.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>
Output	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul>

## Decision Feedback Equalizer

Equalize modulated signals using decision feedback filtering

**Library:** Communications Toolbox / Equalizers

### Description

The Decision Feedback Equalizer block uses a decision feedback filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. Using an estimate of the channel modeled as a finite input response (FIR) filter, the block processes input frames and outputs the estimated signal.

This icon shows the block with all ports enabled for configurations that use the LMS or RLS adaptive algorithm.

This icon shows the block with all ports enabled for configurations that use the CMA adaptive algorithm.

## Ports

### Input

#### **in** — Input signal

column vector

Input signal, specified as a column vector. The vector length of **in** must be equal to an integer multiple of the **Number of input samples per symbol** parameter. For more information, see “Symbol Tap Spacing” on page 3-628.

Data Types: double

Complex Number Support: Yes

#### **Desired** — Training symbols

column vector

Training symbols, specified as a column vector. The vector length of **Desired** must be less than or equal to the length of input **in**. The **Desired** input port is ignored when the **Train** input port is 0.

#### **Dependencies**

To enable this port, set the **Adaptive algorithm** parameter to LMS or RLS.

Data Types: double

Complex Number Support: Yes

#### **Train** — Train equalizer flag

boolean scalar

Train equalizer flag, specified as 1 or 0. The block starts training when this value changes from 0 to 1 (at the rising edge). The block trains until all symbols in the **Desired** input port are processed.

#### **Dependencies**

To enable this port, set the **Adaptive algorithm** parameter to LMS or RLS and select the **Enable training control input** parameter.

Data Types: Boolean

#### **Update** — Update tap weights flag

1 | 0

Update tap weights flag, specified as 1 or 0. The tap weights are updated when this value is 1.

### Dependencies

To enable this port, set the **Adaptive algorithm** parameter to CMA and the **Source of adapt weights flag** parameter to Input port.

Data Types: Boolean

### Reset — Reset equalizer flag

1 | 0

Reset equalizer flag, specified as 1 or 0. If **Reset** is set to 1, the block resets the tap weights before processing the incoming signal. The block performs initial training until all symbols in the **Desired** input port are processed.

### Dependencies

To enable this port, select the **Enable reset input** parameter.

Data Types: Boolean

## Output

### Out — Equalized symbols

column vector

Equalized symbols, returned as a column vector that has the same length as input signal **in**.

This port is unnamed until you select the **Output error signal** or **Output taps weights** parameter.

### Err — Error signal

column vector

Error signal, returned as a column vector that has the same length as input signal **in**.

### w — Tap weights

column vector

Tap weights, returned as an  $N_{\text{Taps}}$ -by-1 vector, where  $N_{\text{Taps}}$  is equal to the sum of the **Number of forward taps** and **Number of feedback taps** parameter values. **w** contains the tap weights from the last tap weight update.

## Parameters

### Structure parameters

#### **Number of forward taps — Number of forward equalizer taps**

5 (default) | positive integer

Number of forward equalizer taps, specified as a positive integer.

#### **Number of feedback taps — Number of feedback equalizer taps**

3 (default) | positive integer

Number of feedback equalizer taps, specified as a positive integer.

#### **Signal constellation — Signal constellation**

`pskmod(0:3,4,pi/4)` (default) | vector

Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: `pskmod(0:3,4,pi/4)`.

**Tunable:** Yes

#### **Number of input samples per symbol — Number of input samples per symbol**

1 (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this parameter to any number greater than 1 effectively creates a fractionally spaced equalizer. For more information, see “Symbol Tap Spacing” on page 3-628.

### Algorithm parameters

#### **Adaptive algorithm — Adaptive algorithm**

LMS (default) | RLS | CMA

Adaptive algorithm used for equalization, specified as one of these values:

- **LMS** — Update the equalizer tap weights using the “Least Mean Square (LMS) Algorithm” on page 3-630.

- RLS — Update the equalizer tap weights using the “Recursive Least Square (RLS) Algorithm” on page 3-631.
- CMA — Update the equalizer tap weights using the “Constant Modulus Algorithm (CMA)” on page 3-631.

#### **Step size — Step size**

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

**Tunable:** Yes

#### **Dependencies**

To enable this parameter, set **Adaptive algorithm** to LMS or CMA.

#### **Forgetting factor — Forgetting factor**

0.99 (default) | scalar in the range (0, 1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

**Tunable:** Yes

#### **Dependencies**

To enable this parameter, set **Adaptive algorithm** to RLS.

#### **Initial inverse correlation matrix — Initial inverse correlation matrix**

0.1 (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an  $N_{\text{Taps}}$ -by- $N_{\text{Taps}}$  matrix.  $N_{\text{Taps}}$  is equal to the sum of the **Number of forward taps** and **Number of feedback taps** parameter values. If you specify this value as a scalar,  $a$ , the equalizer sets the initial inverse correlation matrix to  $a$  times the identity matrix:  $a(\text{eye}(N_{\text{Taps}}))$ .

**Tunable:** Yes

#### **Dependencies**

To enable this parameter, set **Adaptive algorithm** to RLS.

### Control parameters

#### Reference tap — Reference tap

3 (default) | positive integer

Reference tap, specified as a positive integer less than or equal to the **Number of forward taps** parameter value. The equalizer uses the reference tap location to track the main energy of the channel.

#### Input signal delay (samples) — Input signal delay

0 (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the block and to the first call of the block after the **Reset** input port toggles to 1.

#### Dependencies

To enable this parameter, set **Adaptive algorithm** to LMS or RLS.

#### Source of adapt weights flag — Source of adapt tap weights request

Property (default) | Input port

Source of the adapt tap weights request, specified as one of these values:

- **Property** — Specify this value to use the **Adaptive algorithm** parameter to control when the block adapts tap weights.
- **Input port** — Specify this value to use the **Update** input port to control when the block adapts tap weights.

#### Dependencies

To enable this parameter, set **Adaptive algorithm** to CMA.

#### Adapt tap weights — Adapt tap weights

on (default) | off

Select this parameter to adaptively update the equalizer tap weights. If this parameter is cleared, the block keeps the equalizer tap weights unchanged.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to CMA and **Source of adapt weights flag** to Property.

**Initial tap weights source — Source for initial tap weights**

Auto (default) | Property

Source for initial tap weights, specified as one of these values:

- Auto — Initialize the tap weights to the algorithm-specific default values, as described in the **Initial weights** parameter.
- Property — Initialize the tap weights using the **Initial weights** parameter value.

**Initial weights — Initial tap weights**

0 or [0;0;1;0;0] (default) | scalar | column vector

Initial tap weights used by the adaptive algorithm, specified as a scalar or an  $N_{\text{Taps}}$ -by-1 vector.  $N_{\text{Taps}}$  is equal to the sum of the **Number of forward taps** and **Number of feedback taps** parameter values. The default is 0 when the **Adaptive algorithm** parameter is set to LMS or RLS. The default is [0;0;1;0;0] when the **Adaptive algorithm** parameter is set to CMA.

If you specify **Initial weights** as a vector, the vector length must be  $N_{\text{Taps}}$ . If you specify **Initial weights** as a scalar, the equalizer uses scalar expansion to create a vector of length  $N_{\text{Taps}}$  with all values set to **Initial weights**.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Initial tap weights source** to Property.

**Tap weight update period (symbols) — Tap weight update period**

1 (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

**Enable training control input — Enable training control input**

off (default) | on

Select this parameter to enable input port **Train**. If this parameter is cleared, the block does not reenter training mode after the initial tap training.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to LMS or RLS.

**Update tap weights when not training — Update tap weights when not training**

on (default) | off

Select this parameter to use decision directed mode to update equalizer tap weights. If this parameter is cleared, the block keeps the equalizer tap weights unchanged after training.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Adaptive algorithm** to LMS or RLS.

**Enable reset input — Enable reset input**

off (default) | on

Select this parameter to enable input port **Train**. If this parameter is cleared, the block does not reenter training mode after the initial tap training.

**Tunable:** Yes

**Diagnostic parameters**

**Output error signal — Enable error signal output**

off (default) | on

Select this parameter to enable output port **Err** containing the equalizer error signal.

**Tunable:** Yes

**Output taps weights — Enable tap weights output**

off (default) | on

Select this parameter to enable output port **w** containing tap weights from the last tap weight update.

**Tunable:** Yes

### **Simulate using — Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as `Code generation` or `Interpreted execution`.

- `Code generation` -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than `Interpreted execution`.
- `Interpreted execution` -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the `Code generation` method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

## More About

### Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbol-spaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

## Algorithms

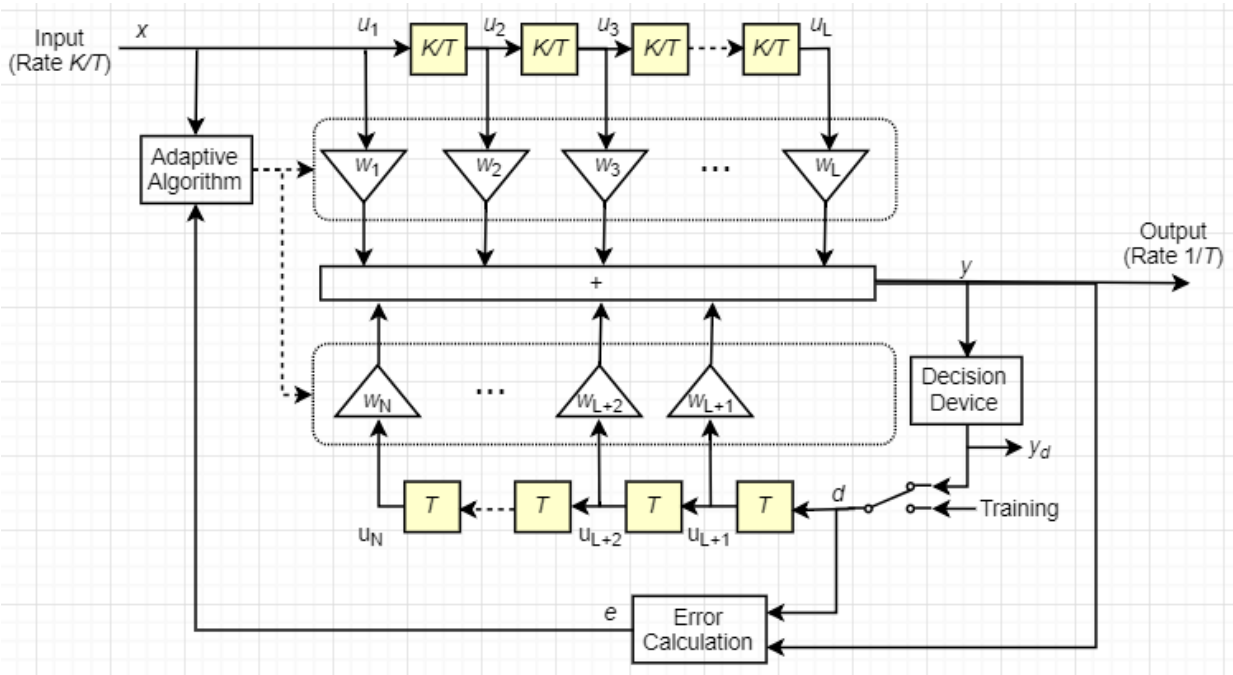

### Decision Feedback Equalizers

A decision feedback equalizer (DFE) is a nonlinear equalizer that reduces intersymbol interference (ISI) in frequency-selective channels. If a null exists in the frequency response of a channel, DFEs do not enhance the noise. A DFE consists of a tapped delay line that stores samples from the input signal and contains a forward filter and a feedback filter. The forward filter is similar to a linear equalizer. The feedback filter contains a tapped delay line whose inputs are the decisions made on the equalized signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

DFEs can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol,  $K$ , is 1. The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol,  $K$ , is an integer greater than 1. Typically,  $K$  is 4 for fractional symbol-spaced equalizers. The output sample rate is  $1/T$  and the input sample rate is  $K/T$ . Tap weight updating occurs at the output rate.

This schematic shows a fractional symbol-spaced DFE with a total of  $N$  weights, a symbol period of  $T$ , and  $K$  samples per symbol. The filter has  $L$  forward weights and  $N-L$  feedback weights. The forward filter is at the top, and the feedback filter is at the bottom. If  $K$  is 1, the result is a symbol-spaced DFE instead of a fractional symbol-spaced DFE.

In each symbol period, the equalizer receives  $K$  input samples at the forward filter and one decision or training sample at the feedback filter. The equalizer then outputs a weighted sum of the values in the forward and feedback delay lines and updates the weights to prepare for the next symbol period.

---

**Note** The algorithm for the Adaptive Algorithm block in the schematic jointly optimizes the forward and feedback weights. Joint optimization is especially important for convergence in the recursive least square (RLS) algorithm.

---

For more information, see “Equalization”.

### Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic,  $w$  is a vector of all weights  $w_i$ , and  $u$  is a vector of all inputs  $u_i$ . Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (\text{StepSize}) u^*e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the `maxstep` object function. The `*` operator denotes the complex conjugate and the error calculation  $e = d - y$ .

## Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic,  $w$  is the vector of all weights  $w_i$ , and  $u$  is the vector of all inputs  $u_i$ . Based on the current set of inputs,  $u$ , and the inverse correlation matrix,  $P$ , the RLS algorithm first computes the Kalman gain vector,  $K$ , as

$$K = \frac{Pu}{(\text{ForgettingFactor}) + u^H Pu}.$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable.  $H$  denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$P_{\text{new}} = \frac{P_{\text{current}}(1 - Ku^H)}{\text{ForgettingFactor}}.$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + K^*e.$$

The `*` operator denotes the complex conjugate and the error calculation  $e = d - y$ .

## Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic,  $w$  is the vector of all weights  $w_i$ , and  $u$  is the vector of all inputs  $u_i$ . Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (\text{StepSize}) u^*e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA

adaptive algorithm, use the `maxstep` object function. The `*` operator denotes the complex conjugate and the error calculation  $e = y(R - |y|^2)$ , where  $R$  is a constant related to the signal constellation.

# Deinterlacer

Distribute elements of input vector alternately between two output vectors

## Library

Sequence Operations

## Description

The Deinterlacer block accepts an even length column vector input signal. The block alternately places the elements in each of two output vectors. As a result, each output vector size is half the input vector size. The output vectors have the same complexity and sample time of the input.

This block accepts a column vector input signal with an even integer length. The block supports the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and `fixed-point`. The output signal inherits its data type from the input signal.

The Deinterlacer block can be useful for separating in-phase and quadrature information from a single vector into separate vectors.

## Examples

If the input vector has the values [1; 5; 2; 6; 3; 7; 4; 8], then the two output vectors are [1; 2; 3; 4] and [5; 6; 7; 8]. Notice that this example is the inverse of the example on the reference page for the Interlacer block.

If the input vector has the values [1; 2; 3; 4; 5; 6], then the two output vectors are [1; 3; 5] and [2; 4; 6].

# Derepeat

Reduce sampling rate by averaging consecutive samples

**Library:** Communications Toolbox / Sequence Operations

## Description

The Derepeat block resamples the discrete input at a rate  $1/N$  times the input sample rate by averaging  $N$  consecutive samples.  $N$  represents the Derepeat factor,  $N$  parameter.

## Ports

### Input

#### In — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: double

Complex Number Support: Yes

### Output

#### Out — Output signal

scalar | vector | matrix

Output signal, returned as a scalar or column vector.

Data Types: double

Complex Number Support: Yes

For more information on the processing rates, see “Single-Rate Processing” on page 3-251, and “Multirate Processing” on page 3-252.

## Parameters

### **Derepeat factor, N — Derepeat factor**

5 (default) | integer

Derepeat factor, specified as an integer. The derepeat factor is the number of consecutive input samples to average to produce each output sample.

Data Types: double

### **Input processing — Input processing control**

Columns as channels (frame based) (default) | Elements as channels (sample based)

Input processing control, specified as one of these options:

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel.

### **Rate options — Block processing rate**

Allow multirate processing (default) | Enforce single-rate processing

Block processing rate, specified as one of these options:

- **Allow multirate processing** — The block downsamples the signal such that the output sample rate is **Derepeat factor, N** times slower than the input sample rate. For more information, see “Multirate Processing” on page 3-252.
- **Enforce single-rate processing** — The block maintains the input sample rate by decreasing the output frame size by a factor equal to the **Derepeat factor, N** parameter value. Also, in single-rate processing mode you can use this block in a triggered subsystem. For more information, see “Single-Rate Processing” on page 3-251

### **Initial condition — Initial condition**

0 (default) | scalar | vector | matrix

Initial condition, specified as a scalar, vector, or matrix. This parameter specifies values that are output when it is too early for the input data to show up in the output. If the dimensions of the **Initial condition** parameter match the output dimensions, then the

parameter represents the initial output value. If **Initial condition** is a scalar, then it represents the initial value of each element in the output. The block does not support empty matrices for initial conditions.

Data Types: double

## Block Characteristics

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### Single-Rate Processing

The block derepeats each frame, treating distinct channels independently. Each element of the output is the average of  $N$  consecutive elements along a *column* of the input matrix.  $N$  must be less than the frame size.  $N$  represents the **Derepeat factor**, **N** parameter.

When you set the **Rate options** parameter to **Enforce single-rate processing**, the input and output of the block have the same sample rate. The block reduces the sampling rate by using a proportionally smaller *frame size* than the input. To process all input values,  $N$  must be an integer factor of the number of rows in the input vector or matrix. For derepetition by a factor of  $N$ , the output frame size is  $1/N$  times the input frame size, but the input and output frame rates are equal. When you use this option, the **Initial condition** parameter does not apply and the block incurs no delay, because the input data immediately shows up in the output.

For example, for a single-channel input with 64 elements that is derepeated by a factor of 4, the block outputs 16 elements. The input and output frame periods are equal.

Also, in single-rate processing mode you can use this block in a triggered subsystem.

## Multirate Processing

When you set the `Rate options` parameter to `Allow multirate processing`, the input and output of the block are the same size, but the sample rate of the output is  $N$  times slower than the input.  $N$  represents the `Derepeat factor`, `N` parameter.

- When you set the `Input processing` parameter to `Elements as channels (sample based)`, the block assumes that the input is a vector or matrix whose elements represent samples from independent channels. The block averages samples from each channel independently over time. The output period is  $N$  times the input period, and the input and output sizes are identical. The output is delayed by one output period, and the first output value is the `Initial condition` value. If you set `Rate options` to `Enforce single-rate processing`, the block generates an error message.
- When you set the `Input processing` parameter to `Columns as channels (frame based)`, the block reduces the sampling rate by using a proportionally longer frame *period* at the output port than at the input port. For derepetition by a factor of  $N$ , the output frame period is  $N$  times the input frame period, but the input and output frame sizes are equal. The output is delayed by one output frame, and the first output frame is the `Initial condition` value. The block derepeats each frame, treating distinct channels independently. Each element of the output is the average of  $N$  consecutive elements along a *column* of the input matrix. The derepeat factor must be less than the frame size.

For example, for a single-channel input with a frame period of 1 second that is derepeated by a factor of 4, the output has a frame period of 4 seconds. The input and output frame sizes are equal.

## Descrambler

Descramble input signal

**Library:** Communications Toolbox / Sequence Operations

## Description

The Descrambler block descrambles a scalar or column vector input signal. The Descrambler block is the inverse of the Scrambler block. If you use the Scrambler block in a transmitter, then you use the Descrambler block in the related receiver.

This schematic shows the descrambler operation. The adders and subtracter operate modulo  $N$ , where  $N$  is the value specified by the Calculation base parameter.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Scramble polynomial parameter, you specify the on or off state for each switch in the descrambler. To make the Descrambler block reverse the operation of the Scrambler block, use the same parameter settings in both blocks. If there is no signal delay between the scrambler and the descrambler, then the **Initial states** in the two blocks must be the same.

To achieve repeatable initial descrambler conditions, you can use one of these optional input ports:

- Select the Reset on nonzero input via port parameter and reset the scrambler with Rst.
- Set the Initial states source parameter to Input port and provide the initial states with ISt.

This block can accept input sequences that vary in length during simulation. For more information about sequences that vary in length, see “Variable-Size Signal Basics” (Simulink).

## Ports

### Input

#### **in** — Input data signal

vector

Input data signal, specified as an  $N_S$ -by-1 vector.  $N_S$  represents the number of samples in the input signal. The input values must be integers from 0 to Calculation base - 1.

Data Types: double

#### **Rst** — Reset scrambler

scalar

Reset scrambler, specified as a scalar. The scrambler is reset if a nonzero input is applied to the port.

#### **Dependencies**

To enable this port, set Initial states source to Dialog Parameter and select Reset on nonzero input via port.

#### **ISt** — Initial states

scalar

Initial states of the descrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of **ISt** must equal the order of the Scramble polynomial parameter. The vector element values must be integers from 0 to Calculation base - 1.

### Dependencies

To enable this port, set Initial states source to Input port.

## Output

### Out1 — Output descrambled data

vector

Output descrambled data, returned as an  $N_S$ -by-1 vector.  $N_S$  equals the number of samples in the input signal.

Data Types: double

## Parameters

### Calculation base — Calculation base

4 (default) | nonnegative integer

Calculation base used in the descrambler for modulo operations, specified as a nonnegative integer. The input and output of this block are integers from 0 to **Calculation base** - 1.

### Scramble polynomial — Polynomial that defines connections in descrambler

'1 + z<sup>-1</sup> + z<sup>-2</sup> + z<sup>-4</sup>' (default) | character vector | integer vector | binary vector

Polynomial that defines the connections in the descrambler, specified as a character vector, integer vector, or binary vector. The **Scramble polynomial** parameter defines if each switch in the descrambler is on or off. Specify the polynomial as:

- A character vector, such as '1 + z<sup>-6</sup> + z<sup>-8</sup>'. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0 -6 -8], listing the descrambler coefficients in order of descending powers of  $z^{-1}$ , where  $p(z^{-1}) = 1 + p_1z^{-1} + p_2z^{-2} + \dots$
- A binary vector, such as [1 0 0 0 0 0 1 0 1], listing the powers of  $z$  that appear in the polynomial that has a coefficient of 1. In this case, the order of the descramble polynomial is one less than the binary vector length.

Example: '1 + z<sup>-6</sup> + z<sup>-8</sup>', [0 -6 -8], and [1 0 0 0 0 0 1 0 1] all represent this polynomial:

$$p(z^{-1}) = 1 + z^{-6} + z^{-8}$$

### Initial states source — Set the source for descrambler initial states

Dialog Parameter (default) | Input port

- Dialog Parameter - Specify descrambler initial states by using the Initial states parameter.
- Input port - Specify descrambler initial states by using the ISt port.

### Initial states — Initial states of descrambler registers

[0 1 2 3] (default) | nonnegative integer vector

Initial states of descrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of **Initial states** must equal the order of the Scramble polynomial parameter. The vector element values must be integers from 0 to Calculation base - 1.

#### Dependencies

This parameter is available when Initial states source is set to Dialog Parameter.

### Reset on nonzero input via port — Reset descrambler via input port

off (default) | on

Select this parameter to reset the Descrambler block via input port Rst.

#### Dependencies

This parameter is available when Initial states source is set to Dialog Parameter.

# Differential Decoder

Decode binary signal using differential coding

## Library

Source Coding

## Description

The Differential Decoder block decodes the binary input signal. The output is the logical difference between the consecutive input element within a channel. More specifically, the block's input and output are related by

$$m(i_0) = d(i_0) \text{ XOR } \text{Initial condition parameter value}$$

$$m(i_k) = d(i_k) \text{ XOR } d(i_{k-1})$$

where

- $d$  is the differentially encoded input.
- $m$  is the output message.
- $i_k$  is the  $k$ th element.
- XOR is the logical exclusive-or operator.

This block accepts a scalar, column vector, or matrix input signal and treats columns as channels.

## Parameters

### Initial conditions

The logical exclusive-or of this value with the initial input value forms the initial output value.

## Supported Data Type

# Discrete-Time VCO

Implement voltage-controlled oscillator in discrete time

## Library

Components sublibrary of Synchronization

## Description

The Discrete-Time VCO (voltage-controlled oscillator) block generates a signal whose frequency shift from the **Quiescent frequency** parameter is proportional to the input signal. The input signal is interpreted as a voltage. If the input signal is  $u(t)$ , then the output signal is

$$y(t) = A_c \cos\left(2\pi f_c t + 2\pi k_c \int^t u(\tau) d\tau + \varphi\right)$$

where  $A_c$  is the **Output amplitude**,  $f_c$  is the **Quiescent frequency**,  $k_c$  is the **Input sensitivity**, and  $\varphi$  is the **Initial phase**

This block uses a discrete-time integrator to interpret the equation above.

This block accepts a scalar-valued input signal with a data type of `single` or `double`. The output signal inherits its data type from the input signal. The block supports double precision only for code generation.

## Parameters

### Output amplitude

The amplitude of the output.

**Quiescent frequency (Hz)**

The frequency of the oscillator output when the input signal is zero.

**Input sensitivity**

This value scales the input voltage and, consequently, the shift from the **Quiescent frequency** value. The units of **Input sensitivity** are Hertz per volt.

**Initial phase (rad)**

The initial phase of the oscillator in radians.

**Sample time**

The calculation sample time.

# DPD

Digital predistorter

**Library:** Communications Toolbox / RF Impairments  
Correction

## Description

Apply digital predistortion (DPD) to a complex baseband signal using a memory polynomial to compensate for nonlinearities in a power amplifier. For more information, see “Digital Predistortion” on page 3-270.

This icon shows the block with all ports enabled.

## Ports

### Input

#### **In** — Input baseband signal

column vector

Input baseband signal, specified as a column vector. This port is unnamed until the **Coefficient source** parameter is set to Input port.

Data Types: double

Complex Number Support: Yes

#### **Coef** — Memory-polynomial coefficients

matrix

Memory-polynomial coefficients, specified as a matrix. The number of rows in the matrix must equal the memory depth of the memory polynomial.

- If the **Polynomial type** parameter is set to `Memory polynomial`, the number of columns in the matrix is the degree of the memory polynomial.
- If **Polynomial type** is set to `Cross-term memory polynomial`, the number of columns in the matrix must equal  $m(n-1)+1$ .  $m$  is the memory depth of the polynomial, and  $n$  is the degree of the memory polynomial.

Example: `complex([1 0 0 0 0; 0 0 0 0 0; 0 0 0 0 0])`

#### Dependencies

To enable this port, set the **Coefficient source** parameter to `Input port`.

Data Types: `double`

Complex Number Support: Yes

## Output

### Out — Predistorted baseband signal

column vector

Predistorted baseband signal, returned as a column vector of the same length as the input signal.

## Parameters

### Polynomial type — Polynomial type

`Memory polynomial` (default) | `Cross-term memory polynomial`

Polynomial type used for predistortion, specified as one of these values:

- `Memory polynomial` — Computes predistortion coefficients by using a memory polynomial without cross terms
- `Cross-term memory polynomial` — Computes predistortion coefficients by using a memory polynomial with cross terms

For more information, see “Digital Predistortion” on page 3-270.

**Coefficient source — Source of memory-polynomial coefficients**

Property (default) | Input port

Source of the memory polynomial coefficients, specified as one of these values:

- **Property** — Specify this value to use the **Coefficients** parameter to define the memory-polynomial coefficients
- **Input port** — Specify this value to use the **Coef** input port to define the memory-polynomial coefficients

**Coefficients — Memory-polynomial coefficients**
`complex([1 0 0 0 0; 0 0 0 0 0; 0 0 0 0 0])` (default) | matrix

Memory-polynomial coefficients, specified as a matrix. The number of rows must equal the memory depth of the memory polynomial.

- If the **Polynomial type** is set to **Memory polynomial**, the number of columns is the degree of the memory polynomial.
- If the **Polynomial type** is set to **Cross-term memory polynomial**, the number of columns must equal  $m(n-1)+1$ .  $m$  is the memory depth of the polynomial, and  $n$  is the degree of the memory polynomial.

For more information, see “Digital Predistortion” on page 3-270.

**Dependencies**

To enable this parameter, set **Coefficient source** to **Property**.

Data Types: double

Complex Number Support: Yes

**Simulate using — Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as **Code generation** or **Interpreted execution**.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than **Interpreted execution**.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the **Code generation** method, but the

speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

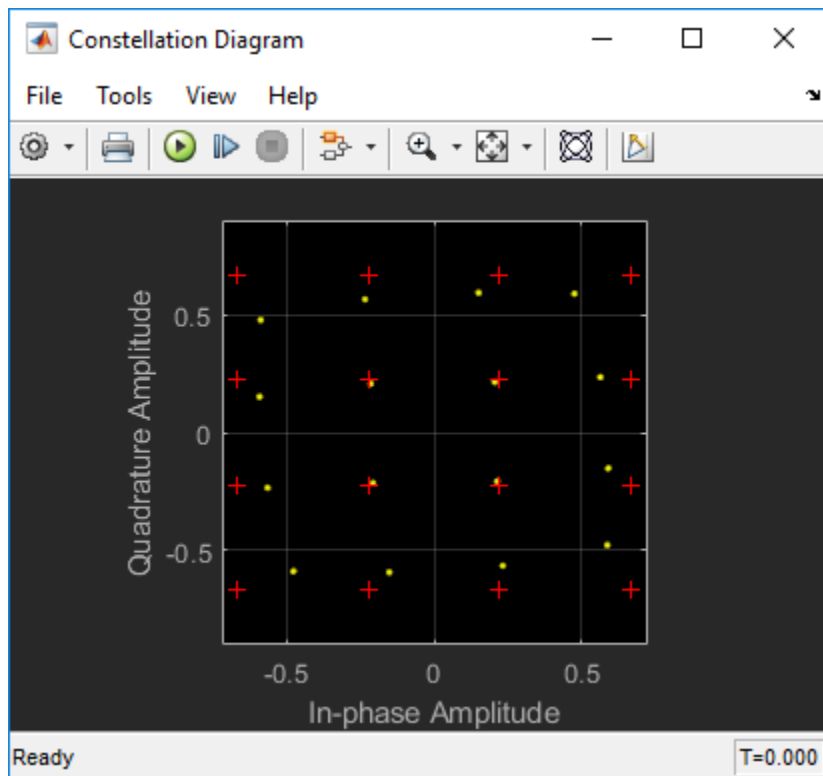

## Block Characteristics

<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

## More About

### Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.

The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is  $x(n)$ , and the predistortion function is  $f(u(n))$ , where  $u(n)$  is the true signal to be amplified, the PA output is approximately equal to  $G \times u(n)$ , where  $G$  is the desired amplitude gain of the PA.

The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} c_m \times u(n-m) + \sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{mjk} \times u(n-m) \times |u(n-j)|^k.$$

The memory polynomial with cross terms has  $(M+M \times M \times (K-1))$  coefficients for  $c_m$  and  $a_{mjk}$ .

- The memory polynomial without cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{mk} \times u(n-m) \times |u(n-m)|^k.$$

The polynomial without cross terms has  $M \times K$  coefficients for  $a_{mk}$ .

### Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function  $f(u(n))$  to predistort input signal  $u(n)$  which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain,  $\{y(n)/G\}$ , to the PA input,  $\{x(n)\}$ , provides a good approximation to the function  $f(u(n))$ , needed to predistort  $\{u(n)\}$  to produce  $\{x(n)\}$ .

Referring to the memory polynomial equations above, estimates are computed for the memory-polynomial coefficients:

- $c_m$  and  $a_{mjk}$  for a memory polynomial with cross terms
- $a_{mk}$  for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing  $\{u(n)\}$  with  $\{y(n)/G\}$ . The function order and

dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see “Power Amplifier Characterization with DPD for Reduced Signal Distortion”.

For background reference material, see the works listed in [1] and [2].

## Description

Estimate memory-polynomial coefficients for digital predistortion (DPD) of a nonlinear power amplifier.

This icon shows the block with all ports enabled.

## Ports

### Input

#### **PA In — Power amplifier baseband-equivalent input**

column vector

Power amplifier baseband-equivalent input, specified as a column vector.

Data Types: `double`

Complex Number Support: Yes

#### **PA Out — Power amplifier baseband-equivalent output**

column vector

Power amplifier baseband-equivalent output, specified as a column vector of the same length as **PA In**.

Data Types: double

Complex Number Support: Yes

#### **Forgetting Factor — Forgetting factor**

scalar in the range (0, 1]

Forgetting factor used by the recursive least squares algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the convergence time but causes the output estimates to be less stable.

#### **Dependencies**

To enable this port, set **Algorithm** to Recursive least squares and set **Forgetting factor source** to Input port.

Data Types: double

## **Output**

#### **Out — Memory-polynomial coefficients**

matrix

Memory-polynomial coefficients, returned as a matrix. For more information, see “Digital Predistortion” on page 3-279.

## **Parameters**

#### **Desired amplitude gain (dB) — Desired amplitude gain**

10 (default) | scalar

Desired amplitude gain in dB, specified as a scalar. This parameter value expresses the desired signal gain at the compensated amplifier output.

**Tunable:** Yes

Data Types: double

#### **Polynomial type — Polynomial type**

Memory polynomial (default) | Cross-term memory polynomial

Polynomial type used for predistortion, specified as one of these values:

- `Memory polynomial` — Computes predistortion coefficients by using a memory polynomial without cross terms
- `Cross-term memory polynomial` — Computes predistortion coefficients by using a memory polynomial with cross terms

For more information, see “Digital Predistortion” on page 3-279.

### **Degree — Memory-polynomial degree**

5 (default) | positive integer

Memory-polynomial degree, specified as a positive integer.

Data Types: double

### **Memory depth — Memory-polynomial depth**

3 (default) | positive integer

Memory-polynomial depth in samples, specified as a positive integer.

Data Types: double

### **Algorithm — Estimation algorithm**

Least squares (default) | Recursive least squares

Adaptive algorithm used for equalization, specified as one of these values:

- `Least squares` — Estimate the memory-polynomial coefficients by using a least squares algorithm
- `Recursive least squares` — Estimate the memory-polynomial coefficients by using a recursive least squares algorithm

For algorithm reference material, see the works listed in [1] and [2].

Data Types: char | string

### **Forgetting factor source — Source of forgetting factor**

Property (default) | Input port

Source of the forgetting factor, specified as one of these values:

- `Property` — Specify this value to use the **Forgetting factor** parameter to specify the forgetting factor.

- **Input port** — Specify this value to use the **Forgetting Factor** input port to specify the forgetting factor.

#### Dependencies

To enable this parameter, set **Algorithm** to Recursive least squares.

Data Types: double

#### Forgetting factor — Forgetting factor

0.99 (default) | scalar in the range (0, 1]

Forgetting factor used by the recursive least squares algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the convergence time but causes the output estimates to be less stable.

#### Dependencies

To enable this parameter, set **Algorithm** to Recursive least squares and set **Forgetting factor source** to Property.

Data Types: double

#### Initial coefficient estimate — Initial coefficient estimate

[] (default) | matrix

Initial coefficient estimate for the recursive least squares algorithm, specified as a matrix.

- If you specify this value as an empty matrix, the initial coefficient estimate for the recursive least squares algorithm is chosen automatically to correspond to a memory polynomial that is an identity function, so that the output is equal to input.
- If you specify this value as a nonempty matrix, the number of rows must be equal to the **Memory depth** parameter value.
  - If the **Polynomial type** parameter is set to **Memory polynomial**, the number of columns is the degree of the memory polynomial.
  - If the **Polynomial type** parameter is set to **Cross-term memory polynomial**, the number of columns must equal  $m(n-1)+1$ .  $m$  is the memory depth of the polynomial, and  $n$  is the degree of the memory polynomial.

For more information, see “Digital Predistortion” on page 3-279.

**Dependencies**

To enable this parameter, set **Algorithm** to Recursive least squares.

Data Types: double

Complex Number Support: Yes

**Simulate using – Type of simulation to run**

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

**Block Characteristics**

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

**More About****Digital Predistortion**

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic

range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.

The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is  $x(n)$ , and the predistortion function is  $f(u(n))$ , where  $u(n)$  is the true signal to be amplified, the PA output is approximately equal to  $G \times u(n)$ , where  $G$  is the desired amplitude gain of the PA.

The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} c_m \times u(n-m) + \sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{mjk} \times u(n-m) \times |u(n-j)|^k.$$

The memory polynomial with cross terms has  $(M+M \times M \times (K-1))$  coefficients for  $c_m$  and  $a_{mjk}$ .

- The memory polynomial without cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{mk} \times u(n-m) \times |u(n-m)|^k.$$

The polynomial without cross terms has  $M \times K$  coefficients for  $a_{mk}$ .

### Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function  $f(u(n))$  to predistort input signal  $u(n)$  which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain,  $\{y(n)/G\}$ , to the PA input,  $\{x(n)\}$ , provides a good approximation to the function  $f(u(n))$ , needed to predistort  $\{u(n)\}$  to produce  $\{x(n)\}$ .

Referring to the memory polynomial equations above, estimates are computed for the memory-polynomial coefficients:

- $c_m$  and  $a_{mjk}$  for a memory polynomial with cross terms
- $a_{mk}$  for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing  $\{u(n)\}$  with  $\{y(n)/G\}$ . The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see “Power Amplifier Characterization with DPD for Reduced Signal Distortion”.

For background reference material, see the works listed in [1] and [2].

## DQPSK Demodulator Baseband

Demodulate DQPSK-modulated data

### Library

PM, in Digital Baseband sublibrary of Modulation

### Description

The DQPSK Demodulator Baseband block demodulates a signal that was modulated using the differential quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

The input must be a discrete-time complex signal. The output depends on the phase difference between the current symbol and the previous symbol. The first integer (or binary pair, if you set the **Output type** parameter to Bit) at the block output is the initial condition of zero because there is no previous symbol.

This block accepts either a scalar or column vector input signal. For information about the data types each block port supports, see “Supported Data Types” on page 3-286.

### Outputs and Constellation Types

When you set **Output type** parameter to Integer, the block maps a phase difference of

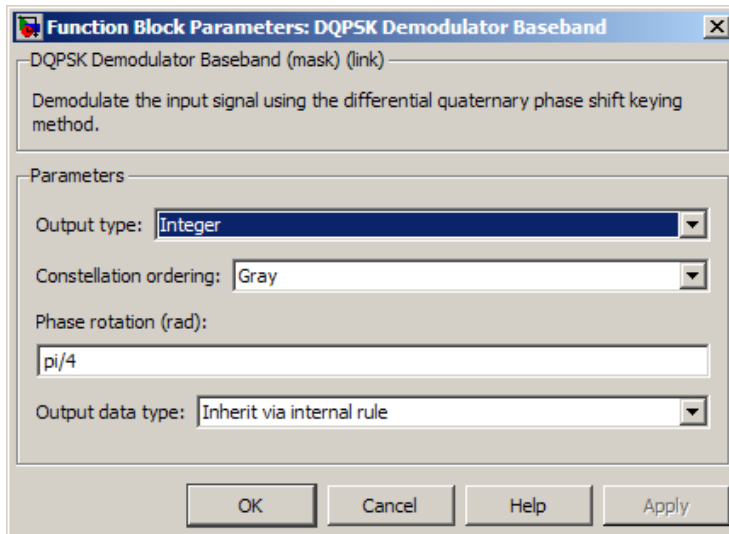

$$\theta + \frac{\pi m}{2}$$

to  $m$ , where  $\theta$  represents the **Phase rotation** parameter and  $m$  is 0, 1, 2, or 3.

When you set the **Output type** parameter to Bit, then the output contains pairs of binary values. The reference page for the DQPSK Modulator Baseband block shows which phase

differences map to each binary pair, for the cases when the **Constellation ordering** parameter is either Binary or Gray.

## Dialog Box

### Output type

Determines whether the output consists of integers or pairs of bits.

### Constellation ordering

Determines how the block maps each integer to a pair of output bits.

### Phase rotation (rad)

This phase difference between the current and previous modulated symbols results in an output of zero.

### Output data type

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type single or double.

For integer outputs, this block can output the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `single`, and `double`. For bit outputs, output can be `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, or `double`.

## Supported Data Types

**Introduced before R2006a**

# DQPSK Modulator Baseband

Modulate using differential quadrature phase shift keying method

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The DQPSK Modulator Baseband block modulates using the differential quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

The input must be a discrete-time signal. For information about the data types each block port supports, see “Supported Data Types” on page 3-290.

## Integer-Valued Signals and Binary-Valued Signals

When you set the **Input type** parameter to **Integer**, the valid input values are 0, 1, 2, and 3. In this case, the block accepts a scalar or column vector input signal. If the first input is  $m$ , then the modulated symbol is

$$\exp(j\theta) + \exp(j\theta + jm\pi/2)$$

where  $\theta$  represents the **Phase rotation** parameter. If a successive input is  $m$ , then the modulated symbol is the previous modulated symbol multiplied by  $\exp(j\theta + jm\pi/2)$ .

When you set the **Input type** parameter to **Bit**, the input contains pairs of binary values. In this case, the block accepts a column vector whose length is an even integer. The following figure shows the complex numbers by which the block multiplies the previous symbol to compute the current symbol, depending on whether you set the **Constellation ordering** parameter to **Binary** or **Gray**. The following figure assumes that you set the

**Phase rotation** parameter to  $\frac{\pi}{4}$ ; in other cases, the two schematics would be rotated accordingly.

The following figure shows the signal constellation for the DQPSK modulation method when you set the **Phase rotation** parameter to  $\frac{\pi}{4}$ . The arrows indicate the four possible transitions from each symbol to the next symbol. The Binary and Gray options determine which transition is associated with each pair of input values.

More generally, if the **Phase rotation** parameter has the form  $\frac{\Pi}{k}$  for some integer  $k$ , then the signal constellation has  $2k$  points.

## Dialog Box

### Input type

Indicates whether the input consists of integers or pairs of bits.

### Constellation ordering

Determines how the block maps each pair of input bits to a corresponding integer, using either a Binary or Gray mapping scheme.

### Phase rotation (rad)

The phase difference between the previous and current modulated symbols when the input is zero.

### Output Data type

The output data type can be either single or double. By default, the block sets this to double.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li><li>• Boolean when <b>Input type</b> is Bit</li><li>• 8-, 16-, and 32-bit signed integers</li><li>• 8-, 16-, and 32-bit unsigned integers</li></ul>
Output	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul>

# DSB AM Demodulator Passband

Demodulate DSB-AM-modulated data

## Library

Analog Passband Modulation, in Modulation

## Description

The DSB AM Demodulator Passband block demodulates a signal that was modulated using double-sideband amplitude modulation. The block uses the envelope detection method. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

In the course of demodulating, this block uses a filter whose order, coefficients, passband ripple and stopband ripple are described by their respective lowpass filter parameters.

Typically, an appropriate **Carrier frequency** value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the **Carrier frequency** parameter.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### Input signal offset

The same as the **Input signal offset** parameter in the corresponding DSB AM Modulator Passband block.

**Carrier frequency (Hz)**

The frequency of the carrier in the corresponding DSB AM Modulator Passband block.

**Initial phase (rad)**

The initial phase of the carrier in radians.

**Lowpass filter design method**

The method used to generate the filter. Available methods are Butterworth, Chebyshev type I, Chebyshev type II, and Elliptic.

**Filter order**

The order of the lowpass digital filter specified in the **Lowpass filter design method** field .

**Cutoff frequency (Hz)**

The cutoff frequency of the lowpass digital filter specified in the **Lowpass filter design method** field in Hertz.

**Passband ripple (dB)**

Applies to Chebyshev type I and Elliptic filters only. This is peak-to-peak ripple in the passband in dB.

**Stopband ripple (dB)**

Applies to Chebyshev type II and Elliptic filters only. This is the peak-to-peak ripple in the stopband in dB.

## **Pair Block**

DSB AM Modulator Passband

**Introduced before R2006a**

# DSB AM Modulator Passband

Modulate using double-sideband amplitude modulation

## Library

Analog Passband Modulation, in Modulation

## Description

The DSB AM Modulator Passband block modulates using double-sideband amplitude modulation. The output is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

If the input is  $u(t)$  as a function of time  $t$ , then the output is

$$(u(t) + k)\cos(2\pi f_c t + \theta)$$

where:

- $k$  is the **Input signal offset** parameter.
- $f_c$  is the **Carrier frequency** parameter.
- $\theta$  is the **Initial phase** parameter.

It is common to set the value of  $k$  to the maximum absolute value of the negative part of the input signal  $u(t)$ .

Typically, an appropriate **Carrier frequency** value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the **Carrier frequency** parameter.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### Input signal offset

The offset factor  $k$ . This value should be greater than or equal to the absolute value of the minimum of the input signal.

### Carrier frequency (Hz)

The frequency of the carrier.

### Initial phase (rad)

The initial phase of the carrier.

# DSBSC AM Demodulator Passband

Demodulate DSBSC-AM-modulated data

## Library

Analog Passband Modulation, in Modulation

## Description

The DSBSC AM Demodulator Passband block demodulates a signal that was modulated using double-sideband suppressed-carrier amplitude modulation. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

In the course of demodulating, this block uses a filter whose order, coefficients, passband ripple and stopband ripple are described by their respective lowpass filter parameters.

Typically, an appropriate **Carrier frequency** value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the **Carrier frequency** parameter.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### Carrier frequency (Hz)

The carrier frequency in the corresponding DSBSC AM Modulator Passband block.

**Initial phase (rad)**

The initial phase of the carrier in radians.

**Lowpass filter design method**

The method used to generate the filter. Available methods are Butterworth, Chebyshev type I, Chebyshev type II, and Elliptic.

**Filter order**

The order of the lowpass digital filter specified in the **Lowpass filter design method** field .

**Cutoff frequency (Hz)**

The cutoff frequency of the lowpass digital filter specified in the Lowpass filter design method field in Hertz.

**Passband Ripple (dB)**

Applies to Chebyshev type I and Elliptic filters only. This is peak-to-peak ripple in the passband in dB.

**Stopband Ripple (dB)**

Applies to Chebyshev type II and Elliptic filters only. This is the peak-to-peak ripple in the stopband in dB.

# DVBS-APSK Demodulator Baseband

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) demodulation

**Library:** Communications Toolbox / Modulation / Digital  
Baseband Modulation / APM  
Communications Toolbox / Modulation / Digital  
Baseband Modulation / Standard-Compliant

## Description

The DVBS-APSK Demodulator Baseband block demodulates the input signal using Digital Video Broadcasting (“DVB-S2/S2X/SH” on page 3-305) standard-specific amplitude phase shift keying (APSK) demodulation. For a description of DVB-compliant APSK demodulation, see “DVB Compliant APSK Hard Demodulation” on page 3-305 and “DVB Compliant APSK Soft Demodulation” on page 3-306.

This icon shows the block with all ports enabled:

## Ports

### Input

**In** — DVB-S2/S2X/SH standard-specific APSK modulated signal

scalar | vector | matrix

DVB-S2/S2X/SH standard-specific APSK modulated signal, specified as a scalar, vector, or matrix. When this input is a matrix, each column is treated as an independent channel. This port is unnamed until the Var port is enabled.

Data Types: double | single

Complex Number Support: Yes

### Var — Noise variance

positive scalar | vector of positive values

Noise variance, specified as a positive scalar or vector of positive values. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “DVB Compliant APSK Soft Demodulation” on page 3-306 for demodulation decision type considerations.

### Dependencies

This parameter applies when Noise variance source is set to Input port.

Data Types: double | single

## Output

### Out — Demodulated signal

scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of the demodulated signal depend on the specified Output type and Decision type. This port is unnamed on the block.

Output type	Decision type	Demodulated Signal Description	Dimensions of Demodulated Signal
Integer	—	Demodulated integer values in the range $[0, (M - 1)]$	The output signal has the same dimensions as the input signal.
Bit	Hard decision	Demodulated bits	The number of rows in the output signal is $\log_2(M)$ times the number of rows in the input signal. Each demodulated symbol is mapped to a group of $\log_2(M)$ elements in a column, where the first element represents the MSB and the last element represents the LSB.
	Log-likelihood ratio	Log-likelihood ratio value for each bit	
	Approximate log-likelihood ratio	Approximate log-likelihood ratio value for each bit	

Output type	Decision type	Demodulated Signal Description	Dimensions of Demodulated Signal
$M$ is the value of Modulation order.			

Use Output data type to specify the output data type.

## Parameters

### DVB standard suffix — Standard suffix

S2 | S2X | SH

Standard suffix for DVB modulation variant, specified as S2, S2X, or SH.

### Frame length — Frame length

Normal (default) | Short

Frame length, specified as Normal or Short.

### Dependencies

This parameter applies only when DVB standard suffix is set to S2 or S2X.

### Modulation order — Modulation order

16 (default) | integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the constellation of the input signal. The list of valid modulation orders varies depending on the setting for DVB standard suffix and Frame length.

DVB standard suffix	Frame length	Modulation order Options
S2	Normal or Short	16 or 32
S2X	Normal	8, 16, 32, 64, or 256
	Short	16 or 32
SH	Not applicable	16

### Code identifier — Code identifier

2/3 | character vector

Code identifier, specified as a character vector. The list of valid code identifier values varies depending on the setting for DVB standard suffix, Frame length, and Modulation order. This table lists the available options for **Code identifier** values.

Modulation order	DVB standard suffix	Frame length	Code identifier Options
8	S2X	Normal	100/180 or 104/180
16	S2 or S2X	Normal	2/3, 3/4, 4/5, 5/6, 8/9, or 9/10
		Short	2/3, 3/4, 4/5, 5/6, or 8/9
16	S2X	Normal	26/45, 3/5, 28/45, 23/36, 25/36, 13/18, 140/180, 154/180, 100/180, 96/180, 90/180, 18/30, or 20/30
		Short	7/15, 8/16, 26/45, 3/5, or 32/45
32	S2 or S2X	Normal	3/4, 4/5, 5/6, 8/9, or 9/10
		Short	3/4, 4/5, 5/6, or 8/9
32	S2X	Normal	128/180, 132/180, 140/180, or 2/3
		Short	2/3 or 32/45
64	S2X	Normal	128/180 , 132/180, 7/9, 4/5, or 5/6
128	S2X	Normal	135/180 or 140/180
256	S2X	Normal	116/180, 124/180, 128/180, 20/30, or 135/180

For more information, refer to Tables 9 and 10 in the DVB-S2 standard [1] and Table 17a in the DVB-S2X standard [2].

### **Dependencies**

This parameter applies only when **DVB standard suffix** is set to S2 or S2X.

### **Constellation scaling – Constellation scaling**

Outer radius as 1 (default) | Unit average power

Constellation scaling, specified as Outer radius as 1 or Unit average power.

### **Dependencies**

This input argument applies only when DVB standard suffix is set to S2 or S2X.

### **Output type – Output type**

Integer (default) | Bit

Output type, specified as Integer or Bit.

Data Types: char | string

### **Decision type – Demodulation decision type**

Hard decision (default) | Log-likelihood ratio | Approximate log-likelihood ratio

Demodulation decision type, specified as Hard decision, Log-likelihood ratio, or Approximate log-likelihood ratio. See “DVB Compliant APSK Soft Demodulation” on page 3-306 for algorithm selection considerations.

### **Dependencies**

This parameter applies when Output type is set to Bit.

### **Noise variance source – Noise variance source**

Property (default) | Input port

Noise variance source, specified as:

- Property — The noise variance is set using the Noise variance parameter.
- Input port — The noise variance is set using the Var input port.

### **Noise variance – Noise variance**

1 (default) | positive scalar | vector of positive values

Noise variance, specified as a positive scalar or vector of positive values.

- When specified as a scalar, that value is used on all elements in the input signal.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal. Each noise variance vector element is applied to its corresponding column in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “DVB Compliant APSK Soft Demodulation” on page 3-306 for demodulation decision type considerations.

**Dependencies**

This parameter applies when Noise variance source is set to Property and Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.

Data Types: double

**Output data type — Output data type**

double (default) | . . .

Output data type, specified as one of the acceptable values from this table. Acceptable **Output data type** values depend on the Output type and Decision type parameter values.

Output type	Decision type	Output data type Options
Integer	Not applicable	double, single, int8, uint8, int16, uint16, int32, or uint32
Bit	Hard decision	double, single, int8, uint8, int16, uint16, int32, uint32, or logical
	Log-likelihood ratio or Approximate log-likelihood ratio	The output signal is the same data type as the input signal.

**Dependencies**

This parameter applies only when Output type is set to Integer or when Output type is set to Bit and Decision type is set to Hard decision.

**Simulate using — Type of simulation to run**

Interpreted execution (default) | Code generation

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

For information on execution speed, see “Tips” on page 3-307.

## Block Characteristics

<b>Data Types</b>	Boolean   double   integer   single
<b>Multidimensional Signals</b>	yes
<b>Variable-Size Signals</b>	no

## More About

### DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see [1], [2], and [3], respectively.

### DVB Compliant APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [4].

### DVB Compliant APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

---

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

---

## Tips

- For faster execution of the DVBS-APSK Demodulator Baseband block, set the Simulate using parameter to:
  - `Code generation` when using hard decision demodulation.
  - `Interpreted execution` when using soft decision demodulation.

## Description

The DVBS-APSK Modulator Baseband block modulates the input signal using Digital Video Broadcasting (“DVB-S2/S2X/SH” on page 3-313) standard-specific amplitude phase shift keying (APSK) modulation.

## Ports

### Input

#### In — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The input signal must be binary values or integers in the range  $[0, (M - 1)]$ , where  $M$  is the Modulation order. This port is unnamed on the block.

---

**Note** To process the input signal as binary elements, set the Input type parameter value to `Bit`. For binary inputs, the number of rows must be an integer multiple of  $\log_2(M)$ . Groups of  $\log_2(M)$  bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

## Output

### Out — DVB-S2/S2X/SH standard-specific APSK modulated signal

scalar | vector | matrix

DVB-S2/S2X/SH standard-specific APSK modulated signal, returned as a complex scalar, vector, or matrix. The output signal dimensions depend on the specified Input type value. This port is unnamed on the block.

Input type	Dimensions of Output Signal
Integer	The output signal has the same dimensions as the input signal.
Bit	The number of rows in the output signal equals the number of rows in the input signal divided by $\log_2(M)$ , where $M$ is the Modulation order.

Use Output data type to specify the output data type.

## Parameters

### DVB standard suffix — Standard suffix

S2 (default) | S2X | SH

Standard suffix for DVB modulation variant, specified as S2, S2X, or SH.

### Frame length — Frame length

Normal (default) | Short

Frame length, specified as Normal or Short.

### Dependencies

This parameter applies only when DVB standard suffix is set to S2 or S2X.

### Modulation order — Modulation order

16 (default) | 8 | 32 | 64 | 256

Modulation order,  $M$ , specified as a power of two. The modulation order specifies the total number of points in the constellation of the output signal. The list of valid modulation orders varies depending on the values of DVB standard suffix and Frame length.

DVB standard suffix	Frame length	Modulation order Options
S2	Normal or Short	16 or 32
S2X	Normal	8, 16, 32, 64, or 256
	Short	16 or 32
SH	Not applicable	16

### Code identifier – Code identifier

2/3 | character vector

Code identifier, specified as a character vector. The list of valid code identifier values varies depending on the specified values of DVB standard suffix, Frame length, and Modulation order. This table lists the options for **Code identifier** values.

Modulation order	DVB standard suffix	Frame length	Code identifier Options
8	S2X	Normal	100/180 or 104/180
16	S2 or S2X	Normal	2/3, 3/4, 4/5, 5/6, 8/9, or 9/10
		Short	2/3, 3/4, 4/5, 5/6, or 8/9
16	S2X	Normal	26/45, 3/5, 28/45, 23/36, 25/36, 13/18, 140/180, 154/180, 100/180, 96/180, 90/180, 18/30, or 20/30
		Short	7/15, 8/16, 26/45, 3/5, or 32/45
32	S2 or S2X	Normal	3/4, 4/5, 5/6, 8/9, or 9/10
		Short	3/4, 4/5, 5/6, or 8/9
32	S2X	Normal	128/180, 132/180, 140/180, or 2/3

Modulation order	DVB standard suffix	Frame length	Code identifier Options
		Short	2/3 or 32/45
64	S2X	Normal	128/180 , 132/180, 7/9, 4/5, or 5/6
128	S2X	Normal	135/180 or 140/180
256	S2X	Normal	116/180, 124/180, 128/180, 20/30, or 135/180

For more information, refer to Tables 9 and 10 in the DVB-S2 standard [1] and Table 17a in the DVB-S2X standard [2].

**Dependencies**

This parameter applies only when **DVB standard suffix** is set to S2 or S2X.

**Constellation scaling – Constellation scaling**

Outer radius as 1 (default) | Unit average power

Constellation scaling, specified as Outer radius as 1 or Unit average power.

**Dependencies**

This parameter applies only when DVB standard suffix is set to S2 or S2X.

**Input type – Input type**

Integer (default) | Bit

Input type, specified as Integer or Bit. To use Integer, the input signal must consist of integers in the range  $[0, (M - 1)]$ . To use Bit, the input data must contain binary values, and the number of rows must be an integer multiple of  $\log_2(M)$ , where  $M$  is the Modulation order.

**Output data type – Output data type**

double (default) | single

Output data type, specified as double or single.

**View Constellation – Plot reference constellation**

button

To plot the reference constellation, click the **View Constellation** button.

### Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In **Interpreted execution** mode, you can debug the source code of the block.

# Error Rate Calculation

Compute bit error rate or symbol error rate of input data

## Library

Comm Sinks

## Description

The Error Rate Calculation block compares input data from a transmitter with input data from a receiver. It calculates the error rate as a running statistic, by dividing the total number of unequal pairs of data elements by the total number of input data elements from one source.

Use this block to compute either symbol or bit error rate, because it does not consider the magnitude of the difference between input data elements. If the inputs are bits, then the block computes the bit error rate. If the inputs are symbols, then it computes the symbol error rate.

---

**Note** When you set the **Output data** parameter to **Workspace**, the block generates no code. Similarly, no data is saved to the workspace if the **Simulation mode** is set to **Accelerator** or **Rapid Accelerator**. If you need error rate information in these cases, set **Output data** to **Port**.

---

## Input Data

This block has between two and four input ports, depending on how you set the dialog parameters. The input ports marked Tx and Rx accept transmitted and received signals, respectively. The Tx and Rx signals must share the same sampling rate.

The Tx and Rx input ports accept scalar or column vector signals. For information about the data types each block port supports, see the “Supported Data Types” on page 3-321 table on this page.

If Tx is a scalar and Rx is a vector, or vice-versa, then the block compares the scalar with each element of the vector. In this case, the block behaves as if you had preprocessed the scalar signal by using the Repeat block with the **Rate options** parameter set to Enforce single rate.

If you select **Reset port**, then an additional input port appears, labeled Rst. The Rst input accepts only a scalar signal (of type double or boolean) and must have the same port sample time as the Tx and Rx ports. When the Rst input is nonzero, the block clears and then recomputes the error statistics.

If you set the **Computation mode** parameter to Select samples from port, then an additional input port appears, labeled Sel. The Sel input indicates which elements of a frame are relevant for the computation. The Sel input can be a column vector of type double.

The guidelines below indicate how you should configure the inputs and the dialog parameters depending on how you want this block to interpret your Tx and Rx data.

- If both data signals are scalar, then this block compares the Tx scalar signal with the Rx scalar signal. For this configuration, use the **Computation mode** parameter default value, Entire frame.
- If both data signals are vectors, then this block compares some or all of the Tx and Rx data:
  - If you set the **Computation mode** parameter to Entire frame, then the block compares all of the Tx frame with all of the Rx frame.
  - If you set the **Computation mode** parameter to Select samples from mask, then the **Selected samples from frame** field appears in the dialog. This parameter field accepts a vector that lists the indices of those elements of the Rx frame that you want the block to consider. For example, to consider only the first and last elements of a length-six receiver frame, set the **Selected samples from frame** parameter to [1 6]. If the **Selected samples from frame** vector includes zeros, then the block ignores them.
  - If you set the **Computation mode** parameter to Select samples from port, then an additional input port, labeled Sel, appears on the block icon. The data at this input port must have the same format as that of the **Selected samples from frame** parameter described above.

- If one data signal is a scalar and the other is a vector, then the scalar is with each entry of the vector. In this case, if Rx is a scalar, then the phrase “Rx frame” above refers to the vector expansion of Rx.

---

**Note** This block does not support variable-size signals. If you choose the **Select samples from port** option and want the number of elements in the subframe to vary during the simulation, then you should pad the **Sel** signal with zeros. The Error Rate Calculation block ignores zeros in the **Sel** signal.

---

## Output Data

This block produces a vector of length three, whose entries correspond to:

- The error rate
- The total number of errors, that is, the number of instances that an Rx element does not match the corresponding Tx element
- The total number of comparisons that the block made

The block sends this output data to the base MATLAB workspace or to an output port, depending on how you set the **Output data** parameter:

- If you set the **Output data** parameter to **Workspace** and fill in the **Variable name** parameter, then that variable in the base MATLAB workspace contains the current value when the simulation *ends*. Pausing the simulation does not cause the block to write interim data to the variable.

If you plan to use this block along with the Simulink Coder software, then you should not use the **Workspace** option. Instead, use the **Port** option and connect the output port to a Simulink To Workspace block.

- If you set the **Output data** parameter to **Port**, then an output port appears. This output port contains the *running* error statistics.

## Delays

The **Receive delay** and **Computation delay** parameters implement two different types of delays for this block. One delay is useful if you want this block to compensate for the delay in the received signal. The other is useful if you want to ignore the initial transient behavior of both input signals.

- The **Receive delay** parameter represents the number of samples by which the received data lags behind the transmitted data. The transmit signal is implicitly delayed by that same amount before the block compares it to the received data. This value is helpful when you delay the transmit signal so that it aligns with the received signal. The receive delay persists throughout the simulation.
- The **Computation delay** parameter represents the number of samples the block ignores at the beginning of the comparison.

Use the Find Delay block to determine the delay, and then set the **Receive delay** to the delay reported by the Find Delay block.

If you use the `Select samples from mask` or `Select samples from port` option, then each delay parameter refers to the number of samples that the block receives, whether the block ultimately ignores some of them or not.

If using the **Sel** port to calculate errors on a delayed signal, the delay must be added to the **Sel** indices. For more information, see “Calculate Errors for Delayed Selected Samples”.

## Stopping the Simulation Based on Error Statistics

You can configure this block so that its error statistics control the duration of simulation. This is useful for computing reliable steady-state error statistics without knowing in advance how long transient effects might last. To use this mode, check **Stop simulation**. The block attempts to run the simulation until it detects the number of errors the **Target number of errors** parameter specifies. However, the simulation stops before detecting enough errors if the time reaches the model's **Stop time** setting (in the **Configuration Parameters** dialog box), if the Error Rate Calculation block makes **Maximum number of symbols** comparisons, or if another block in the model directs the simulation to stop.

To ignore either of the two stopping criteria in this block, set the corresponding parameter (**Target number of errors** or **Maximum number of symbols**) to Inf. For example, to reach a target number of errors without stopping the simulation early, set **Maximum number of symbols** to Inf and set the model's **Stop time** to Inf.

## Tuning Parameters in an RSim Executable (Simulink Coder Software)

If you use the Simulink Coder rapid simulation (RSim) target to build an RSim executable, then you can tune the **Target number of errors** and **Maximum number of symbols**

parameters without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

## Examples

### Full Frame Error Calculation

The figure below shows how the block compares pairs of elements and counts the number of error events. The Tx and Rx inputs are column vectors.

This example assumes that the sample time of each input signal is 1 second and that the block's parameters are as follows:

- **Receive delay** = 2
- **Computation delay** = 0
- **Computation mode** = Entire frame

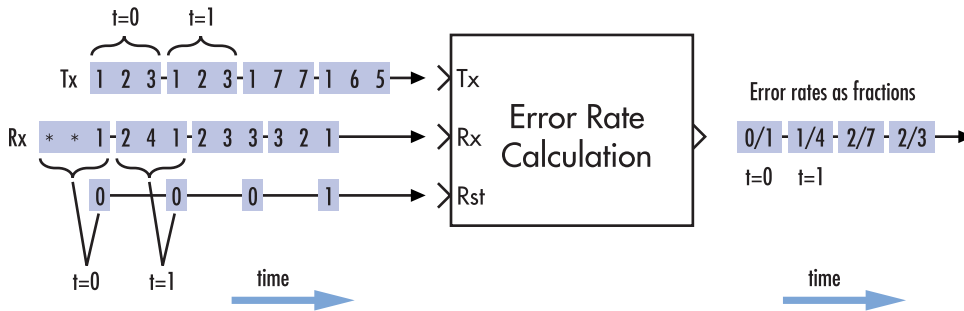

Both input signals are column vectors of length three. However, the schematic arranges each column vector horizontally and aligns pairs of vectors so as to reflect a receive delay of two samples. At each time step, the block compares elements of the Rx signal with those of the Tx signal that appear directly above them in the schematic. For instance, at time 1, the block compares 2, 4, and 1 from the Rx signal with 2, 3, and 1 from the Tx signal.

The values of the first two elements of Rx appear as asterisks because they do not influence the output. Similarly, the 6 and 5 in the Tx signal do not influence the output up to time 3, though they *would* influence the output at time 4.

In the error rates on the right side of the figure, each numerator at time  $t$  reflects the number of errors when considering the elements of Rx up through time  $t$ .

### Full Frame Error Calculation with Reset

If the block's **Reset port** box had been checked and a reset had occurred at time = 3 seconds, then the last error rate would have been 2/3 instead of 4/10. This value 2/3 would reflect the comparison of 3, 2, and 1 from the Rx signal with 7, 7, and 1 from the Tx signal. The figure below illustrates this scenario. The Tx and Rx inputs are column vectors.

### Error Calculation on Selected Samples in the Frame

If using the **Sel** port to calculate errors on a delayed signal, the delay must be added to the **Sel** indices. For more information, see “Calculate Errors for Delayed Selected Samples”.

## Parameters

### Receive delay

Number of samples by which the received data lags behind the transmitted data. (If Tx or Rx is a vector, then each entry represents a sample.)

### Computation delay

Number of samples that the block should ignore at the beginning of the comparison.

### Computation mode

Either Entire frame, Select samples from mask, or Select samples from port, depending on whether the block should consider all or only part of the input frames.

**Selected samples from frame**

A vector that lists the indices of the elements of the Rx frame vector that the block should consider when making comparisons. This field appears only if **Computation mode** is set to `Select samples from mask`.

**Output data**

Either `Workspace` or `Port`, depending on where you want to send the output data.

**Variable name**

Name of variable for the output data vector in the base MATLAB workspace. This field appears only if **Output data** is set to `Workspace`.

**Reset port**

If you check this box, then an additional input port appears, labeled `Rst`.

**Stop simulation**

If you check this box, then the simulation runs only until this block detects a specified number of errors or performs a specified number of comparisons, whichever comes first.

**Target number of errors**

The simulation stops after detecting this number of errors. This field is active only if **Stop simulation** is checked.

**Maximum number of symbols**

The simulation stops after making this number of comparisons. This field is active only if **Stop simulation** is checked.

## Supported Data Types

Port	Supported Data Types
Tx	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>

<b>Port</b>	<b>Supported Data Types</b>

# EVM Measurement

Measure error vector magnitude

## Library

Utility Blocks

## Description

The EVM Measurement block measures the error vector magnitude (EVM), which is an indication of modulator or demodulator performance.

The block has one or two input signals: a received signal and, optionally, a reference signal. You must select if the block uses a reference from an input port or from a reference constellation.

The block normalizes to the average reference signal power, average constellation power, or peak constellation power. For RMS EVM, maximum EVM, and  $X$ -percentile EVM, the output computations reflect the normalization method.

The default EVM output is the RMS EVM in percent, with an option of maximum EVM or  $X$ -percentile EVM values. The maximum EVM represents the worst-case EVM value per burst. For the  $X$ -percentile option, you can enable an output port that returns the number of symbols processed in the percentile computations.

The table shows the output type, the parameter that selects the output type, the computation units, and the corresponding measurement interval.

Output	Activation Parameter	Units	Measurement Interval
RMS EVM	None (output by default)	Percentage	Current length   Entire history   Custom   Custom with periodic reset
Maximum EVM	<b>Output maximum EVM</b>	Percentage	Current length   Entire history   Custom   Custom with periodic reset
Percentile EVM	<b>Output X-percentile EVM</b>	Percentage	Entire history
Number of symbols	<b>Output X-percentile EVM and Output the number of symbols processed</b>	None	Entire history

## Data Type

The block accepts double, single, and fixed-point data types. The output of the block is always double.

## Parameters

### Normalize RMS error vector by

Selects the method by which the block normalizes measurements:

- Average reference signal power
- Average constellation power
- Peak constellation power

The default is Average reference signal power.

**Average constellation power**

Normalizes EVM measurement by the average constellation power. This parameter is available only when you set **Normalize RMS error vector** to Average constellation power.

**Peak constellation power**

Normalizes EVM measurement by the peak constellation power. This parameter only is available if you set **Normalize RMS error vector** to Peak constellation power.

**Reference signal**

Specifies the reference signal source as either Input port or Estimated from reference constellation.

**Reference constellation**

Specifies the reference constellation points as a vector. This parameter is available only when **Reference signal** is Estimated from reference constellation. The default is constellation(comm.QPSKModulator).

**Measurement interval**

Specify the measurement interval as: Input length, Entire history, Custom, or Custom with periodic reset. This parameter affects the RMS and maximum EVM outputs only.

- To calculate EVM using only the current samples, set this parameter to 'Input length'.
- To calculate EVM for all samples, set this parameter to 'Entire history'.
- To calculate EVM over an interval you specify and to use a sliding window, set this parameter to 'Custom'.
- To calculate EVM over an interval you specify and to reset the object each time the measurement interval is filled, set this parameter to 'Custom with periodic reset'.

**Custom measurement interval**

Specify the custom measurement interval in samples as a real positive integer. This is the interval over which the EVM is calculated. This parameter is available when **Measurement interval** is Custom or Custom with periodic reset. The default is 100.

**Averaging dimensions**

Specify the dimensions over which to average the EVM measurements as a scalar or row vector whose elements are positive integers. For example, to average across the rows, set this parameter to 2. The default is 1.

This block supports var-size inputs of the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must be constant. For example, if the input size is [1000 3 2] and **Averaging dimensions** is [1 3], then the output size is [1 3 1]. The number of elements in the second dimension is fixed at 3.

**Output maximum EVM**

Outputs the maximum EVM of an input vector or frame.

**Output X-percentile EVM**

Enables an output X-percentile EVM measurement. When you select this option, specify **X-percentile value (%)**.

**X-percentile value (%)**

This parameter is available only when you select **Output X-percentile EVM**. The Xth percentile is the EVM value below which X% of all the computed EVM values lie. The parameter defaults to the 95th percentile. That is, 95% of all EVM values are below this value.

**Output the number of symbols processed**

Outputs the number of symbols that the block uses to compute the X-percentile value. This parameter is available only when you select **Output X-percentile EVM**.

**Simulate using**

Select the simulation mode.

**Code generation**

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is **Code generation**, System objects corresponding to the blocks accept a maximum of nine inputs.

**Interpreted execution**

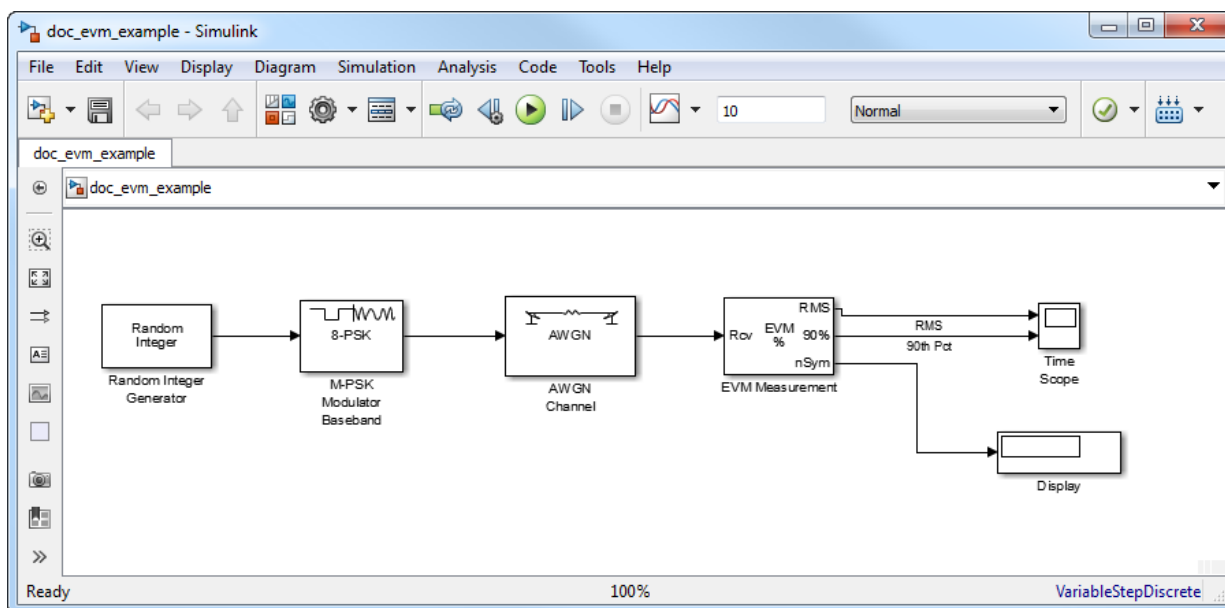

Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## Examples

### Measure RMS and 90th Percentile EVM

Measure the RMS and 90th percentile EVM for an 8-PSK signal in an AWGN channel.

Open the model by typing `doc_evm_example` on the command line.

Run the model. The Display block shows the number of symbols used to estimate the EVM. The Time Scope shows the RMS and 90th percentile EVM values.

Observe that 90% of the symbols had an EVM value of less than 28% and that the average EVM is approximately 17%.

Experiment with the model by changing the signal-to-noise ratio in the AWGN Channel block. Examine its effect on the EVM values.

## Algorithms

Both the EVM block and the EVM object provide three normalization methods. You can normalize measurements according to the average power of the reference signal, average constellation power, or peak constellation power. Different industry standards follow one of these normalization methods.

The block or object calculates the RMS EVM value differently for each normalization method.

EVM Normalization Method	Algorithm
Reference signal	$EVM_{RMS} = \sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{\frac{1}{N} \sum_{k=1}^N (I_k^2 + Q_k^2)}} * 100$
Average power	$EVM_{RMS}(\%) = 100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{avg}}}$
Peak power	$EVM_{RMS}(\%) = 100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{max}}}$

Where:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- $I_k$  = In-phase measurement of the  $k$ th symbol in the burst
- $Q_k$  = Quadrature phase measurement of the  $k$ th symbol in the burst
- $N$  = Input vector length
- $P_{avg}$  = The value for **Average constellation power**

- $P_{max}$  = The value for **Peak constellation power**
- $I_k$  and  $Q_k$  represent ideal (reference) values.  $\tilde{I}_k$  and  $\tilde{Q}_k$  represent measured (received) symbols.

The max EVM is the maximum EVM value in a frame or  $EVM_{max} = \max_{k \in [1, \dots, N]} \{EVM_k\}$ , where  $k$  is the  $k$ th symbol in a burst of length  $N$ .

The definition for  $EVM_k$  varies depending upon which normalization method you select for computing measurements. The block or object supports these algorithms.

EVM Normalization	Algorithm
Reference signal	$EVM_k = \sqrt{\frac{e_k}{\frac{1}{N} \sum_{k=1}^N (I_k^2 + Q_k^2)}} * 100$
Average power	$EVM_k = 100 \sqrt{\frac{e_k}{P_{avg}}}$
Peak power	$EVM_k = 100 \sqrt{\frac{e_k}{P_{max}}}$

The block or object computes the X-percentile EVM by creating a histogram of all the incoming  $EVM_k$  values. The output provides the EVM value below which X% of the EVM values fall.

## Eye Diagram Scope

Display eye diagram of time-domain signal

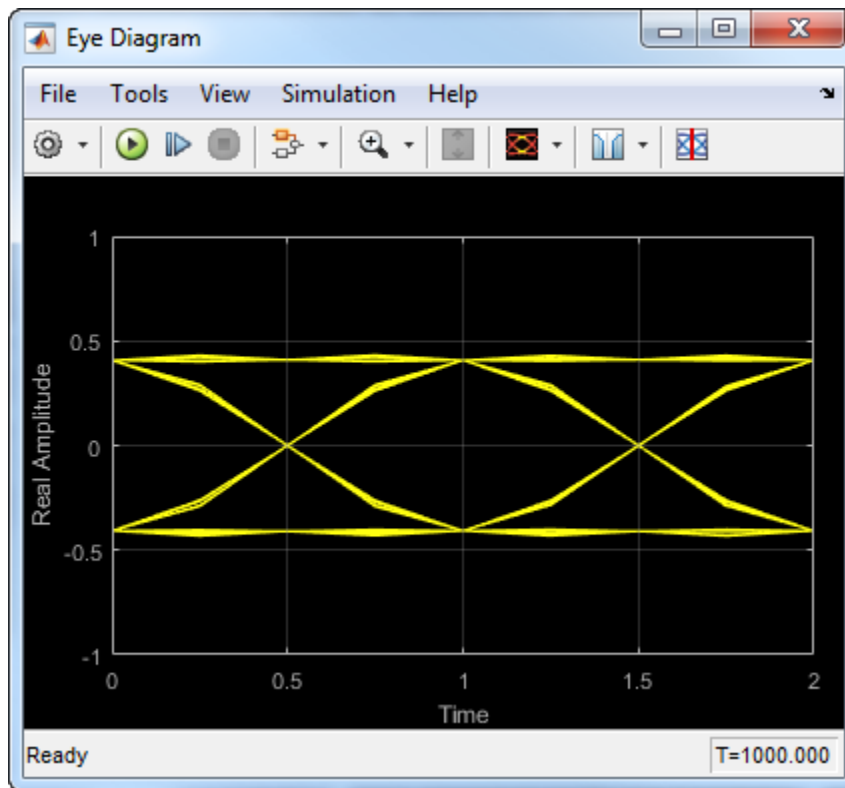

## Library

Comm Sinks

## Description

The Eye Diagram block displays multiple traces of a modulated signal to produce an eye diagram. You can use the block to reveal the modulation characteristics of the signal, such as the effects of pulse shaping or channel distortions.

The Eye Diagram block has one input port. This block accepts a column vector or scalar input signal. The block accepts a signal with the following data types: double, single, base integer, and fixed point. All data types are cast as double before the block displays results.

## Dialog Box

To modify the eye diagram display, select **View > Configuration Properties** or click the **Configuration Properties** button (). Then select the **Main**, **2D color histogram**, **Axes**, or **Export** tabs and modify the settings.

## Visuals — Eye Diagram Properties

### Main Tab

#### Display mode

Display mode of the eye diagram, specified as `Line plot` or `2D color histogram`. Selecting `2D color histogram` makes the histogram tab available. This parameter is tunable.

#### Enable measurements

Select this check box to enable eye measurements of the input signal.

### Show horizontal (jitter) histogram

Select this radio button to display the jitter histogram. This parameter is available when **Display mode** is 2D color histogram and **Enable measurements** is selected. This can also be accessed by using the histogram button drop down on the toolbar.

### Show vertical (noise) histogram

Select this radio button to display the noise histogram. This parameter is available when **Display mode** is 2D color histogram and **Enable measurements** is selected. This can also be accessed by using the histogram button drop down on the toolbar.

### Show horizontal bathtub curve

Select this check box to display the horizontal bathtub curve. This parameter is available when **Enable measurements** is selected. This can also be accessed by using the bathtub curve button on the toolbar.

### Show vertical bathtub curve

Select this check box to display the vertical bathtub curve. This parameter is available when **Enable measurements** is selected. This can also be accessed by using the bathtub curve button on the toolbar.

### Eye diagram to display

Select either `Real only` or `Real and imaginary` to display one or both eye diagrams. To make eye measurements, this parameter must be `Real only`. This parameter is tunable.

### Color fading

Select this check box to fade the points in the display as the interval of time after they are first plotted increases. The default value is `false`. This parameter is available only when the **Display mode** is `Line plot`. This property is tunable.

### Samples per symbol

Number of samples per symbol. Use with **Symbols per trace** to determine the number of samples per trace. This parameter is tunable.

### **Sample offset**

Sample offset, specified as a nonnegative integer smaller than the product of **Samples per symbol** and **Symbols per trace**. The offset provides the number of samples to omit before plotting the first point. This parameter is tunable.

### **Symbols per trace**

Number of symbols plotted per trace, specified as a positive integer. This parameter is tunable.

### **Traces to display**

Number of traces plotted. This parameter is available only when the **Display mode** is `Line plot`. This parameter is tunable.

## Axes Tab

### Title

Label that appears above the eye diagram plot. By default, the plot has no title. This parameter is tunable.

### Show grid

Toggle this check box to turn the grid on and off. This parameter is tunable.

### Y-limits (Minimum)

Minimum value of the y-axis. This parameter is tunable.

**Y-limits (Maximum)**

Maximum value of the y-axis. This parameter is tunable.

**Real axis label**

Text that the scope displays along the real axis. This parameter is tunable.

**Imaginary axis label**

Text that the scope displays along the imaginary axis. This parameter is tunable.

**2D Histogram Tab**

The 2D histogram tab is available when you click the histogram button or when the display mode is set to `2D color histogram`.

### Oversampling method

Oversampling method, specified as None, Input interpolation, or Histogram interpolation. This parameter is tunable.

To plot eye diagrams as quickly as possible, set the **Oversampling method** to None. The drawback to not oversampling is that the plots look pixelated when the number of samples per trace is small. To create smoother, less-pixelated plots using a small number of samples per trace, set the **Oversampling method** to Input interpolation or Histogram interpolation. Input interpolation is the faster of the two interpolation methods and produces good results when the signal-to-noise ratio (SNR) is high. With a lower SNR, this oversampling method is not recommended because it

introduces a bias to the centers of the histogram ranges. Histogram interpolation is not as fast as the other techniques, but it provides good results even when the SNR is low.

#### Color scale

Color scale of the histogram plot, specified as either `Linear` or `Logarithmic`. Set **Color scale** to `Logarithmic` if certain areas of the eye diagram include a disproportionate number of points. This parameter is tunable.

#### Reset

The toolbar contains a histogram reset button , which resets the internal histogram buffers and clears the display. This button is not available when the display mode is set to `Line plot`.

#### Export Tab

### Export measurements

Select this check box export the eye diagram measurements to the MATLAB workspace. This parameter is tunable.

### Variable name

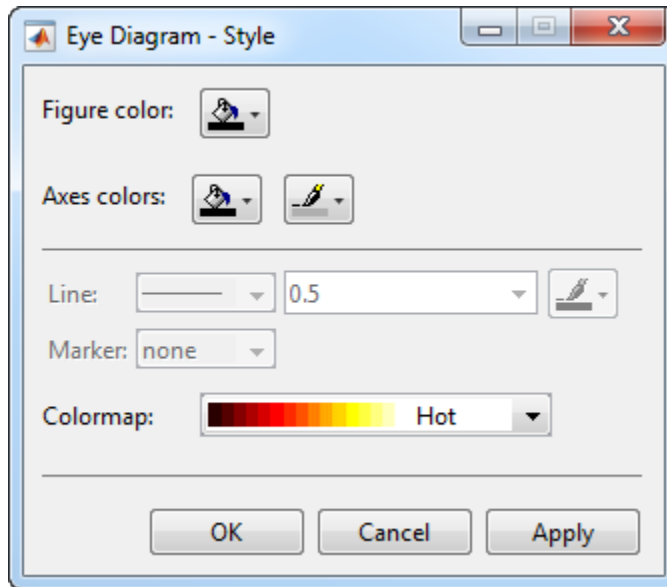

Specify the name of the variable to which the eye diagram measurements are saved. The default is EyeData. This parameter is tunable. The data is saved as a structure having these fields:

- MeasurementSettings
- Measurements
- JitterHistogram
- NoiseHistogram
- HorizontalBathtub
- VerticalBathtub
- BlockName

## Style Dialog Box

In the **Style** dialog box, you can customize the style of the active display. You can change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. To open this dialog box, select **View > Style**.

## Properties

### Figure color

Specify the background color of the scope figure. By default, the figure color is black.

### Axes colors

Specify the fill and line colors for the axes.

### Line

Specify the line style, line width, and line color for the displayed signal.

### Marker

Specify data point markers for the selected signal. This parameter is similar to the Marker property for MATLAB Handle Graphics® plot objects.

Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
*	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
☆☆	Six-pointed star (hexagram)

### Colormap

Specify the colormap of the histogram plots as one of these schemes: Parula, Jet, HSV, Hot, Cool, Spring, Summer, Autumn, Winter, Gray, Bone, Copper, Pink, Lines, or Custom. This parameter is active when the Eye Diagram is in Histogram mode. The default is Hot. If you select Custom, a dialog box pops up from which you can enter code to specify your own colormap.

## Measurements

To open the measurements panel, click on the **Eye Measurements** button or select Tools > Measurements > Eye Measurements from the toolbar menu.

---

### Note

- For amplitude measurements, at least one bin per vertical histogram must reach 10 hits before the measurement is taken, ensuring higher accuracy.

- For time measurements, at least one bin per horizontal histogram must reach 10 hits before the measurement is taken.
  - When an eye crossing time measurement falls within the  $[-0.5/F_s, 0)$  seconds interval, the time measurement wraps to the end of the eye diagram, i.e., the measurement wraps by  $2 \cdot T_s$  seconds (where  $T_s$  is the symbol time). For a complex signal case, the analyze method issues a warning if the crossing time measurement of the in-phase branch wraps while that of the quadrature branch does not (or vice versa). To avoid the time-wrapping or a warning, add a half-symbol duration delay to the current value in the `MeasurementDelay` property of the eye diagram object. This additional delay repositions the eye in the approximate center of the scope.
- 

#### Eye Levels — Amplitude level used to represent data bits

Eye level is the amplitude level used to represent data bits. For the displayed NRZ signal, the levels are -1 V and +1 V. The eye levels are calculated by averaging the 2-D histogram within the eye level boundaries.

**Eye Amplitude — Distance between eye levels**

Eye amplitude is the distance in V between the mean value of two eye levels.

**Eye Height — Statistical minimum distance between eye levels**

Eye height is the distance between  $\mu - 3\sigma$  of the upper eye level and  $\mu + 3\sigma$  of the lower eye level.  $\mu$  is the mean of the eye level and  $\sigma$  is the standard deviation.

**Vertical Opening — Distance between BER threshold points**

The vertical opening is the distance between the two points that correspond to the BER threshold. For example, for a BER threshold of  $10^{-12}$ , these points correspond to the  $7\sigma$  distance from each eye level.

### Eye SNR — Signal-to-noise ratio

The eye SNR is the ratio of the eye level difference to the difference of the vertical standard deviations corresponding to each eye level:

$$\text{SNR} = \frac{L_1 - L_0}{\sigma_1 - \sigma_0},$$

where  $L_1$  and  $L_0$  represent the means of the upper and lower eye levels and  $\sigma_1$  and  $\sigma_0$  represent their standard deviations.

### Q Factor — Quality factor

The Q factor is calculated using the same formula as the Eye SNR. However, the standard deviations of the vertical histograms are replaced with those computed with the dual-Dirac analysis.

### Crossing Levels — Amplitude levels for eye crossings

The crossing levels are the amplitude levels at which the eye crossings occur.

**Crossing Times — Times for which crossings occur**

The crossing times are the times at which the crossings occur. The times are computed as the mean values of the horizontal (jitter) histograms.

**Eye Delay – Mean time between eye crossings**

Eye delay is the midpoint between the two crossing times.

**Eye Width — Statistical minimum time between eye crossings**

Eye width is the horizontal distance between  $\mu + 3\sigma$  of the left crossing time and  $\mu - 3\sigma$  of the right crossing time.  $\mu$  is the mean of the jitter histogram and  $\sigma$  is the standard deviation.

### Horizontal Opening – Time between BER threshold points

The horizontal opening is the distance between the two points that correspond to the BER threshold. For example, for a  $10^{-12}$  BER, these two points correspond to the  $7\sigma$  distance from each crossing time.

**Rise Time — Time to transition from low to high**

Rise time is the mean time between the low and high thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.

### Fall Time – Time to transition from high to low

Fall time is the mean time between the high and low thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.

**Deterministic Jitter — Deterministic deviation from ideal signal timing**

The deterministic jitter (DJ) is the distance between the two peaks of the dual-Dirac histograms. The probability density function (PDF) of DJ is composed of two delta functions.

### Random Jitter — Random deviation from ideal signal timing

The random jitter (RJ) is the Gaussian unbounded jitter component. The random component of jitter is modeled as a zero-mean Gaussian random variable with a specified standard-deviation,  $\sigma$ . The random jitter is computed as:

$$RJ = (Q_L + Q_R)\sigma,$$

where

$$Q = \sqrt{2} \operatorname{erfc}^{-1} \left( 2 \frac{BER}{\rho} \right).$$

BER is the specified BER threshold.  $\rho$  is the amplitude of the left and right Dirac function, which is determined from the bin counts of the jitter histograms.

**Total Jitter — Deviation from ideal signal timing**

Total jitter (TJ) is the sum of the deterministic and random jitter, such that  $TJ = DJ + RJ$ .

The total jitter PDF is the convolution of the DJ PDF and the RJ PDF.

**RMS Jitter — Standard deviation of jitter**

RMS jitter is the standard deviation of the jitter calculated in the horizontal (jitter) histogram at the decision boundary.

**Peak-to-Peak Jitter — Distance between extreme data points of histogram**

Peak-to-peak jitter is the maximum horizontal distance between the left and right nonzero values in the horizontal histogram of each crossing time.

## Measurement Settings

To change measurement settings, first select **Enable measurements**. Then, in the **Eye Measurements** pane, click the arrow next to **Settings**. You can control these measurement settings.

### Eye level boundaries — Time range for calculating eye levels

[40 60] (default) | two-element vector

Time range for calculating eye levels, specified as a two-element vector. These values are expressed as a percentage of the symbol duration. Tunable.

**Decision boundary — Amplitude level threshold**

0 (default) | scalar

Amplitude level threshold in  $V$ , specified as a scalar. This parameter separates the different signaling regions for horizontal (jitter) histograms. This parameter is tunable, but the jitter histograms reset when the parameter changes.

For non-return-to-zero (NRZ) signals, set **Decision boundary** to 0. For return-to-zero (RZ) signals, set **Decision boundary** to half the maximum amplitude.

**Rise/Fall Thresholds — Amplitude levels of the rise and fall transitions**

[10 90] (default) | two-element vector

Amplitude levels of the rise and fall transitions, specified as a two-element vector. These values are expressed as a percentage of the eye amplitude. This parameter is tunable, but the crossing histograms of the rise and fall thresholds reset when the parameter changes.

**Hysteresis — Amplitude tolerance of the horizontal crossings**

0 (default) | scalar

Amplitude tolerance of the horizontal crossings in  $V$ , specified as a scalar. Increase hysteresis to provide more tolerance to spurious crossings due to noise. This parameter is tunable, but the jitter and the rise and fall histograms reset when the parameter changes.

**BER threshold — BER used for eye measurements**

1e-12 (default) | nonnegative scalar from 0 to 0.5

BER used for eye measurements, specified as a nonnegative scalar from 0 to 0.5. The value is used to make measurements of random jitter, total jitter, horizontal eye openings, and vertical eye openings. Tunable.

**Bathtub BERs — BER values used to calculate openings of bathtub curves**

[0.5 0.1 0.01 0.001 0.0001 1e-05 1e-06 1e-07 1e-08 1e-09 1e-10 1e-11 1e-12] (default) | vector

BER values used to calculate openings of bathtub curves, specified as a vector whose elements range from 0 to 0.5. Horizontal and vertical eye openings are calculated for

each of the values specified by this parameter. To enable this parameter, select **Show horizontal bathtub curve**, **Show vertical bathtub curve**, or both. Tunable.

### Measurement delay — Duration of initial data discarded from measurements

0 (default) | nonnegative scalar

Duration of initial data discarded from measurements, in seconds, specified as a nonnegative scalar.

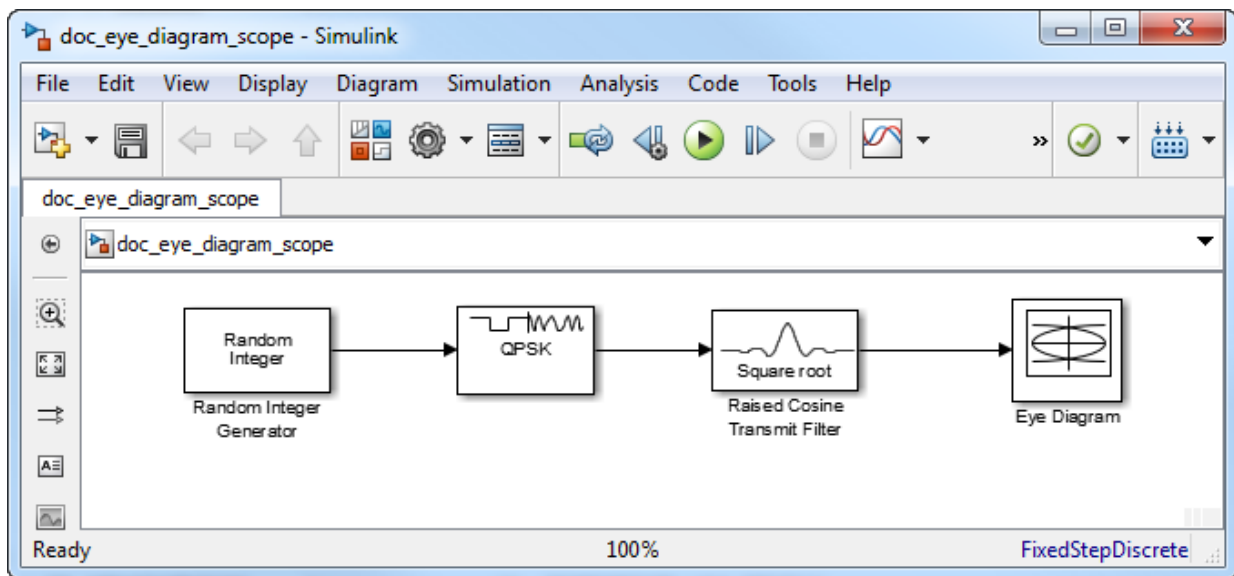

## Examples

### View Eye Diagram

Display the eye diagram of a filtered QPSK signal using the Eye Diagram block.

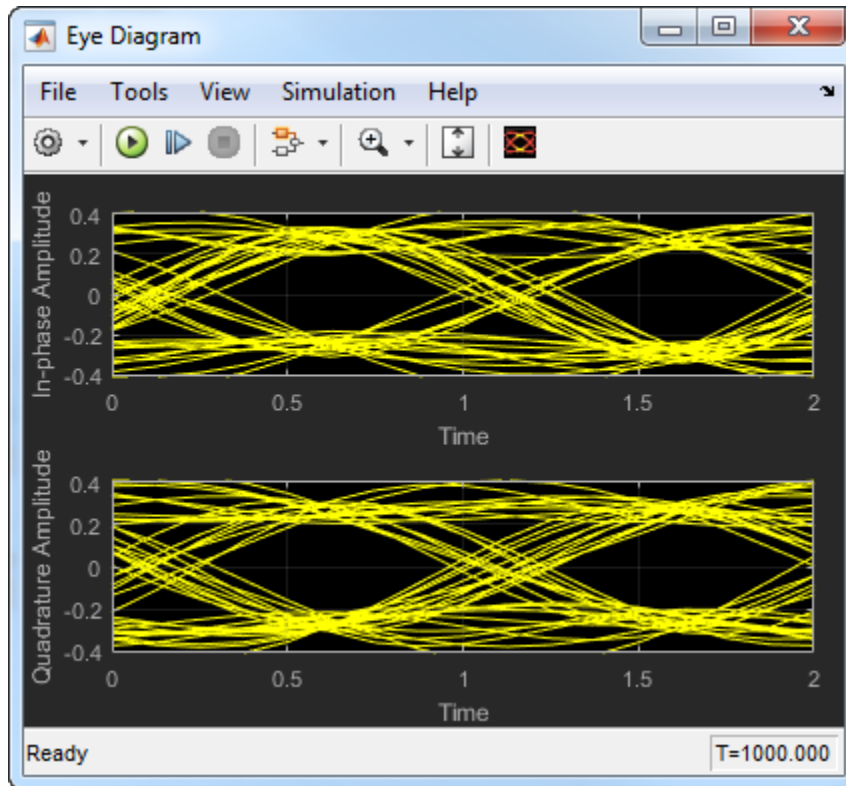

Load the `doc_eye_diagram_scope` model from the MATLAB command prompt.

```
doc_eye_diagram_scope
```

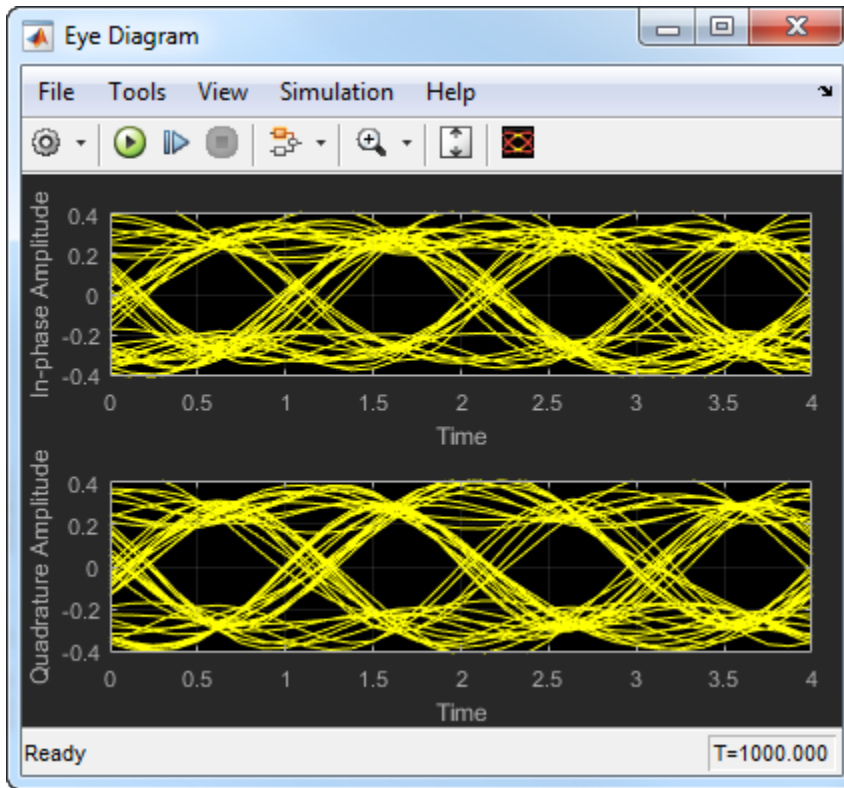

Run the model and observe that two symbols are displayed.

Open the configuration parameters dialog box. Change the **Symbols per trace** parameter to 4. Run the simulation and observe that four symbols are displayed.

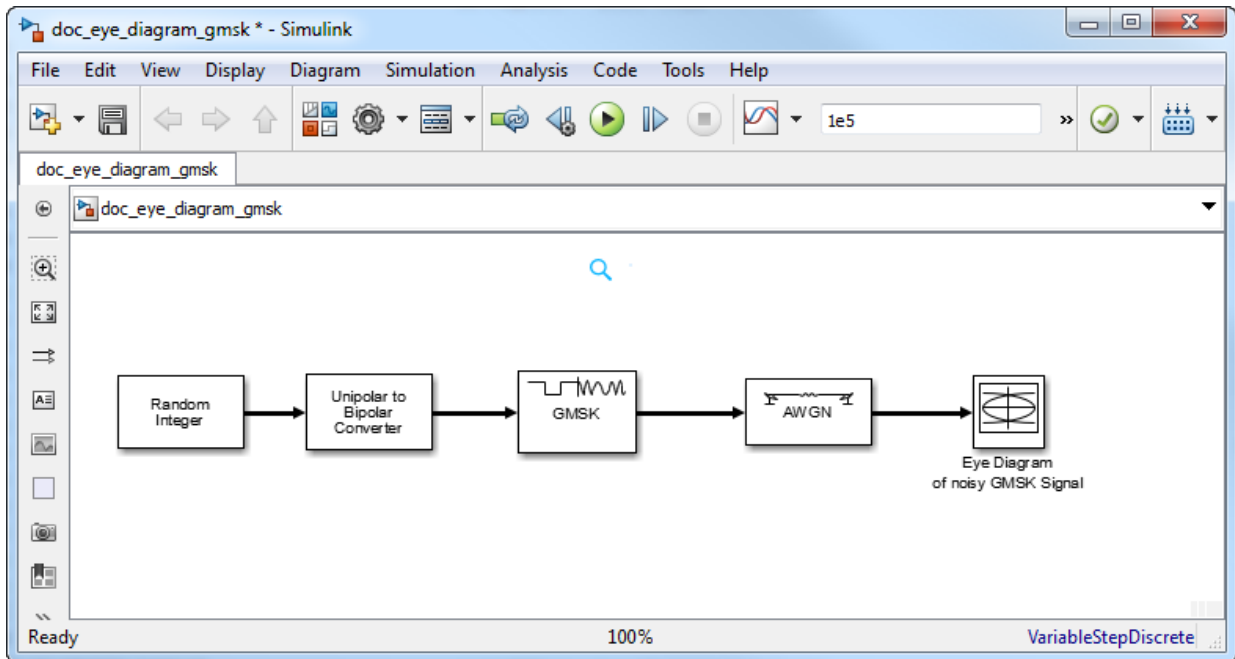

Try changing the Raised Cosine Transmit Filter parameters or changing additional Eye Diagram parameters to see their effects on the eye diagram.

### Histogram Plots

Display histogram plots of a noisy GMSK signal.

Load the `doc_eye_diagram_gmsk` model from the MATLAB command prompt.

```
doc_eye_diagram_gmsk
```

Run the model. The eye diagram is configured to show a histogram without interpolation.

The lack of interpolation results in a plot having piecewise-continuous behavior.

Open the **2D Histogram** tab of the Configuration Properties dialog box. Set the **Oversampling method** to Input interpolation. Run the model.

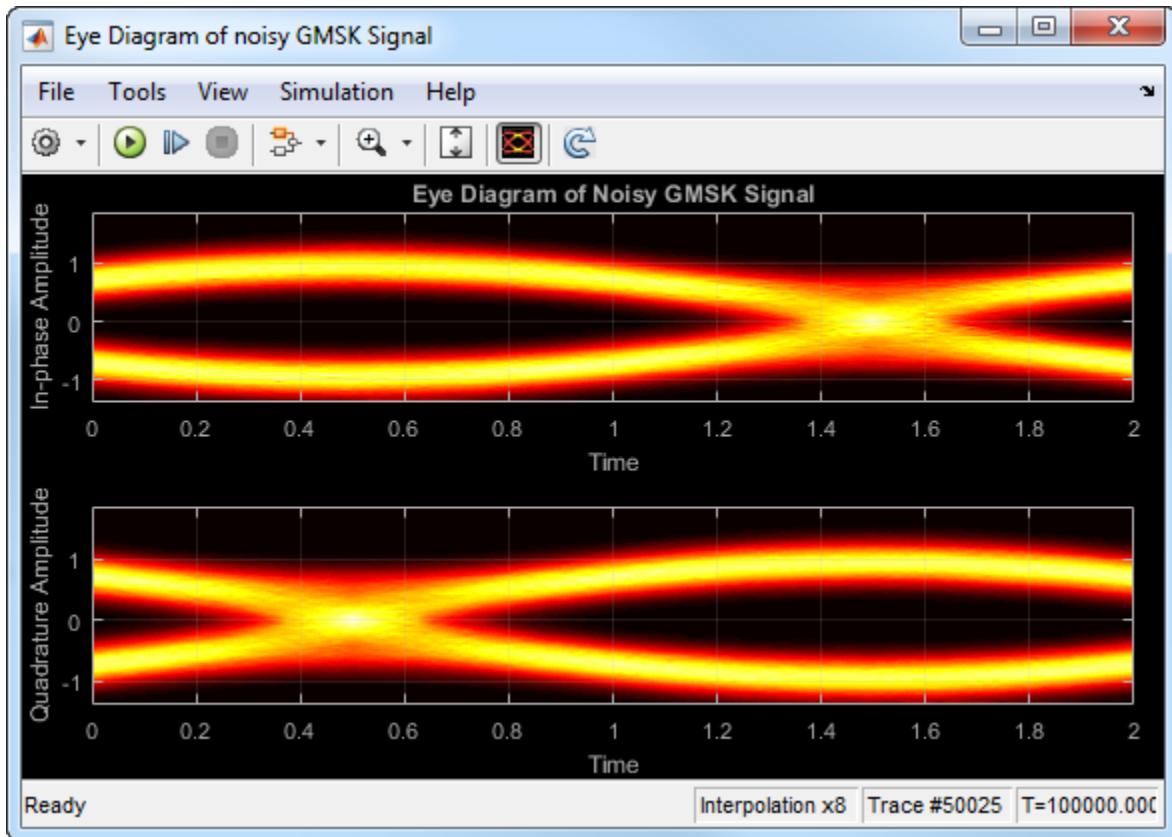

The interpolation smooths the eye diagram.

On the AWGN Channel block, change **SNR (dB)** from 25 to 10. Run the model.

Observe that vertical striping is present in the eye diagram. This striping is the result of input interpolation, which has limited accuracy in low-SNR conditions.

Set the **Oversampling method** to Histogram interpolation. Run the model.

The eye diagram plot now renders accurately because the histogram interpolation method works for all SNR values. This method is not as fast as the other techniques and results in increased execution time.

### Visualize Random and Deterministic Jitter

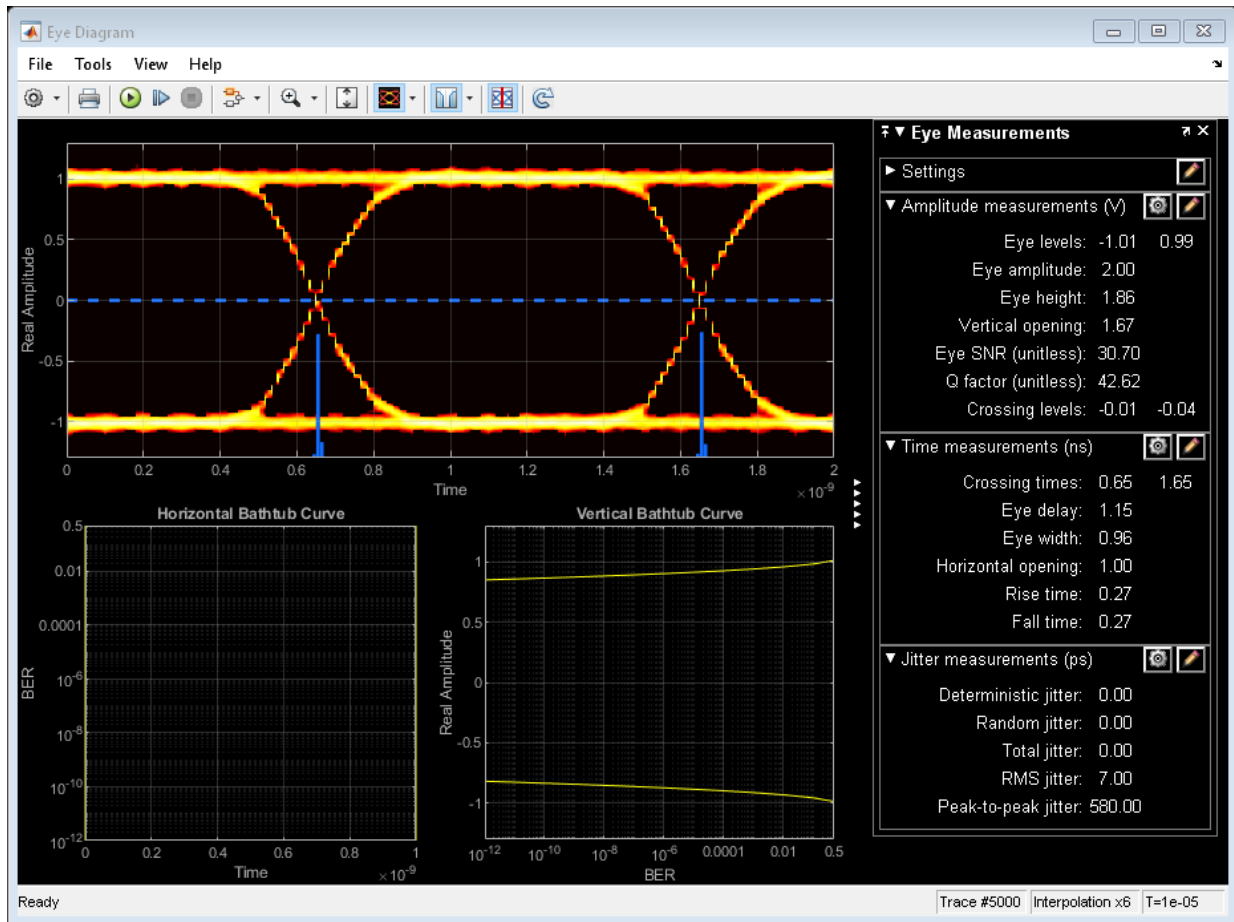

The `doc_visualize_jitter` model generates bipolar data, adds deterministic and random jitter, applies white noise, and displays the resulting eye diagram.

#### No Jitter Added

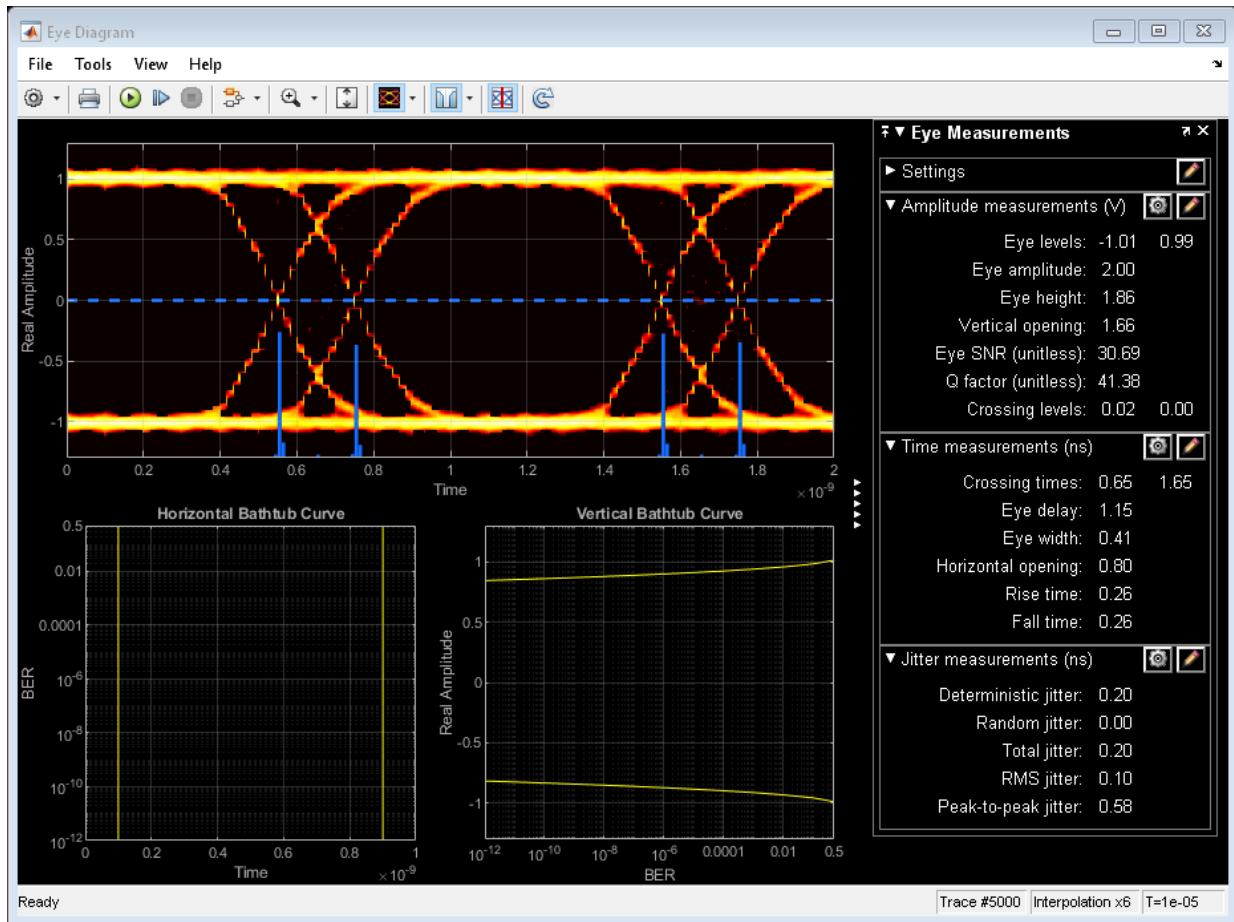

In the Channel Model with Jitter block, set the **Deterministic jitter** parameter to 0 and set the **RMS jitter** parameter to 0. When the model runs, the signal shows clean crossings as there is no jitter.

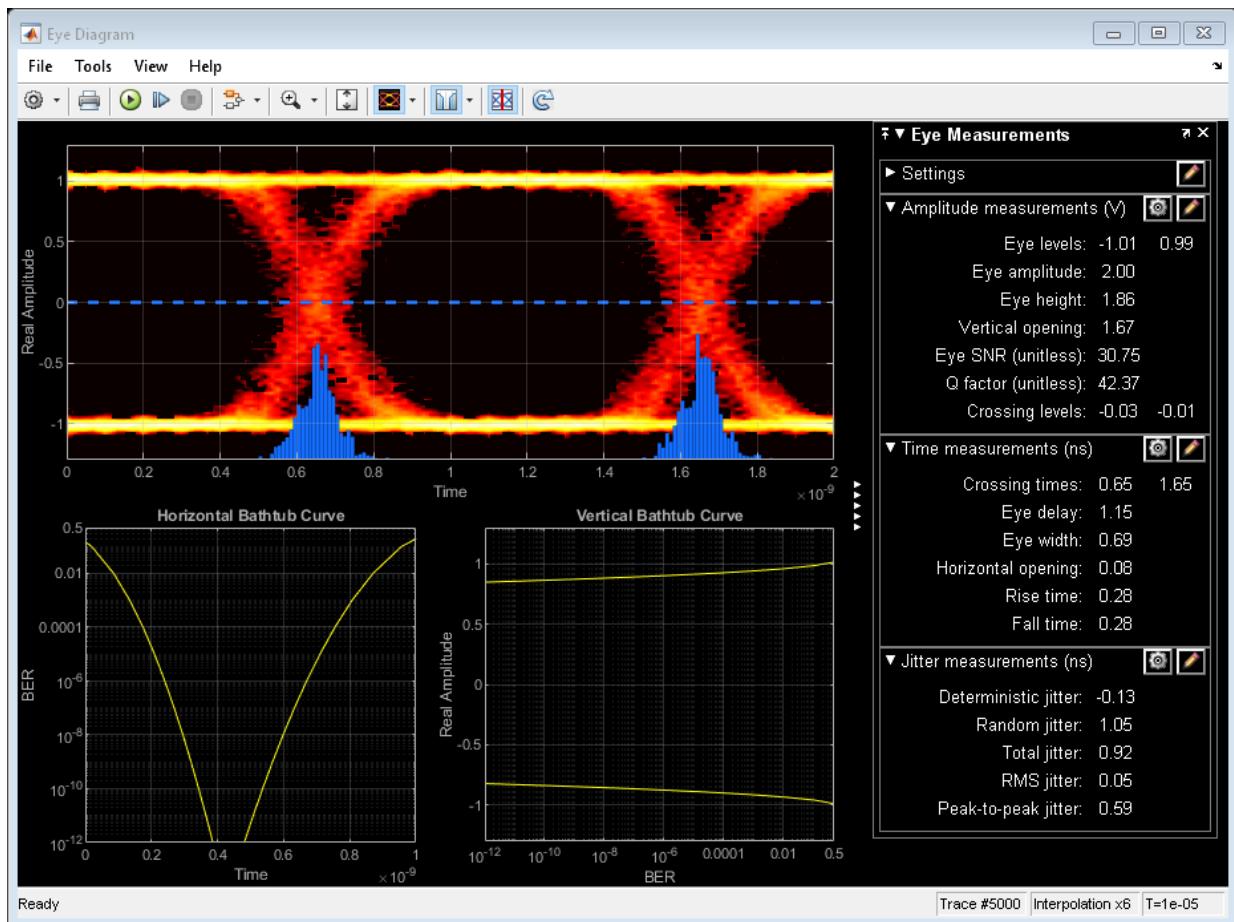

### Deterministic Jitter Added

Set the **Deterministic jitter** parameter to  $100e-12$ . Run the model to show the effect of the deterministic jitter. The separation between the two peaks in the jitter histogram indicates the deterministic jitter.

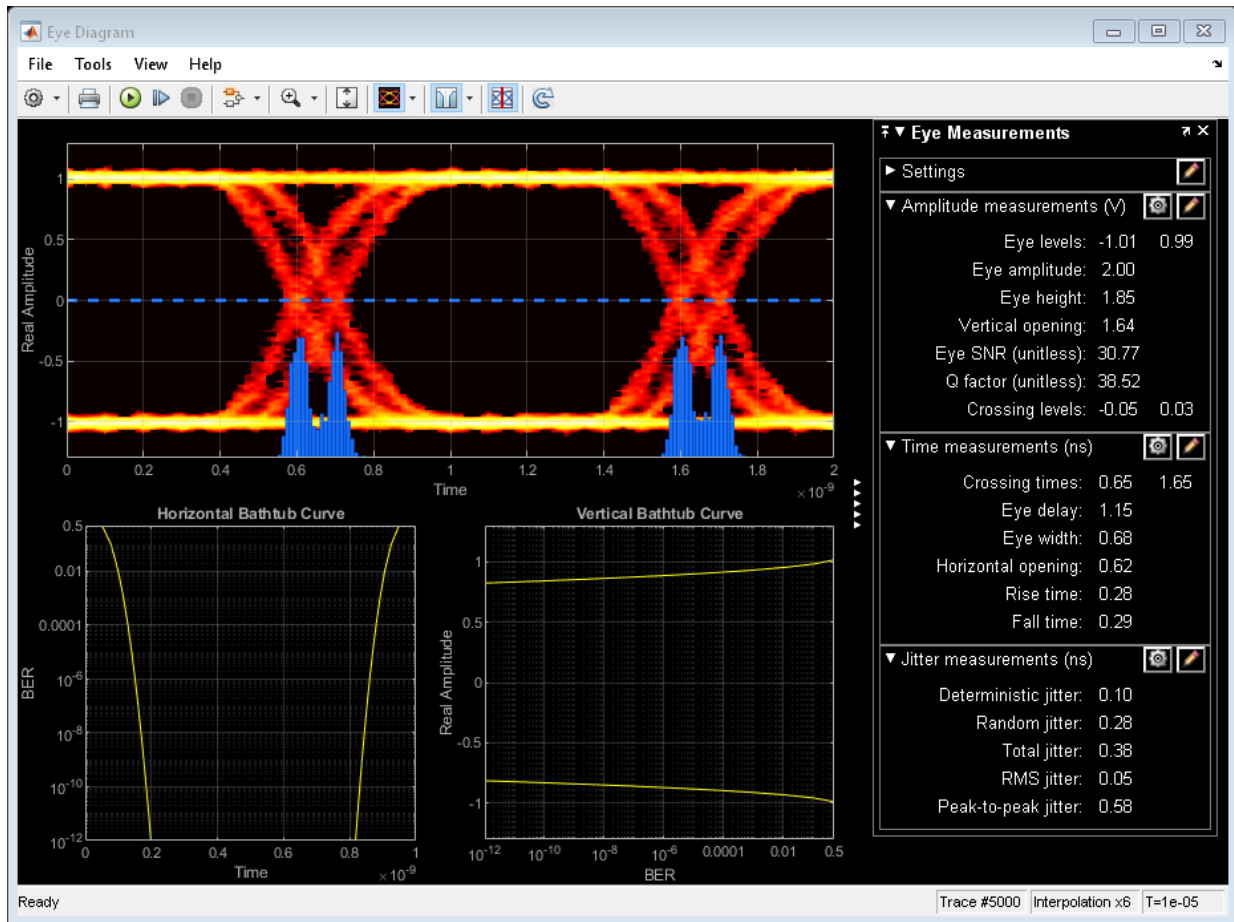

### RMS Jitter Added

Set the **Deterministic jitter** parameter to 0 and set the **RMS jitter** parameter to  $50e-12$ . Run the model to show the effect of the RMS jitter. The fuzziness around each of the crossings indicates the RMS jitter.

### Deterministic and RMS Jitter Added

Set the **Deterministic jitter** parameter to  $50e-12$  and set the **RMS jitter** parameter to  $20e-12$ . Run the model to show the combined effects of both jitter types.

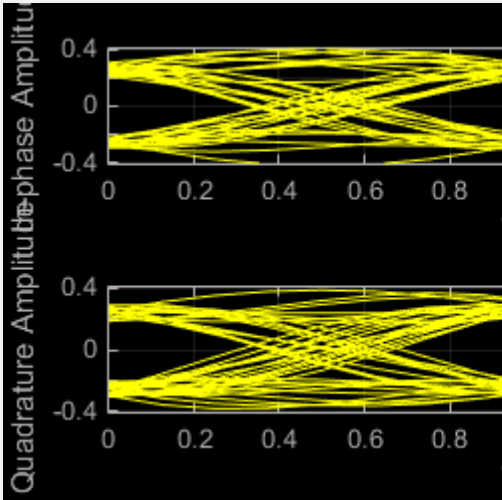

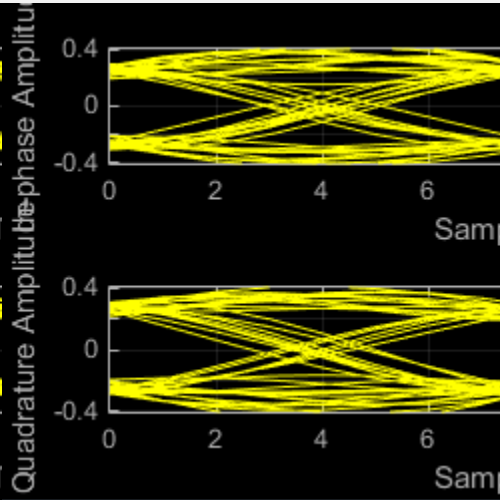

## More About

### Using Eye Diagram in Conditionally Executed Subsystems

When an Eye Diagram block is placed in a conditionally executed subsystem, for example in a triggered or enabled subsystem:

- Input size must be an integer multiple of  $\text{SamplesPerSymbol} * \text{SymbolsPerTrace}$

- Sample offset must be zero
- The rightmost part of the display is intentionally omitted. This figure compares typical eye diagram display when placed in a normal system versus one placed in a conditionally executed subsystem.

Eye Diagram Plot in Normal System	Eye Diagram Plot in Conditionally Executed Subsystem
	
<p>In a regular Eye Diagram, the rightmost part is a line between the last sample of a trace and the first sample of the next trace.</p>	<p>In conditionally executed subsystems, these traces may be non-contiguous, thus this rightmost segment could corrupt the display and is omitted.</p>

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block is excluded from the generated code when code generation is performed on a system containing this block.

## **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

## Find Delay

Find delay between two signals

## Library

Utility Blocks

## Description

The Find Delay block finds the delay between a signal and a delayed, and possibly distorted, version of itself. This is useful when you want to compare a transmitted and received signal to find the bit error rate, but do not know the delay in the received signal. This block accepts a column vector or matrix input signal. For a matrix input, the block outputs a row vector, and finds the delay in each channel of the matrix independently. See “Delays” for more information about signal delays.

The `sRef` input port receives the original signal, while the `sDel` input port receives the delayed version of the signal. The two input signals must have the same dimensions and sample times.

The output port labeled `delay` outputs the delay in units of samples. If you select Include "change signal" output port, then an output port labeled `chg` appears. The `chg` output port outputs 1 when there is a change from the delay computed at the previous sample, and 0 when there is no change. The `delay` output port outputs signals of type double, and the `chg` output port outputs signals of type boolean.

The block's **Correlation window length** parameter specifies how many samples of the signals the block uses to calculate the cross-correlation. The delay output is a nonnegative integer less than the **Correlation window length**.

As the **Correlation window length** is increased, the reliability of the computed delay also increases. However, the processing time to compute the delay increases as well.

You can make the Find Delay block stop updating the delay after it computes the same delay value for a specified number of samples. To do so, select **Disable recurring updates**, and enter a positive integer in the **Number of constant delay outputs to disable updates** field. For example, if you set **Number of constant delay outputs to disable updates** to 20, the block will stop recalculating and updating the delay after it calculates the same value 20 times in succession. Disabling recurring updates causes the simulation to run faster after the target number of constant delays occurs.

## Tips for Using the Block Effectively

- Set **Correlation window length** sufficiently large so that the computed delay eventually stabilizes at a constant value. When this occurs, the signal from the optional `chg` output port stabilizes at the constant value of zero. If the computed delay is not constant, you should increase **Correlation window length**. If the increased value of **Correlation window length** exceeds the duration of the simulation, then you should also increase the duration of the simulation accordingly.
- If the cross-correlation between the two signals is broad, then the **Correlation window length** value should be much larger than the expected delay, or else the algorithm might stabilize at an incorrect value. For example, a CPM signal has a broad autocorrelation, so it has a broad cross-correlation with a delayed version of itself. In this case, the **Correlation window length** value should be much larger than the expected delay.
- If the block calculates a delay that is greater than 75 percent of the **Correlation window length**, the signal `sRef` is probably delayed relative to the signal `sDel`. In this case, you should switch the signal lines leading into the two input ports.

## Examples

### Finding the Delay Before Calculating an Error Rate

A typical use of this block is to determine the correct **Receive delay** parameter in the Error Rate Calculation block. This is illustrated in “Use the Find Delay Block”. In that example, the modulation/demodulation operation introduces a computational delay into the received signal and the Find Delay block determines that the delay is 6 samples. This value of 6 becomes a parameter in the Error Rate Calculation block, which computes the bit error rate of the system.

Another example of this usage is in “Delays”.

## Finding the Delay to Help Align Words

Another typical use of this block is to determine how to align the boundaries of frames with the boundaries of codewords or other types of data blocks. “Delays” describes when such alignment is necessary and also illustrates, in the “Aligning Words of a Block Code” discussion, how to use the Find Delay block to solve the problem.

## Setting the Correlation Window Length

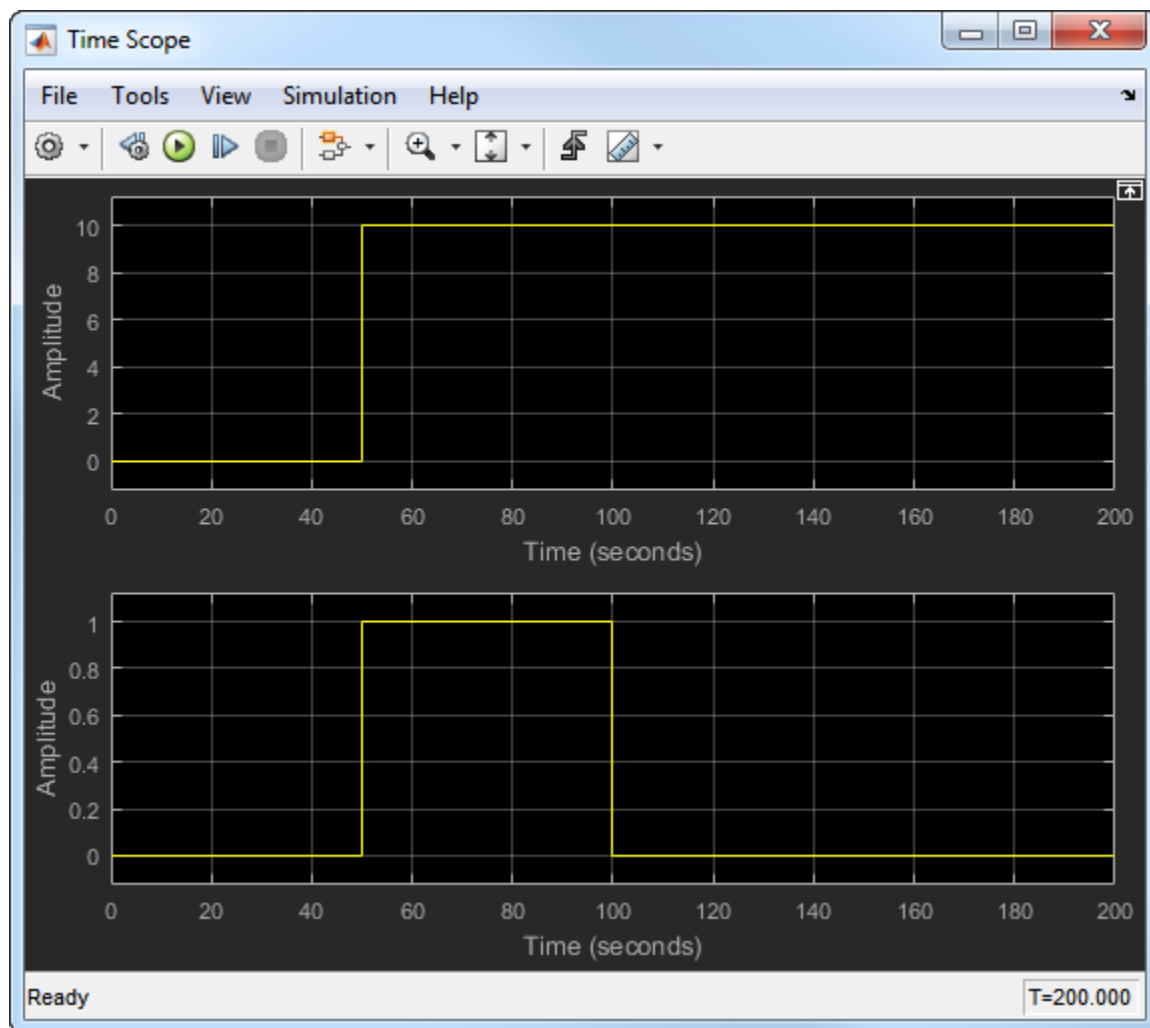

The next example illustrates how to tell when the **Correlation window length** is not sufficiently large. Load this model by typing `doc_find_delay_example` at the command prompt.

The model uses a Delay block to delay a signal by 10 samples. The Find Delay block compares the original signal with the delayed version. In this model, the **Input processing** parameter of the Delay block is set to `Columns as channels`. The model then displays the output of the Find Delay block in a scope. If the **Correlation window length** is 15, the scope shows that the calculated delay is not constant over time, as you can see in the following image.

This result tells you to increase the **Correlation window length**. If you increase it to 50, the calculated delay stabilizes at 10, as shown below.

## Parameters

### Correlation window length

The number of samples the block uses to calculate the cross-correlations of the two signals.

### **Include "change signal" output port**

If you select this option, then the block has an extra output port that emits an impulse when the current computed delay differs from the previous computed delay.

### **Disable recurring updates**

Selecting this option causes the block to stop computing the delay after it computes the same delay value for a specified number of samples.

### **Number of constant delay outputs to disable updates**

A positive integer specifying how many times the block must compute the same delay before ceasing to update. This field appears only if **Disable recurring updates** is selected.

## **Algorithm**

The Find Delay block finds the delay by calculating the cross-correlations of the first signal with time-shifted versions of the second signal, and then finding the index at which the cross-correlation is maximized.

## FM Broadcast Demodulator Baseband

Demodulate using broadcast FM method

### Library

Modulation > Analog Baseband Modulation

### Description

The FM Broadcast Demodulator Baseband block demodulates a complex baseband FM signal by using the conjugate delay method, and filters the signal by using a de-emphasis filter. To demodulate stereo audio using 38 kHz, enable stereo demodulation. To demodulate RBDS signals from the 57 kHz band, enable RBDS demodulation.

### Parameters

#### Sample rate (Hz)

Specify the input signal sample rate as a positive real scalar.

#### Frequency deviation (Hz)

Specify the frequency deviation of the modulator in Hz as a positive real scalar. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

**De-emphasis filter time constant (s)**

Specify the de-emphasis lowpass filter time constant in seconds as a positive real scalar. FM broadcast standards specify a value of 75  $\mu$ s in the United States and 50  $\mu$ s in Europe.

**Output audio sample rate (Hz)**

Specify the output audio sample rate as a positive real scalar.

**Play audio device**

Select this check box to play sound from a default audio device.

**Buffer size (samples)**

Specify the buffer size the block uses to communicate with an audio device as a positive integer scalar. This parameter is available only when the **Play audio device** check box is selected.

**Stereo audio**

Select this check box to enable demodulation of a stereo audio signal. If not selected, the audio signal is assumed to be monophonic.

**RBDS demodulation**

Select this check box to demodulate the RBDS signal from the input complex baseband FM signal. By default, this check box is not selected.

**Number of samples per RBDS symbol**

Specify the number of samples of the RBDS output as a positive integer. The RBDS sample rate is given by **Number of samples per RBDS symbol**  $\times$  1187.5 Hz. According to the RBDS standard, the sample rate of each bit is 1187.5 Hz.

This parameter appears when you select the **RBDS demodulation** check box.

The default is 10.

**RBDS Costas loop**

Specify whether a Costas loop is used to recover the phase of the RBDS signal. Select this check box for radio stations that do not lock the 57 kHz RBDS signal in phase with the third harmonic of the 19 kHz pilot tone.

This parameter appears when you select the **RBDS demodulation** check box.

By default, this check box is not selected.

**Simulate using**

Select the type of simulation to run.

- **Code generation.** Simulate model using generate C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.
- **Interpreted execution.** Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Algorithms

The FM Broadcast demodulator includes the functionality of the baseband FM demodulator, de-emphasis filtering, and the ability to receive stereophonic signals. The algorithms which govern basic FM modulation and demodulation are covered in `comm.FMDemodulator`.

## Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s,$$

where  $\tau_s$  is the filter time constant. The time constant is 50  $\mu\text{s}$  in Europe and 75  $\mu\text{s}$  in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s}.$$

For an audio sample rate of 44.1 kHz, the de-emphasis filter has the following response.

## Stereo and RDS/RBDS FM — Multiplex Signal

The FM broadcast demodulator supports stereophonic and monophonic operations. To support stereo transmission, the left (L) and right (R) channel information (L+R) is assigned to the mono portion of the spectrum (0 to 15 kHz). The (L-R) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals.

Here is the spectrum of the multiplex baseband signal,  $m(t)$ .

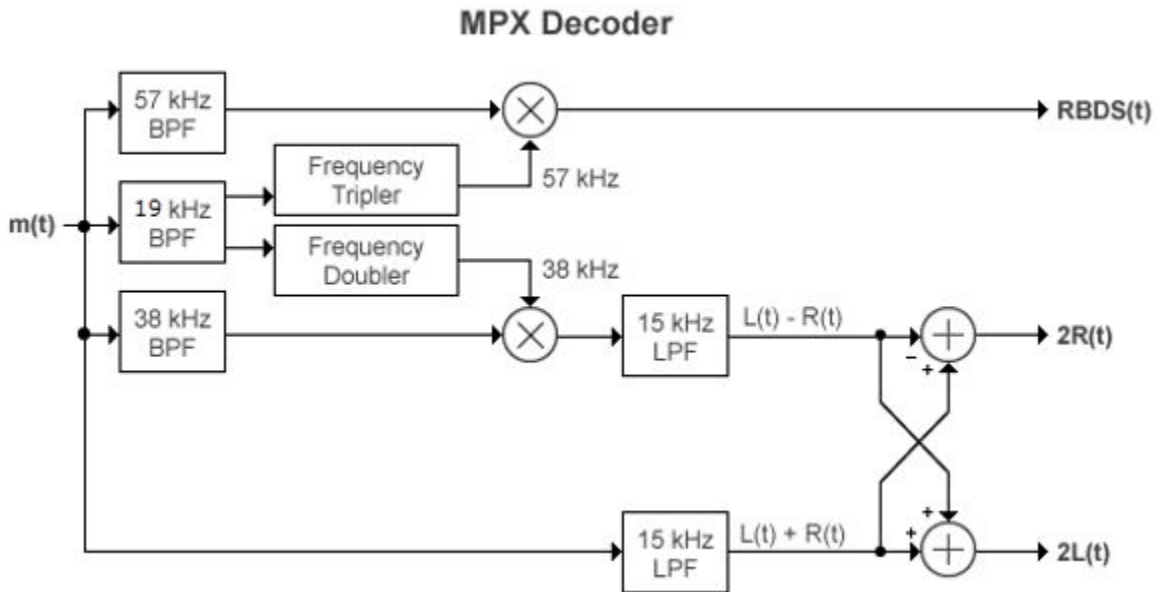

$m(t)$  is given by

$$m(t) = C_0[L(t) + R(t)] + C_1\cos(2\pi \times 19\text{kHz} \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38\text{kHz} \times t) + C_2\text{RBDS}(t)\cos(2\pi \times 57\text{kHz} \times t),$$

where  $C_0$ ,  $C_1$ , and  $C_2$  are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the  $(L(t) \pm R(t))$  signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

The demodulator applies  $m(t)$  to three bandpass filters with center frequencies at 19, 38, and 57 kHz, and to a lowpass filter with a 3-dB cutoff frequency of 15 kHz. The 19 kHz bandpass filter extracts the pilot tone from the modulated signal. The recovered pilot tone is doubled and tripled in frequency to produce the 38 kHz and 57 kHz signals, which demodulate the  $(L - R)$  and RDS/RBDS signals, respectively. To generate a scaled version of the left and right channels that produce the stereo sound, the  $(L + R)$  and  $(L - R)$  signals are added and subtracted. The RDS/RBDS signal is recovered by mixing with the 57 kHz signal.

Here is the block diagram of the FM broadcast demodulator.

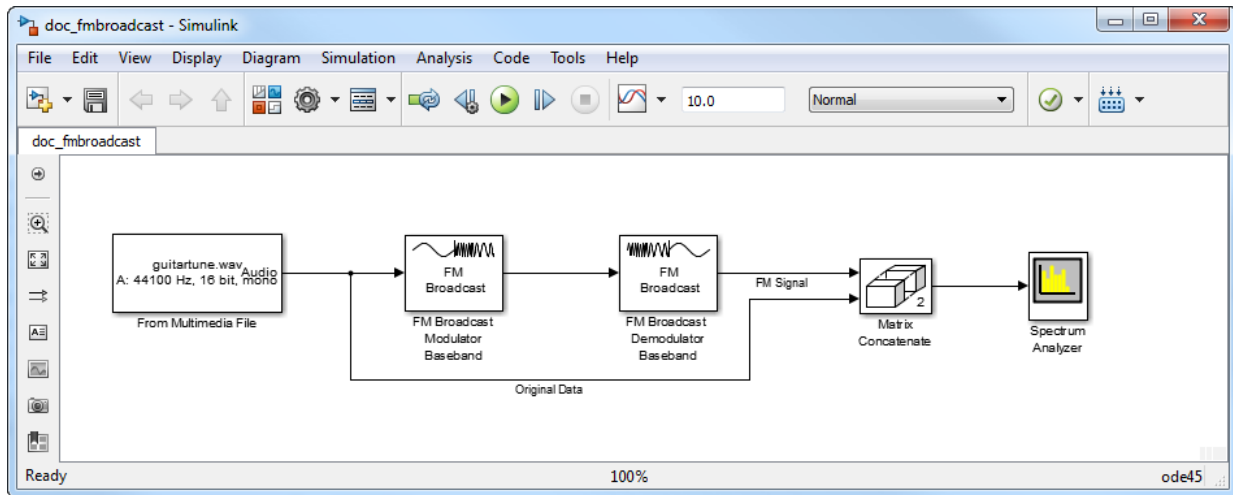

## Examples

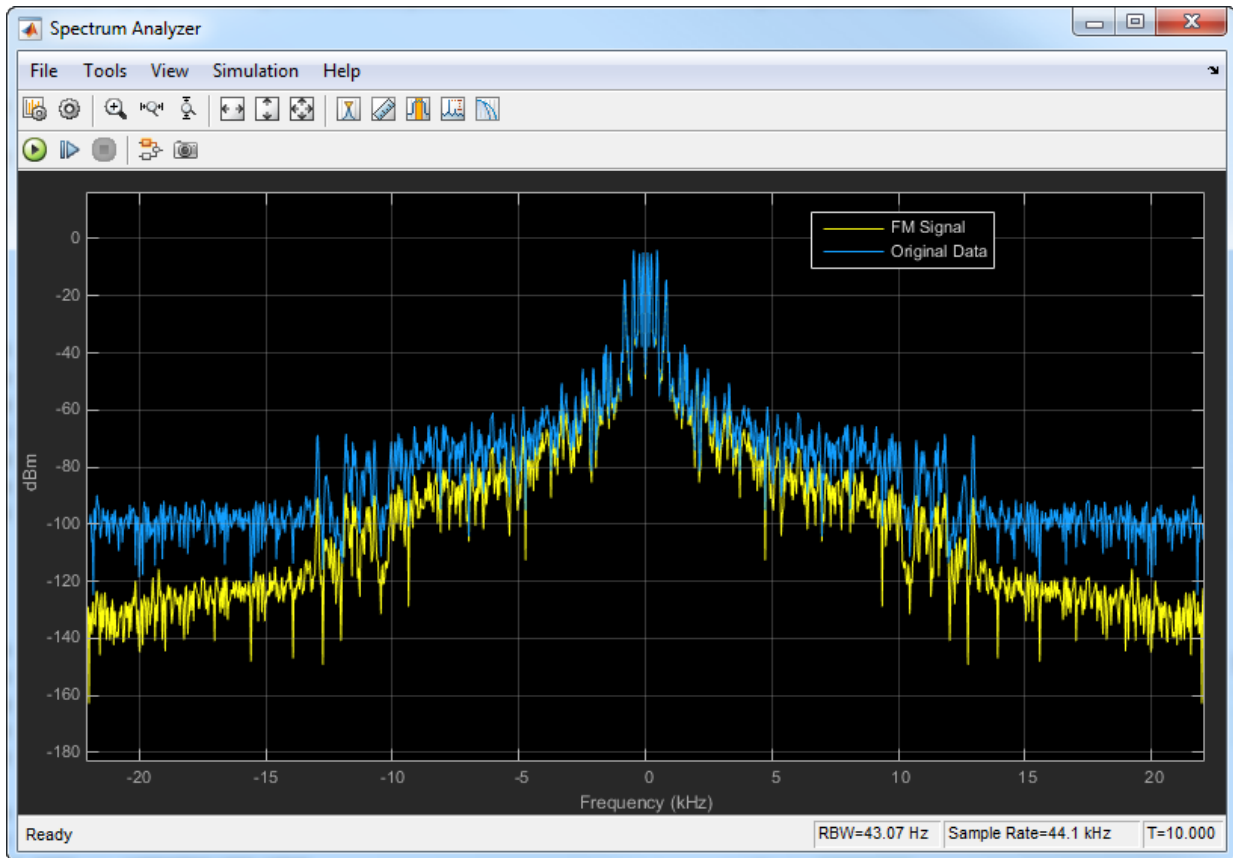

### Modulate and Demodulate an Audio Signal

Load an audio input file, modulate and demodulate using the FM broadcast blocks. Compare the input signal spectrum with the demodulated signal spectrum.

Open the doc\_fmroadcast model.

Run the model. The spectrum of the baseband FM signal is attenuated at the higher frequencies relative to the original waveform.

Experiment with the model by changing the **Frequency deviation (Hz)** and the **Pre-emphasis filter time constant (s)** parameters on the modulator and demodulator and observe the impact on the FM signal spectrum.

## Limitations

The input length must be an integer multiple of the audio decimation factor. If the **RBDS demodulation** check box is selected, the input length in addition must be an integer multiple of the RBDS decimation factor.

## Supported Data Types

## FM Broadcast Modulator Baseband

Modulate using broadcast FM method

### Library

Modulation > Analog Baseband Modulation

### Description

The FM Broadcast Modulator Baseband block pre-emphasizes an audio signal and modulates it onto a baseband FM signal. If you select the **Stereo audio** check box, the block modulates the stereo audio (*L-R*) at the 38 kHz band, in addition to the baseband (*L+R*). If you select the **RBDS modulation** check box, the block also modulates a baseband RBDS signal at 57 kHz. For more details, see “Algorithms” on page 3-395.

### Parameters

#### Sample rate (Hz)

Specify the output signal sample rate as a positive real scalar.

#### Frequency deviation (Hz)

Specify the frequency deviation of the modulator in Hz as a positive real scalar. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

**Pre-emphasis filter time constant (s)**

Specify the pre-emphasis highpass filter time constant as a positive real scalar. FM broadcast standards specify a value of 75  $\mu$ s in the United States and 50  $\mu$ s in Europe.

**Sample rate of audio input signal (Hz)**

Specify the input audio sample rate as a positive real scalar.

**Stereo audio**

Select this check box if the input signal is a stereophonic audio signal.

**RBDS modulation**

Select this check box to modulate a baseband RBDS signal at 57 kHz. By default, this check box is not selected.

**Oversampling factor of RBDS input**

Specify the number of samples per RBDS symbol as a positive integer. The RBDS sample rate is given by **Oversampling factor of RBDS input**  $\times$  1187.5 Hz. According to the RBDS standard, the sample rate of each bit is 1187.5 Hz.

This parameter appears when you select the **RBDS modulation** check box.

The default is 10.

**Simulate using**

Select the type of simulation to run.

- **Code generation.** Simulate model using generate C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution.** Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Algorithms

The FM Broadcast modulator includes the functionality of the baseband FM modulator, pre-emphasis filtering, and the ability to transmit stereophonic signals. The algorithms which govern basic FM modulation and demodulation are covered in `comm.FMModulator`.

## Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s,$$

where  $\tau_s$  is the filter time constant. The time constant is 50  $\mu\text{s}$  in Europe and 75  $\mu\text{s}$  in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s}.$$

Irrespective of the audio sampling rate, the signal is converted to a 152 kHz output sampling rate. For an audio sample rate of 44.1 kHz, the pre-emphasis filter has the following response.

## Stereo and RDS/RBDS FM - Multiplex Signal

The FM broadcast modulator supports stereophonic and monophonic operations. To support stereo transmission, the left (L) and right (R) channel information (L+R) is assigned to the mono portion of the spectrum (0 to 15 kHz). The (L-R) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals. Here is the spectrum of the multiplex baseband signal.

Here is the block diagram of the FM broadcast modulator, which is used to generate the multiplex baseband signal.  $L(t)$  and  $R(t)$  denote the time-domain waveforms from the left and right channels.  $RBDS(t)$  denotes the time-domain waveform of the RDS/RBDS signal.

### MPX Encoder

The multiplex message signal,  $m(t)$  is given by

$$m(t) = C_0[L(t) + R(t)] + C_1\cos(2\pi \times 19\text{kHz} \times t) + C_2[L(t) - R(t)]\cos(2\pi \times 38\text{kHz} \times t) + C_2RBDS(t)\cos(2\pi \times 57\text{kHz} \times t),$$

where  $C_0$ ,  $C_1$ , and  $C_2$  are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the  $(L(t) \pm R(t))$  signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

## Limitations

- If you select the **RBDS modulation** check box, both the audio and RBDS inputs must satisfy the following equation:

$$\frac{\text{audioLength}}{\text{audioSampleRate}} = \frac{\text{RBDSLength}}{\text{RBDSSampleRate}}$$

- The input length of the audio signal must be an integer multiple of the audio decimation factor. The input length of the RBDS signal must be an integer multiple of the RBDS decimation factor.

## Examples

### Modulate and Demodulate an Audio Signal

Load an audio input file, modulate and demodulate using the FM broadcast blocks. Compare the input signal spectrum with the demodulated signal spectrum.

Open the `doc_fmroadcast` model.

Run the model. The spectrum of the baseband FM signal is attenuated at the higher frequencies relative to the original waveform.

Experiment with the model by changing the **Frequency deviation (Hz)** and the **Pre-emphasis filter time constant (s)** parameters on the modulator and demodulator and observe the impact on the FM signal spectrum.

# FM Demodulator Baseband

Demodulate using FM method

**Library:** Communications Toolbox / Modulation / Analog Baseband Modulation

## Description

The FM Demodulator Baseband block demodulates a complex input signal and returns a real output signal.

## Ports

### Input

**In — Input data signal**

scalar | vector | matrix

Input signal, specified as a real scalar, vector, or matrix.

Data Types: double | single

### Output

**Out — Output data signal**

scalar | vector | matrix

Output signal, returned as a real scalar, vector, or matrix. The data at this port has the same data type and size as the input signal.

Data Types: double | single

## Parameters

### Frequency deviation (Hz) — Frequency deviation of demodulator

75e3 (default) | positive scalar

Frequency deviation of the demodulator, in Hz, specified as a positive scalar. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth.

### Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

<b>Data Types</b>	double   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## Algorithms

Represent a frequency modulated passband signal,  $Y(t)$ , as

$$Y(t) = A \cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right),$$

where  $A$  is the carrier amplitude,  $f_c$  is the carrier frequency,  $x(\tau)$  is the baseband input signal, and  $f_\Delta$  is the frequency deviation in Hz. The frequency deviation is the maximum shift from  $f_c$  in one direction, assuming  $|x(t)| \leq 1$ .

A baseband FM signal can be derived from the passband representation by downconverting it by  $f_c$  such that

$$\begin{aligned} y_s(t) &= Y(t)e^{-j2\pi f_c t} = \frac{A}{2} \left[ e^{j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} + e^{-j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} \right] e^{-j2\pi f_c t} \\ &= \frac{A}{2} \left[ e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau) d\tau} \right]. \end{aligned}$$

Removing the component at  $-2f_c$  from  $y_s(t)$  leaves the baseband signal representation,  $y(t)$ , which is expressed as

$$y(t) = \frac{A}{2} e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau}.$$

The expression for  $y(t)$  is rewritten as

$$y(t) = \frac{A}{2} e^{j\phi(t)},$$

where  $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau) d\tau$ , which implies that the input signal is a scaled version of the derivative of the phase,  $\phi(t)$ .

A baseband delay demodulator is used to recover the input signal from  $y(t)$ .

A delayed and conjugated copy of the received signal is subtracted from the signal itself,

$$w(t) = \frac{A^2}{4} e^{j\phi(t)} e^{-j\phi(t-T)} = \frac{A^2}{4} e^{j[\phi(t) - \phi(t-T)]},$$

where  $T$  is the sample period. In discrete terms,  $w_n = w(nT)$ , and

$$w_n = \frac{A^2}{4} e^{j[\phi_n - \phi_{n-1}]},$$

$$v_n = \phi_n - \phi_{n-1}.$$

The signal  $v_n$  is the approximate derivative of  $\phi_n$ , such that  $v_n \approx \dot{\phi}_n$ .

## FM Modulator Baseband

Modulate using FM method

**Library:** Communications Toolbox / Modulation / Analog Baseband Modulation

### Description

The FM Modulator Baseband block applies frequency modulation to a real input signal and returns a complex output signal.

### Ports

#### Input

**In — Input data signal**

scalar | vector | matrix

Input signal, specified as a real scalar, vector, or matrix.

Data Types: double | single

#### Output

**Out — Output data signal**

scalar | vector | matrix

Output signal, returned as a real scalar, vector, or matrix. The data at this port has the same data type and size as the input signal.

Data Types: double | single

## Parameters

### Frequency deviation (Hz) — Frequency deviation of modulator

75e3 (default) | positive scalar

Frequency deviation of the modulator, in Hz, specified as a positive scalar. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth.

### Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

# FM Demodulator Passband

Demodulate FM-modulated data

## Library

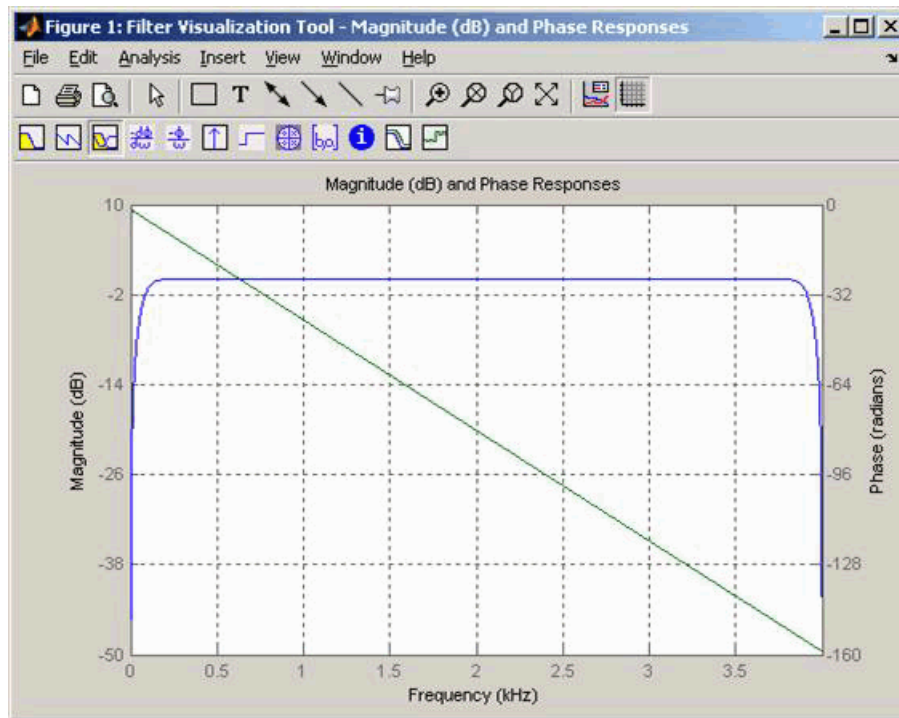

Analog Passband Modulation, in Modulation

## Description

The FM Demodulator Passband block demodulates a signal that was modulated using frequency modulation. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

For best results, use a carrier frequency which is estimated to be larger than 10% of the reciprocal of your input signal's sample rate. This is due to the implementation of the Hilbert transform by means of a filter.

In the following example, we sample a 10Hz input signal at 8000 samples per second. We then designate a Hilbert Transform filter of order 100. Below is the response of the Hilbert Transform filter as returned by `fvtool`.

Note the bandwidth of the filter's magnitude response. By choosing a carrier frequency larger than 10% (but less than 90%) of the reciprocal of your input signal's sample time (8000 samples per second, in this example) or equivalently, a carrier frequency larger than 400Hz, we ensure that the Hilbert Transform Filter will be operating in the flat section of the filter's magnitude response (shown in blue), and that our modulated signal will have the desired magnitude and form.

Typically, an appropriate **Carrier frequency** value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the **Carrier frequency** parameter.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### Carrier frequency (Hz)

The frequency of the carrier.

### Initial phase (rad)

The initial phase of the carrier in radians.

### Frequency deviation (Hz)

The frequency deviation of the carrier frequency in Hertz. Sometimes it is referred to as the "variation" in the frequency.

### Hilbert transform filter order

The length of the FIR filter used to compute the Hilbert transform.

## FM Modulator Passband

Modulate using frequency modulation

### Library

Analog Passband Modulation, in Modulation

### Description

The FM Modulator Passband block modulates using frequency modulation. The output is a passband representation of the modulated signal. The output signal's frequency varies with the input signal's amplitude. Both the input and output signals are real scalar signals.

If the input is  $u(t)$  as a function of time  $t$ , then the output is

$$\cos\left(2\pi f_c t + 2\pi K_c \int_0^t u(\tau) d\tau + \theta\right)$$

where:

- $f_c$  represents the **Carrier frequency** parameter.
- $\theta$  represents the **Initial phase** parameter.
- $K_c$  represents the **Frequency deviation** parameter.

Typically, an appropriate **Carrier frequency** value is much higher than the highest frequency of the input signal.

By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the **Carrier frequency** parameter.

This block works only with real inputs of type `double`. This block does not work inside a triggered subsystem.

## Parameters

### Carrier frequency (Hz)

The frequency of the carrier.

### Initial phase (rad)

The initial phase of the carrier in radians.

### Frequency deviation (Hz)

The frequency deviation of the carrier frequency in Hertz. Sometimes it is referred to as the "variation" in the frequency.

## Free Space Path Loss

Reduce amplitude of input signal by amount specified

## Library

RF Impairments

## Description

The Free Space Path Loss block simulates the loss of signal power due to the distance between transmitter and receiver. The block reduces the amplitude of the input signal by an amount that is determined in either of two ways:

- By the **Distance (km)** and **Carrier frequency (MHz)** parameters, if you specify **Distance** and **Frequency** in the **Mode** field
- By the **Loss (dB)** parameter, if you specify **Decibels** in the **Mode** field

This block accepts a column vector input signal. The input signal to this block must be a complex signal.

## Parameters

### Mode

Method of specifying the amount by which the signal power is reduced. The choices are **Decibels** and **Distance and Frequency**.

### Loss

The signal loss in decibels. This parameter appears when you set **Mode** to **Decibels**. The decibel amount shown on the mask is rounded for display purposes only.

### Distance

Distance between transmitter and receiver in kilometers. This parameter appears when you set **Mode** to Distance and Frequency.

### Carrier frequency (MHz)

The carrier frequency in megahertz. This parameter appears when you set **Mode** to Distance and Frequency.

## Examples

The model below illustrates the effect of the Free Space Path Loss block with the following parameter settings:

- **Mode** is set to Distance and Frequency.
- **Distance (km)** is set to 0.5
- **Carrier frequency (MHz)** is set to 180

# Gaussian Filter

(To be removed) Filter input signal using Gaussian FIR filter

## Library

Comm Filters

---

**Note** The Gaussian Filter block will be removed in a future release. Use the `gaussdesign` function and the Discrete FIR Filter block instead.

---

## Description

The Gaussian Filter block filters the input signal using a Gaussian FIR filter. The block expects the input signal to be upsampled as its input, so that the **Input samples per symbol** parameter,  $N$ , is at least 2. The block's icon shows the filter's impulse response."

## Characteristics of the Filter

The impulse response of the Gaussian filter is

$$h(t) = \frac{\exp\left(\frac{-t^2}{2\delta^2}\right)}{\sqrt{2\pi} \cdot \delta}$$

where

$$\delta = \frac{\sqrt{\ln(2)}}{2\pi BT}$$

and  $B$  is the filter's 3-dB bandwidth. The **BT product** parameter is  $B$  times the input signal's symbol period. For a given  $BT$  product, the Signal Processing Toolbox `gaussfir`

function generates a filter that is half the bandwidth of the filter generated by the Communications Toolbox Gaussian Filter block.

The **Group delay** parameter is the number of symbol periods between the start of the filter's response and the peak of the filter's response. The group delay and  $N$  determine the length of the filter's impulse response, which is  $2 * N * \text{Group delay} + 1$ .

The **Filter coefficient normalization** parameter indicates how the block scales the set of filter coefficients:

- **Sum of coefficients** means that the sum of the coefficients equals 1.
- **Filter energy** means that the sum of the squares of the coefficients equals 1.
- **Peak amplitude** means that the maximum coefficient equals 1.

After the block normalizes the set of filter coefficients as above, it multiplies all coefficients by the **Linear amplitude filter gain** parameter. As a result, the output is scaled by  $\sqrt{N}$ . If the output of this block feeds the input to the AWGN Channel block, specify the AWGN signal power parameter to be  $1/N$ .

## Input and Output Signals

This block accepts scalar, column vector, and  $M$ -by- $N$  matrix input signals. The block filters an  $M$ -by- $N$  input matrix as follows:

- When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats each column as a separate channel. In this mode, the block creates  $N$  instances of the same filter, each with its own independent state buffer. Each of the  $N$  filters process  $M$  input samples at every Simulink time step.
- When you set the **Input processing** parameter to **Elements as channels (sample based)**, the block treats each element as a separate channel. In this mode, the block creates  $M*N$  instances of the same filter, each with its own independent state buffer. Each filter processes one input sample at every Simulink time step.

The output dimensions always equal those of the input signal. For information about the data types each block port supports, see the table on this page.

## Exporting Filter Coefficients to the MATLAB Workspace

To examine or manipulate the coefficients of the filter that this block designs, select **Export filter coefficients to workspace**. Then set the **Coefficient variable name**

parameter to the name of a variable that you want the block to create in the MATLAB workspace. Running the simulation causes the block to create the variable, overwriting any previous contents in case the variable already exists.

## Parameters

### Input samples per symbol

A positive integer representing the number of samples per symbol in the input signal.

### BT product

The product of the filter's 3-dB bandwidth and the input signal's symbol period

### Group delay

A positive integer that represents the number of symbol periods between the start of the filter response and its peak.

### Filter coefficient normalization

The block scales the set of filter coefficients so that this quantity equals 1. Choices are `Sum of coefficients`, `Filter energy`, and `Peak amplitude`.

### Input processing

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

### Linear amplitude filter gain

A positive scalar used to scale the filter coefficients after the block uses the normalization specified in the **Filter coefficient normalization** parameter.

### Export filter coefficients to workspace

If you check this box, then the block creates a variable in the MATLAB workspace that contains the filter coefficients.

### Coefficient variable name

The name of the variable to create in the MATLAB workspace. This field appears only if **Export filter coefficients to workspace** is selected.

### Visualize filter with FVTool

If you click this button, then MATLAB launches the Filter Visualization Tool, `fvtool`, to analyze the Gaussian filter whenever you apply any changes to the block's parameters. If you launch `fvtool` for the filter, and subsequently change parameters in the mask, `fvtool` will not update. You will need to launch a new `fvtool` in order to see the new filter characteristics. Also note that if you have launched `fvtool`, then it will remain open even after the model is closed.

### Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to **Nearest**. The block uses the **Rounding** selection if a number cannot be represented exactly by the specified data type and

scaling, it is rounded to a representable number. For more information, see *Rounding Modes* (DSP System Toolbox) or “Rounding Mode: Simplest” (Fixed-Point Designer).

### **Overflow mode**

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

### **Coefficients**

The block implementation uses a Direct-Form FIR filter. The **Coefficients** parameter controls which data type represents the coefficients when the input data is a fixed-point signal.

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See “Filter Structure Diagrams” (DSP System Toolbox) for illustrations depicting the use of the coefficient data types in this block:

- When you select **Same word length as input**, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Specify word length**, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; they are always saturated and rounded to Nearest.

### **Product output**

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Multiplication Data Types” (DSP System Toolbox) and

“Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the product output data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

#### **Accumulator**

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Same as product output**, these characteristics match those of the product output.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

#### **Output**

Choose how you specify the output word length and fraction length:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Same as accumulator**, these characteristics match those of the accumulator.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the output, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

**Lock scaling against changes by the autoscaling tool**

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

**Supported Data Type**

Port	Supported Data Types
In	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed fixed-point</li> </ul>
Out	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed fixed-point</li> </ul>

## Gaussian Noise Generator

(To be removed) Generate Gaussian distributed noise with given mean and variance values

---

**Note** Gaussian Noise Generator will be removed in a future release. Use the MATLAB Function block and `randn` function instead.

---

### Library

Noise Generators sublibrary of Comm Sources

### Description

The Gaussian Noise Generator block generates discrete-time white Gaussian noise. You must specify the **Initial seed** vector in the simulation.

The **Mean Value** and the **Variance** can be either scalars or vectors. If either of these is a scalar, then the block applies the same value to each element of a sample-based output or each column of a frame-based output. Individual elements or columns, respectively, are uncorrelated with each other.

When the **Variance** is a vector, its length must be the same as that of the **Initial seed** vector. In this case, the covariance matrix is a diagonal matrix whose diagonal elements come from the **Variance** vector. Since the off-diagonal elements are zero, the output Gaussian random variables are uncorrelated.

When the **Variance** is a square matrix, it represents the covariance matrix. Its off-diagonal elements are the correlations between pairs of output Gaussian random variables. In this case, the **Variance** matrix must be positive definite, and it must be N-by-N, where N is the length of the **Initial seed**.

The probability density function of  $n$ -dimensional Gaussian noise is

$$f(x) = ((2\pi)^n \det K)^{-1/2} \exp\left(-\frac{(x - \mu)^T K^{-1} (x - \mu)}{2}\right)$$

where  $x$  is a length- $n$  vector,  $K$  is the  $n$ -by- $n$  covariance matrix,  $\mu$  is the mean value vector, and the superscript  $T$  indicates matrix transpose.

## Initial Seed

The **Initial seed** parameter initializes the random number generator that the Gaussian Noise Generator block uses to add noise to the input signal. When multiple blocks in a model have the **Initial seed** parameter, you can choose different initial seeds for each block to ensure different random streams are used in each block. Set **Initial seed** to an integer value for repeatable results or use the `randi` function to randomize your results.

## Attributes of Output Signal

The output signal can be a frame-based matrix, a sample-based row or column vector, or a sample-based one-dimensional array. These attributes are controlled by the **Frame-based outputs**, **Samples per frame**, and **Interpret vector parameters as 1-D** parameters. For additional information, see “Sources and Sinks”.

If the **Initial seed** parameter is a vector, then its length becomes the number of columns in a frame-based output or the number of elements in a sample-based vector output. In this case, the shape (row or column) of the **Initial seed** parameter becomes the shape of a sample-based two-dimensional output signal. If the **Initial seed** parameter is a scalar but either the **Mean value** or **Variance** parameter is a vector, then the vector length determines the output attributes mentioned above.

## Parameters

### Mean value

The mean value of the random variable output.

### Variance

The covariance among the output random variables.

### Initial seed

The initial seed value for the random number generator.

### Sample time

The period of each sample-based vector or each row of a frame-based matrix.

### **Frame-based outputs**

Determines whether the output is frame-based or sample-based. This box is active only if **Interpret vector parameters as 1-D** is unchecked.

### **Samples per frame**

The number of samples in each column of a frame-based output signal. This field is active only if **Frame-based outputs** is checked.

### **Interpret vector parameters as 1-D**

If this box is checked, then the output is a one-dimensional signal. Otherwise, the output is a two-dimensional signal. This box is active only if **Frame-based outputs** is unchecked.

### **Output data type**

The output can be set to `double` or `single` data types.

# General Block Deinterleaver

Restore ordering of symbols in input vector

## Library

Block sublibrary of Interleaving

## Description

The General Block Deinterleaver block rearranges the elements of its input vector without repeating or omitting any elements. If the input contains  $N$  elements, then the **Permutation vector** parameter is a column vector of length  $N$ . The column vector indicates the indices, in order, of the output elements that came from the input vector. That is, for each integer  $k$  between 1 and  $N$ ,

$$\text{Output}(\mathbf{Permutation} \quad \mathbf{vector}(k)) = \text{Input}(k)$$

The **Permutation vector** parameter must contain unique integers between 1 and  $N$ .

Both the input and the **Permutation vector** parameter must be column vector signals.

This block can output sequences that vary in length during simulation. For more information about sequences that vary in length, or variable-size signals, see “Variable-Size Signal Basics” (Simulink).

This block accept the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

To use this block as an inverse of the General Block Interleaver block, use the same **Permutation vector** parameter in both blocks. In that case, the two blocks are inverses

in the sense that applying the General Block Interleaver block followed by the General Block Deinterleaver block leaves data unchanged.

## Parameters

### Permutation vector source

A selection that specifies the source of the permutation vector. The source can be either `Dialog` or `Input port`. The default value is `Dialog`.

### Permutation vector

A vector of length  $N$  that lists the indices of the output elements that came from the input vector. This parameter is available only when **Permutation vector source** is set to `Dialog`.

## Examples

This example reverses the operation in the example on the General Block Interleaver block reference page. If you set **Permutation vector** to `[4, 1, 3, 2]'` and you set the General Block Deinterleaver block input to `[1; 40; 59; 32]`, then the output of the General Block Deinterleaver block is `[40; 32; 59; 1]`.

## General Block Interleaver

Reorder symbols in input vector

### Library

Block sublibrary of Interleaving

### Description

The General Block Interleaver block rearranges the elements of its input vector without repeating or omitting any elements. If the input contains  $N$  elements, then the **Permutation vector** parameter is a column vector of length  $N$ . The column vector indicates the indices, in order, of the input elements that form the length- $N$  output vector; that is,

$$\text{Output}(k) = \text{Input}(\mathbf{Permutation\ vector}(k))$$

for each integer  $k$  between 1 and  $N$ . The contents of **Permutation vector** must be integers between 1 and  $N$ , and must have no repetitions.

Both the input and the **Permutation vector** parameter must be column vector signals.

This block can output sequences that vary in length during simulation. For more information about sequences that vary in length, or variable-size signals, see “Variable-Size Signal Basics” (Simulink).

This block accept the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

### Permutation vector source

A selection that specifies the source of the permutation vector. The source can be either `Dialog` or `Input port`. The default value is `Dialog`.

### Permutation vector

A vector of length  $N$  that lists the indices of the output elements that came from the input vector. This parameter is available only when **Permutation vector source** is set to `Dialog`.

## Examples

If **Permutation vector** is `[4;1;3;2]` and the input vector is `[40;32;59;1]`, then the output vector is `[1;40;59;32]`. Notice that all of these vectors have the same length and that the vector **Permutation vector** is a permutation of the vector `[1:4]'`.

# General CRC Generator

Generate CRC code bits according to generator polynomial and append to input data frames

**Library:** Communications Toolbox / Error Detection and Correction / CRC

## Description

The General CRC Generator block generates cyclic redundancy check (CRC) code bits for each input data frame and appends them to the frame. For more information, see “CRC Generator Operation” on page 3-441.

## Ports

### Input

#### **In — Input signal**

binary column vector

Input signal, specified as a binary column vector. The length of the input frame must be a multiple of the value of the **Checksums per frame** parameter.

Data Types: double | Boolean

### Output

#### **Out — Output codeword frame**

binary column vector

Output codeword frame, returned as a binary column vector that inherits the data type of the input signal. The output contains the input data frames with the CRC bit sequences appended to them.

The length of the output frame is  $m + k * r$ , where  $m$  is the size of the input frame,  $k$  is the number of checksums per frame, and  $r$  is the degree of the generator polynomial.

## Parameters

### Generator polynomial — Generator polynomial

'z<sup>16</sup> + z<sup>12</sup> + z<sup>5</sup> + 1' (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as 'z<sup>3</sup> + z<sup>2</sup> + 1'.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is  $(N+1)$ , where  $N$  is the degree of the generator polynomial. For example, [1 1 0 1] represents the polynomial  $x^3 + x^2 + 1$ .
- An integer row vector containing the exponents of  $z$  for the nonzero terms in the polynomial in descending order. For example, [3 2 0] represents the polynomial  $z^3 + z^2 + 1$ .

For more information, see “Character Representation of Polynomials”.

Some commonly used generator polynomials include:

CRC method	Generator polynomial
CRC-32	'z <sup>32</sup> + z <sup>26</sup> + z <sup>23</sup> + z <sup>22</sup> + z <sup>16</sup> + z <sup>12</sup> + z <sup>11</sup> + z <sup>10</sup> + z <sup>8</sup> + z <sup>7</sup> + z <sup>5</sup> + z <sup>4</sup> + z <sup>2</sup> + z + 1'
CRC-24	'z <sup>24</sup> + z <sup>23</sup> + z <sup>14</sup> + z <sup>12</sup> + z <sup>8</sup> + 1'
CRC-16	'z <sup>16</sup> + z <sup>15</sup> + z <sup>2</sup> + 1'
Reversed CRC-16	'z <sup>16</sup> + z <sup>14</sup> + z + 1'
CRC-8	'z <sup>8</sup> + z <sup>7</sup> + z <sup>6</sup> + z <sup>4</sup> + z <sup>2</sup> + 1'
CRC-4	'z <sup>4</sup> + z <sup>3</sup> + z <sup>2</sup> + z + 1'

Example: 'z<sup>7</sup> + z<sup>2</sup> + 1', [1 0 0 0 0 1 0 1], and [7 2 0] represent the same polynomial,  $p(z) = z^7 + z^2 + 1$ .

**Initial states — Initial states of internal shift register**

0 (default) | 1 | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

**Direct method — Use direct algorithm for CRC checksum calculations**

off (default) | on

Select to use the direct algorithm for CRC checksum calculations. When cleared, the block uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see “Error Detection and Correction”.

**Reflect input bytes — Reflect input bytes**

off (default) | on

Select to flip the input data on a bitwise basis before entering the data into the shift register. When **Reflect input bytes** is selected, the input frame length divided by the value of the **Checksums per frame** parameter must be an integer and a multiple of 8. When **Reflect input bytes** is cleared, the block does not flip the input data.

**Reflect checksums before final XOR — Reflect checksums before final XOR**

off (default) | on

Select to flip the CRC checksums around their centers after the input data are completely through the shift register. When **Reflect checksums before final XOR** is cleared, the block does not flip the CRC checksums.

**Final XOR — Final XOR**

0 (default) | 1 | binary row vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the **Final XOR** parameter the CRC checksum before appending the CRC to the input data. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of 0 is equivalent to no XOR operation.

**Checksums per frame — Number of checksums calculated for each frame**

1 (default) | positive integer

Number of checksums calculated for each frame, specified as a positive integer.

## Block Characteristics

<b>Data Types</b>	Boolean   double
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

## More About

### Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the *checksum* or *syndrome*, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see “Cyclic Redundancy Check Codes”.

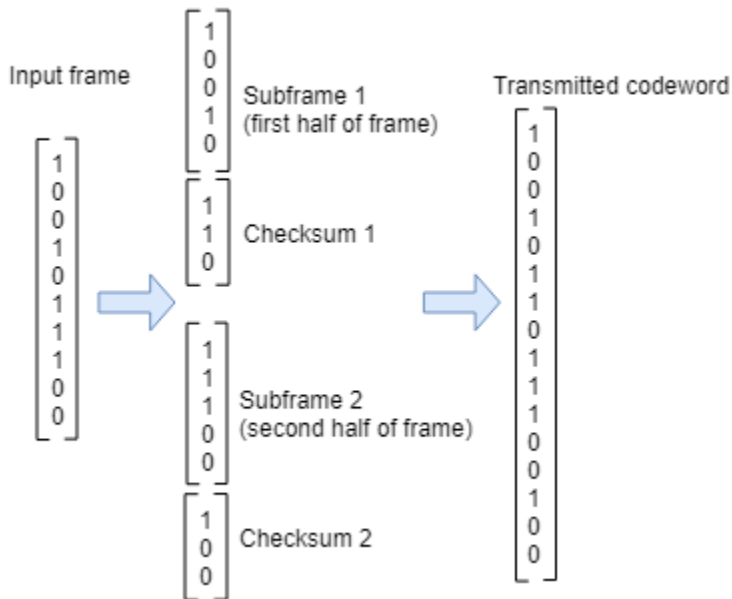

## CRC Generator Operation

The CRC generator appends CRC checksums to the input frame according to the specified generator polynomial and number of checksums per frame.

For a specific initial state of the internal shift register and  $k$  checksums per input frame:

- 1 The input signal is divided into  $k$  subframes of equal size.
- 2 Each of the  $k$  subframes are prefixed with the initial states vector.
- 3 The CRC algorithm is applied to each subframe.
- 4 The resulting checksums are appended to the end of each subframe.
- 5 The subframes are concatenated and output as a column vector.

For the scenario shown here, a 10-bit frame is input, a third degree generator polynomial computes the CRC checksum, the initial state is 0, and the number of checksums per frame is 2.

The input frame is divided into two subframes of size 5 and checksums of size 3 are computed and appended to each subframe. The initial states are not shown, because an

initial state of [0] does not affect the output of the CRC algorithm. The output transmitted codeword frame has the size  $5 + 3 + 5 + 3 = 16$ .

# General CRC Generator HDL Optimized

Generate CRC code bits and append to input data, optimized for HDL code generation

## Library

Communications Toolbox > Error Correction and Detection > CRC (commcrc2)

Communications Toolbox HDL Support > Error Correction and Detection > CRC (commhdlcrc)

## Description

This hardware-friendly CRC generator block, like the General CRC Generator block, generates a cyclic redundancy check (CRC) checksum and appends it to the input message. With the General CRC Generator HDL Optimized block, the processing is optimized for HDL code generation. Instead of processing an entire frame at once, the block accepts and returns a data sample stream with accompanying control signals. The control signals indicate the validity of the samples and the boundaries of the frame. To achieve higher throughput, the block accepts vector data up to the CRC length, and implements a parallel architecture.

## Signal Attributes

Port	Direction	Description	Data Type
dataIn	Input	Message data. Data can be a vector of binary values, or a scalar integer representing several bits. For example, vector input [0 0 0 1 0 0 1 1] is equivalent to uint8 input 19. The data width must be less than or equal to the CRC length, and the CRC length must be divisible by the data width. For example, for CRC-CCITT/CRC-16, the valid data widths are 16, 8, 4, 2, and 1.	Vector: double or Boolean  Scalar: unsigned integer (uint8/16/32) or fixdt(0,N,0)
startIn	Input	Indicates the start of a frame of data.	Boolean
endIn	Input	Indicates the end of a frame of data.	Boolean
validIn	Input	Indicates that input data is valid.	Boolean
dataOut	Output	Message data with the checksum appended. The output data has the same vector size as the input data.	Same as dataIn
startOut	Output	Indicates the start of a frame of data.	Boolean
endOut	Output	Indicates the end of a frame of data, including checksum.	Boolean
validOut	Output	Indicates that output data is valid.	Boolean

## Parameters

### Polynomial

A double or Boolean vector specifying the polynomial, in descending order of powers. CRC length is  $\text{length}(\text{polynomial}) - 1$ . The default value is [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1].

### Initial state

A double or Boolean scalar or vector of length equal to the CRC length, specifying the initial state of the internal shift register. The default value is 0.

**Direct method**

- When this parameter is selected, the block uses the direct algorithm for CRC checksum calculations.
- When this parameter is not selected, the block uses the nondirect algorithm for CRC checksum calculations.

The parameter is cleared by default.

To learn about the direct and non-direct algorithms, see “Cyclic Redundancy Check Codes”.

**Reflect input**

The input data width must be a multiple of 8.

- When this parameter is selected, each input byte is flipped before entering the shift register.
- When this parameter is not selected, the message data is passed to the shift register unchanged.

The parameter is cleared by default.

**Reflect CRC checksum**

The CRC length must be a multiple of 8.

- When this parameter is selected, each checksum byte is flipped before it is passed to the final XOR stage.
- When this parameter is not selected, the checksum byte is passed to the final XOR stage unchanged.

The parameter is cleared by default.

**Final XOR value**

The value that the CRC checksum is XORed with before it is appended to the input data. This parameter can be a double or Boolean scalar or vector of length equal to the CRC length. The default value is 0.

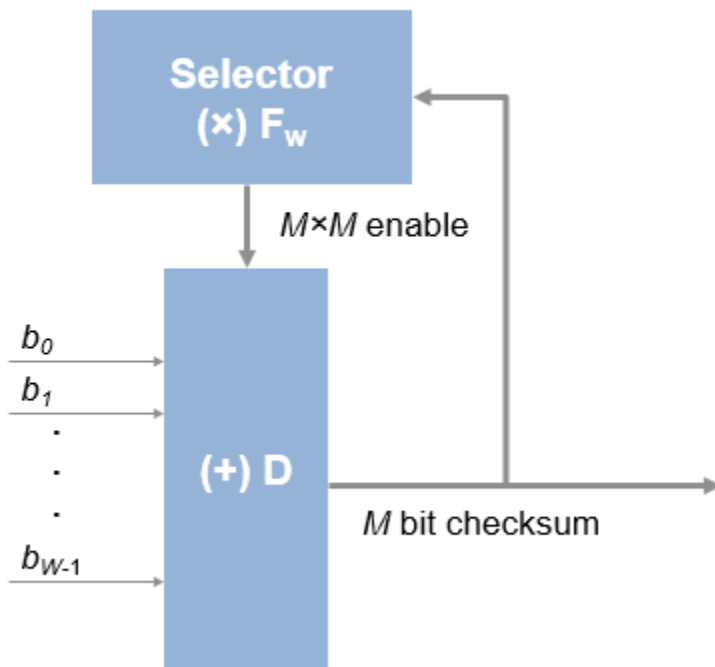

## Algorithm

When you use vector or integer input, the block implements a parallel CRC algorithm [1].

To provide high throughput for modern communications systems, the CRC algorithm is implemented with a parallel architecture. This architecture recursively calculates  $M$  bits of CRC checksum for each  $W$  input bits. At the end of the frame, the final checksum result is appended to the message. For a polynomial length of  $M$ , the recursive checksum calculation for  $W$  bits in parallel is:

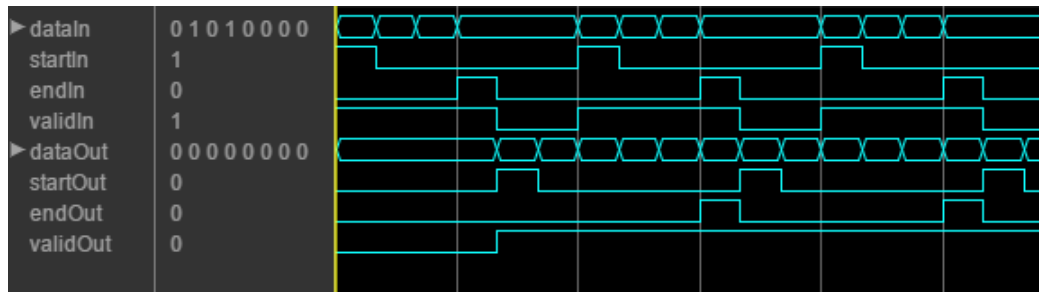

$$X' = F_W(\times)X(+)D$$

$F_W$  is an  $M$ -by- $M$  matrix that selects elements of the current state for the polynomial calculation with the new input bits.  $D$  is an  $M$ -sample vector that provides the new input bits, ordered in relation to the polynomial and padded with zeroes. ( $\times$ ) is implemented with logical AND, and ( $+$ ) is implemented with logical XOR.

## Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. There must be enough space between the input frames to insert the checksum word.

This waveform diagram shows continuous input data. Non-continuous data is also supported. The output valid signal matches the input valid pattern.

## Initial Delay

The General CRC Generator HDL Optimized block introduces a latency on the output. This latency can be computed with the following equation, assuming the input data is continuous:

$$\text{initialdelay} = (\text{CRC length}/\text{input data width}) + 2$$

# General CRC Syndrome Detector

Detect errors in received codeword frames according to generator polynomial

**Library:** Communications Toolbox / Error Detection and Correction / CRC

## Description

The General CRC Syndrome Detector block computes cyclic redundancy check (CRC) checksums for received codeword frames. For successful CRC detection in a communications system link, you must align the parameter settings of the General CRC Syndrome Detector block with the paired General CRC Generator block.

For more information, see “CRC Syndrome Detector Operation” on page 3-453.

## Ports

### Input

#### **In — Received codeword**

binary column vector

Received codeword, specified as a binary column vector.

Data Types: double | Boolean

### Output

#### **Out — Output frame**

binary column vector

Output frame, returned as a binary column vector that inherits the data type of the input signal. The output frame contains the received codeword with the checksums removed.

The length of the output frame is  $n - k * r$  bits, where  $n$  is the size of the received codeword,  $k$  is the number of checksums per frame, and  $r$  is the degree of the generator polynomial.

**Err — Checksum error signal**

binary column vector

Checksum error signal, returned as a binary column vector that inherits the data type of the input signal. The length of Err equals the value of **Checksums per frame**. For each checksum computation, an element value of 0 in Err indicates no checksum error, and an element value of 1 in Err indicates a checksum error.

## Parameters

**Generator polynomial — Generator polynomial**

'z<sup>16</sup> + z<sup>12</sup> + z<sup>5</sup> + 1' (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as 'z<sup>3</sup> + z<sup>2</sup> + 1'.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is  $(N+1)$ , where  $N$  is the degree of the generator polynomial. For example, [1 1 0 1] represents the polynomial  $x^3 + x^2 + 1$ .
- An integer row vector containing the exponents of  $z$  for the nonzero terms in the polynomial in descending order. For example, [3 2 0] represents the polynomial  $z^3 + z^2 + 1$ .

For more information, see “Character Representation of Polynomials”.

Some commonly used generator polynomials include:

CRC method	Generator polynomial
CRC-32	'z <sup>32</sup> + z <sup>26</sup> + z <sup>23</sup> + z <sup>22</sup> + z <sup>16</sup> + z <sup>12</sup> + z <sup>11</sup> + z <sup>10</sup> + z <sup>8</sup> + z <sup>7</sup> + z <sup>5</sup> + z <sup>4</sup> + z <sup>2</sup> + z + 1'
CRC-24	'z <sup>24</sup> + z <sup>23</sup> + z <sup>14</sup> + z <sup>12</sup> + z <sup>8</sup> + 1'

CRC method	Generator polynomial
CRC-16	'z <sup>16</sup> + z <sup>15</sup> + z <sup>2</sup> + 1'
Reversed CRC-16	'z <sup>16</sup> + z <sup>14</sup> + z + 1'
CRC-8	'z <sup>8</sup> + z <sup>7</sup> + z <sup>6</sup> + z <sup>4</sup> + z <sup>2</sup> + 1'
CRC-4	'z <sup>4</sup> + z <sup>3</sup> + z <sup>2</sup> + z + 1'

Example: 'z<sup>7</sup> + z<sup>2</sup> + 1', [1 0 0 0 0 1 0 1], and [7 2 0] represent the same polynomial,  $p(z) = z^7 + z^2 + 1$ .

### Initial states — Initial states of internal shift register

0 (default) | 1 | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

### Direct method — Use direct algorithm for CRC checksum calculations

off (default) | on

Select to use the direct algorithm for CRC checksum calculations. When cleared, the block uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see “Error Detection and Correction”.

### Reflect input bytes — Reflect input bytes

off (default) | on

Select to flip the received codeword on a bitwise basis before entering the data into the shift register. When **Reflect input bytes** is selected, the received codeword length divided by the value of the **Checksums per frame** parameter must be an integer and a multiple of 8. When **Reflect input bytes** is cleared, the block does not flip the input data.

### Reflect checksums before final XOR — Reflect checksums before final XOR

off (default) | on

Select **Reflect checksums before final XOR** to flip the CRC checksums around their centers after the input data are completely through the shift register. When **Reflect checksums before final XOR** is cleared, the block does not flip the CRC checksums.

**Final XOR — Final XOR** $0$  (default) | 1 | binary row vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the **Final XOR** parameter and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of  $0$  is equivalent to no XOR operation.

**Checksums per frame — Number of checksums calculated for each frame**

1 (default) | positive integer

Number of checksums calculated for each frame, specified as a positive integer.

## Block Characteristics

<b>Data Types</b>	Boolean   double
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	yes

## More About

### Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the *checksum* or *syndrome*, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received

codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see “Cyclic Redundancy Check Codes”.

## CRC Syndrome Detector Operation

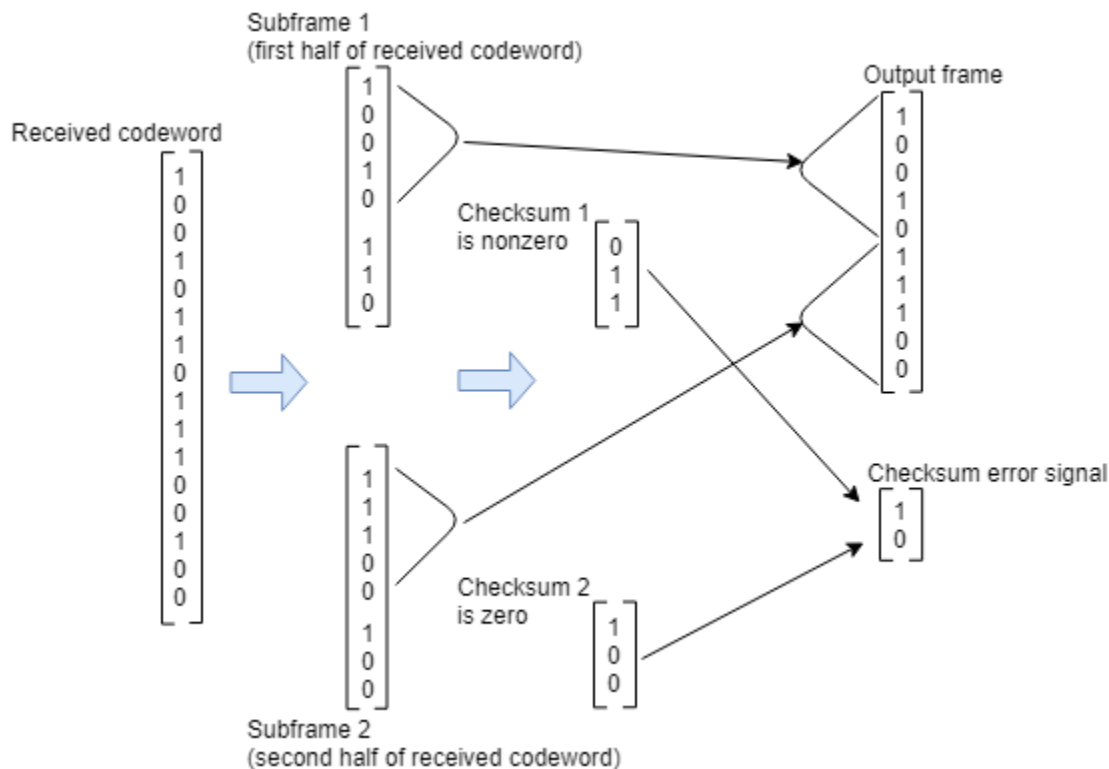

The CRC syndrome detector outputs the received message frame and a checksum error vector according to the specified generator polynomial and number of checksums per frame.

The checksum bits are removed from each subframe, so that the resulting the output frame length is  $n - k \times r$ , where  $n$  is the size of the received codeword,  $k$  is the number of checksums per frame, and  $r$  is the degree of the generator polynomial. The input frame must be evenly divisible by  $k$ .

For a specific initial state of the internal shift register:

- 1 The received codeword is divided into  $k$  equal sized subframes.
- 2 The CRC is removed from each of the  $k$  subframes and compared to the checksum calculated on the received codeword subframes.
- 3 The output frame is assembled by concatenating the subframe bits of the  $k$  subframes and then output as a column vector.
- 4 The checksum error is output as a binary column vector of length  $k$ . An element value of 0 indicates an error-free received subframe, and an element value of 1 indicates an error occurred in the received subframe.

For the scenario shown here, a 16-bit codeword is received, a third degree generator polynomial computes the CRC checksum, the initial state is 0, and the number of checksums per frame is 2.

Since the number of checksums per frame is 2 and the generator polynomial degree is 3, the received codeword is split in half and two checksums of size 3 are computed, one for each half of the received codeword. The initial states are not shown, because an initial state of  $[0]$  does not affect the output of the CRC algorithm. The output frame contains the concatenation of the two halves of the received codeword as a single vector of size 10. The checksum error signal output contains a 2-by-1 binary frame vector whose entries depend on whether the computed checksums are zero. As shown in the figure, the first checksum is nonzero and the second checksum is zero, indicating an error occurred in reception of the first half of the codeword.

## General CRC Syndrome Detector HDL Optimized

Detect errors in input data using CRC, optimized for HDL code generation

### Library

Communications Toolbox > Error Correction and Detection > CRC (commcrc2)

Communications Toolbox HDL Support > Error Correction and Detection > CRC (commhdlcrc)

### Description

This hardware-friendly CRC detector block performs a cyclic redundancy check (CRC) on data and compares the resulting checksum with the appended checksum. If the two checksums do not match, the block reports an error. Instead of processing an entire frame at once, the block accepts and returns a data sample stream with accompanying control signals. The control signals indicate the validity of the samples and the boundaries of the frame. To achieve higher throughput, the block accepts vector data up to the CRC length, and implements a parallel architecture.

## Signal Attributes

Port	Direction	Description	Data Type
dataIn	Input	Message data plus checksum. Data can be a vector of binary values, or a scalar integer representing several bits. For example, vector input [0 0 0 1 0 0 1 1] is equivalent to uint8 input 19. The data width must be less than or equal to the CRC length, and the CRC length must be divisible by the data width. For example, for CRC-CCITT/CRC-16, the valid data widths are 16, 8, 4, 2, and 1.	Vector: double or Boolean  Scalar: unsigned integer (uint8/16/32) or fixdt(0,N,0)
startIn	Input	Indicates the start of a frame of data, including checksum.	Boolean
endIn	Input	Indicates the end of a frame of data.	Boolean
validIn	Input	Indicates that input data is valid.	Boolean
dataOut	Output	Message data. The output data has the same width as the input data.	Same as dataIn
startOut	Output	Indicates the start of a frame of data.	Boolean
endOut	Output	Indicates the end of a frame of data.	Boolean
validOut	Output	Indicates that output data is valid.	Boolean
err	Output	Indicates the corruption of the received data, when err is high(1).	Boolean

## Parameters

### Polynomial

A double or Boolean vector specifying the polynomial, in descending order of powers. The CRC length is length(polynomial) - 1. The default value is [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1].

### Initial state

A double or Boolean scalar or vector of length equal to the CRC length, specifying the initial state of the internal shift register. The default value is 0.

**Direct method**

- When this parameter is selected, the block uses the direct algorithm for CRC checksum calculations.
- When this parameter is not selected, the block uses the nondirect algorithm for CRC checksum calculations.

The parameter is cleared by default.

To learn about the direct and non-direct algorithms, see “Cyclic Redundancy Check Codes”.

**Reflect input**

The input data width must be a multiple of 8.

- When this parameter is selected, each input byte is flipped before entering the shift register.
- When this parameter is not selected, the message data is passed to the shift register unchanged.

The parameter is cleared by default.

**Reflect CRC checksum**

The CRC length must be a multiple of 8.

- When this parameter is selected, each checksum byte is flipped before it is passed to the final XOR stage.
- When this parameter is not selected, the checksum byte is passed to the final XOR stage unchanged.

The parameter is cleared by default.

**Final XOR value**

The value that the CRC checksum is XORed with before it is appended to the input data. This parameter can be a double or Boolean scalar or vector of length equal to the CRC length. The default value is 0.

## Algorithm

When you use vector or integer input, the block implements a parallel CRC algorithm [1].

To provide high throughput for modern communications systems, the CRC algorithm is implemented with a parallel architecture. This architecture recursively calculates  $M$  bits of CRC checksum for each  $W$  input bits. At the end of the frame, the final checksum result is appended to the message. For a polynomial length of  $M$ , the recursive checksum calculation for  $W$  bits in parallel is:

$$X' = F_W(\times)X(+)D$$

$F_W$  is an  $M$ -by- $M$  matrix that selects elements of the current state for the polynomial calculation with the new input bits.  $D$  is an  $M$ -sample vector that provides the new input bits, ordered in relation to the polynomial and padded with zeroes. ( $\times$ ) is implemented with logical AND, and ( $+$ ) is implemented with logical XOR.

## Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. The input frames are contiguous, and the output frames show space between them because the detector block removes the checksum word.

This waveform diagram shows continuous input data. Non-continuous data is also supported.

## Initial Delay

The General CRC Syndrome Detector HDL Optimized block introduces a latency on the output. This latency can be computed with the following equation, assuming the input data is continuous:

$$\text{initialdelay} = 3 * (\text{CRC length}/\text{input data width}) + 2$$

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### HDL Architecture

This block has a single, default HDL architecture.

### HDL Block Properties

<b>ConstrainedOutputPipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

## General Multiplexed Deinterleaver

Restore ordering of symbols using specified-delay shift registers

### Library

Convolutional sublibrary of Interleaving

### Description

The General Multiplexed Deinterleaver block restores the original ordering of a sequence that was interleaved using the General Multiplexed Interleaver block.

In typical usage, the parameters in the two blocks have the same values. As a result, the **Interleaver delay** parameter,  $V$ , specifies the delays for each shift register in the corresponding *interleaver*, so that the delays of the deinterleaver's shift registers are actually  $\max(V) - V$ .

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

The block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The data type of the output will be the same as that of the input signal.

### Parameters

#### Interleaver delay (samples)

A vector that lists the number of symbols that fit in each shift register of the corresponding interleaver. The length of this vector is the number of shift registers.

**Initial conditions**

The values that fill each shift register when the simulation begins.

**Pair Block**

General Multiplexed Interleaver

**References**

**Extended Capabilities****C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

**HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

**HDL Architecture**

The implementation for the General Multiplexed Deinterleaver block is shift register based. If you want to suppress generation of reset logic, set the implementation parameter `ResetType` to `none`.

When you set `ResetType` to `none`, reset is not applied to the shift registers. When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench

errors, determine the number of samples required to fill the shift registers. Set the **Ignore output data checking (number of samples)** option accordingly. (If you are using the command-line interface, you can use the `IgnoreDataChecking` property for this purpose.)

### HDL Block Properties

<b>ConstrainedOutputPipeline</b>	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
<b>InputPipeline</b>	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
<b>OutputPipeline</b>	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
<b>ResetType</b>	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also “ResetType” (HDL Coder).

# General Multiplexed Interleaver

Permute input symbols using set of shift registers with specified delays

## Library

Convolutional sublibrary of Interleaving

## Description

The General Multiplexed Interleaver block permutes the symbols in the input signal. Internally, it uses a set of shift registers, each with its own delay value.

This block accepts a scalar or column vector input signal, which can be real or complex. The input and output signals have the same sample time.

The block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal has the same data type as the input signal.

## Parameters

### Interleaver delay (samples)

A column vector listing the number of symbols that fit into each shift register. The length of this vector is the number of shift registers. (In sample-based mode, it can also be a row vector.)

### Initial conditions

The values that fill each shift register at the beginning of the simulation.

If **Initial conditions** is a scalar, then its value fills all shift registers. If **Initial conditions** is a column vector, then each entry fills the corresponding shift register.

(In sample-based mode, **Initial conditions** can also be a row vector.) If a given shift register has zero delay, then the value of the corresponding entry in the **Initial conditions** vector is unimportant.

## General QAM Demodulator Baseband

Demodulate QAM-modulated data

### Library

AM, in Digital Baseband sublibrary of Modulation

### Description

The General QAM Demodulator Baseband block demodulates a signal that was modulated using quadrature amplitude modulation. The input is a baseband representation of the modulated signal.

The input must be a discrete-time complex signal. The **Signal constellation** parameter defines the constellation by listing its points in a length-M vector of complex numbers. The block maps the  $m$ th point in the **Signal constellation** vector to the integer  $m-1$ .

This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see the “Supported Data Types” on page 3-477 table on this page.

### Parameters

#### Signal constellation

A real or complex vector that lists the constellation points.

#### Output type

Determines whether the block produces integers or binary representations of integers.

If you set this parameter to Integer, the block produces integers.

If you set this parameter to **Bit**, the block produces a group of  $K$  bits, called a *binary word*, for each symbol, when **Decision type** is set to **Hard decision**. If **Decision type** is set to **Log-likelihood ratio** or **Approximate log-likelihood ratio**, the block outputs bitwise LLR and approximate LLR, respectively.

### Decision type

This field appears when **Bit** is selected in the pull-down list **Output type**.

Specifies the use of hard decision, LLR, or approximate LLR during demodulation. See “Exact LLR Algorithm” and “Approximate LLR Algorithm” in the *Communications Toolbox User's Guide* for algorithm details.

### Noise variance source

This field appears when you set **Approximate log-likelihood ratio** or **Log-likelihood ratio** for **Decision type**.

When you set this parameter to **Dialog**, you can then specify the noise variance in the **Noise variance** field. When you set this option to **Port**, a port appears on the block through which the noise variance can be input.

### Noise variance

This parameter appears when the **Noise variance source** is set to **Dialog** and specifies the noise variance in the input signal. This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- **Inf** to **-Inf** if **Noise variance** is very high
- **NaN** if **Noise variance** and signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

## Fixed-Point Signal Flow Diagrams

### Fixed-Point Signal Flow Diagram for Hard Decision Mode

---

**Note** In the figure above,  $M$  represents the size of the **Signal constellation** .

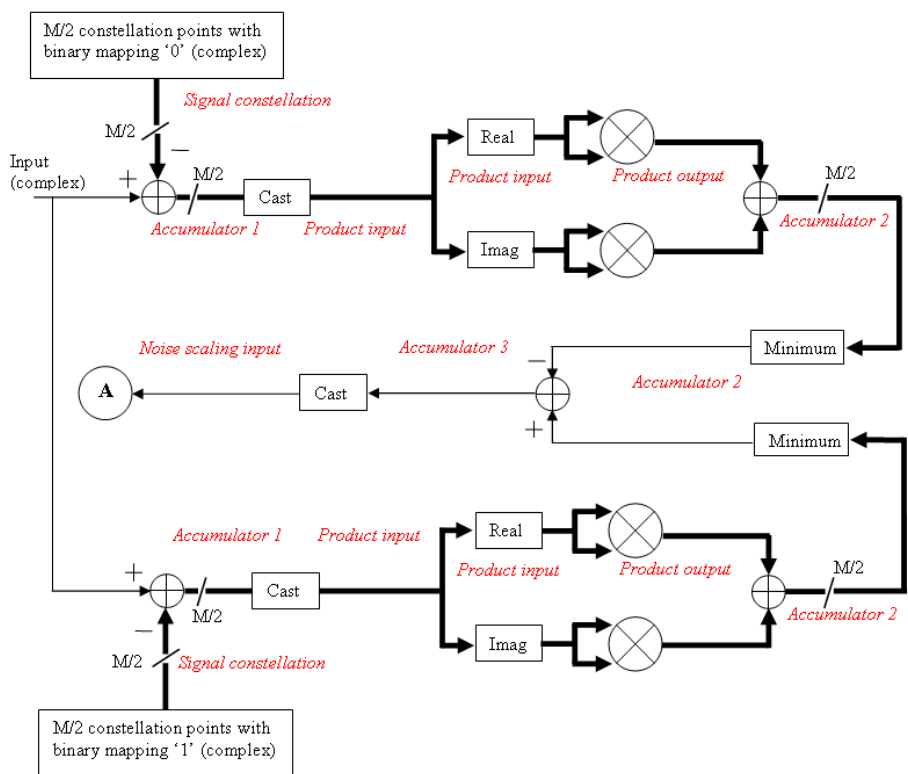

---

The general QAM Demodulator Baseband block supports fixed-point operations for computing Hard Decision (**Output type** set to Bit and **Decision type** is set to Hard decision) and Approximate LLR (**Output type** is set to Bit and **Decision type** is set to Approximate Log-Likelihood ratio) output values. The input values must have fixed-point data type for fixed-point operations.

---

**Note** Fixed-Point operations are NOT yet supported for Exact LLR output values.

---

### Fixed-Point Signal Flow Diagram for Approximate LLR Mode

**Note** In the figure above,  $M$  represents the size of the **Signal constellation**.

### Fixed-Point Signal Flow Diagram for Approximate LLR Mode: Noise Variance Operation Modes

**Note** If **Noise variance** is set to **Dialog**, the block performs the operations shown inside the dotted line once during initialization. The block also performs these operations if the **Noise variance** value changes during simulation.

## Data Types Attributes

### Output

The block supports the following Output options:

When you set the parameter to **Inherit via internal rule** (default setting), the block inherits the output data type from the input port. The output data type is the same as the input data type if the input is of type **single** or **double**.

For integer outputs, you can set this block's output to **Inherit via internal rule** (default setting), **Smallest unsigned integer**, **int8**, **uint8**, **int16**, **uint16**, **int32**, **uint32**, **single**, and **double**.

For bit outputs, when you set **Decision type** to **Hard decision**, you can set the output to **Inherit via internal rule**, **Smallest unsigned integer**, **int8**, **uint8**, **int16**, **uint16**, **int32**, **uint32**, **boolean**, **single**, or **double**.

When you set **Decision type** to `Hard decision` or `Approximate log-likelihood ratio` and the input is a floating point data type, then the output inherits its data type from the input. For example, if the input is of data type `double`, the output is also of data type `double`. When you set **Decision type** to `Hard decision` or `Approximate log-likelihood ratio`, and the input is a fixed-point signal, the **Output** parameter, located in the Fixed-Point algorithm parameters region of the Data-Type tab, specifies the output data type.

When you set the parameter to `Smallest unsigned integer`, the output data type is selected based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box. If you select ASIC/FPGA in the **Hardware Implementation** pane, the output data type is the ideal minimum size, i.e., `ufix(1)` for bit outputs, and `ufix(floor(log2M))` for integer outputs. For all other choices, the **Output** data type is an unsigned integer with the smallest available word length large enough to fit the ideal minimum size, usually corresponding to the size of a char (e.g., `uint8`).

### **Rounding Mode Parameter**

Use this parameter to specify the rounding method to be used when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result.

For more information, see “Rounding Modes” (DSP System Toolbox) or “Rounding Mode: Simplest” (Fixed-Point Designer).

### **Saturate on integer overflow**

Use this parameter to specify the method to be used if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result:

- Saturate represents positive overflows as the largest positive number in the range being used, and negative overflows as the largest negative number in the range being used.
- Wrap uses modulo arithmetic to cast an overflow back into the representable range of the data type. See Modulo Arithmetic (Fixed-Point Designer) for more information.

For more information, see the **Saturate on integer overflow** parameter subsection of “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

### **Signal constellation**

Use this parameter to define the data type of the **Signal constellation** parameter.

- When you select `Same word length as input` the word length of the **Signal constellation** parameter matches that of the input to the block. The fraction length is computed to provide the best precision for given signal constellation values.
- When you select `Specify word length`, the **Word Length** field appears, and you may enter a value for the word length. The fraction length is computed to provide the best precision for given signal constellation values.

#### **Accumulator 1**

Use this parameter to specify the data type for **Accumulator 1**:

- When you select `Inherit via internal rule`, the block automatically calculates the output word and fraction lengths. For more information, see the “Inherit via Internal Rule” (DSP System Toolbox) subsection of the *DSP System Toolbox™ User's Guide*.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of **Accumulator 1**, in bits.

#### **Product Input**

Use this parameter to specify the data type for **Product input**.

- When you select `Same as accumulator 1`, the **Product Input** characteristics match those of **Accumulator 1**.
- When you select `Binary point scaling` you can enter the word length and the fraction length of **Product input**, in bits.

#### **Product Output**

Use this parameter to select the data type for Product output.

- When you select `Inherit via internal rule`, the block automatically calculates the output signal type. For more information, see the `Inherit via Internal Rule` (DSP System Toolbox) subsection of the *DSP System Toolbox User's Guide*.
- When you select `Binary point scaling` enter the word length and the fraction length for **Product output**, in bits.

#### **Accumulator 2**

Use this parameter to specify the data type for **Accumulator 2**:

- When you select **Inherit via internal rule**, the block automatically calculates the accumulator data type. The internal rule calculates the ideal, full-precision word length and fraction length as follows:

$$WL_{\text{ideal accumulator 2}} = WL_{\text{input to accumulator 2}}$$

$$FL_{\text{ideal accumulator 2}} = FL_{\text{input to accumulator 2}}$$

After the full-precision result is calculated, your particular hardware may still affect the final word and fraction lengths set by the internal rule. For more information, see *The Effect of the Hardware Implementation Pane on the Internal Rule (DSP System Toolbox)* subsection of the *DSP System Toolbox User's Guide*.

The internal rule always sets the sign of data-type to **Unsigned**.

- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of **Accumulator 2**, in bits.

The settings for the following fixed-point parameters only apply when you set **Decision type** to **Approximate log-likelihood ratio**.

### Accumulator 3

When you select **Inherit via internal rule**, the block automatically calculates the accumulator data type. The internal rule first calculates ideal, full-precision word length and fraction length as follows:

$$WL_{\text{ideal accumulator 3}} = WL_{\text{input to accumulator 3}} + 1$$

$$FL_{\text{ideal accumulator 3}} = FL_{\text{input to accumulator 3}}$$

After the full-precision result is calculated, your particular hardware may still affect the final word and fraction lengths set by the internal rule. For more information, see *The Effect of the Hardware Implementation Pane on the Internal Rule (DSP System Toolbox)* subsection of the *DSP System Toolbox User's Guide*.

The internal rule always sets the sign of data-type to **Signed**.

### Noise scaling input

- When you select **Same as accumulator 3**, the **Noise scaling input** characteristics match those of **Accumulator 3**.
- When you select **Binary point scaling** you are able to enter the word length and the fraction length of **Noise scaling input**, in bits.

**Inverse noise variance**

This field appears when **Noise variance** source is set to Dialog.

- When you select **Same word length as input** the word length of the **Inverse noise variance** parameter matches that of the input to the block. The fraction length is computed to provide the best precision for a given inverse noise variance value.
- When you select **Specify word length**, the **Word Length** field appears, and you may enter a value for the word length. The fraction length is computed to provide the best precision for a given inverse noise variance value.

**Output**

When you select **Inherit via internal rule**, the **Output data type** is automatically set for you.

If you set the **Noise variance source** parameter to **Dialog**, the output is a result of product operation as shown in the Noise Variance Operation Modes Signal Flow Diagram “Fixed-Point Signal Flow Diagram for Approximate LLR Mode: Noise Variance Operation Modes” on page 3-472. In this case, it follows the internal rule for Product data types specified in the **Inherit via Internal Rule (DSP System Toolbox)** subsection of the *DSP System Toolbox User's Guide*.

If the **Noise variance source** parameter is set to **Port**, the output is a result of division operation as shown in the signal flow diagram. In this case, the internal rule calculates the ideal, full-precision word length and fraction length as follows:

$$WL_{\text{output}} = \max(WL_{\text{Noise scaling input}}, WL_{\text{Noise variance}})$$

$$FL_{\text{output}} = FL_{\text{Noise scaling input (dividend)}} - FL_{\text{Noise variance (divisor)}} \cdot$$

After the full-precision result is calculated, your particular hardware may still affect the final word and fraction lengths set by the internal rule. For more information, see “The Effect of the Hardware Implementation Pane on the Internal Rule” (DSP System Toolbox) subsection of the *DSP System Toolbox User's Guide*.

The internal rule for **Output** always sets the sign of data-type to **Signed**.

For additional information about the parameters pertaining to fixed-point applications, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

# General QAM Modulator Baseband

Modulate using quadrature amplitude modulation

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The General QAM Modulator Baseband block modulates using quadrature amplitude modulation. The output is a baseband representation of the modulated signal.

The **Signal constellation** parameter defines the constellation by listing its points in a length- $M$  vector of complex numbers. The input signal values must be integers between 0 and  $M-1$ . The block maps an input integer  $m$  to the  $(m+1)$ st value in the **Signal constellation** vector.

This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see the “Supported Data Types” on page 3-481 table on this page.

## Constellation Visualization

The General QAM Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the Constellation Visualization section of the *Communications Toolbox User's Guide*.

## Parameters

### Signal constellation

A real or complex vector that lists the constellation points.

### Output data type

The output data type can be set to `double`, `single`, `Fixed-point`, `User-defined`, or `Inherit via back propagation`.

Setting this to `Fixed-point` or `User-defined` will enable fields in which you can further specify details. Setting this to `Inherit via back propagation`, sets the output data type and scaling to match the following block..

### Output word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

### User-defined data type

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the `sfix`, `sint`, `sfrac`, and `fixdt` functions from Fixed-Point Designer software. This parameter is only visible when you select `User-defined` for the **Output data type** parameter.

### Set output fraction length to

Specify the scaling of the fixed-point output by either of the following two methods:

- Choose `Best precision` to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the output scaling in the **Output fraction length** parameter.

This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter, or when you select `User-defined` and the specified output data type is a fixed-point data type.

### Output fraction length

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Output data type** parameter and `User-defined` for the **Set output fraction length to** parameter.

General QAM Demodulator Baseband | Rectangular QAM Modulator Baseband

**Introduced before R2006a**

## General TCM Decoder

Decode trellis-coded modulation data, mapped using arbitrary constellation

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The General TCM Decoder block uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using an arbitrary signal constellation.

The **Trellis structure** and **Signal constellation** parameters in this block should match those in the General TCM Encoder block, to ensure proper decoding. In particular, the **Signal constellation** parameter must be in set-partitioned order.

## Input and Output Signals

This block accepts a column vector input signal containing complex numbers. The input signal must be `double` or `single`. The reset port signal must be `double` or `Boolean`. For information about the data types each block port supports, see “Supported Data Types” on page 3-484.

If the convolutional encoder described by the trellis structure represents a rate  $k/n$  code, then the General TCM Decoder block's output is a binary column vector whose length is  $k$  times the vector length of the input signal.

## Operation Modes

The block has three possible methods for transitioning between successive frames. The **Operation mode** parameter controls which method the block uses. This parameter also affects the range of possible values for the **Traceback depth** parameter,  $D$ .

- In **Continuous** mode, the block initializes all state metrics to zero at the beginning of the simulation, waits until it accumulates  $D$  symbols, and then uses a sequence of  $D$  symbols to compute each of the traceback paths.  $D$  can be any positive integer. At the end of each frame, the block saves its internal state metric for use with the next frame.

If you select **Enable the reset input port**, the block displays another input port, labeled **Rst**. This port receives an integer scalar signal. Whenever the value at the **Rst** port is nonzero, the block resets all state metrics to zero and sets the traceback memory to zero.

- In **Truncated** mode, the block treats each frame independently. The traceback path starts at the state with the lowest metric.  $D$  must be less than or equal to the vector length of the input.
- In **Terminated** mode, the block treats each frame independently. The traceback path always starts at the all-zeros state.  $D$  must be less than or equal to the vector length of the input. If you know that each frame of data typically ends at the all-zeros state, then this mode is an appropriate choice.

## Decoding Delay

If you set **Operation mode** to **Continuous**, then this block introduces a decoding delay equal to **Traceback depth** $\cdot k$  bits for a rate  $k/n$  convolutional code. The decoding delay is the number of zeros that precede the first decoded bit in the output.

The block incurs no delay for other values of **Operation mode**.

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

**Signal constellation**

A complex vector that lists the points in the signal constellation in set-partitioned order.

**Traceback depth**

The number of trellis branches (equivalently, the number of symbols) the block uses in the Viterbi algorithm to construct each traceback path.

**Operation mode**

The operation mode of the Viterbi decoder. The choices are `Continuous`, `Truncated`, and `Terminated`.

**Enable the reset input port**

When you select this check box, the block has a second input port labeled `Rst`. Providing a nonzero value to this port causes the block to set its internal memory to the initial state before processing the input data. This field appears only if you set **Operation mode** to `Continuous`.

**Output data type**

Select the data type for the block output signal as `boolean` or `single`. By default, the block sets this to `double`.

## Supported Data Types

### Functions

`poly2trellis`

**Introduced before R2006a**

## General TCM Encoder

Convolutionally encode binary data and map using arbitrary constellation

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The General TCM Encoder block implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to an arbitrary signal constellation. The **Signal constellation** parameter lists the signal constellation points in set-partitioned order. This parameter is a complex vector with a length,  $M$ , equal to the number of possible output symbols from the convolutional encoder. (That is,  $\log_2 M$  is equal to  $n$  for a rate  $k/n$  convolutional code.)

## Input Signals and Output Signals

If the convolutional encoder represents a rate  $k/n$  code, then the General TCM Encoder block's input must be a binary column vector with a length of  $L*k$  for some positive integer  $L$ .

This block accepts a binary-valued input signal. The output signal is a complex column vector of length  $L$ . For information about the data types each block port supports, see “Supported Data Types” on page 3-489.

## Specifying the Encoder

To define the convolutional encoder, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, then use a `poly2trellis` command within the **Trellis structure** field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

- If you have a variable in the MATLAB workspace that contains the trellis structure, then enter its name as the **Trellis structure** parameter. This way is faster because it causes Simulink software to spend less time updating the diagram at the beginning of each simulation, compared to the usage in the previous bulleted item.

The encoder registers begin in the all-zeros state. You can configure the encoder so that it resets its registers to the all-zeros state during the course of the simulation. To do this, set the `Operation` mode to **Reset on nonzero input via port**. The block then opens a second input port, labeled `Rst`. The signal at the `Rst` port is a scalar signal. When it is nonzero, the encoder resets before processing the data at the first input port.

## Signal Constellations

The trellis-coded modulation technique partitions the constellation into subsets called cosets so as to maximize the minimum distance between pairs of points in each coset.

---

**Note** When you set the **Signal constellation** parameter, you must ensure that the constellation vector is already in set-partitioned order. Otherwise, the block might produce unexpected or suboptimal results.

---

As an example, the diagram below shows one way to devise a set-partitioned order for the points for an 8-PSK signal constellation. The figure at the top of the tree is the entire 8-PSK signal constellation, while the eight figures at the bottom of the tree contain one constellation point each. Each level of the tree corresponds to a different bit in a binary sequence  $(b_3, b_2, b_1)$ , while each branch in a given level of the tree corresponds to a

particular value for that bit. Listing the constellation points using the sequence at the bottom of the tree leads to the vector

$$\exp(2\pi j * [0 \ 4 \ 2 \ 6 \ 1 \ 5 \ 3 \ 7] / 8)$$

which is a valid value for the **Signal constellation** parameter in this block.

For other examples of signal constellations in set-partitioned order, see [1] or the reference pages for the M-PSK TCM Encoder and Rectangular QAM TCM Encoder blocks.

## Coding Gains

Coding gains of 3 to 6 decibels, relative to the uncoded case can be achieved in the presence of AWGN with multiphase trellis codes [3].

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

### Operation mode

In Continuous mode (default setting), the block retains the encoder states at the end of each frame, for use with the next frame.

In **Truncated (reset every frame)** mode, the block treats each frame independently. I.e., the encoder states are reset to all-zeros state at the start of each frame.

In **Terminate trellis by appending bits** mode, the block treats each frame independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by  $y = n \cdot (x + s)/k$ , where  $x$  is the number of input bits, and  $s = \text{constraint length} - 1$  (or, in the case of multiple constraint lengths,  $s = \text{sum}(\text{ConstraintLength}(i) - 1)$ ). The block supports this mode for column vector input signals.

In **Reset on nonzero input via port** mode, the block has an additional input port, labeled **Rst**. When the **Rst** input is nonzero, the encoder resets to the all-zeros state.

### Signal constellation

A complex vector that lists the points in the signal constellation in set-partitioned order.

### Output data type

The output type of the block can be specified as a **single** or **double**. By default, the block sets this to **double**.

# GMSK Demodulator Baseband

Demodulate GMSK-modulated data

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The GMSK Demodulator Baseband block uses a Viterbi algorithm to demodulate a signal that was modulated using the Gaussian minimum shift keying method. The input to this block is a baseband representation of the modulated signal.

## Integer-Valued Signals and Binary-Valued Signals

This block accepts a scalar-valued or column vector input signal with a data type of `single` or `double`. If you set the **Output type** parameter to `Integer`, then the block produces values of 1 and -1. If you set the **Output type** parameter to `Bit`, then the block produces values of 0 and 1.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to `Bit`, the output width is two times the number of input symbols.

- When you set **Output type** to Integer, the output width is the number of input symbols.

For a column vector input signal, the width of the input equals the product of the number of symbols and the value for the **Samples per symbol** parameter.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to Bit, the output width equals the number of bits per symbol.
- When you set **Output type** to Integer, the output is a scalar.

## Traceback Depth and Output Delays

Internally, this block creates a trellis description of the modulation scheme and uses the Viterbi algorithm. The **Traceback depth** parameter, D, in this block is the number of trellis branches used to construct each traceback path. D influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When you set the **Rate options** parameter to Allow multirate processing, and the model uses a variable-step solver or a fixed-step solver with the **Tasking Mode** parameter set to SingleTasking, then the delay consists of D+1 zero symbols.
- When you set the **Rate options** parameter to Enforce single-rate processing, then the delay consists of D zero symbols.

The optimal **Traceback depth** parameter value is dependent on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the five-times-the-constraint-length rule, which

corresponds to  $5 \cdot \log_2(\text{numStates})$ . The number of states is determined by the following equation:

$$\text{numStates} = \begin{cases} p \cdot 2^{(L-1)}, & \text{for even } m \\ 2p \cdot 2^{(L-1)}, & \text{for odd } m \end{cases}$$

where:

- $h = m/p$  is the modulation index in proper rational form
  - $m$  = numerator of modulation index
  - $p$  = denominator of modulation index
- $L$  is the Pulse length

## Parameters

### Output type

Determines whether the output consists of bipolar or binary values.

### BT product

The product of bandwidth and time.

### Pulse length (symbol intervals)

The length of the frequency pulse shape.

### Symbol prehistory

The data symbols the modulator uses before the start of the simulation.

### Phase offset (rad)

The initial phase of the modulated waveform.

### Samples per symbol

The number of input samples that represent each modulated symbol, which must be a positive integer. For more information, see “Upsample Signals and Rate Changes” in *Communications Toolbox User's Guide*.

### Rate options

Select the rate processing method for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to Integer).
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output period is the same as

the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

**Traceback depth**

The number of trellis branches that the GMSK Demodulator Baseband block uses to construct each traceback path.

**Output data type**

The output data type can be `boolean`, `int8`, `int16`, `int32`, or `double`.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul>
Output	<ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Boolean (When <b>Output type</b> set to Bit)</li><li>• 8-, 16-, and 32-bit signed integers (When <b>Output type</b> set to Integer)</li></ul>

## GMSK Modulator Baseband

Modulate using Gaussian minimum shift keying method

### Library

CPM, in Digital Baseband sublibrary of Modulation

### Description

The GMSK Modulator Baseband block modulates using the Gaussian minimum shift keying method. The output is a baseband representation of the modulated signal.

The **BT product** parameter represents bandwidth multiplied by time. This parameter is a nonnegative scalar. It is used to reduce the bandwidth at the expense of increased intersymbol interference. The **Pulse length** parameter measures the length of the Gaussian pulse shape, in symbol intervals. For an explanation of the pulse shape, see the work by Anderson, Aulin, and Sundberg among the references on page 3-499 listed below. The frequency pulse shape is defined by the following equations.

$$g(t) = \frac{1}{2T} \left\{ Q \left[ 2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln(2)}} \right] - Q \left[ 2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln(2)}} \right] \right\}$$

$$Q(t) = \int_t^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$$

For this block, an input symbol of 1 causes a phase shift of  $\pi/2$  radians.

The group delay is the number of samples between the start of a filter's response and its peak. The group delay that the block introduces is **Pulse length/2 \* Samples per symbol** (using a reference of output sample periods). For GMSK, **Pulse length** denotes

the truncated frequency pulse length in symbols. The net delay effect at the receiver (demodulator) is due to the **Traceback depth** parameter, which in most cases would be larger than the group delay.

## Integer-Valued Signals and Binary-Valued Signals

When you set the **Input type** parameter to **Integer**, then the block accepts values of 1 and -1.

When you set the **Input type** parameter to **Bit**, then the block accepts values of 0 and 1.

This block accepts a scalar-valued or column vector input signal. For a column vector input signal, the width of the output equals the product of the number of symbols and the value for the **Samples per symbol** parameter.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set **Input type** to **Integer**, the input can be a column vector, the length of which is the number of input symbols.
- When you set **Input type** to **Bit**, the input width must be an integer multiple of 2.

The output width equals the product of the number of input symbols and the **Samples per symbol** parameter value.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to **Integer**, the input must be a scalar.
- When you set **Input type** to **Bit**, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

## Parameters

### Input type

Indicates whether the input consists of bipolar or binary values.

### BT product

The product of bandwidth and time.

The block uses this parameter to reduce bandwidth at the expense of increased intersymbol interference. Enter a nonnegative scalar value for this parameter.

### Pulse length (symbol intervals)

The length of the frequency pulse shape.

### Symbol prehistory

A scalar or vector value that specifies the data symbols the block uses before the start of the simulation, in reverse chronological order. If it is a vector, then its length must be one less than the **Pulse length** parameter.

### Phase offset (rad)

The initial phase of the output waveform, measured in radians.

### Samples per symbol

The number of output samples that the block produces for each integer or bit in the input, which must be a positive integer. For all non-binary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes” in *Communications Toolbox User's Guide*.

### Rate options

Select the rate processing option for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

### Output data type

The output type of the block can be specified as a `single` or `double`. By default, the block sets this to `double`.

## Supported Data Types

# Gold Sequence Generator

Generate Gold sequence from set of sequences

## Library

Sequence Generators sublibrary of Comm Sources

## Description

The Gold Sequence Generator block generates a Gold sequence. Gold sequences form a large class of sequences that have good periodic cross-correlation properties.

This block can output sequences that vary in length during simulation. For more information about variable-size signals, see “Variable-Size Signal Basics” (Simulink).

## Gold Sequences

The Gold sequences are defined using a specified pair of sequences  $u$  and  $v$ , of period  $N = 2^n - 1$ , called a *preferred pair*, as defined in “Preferred Pairs of Sequences” on page 3-504 below. The set  $G(u, v)$  of Gold sequences is defined by

$$G(u, v) = \{u, v, u \oplus v, u \oplus Tv, u \oplus T^2v, \dots, u \oplus T^{N-1}v\}$$

where  $T$  represents the operator that shifts vectors cyclically to the left by one place, and  $\oplus$  represents addition modulo 2. Note that  $G(u,v)$  contains  $N + 2$  sequences of period  $N$ . The Gold Sequence Generator block outputs one of these sequences according to the block's parameters.

Gold sequences have the property that the cross-correlation between any two, or between shifted versions of them, takes on one of three values:  $-t(n)$ ,  $-1$ , or  $t(n) - 2$ , where

$$t(n) = \begin{cases} 1 + 2^{(n+1)/2} & n \text{ even} \\ 1 + 2^{(n+2)/2} & n \text{ odd} \end{cases}$$

The Gold Sequence Generator block uses two PN Sequence Generator blocks to generate the preferred pair of sequences, and then XORs these sequences to produce the output sequence, as shown in the following diagram.

You can specify the preferred pair by the **Preferred polynomial [1]** and **Preferred polynomial [2]** parameters in the dialog for the Gold Sequence Generator block. These polynomials, both of which must have degree  $n$ , describe the shift registers that the PN Sequence Generator blocks use to generate their output. For more details on how these sequences are generated, see the reference page for the PN Sequence Generator block. You can specify the preferred polynomials using these formats:

- A polynomial character vector that includes the number 1, for example, ' $z^4 + z + 1$ '.
- A vector that lists the coefficients of the polynomial in descending order of powers. The first and last entries must be 1. Note that the length of this vector is one more than the degree of the generator polynomial.
- A vector containing the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0.

For example, the character vector ' $z^5 + z^2 + 1$ ', the vector [5 2 0], and the vector [1 0 0 1 0 1] represent the polynomial  $z^5 + z^2 + 1$ .

The following table provides a short list of preferred pairs.

n	N	Preferred Polynomial[1]	Preferred Polynomial[2]
5	31	[5 2 0]	[5 4 3 2 0]
6	63	[6 1 0]	[6 5 2 1 0]
7	127	[7 3 0]	[7 3 2 1 0]

<b>n</b>	<b>N</b>	<b>Preferred Polynomial[1]</b>	<b>Preferred Polynomial[2]</b>
9	511	[9 4 0]	[9 6 4 3 0]
10	1023	[10 3 0]	[10 8 3 2 0]
11	2047	[11 2 0]	[11 8 5 2 0]

The **Initial states[1]** and **Initial states[2]** parameters are vectors specifying the initial values of the registers corresponding to **Preferred polynomial [1]** and **Preferred polynomial [2]**, respectively. These parameters must satisfy these criteria:

- All elements of the **Initial states[1]** and **Initial states[2]** vectors must be binary numbers.
- The length of the **Initial states[1]** vector must equal the degree of the **Preferred polynomial[1]**, and the length of the **Initial states[2]** vector must equal the degree of the **Preferred polynomial[2]**.

---

**Note** At least one element of the **Initial states** vectors must be nonzero in order for the block to generate a nonzero sequence. That is, the initial state of at least one of the registers must be nonzero.

---

The **Sequence index** parameter specifies which sequence in the set  $G(u, v)$  of Gold sequences the block outputs. The range of **Sequence index** is  $[-2, -1, 0, 1, 2, \dots, 2^n-2]$ . The correspondence between **Sequence index** and the output sequence is given in the following table.

<b>Sequence Index</b>	<b>Output Sequence</b>
-2	$u$
-1	$v$
0	$u \oplus v$
1	$u \oplus Tv$
2	$u \oplus T^2v$
...	...
$2^n-2$	$u \oplus T^{2^n-2}v$

You can shift the starting point of the Gold sequence with the **Shift** parameter, which is an integer representing the length of the shift.

You can use an external signal to reset the values of the internal shift register to the initial state by selecting **Reset on nonzero input**. This creates an input port for the external signal in the Gold Sequence Generator block. The way the block resets the internal shift register depends on whether its output signal and the reset signal are sample-based or frame-based. The following example demonstrates the possible alternatives. See “Resetting a Signal” on page 3-905 for an example.

## Preferred Pairs of Sequences

The requirements for a pair of sequences  $u, v$  of period  $N = 2^n - 1$  to be a preferred pair are as follows:

- $n$  is not divisible by 4
- $v = u[q]$ , where
  - $q$  is odd
  - $q = 2^k + 1$  or  $q = 2^{2k} - 2^k + 1$
  - $v$  is obtained by sampling every  $q$ th symbol of  $u$
- $\gcd(n, k) = \begin{cases} 1 & n \equiv 1 \pmod{2} \\ 2 & n \equiv 2 \pmod{4} \end{cases}$

## Parameters

### Preferred polynomial[1]

Character vector or vector specifying the polynomial for the first sequence of the preferred pair.

### Initial states[1]

Vector of initial states of the shift register for the first sequence of the preferred pair.

### Preferred polynomial[2]

Character vector or vector specifying the polynomial for the second sequence of the preferred pair.

**Initial states[2]**

Vector of initial states of the shift register for the second sequence of the preferred pair.

**Sequence index**

Integer specifying the index of the output sequence from the set of sequences.

**Shift**

Integer scalar that determines the offset of the Gold sequence from the initial time.

**Output variable-size signals**

Select this check box if you want the output sequences to vary in length during simulation. The default selection outputs fixed-length signals.

**Maximum output size source**

Specify how the block defines maximum output size for a signal.

- When you select `Dialog` parameter, the value you enter in the **Maximum output size** parameter specifies the maximum size of the output. When you make this selection, the `oSiz` input port specifies the current size of the output signal and the block output inherits sample time from the input signal. The input value must be less than or equal to the **Maximum output size** parameter.
- When you select `Inherit from reference port`, the block output inherits sample time, maximum size, and current size from the variable-sized signal at the `Ref` input port.

This parameter only appears when you select **Output variable-size signals**. The default selection is `Dialog` parameter.

**Maximum output size**

Specify a two-element row vector denoting the maximum output size for the block. The second element of the vector must be 1. For example, `[10 1]` gives a 10-by-1 maximum sized output signal. This parameter only appears when you select **Output variable-size signals**.

**Sample time**

The time between each sample of a column of the output signal.

**Samples per frame**

The number of samples per frame in one channel of the output signal.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame**

equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

---

#### **Reset on nonzero input**

When selected, you can specify an input signal that resets the internal shift registers to the original values of the **Initial states** parameter

#### **Output data type**

The output type of the block can be specified as `boolean`, `double` or `Smallest unsigned integer`. By default, the block sets this to `double`.

When the parameter is set to `Smallest unsigned integer`, the output data type is selected based on the settings used in the “Hardware Implementation Pane” (Simulink) of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the Hardware Implementation pane, the output data type is the ideal minimum one-bit size, i.e., `ufix(1)`. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a char (e.g., `uint8`).

## Hadamard Code Generator

Generate Hadamard code from orthogonal set of codes

### Library

Sequence Generators sublibrary of Comm Sources

### Description

The Hadamard Code Generator block generates a Hadamard code from a Hadamard matrix, whose rows form an orthogonal set of codes. Orthogonal codes can be used for spreading in communication systems in which the receiver is perfectly synchronized with the transmitter. In these systems, the despreading operation is ideal, as the codes are decorrelated completely.

The Hadamard codes are the individual rows of a Hadamard matrix. Hadamard matrices are square matrices whose entries are +1 or -1, and whose rows and columns are mutually orthogonal. If  $N$  is a nonnegative power of 2, the  $N$ -by- $N$  Hadamard matrix, denoted  $H_N$ , is defined recursively as follows.

$$H_1 = [1]$$

$$H_{2N} = \begin{bmatrix} H_N & H_N \\ H_N & -H_N \end{bmatrix}$$

The  $N$ -by- $N$  Hadamard matrix has the property that

$$H_N H_N^T = N I_N$$

where  $I_N$  is the  $N$ -by- $N$  identity matrix.

The Hadamard Code Generator block outputs a row of  $H_N$ . The output is bipolar. You specify the length of the code,  $N$ , by the **Code length** parameter. The **Code length** must

be a power of 2. You specify the index of the row of the Hadamard matrix, which is an integer in the range  $[0, 1, \dots, N-1]$ , by the **Code index** parameter.

## Parameters

### Code length

A positive integer that is a power of two specifying the length of the Hadamard code.

### Code index

An integer between 0 and  $N-1$ , where  $N$  is the **Code length**, specifying a row of the Hadamard matrix.

### Sample time

The time between each sample of the output signal. Specify as a nonnegative real scalar.

### Samples per frame

The number of samples in one column of the output signal. Specify as a positive integer scalar.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

---

### Output data type

The output type of the block can be specified as an `int8` or `double`. By default, the block sets this to `double`.

### Simulate using

Select the simulation mode.

#### Code generation

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is `Code generation`, System objects corresponding to the blocks accept a maximum of nine inputs.

### Interpreted execution

Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

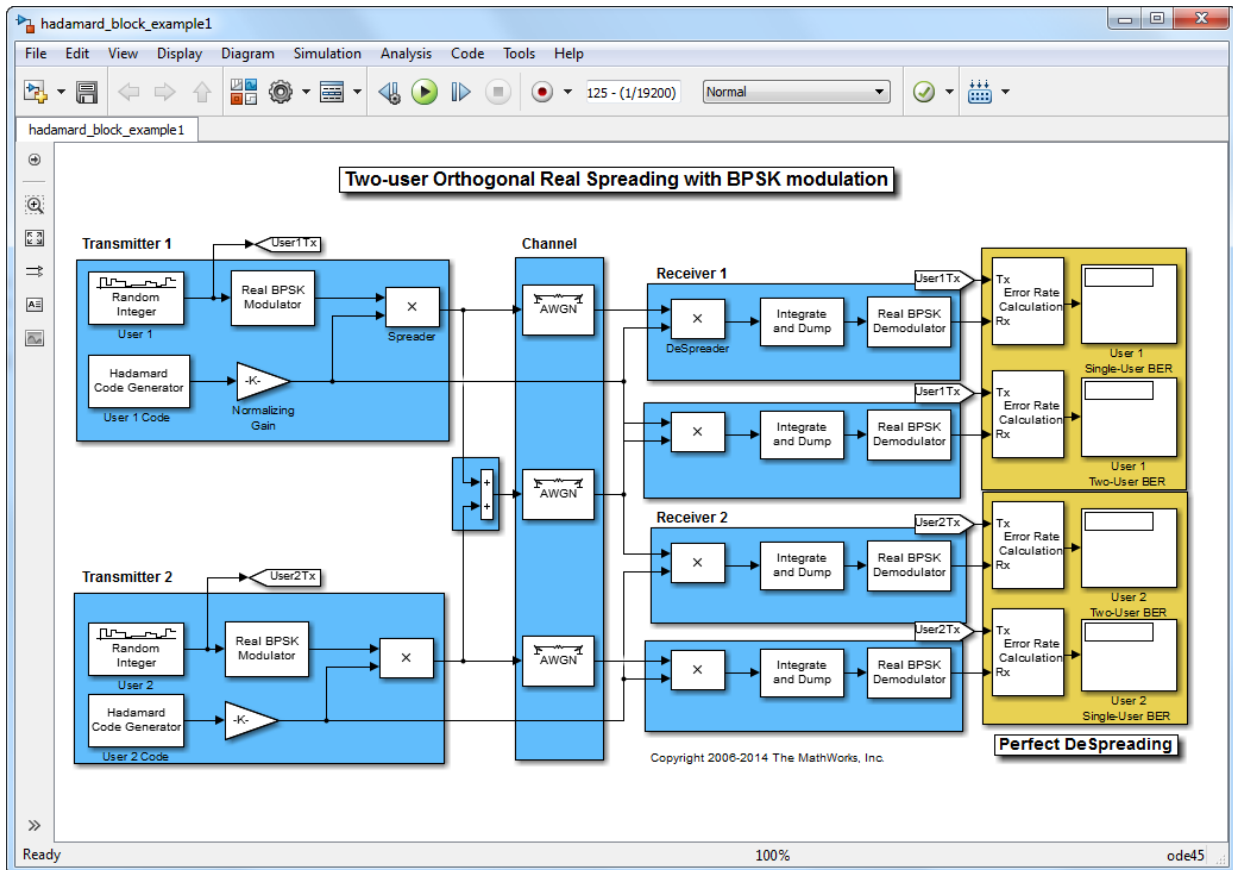

## Examples

### Orthogonal Spreading - Single-User vs. Two-User Comparison

This example model compares a single-user system vs. a two-user data transmission system with the two data streams being independently spread by different orthogonal codes.

The model uses random binary data which is BPSK modulated (real), spread by Hadamard codes of length 64 and then transmitted over an AWGN channel. The receiver consists of a despreader followed by a BPSK demodulator. Open the model here: [hadamard\\_block\\_example1](#).

```
modelname = 'hadamard_block_example1';  
open_system(modelname);  
sim(modelname);
```

For the same data and channel settings, the model calculates the performance for one- and two-user transmissions.

Note that for the individual users, the error rates are exactly the same in both cases. This shows that perfect despreading is possible due to the ideal cross-correlation properties of the Hadamard codes.

To experiment with this model further, specify a different **Code length** or **Code index** for the individual users to examine the variations in relative performance.

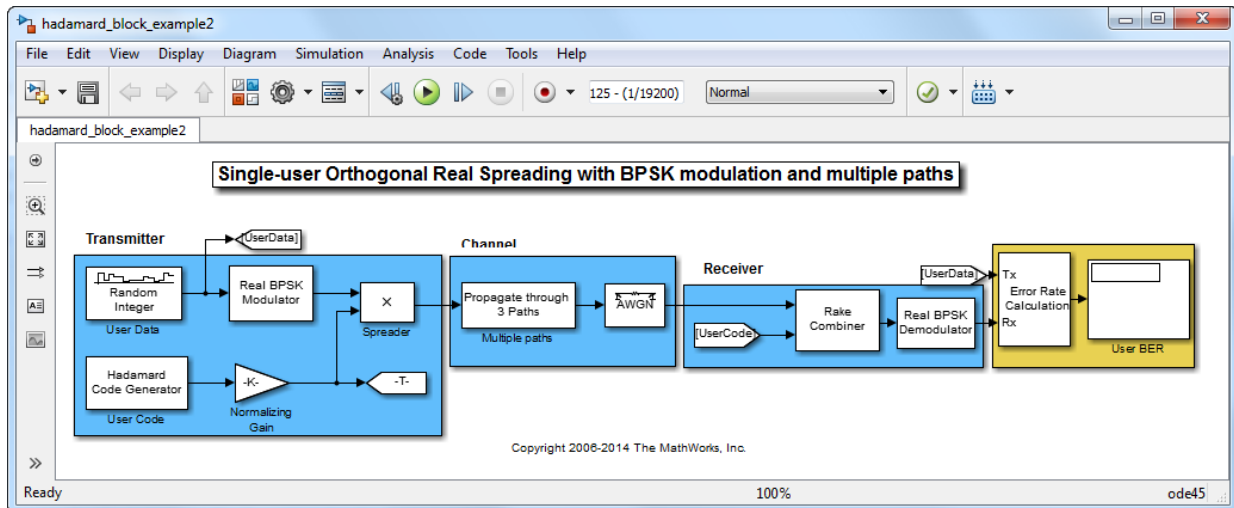

```
close_system(modelname, 0);
```

## Orthogonal Spreading - Multipath Scenario

This example model considers a single-user system in which the signal is transmitted over multiple paths. This is similar to a mobile channel environment where the signals are received over multiple paths, each of which have different amplitudes and delays. To take advantage of the multipath transmission, the receiver employs diversity reception which combines the independent paths coherently.

Note, to keep the system simple, no shadowing effects are considered and the receiver has *a priori* knowledge of the number of paths and their respective delays. Open the model here: `hadamard_block_example2`.

```
modelname = 'hadamard_block_example2';
open_system(modelname);
sim(modelname);
```

For the data transmission with the same spreading code that was used in the first example, we now see deterioration in performance when compared with that example (compare the 180 errors with 81 in the previous case). This can be attributed to the non-ideal auto-correlation values of the orthogonal spreading codes chosen, which prevents perfect resolution of the individual paths. Consequently, we don't see the merits of diversity combining.

To experiment with this model further, try selecting other path delays to see how the performance varies for the same code. Also try different codes with the same delays.

```
close_system(modelname, 0);
```

## Hamming Decoder

Decode Hamming code to recover binary vector data

## Library

Block sublibrary of Error Detection and Correction

## Description

The Hamming Decoder block recovers a binary message vector from a binary Hamming codeword vector. For proper decoding, the parameter values in this block should match those in the corresponding Hamming Encoder block.

If the Hamming code has message length  $K$  and codeword length  $N$ , then  $N$  must have the form  $2^M - 1$  for some integer  $M$  greater than or equal to 3. Also,  $K$  must equal  $N - M$ .

This block accepts a column vector input signal of length  $N$ . The output signal is a column vector of length  $K$ .

The coding scheme uses elements of the finite field  $GF(2^M)$ . You can either specify the primitive polynomial that the algorithm should use, or you can rely on the default setting:

- To use the default primitive polynomial, simply enter  $N$  and  $K$  as the first and second dialog parameters, respectively. The algorithm uses `gfprimdf(M)` as the primitive polynomial for  $GF(2^M)$ .
- To specify the primitive polynomial, enter  $N$  as the first parameter and a binary vector as the second parameter. The vector represents the primitive polynomial by listing its coefficients in order of ascending exponents. You can create primitive polynomials using the Communications Toolbox `gfprimfd` function.
- In addition, you can specify the primitive polynomial as a character vector, for example, `'D^3 + D + 1'`.

For information about the data types each block port supports, see the “Supported Data Type” on page 3-515 table on this page.

## Parameters

### Codeword length $N$

The codeword length  $N$ , which is also the input vector length.

### Message length $K$ , or $M$ -degree primitive polynomial

The message length, which is also the input vector length or a binary vector that represents a primitive polynomial for  $GF(2^M)$  or a polynomial character vector.

# Hamming Encoder

Create Hamming code from binary vector data

## Library

Block sublibrary of Error Detection and Correction

## Description

The Hamming Encoder block creates a Hamming code with message length  $K$  and codeword length  $N$ . The number  $N$  must have the form  $2^M - 1$ , where  $M$  is an integer greater than or equal to 3. Then  $K$  equals  $N - M$ .

This block accepts a column vector input signal of length  $K$ . The output signal is a column vector of length  $N$ .

The coding scheme uses elements of the finite field  $GF(2^M)$ . You can either specify the primitive polynomial that the algorithm should use, or you can rely on the default setting:

- To use the default primitive polynomial, simply enter  $N$  and  $K$  as the first and second dialog parameters, respectively. The algorithm uses `gfprimdf(M)` as the primitive polynomial for  $GF(2^M)$ .
- To specify the primitive polynomial, enter  $N$  as the first parameter and a binary vector as the second parameter. The vector represents the primitive polynomial by listing its coefficients in order of ascending exponents. You can create primitive polynomials using the Communications Toolbox `gfprimfd` function.
- In addition, you can specify the primitive polynomial as a character vector, for example, `'D^3 + D + 1'`.

For information about the data types each block port supports, see the “Supported Data Type” on page 3-518 table on this page.

## Parameters

### Codeword length $N$

The codeword length, which is also the output vector length.

### Message length $K$ , or $M$ -degree primitive polynomial

The message length, which is also the input vector length or a binary vector that represents a primitive polynomial for  $GF(2^M)$  or a polynomial character vector.

## Helical Deinterleaver

Restore ordering of symbols permuted by helical interleaver

## Library

Convolutional sublibrary of Interleaving

## Description

The Helical Deinterleaver block permutes the symbols in the input signal by placing them in an array row by row and then selecting groups in a helical fashion to send to the output port.

The block uses the array internally for its computations. If  $C$  is the **Number of columns in helical array** parameter, then the array has  $C$  columns and unlimited rows. If  $N$  is the **Group size** parameter, then the block accepts an input of length  $C \cdot N$  at each time step and inserts them into the next  $N$  rows of the array. The block also places the **Initial condition** parameter into certain positions in the top few rows of the array (not only to accommodate the helical pattern but also to preserve the vector indices of symbols that pass through the Helical Interleaver and Helical Deinterleaver blocks in turn).

The output consists of consecutive groups of  $N$  symbols. Counting from the beginning of the simulation, the block selects the  $k$ th output group in the array from column  $k \bmod C$ . The selection is helical because of the reduction modulo  $C$  and because the first symbol in the  $k^{\text{th}}$  group is in row  $1 + (k-1) \cdot s$ , where  $s$  is the **Helical array step size** parameter.

This block accepts a column vector input signal containing  $C \cdot N$  elements.

The block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The data type of this output will be the same as that of the input signal.

## Delay of Interleaver-Deinterleaver Pair

After processing a message with the Helical Interleaver block and the Helical Deinterleaver block, the deinterleaved data lags the original message by

$$CN \left\lceil \frac{s(C-1)}{N} \right\rceil$$

samples. Before this delay elapses, the deinterleaver output is either the **Initial condition** parameter in the Helical Deinterleaver block or the **Initial condition** parameter in the Helical Interleaver block.

If your model incurs an additional delay between the interleaver output and the deinterleaver input, then the restored sequence lags the original sequence by the sum of the additional delay and the amount in the formula above. For proper synchronization, the delay between the interleaver and deinterleaver must be  $m \cdot C \cdot N$  for some nonnegative integer  $m$ . You can use the DSP System Toolbox Delay block to adjust delays manually, if necessary.

## Parameters

### Number of columns in helical array

The number of columns,  $C$ , in the helical array.

### Group size

The size,  $N$ , of each group of symbols. The input width is  $C$  times  $N$ .

### Helical array step size

The number of rows of separation between consecutive output groups as the block selects them from their respective columns of the helical array.

### Initial conditions

A scalar that fills the array before the first input is placed.

# Helical Interleaver

Permute input symbols using helical array

## Library

Convolutional sublibrary of Interleaving

## Description

The Helical Interleaver block permutes the symbols in the input signal by placing them in an array in a helical fashion and then sending rows of the array to the output port.

The block uses the array internally for its computations. If  $C$  is the **Number of columns in helical array** parameter, then the array has  $C$  columns and unlimited rows. If  $N$  is the **Group size** parameter, then the block accepts an input of length  $C \cdot N$  at each time step and partitions the input into consecutive groups of  $N$  symbols. Counting from the beginning of the simulation, the block places the  $k^{\text{th}}$  group in the array along column  $k \bmod C$ . The placement is helical because of the reduction modulo  $C$  and because the first symbol in the  $k^{\text{th}}$  group is in row  $1 + (k-1) \cdot s$ , where  $s$  is the **Helical array step size** parameter. Positions in the array that do not contain input symbols have default contents specified by the **Initial condition** parameter.

The block sends  $C \cdot N$  symbols from the array to the output port by reading the next  $N$  rows sequentially. At a given time step, the output symbols might be the **Initial condition** parameter value, symbols from that time step's input vector, or symbols left in the array from a previous time step.

This block accepts a column vector input signal containing  $C \cdot N$  elements.

The block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The data type of this output will be the same as that of the input signal.

## Parameters

### Number of columns in helical array

The number of columns,  $C$ , in the helical array.

### Group size

The size,  $N$ , of each group of input symbols. The input width is  $C$  times  $N$ .

### Helical array step size

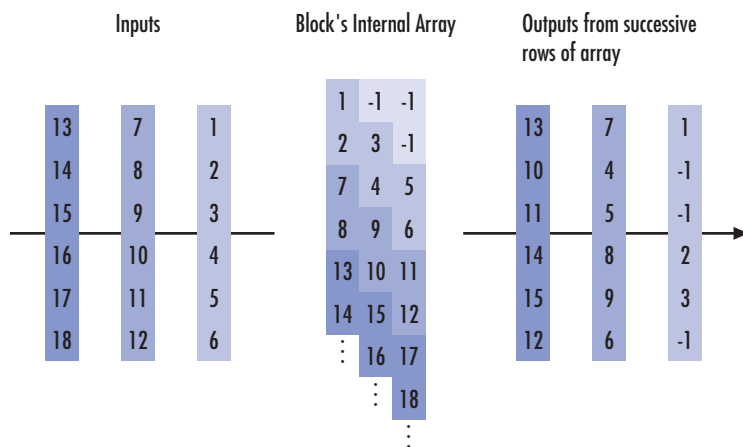

The number of rows of separation between consecutive input groups in their respective columns of the helical array.

### Initial conditions

A scalar that fills the array before the first input is placed.

## Examples

Suppose that  $C = 3$ ,  $N = 2$ , the **Helical array step size** parameter is 1, and the **Initial condition** parameter is -1. After receiving inputs of  $[1:6]'$ ,  $[7:12]'$ , and  $[13:18]'$ , the block's internal array looks like the schematic below. The coloring of the inputs and the array indicate how the input symbols are placed within the array. The outputs at the first three time steps are  $[1; -1; -1; 2; 3; -1]$ ,  $[7; 4; 5; 8; 9; 6]$ , and  $[13; 10; 11; 14; 15; 12]$ . (The outputs are not color-coded in the schematic.)

## Ideal Rectangular Pulse Filter

Shape input signal using ideal rectangular pulses

### Library

Comm Filters

### Description

The Ideal Rectangular Pulse Filter block upsamples and shapes the input signal using rectangular pulses. The block replicates each input sample  $N$  times, where  $N$  is the **Pulse length** parameter. After replicating input samples, the block can also normalize the output signal and/or apply a linear amplitude gain.

If the **Pulse delay** parameter is nonzero, then the block outputs that number of zeros at the beginning of the simulation, before starting to replicate any of the input values.

This block accepts a scalar, column vector, or matrix input signal. For information about the data types each block port supports, see the “Supported Data Type” on page 3-531 table on this page.

The vector size, the pulse length, and the pulse delay are mutually independent. They do not need to satisfy any conditions with respect to each other.

### Single-Rate Processing

When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To generate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output ( $M_o$ ) is  $L$  times larger than that of the input ( $M_o = M_i * L$ ), where  $L$  is the **Pulse length (number of samples)** parameter value.

## Multirate Processing

When you set the **Rate options** parameter to Allow multirate processing, the input and output of the block are the same size. However, the sample rate of the output is  $L$  times faster than that of the input (i.e. the output sample time is  $1/N$  times the input sample time). When the block is in multirate processing mode, you must also specify a value for the **Input processing** parameter:

- When you set the **Input processing** parameter to Elements as channels (sample based), the block treats an  $M$ -by- $N$  matrix input as  $M*N$  independent channels, and processes each channel over time. The output sample period ( $T_{so}$ ) is  $L$  times shorter than the input sample period ( $T_{si} = T_{so}/L$ ), while the input and output sizes remain identical.
- When you set the **Input processing** parameter to Columns as channels (frame based), the block treats an  $M_i$ -by- $N$  matrix input as  $N$  independent channels. The block processes each column of the input over time by keeping the frame size constant ( $M_i=M_o$ ), while making the output frame period ( $T_{fo}$ )  $L$  times shorter than the input frame period ( $T_{fi} = T_{fo}/L$ ).

## Normalization Methods

You determine the block's normalization behavior using the **Normalize output signal** and **Linear amplitude gain** parameters.

- If you clear **Normalize output signal**, then the block multiplies the set of replicated values by the **Linear amplitude gain** parameter. This parameter must be a scalar.
- If you select **Normalize output signal**, then the **Normalization method** parameter appears. The block scales the set of replicated values so that one of these conditions is true:
  - The sum of the samples in each pulse equals the original input value that the block replicated.
  - The energy in each pulse equals the energy of the original input value that the block replicated. That is, the sum of the squared samples in each pulse equals the square of the input value.

After the block applies the scaling specified in the **Normalization method** parameter, it multiplies the scaled signal by the constant scalar value specified in the **Linear amplitude gain** parameter.

The output is scaled by  $\sqrt{N}$ . If the output of this block feeds the input to the AWGN Channel block, specify the AWGN signal power parameter to be  $1/N$ .

## Parameters

### **Pulse length (number of samples)**

The number of samples in each output pulse; that is, the number of times the block replicates each input value when creating the output signal.

### **Pulse delay (number of samples)**

The number of zeros that appear in the output at the beginning of the simulation, before the block replicates any input values.

### **Input processing**

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

### **Rate options**

Specify the method by which the block should upsample and shape the input signal. You can select one of the following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the input sample rate, and processes the signal by increasing the output frame size by a factor of  $L$ . To select this option, you must set the **Input processing** parameter to **Columns as channels (frame based)**.
- **Allow multirate processing** — When you select this option, the block processes the signal such that the output sample rate is  $L$  times faster than the input sample rate.

### **Normalize output signal**

If you select this, then the block scales the set of replicated values before applying the linear amplitude gain.

**Normalization method**

The quantity that the block considers when scaling the set of replicated values. Choices are **Sum of samples** and **Energy per pulse**. This field appears only if you select **Normalize method**.

**Linear amplitude gain**

A positive scalar used to scale the output signal.

**Rounding mode**

Use this parameter to specify the rounding method to be used when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. The filter coefficients do not obey this parameter; they always round to **Nearest**.

For more information, see **Rounding Modes** (DSP System Toolbox) or “**Rounding Mode: Simplest**” (Fixed-Point Designer).

**Saturate on integer overflow**

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

**Coefficients**

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See “**Filter Structure Diagrams**” (DSP System Toolbox) in *DSP System Toolbox Reference Guide* for illustrations depicting the use of the coefficient data types in this block:

- When you select **Same word length as input**, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Specify word length**, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter

separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.

- The filter coefficients do not obey the **Rounding mode** and the **Saturate on integer overflow** parameters; they are always saturated and rounded to Nearest.

#### **Product output**

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) in *DSP System Toolbox Reference Guide* for illustrations depicting the use of the product output data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

#### **Accumulator**

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Filter Structure Diagrams” (DSP System Toolbox) and “Multiplication Data Types” (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Binary point scaling`, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

#### **Output**

Choose how you specify the output word length and fraction length:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Same as accumulator**, these characteristics match those of the accumulator.
- When you select **Binary point scaling**, you are able to enter the word length and the fraction length of the output, in bits.
- When you select **Slope and bias scaling**, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

### Lock scaling against changes by the autoscaling tool

Select this check box to prevent any fixed-point scaling you specify in the block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

## Supported Data Type

Port	Supported Data Types
In	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed-point</li> </ul>

# Insert Zero

Distribute input elements in output vector

## Library

Sequence Operations

## Description

The Insert Zero block constructs an output vector by inserting zeros among the elements of the input vector. The input signal can be real or complex. Both the input signal and the **Insert zero vector** parameter are column vector signals. The number of 1s in the **Insert zero vector** parameter must be evenly divisible by the input data length. If the input vector length is greater than the number of 1s in the **Insert zero vector** parameter, then the block repeats the insertion pattern until it has placed all input elements in the output vector.

The block determines where to place the zeros by using the **Insert zero vector** parameter.

- For each 1 the block places the *next* element of the input vector in the output vector
- For each 0 the block places a 0 in the output vector

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

To implement punctured coding using the Puncture and Insert Zero blocks, use the same vector for the **Insert zero vector** parameter in this block and for the **Puncture vector** parameter in the Puncture block.

## Parameters

### **Insert zero vector**

A binary vector with a pattern of 0s and 1s that indicate where the block places either 0s or input vector elements in the output vector.

## Examples

If the **Insert zero vector** parameter is the six-element vector  $[1;0;1;1;1;0]$ , then the block inserts zeros after the first and last elements of each consecutive grouping of four input elements. It considers groups of four elements because the **Insert zero vector** parameter has four 1s.

The diagram below depicts the block's operation using this **Insert zero vector** parameter. Notice that the insertion pattern applies twice.

Compare this example with that on the reference page for the Puncture block.

# Integer-Input RS Encoder

Create Reed-Solomon code from integer vector data

**Library:** Communications Toolbox / Error Detection and Correction / Block

## Description

The Integer-Input RS Encoder block creates a Reed-Solomon code.

The symbols for the code are integers between 0 and  $2^M-1$ , which represent elements of the finite field  $GF(2^M)$ . The default value of  $M$  is the smallest integer that is greater than or equal to  $\log_2(N+1)$ , that is,  $\text{ceil}(\log_2(N+1))$ . You can change the default value of  $M$  by specifying the primitive polynomial for  $GF(2^M)$ , as described in “Specify the Primitive Polynomial” on page 3-543 below. Restrictions on  $M$  and  $N$  are described in “Restrictions on  $M$  and the Codeword Length  $N$ ” on page 3-543.

The input and output are integer-valued signals that represent messages and codewords, respectively. For more information, see “Input and Output Signal Length in RS Blocks” on page 3-541.

An  $(N, K)$  Reed-Solomon code can correct up to  $\text{floor}((N-K)/2)$  symbol errors (not bit errors) in each codeword.

Suppose  $M = 3$ ,  $N = 2^3-1 = 7$ , and  $K = 5$ . Then a message is a vector of length 5 whose entries are integers between 0 and 7. A corresponding codeword is a vector of length 7 whose entries are integers between 0 and 7. The following figure illustrates possible input and output signals to this block when **Codeword length  $N$**  is set to 7, **Message length  $K$**  is set to 5, and the default primitive and generator polynomials are used.

## Ports

### Input

#### In — Message

integer column vector

Message, specified as one of the following:

- When there is no message shortening, a  $(N_C \times K)$ -by-1 integer column vector.
- When there is message shortening, a  $(N_C \times S)$ -by-1 integer column vector.

$N_C$  is the number of message words,  $K$  is the **Message length K**, and  $S$  is the **Shortened message length S**.

---

**Note** The number of decoded message words equals the number of codewords.

---

For more information, see “Input and Output Signal Length in RS Blocks” on page 3-541.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### Output

#### Out — Reed-Solomon codeword

integer column vector

Reed-Solomon codeword, returned as an  $(N_C \times (N - K + S - P))$ -by-1 integer column vector.  $N_C$  is the number of codewords,  $N$  is the **Codeword length N**,  $K$  is the **Message length K**,  $S$  is the **Shortened message length S**,  $P$  is the number of punctures per codeword.

For more information, see “Input and Output Signal Length in RS Blocks” on page 3-541.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

For more information, see “Supported Data Types” on page 3-545.

## Parameters

### Codeword length N — Codeword length

7 (default) | integer

Codeword length, specified as an integer.

For more information, see “Restrictions on M and the Codeword Length N” on page 3-543 and “Input and Output Signal Length in RS Blocks” on page 3-541.

### Message length K — Message word length

3 (default) | integer

Message word length, specified as an integer in the range  $[1, N-2]$ , where  $N$  is the codeword length.

### Shortened message length S — Shortened message word length

3 (default) | integer

Shortened message word length, specified as an integer, such that  $S \leq K$ . When **Shortened message length S < Message length K**, the Reed-Solomon code is shortened.

You still specify  $N$  and  $K$  values for the full-length  $(N, K)$  code but the decoding is shortened to an  $(N-K+S, S)$  code.

### Dependencies

To enable this parameter, select **Specify shortened message length**.

**Generator polynomial — Generator polynomial**

`rsgenpoly(7, 3, [], [], 'double')` (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values in the range  $[0 \text{ to } 2^M-1]$ , in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see “Specify the Generator Polynomial” on page 3-543.

Example: `[1 3 1 2 3]`, which is equivalent to `rsgenpoly(7,3)`

**Dependencies**

To enable this parameter, select **Specify generator polynomial**.

**Primitive polynomial — Primitive polynomial**

`'X^3 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. This polynomial is of order  $M$  and defines the finite Galois field  $GF(2^M)$  corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see “Specify the Primitive Polynomial” on page 3-543.

Example: `'X^3 + X + 1'`, which is the primitive polynomial used for a (7,3) code, `de2bi(primpoly(3, 'nodisplay'), 'left-msb')`

**Dependencies**

To enable this parameter, select **Specify primitive polynomial**.

**Puncture vector — Puncture vector**

[ones(2,1); zeros(2,1)] (default) | binary column vector

Puncture vector, specified as an  $(N-K)$ -by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 3-544.

---

**Note** If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

---

**Dependencies**

To enable this parameter, select **Puncture code**.

## Block Characteristics

<b>Data Types</b>	double   integer   single
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## More About

### Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length,  $K$ , or shortened message word length,  $S$ . The codeword length is  $N - K + S - P$ , where  $N$  is the full codeword length and  $P$  is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to  $N - P$ , because  $K = S$ . If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation  $y = N_C \times x$  denotes that  $y$  is an integer multiple of  $x$ .

	Input, Erasure, and Output Vector Lengths	
RS Block Coder	No Message Shortening Used	Message Shortening Used
Integer-Input RS Encoder	<b>Input Length (symbols):</b> $N_C \times K$ <b>Output Length (symbols):</b> $N_C \times (N-P)$	<b>Input Length (symbols):</b> $N_C \times S$ <b>Output Length (symbols):</b> $N_C \times (N-K+S-P)$
Integer-Output RS Decoder	<b>Input Length (symbols):</b> $N_C \times (N-P)$ <b>Erasures Length (symbols):</b> $N_C \times (N-P)$ <b>Output Length (symbols):</b> $N_C \times K$	<b>Input Length (symbols):</b> $N_C \times (N-K+S-P)$ <b>Erasures Length (symbols):</b> $N_C \times (N-K+S-P)$ <b>Output Length (symbols):</b> $N_C \times S$

- $N$  is the codeword length.
- $K$  is the message word length.
- $S$  is the shortened message word length.
- $N_C$  is the number of codewords (and message words).
- $P$  is the number of punctures, and is equal to the number of zeros in the puncture vector.
- $M$  is the degree of the primitive polynomial. Each group of  $M$  bits represents an integer between  $0$  and  $2^M-1$  that belongs to the finite Galois field  $GF(2^M)$ .

For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

## Restrictions on M and the Codeword Length N

- If you do not select **Specify primitive polynomial**, valid values for the codeword length,  $N$ , are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree  $M = \text{ceil}(\log_2(N+1))$ . You can display the default primitive polynomial by running `primpoly(ceil(log2(N+1)))`.
- If you select **Specify primitive polynomial**, valid values for the primitive polynomial degree,  $M$ , are from 3 to 16. The valid values for  $N$  in this case are from 7 to  $2^M-1$ . Selecting **Specify primitive polynomial** enables you to specify the primitive polynomial that defines the finite field  $GF(2^M)$ , which corresponds to the values that form message words and codewords.

## Specify the Primitive Polynomial

You can specify the primitive polynomial that defines the finite field  $GF(2^M)$ , corresponding to the integers that form messages and codewords. To do so, first select **Specify primitive polynomial**. Then, in the **Primitive polynomial** text box, enter a binary row vector that represents a primitive polynomial over  $GF(2^M)$ , in descending order of powers. For example, to specify the polynomial  $x^3+x+1$ , enter the vector `[1 0 1 1]`.

If you do not select **Specify primitive polynomial**, the block uses the default primitive polynomial of degree  $M = \text{ceil}(\log_2(N+1))$ . You can display the default polynomial by entering `primpoly(ceil(log2(N+1)))` at the MATLAB prompt.

## Specify the Generator Polynomial

Select **Specify generator polynomial** to enable the **Generator polynomial** parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to  $2^M-1$ . The vector represents a polynomial, in descending order of powers, whose coefficients are elements of  $GF(2^M)$  represented in integer format. For more information about integer and binary format, see “Integer Format (Reed-Solomon Only)”. The generator polynomial must be equal to a polynomial with this factored form:

$$g(x) = (x+\alpha^b)(x+\alpha^{b+1})(x+\alpha^{b+2})\dots(x+\alpha^{b+N-K-1})$$

$\alpha$  is the primitive element of the Galois field over which the input message is defined, and  $b$  is an integer.

If you do not select **Specify generator polynomial**, the block uses the default generator polynomial, corresponding to  $b=1$ , for Reed-Solomon encoding. You can display the default generator polynomial by running `rsgenpoly`.

- If you are using the default primitive polynomial (**Specify primitive polynomial** is not selected), the default generator polynomial is `rsgenpoly(N,K)`, where  $N = 2^M - 1$ .
- If you are not using the default primitive polynomial (**Specify primitive polynomial** is selected) and you specify the primitive polynomial as `poly`, the generator polynomial is `rsgenpoly(N,K,poly)`.

---

**Note** The degree of the generator polynomial is  $N - K$ , where  $N$  is the codeword length and  $K$  is the message word length.

---

## Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

# Integer-Input RS Encoder HDL Optimized

Encode data using a Reed-Solomon encoder

## Library

Block sublibrary of Error Correction and Detection

## Description

Reed-Solomon encoding follows the same standards as any other cyclic redundancy code. The Integer-Input RS Encoder HDL Optimized block can be used to model many communication system Forward Error Correcting (FEC) codes.

For more about the Reed-Solomon encoder, see the Integer-Input RS Encoder block reference. For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

## Signal Attributes

The Integer-Input RS Encoder HDL Optimized block has four input ports and four output ports.

Port	Direction	Description	Data Type
dataIn	Input	Message data, one symbol at a time. The wordlength of each symbol must be $\text{ceil}(\log_2(\text{codewordLength}+1))$ .	Integer or <code>fixdt</code> with any binary point scaling. <code>double</code> is allowed for simulation but not for HDL code generation.
startIn	Input	Indicates the start of a frame of data.	Boolean
endIn	Input	Indicates the end of a frame of data.	Boolean
validIn	Input	Indicates that input data is valid.	Boolean
dataOut	Output	Message data with the checksum appended. The data width is the same as the input data port.	Same as <code>dataIn</code>
startOut	Output	Indicates the start of a frame of data.	Boolean
endOut	Output	Indicates the end of a frame of data, including checksum.	Boolean
validOut	Output	Indicates that output data is valid.	Boolean

## Parameters

### Codeword length

The length of the code word,  $N$ , must be equal to  $2^M - 1$ , where  $M$  is the input word length.  $M$  can be between 3 and 16 bits.

### Message length

The message length,  $K$ . The number of parity symbols,  $N - K$ , must be a positive even integer, greater than or equal to the input word length,  $M$ .

Each input frame, i.e. the number of valid data samples between `start` and `end`, must contain more than  $N - K$  symbols, and fewer than or equal to  $K$  symbols. A shortened code is inferred anytime the number of input data samples in a frame is less than  $K$ .

**Source of primitive polynomial**

Select Property to enable the **Primitive polynomial** parameter.

**Primitive polynomial**

Binary row vector representing the primitive polynomial in descending order of powers. When you provide a primitive polynomial, the number of input bits,  $M$ , must be an integer multiple of  $K$  times the order of the primitive polynomial.

This parameter applies when only when Property is selected for **Primitive polynomial**.

**Source of puncture pattern**

Select Property to enable the **Puncture pattern vector** parameter.

**Puncture pattern vector**

A column vector of length  $N-K$ . In a puncture vector, 1 represents that the data symbol passes unaltered. The value 0 represents that the data symbol is punctured, or removed from the data stream.

The default value is `[ones(2,1); zeros(2,1)]`.

This field is available only when Property is selected for **Source of puncture pattern**.

**Source of B, the starting power for roots of the primitive polynomial**

Select Property to enable the **B value** parameter. When you select Auto, the block uses  $B = 1$ .

**B value**

The starting exponent of the roots.

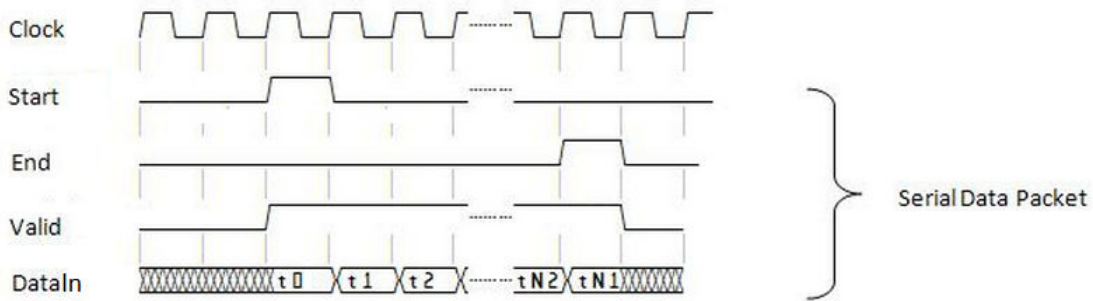

This field is available only when you select Property for **Source of B, the starting power for roots of the primitive polynomial**.

The generator polynomial is not specified explicitly. However, it is defined by the code word length, the message length, and the B value for the starting exponent of the roots. To get the value of B from a generator polynomial, use the `genpoly2b` function. The default value is 1.

## Integer-Output RS Decoder

Decode Reed-Solomon code to recover integer vector data

**Library:** Communications Toolbox / Error Detection and Correction / Block

### Description

The Integer-Output RS Decoder block recovers a message vector from a Reed-Solomon codeword vector. For proper decoding, the parameter values in this block must match those in the corresponding Integer-Input RS Encoder block.

The Reed-Solomon code has message length  $K$ , and codeword length  $N$  - *number of punctures*. You specify  $N$  and  $K$  directly in the block dialog. The symbols for the code are integers in the range  $[0, 2^M-1]$ , which represent elements of the finite field  $GF(2^M)$ . Restrictions on  $M$  and  $N$  are described in “Restrictions on the  $M$  and the Codeword Length  $N$ ” on page 3-559 below.

This icon shows optional ports.

The input and output are integer-valued signals that represent codewords and messages, respectively. For more information, see “Input and Output Signal Length in RS Blocks” on page 3-557. The block inherits the output data type from the input data type. For information about the data types each block port supports, see “Supported Data Types” on page 3-561.

For more information on representing data for Reed-Solomon codes, see the section “Integer Format (Reed-Solomon Only)”.

If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

The default value of  $M$  is  $\text{ceil}(\log_2(N+1))$ , that is, the smallest integer greater than or equal to  $\log_2(N+1)$ . You can change the value of  $M$  from the default by specifying the primitive polynomial for  $\text{GF}(2^M)$ , as described in “Specify the Primitive Polynomial” on page 3-559 below.

You can also specify the generator polynomial for the Reed-Solomon code, as described in “Specify the Generator Polynomial” on page 3-559.

An  $(N, K)$  Reed-Solomon code can correct up to  $\text{floor}((N-K)/2)$  symbol errors (*not* bit errors) in each codeword.

If decoding fails, the message portion of the decoder input is returned unchanged as the decoder output.

The sample times of the input and output signals are equal.

## Ports

### Input

#### In — Reed-Solomon codeword

integer column vector

Reed-Solomon codeword, specified as an  $(N_C \times (N - K + S - P))$ -by-1 integer column vector.  $N_C$  is the number of codewords,  $N$  is the **Codeword length N**,  $K$  is the **Message length K**,  $S$  is the **Shortened message length S**,  $P$  is the number of punctures per codeword.

For more information, see “Input and Output Signal Length in RS Blocks” on page 3-557.

Data Types: `single` | `double` | `integer`

#### Era — Erasure vector

binary column vector

Erasure vector, specified as a binary column vector input signal with the same size as the input Reed-Solomon codeword.

Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased. For more information, see “Puncturing and Erasures” on page 3-560.

#### Dependencies

To enable this port, select **Enable erasures input port**.

Data Types: double | Boolean

#### Output

##### Out — Decoded message

integer column vector

Decoded message, returned as one of the following:

- When there is no message shortening, a  $(N_C \times K)$ -by-1 integer column vector.
- When there is message shortening, a  $(N_C \times S)$ -by-1 integer column vector.

$N_C$  is the number of message words,  $K$  is the **Message length K (symbols)**, and  $S$  is the **Shortened message length S (symbols)**.

---

**Note** The number of decoded message words equals the number of codewords.

---

For more information, see “Input and Output Signal Length in RS Blocks” on page 3-557.

##### Err — Decoding errors

integer vector

Symbol decoding errors, returned as an integer vector with  $N_C$  elements, where  $N_C$  is the number of codewords. This port indicates the number of symbol errors detected during decoding of each codeword. A negative integer indicates that the block detected more errors than it could correct by using the specified coding scheme.

---

**Note** An  $(N,K)$  Reed-Solomon code can correct up to  $\text{floor}((N-K)/2)$  symbol errors (not bit errors) in each codeword. When a received codeword contains more than  $(N-K)/2$  symbol errors, a decoding failure occurs.

---

#### Dependencies

To enable this port, select **Output number of corrected symbol errors**.

Data Types: double

For more information, see “Supported Data Types” on page 3-561.

## Parameters

### **Codeword length N — Codeword length**

7 (default) | integer

Codeword length, specified as an integer.

For more information, see “Restrictions on the M and the Codeword Length N” on page 3-559 and “Input and Output Signal Length in RS Blocks” on page 3-557.

### **Message length K — Message word length**

3 (default) | integer

Message word length, specified as an integer in the range  $[1, N-2]$ , where  $N$  is the codeword length.

### **Shortened message length S — Shortened message word length**

3 (default) | integer

Shortened message word length, specified as an integer, such that  $S \leq K$ . When **Shortened message length S < Message length K**, the Reed-Solomon code is shortened.

You still specify  $N$  and  $K$  values for the full-length  $(N, K)$  code but the decoding is shortened to an  $(N-K+S, S)$  code.

### **Dependencies**

To enable this parameter, select **Specify shortened message length**.

### **Generator polynomial — Generator polynomial**

rsgenpoly(7, 3, [], [], 'double') (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values in the range  $[0, 2^M-1]$ , in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see “Specify the Generator Polynomial” on page 3-543.

Example: `[1 3 1 2 3]`, which is equivalent to `rsngenpoly(7,3)`

**Dependencies**

To enable this parameter, select **Specify generator polynomial**.

**Primitive polynomial — Primitive polynomial**

`'X^3 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. This polynomial is of order  $M$  and defines the finite Galois field  $GF(2^M)$  corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see “Specify the Primitive Polynomial” on page 3-543.

Example: `'X^3 + X + 1'`, which is the primitive polynomial used for a (7,3) code, `de2bi(primpoly(3, 'nodisplay'), 'left-msb')`

**Dependencies**

To enable this parameter, select **Specify primitive polynomial**.

**Puncture vector — Puncture vector**

`[ones(2,1); zeros(2,1)]` (default) | binary column vector

Puncture vector, specified as an  $(N-K)$ -by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 3-560.

---

**Note** If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

---

### Dependencies

To enable this parameter, select **Puncture code**.

**Enable erasures input port — Enable erasures input port**  
off (default) | on

Selecting this check box enables the erasures port, **Era**. For more information, see “Puncturing and Erasures” on page 3-560.

**Output number of corrected symbol errors — Enable port to output number of corrected symbol errors**  
off (default) | on

Selecting this check box enables an additional output port, **Err**, which indicates the number of symbol errors the block corrected in the input codeword.

## Block Characteristics

<b>Data Types</b>	double   integer   single

<b>Variable-Size Signals</b>	no

## More About

### Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length,  $K$ , or shortened message word length,  $S$ . The codeword length is  $N - K + S - P$ , where  $N$  is the full codeword length and  $P$  is the number of punctures per codeword. When there is no message shortening, the

codeword length expression reduces to  $N - P$ , because  $K = S$ . If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation  $y = N_C \times x$  denotes that  $y$  is an integer multiple of  $x$ .

	<b>Input, Erasure, and Output Vector Lengths</b>	
<b>RS Block Coder</b>	<b>No Message Shortening Used</b>	<b>Message Shortening Used</b>
Integer-Input RS Encoder	<b>Input Length (symbols):</b> $N_C \times K$  <b>Output Length (symbols):</b> $N_C \times (N-P)$	<b>Input Length (symbols):</b> $N_C \times S$  <b>Output Length (symbols):</b> $N_C \times (N-K+S-P)$
Integer-Output RS Decoder	<b>Input Length (symbols):</b> $N_C \times (N-P)$  <b>Erasures Length (symbols):</b> $N_C \times (N-P)$  <b>Output Length (symbols):</b> $N_C \times K$	<b>Input Length (symbols):</b> $N_C \times (N-K+S-P)$  <b>Erasures Length (symbols):</b> $N_C \times (N-K+S-P)$  <b>Output Length (symbols):</b> $N_C \times S$

- $N$  is the codeword length.
- $K$  is the message word length.
- $S$  is the shortened message word length.
- $N_C$  is the number of codewords (and message words).
- $P$  is the number of punctures, and is equal to the number of zeros in the puncture vector.
- $M$  is the degree of the primitive polynomial. Each group of  $M$  bits represents an integer between  $0$  and  $2^M - 1$  that belongs to the finite Galois field  $GF(2^M)$ .

For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

## Restrictions on the M and the Codeword Length N

- If you do not select **Specify primitive polynomial**, valid values for the codeword length,  $N$ , are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree  $M = \text{ceil}(\log_2(N+1))$ . You can display the default primitive polynomial by running `primpoly(ceil(log2(N+1)))`.
- If you select **Specify primitive polynomial**, valid values for the primitive polynomial degree,  $M$ , are from 3 to 16. The valid values for  $N$  in this case are from 7 to  $2^M-1$ . Selecting **Specify primitive polynomial** enables you to specify the primitive polynomial that defines the finite field  $GF(2^M)$ , which corresponds to the values that form message words and codewords.

## Specify the Primitive Polynomial

You can specify the primitive polynomial that defines the finite field  $GF(2^M)$ , corresponding to the integers that form messages and codewords. To do so, first select **Specify primitive polynomial**. Then, in the **Primitive polynomial** text box, enter a binary row vector that represents a primitive polynomial over  $GF(2^M)$ , in descending order of powers. For example, to specify the polynomial  $x^3+x+1$ , enter the vector `[1 0 1 1]`.

If you do not select **Specify primitive polynomial**, the block uses the default primitive polynomial of degree  $M = \text{ceil}(\log_2(N+1))$ . You can display the default polynomial by entering `primpoly(ceil(log2(N+1)))` at the MATLAB prompt.

## Specify the Generator Polynomial

Select **Specify generator polynomial** to enable the **Generator polynomial** parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to  $2^M-1$ . The vector represents a polynomial, in descending order of powers, whose coefficients are elements of  $GF(2^M)$  represented in integer format. For more information about integer and binary format, see “Integer Format (Reed-Solomon Only)”. The generator polynomial must be equal to a polynomial with this factored form:

$$g(x) = (x+\alpha^b)(x+\alpha^{b+1})(x+\alpha^{b+2})\dots(x+\alpha^{b+N-K-1})$$

$\alpha$  is the primitive element of the Galois field over which the input message is defined, and  $b$  is an integer.

If you do not select **Specify generator polynomial**, the block uses the default generator polynomial, corresponding to  $b=1$ , for Reed-Solomon encoding. You can display the default generator polynomial by running `rsgenpoly`.

- If you are using the default primitive polynomial (**Specify primitive polynomial** is not selected), the default generator polynomial is `rsgenpoly(N,K)`, where  $N = 2^M - 1$ .
- If you are not using the default primitive polynomial (**Specify primitive polynomial** is selected) and you specify the primitive polynomial as `poly`, the generator polynomial is `rsgenpoly(N,K,poly)`.

---

**Note** The degree of the generator polynomial is  $N - K$ , where  $N$  is the codeword length and  $K$  is the message word length.

---

## Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

## Supported Data Types

# Integer-Output RS Decoder HDL Optimized

Decode data using a Reed-Solomon decoder

## Library

Block sublibrary of Error Correction and Detection

## Description

Reed-Solomon encoding follows the same standards as any other cyclic redundancy code. The Integer-Output RS Decoder HDL Optimized block can be used to model many communication system Forward Error Correcting (FEC) codes.

For more about the Reed-Solomon decoder, see the Integer-Output RS Decoder block reference. For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

## Signal Attributes

The Integer-Output RS Decoder HDL Optimized block has four input ports and six output ports (5 required, 1 optional).

Port	Direction	Description	Data Type
dataIn	Input	Message data, one symbol at a time.	Integer or fixdt with any binary point scaling. double is allowed for simulation but not for HDL code generation.
startIn	Input	Indicates the start of a frame of data.	Boolean
endIn	Input	Indicates the end of a frame of data.	Boolean
validIn	Input	Indicates that input data is valid.	Boolean
dataOut	Output	Message data with the checksum appended. The data width is the same as the input data port.	Same as dataIn
startOut	Output	Indicates the start of a frame of data.	Boolean
endOut	Output	Indicates the end of a frame of data, including checksum.	Boolean
validOut	Output	Indicates that output data is valid.	Boolean
errOut	Output	Indicates the corruption of the received data when error is high.	Boolean
numErrors	Output (optional)	Count of detected errors.	uint8

## Troubleshooting

- Each input frame must contain more than  $(N-K) * 2$  symbols, and fewer than or equal to  $N$  symbols. A shortened code is inferred when the number of valid data samples between `startIn` and `endIn` is less than  $N$ . A shortened code still requires  $N$  cycles to perform the Chien search. If the input is less than  $N$  symbols, leave a guard interval of at least  $N$ -size inactive cycles before starting the next frame.
- The decoder can operate on up to 4 messages at a time. If the block receives the start of a fifth message before completely decoding the first message, the block drops data samples from the first message. To avoid this issue, increase the number of inactive cycles between input messages.

- The generator polynomial is not specified explicitly. However, it is defined by the code word length, the message length, and the B value for the starting exponent of the roots. To get the value of B from a generator polynomial, use the `genpoly2b` function.

## Parameters

### Codeword length

The length of the code word in symbols, N, must be equal to  $2^M - 1$ , where M is the input word length. M can be between 3 and 16 bits.

### Message length

The message length in symbols, K. The number of parity symbols, N-K, must be a positive even integer, greater than or equal to the input word length, M.

### Source of primitive polynomial

Select Property to enable the **Primitive polynomial** parameter.

### Primitive polynomial

Binary row vector representing the primitive polynomial in descending order of powers. When you provide a primitive polynomial, the number of input bits must be an integer multiple of K times the order of the primitive polynomial instead.

This parameter applies when only when Property is selected for **Primitive polynomial**.

### Source of B, the starting power for roots of the primitive polynomial

Select Property to enable the **B value** parameter. When you select Auto, the block uses  $B = 1$ .

### B value

The starting exponent of the roots.

This field is available only when you select Property for **Source of B, the starting power for roots of the primitive polynomial**. The default is 1.

### Enable number of errors output

Check this box to enable the numErrors output port. This port outputs the detected symbol error count.

## Integer to Bit Converter

Map vector of integers to vector of bits

### Library

Utility Blocks

### Description

The Integer to Bit Converter block maps each integer (or fixed-point value) in the input vector to a group of bits in the output vector.

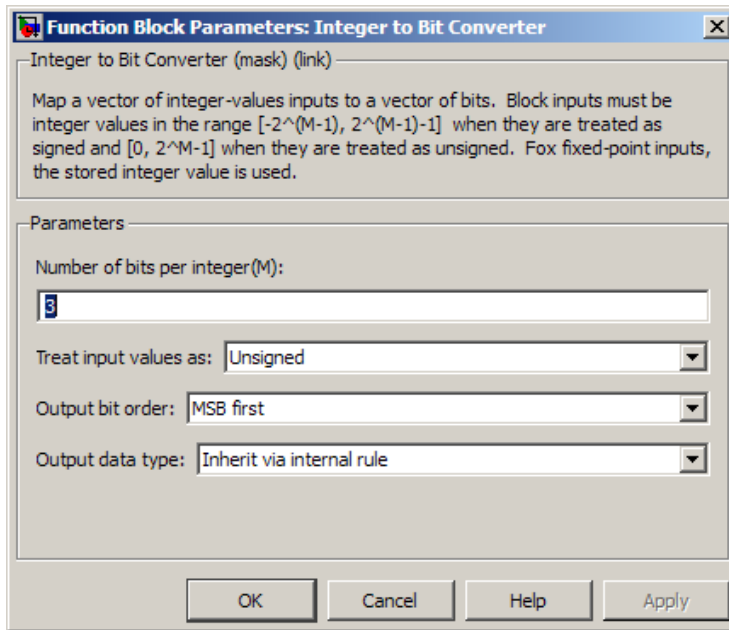

The block maps each integer value (or stored integer when you use a fixed point input) to a group of  $M$  bits, using the selection for the **Output bit order** to determine the most significant bit. The resulting output vector length is  $M$  times the input vector length.

When you set the **Number of bits per integer** parameter to  $M$  and **Treat input values as** to **Unsigned**, then the input values must be between 0 and  $2^M-1$ . When you set **Number of bits per integer** to  $M$  and **Treat input values as** to **Signed**, then the input values must be between  $-2^{M-1}$  and  $2^{M-1}-1$ . During simulation, the block performs a run-time check and issues an error if any input value is outside of the appropriate range. When the block generates code, it does not perform this run-time check.

This block is single-rate and single-channel. It accepts a length  $N$  column vector or a scalar-valued ( $N = 1$ ) input signal and outputs a length  $N \cdot M$  column vector.

The block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `single`, `double`, and `fixed point`.

## Dialog Box

### Number of bits per integer

The number of bits the block uses to represent each integer of the input. This parameter must be an integer between 1 and 32.

### Treat input values as

Indicate if the integer value input ranges should be treated as signed or unsigned. The default setting is Unsigned.

### Output bit order

Define whether the first bit of the output signal is the most significant bit (MSB) or the least significant bit (LSB). The default selection is MSB first.

### Output data type

You can choose the following **Output data type** options:

- Inherit via internal rule
- Smallest integer

- Same as input
- double
- single
- uint8
- uint16
- uint32

The default selection for this parameter is `Inherit via internal rule`.

When the parameter is set to `Inherit via internal rule`, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either `single` or `double`), the output data type is the same as the input data type.
- If the input data type is not floating-point, the output data type is determined as if the parameter is set to `Smallest integer`.

When the parameter is set to `Smallest integer`, the block selects the output data type based on settings used in the “Hardware Implementation Pane” (Simulink) of the Configuration Parameters dialog box.

- If you select ASIC/FPGA, the output data type is the ideal one-bit size; `ufix1`.
- For all other selections, the output data type is an unsigned integer with the smallest available word length, as defined in the Hardware Implementation settings (e.g. `uint8`)

## Examples

### Fixed-Point Integer To Bit and Bit To Integer Conversion (Audio Scrambling and Descrambling Example)

#### Overview

This example illustrates how to use the Bit to Integer and Integer to Bit Converter blocks with fixed-point signals.

This example uses a simplified audio scrambler configuration and a 16-bit, fixed-point digital audio source, which is recorded speech. The left-side of the model represents the audio scrambler subsystem and the right-side represents the descrambler subsystem.

## Opening the Model

You can open the model by typing `doc_audioscrambler` at the MATLAB command line.

## Structure

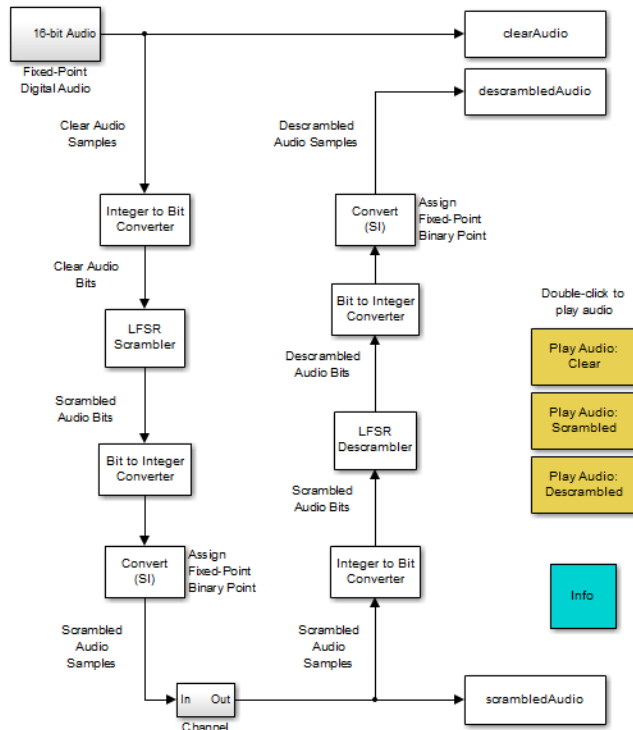

In the audio scrambler subsystem, the Integer to Bit Converter block unpacks each 16-bit audio sample into a binary, 1-bit signal. The binary signal passes to a linear feedback shift register (LFSR) scrambler, which randomizes the bits in a controllable way, thereby scrambling the signal. The Communications Toolbox Scrambler block is used in the LFSR implementation. From the LFSR, the scrambled audio bits pass to the Bit to Integer Converter block. This block packs the scrambled 1-bit samples into 16-bit audio samples. The audio samples pass to the Data Type Conversion block, which converts the integer-based audio samples back into fixed-point samples.

The fixed-point samples pass from the scrambler subsystem to a channel. The channel sends the samples to the descrambler subsystem. For illustrative purposes, this example uses a noiseless channel. In an actual system, a channel may introduce noise. Removing such noise requires a more sophisticated design.

In the audio descrambler subsystem, the Integer to Bit Converter block unpacks each 16-bit audio sample into a binary, 1-bit signal. The binary signal passes to a linear feedback shift register (LFSR) descrambler, which randomizes the bits in a controllable way, reversing the scrambling process. This LFSR descrambler implementation uses the Communications Toolbox Descrambler block. From the LFSR, the descrambled audio bits pass to the Bit to Integer Converter block. This block packs the descrambled 1-bit samples into 16-bit audio samples. The audio samples pass to the Data Type Conversion block, which converts the integer-based audio samples back into fixed-point samples.

In Simulink, the `sfix16_En15` data type represents a signed (s) fixed-point (fix) signal with word length 16 and fraction length 15. Therefore, this model represents audio signals using the `sfix16_En15` data type, except when converting to and from 1-bit binary signals. All 1-bit signals are represented by `ufix1`, as seen at the output of the Integer to Bit Converter block. The audio source has a frame size (or number of samples per frame) of 1024. For more information on fixed-point signals, please refer to Fixed-Point Numbers in the Simulink documentation.

#### Fixed-Point Integer to Bit and Bit to Integer Conversion (Audio Scrambler and Descrambler Example)

### Running the Model

You must run the example before you can listen to any of the audio signals.

You can run the example by clicking **Simulation > Run**.

You can hear the audio signals by clicking the model's yellow, audio icons.

### Converter Block Settings

In the audio scrambler and descrambler subsystems, the Integer to Bit Converter block settings are:

- **Number of bits per integer:** 16

- **Treat input values as:** Signed
- **Output bit order:** MSB first
- **Output data type:** Inherit via internal rule

In the audio scrambler and descrambler subsystems, the Bit to Integer Converter block settings are:

- **Number of bits per integer:** 16
- **Input bit order:** MSB first
- **After bit packing, treat resulting integer values as:** Signed
- **Output data type:** Inherit via internal rule

## Integrate and Dump

Integrate discrete-time signal, resetting to zero periodically

### Library

Comm Filters

### Description

The Integrate and Dump block creates a cumulative sum of the discrete-time input signal, while resetting the sum to zero according to a fixed schedule. When the simulation begins, the block discards the number of samples specified in the **Offset** parameter. After this initial period, the block sums the input signal along columns and resets the sum to zero every  $N$  input samples, where  $N$  is the **Integration period** parameter value. The reset occurs after the block produces its output at that time step.

Receiver models often use the integrate-and-dump operation when the system's transmitter uses a simple square-pulse model. Fiber optics and in spread-spectrum communication systems, such as CDMA (code division multiple access) applications, also use the operation.

This block accepts a scalar, column vector, or matrix input signal. When the input signal is not a scalar value, it must contain  $k \cdot N$  rows for some positive integer  $k$ . For these input signals, the block processes each column independently.

Selecting **Output intermediate values** affects the contents, dimensions, and sample time as follows:

- If you clear the check box, then the block outputs the cumulative sum at each reset time.

- If the input is a scalar value, then the output sample time is  $N$  times the input sample time and the block experiences a delay whose duration is one output sample period. In this case, the output dimensions match the input dimensions.
- If the input is a  $(k \cdot N)$ -by- $n$  matrix, then the output is  $k$ -by- $n$ . In this case, the block experiences no delay and the output period matches the input period.
- If you select the check box, then the block outputs the cumulative sum at each time step. The output has the same sample time and the same matrix dimensions as the input.

## Transients and Delays

A nonzero value in the **Offset** parameter causes the block to output one or more zeros during the initial period while it discards input samples. If the input is a matrix with  $n$  columns and the **Offset** parameter is a length- $n$  vector, then the  $m^{\text{th}}$  element of the **Offset** vector is the offset for the  $m^{\text{th}}$  column of data. If **Offset** is a scalar, then the block applies the same offset to each column of data. The output of initial zeros due to a nonzero **Offset** value is a transient effect, not a persistent delay.

When you clear **Output intermediate values**, the block's output is delayed, relative to its input, throughout the simulation:

- If the input is a scalar value, then the output is delayed by one sample after any transient effect is over. That is, after removing transients from the input and output, you can see the result of the  $m^{\text{th}}$  integration period in the output sample indexed by  $m + 1$ .
- If the input is a column vector or matrix and the **Offset** parameter is nonzero, then after the transient effect is over, the result of each integration period appears in the output frame corresponding to the *last* input sample of that integration period. This is one frame later than the output frame corresponding to the first input sample of that integration period, in cases where an integration period spans two input frames. For an example of this situation, see “Example of Transient and Delay” on page 3-579.

## Parameters

### Integration period

The number of input samples between resets.

**Offset**

A nonnegative integer vector or scalar specifying the number of input samples to discard from each column of input data at the beginning of the simulation.

**Output intermediate values**

Determines whether the block outputs the intermediate cumulative sums between successive resets.

**Fixed-Point Signal Flow Diagram****Fixed-Point Attributes**

The settings for the following parameters only apply when block inputs are fixed-point signals.

**Rounding mode**

Use this parameter to specify the rounding method to be used when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result.

For more information, see “Rounding Modes” (DSP System Toolbox) or “Rounding Mode: Simplest” (Fixed-Point Designer).

**Saturate on integer overflow**

Use this parameter to specify the method to be used if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result:

- Saturate represents positive overflows as the largest positive number in the range being used, and negative overflows as the largest negative number in the range being used.
- Wrap uses modulo arithmetic to cast an overflow back into the representable range of the data type. See “Modulo Arithmetic” (Fixed-Point Designer) for more information.

### **Accumulator—Mode**

Use the **Accumulator—Mode** parameter to specify how you would like to designate the accumulator word and fraction lengths:

- When you select `Inherit via internal rule`, the block automatically calculates the accumulator output word and fraction lengths.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you are able to enter the word length, in bits, and the slope of the accumulator.

### **Output**

Use the **Output** parameter to choose how you specify the word length and fraction length of the output of the block:

- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, enter the word length, in bits, and the slope of the output.

For additional information about the parameters pertaining to fixed-point applications, see “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

## Supported Data Type

Port	Supported Data Types
In	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed-point</li> </ul>
Out	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed-point</li> </ul>

## Examples

If **Integration period** is 4 and **Offset** is the scalar 3, then the table below shows how the block treats the beginning of a ramp (1, 2, 3, 4,...) in several situations. (The values shown in the table do not reflect vector sizes but merely indicate numerical values.)

Output intermediate values Check Box	Input Signal Properties	First Several Output Values
Cleared	Scalar	0, 0, 4+5+6+7, and 8+9+10+11, where one 0 is an initial transient value and the other 0 is a delay value that results from the cleared check box and scalar value input.
Cleared	Column vector of length 4	0, 4+5+6+7, and 8+9+10+11, where 0 is an initial delay value that results from the nonzero offset. The output is a scalar value.
Selected	Scalar	0, 0, 0, 4, 4+5, 4+5+6, 4+5+6+7, 8, 8+9, 8+9+10, 8+9+10+11, and 12, where the three 0s are initial transient values.

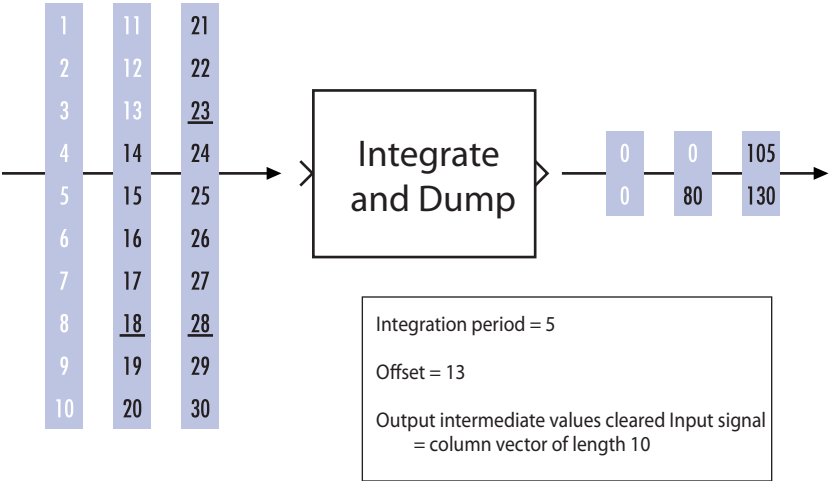

Output intermediate values Check Box	Input Signal Properties	First Several Output Values
Selected	Column vector of length 4	0, 0, 0, 4, 4+5, 4+5+6, 4+5+6+7, 8, 8+9, 8+9+10, 8+9+10+11, and 12, where the three 0s are initial transient values. The output is a column vector of length 4.

In all cases, the block discards the first three input samples (1, 2, and 3).

### Example of Transient and Delay

The figure below illustrates a situation in which the block exhibits both a transient effect for three output samples, as well as a one-sample delay in alternate subsequent output samples for the rest of the simulation. The figure also indicates how the input and output values are organized as column vectors. In each vector in the figure, the last sample of each integration period is underlined, discarded input samples are white, and transient zeros in the output are white.

The transient effect lasts for  $\text{ceil}(13/5)$  output samples because the block discards 13 input samples and the integration period is 5. The first output sample after the transient effect is over, 80, corresponds to the sum  $14+15+16+17+18$  and appears at the time of the input sample 18. The next output sample, 105, corresponds to the sum

$19+20+21+22+23$  and appears at the time of the input sample 23. Notice that the input sample 23 is one frame later than the input sample 19; that is, this five-sample integration period spans two input frames. As a result, the output of 105 is delayed compared to the first input (19) that contributes to that sum.

# Interlacer

Alternately select elements from two input vectors to generate output vector

## Library

Sequence Operations

## Description

The Interlacer block accepts two inputs that have the same vector size, complexity, and sample time. It produces one output vector by alternating elements from the first input (labeled O for odd) and from the second input (labeled E for even) . As a result, the output vector size is twice that of either input. The output vector has the same complexity and sample time of the inputs.

Both input ports accept scalars or column vectors with the same number of elements. The block accepts the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

This block can be useful for combining in-phase and quadrature information from separate vectors into a single vector.

## Examples

If the two input vectors have the values `[1; 2; 3; 4]` and `[5; 6; 7; 8]`, then the output vector is `[1; 5; 2; 6; 3; 7; 4; 8]`.

## I/Q Imbalance

Create complex baseband model of signal impairments caused by imbalances between in-phase and quadrature receiver components

## Library

RF Impairments

## Description

The I/Q Imbalance block creates a complex baseband model of the signal impairments caused by imbalances between in-phase and quadrature receiver components. Typically, these are caused by differences in the physical channels for the two components of the signal.

The I/Q Imbalance block applies amplitude and phase imbalances to the in-phase and quadrature components of the input signal, and then combines the results into a complex signal. The block

- 1 Separates the signal into its in-phase and quadrature components.
- 2 Applies amplitude and phase imbalances, specified by the **I/Q amplitude imbalance (dB)** and **I/Q phase imbalance (deg)** parameters, respectively, to both components.
- 3 Combines the in-phase and quadrature components into a complex signal.
- 4 Applies an in-phase dc offset, specified by the **I dc offset** parameter, and a quadrature offset, specified by the **Q dc offset** parameter, to the signal.

The block performs these operations in the subsystem shown in the following diagram, which you can view by right-clicking the block and selecting **Mask > Look under mask**:

Let

$I_a = I/Q$  amplitude imbalance

$I_p = I/Q$  phase imbalance

$I_{DC} =$  in-phase DC offset

$Q_{DC} =$  quadrature DC offset

Also let  $x = x_r + j * x_i$  be the complex input to the block, with  $x_r$  and  $x_i$  being the real and imaginary parts, respectively, of  $x$ . Let  $y$  be the complex output of the block.

Then, for an I/Q amplitude imbalance,  $I_a$

$$y_{AmplitudeImbalance} = [10^{(0.5 * \frac{I_a}{20})} * x_r] + j[10^{(-0.5 * \frac{I_a}{20})} * x_i]$$

$$\triangleq y_{r_{AmplitudeImbalance}} + j * y_{i_{AmplitudeImbalance}}$$

For an I/Q phase imbalance  $I_p$

$$y_{PhaseImbalance} =$$

$$\left[ \exp(-0.5 * j * \pi * \frac{I_p}{180}) * y_{r_{AmplitudeImbalance}} \right] + \left\{ \exp[j(\frac{\pi}{2} + 0.5 * \pi * \frac{I_p}{180})] * y_{i_{AmplitudeImbalance}} \right\}$$

$$\triangleq y_{r_{\text{PhaseImbalance}}} + j * y_{i_{\text{PhaseImbalance}}}$$

For DC offsets  $I_{DC}$  and  $Q_{DC}$

$$y = (y_{r_{\text{PhaseImbalance}}} + I_{DC}) + j * (y_{i_{\text{PhaseImbalance}}} + Q_{DC})$$

The value of the **I/Q amplitude imbalance (dB)** parameter is divided between the in-phase and quadrature components such that the block applies a gain of  $+X/2$  dB to the in-phase component and a gain of  $-X/2$  dB to the quadrature component where  $X$  can be positive or negative.

The effects of changing the block's parameters are illustrated by the following scatter plots of a signal modulated by 16-ary quadrature amplitude modulation (QAM) with an average power of 0.01 watts. The usual 16-ary QAM constellation without distortion is shown in the first scatter plot:

The following figure shows a scatter plot of an output signal, modulated by 16-ary QAM, from the I/Q block with **I/Q amplitude imbalance (dB)** set to 8 and all other parameters set to 0:

Observe that the scatter plot is stretched horizontally and compressed vertically compared to the undistorted constellation.

If you set **IQ phase imbalance (deg)** to 30 and all other parameters to 0, the scatter plot is skewed clockwise by 30 degrees, as shown below:

Setting the **I dc offset** to  $0.02$  and the **Q dc offset** to  $0.04$  shifts the constellation  $0.02$  to the right and  $0.04$  up, as shown below:

See “Illustrate RF Impairments That Distort a Signal” for a description of the model that generates this plot.

## **Parameters**

### **I/Q amplitude imbalance (dB)**

Scalar specifying the I/Q amplitude imbalance in decibels.

### **I/Q phase imbalance (deg)**

Scalar specifying the I/Q phase imbalance in degrees.

### **I dc offset**

Scalar specifying the in-phase dc offset.

### **Q dc offset**

Scalar specifying the amplitude dc offset.

## I/Q Compensator Coefficient to Imbalance

Convert compensator coefficient into amplitude and phase imbalance

## Library

RF Impairments Correction

## Description

The I/Q Compensator Coefficient to Imbalance block converts a compensator coefficient into its equivalent amplitude and phase imbalance.

This block has a single input port, which accepts a complex coefficient or a vector of coefficients. There are amplitude and phase imbalance output ports both of which are real. The amplitude imbalance is expressed in dB while the phase imbalance is expressed in degrees.

## Algorithms

See the `iqcoef2imbal` function reference page for more information on the inputs, outputs, and algorithms.

# I/Q Imbalance Compensator

Compensate for imbalance between in-phase and quadrature components

## Library

RF Impairments Correction

## Description

The I/Q Imbalance Compensator mitigates the effects of an amplitude and phase imbalance between the in-phase and quadrature components of a modulated signal. The supported modulation schemes include OFDM, M-PSK, and M-QAM, where  $M > 2$ .

This block accepts up to three input ports, of which one is the input signal. When you set the **Source of compensator coefficient** parameter to `Estimated from input signal`, two additional input ports are enabled. The first is enabled when you set the **Source of adaptation step size** parameter to `Input port` and the second is enabled when you check the **Coefficient adaptation input port** box. The two options are independent. Additionally, you can check the **Estimated coefficient output port** box to create an optional output port from which the estimated compensator coefficients are made available.

When you set the **Source of compensator coefficient** parameter to `Input port`, only one possible configuration is possible (input signal port, coefficient input port, and output signal port).

## Parameters

### Source of compensator coefficient

Specify the source of the compensator coefficients as `Estimated from input signal` or `Input port`. If set to `Estimated from input signal`, the compensator calculates the coefficients from the input signal. If set to `Input port`, all other properties are disabled and you must provide the coefficients through the input port. The default value is `Estimated from input signal`.

### Initial compensator coefficient

Specify the initial coefficient used by the internal algorithm to compensate for the I/Q imbalance. The default value is  $0+0j$ .

### Source of adaptation step size

Specify the source of the adaptation step size as `Property` or `Input port`. If set to `Property`, specify the step size in the **Adaptation step size** field. If set to `Input port`, you must specify the step size through an input port. The default value is `Property`.

### Adaptation step size

Specify the step size of the adaptation algorithm as a real scalar. This parameter is available only when **Source of adaptation step size** is set to `Property`. The default value is `0.00001`.

### Coefficient adaptation input port

Select this check box to create an input port that permits a signal to control the adaptation process. If the check box is selected and if the input signal is `true`, the estimated compensation coefficients are updated. If the adaptation port is not enabled or if the input signal is `false`, the compensation coefficients do not change. By default, the check box is not selected.

### Estimated coefficient output port

Select this check box to provide the estimated compensation coefficients to an output port. By default, the check box is not selected.

## Algorithms

This block implements the algorithm, inputs, and outputs described on the `comm.IQImbalanceCompensator` reference page. The object properties correspond to the block parameters.

## Examples

### Compensate for I/Q Imbalance

This example shows how to use the I/Q Imbalance Compensator block to remove the effects of an amplitude and phase imbalance on a modulated signal.

Open the model, `doc_iqimbcomp`, from the MATLAB command prompt.

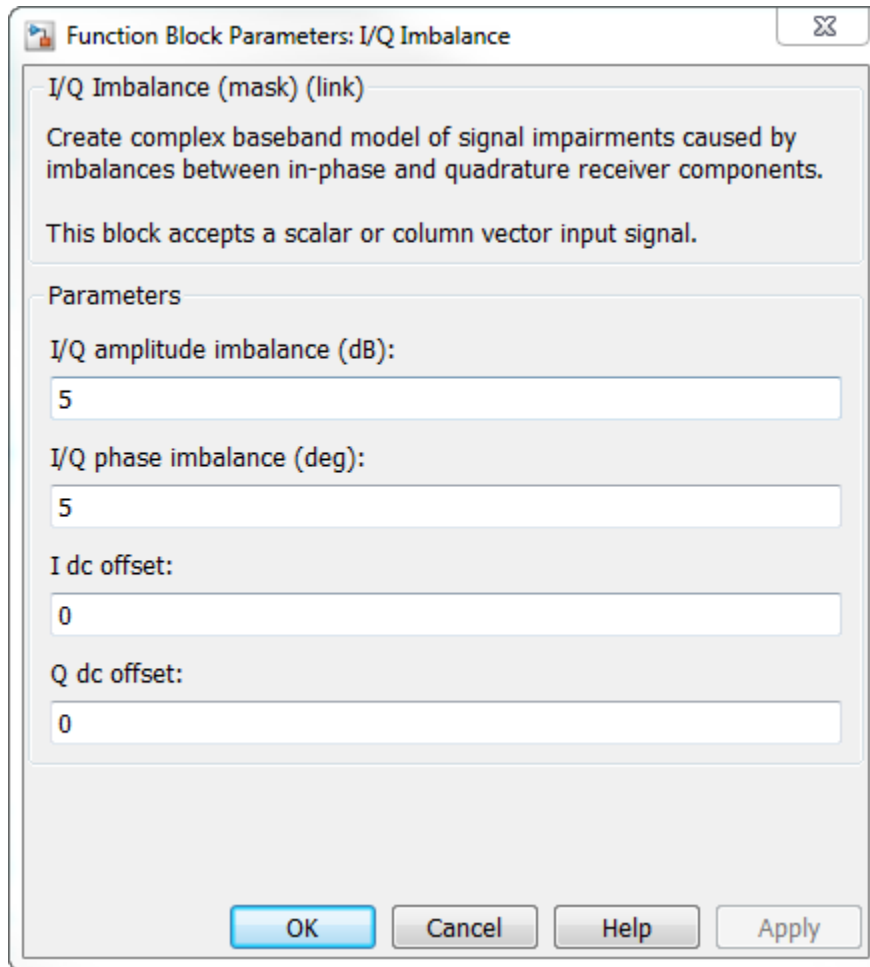

```
doc_iqimbcomp
```

The model includes these blocks:

- Random Integer Generator
- M-PSK Modulator Baseband
- I/Q Imbalance
- I/Q Imbalance Compensator
- Constellation Diagram

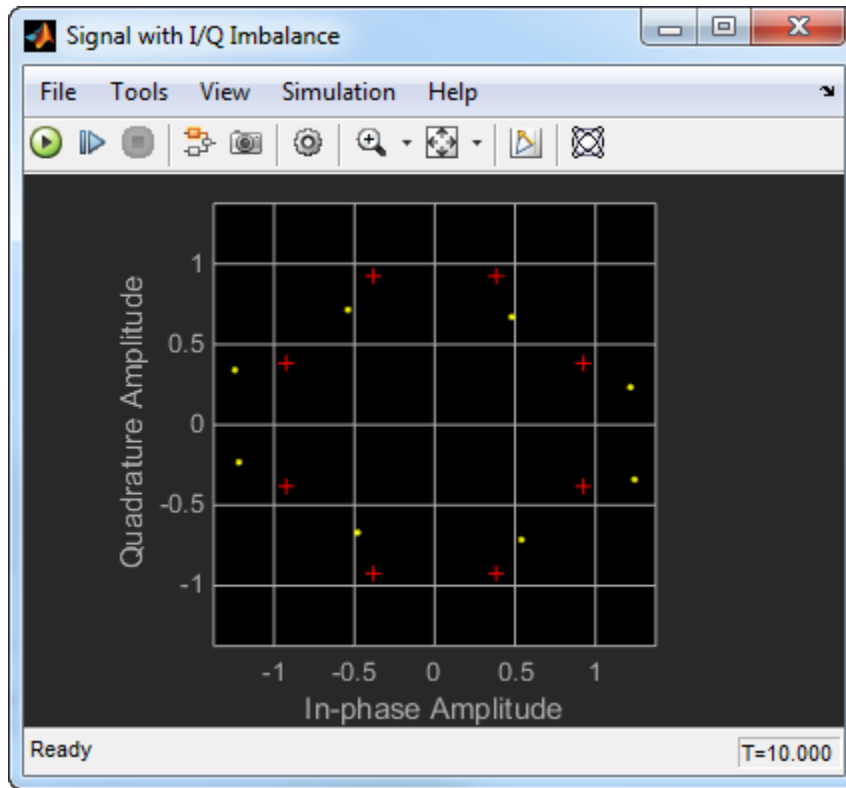

Double-click the I/Q Imbalance block. You can see that the **I/Q amplitude imbalance (dB)** parameter is set to 5 and the **I/Q phase imbalance (deg)** parameter is also set to 5.

Run the model. In the *Signal with I/Q Imbalance* constellation diagram, observe the effects of the amplitude imbalance and phase imbalance on the 8-PSK signal.

Look at the *Compensated Signal* constellation diagram. Observe that the signal is not well aligned with the reference constellation (shown in red).

Increase the simulation time from 20 seconds to 100 seconds and run the model again. You can see that the constellation is now well aligned with the reference constellation. This is because the compensation algorithm is adaptive; consequently, it requires time to accurately estimate the I/Q imbalance.

Try changing other simulation parameters such as the step size in the I/Q Imbalance Compensator block, the amplitude and phase imbalance in the I/Q Imbalance block, the modulation type etc. Observe the effects on the *Compensated Signal* constellation diagram.

## Supported Data Types

## I/Q Imbalance to Compensator Coefficient

Converts amplitude and phase imbalance into I/Q compensator coefficient

### Library

RF Impairments Correction

### Description

The I/Q Imbalance to Compensator Coefficient block returns a complex coefficient to compensate for amplitude and phase imbalance.

This block has an amplitude imbalance input port and a phase imbalance input port, where the amplitude imbalance is a real number expressed in dB and the phase imbalance is a real number expressed in degrees. The imbalance inputs are vectors. The complex coefficients are returned from a single output port.

### Algorithms

See `iqimbal2coef` for more information on the inputs, outputs, and algorithms.

## Supported Data Types

Port	Supported Data Types
Compensator Coefficient	<ul style="list-style-type: none"><li>• Double-precision, complex floating point</li><li>• Single-precision, complex floating point</li></ul>

# Kasami Sequence Generator

Generate Kasami sequence from set of Kasami sequences

## Library

Sequence Generators sublibrary of Comm Sources

## Description

The Kasami Sequence Generator block generates a sequence from the set of Kasami sequences. The Kasami sequences are a set of sequences that have good cross-correlation properties.

This block can output sequences that vary in length during simulation. For more information about variable-size signals, see “Variable-Size Signal Basics” (Simulink).

## Kasami Sequences

There are two sets of Kasami sequences: the *small set* and the *large set*. The large set contains all the sequences in the small set. Only the small set is optimal in the sense of matching Welch's lower bound for correlation functions.

Kasami sequences have period  $N = 2^n - 1$ , where  $n$  is a nonnegative, even integer. Let  $u$  be a binary sequence of length  $N$ , and let  $w$  be the sequence obtained by decimating  $u$  by  $2^{n/2} + 1$ . The small set of Kasami sequences is defined by the following formulas, in which  $T$  denotes the left shift operator,  $m$  is the shift parameter for  $w$ , and  $\oplus$  denotes addition modulo 2.

$$K_s(u, n, m) = \begin{cases} u & m = -1 \\ u \oplus T^m w & m = 0, \dots, 2^{n/2} - 2 \end{cases}$$

### Small Set of Kasami Sequences for n Even

Note that the small set contains  $2^{n/2}$  sequences.

For  $\text{mod}(n, 4) = 2$ , the large set of Kasami sequences is defined as follows. Let  $v$  be the sequence formed by decimating the sequence  $u$  by  $2^{n/2} + 1$ . The large set is defined by the following table, in which  $k$  and  $m$  are the shift parameters for the sequences  $v$  and  $w$ , respectively.

$$K_L(u, n, k, m) = \begin{cases} u & k = -2; m = -1 \\ v & k = -1; m = -1 \\ u \oplus T^k v & k = 0, \dots, 2^n - 2; m = -1 \\ u \oplus T^m w & k = -2; m = 0, \dots, 2^{n/2} - 2 \\ v \oplus T^m w & k = -1; m = 0, \dots, 2^{n/2} - 2 \\ u \oplus T^k v \oplus T^m w & k = 0, \dots, 2^n - 2; m = 0, \dots, 2^{n/2} - 2 \end{cases}$$

### Large Set of Kasami Sequences for $\text{mod}(n, 4) = 2$

The sequences described in the first three rows of the preceding figure correspond to the Gold sequences for  $\text{mod}(n, 4) = 2$ . See the reference page for the Gold Sequence Generator block for a description of Gold sequences. However, the Kasami sequences form a larger set than the Gold sequences.

The correlation functions for the sequences takes on the values

$$\{-t(n), -s(n), -1, s(n) - 2, t(n) - 2\}$$

where

$$t(n) = 1 + 2^{(n+2)/2}, n \text{ even}$$

$$s(n) = \frac{1}{2}(t(n) + 1)$$

### Block Parameters

The **Generator polynomial** parameter specifies the generator polynomial, which determines the connections in the shift register that generates the sequence  $u$ . You can specify the **Generator polynomial** parameter using these formats:

- A polynomial character vector that includes the number 1, for example, 'z^4 + z + 1'.

- A vector that lists the coefficients of the polynomial in descending order of powers. The first and last entries must be 1. Note that the length of this vector is one more than the degree of the generator polynomial.
- A vector containing the exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0.

For example, ' $z^8 + z^2 + 1$ ',  $[1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0 \ 1]$ , and  $[8 \ 2 \ 0]$  represent the same polynomial,  $p(z) = z^8 + z^2 + 1$ .

The **Initial states** parameter specifies the initial states of the shift register that generates the sequence  $u$ . **Initial States** is a binary scalar or row vector of length equal to the degree of the **Generator polynomial**. If you choose a binary scalar, the block expands the scalar to a row vector of length equal to the degree of the **Generator polynomial**, all of whose entries equal the scalar.

The **Sequence index** parameter specifies the shifts of the sequences  $v$  and  $w$  used to generate the output sequence. You can specify the parameter in either of two ways:

- To generate sequences from the small set, for  $n$  is even, you can specify the **Sequence index** as an integer  $m$ . The range of  $m$  is  $[-1, \dots, 2^{n/2} - 2]$ . The following table describes the output sequences corresponding to **Sequence index**  $m$ :

Sequence Index	Range of Indices	Output Sequence
-1	$m = -1$	$u$
$m$	$m = 0, \dots, 2^{n/2} - 2$	$u \oplus T^m w$

- To generate sequences from the large set, for  $\text{mod}(n, 4) = 2$ , where  $n$  is the degree of the **Generator polynomial**, you can specify **Sequence index** as an integer vector  $[k \ m]$ . In this case, the output sequence is from the large set. The range for  $k$  is  $[-2, \dots, 2^n - 2]$ , and the range for  $m$  is  $[-1, \dots, 2^{n/2} - 2]$ . The following table describes the output sequences corresponding to **Sequence index**  $[k \ m]$ :

Sequence Index $[k \ m]$	Range of Indices	Output Sequence
$[-2 \ -1]$	$k = -2, m = -1$	$u$
$[-1 \ -1]$	$k = -1, m = -1$	$v$
$[k \ -1]$	$k = 0, 1, \dots, 2^n - 2$ $m = -1$	$u \oplus T^k v$

Sequence Index [k m]	Range of Indices	Output Sequence
[-2 m]	$k = -2$ $m = 0, 1, \dots, 2^{n/2} - 2$	$u \oplus T^m w$
[-1 m]	$k = -1$ $m = 0, \dots, 2^{n/2} - 2$	$v \oplus T^m w$
[k m]	$k = 0, \dots, 2^n - 2$ $m = 0, \dots, 2^{n/2} - 2$	$u \oplus T^k v \oplus T^m w$

You can shift the starting point of the Kasami sequence with the **Shift** parameter, which is an integer representing the length of the shift.

You can use an external signal to reset the values of the internal shift register to the initial state by selecting **Reset on nonzero input**. This creates an input port for the external signal in the Kasami Sequence Generator block. The way the block resets the internal shift register depends on whether its output signal and the reset signal are sample-based or frame-based. See “Resetting a Signal” on page 3-905 for an example.

### Polynomials for Generating Kasami Sequences

The following table lists some of the polynomials that you can use to generate the Kasami set of sequences.

n	N	Polynomial	Set
4	15	[4 1 0]	Small
6	63	[6 1 0]	Large
8	255	[8 4 3 2 0]	Small
10	1023	[10 3 0]	Large
12	4095	[12 6 4 1 0]	Small

## Parameters

### Generator polynomial

Character vector or binary vector specifying the generator polynomial for the sequence  $u$ .

### Initial states

Binary scalar or row vector of length equal to the degree of the **Generator polynomial**, which specifies the initial states of the shift register that generates the sequence  $u$ .

### Sequence index

Integer or vector specifying the shifts of the sequences  $v$  and  $w$  used to generate the output sequence.

### Shift

Integer scalar that determines the offset of the Kasami sequence from the initial time.

### Output variable-size signals

Select this if you want the output sequences to vary in length during simulation. The default selection outputs fixed-length signals.

### Maximum output size source

Specify how the block defines maximum output size for a signal.

- When you select **Dialog parameter**, the value you enter in the **Maximum output size** parameter specifies the maximum size of the output. When you make this selection, the **oSiz** input port specifies the current size of the output signal and the block output inherits sample time from the input signal. The input value must be less than or equal to the **Maximum output size** parameter.
- When you select **Inherit from reference port**, the block output inherits sample time, maximum size, and current size from the variable-sized signal at the **Ref** input port.

This parameter only appears when you select **Output variable-size signals**. The default selection is **Dialog parameter**.

### Maximum output size

Specify a two-element row vector denoting the maximum output size for the block. The second element of the vector must be 1. For example, [10 1] gives a 10-by-1 maximum sized output signal. This parameter only appears when you select **Output variable-size signals**.

### Sample time

The time between each sample of a column of the output signal.

### Samples per frame

The number of samples per frame in one channel of the output signal.

---

**Note** The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

---

### Reset on nonzero input

When selected, you can specify an input signal that resets the internal shift registers to the original values of the **Initial states**.

### Output data type

The output type of the block can be specified as a boolean or double. By default, the block sets this to double.

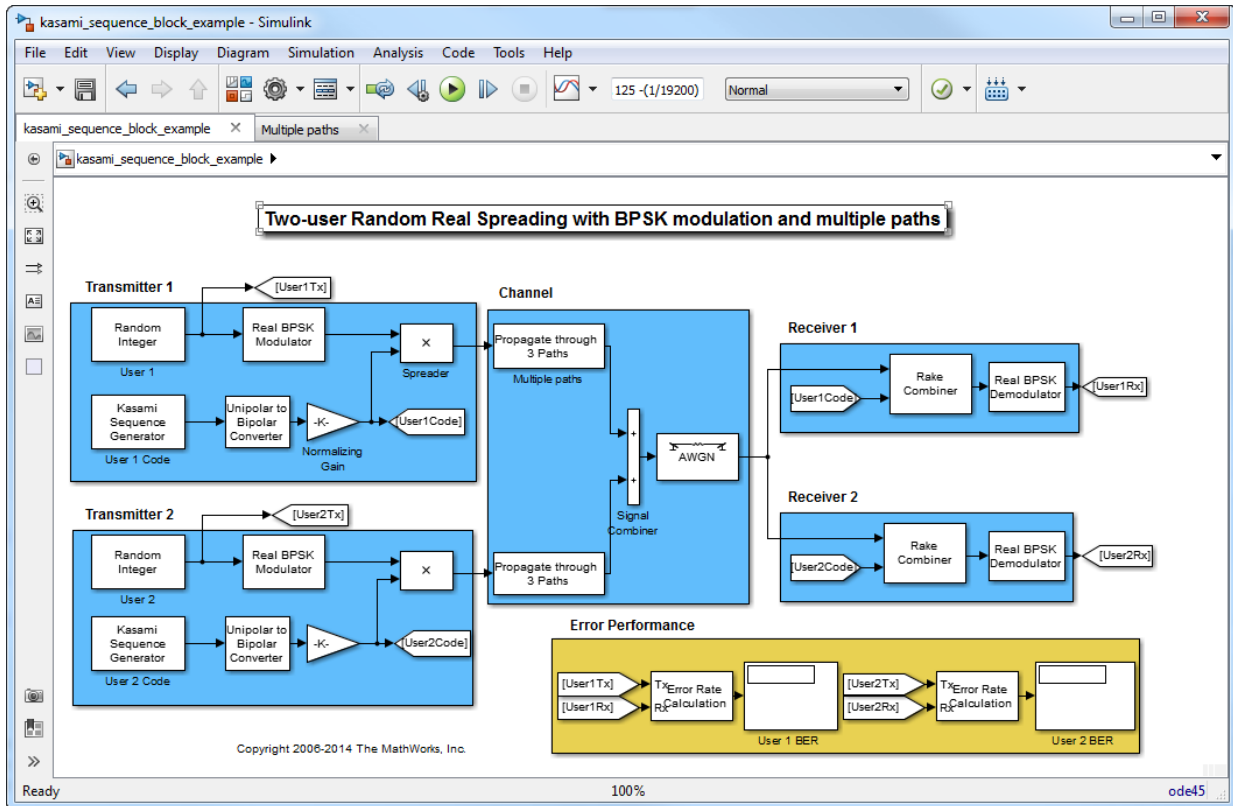

## Example

### Kasami Spreading with Two Users and Multipath

This model considers Kasami spreading for a combined two-user transmission in a multipath environment.

Open the model here: `kasami_sequence_block_example`

```
modelName = 'kasami_sequence_block_example';  
open_system(modelname);  
sim(modelname);
```

You can see very good user separation over multiple paths with the gains of combining. This can be attributed to the "good" correlation properties of Kasami sequences, which provide a balance between the ideal cross-correlation properties of orthogonal codes and the ideal auto-correlation properties of PN sequences. See the relevant examples on the Hadamard Code Generator and PN Sequence Generator reference pages.

To experiment with this model further, try selecting other path delays to see how the performance varies for the same code. Also try different codes with the same delays.

```
close_system(modelname, 0);
```

# LDPC Decoder

Decode binary low-density parity-check (LDPC) code

**Library:** Communications Toolbox / Error Detection and Correction / Block

## Description

The LDPC Decoder block uses the belief propagation algorithm to decode a binary LDPC code, which is input to the block as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The block decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 3-613.

The input and output are discrete-time signals. The ratio of the output sample time to the input sample time is:

- $N/K$  when only the information-part of the codeword is decoded
- 1 when the entire codeword is decoded

$N$  is the length of the received signal and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ .

This icon shows all ports, including optional ports, for the LDPC Decoder block.

## Ports

### Input

#### **In — Log-likelihood ratios**

column vector

Log-likelihood ratios, specified as an  $N$ -by-1 column vector containing the soft-decision output from demodulation.  $N$  is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit and the value is more likely to be 0 if the log-likelihood ratio is positive. The first  $K$  elements correspond to the information-part of the input message.

Data Types: double

### Output

#### **Out — Decoded data**

column vector

Decoded data, returned as a column vector. The **Decision type** parameter specifies whether the block outputs hard decisions or soft decisions (log-likelihood ratios).

- If the **Output format** parameter is set to `Information part`, the output includes only the information-part of the received codeword.
- If the **Output format** parameter is set to `Whole codeword`, the output includes the whole log-likelihood ratio vector.

Data Types: double | Boolean

#### **Iter — Number of executed decoding iterations**

positive integer

Number of executed decoding iterations, returned as a positive integer.

#### **Dependencies**

To enable this port, select the **Output number of iterations executed** parameter.

Data Types: double

**ParChk — Final parity checks**

column vector

Final parity checks after decoding the input LDPC code, returned as an  $(N-K)$ -by-1 column vector.  $N$  is the number of bits in the LDPC codeword before modulation.  $K$  is the length of the uncoded message.

**Dependencies**

To enable this port, select the **Output final parity checks** parameter.

**Parameters****Parity-check matrix (sparse binary  $(N-K)$ -by- $N$  matrix) — Parity-check matrix**

dvbs2ldpc(1/2) (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse  $(N - K)$ -by- $N$  binary-valued matrix.  $N$  is the length of the received signal and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ . The last  $(N - K)$  columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2,  $gf(2)$ .

You can also specify the parity-check matrix as a two-column nonsparse index matrix,  $I$ , that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1), I(:,2), 1)`.

This parameter accepts numeric data types. When you set this parameter to a sparse binary matrix, this parameter also accepts the `Boolean` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R, 'indices')` configures the index matrix for the DVB-S.2 standard, where  $R$  is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `Boolean`

**Output format — Output value format**

Information part (default) | Whole codeword

Output value format, specified as one of these values:

- **Information part** — The block outputs a  $K$ -by-1 column vector containing only the information-part of the received log-likelihood ratio vector.  $K$  is the length of the uncoded message.
- **Whole codeword** — The block outputs an  $N$ -by-1 column vector containing the whole log-likelihood ratio vector.  $N$  is the length of the received signal.

$N$  and  $K$  must align with the dimension of the  $(N-K)$ -by- $K$  parity-check matrix.

#### **Decision type — Decision method**

Hard decision (default) | Soft decision

Decision method used for decoding, specified as one of these values:

- **Hard decision** — The block outputs decoded data of data type `double` or `boolean`. Specify this data type using the **Output data type** parameter.
- **Soft decision** — The block outputs log-likelihood ratios of data type `double`.

#### **Output data type — Output value data type**

double (default) | boolean

Output value data type, specified as `double` or `boolean`.

#### **Dependencies**

To enable this parameter, set the **Decision type** parameter to `Hard decision`.

#### **Number of iterations — Maximum number of decoding iterations**

50 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

#### **Stop iterating when all parity-checks are satisfied — Condition for iteration termination**

off (default) | on

Select this parameter to terminate decoding after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the **Number of iterations** parameter.

**Output number of iterations executed — Output number of iterations executed**

off (default) | on

Select this parameter to enable the **Iter** output port.**Output final parity-checks — Output number of iterations executed**

off (default) | on

Select this parameter to enable the **ParChk** output port.

## Block Characteristics

<b>Data Types</b>	Boolean   double
<b>Multidimensional Signals</b>	no
<b>Variable-Size Signals</b>	no

## Algorithms

This block performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

### Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager.

For transmitted LDPC-encoded codeword  $c = c_0, c_1, \dots, c_{n-1}$ , the input to the LDPC decoder is the log-likelihood ratio (LLR) value

$$L(c_i) = \log \left( \frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)} \right).$$

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left( \prod_{i' \in V_j \setminus i} \tanh \left( \frac{1}{2} L(q_{i'j}) \right) \right),$$

$$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \setminus j} L(r_{ji'}), \text{ initialized as } L(q_{ij}) = L(c_i) \text{ before the first iteration, and}$$

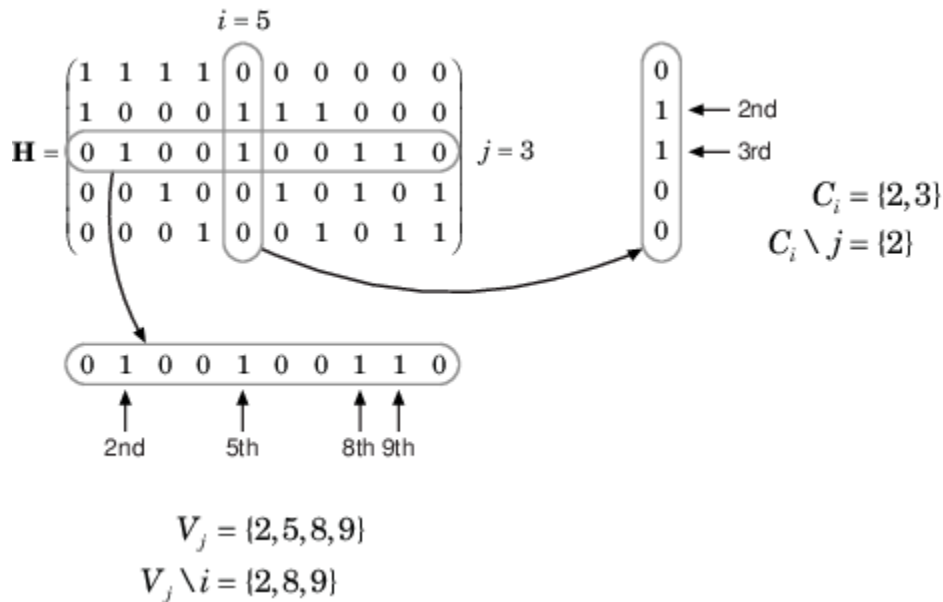

$$L(Q_i) = L(c_i) + \sum_{j' \in C_i} L(r_{ji'}).$$

At the end of each iteration,  $L(Q_i)$  contains the updated estimate of the LLR value for transmitted bit  $c_i$ . The value  $L(Q_i)$  is the soft-decision output for  $c_i$ . If  $L(Q_i) < 0$ , the hard-decision output for  $c_i$  is 1. Otherwise, the hard-decision output for  $c_i$  is 0.

If configured to stop when all parity checks are satisfied, the algorithm verifies the parity-check equation ( $Hc^T = 0$ ) at the end of each iteration. When all parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets  $C_i \setminus j$  and  $V_j \setminus i$  are based on the parity-check matrix (PCM). Index sets  $C_i$  and  $V_j$  correspond to all nonzero elements in column  $i$  and row  $j$  of the PCM, respectively.

This figure highlights the computation of these index sets in a given PCM for  $i = 5$  and  $j = 3$ .

To avoid infinite numbers in the algorithm equations,  $\operatorname{atanh}(1)$  and  $\operatorname{atanh}(-1)$  are set to 19.07 and -19.07, respectively. Due to finite precision, MATLAB returns 1 for  $\tanh(19.07)$  and -1 for  $\tanh(-19.07)$ .

# LDPC Encoder

Encode binary low-density parity-check (LDPC) code

**Library:** Communications Toolbox / Error Detection and Correction / Block

## Description

The LDPC Encoder block applies LDPC coding to a binary input message. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

The input and output are discrete-time signals. The ratio of the output sample time to the input sample time is  $K/N$ , where:

- $N$  is the length of the received signal and must be in the range  $(0, 2^{31})$ .
- $K$  is the length of the uncoded message and must be less than  $N$ .

## Ports

### Input

#### In — Input message

binary column vector

Input message, specified as a  $K$ -by-1 column vector containing binary-valued elements.  $K$  is the length of the uncoded message.

Data Types: double | Boolean

### Output

#### Out — LDPC codeword

column vector

LDPC codeword, returned as an  $N$ -by-1 column vector.  $N$  is the number of bits in the LDPC codeword. The output signal inherits its data type from the input signal. The LDPC codeword output is a solution to the parity-check equation. The input message comprises the first  $K$  bits of the LDPC codeword output, and the parity check comprises the remaining  $(N - K)$  bits.

Data Types: `double` | `Boolean`

## Parameters

### **Parity-check matrix (sparse binary (N-K)-by-N matrix) — Parity-check matrix**

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse  $(N - K)$ -by- $N$  binary-valued matrix.  $N$  is the length of the output LDPC codeword and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ . The last  $(N - K)$  columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2,  $gf(2)$ .

You can also specify the parity-check matrix as a two-column nonsparse index matrix,  $I$ , that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This parameter accepts numeric data types. When you set this parameter to a sparse binary matrix, this parameter also accepts the `Boolean` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

---

### Note

- When the last  $(N - K)$  columns of the parity-check matrix form a triangular matrix, forward or backward substitution is performed to solve the parity-check equation.
  - When the last  $(N - K)$  columns of the parity-check matrix do not form a triangular matrix, a matrix inversion is performed to solve the parity-check equation. If a large matrix needs to be inverted, initializations or updates take more time.
- 

Example: `dvbs2ldpc(R, 'indices')` configures the index matrix for the DVB-S.2 standard, where  $R$  is the code rate, and `'indices'` specifies the output format of

`dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `Boolean`

## Block Characteristics

<b>Data Types</b>	<code>Boolean</code>   <code>double</code>   <code>integer</code>   <code>single</code>
<b>Multidimensional Signals</b>	<code>no</code>
<b>Variable-Size Signals</b>	<code>no</code>

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

## See Also

### Blocks

LDPC Decoder

### Objects

`comm.LDPCDecoder`

### Functions

`dvbs2ldpc`

**Introduced in R2007a**

# Linear Equalizer

Equalize modulated signals using linear filtering
