Monocular Visual Odometry

Visual odometry is the process of determining the location and orientation of a camera by analyzing a sequence of images. Visual odometry is used in a variety of applications, such as mobile robots, self-driving cars, and unmanned aerial vehicles. This example shows you how to estimate the trajectory of a single calibrated camera from a sequence of images.

Overview

This example shows how to estimate the trajectory of a calibrated camera from a sequence of 2-D views. This example uses images from the New Tsukuba Stereo Dataset created at Tsukuba University's CVLAB. (<https://cvlab.cs.tsukuba.ac.jp>). The dataset consists of synthetic images, generated using computer graphics, and includes the ground truth camera poses.

Without additional information, the trajectory of a monocular camera can only be recovered up to an unknown scale factor. Monocular visual odometry systems used on mobile robots or autonomous vehicles typically obtain the scale factor from another sensor (e.g. wheel odometer or GPS), or from an object of a known size in the scene. This example computes the scale factor from the ground truth.

The example is divided into three parts:

- 1 Estimating the pose of the second view relative to the first view.** Estimate the pose of the second view by estimating the essential matrix and decomposing it into camera location and orientation.
- 2 Bootstrapping estimating camera trajectory using global bundle adjustment.** Eliminate outliers using the epipolar constraint. Find 3D-to-2D correspondences between points triangulated from the previous two views and the current view. Compute the world camera pose for the current view by solving the perspective-n-point (PnP) problem. Estimating the camera poses inevitably results in errors, which accumulate over time. This effect is called *the drift*. To reduce the drift, the example refines all the poses estimated so far using bundle adjustment.
- 3 Estimating remaining camera trajectory using windowed bundle adjustment.** With each new view the time it takes to refine all the poses increases. Windowed bundle adjustment is a way to reduce computation time by only optimizing the last n views, rather than the entire trajectory. Computation time is further reduced by not calling bundle adjustment for every view.

Read Input Image Sequence and Ground Truth

This example uses images from the New Tsukuba Stereo Dataset created at Tsukuba University's CVLAB. If you use these images in your own work or publications, please cite the following papers:

[1] Martin Peris Martorell, Atsuto Maki, Sarah Martull, Yasuhiro Ohkawa, Kazuhiro Fukui, "Towards a Simulation Driven Stereo Vision System". Proceedings of ICPR, pp.1038-1042, 2012.

[2] Sarah Martull, Martin Peris Martorell, Kazuhiro Fukui, "Realistic CG Stereo Image Dataset with Ground Truth Disparity Maps", Proceedings of ICPR workshop TrakMark2012, pp.40-42, 2012.

```
images = imageDatastore(fullfile(toolboxdir('vision'), 'visiondata', ...
    'NewTsukuba'));
```

```
% Load ground truth camera poses.
load(fullfile(toolboxdir('vision'), 'visiondata', ...
    'visualOdometryGroundTruth.mat'));
```

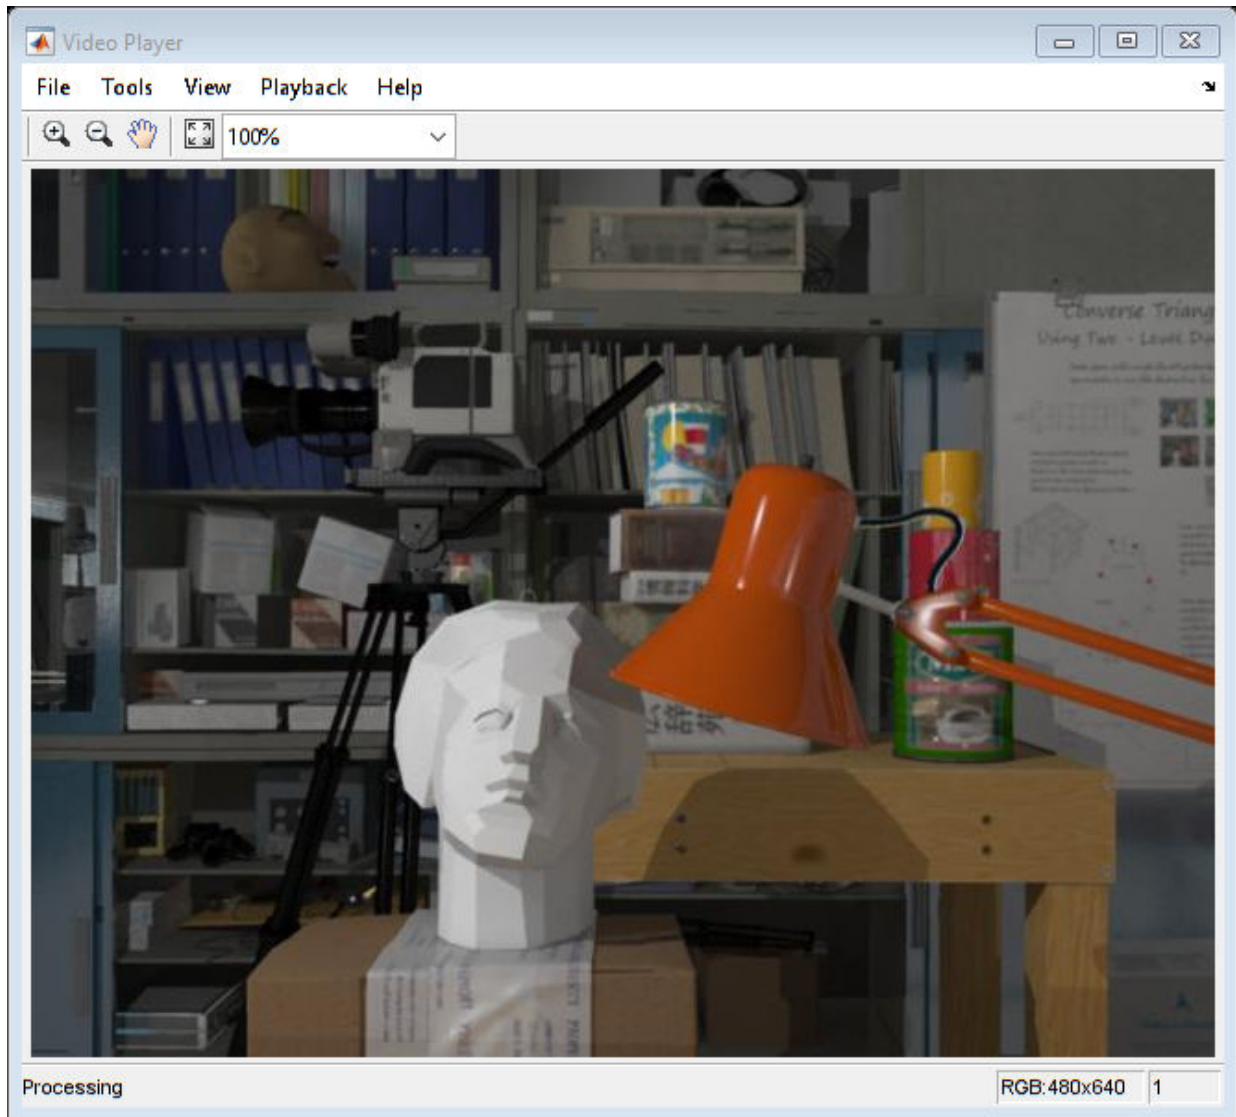

Create a View Set Containing the First View of the Sequence

Use a `viewSet` object to store and manage the image points and the camera pose associated with each view, as well as point matches between pairs of views. Once you populate a `viewSet` object, you can use it to find point tracks across multiple views and retrieve the camera poses to be used by `triangulateMultiview` and `bundleAdjustment` functions.

```
% Create an empty viewSet object to manage the data associated with each view.
vSet = viewSet;
```

```
% Read and display the first image.
Irgb = readimage(images, 1);
player = vision.VideoPlayer('Position', [20, 400, 650, 510]);
step(player, Irgb);
```

1 Featured Examples

```
% Create the camera intrinsics object using camera intrinsics from the  
% New Tsukuba dataset.  
focalLength = [615 615];           % specified in units of pixels
```

```
principalPoint = [320 240];           % in pixels [x, y]
imageSize      = size(Irgb,[1,2]); % in pixels [mrows, ncols]
intrinsics     = cameraIntrinsics(focalLength, principalPoint, imageSize);
```

Convert to gray scale and undistort. In this example, undistortion has no effect, because the images are synthetic, with no lens distortion. However, for real images, undistortion is necessary.

```
prevI = undistortImage(rgb2gray(Irgb), intrinsics);
```

```
% Detect features.
```

```
prevPoints = detectSURFFeatures(prevI, 'MetricThreshold', 500);
```

```
% Select a subset of features, uniformly distributed throughout the image.
```

```
numPoints = 150;
```

```
prevPoints = selectUniform(prevPoints, numPoints, size(prevI));
```

```
% Extract features. Using 'Upright' features improves matching quality if
```

```
% the camera motion involves little or no in-plane rotation.
```

```
prevFeatures = extractFeatures(prevI, prevPoints, 'Upright', true);
```

```
% Add the first view. Place the camera associated with the first view
```

```
% at the origin, oriented along the Z-axis.
```

```
viewId = 1;
```

```
vSet = addView(vSet, viewId, 'Points', prevPoints, 'Orientation', eye(3),...
    'Location', [0 0 0]);
```

Plot Initial Camera Pose

Create two graphical camera objects representing the estimated and the actual camera poses based on ground truth data from the New Tsukuba dataset.

```
% Setup axes.
```

```
figure
```

```
axis([-220, 50, -140, 20, -50, 300]);
```

```
% Set Y-axis to be vertical pointing down.
```

```
view(gca, 3);
```

```
set(gca, 'CameraUpVector', [0, -1, 0]);
```

```
camorbit(gca, -120, 0, 'data', [0, 1, 0]);
```

```
grid on
```

```
xlabel('X (cm)');
```

```
ylabel('Y (cm)');
```

```
zlabel('Z (cm)');
```

```
hold on

% Plot estimated camera pose.
cameraSize = 7;
camEstimated = plotCamera('Size', cameraSize, 'Location', ...
    vSet.Views.Location{1}, 'Orientation', vSet.Views.Orientation{1}, ...
    'Color', 'g', 'Opacity', 0);

% Plot actual camera pose.
camActual = plotCamera('Size', cameraSize, 'Location', ...
    groundTruthPoses.Location{1}, 'Orientation', ...
    groundTruthPoses.Orientation{1}, 'Color', 'b', 'Opacity', 0);

% Initialize camera trajectories.
trajectoryEstimated = plot3(0, 0, 0, 'g-');
trajectoryActual    = plot3(0, 0, 0, 'b-');

legend('Estimated Trajectory', 'Actual Trajectory');
title('Camera Trajectory');
```

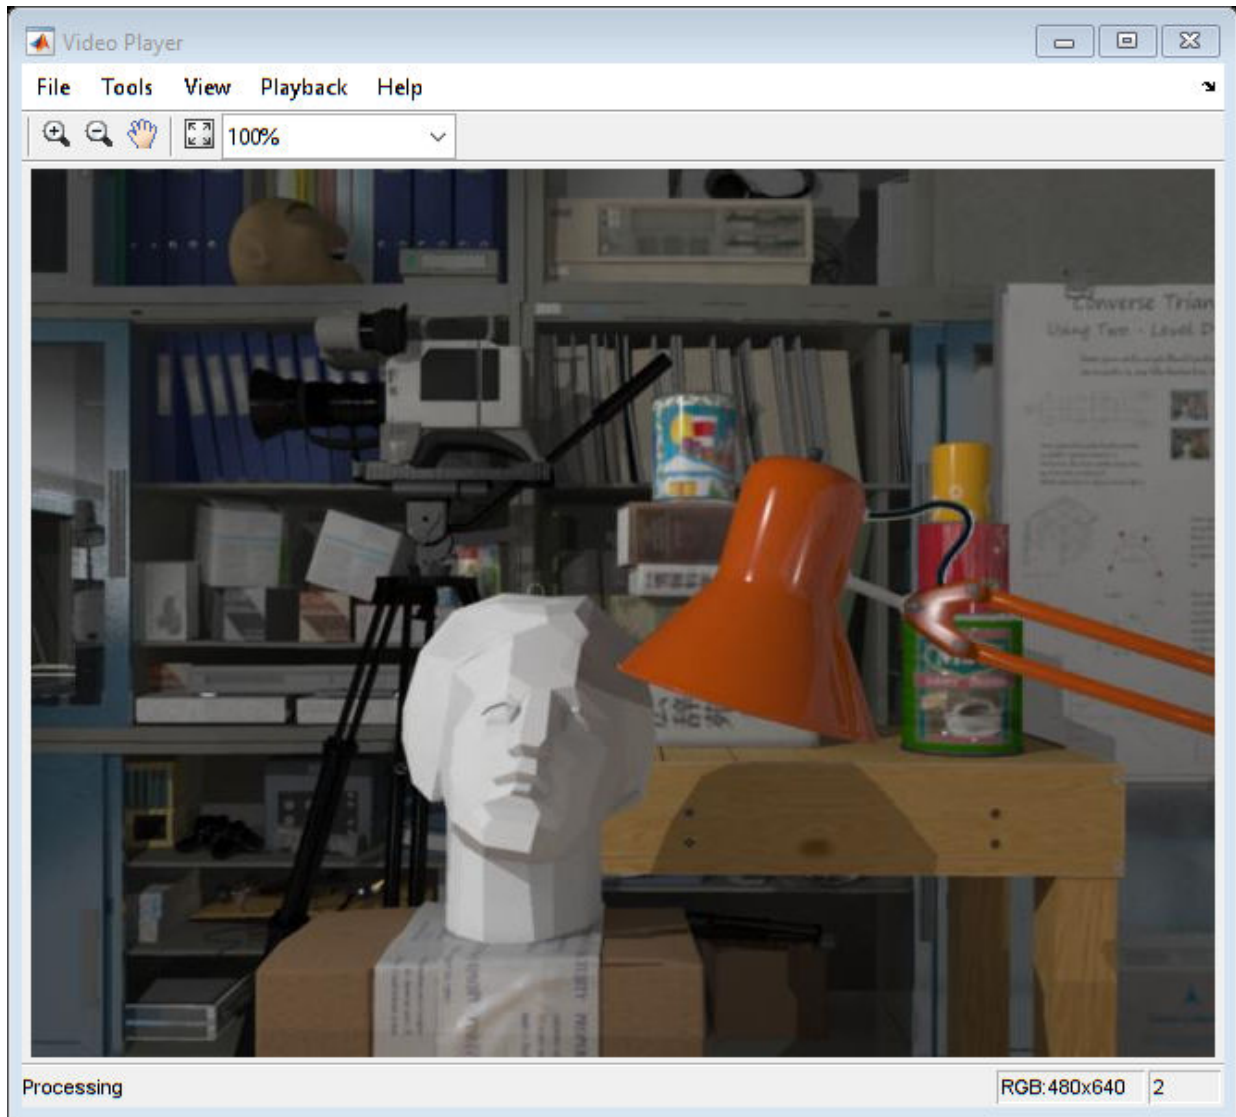

Estimate the Pose of the Second View

Detect and extract features from the second view, and match them to the first view using `helperDetectAndMatchFeatures`. Estimate the pose of the second view relative to the first view using `helperEstimateRelativePose`, and add it to the `viewSet`.

```
% Read and display the image.  
viewId = 2;  
Irgb = readimage(images, viewId);  
step(player, Irgb);
```

1 Featured Examples

```
% Convert to gray scale and undistort.  
I = undistortImage(rgb2gray(Irgb), intrinsics);
```

```

% Match features between the previous and the current image.
[currPoints, currFeatures, indexPairs] = helperDetectAndMatchFeatures(...
    prevFeatures, I);

% Estimate the pose of the current view relative to the previous view.
[orient, loc, inlierIdx] = helperEstimateRelativePose(...
    prevPoints(indexPairs(:,1)), currPoints(indexPairs(:,2)), intrinsics);

% Exclude epipolar outliers.
indexPairs = indexPairs(inlierIdx, :);

% Add the current view to the view set.
vSet = addView(vSet, viewId, 'Points', currPoints, 'Orientation', orient, ...
    'Location', loc);
% Store the point matches between the previous and the current views.
vSet = addConnection(vSet, viewId-1, viewId, 'Matches', indexPairs);

```

The location of the second view relative to the first view can only be recovered up to an unknown scale factor. Compute the scale factor from the ground truth using `helperNormalizeViewSet`, simulating an external sensor, which would be used in a typical monocular visual odometry system.

```
vSet = helperNormalizeViewSet(vSet, groundTruthPoses);
```

Update camera trajectory plots using `helperUpdateCameraPlots` and `helperUpdateCameraTrajectories`.

```

helperUpdateCameraPlots(viewId, camEstimated, camActual, poses(vSet), ...
    groundTruthPoses);
helperUpdateCameraTrajectories(viewId, trajectoryEstimated, trajectoryActual, ...
    poses(vSet), groundTruthPoses);

```

```
prevI = I;  
prevFeatures = currFeatures;  
prevPoints = currPoints;
```

Bootstrap Estimating Camera Trajectory Using Global Bundle Adjustment

Find 3D-to-2D correspondences between world points triangulated from the previous two views and image points from the current view. Use `helperFindEpipolarInliers` to find the matches that satisfy the epipolar constraint, and then use `helperFind3Dto2DCorrespondences` to triangulate 3-D points from the previous two views and find the corresponding 2-D points in the current view.

Compute the world camera pose for the current view by solving the perspective-n-point (PnP) problem using `estimateWorldCameraPose`. For the first 15 views, use global bundle adjustment to refine the entire trajectory. Using global bundle adjustment for a limited number of views bootstraps estimating the rest of the camera trajectory, and it is not prohibitively expensive.

```

for viewId = 3:15
    % Read and display the next image
    Irgb = readimage(images, viewId);
    step(player, Irgb);

    % Convert to gray scale and undistort.
    I = undistortImage(rgb2gray(Irgb), intrinsics);

    % Match points between the previous and the current image.
    [currPoints, currFeatures, indexPairs] = helperDetectAndMatchFeatures(...
        prevFeatures, I);

    % Eliminate outliers from feature matches.
    inlierIdx = helperFindEpipolarInliers(prevPoints(indexPairs(:,1)),...
        currPoints(indexPairs(:, 2)), intrinsics);
    indexPairs = indexPairs(inlierIdx, :);

    % Triangulate points from the previous two views, and find the
    % corresponding points in the current view.
    [worldPoints, imagePoints] = helperFind3Dto2DCorrespondences(vSet,...
        intrinsics, indexPairs, currPoints);

    % Since RANSAC involves a stochastic process, it may sometimes not
    % reach the desired confidence level and exceed maximum number of
    % trials. Disable the warning when that happens since the outcomes are
    % still valid.
    warningstate = warning('off', 'vision:ransac:maxTrialsReached');

    % Estimate the world camera pose for the current view.
    [orient, loc] = estimateWorldCameraPose(imagePoints, worldPoints, ...
        intrinsics, 'Confidence', 99.99, 'MaxReprojectionError', 0.8);

    % Restore the original warning state
    warning(warningstate)

    % Add the current view to the view set.
    vSet = addView(vSet, viewId, 'Points', currPoints, 'Orientation', orient, ...
        'Location', loc);

```

```
% Store the point matches between the previous and the current views.
vSet = addConnection(vSet, viewId-1, viewId, 'Matches', indexPairs);

tracks = findTracks(vSet); % Find point tracks spanning multiple views.

camPoses = poses(vSet); % Get camera poses for all views.

% Triangulate initial locations for the 3-D world points.
xyzPoints = triangulateMultiview(tracks, camPoses, intrinsics);

% Refine camera poses using bundle adjustment.
[~, camPoses] = bundleAdjustment(xyzPoints, tracks, camPoses, ...
    intrinsics, 'PointsUndistorted', true, 'AbsoluteTolerance', 1e-9, ...
    'RelativeTolerance', 1e-9, 'MaxIterations', 300);

vSet = updateView(vSet, camPoses); % Update view set.

% Bundle adjustment can move the entire set of cameras. Normalize the
% view set to place the first camera at the origin looking along the
% Z-axis and adjust the scale to match that of the ground truth.
vSet = helperNormalizeViewSet(vSet, groundTruthPoses);

% Update camera trajectory plot.
helperUpdateCameraPlots(viewId, camEstimated, camActual, poses(vSet), ...
    groundTruthPoses);
helperUpdateCameraTrajectories(viewId, trajectoryEstimated, ...
    trajectoryActual, poses(vSet), groundTruthPoses);

prevI = I;
prevFeatures = currFeatures;
prevPoints = currPoints;
end
```

Estimate Remaining Camera Trajectory Using Windowed Bundle Adjustment

Estimate the remaining camera trajectory by using windowed bundle adjustment to only refine the last 15 views, in order to limit the amount of computation. Furthermore, bundle adjustment does not have to be called for every view, because `estimateWorldCameraPose` computes the pose in the same units as the 3-D points. This section calls bundle adjustment for every 7th view. The window size and the frequency of calling bundle adjustment have been chosen experimentally.

```
for viewId = 16:numel(images.Files)
    % Read and display the next image
    Irgb = readimage(images, viewId);
    step(player, Irgb);
```

```

% Convert to gray scale and undistort.
I = undistortImage(rgb2gray(Irgb), intrinsics);

% Match points between the previous and the current image.
[currPoints, currFeatures, indexPairs] = helperDetectAndMatchFeatures(...
    prevFeatures, I);

% Triangulate points from the previous two views, and find the
% corresponding points in the current view.
[worldPoints, imagePoints] = helperFind3Dto2DCorrespondences(vSet, ...
    intrinsics, indexPairs, currPoints);

% Since RANSAC involves a stochastic process, it may sometimes not
% reach the desired confidence level and exceed maximum number of
% trials. Disable the warning when that happens since the outcomes are
% still valid.
warningstate = warning('off', 'vision:ransac:maxTrialsReached');

% Estimate the world camera pose for the current view.
[orient, loc] = estimateWorldCameraPose(imagePoints, worldPoints, ...
    intrinsics, 'MaxNumTrials', 5000, 'Confidence', 99.99, ...
    'MaxReprojectionError', 0.8);

% Restore the original warning state
warning(warningstate)

% Add the current view and connection to the view set.
vSet = addView(vSet, viewId, 'Points', currPoints, 'Orientation', orient, ...
    'Location', loc);
vSet = addConnection(vSet, viewId-1, viewId, 'Matches', indexPairs);

% Refine estimated camera poses using windowed bundle adjustment. Run
% the optimization every 7th view.
if mod(viewId, 7) == 0
    % Find point tracks in the last 15 views and triangulate.
    windowSize = 15;
    startFrame = max(1, viewId - windowSize);
    tracks = findTracks(vSet, startFrame:viewId);
    camPoses = poses(vSet, startFrame:viewId);
    [xyzPoints, reprojErrors] = triangulateMultiview(tracks, camPoses, ...
        intrinsics);

    % Hold the first two poses fixed, to keep the same scale.
    fixedIds = [startFrame, startFrame+1];

```

```
% Exclude points and tracks with high reprojection errors.
idx = reprojErrors < 2;

[~, camPoses] = bundleAdjustment(xyzPoints(idx, :), tracks(idx), ...
    camPoses, intrinsics, 'FixedViewIDs', fixedIds, ...
    'PointsUndistorted', true, 'AbsoluteTolerance', 1e-9, ...
    'RelativeTolerance', 1e-9, 'MaxIterations', 300);

vSet = updateView(vSet, camPoses); % Update view set.
end

% Update camera trajectory plot.
helperUpdateCameraPlots(viewId, camEstimated, camActual, poses(vSet), ...
    groundTruthPoses);
helperUpdateCameraTrajectories(viewId, trajectoryEstimated, ...
    trajectoryActual, poses(vSet), groundTruthPoses);

prevI = I;
prevFeatures = currFeatures;
prevPoints = currPoints;
end
```

hold off

Summary

This example showed how to estimate the trajectory of a calibrated monocular camera from a sequence of views. Notice that the estimated trajectory does not exactly match the ground truth. Despite the non-linear refinement of camera poses, errors in camera pose estimation accumulate, resulting in drift. In visual odometry systems this problem is typically addressed by fusing information from multiple sensors, and by performing loop closure.

Object Detection Using YOLO v2 Deep Learning

This example shows how to train a you only look once (YOLO) v2 object detector.

Deep learning is a powerful machine learning technique that you can use to train robust object detectors. Several techniques for object detection exist, including Faster R-CNN and you only look once (YOLO) v2. This example trains a YOLO v2 vehicle detector using the `trainYOLOv2ObjectDetector` function. For more information, see “Object Detection using Deep Learning”.

Download Pretrained Detector

Download a pretrained detector to avoid having to wait for training to complete. If you want to train the detector, set the `doTraining` variable to true.

```
doTraining = false;
if ~doTraining && ~exist('yolov2ResNet50VehicleExample_19b.mat','file')
    disp('Downloading pretrained detector (98 MB)...');
    pretrainedURL = 'https://www.mathworks.com/supportfiles/vision/data/yolov2ResNet50';
    websave('yolov2ResNet50VehicleExample_19b.mat',pretrainedURL);
end
```

Load Dataset

This example uses a small vehicle dataset that contains 295 images. Each image contains one or two labeled instances of a vehicle. A small dataset is useful for exploring the YOLO v2 training procedure, but in practice, more labeled images are needed to train a robust detector. Unzip the vehicle images and load the vehicle ground truth data.

```
unzip('vehicleDatasetImages.zip');
data = load('vehicleDatasetGroundTruth.mat');
vehicleDataset = data.vehicleDataset;
```

The vehicle data is stored in a two-column table, where the first column contains the image file paths and the second column contains the vehicle bounding boxes.

```
% Display first few rows of the data set.
vehicleDataset(1:4,:)
```

```
ans=4x2 table
      imageFilename      vehicle
```

```
{'vehicleImages/image_00001.jpg'} {1x4 double}
{'vehicleImages/image_00002.jpg'} {1x4 double}
{'vehicleImages/image_00003.jpg'} {1x4 double}
{'vehicleImages/image_00004.jpg'} {1x4 double}
```

% Add the fullpath to the local vehicle data folder.

```
vehicleDataset.imageFilename = fullfile(pwd,vehicleDataset.imageFilename);
```

Split the data set into a training set for training the detector, and a test set for evaluating the detector. Select 60% of the data for training. Use the rest for evaluation.

```
rng(0);
shuffledIndices = randperm(height(vehicleDataset));
idx = floor(0.6 * length(shuffledIndices) );
trainingDataTbl = vehicleDataset(shuffledIndices(1:idx),:);
testDataTbl = vehicleDataset(shuffledIndices(idx+1:end),:);
```

Use `imageDatastore` and `boxLabelDatastore` to create datastores for loading the image and label data during training and evaluation.

```
imdsTrain = imageDatastore(trainingDataTbl{:, 'imageFilename'});
bldsTrain = boxLabelDatastore(trainingDataTbl(:, 'vehicle'));

imdsTest = imageDatastore(testDataTbl{:, 'imageFilename'});
bldsTest = boxLabelDatastore(testDataTbl(:, 'vehicle'));
```

Combine image and box label datastores.

```
trainingData = combine(imdsTrain,bldsTrain);
testData = combine(imdsTest,bldsTest);
```

Display one of the training images and box labels.

```
data = read(trainingData);
I = data{1};
bbox = data{2};
annotatedImage = insertShape(I, 'Rectangle', bbox);
annotatedImage = imresize(annotatedImage,2);
figure
imshow(annotatedImage)
```

Create a YOLO v2 Object Detection Network

A YOLO v2 object detection network is composed of two subnetworks. A feature extraction network followed by a detection network. The feature extraction network is typically a pretrained CNN (for details, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox)). This example uses ResNet-50 for feature extraction. You can also use other pretrained networks such as MobileNet v2 or ResNet-18 can also be used depending on application requirements. The detection sub-network is a small CNN compared to the feature extraction network and is composed of a few convolutional layers and layers specific for YOLO v2.

Use the `yoloV2Layers` function to create a YOLO v2 object detection network automatically given a pretrained ResNet-50 feature extraction network. `yoloV2Layers` requires you to specify several inputs that parameterize a YOLO v2 network:

- Network input size
- Anchor boxes
- Feature extraction network

First, specify the network input size and the number of classes. When choosing the network input size, consider the minimum size required by the network itself, the size of the training images, and the computational cost incurred by processing data at the selected size. When feasible, choose a network input size that is close to the size of the training image and larger than the input size required for the network. To reduce the computational cost of running the example, specify a network input size of [224 224 3], which is the minimum size required to run the network.

```
inputSize = [224 224 3];
```

Define the number of object classes to detect.

```
numClasses = width(vehicleDataset)-1;
```

Note that the training images used in this example are bigger than 224-by-224 and vary in size, so you must resize the images in a preprocessing step prior to training.

Next, use `estimateAnchorBoxes` to estimate anchor boxes based on the size of objects in the training data. To account for the resizing of the images prior to training, resize the training data for estimating anchor boxes. Use `transform` to preprocess the training data, then define the number of anchor boxes and estimate the anchor boxes. Resize the training data to the input image size of the network using the supporting function `preprocessData`.

```
trainingDataForEstimation = transform(trainingData,@(data)preprocessData(data,inputSize));  
numAnchors = 7;
```

```
[anchorBoxes, meanIoU] = estimateAnchorBoxes(trainingDataForEstimation, numAnchors)
```

```
anchorBoxes = 7x2
```

```
145 122  
81 76  
160 132  
41 34  
63 62  
103 97  
33 23
```

```
meanIoU = 0.8630
```

For more information on choosing anchor boxes, see “Estimate Anchor Boxes From Training Data” on page 1-33 (Computer Vision Toolbox™) and “Anchor Boxes for Object Detection” on page 7-12.

Now, use `resnet50` to load a pretrained ResNet-50 model.

```
featureExtractionNetwork = resnet50;
```

Select `'activation_40_relu'` as the feature extraction layer to replace the layers after `'activation_40_relu'` with the detection subnetwork. This feature extraction layer outputs feature maps that are downsampled by a factor of 16. This amount of downsampling is a good trade-off between spatial resolution and the strength of the extracted features, as features extracted further down the network encode stronger image features at the cost of spatial resolution. Choosing the optimal feature extraction layer requires empirical analysis.

```
featureLayer = 'activation_40_relu';
```

Create the YOLO v2 object detection network.

```
lgraph = yolov2Layers(inputSize,numClasses,anchorBoxes,featureExtractionNetwork,featureLayer);
```

You can visualize the network using `analyzeNetwork` or Deep Network Designer from Deep Learning Toolbox™.

If more control is required over the YOLO v2 network architecture, use Deep Network Designer to design the YOLO v2 detection network manually. For more information, see “Design a YOLO v2 Detection Network” on page 7-21.

Data Augmentation

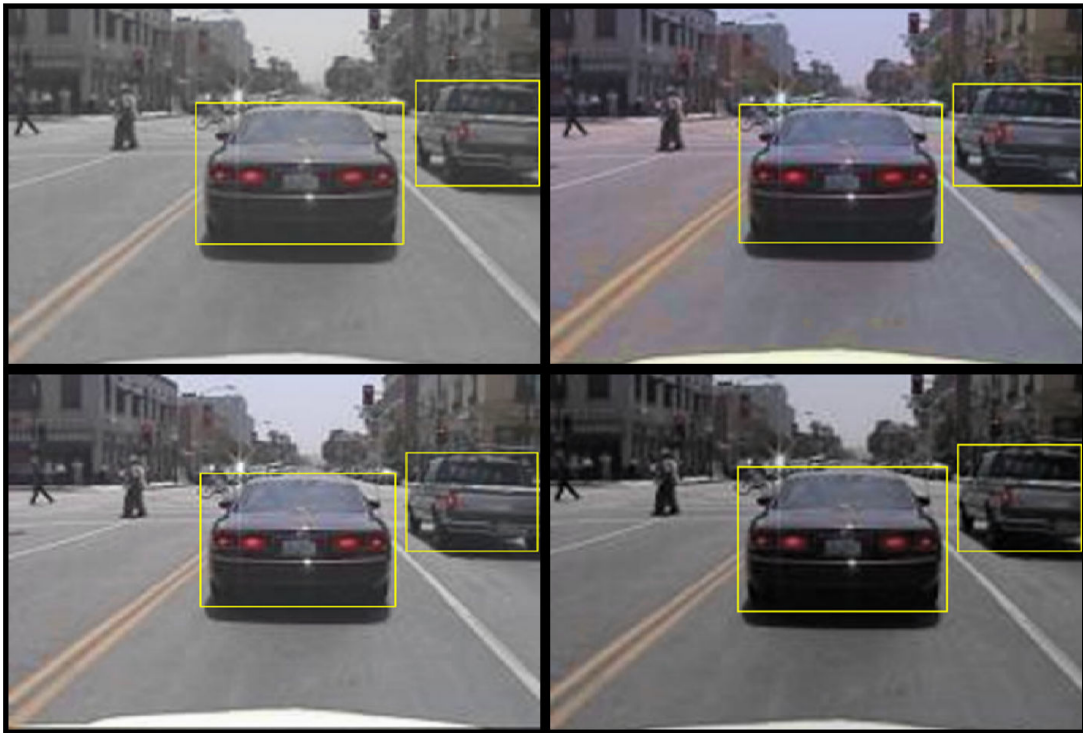

Data augmentation is used to improve network accuracy by randomly transforming the original data during training. By using data augmentation you can add more variety to the training data without actually having to increase the number of labeled training samples.

Use `transform` to augment the training data by randomly flipping the image and associated box labels horizontally. Note that data augmentation is not applied to the test data. Ideally, test data should be representative of the original data and is left unmodified for unbiased evaluation.

```
augmentedTrainingData = transform(trainingData,@augmentData);
```

Read the same image multiple times and display the augmented training data.

```
% Visualize the augmented images.
augmentedData = cell(4,1);
for k = 1:4
    data = read(augmentedTrainingData);
    augmentedData{k} = insertShape(data{1}, 'Rectangle', data{2});
    reset(augmentedTrainingData);
end
figure
montage(augmentedData, 'BorderSize', 10)
```

Preprocess Training Data

Preprocess the augmented training data to prepare for training.

```
preprocessedTrainingData = transform(augmentedTrainingData,@(data)preprocessData(data, ...
```

Read the preprocessed training data.

```
data = read(preprocessedTrainingData);
```

Display the image and bounding boxes.

```
I = data{1};  
bbox = data{2};  
annotatedImage = insertShape(I, 'Rectangle',bbox);  
annotatedImage = imresize(annotatedImage,2);  
figure  
imshow(annotatedImage)
```

Train YOLO v2 Object Detector

Use `trainingOptions` to specify network training options. Set `'CheckpointPath'` to a temporary location. This enables the saving of partially trained detectors during the training process. If training is interrupted, such as by a power outage or system failure, you can resume training from the saved checkpoint.

```
options = trainingOptions('sgdm', ...
    'MiniBatchSize', 16, ...
    'InitialLearnRate', 1e-3, ...
    'MaxEpochs', 20, ...
    'CheckpointPath', tempdir, ...
    'Shuffle', 'never');
```

Use `trainYOLOv2ObjectDetector` function to train YOLO v2 object detector if `doTraining` is true. Otherwise, load the pretrained network.

```
if doTraining
    % Train the YOLO v2 detector.
    [detector,info] = trainYOLOv2ObjectDetector(preprocessedTrainingData,lgraph,options)
else
    % Load pretrained detector for the example.
    pretrained = load('yolov2ResNet50VehicleExample_19b.mat');
    detector = pretrained.detector;
end
```

This example was verified on an NVIDIA™ Titan X GPU with 12 GB of memory. If your GPU has less memory, you may run out of memory. If this happens, lower the `'MiniBatchSize'` using the `trainingOptions` function. Training this network took approximately 7 minutes using this setup. Training time varies depending on the hardware you use.

As a quick test, run the detector on one test image. Make sure you resize the image to the same size as the training images.

```
I = imread(testDataTbl.imageFilename{1});
I = imresize(I,inputSize(1:2));
[bboxes,scores] = detect(detector,I);
```

Display the results.

```
I = insertObjectAnnotation(I, 'rectangle', bboxes, scores);
figure
imshow(I)
```

Evaluate Detector Using Test Set

Evaluate the trained object detector on a large set of images to measure the performance. Computer Vision Toolbox™ provides object detector evaluation functions to measure common metrics such as average precision (`evaluateDetectionPrecision`) and log-average miss rates (`evaluateDetectionMissRate`). For this example, use the average precision metric to evaluate performance. The average precision provides a single number that incorporates the ability of the detector to make correct classifications (precision) and the ability of the detector to find all relevant objects (recall).

Apply the same preprocessing transform to the test data as for the training data. Note that data augmentation is not applied to the test data. Test data should be representative of the original data and be left unmodified for unbiased evaluation.

```
preprocessedTestData = transform(testData,@(data)preprocessData(data,inputSize));
```

Run the detector on all the test images.

```
detectionResults = detect(detector, preprocessedTestData);
```

Evaluate the object detector using average precision metric.

```
[ap,recall,precision] = evaluateDetectionPrecision(detectionResults, preprocessedTestD
```

The precision/recall (PR) curve highlights how precise a detector is at varying levels of recall. The ideal precision is 1 at all recall levels. The use of more data can help improve the average precision but might require more training time. Plot the PR curve.

```
figure
plot(recall,precision)
xlabel('Recall')
ylabel('Precision')
grid on
title(sprintf('Average Precision = %.2f',ap))
```

Code Generation

Once the detector is trained and evaluated, you can generate code for the `yolov2objectDetector` using GPU Coder™. See “Code Generation for Object Detection by Using YOLO v2” (GPU Coder) example for more details.

Supporting Functions

```
function B = augmentData(A)
% Apply random horizontal flipping, and random X/Y scaling. Boxes that get
% scaled outside the bounds are clipped if the overlap is above 0.25. Also,
% jitter image color.
B = cell(size(A));

I = A{1};
sz = size(I);
if numel(sz)==3 && sz(3) == 3
    I = jitterColorHSV(I,...
        'Contrast',0.2,...
        'Hue',0,...
        'Saturation',0.1,...
        'Brightness',0.2);
end

% Randomly flip and scale image.
tform = randomAffine2d('XReflection',true,'Scale',[1 1.1]);
rout = affineOutputView(sz,tform,'BoundsStyle','CenterOutput');
B{1} = imwarp(I,tform,'OutputView',rout);

% Apply same transform to boxes.
[B{2},indices] = bboxwarp(A{2},tform,rout,'OverlapThreshold',0.25);
B{3} = A{3}(indices);

% Return original data only when all boxes are removed by warping.
if isempty(indices)
    B = A;
end
end

function data = preprocessData(data,targetSize)
% Resize image and bounding boxes to the targetSize.
scale = targetSize(1:2)./size(data{1},[1 2]);
data{1} = imresize(data{1},targetSize(1:2));
```

```
data{2} = bboxresize(data{2},scale);  
end
```

Estimate Anchor Boxes From Training Data

Anchor boxes are important parameters of deep learning object detectors such as Faster R-CNN and YOLO v2. The shape, scale, and number of anchor boxes impact the efficiency and accuracy of the detectors.

For more information, see “Anchor Boxes for Object Detection” on page 7-12.

Load Training Data

Load the vehicle dataset, which contains 295 images and associated box labels.

```
data = load('vehicleTrainingData.mat');  
vehicleDataset = data.vehicleTrainingData;
```

Add the full path to the local vehicle data folder.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata');  
vehicleDataset.imageFilename = fullfile(dataDir,vehicleDataset.imageFilename);
```

Display the data set summary.

```
summary(vehicleDataset)
```

Variables:

```
imageFilename: 295×1 cell array of character vectors  
vehicle: 295×1 cell
```

Visualize Ground Truth Box Distribution

Visualize the labeled boxes to better understand the range of object sizes present in the data set.

Combine all the ground truth boxes into one array.

```
allBoxes = vertcat(vehicleDataset.vehicle{:});
```

Plot the box area versus the box aspect ratio.

```
aspectRatio = allBoxes(:,3) ./ allBoxes(:,4);  
area = prod(allBoxes(:,3:4),2);
```

```
figure
scatter(area,aspectRatio)
xlabel("Box Area")
ylabel("Aspect Ratio (width/height)");
title("Box Area vs. Aspect Ratio")
```

The plot shows a few groups of objects that are of similar size and shape, However, because the groups are spread out, manually choosing anchor boxes is difficult. A better way to estimate anchor boxes is to use a clustering algorithm that can group similar boxes together using a meaningful metric.

Estimate Anchor Boxes

Estimate anchor boxes from training data using the `estimateAnchorBoxes` function, which uses the intersection-over-union (IoU) distance metric.

A distance metric based on IoU is invariant to the size of boxes, unlike the Euclidean distance metric, which produces larger errors as the box sizes increase [1]. In addition, using an IoU distance metric leads to boxes of similar aspect ratios and sizes being clustered together, which results in anchor box estimates that fit the data.

Create a `boxLabelDatastore` using the ground truth boxes in the vehicle data set. If the preprocessing step for training an object detector involves resizing of the images, use `transform` and `bboxresize` to resize the bounding boxes in the `boxLabelDatastore` before estimating the anchor boxes.

```
trainingData = boxLabelDatastore(vehicleDataset(:,2:end));
```

Select the number of anchors and estimate the anchor boxes using `estimateAnchorBoxes` function.

```
numAnchors = ;
[anchorBoxes,meanIoU] = estimateAnchorBoxes(trainingData,numAnchors);
anchorBoxes
```

```
anchorBoxes = 5×2
```

```
    21    27
    87   116
    67    92
    43    61
    86   105
```

Choosing the number of anchors is another training hyperparameter that requires careful selection using empirical analysis. One quality measure for judging the estimated anchor boxes is the mean IoU of the boxes in each cluster. The `estimateAnchorBoxes` function uses a k -means clustering algorithm with the IoU distance metric to calculate the overlap using the equation, `1 - bboxOverlapRatio(allBoxes,boxInCluster)`.

```
meanIoU
```

```
meanIoU = 0.8411
```

The mean IoU value greater than 0.5 ensures that the anchor boxes overlap well with the boxes in the training data. Increasing the number of anchors can improve the mean IoU

measure. However, using more anchor boxes in an object detector can also increase the computation cost and lead to overfitting, which results in poor detector performance.

Sweep over a range of values and plot the mean IoU versus number of anchor boxes to measure the trade-off between number of anchors and mean IoU.

```
maxNumAnchors = 15;
meanIoU = zeros([maxNumAnchors,1]);
anchorBoxes = cell(maxNumAnchors, 1);
for k = 1:maxNumAnchors
    % Estimate anchors and mean IoU.
    [anchorBoxes{k},meanIoU(k)] = estimateAnchorBoxes(trainingData,k);
end

figure
plot(1:maxNumAnchors,meanIoU,'-o')
ylabel("Mean IoU")
xlabel("Number of Anchors")
title("Number of Anchors vs. Mean IoU")
```

Using two anchor boxes results in a mean IoU value greater than 0.65, and using more than 7 anchor boxes yields only marginal improvement in mean IoU value. Given these results, the next step is to train and evaluate multiple object detectors using values between 2 and 6. This empirical analysis helps determine the number of anchor boxes required to satisfy application performance requirements, such as detection speed, or accuracy.

Code Generation for Object Detection by Using YOLO v2

This example shows how to generate CUDA® MEX for a you only look once (YOLO) v2 object detector. A YOLO v2 object detection network is composed of two subnetworks. A feature extraction network followed by a detection network. This example generates code for the network trained in the *Object Detection Using YOLO v2* example from Computer Vision Toolbox™. For more information, see “Object Detection Using YOLO v2 Deep Learning” on page 1-68.

Prerequisites

- CUDA enabled NVIDIA® GPU with compute capability 3.2 or higher.
- NVIDIA CUDA toolkit and driver.
- NVIDIA cuDNN library.
- Environment variables for the compilers and libraries. For information on the supported versions of the compilers and libraries, see “Third-party Products” (GPU Coder). For setting up the environment variables, see “Setting Up the Prerequisite Products” (GPU Coder).
- GPU Coder Interface for Deep Learning Libraries support package. To install this support package, use the Add-On Explorer.

Verify GPU Environment

Use the `coder.checkGpuInstall` function to verify that the compilers and libraries necessary for running this example are set up correctly.

```
envCfg = coder.gpuEnvConfig('host');  
envCfg.DeepLibTarget = 'cudnn';  
envCfg.DeepCodegen = 1;  
envCfg.Quiet = 1;  
coder.checkGpuInstall(envCfg);
```

Get Pretrained DAGNetwork

```
net = getYOLOv2();
```

The DAG network contains 150 layers including convolution, ReLU, and batch normalization layers and the YOLO v2 transform and YOLO v2 output layers. To display an interactive visualization of the deep learning network architecture, use the `analyzeNetwork` function.

```
analyzeNetwork(net);
```

The yolov2_detect Entry-Point Function

The `yolov2_detect.m` entry-point function takes an image input and runs the detector on the image using the deep learning network saved in the `yolov2ResNet50VehicleExample.mat` file. The function loads the network object from the `yolov2ResNet50VehicleExample.mat` file into a persistent variable `mynet` and reuses the persistent object on subsequent detection calls.

```
type('yolov2_detect.m')

function outImg = yolov2_detect(in)

% Copyright 2018-2019 The MathWorks, Inc.

persistent yolov2obj;

if isempty(yolov2obj)
    yolov2obj = coder.loadDeepLearningNetwork('yolov2ResNet50VehicleExample.mat');
end

% pass in input
[bboxes,~,labels] = yolov2obj.detect(in,'Threshold',0.5);

% convert categorical labels to cell array of character vectors for MATLAB
% execution
if coder.target('MATLAB')
    labels = cellstr(labels);
end

% Annotate detections in the image.
outImg = insertObjectAnnotation(in,'rectangle',bboxes,labels);
```

Run MEX Code Generation

To generate CUDA code for the `yolov2_detect.m` entry-point function, create a GPU code configuration object for a MEX target and set the target language to C++. Use the `coder.DeepLearningConfig` function to create a CuDNN deep learning configuration object and assign it to the `DeepLearningConfig` property of the GPU code configuration object. Run the `codegen` command specifying an input size of `[224,224,3]`. This value corresponds to the input layer size of YOLOv2.

```
cfg = coder.gpuConfig('mex');
cfg.TargetLang = 'C++';
```

```
cfg.DeepLearningConfig = coder.DeepLearningConfig('cudnn');  
codegen -config cfg yolov2_detect -args {ones(224,224,3,'uint8')} -report
```

Code generation successful: To view the report, open('codegen/mex/yolov2_detect/html/re

Run Generated MEX

Set up the video file reader and read the input video. Create a video player to display the video and the output detections.

```
videoFile = 'highway_lanechange.mp4';  
videoFreader = vision.VideoFileReader(videoFile,'VideoOutputDataType','uint8');  
depVideoPlayer = vision.DeployableVideoPlayer('Size','Custom','CustomSize',[640 480]);
```

Read the video input frame-by-frame and detect the vehicles in the video using the detector.

```
cont = ~isDone(videoFreader);  
while cont  
    I = step(videoFreader);  
    in = imresize(I,[224,224]);  
    out = yolov2_detect_mex(in);  
    step(depVideoPlayer, out);  
    cont = ~isDone(videoFreader) && isOpen(depVideoPlayer); % Exit the loop if the vid  
end
```

Track Vehicles Using Lidar: From Point Cloud to Track List

This example shows you how to track vehicles using measurements from a lidar sensor mounted on top of an ego vehicle. Lidar sensors report measurements as a point cloud. The example illustrates the workflow in MATLAB® for processing the point cloud and tracking the objects. For a Simulink® version of the example, refer to “Track Vehicles Using Lidar Data in Simulink” (Sensor Fusion and Tracking Toolbox). The lidar data used in this example is recorded from a highway driving scenario. In this example, you use the recorded data to track vehicles with a joint probabilistic data association (JPDA) tracker and an interacting multiple model (IMM) approach.

3-D Bounding Box Detector Model

Due to high resolution capabilities of the lidar sensor, each scan from the sensor contains a large number of points, commonly known as a point cloud. This raw data must be preprocessed to extract objects of interest, such as cars, cyclists, and pedestrians. For more details about segmentation of lidar data into objects such as the ground plane and obstacles, refer to the “Ground Plane and Obstacle Detection Using Lidar” (Automated Driving Toolbox) example. In this example, the point clouds belonging to obstacles are further classified into clusters using the `pcsegdist` function, and each cluster is converted to a bounding box detection with the following format:

$$[x \ y \ z \ l \ w \ h]$$

x , y and z refer to the x-, y- and z-positions of the bounding box and l , w and h refer to its length, width, and height, respectively.

The bounding box is fit onto each cluster by using minimum and maximum of coordinates of points in each dimension. The detector is implemented by a supporting class `HelperBoundingBoxDetector`, which wraps around point cloud segmentation and clustering functionalities. An object of this class accepts a `pointCloud` input and returns a list of `objectDetection` objects with bounding box measurements.

The diagram shows the processes involved in the bounding box detector model and the Computer Vision Toolbox™ functions used to implement each process. It also shows the properties of the supporting class that control each process.

```

% Load data if unavailable. The lidar data is stored as a cell array of
% pointCloud objects.

```

```

if ~exist('lidarData','var')
    % Specify initial and final time for simulation.
    initTime = 0;
    finalTime = 35;
    [lidarData, imageData] = loadLidarAndImageData(initTime,finalTime);
end

```

```

% Set random seed to generate reproducible results.
S = rng(2018);

```

```

% A bounding box detector model.

    'GroundMaxDistance',0.3);      % maximum distance of ground points from ground

```

Target State and Sensor Measurement Model

The first step in tracking an object is defining its state, and the models that define the transition of state and the corresponding measurement. These two sets of equations are collectively known as the state-space model of the target. To model the state of vehicles for tracking using lidar, this example uses a cuboid model with following convention:

$$x = [x_{kin} \ \theta \ l \ w \ h]$$

x_{kin} refers to the portion of the state that controls the kinematics of the motion center, and θ is the yaw angle. The length, width, height of the cuboid are modeled as constants, whose estimates evolve in time during correction stages of the filter.

In this example, you use two state-space models: a constant velocity (cv) cuboid model and a constant turn-rate (ct) cuboid model. These models differ in the way they define the kinematic part of the state, as described below:

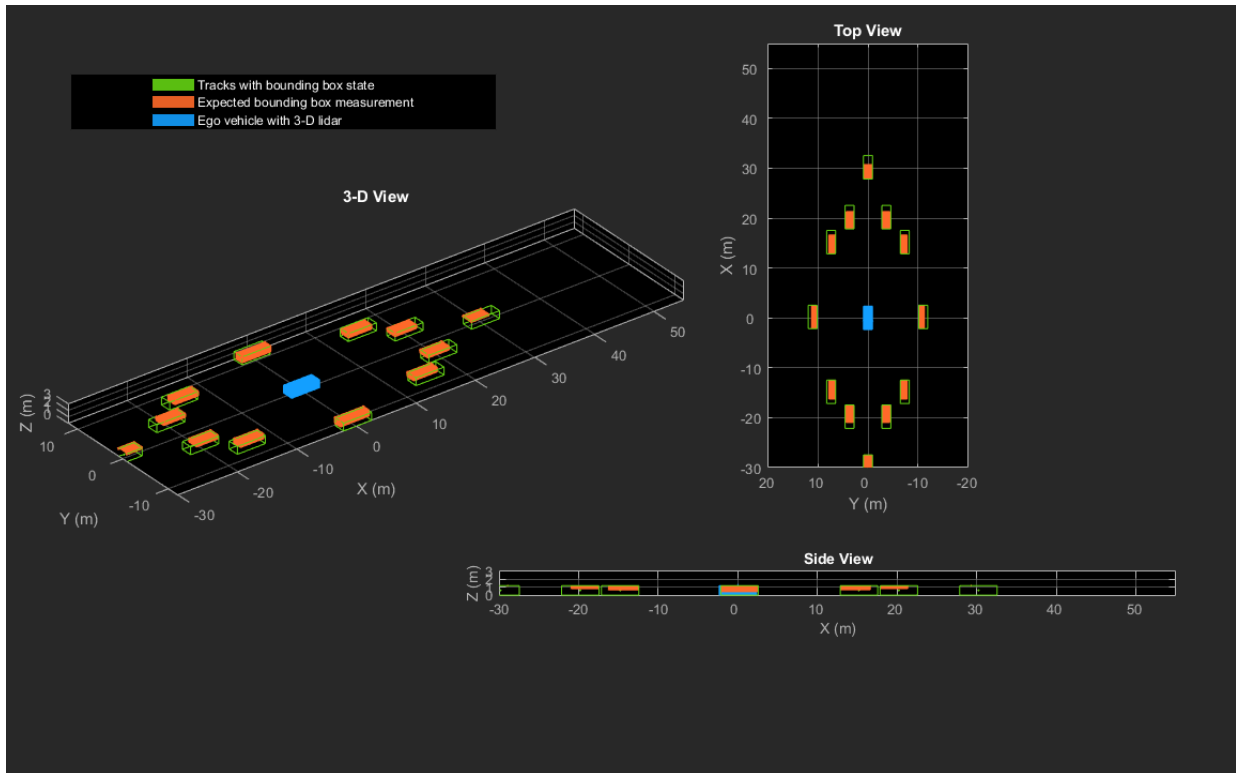

$$x_{cv} = [x \dot{x} y \dot{y} z \dot{z} \theta l w h]$$

$$x_{ct} = [x \dot{x} y \dot{y} \dot{\theta} z \dot{z} \theta l w h]$$

For information about their state transition, refer to the `helperConstvelCuboid` and `helperConstturnCuboid` functions used in this example.

The `helperCvmeasCuboid` and `helperCtmeasCuboid` measurement models describe how the sensor perceives the constant velocity and constant turn-rate states respectively, and they return bounding box measurements. Because the state contains information about size of the target, the measurement model includes the effect of center-point offset and bounding box shrinkage, as perceived by the sensor, due to effects like self-occlusion [1]. This effect is modeled by a shrinkage factor that is directly proportional to the distance from the tracked vehicle to the sensor.

The image below demonstrates the measurement model operating at different state-space samples. Notice the modeled effects of bounding box shrinkage and center-point offset as the objects move around the ego vehicle.

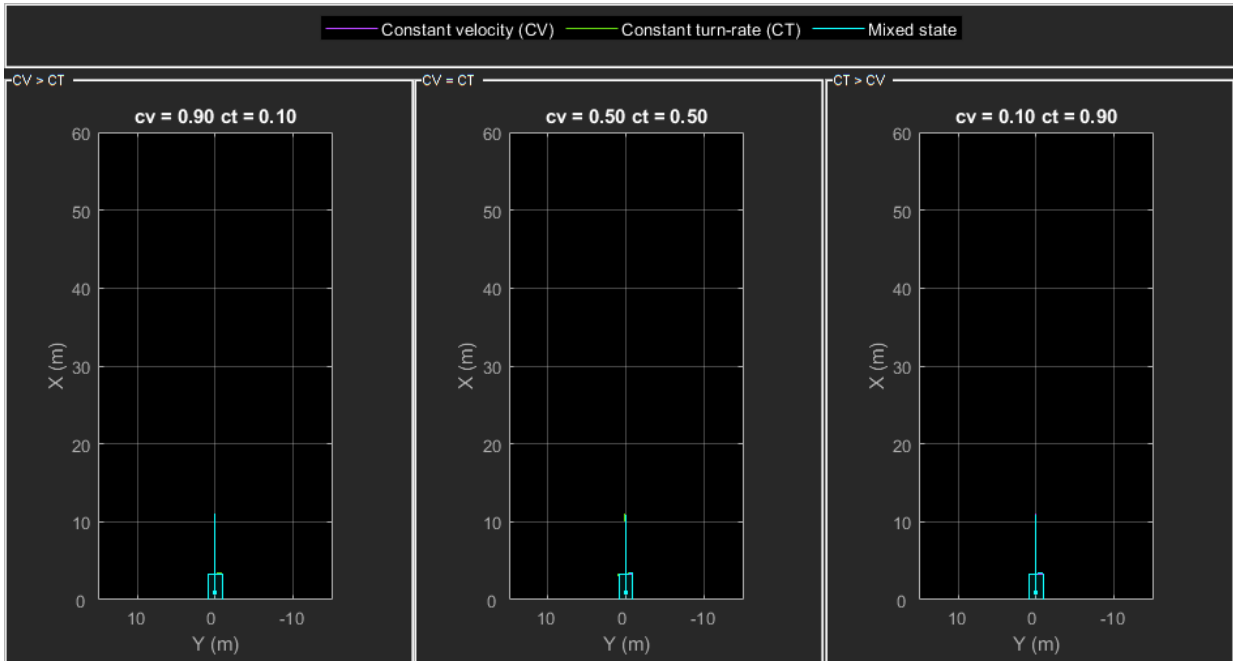

Set Up Tracker and Visualization

The image below shows the complete workflow to obtain a list of tracks from a pointCloud input.

Now, set up the tracker and the visualization used in the example.

A joint probabilistic data association tracker (`trackerJPDA`) coupled with an IMM filter (`trackingIMM`) is used to track objects in this example. The IMM filter uses a constant velocity and constant turn-rate model and is initialized using the supporting function, `helperInitIMMFilter`, included with this example. The IMM approach helps a track to switch between motion models and thus achieve good estimation accuracy during events like maneuvering or lane changing. The animation below shows the effect of mixing the constant velocity and constant turn-rate model during prediction stages of the IMM filter.

The IMM filter updates the probability of each model when it is corrected with detections from the object. The animation below shows the estimated trajectory of a vehicle during a lane change event and the corresponding estimated probabilities of each model.

Set the `HasDetectableTrackIDsInput` property of the tracker as `true`, which enables you to specify a state-dependent probability of detection. The detection probability of a

track is calculated by the helperCalcDetectability function, listed at the end of this example.

```
assignmentGate = [10 100]; % Assignment threshold;
confThreshold = [7 10];   % Confirmation threshold for history logic
delThreshold = [8 10];    % Deletion threshold for history logic
Kc = 1e-5;                % False-alarm rate per unit volume

% IMM filter initialization function
filterInitFcn = @helperInitIMMFilter;

% A joint probabilistic data association tracker with IMM filter
tracker = trackerJPDA('FilterInitializationFcn',filterInitFcn,...
    'TrackLogic','History',...
    'AssignmentThreshold',assignmentGate,...
    'ClutterDensity',Kc,...
    'ConfirmationThreshold',confThreshold,...
    'DeletionThreshold',delThreshold,...
    'HasDetectableTrackIDsInput',true,...
    'InitializationThreshold',0);
```

The visualization is divided into these main categories:

- 1 Lidar Preprocessing and Tracking - This display shows the raw point cloud, segmented ground, and obstacles. It also shows the resulting detections from the detector model and the tracks of vehicles generated by the tracker.
- 2 Ego Vehicle Display - This display shows the 2-D bird's-eye view of the scenario. It shows the obstacle point cloud, bounding box detections, and the tracks generated by the tracker. For reference, it also displays the image recorded from a camera mounted on the ego vehicle and its field of view.
- 3 Tracking Details - This display shows the scenario zoomed around the ego vehicle. It also shows finer tracking details, such as error covariance in estimated position of each track and its motion model probabilities, denoted by cv and ct.

```
% Create display
displayObject = HelperLidarExampleDisplay(imageData{1},...
    'PositionIndex',[1 3 6],...
    'VelocityIndex',[2 4 7],...
    'DimensionIndex',[9 10 11],...
    'YawIndex',8,...
    'MovieName','',... % Specify a movie name to record a movie.
    'RecordGIF',false); % Specify true to record new GIFs
```

Loop Through Data

Loop through the recorded lidar data, generate detections from the current point cloud using the detector model and then process the detections using the tracker.

```
time = 0;           % Start time
dT = 0.1;          % Time step

% Initiate all tracks.
allTracks = struct([]);

% Initiate variables for comparing MATLAB and MEX simulation.
numTracks = zeros(numel(lidarData),2);

% Loop through the data
for i = 1:numel(lidarData)
    % Update time
    time = time + dT;

    % Get current lidar scan
    currentLidar = lidarData{i};

    % Generator detections from lidar scan.
    [detections,obstacleIndices,groundIndices,croppedIndices] = detectorModel(currentLidar);

    % Calculate detectability of each track.
    detectableTracksInput = helperCalcDetectability(allTracks,[1 3 6]);

    % Pass detections to track.
    [confirmedTracks,tentativeTracks,allTracks] = tracker(detections,time,detectableTracksInput,numTracks(i,1) = numel(confirmedTracks));

    % Get model probabilities from IMM filter of each track using
    % getTrackFilterProperties function of the tracker.
    modelProbs = zeros(2,numel(confirmedTracks));
    for k = 1:numel(confirmedTracks)
        c1 = getTrackFilterProperties(tracker,confirmedTracks(k).TrackID,'ModelProbabilities');
        modelProbs(:,k) = c1{1};
    end

    % Update display
    if isvalid(displayObject.PointCloudProcessingDisplay.ObstaclePlotter)
        % Get current image scan for reference image
        currentImage = imageData{i};
    end
end
```

```
        % Update display object
        displayObject(detections,confirmedTracks,currentLidar,obstacleIndices,...
            groundIndices,croppedIndices,currentImage,modelProbs);
    end

    % Snap a figure at time = 18
    if abs(time - 18) < dT/2
        snapnow(displayObject);
    end
end

% Write movie if requested
if ~isempty(displayObject.MovieName)
    writeMovie(displayObject);
end

% Write new GIFs if requested.
if displayObject.RecordGIF
    % second input is start frame, third input is end frame and last input
    % is a character vector specifying the panel to record.
    writeAnimatedGIF(displayObject,10,170,'trackMaintenance','ego');
    writeAnimatedGIF(displayObject,310,330,'jpda','processing');
    writeAnimatedGIF(displayObject,140,170,'imm','details');
end
```

The figure above shows the three displays at time = 18 seconds. The tracks are represented by green bounding boxes. The bounding box detections are represented by orange bounding boxes. The detections also have orange points inside them, representing the point cloud segmented as obstacles. The segmented ground is shown in purple. The cropped or discarded point cloud is shown in blue.

Generate C Code

You can generate C code from the MATLAB® code for the tracking and the preprocessing algorithm using MATLAB Coder™. C code generation enables you to accelerate MATLAB code for simulation. To generate C code, the algorithm must be restructured as a MATLAB function, which can be compiled into a MEX file or a shared library. For this purpose, the point cloud processing algorithm and the tracking algorithm is restructured into a MATLAB function, `mexLidarTracker`. Some variables are defined as persistent to preserve their state between multiple calls to the function (see `persistent`). The

inputs and outputs of the function can be observed in the function description provided in the "Supporting Files" section at the end of this example.

MATLAB coder requires specifying the properties of all the input arguments. An easy way to do this is by defining the input properties by example at the command line using the `-args` option. For more information, see "Define Input Properties by Example at the Command Line" (MATLAB Coder). Note that the top-level input arguments cannot be objects of the `handle` class. Therefore, the function accepts the `x`, `y` and `z` locations of the point cloud as an input. From the stored point cloud, this information can be extracted using the `Location` property of the `pointCloud` object. This information is also directly available as the raw data from the lidar sensor.

```
% Input lists
inputExample = {lidarData{1}.Location, 0};

% Create configuration for MEX generation
cfg = coder.config('mex');

% Replace cfg with the following to generate static library and perform
% software-in-the-loop simulation. This requires Embedded Coder license.
%
% cfg = coder.config('lib'); % Static library
% cfg.VerificationMode = 'SIL'; % Software-in-the-loop

% Generate code if file does not exist.
if ~exist('mexLidarTracker_mex','file')
    h = msgbox({'Generating code. This may take a few minutes...'; 'This message box will close when the code is generated.'});
    % -config allows specifying the codegen configuration
    % -o allows specifying the name of the output file
    codegen -config cfg -o mexLidarTracker_mex mexLidarTracker -args inputExample
    close(h);
else
    clear mexLidarTracker_mex;
end
```

Rerun simulation with MEX Code

Rerun the simulation using the generated MEX code, `mexLidarTracker_mex`.

```
% Reset time
time = 0;

for i = 1:numel(lidarData)
    time = time + dT;
```

```
currentLidar = lidarData{i};

[detectionsMex,obstacleIndicesMex,groundIndicesMex,croppedIndicesMex,...
 confirmedTracksMex, modelProbsMex] = mexLidarTracker_mex(currentLidar.Location,

% Record data for comparison with MATLAB execution.
numTracks(i,2) = numel(confirmedTracksMex);
end
```

Compare results between MATLAB and MEX Execution

```
disp(isequal(numTracks(:,1),numTracks(:,2)));
```

```
1
```

Notice that the number of confirmed tracks is the same for MATLAB and MEX code execution. This assures that the lidar preprocessing and tracking algorithm returns the same results with generated C code as with the MATLAB code.

Results

Now, analyze different events in the scenario and understand how the combination of lidar measurement model, joint probabilistic data association, and interacting multiple model filter, helps achieve a good estimation of the vehicle tracks.

Track Maintenance

The animation above shows the simulation between time = 3 seconds and time = 16 seconds. Notice that tracks such as T9 and T6 maintain their IDs and trajectory during the time span. However, track T10 is lost because the tracked vehicle was missed (not detected) for a long time by the sensor. Also, notice that the tracked objects are able to maintain their shape and kinematic center by positioning the detections onto the visible portions of the vehicles. For example, as Track T7 moves forward, bounding box detections start to fall on its visible rear portion and the track maintains the actual size of

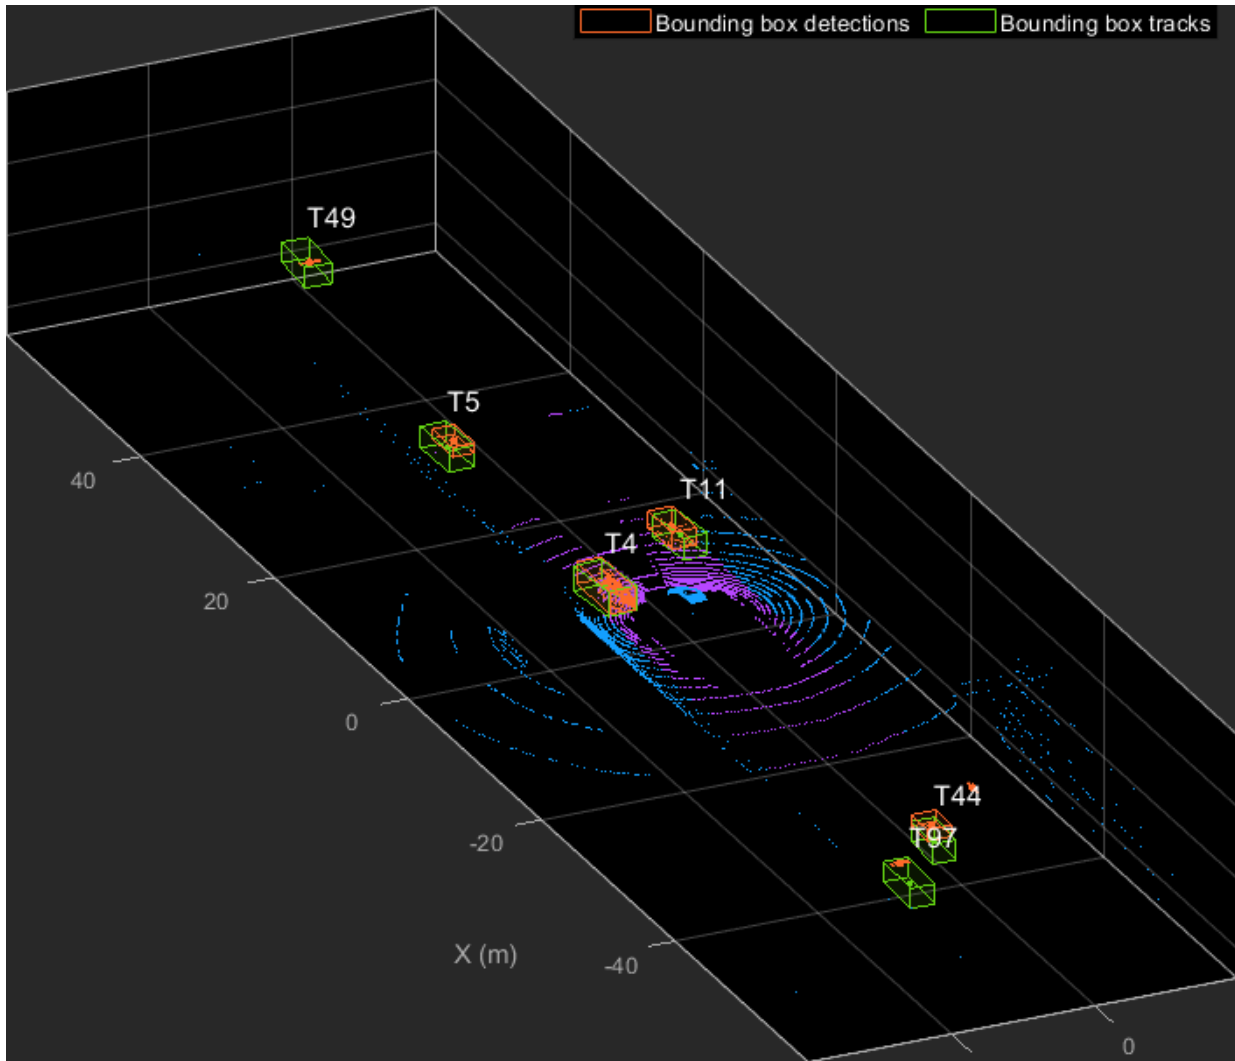

the vehicle. This illustrates the offset and shrinkage effect modeled in the measurement functions.

Capturing Maneuvers

The animation shows that using an IMM filter helps the tracker to maintain tracks on maneuvering vehicles. Notice that the vehicle tracked by T4 changes lanes behind the ego vehicle. The tracker is able maintain a track on the vehicle during this maneuvering event. Also notice in the display that its probability of following the constant turn model, denoted by ct , increases during the lane change maneuver.

Joint Probabilistic Data Association

This animation shows that using a joint probabilistic data association tracker helps in maintaining tracks during ambiguous situations. Here, vehicles tracked by T44 and T97, have a low probability of detection due to their large distance from the sensor. Notice that the tracker is able to maintain tracks during events when one of the vehicles is not detected. During the event, the tracks first coalesce, which is a known phenomenon in JPDA, and then separate as soon as the vehicle was detected again.

Summary

This example showed how to use a JPDA tracker with an IMM filter to track objects using a lidar sensor. You learned how a raw point cloud can be preprocessed to generate detections for conventional trackers, which assume one detection per object per sensor scan. You also learned how to define a cuboid model to describe the kinematics, dimensions, and measurements of extended objects being tracked by the JPDA tracker. In addition, you generated C code from the algorithm and verified its execution results with the MATLAB simulation.

Supporting Files

helperLidarModel

This function defines the lidar model to simulate shrinkage of the bounding box measurement and center-point offset. This function is used in the helperCvmeasCuboid and helperCtmeasCuboid functions to obtain bounding box measurement from the state.

```
function meas = helperLidarModel(pos,dim,yaw)
% This function returns the expected bounding box measurement given an
% object's position, dimension, and yaw angle.

% Copyright 2019 The MathWorks, Inc.

% Get x,y and z.
x = pos(1,:);
y = pos(2,:);
z = pos(3,:) - 2; % lidar mounted at height = 2 meters.

% Get spherical measurement.
[az,~,r] = cart2sph(x,y,z);

% Shrink rate
s = 3/50; % 3 meters radial length at 50 meters.
sz = 2/50; % 2 meters height at 50 meters.

% Get length, width and height.
L = dim(1,:);
W = dim(2,:);
H = dim(3,:);

az = az - deg2rad(yaw);
```

```

% Shrink length along radial direction.
Lshrink = min(L,abs(s*r.*(cos(az))));
Ls = L - Lshrink;

% Shrink width along radial direction.
Wshrink = min(W,abs(s*r.*(sin(az))));
Ws = W - Wshrink;

% Shrink height.
Hshrink = min(H,sz*r);
Hs = H - Hshrink;

% Measurement is given by a min-max detector hence length and width must be
% projected along x and y.
Lmeas = Ls.*cosd(yaw) + Ws.*sind(yaw);
Wmeas = Ls.*sind(yaw) + Ws.*cosd(yaw);

% Similar shift is for x and y directions.
shiftX = Lshrink.*cosd(yaw) + Wshrink.*sind(yaw);
shiftY = Lshrink.*sind(yaw) + Wshrink.*cosd(yaw);
shiftZ = Hshrink;

% Modeling the affect of box origin offset
x = x - sign(x).*shiftX/2;
y = y - sign(y).*shiftY/2;
z = z + shiftZ/2 + 2;

% Measurement format
meas = [x;y;z;Lmeas;Wmeas;Hs];

end

```

helperInverseLidarModel

This function defines the inverse lidar model to initiate a tracking filter using a lidar bounding box measurement. This function is used in the `helperInitIMMFilter` function to obtain state estimates from a bounding box measurement.

```

function [pos,posCov,dim,dimCov,yaw,yawCov] = helperInverseLidarModel(meas,measCov)
% This function returns the position, dimension, yaw using a bounding
% box measurement.

```

```
% Copyright 2019 The MathWorks, Inc.

% Shrink rate.
s = 3/50;
sz = 2/50;

% x,y and z of measurement
x = meas(1,:);
y = meas(2,:);
z = meas(3,:);

[az,~,r] = cart2sph(x,y,z);

% Shift x and y position.
Lshrink = abs(s*r.*(cos(az)));
Wshrink = abs(s*r.*(sin(az)));
Hshrink = sz*r;

shiftX = Lshrink;
shiftY = Wshrink;
shiftZ = Hshrink;

x = x + sign(x).*shiftX/2;
y = y + sign(y).*shiftY/2;
z = z + sign(z).*shiftZ/2;

pos = [x;y;z];
posCov = measCov(1:3,1:3,:);

yaw = zeros(1,numel(x),'like',x);
yawCov = ones(1,1,numel(x),'like',x);

% Dimensions are initialized for a standard passenger car with low
% uncertainty.
dim = [4.7;1.8;1.4];
dimCov = 0.01*eye(3);
end
```

HelperBoundingBoxDetector

This is the supporting class `HelperBoundingBoxDetector` to accept a point cloud input and return a list of `objectDetection`

```

classdef HelperBoundingBoxDetector < matlab.System
    % HelperBoundingBoxDetector A helper class to segment the point cloud
    % into bounding box detections.
    % The step call to the object does the following things:
    %
    % 1. Removes point cloud outside the limits.
    % 2. From the survived point cloud, segments out ground
    % 3. From the obstacle point cloud, forms clusters and puts bounding
    %    box on each cluster.

    % Cropping properties
    properties
        % XLimits XLimits for the scene
        XLimits = [-70 70];
        % YLimits YLimits for the scene
        YLimits = [-6 6];
        % ZLimits ZLimits fot the scene
        ZLimits = [-2 10];
    end

    % Ground Segmentation Properties
    properties
        % GroundMaxDistance Maximum distance of point to the ground plane
        GroundMaxDistance = 0.3;
        % GroundReferenceVector Reference vector of ground plane
        GroundReferenceVector = [0 0 1];
        % GroundMaxAngularDistance Maximum angular distance of point to reference vector
        GroundMaxAngularDistance = 5;
    end

    % Bounding box Segmentation properties
    properties
        % SegmentationMinDistance Distance threshold for segmentation
        SegmentationMinDistance = 1.6;
        % MinDetectionsPerCluster Minimum number of detections per cluster
        MinDetectionsPerCluster = 2;
        % MaxZDistanceCluster Maximum Z-coordinate of cluster
        MaxZDistanceCluster = 3;
        % MinZDistanceCluster Minimum Z-coordinate of cluster
        MinZDistanceCluster = -3;
    end

    % Ego vehicle radius to remove ego vehicle point cloud.

    'HasDetectableTrackIDsInput',true,...
    'InitializationThreshold',0,...
    'MaxNumTracks',30);

detectableTracksInput = zeros(tracker.MaxNumTracks,2);

currentNumTracks = 0;
end

ptCloud = pointCloud(ptCloudLocations);

% Detector model
[detections,obstacleIndices,groundIndices,croppedIndices] = detectorModel(ptCloud,time)

% Call tracker
[confirmedTracks~,allTracks] = tracker(detections,time,detectableTracksInput(1:currentNumTracks,:))
% Update the detectability input
currentNumTracks = numel(allTracks);
detectableTracksInput(1:currentNumTracks,:) = helperCalcDetectability(allTracks,[1 3 6]);

% Get model probabilities
modelProbs = zeros(2,numel(confirmedTracks));
if isLocked(tracker)
    for k = 1:numel(confirmedTracks)
        c1 = getTrackFilterProperties(tracker,confirmedTracks(k).TrackID,'ModelProbabilities');
        probs = c1{1};
        modelProbs(1,k) = probs(1);
        modelProbs(2,k) = probs(2);
    end
end
end

```

end

helperCalcDetectability

The function calculate the probability of detection for each track. This function is used to generate the "DetectableTracksIDs" input for the trackerJPDA.

```
function detectableTracksInput = helperCalcDetectability(tracks,posIndices)
% This is a helper function to calculate the detection probability of
% tracks for the lidar tracking example. It may be removed in a future
% release.

% Copyright 2019 The MathWorks, Inc.

% The bounding box detector has low probability of segmenting point clouds
% into bounding boxes are distances greater than 40 meters. This function
% models this effect using a state-dependent probability of detection for
% each tracker. After a maximum range, the Pd is set to a high value to
% enable deletion of track at a faster rate.
if isempty(tracks)
    detectableTracksInput = zeros(0,2);
    return;
end
rMax = 75;
rAmbig = 40;
stateSize = numel(tracks(1).State);
posSelector = zeros(3,stateSize);
posSelector(1,posIndices(1)) = 1;
posSelector(2,posIndices(2)) = 1;
posSelector(3,posIndices(3)) = 1;
pos = getTrackPositions(tracks,posSelector);
if coder.target('MATLAB')
    trackIDs = [tracks.TrackID];
else
    trackIDs = zeros(1,numel(tracks),'uint32');
    for i = 1:numel(tracks)
        trackIDs(i) = tracks(i).TrackID;
    end
end
[~,~,r] = cart2sph(pos(:,1),pos(:,2),pos(:,3));
probDetection = 0.9*ones(numel(tracks),1);
probDetection(r > rAmbig) = 0.4;
```

```

probDetection(r > rMax) = 0.99;
detectableTracksInput = [double(trackIDs(:)) probDetection(:)];
end

```

loadLidarAndImageData

Stitches Lidar and Camera data for processing using initial and final time specified.

```

function [lidarData,imageData] = loadLidarAndImageData(initTime,finalTime)
initFrame = max(1,floor(initTime*10));
lastFrame = min(350,ceil(finalTime*10));
load ('imageData_35seconds.mat','allImageData');
imageData = allImageData(initFrame:lastFrame);

numFrames = lastFrame - initFrame + 1;
lidarData = cell(numFrames,1);

% Each file contains 70 frames.
initFileIndex = floor(initFrame/70) + 1;
lastFileIndex = ceil(lastFrame/70);

frameIndices = [1:70:numFrames numFrames + 1];

counter = 1;
for i = initFileIndex:lastFileIndex
    startFrame = frameIndices(counter);
    endFrame = frameIndices(counter + 1) - 1;
    load(['lidarData_',num2str(i)], 'currentLidarData');
    lidarData(startFrame:endFrame) = currentLidarData(1:(endFrame + 1 - startFrame));
    counter = counter + 1;
end
end

```

Object Detection Using YOLO v2 Deep Learning

This example shows how to train a you only look once (YOLO) v2 object detector.

Deep learning is a powerful machine learning technique that you can use to train robust object detectors. Several techniques for object detection exist, including Faster R-CNN and you only look once (YOLO) v2. This example trains a YOLO v2 vehicle detector using the `trainYOLOv2ObjectDetector` function. For more information, see “Object Detection using Deep Learning”.

Download Pretrained Detector

Download a pretrained detector to avoid having to wait for training to complete. If you want to train the detector, set the `doTraining` variable to true.

```
doTraining = false;
if ~doTraining && ~exist('yolov2ResNet50VehicleExample_19b.mat','file')
    disp('Downloading pretrained detector (98 MB)...');
    pretrainedURL = 'https://www.mathworks.com/supportfiles/vision/data/yolov2ResNet50';
    websave('yolov2ResNet50VehicleExample_19b.mat',pretrainedURL);
end
```

Load Dataset

This example uses a small vehicle dataset that contains 295 images. Each image contains one or two labeled instances of a vehicle. A small dataset is useful for exploring the YOLO v2 training procedure, but in practice, more labeled images are needed to train a robust detector. Unzip the vehicle images and load the vehicle ground truth data.

```
unzip('vehicleDatasetImages.zip');
data = load('vehicleDatasetGroundTruth.mat');
vehicleDataset = data.vehicleDataset;
```

The vehicle data is stored in a two-column table, where the first column contains the image file paths and the second column contains the vehicle bounding boxes.

```
% Display first few rows of the data set.
vehicleDataset(1:4,:)
```

```
ans=4x2 table
      imageFilename      vehicle
```

```
{'vehicleImages/image_00001.jpg'} {1x4 double}
{'vehicleImages/image_00002.jpg'} {1x4 double}
{'vehicleImages/image_00003.jpg'} {1x4 double}
{'vehicleImages/image_00004.jpg'} {1x4 double}
```

% Add the fullpath to the local vehicle data folder.

```
vehicleDataset.imageFilename = fullfile(pwd,vehicleDataset.imageFilename);
```

Split the data set into a training set for training the detector, and a test set for evaluating the detector. Select 60% of the data for training. Use the rest for evaluation.

```
rng(0);
shuffledIndices = randperm(height(vehicleDataset));
idx = floor(0.6 * length(shuffledIndices) );
trainingDataTbl = vehicleDataset(shuffledIndices(1:idx),:);
testDataTbl = vehicleDataset(shuffledIndices(idx+1:end),:);
```

Use `imageDatastore` and `boxLabelDatastore` to create datastores for loading the image and label data during training and evaluation.

```
imdsTrain = imageDatastore(trainingDataTbl{:, 'imageFilename'});
bldsTrain = boxLabelDatastore(trainingDataTbl(:, 'vehicle'));

imdsTest = imageDatastore(testDataTbl{:, 'imageFilename'});
bldsTest = boxLabelDatastore(testDataTbl(:, 'vehicle'));
```

Combine image and box label datastores.

```
trainingData = combine(imdsTrain,bldsTrain);
testData = combine(imdsTest,bldsTest);
```

Display one of the training images and box labels.

```
data = read(trainingData);
I = data{1};
bbox = data{2};
annotatedImage = insertShape(I, 'Rectangle', bbox);
annotatedImage = imresize(annotatedImage,2);
figure
imshow(annotatedImage)
```

Create a YOLO v2 Object Detection Network

A YOLO v2 object detection network is composed of two subnetworks. A feature extraction network followed by a detection network. The feature extraction network is typically a pretrained CNN (for details, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox)). This example uses ResNet-50 for feature extraction. You can also use other pretrained networks such as MobileNet v2 or ResNet-18 can also be used depending on application requirements. The detection sub-network is a small CNN compared to the feature extraction network and is composed of a few convolutional layers and layers specific for YOLO v2.

Use the `yoloV2Layers` function to create a YOLO v2 object detection network automatically given a pretrained ResNet-50 feature extraction network. `yoloV2Layers` requires you to specify several inputs that parameterize a YOLO v2 network:

- Network input size
- Anchor boxes
- Feature extraction network

First, specify the network input size and the number of classes. When choosing the network input size, consider the minimum size required by the network itself, the size of the training images, and the computational cost incurred by processing data at the selected size. When feasible, choose a network input size that is close to the size of the training image and larger than the input size required for the network. To reduce the computational cost of running the example, specify a network input size of [224 224 3], which is the minimum size required to run the network.

```
inputSize = [224 224 3];
```

Define the number of object classes to detect.

```
numClasses = width(vehicleDataset)-1;
```

Note that the training images used in this example are bigger than 224-by-224 and vary in size, so you must resize the images in a preprocessing step prior to training.

Next, use `estimateAnchorBoxes` to estimate anchor boxes based on the size of objects in the training data. To account for the resizing of the images prior to training, resize the training data for estimating anchor boxes. Use `transform` to preprocess the training data, then define the number of anchor boxes and estimate the anchor boxes. Resize the training data to the input image size of the network using the supporting function `preprocessData`.

```
trainingDataForEstimation = transform(trainingData,@(data)preprocessData(data,inputSize));  
numAnchors = 7;
```

```
[anchorBoxes, meanIoU] = estimateAnchorBoxes(trainingDataForEstimation, numAnchors)
```

```
anchorBoxes = 7x2
```

```
145 122  
81 76  
160 132  
41 34  
63 62  
103 97  
33 23
```

```
meanIoU = 0.8630
```

For more information on choosing anchor boxes, see “Estimate Anchor Boxes From Training Data” on page 1-33 (Computer Vision Toolbox™) and “Anchor Boxes for Object Detection” on page 7-12.

Now, use `resnet50` to load a pretrained ResNet-50 model.

```
featureExtractionNetwork = resnet50;
```

Select `'activation_40_relu'` as the feature extraction layer to replace the layers after `'activation_40_relu'` with the detection subnetwork. This feature extraction layer outputs feature maps that are downsampled by a factor of 16. This amount of downsampling is a good trade-off between spatial resolution and the strength of the extracted features, as features extracted further down the network encode stronger image features at the cost of spatial resolution. Choosing the optimal feature extraction layer requires empirical analysis.

```
featureLayer = 'activation_40_relu';
```

Create the YOLO v2 object detection network.

```
lgraph = yolov2Layers(inputSize,numClasses,anchorBoxes,featureExtractionNetwork,featureLayer);
```

You can visualize the network using `analyzeNetwork` or Deep Network Designer from Deep Learning Toolbox™.

If more control is required over the YOLO v2 network architecture, use Deep Network Designer to design the YOLO v2 detection network manually. For more information, see “Design a YOLO v2 Detection Network” on page 7-21.

Data Augmentation

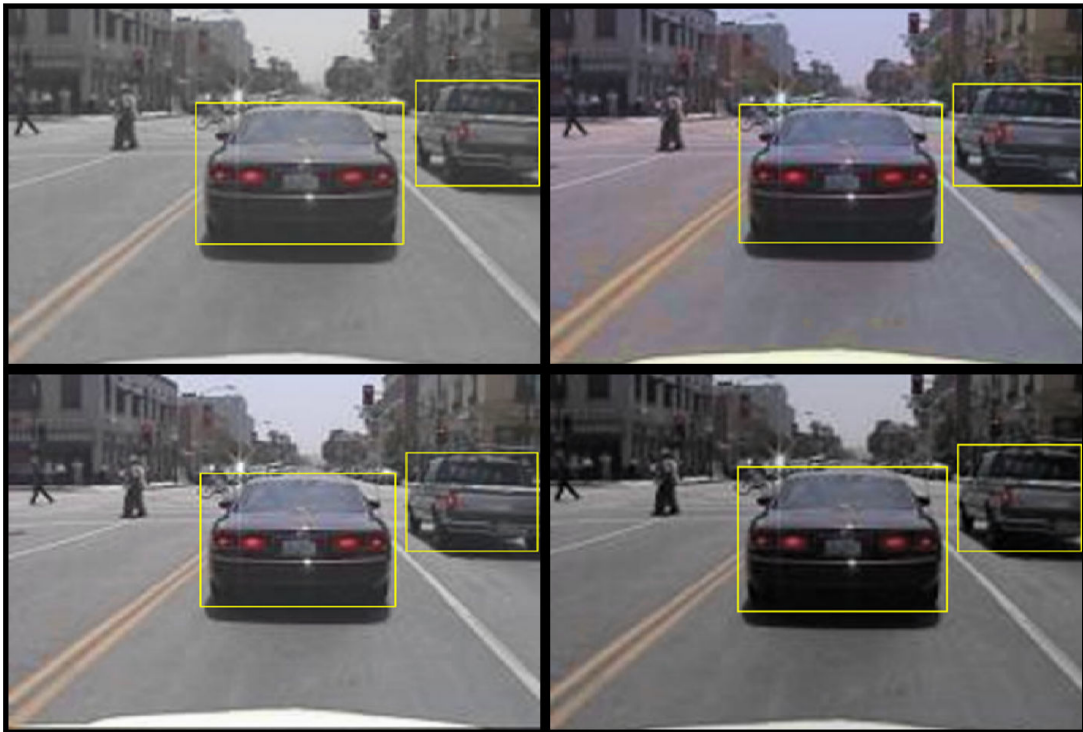

Data augmentation is used to improve network accuracy by randomly transforming the original data during training. By using data augmentation you can add more variety to the training data without actually having to increase the number of labeled training samples.

Use `transform` to augment the training data by randomly flipping the image and associated box labels horizontally. Note that data augmentation is not applied to the test data. Ideally, test data should be representative of the original data and is left unmodified for unbiased evaluation.

```
augmentedTrainingData = transform(trainingData,@augmentData);
```

Read the same image multiple times and display the augmented training data.

```
% Visualize the augmented images.
augmentedData = cell(4,1);
for k = 1:4
    data = read(augmentedTrainingData);
    augmentedData{k} = insertShape(data{1}, 'Rectangle', data{2});
    reset(augmentedTrainingData);
end
figure
montage(augmentedData, 'BorderSize', 10)
```

Preprocess Training Data

Preprocess the augmented training data to prepare for training.

```
preprocessedTrainingData = transform(augmentedTrainingData,@(data)preprocessData(data, ...
```

Read the preprocessed training data.

```
data = read(preprocessedTrainingData);
```

Display the image and bounding boxes.

```
I = data{1};  
bbox = data{2};  
annotatedImage = insertShape(I, 'Rectangle',bbox);  
annotatedImage = imresize(annotatedImage,2);  
figure  
imshow(annotatedImage)
```

Train YOLO v2 Object Detector

Use `trainingOptions` to specify network training options. Set `'CheckpointPath'` to a temporary location. This enables the saving of partially trained detectors during the training process. If training is interrupted, such as by a power outage or system failure, you can resume training from the saved checkpoint.

```
options = trainingOptions('sgdm', ...
    'MiniBatchSize', 16, ...
    'InitialLearnRate', 1e-3, ...
    'MaxEpochs', 20, ...
    'CheckpointPath', tempdir, ...
    'Shuffle', 'never');
```

Use `trainYOLOv2ObjectDetector` function to train YOLO v2 object detector if `doTraining` is true. Otherwise, load the pretrained network.

```
if doTraining
    % Train the YOLO v2 detector.
    [detector,info] = trainYOLOv2ObjectDetector(preprocessedTrainingData,lgraph,options)
else
    % Load pretrained detector for the example.
    pretrained = load('yolov2ResNet50VehicleExample_19b.mat');
    detector = pretrained.detector;
end
```

This example was verified on an NVIDIA™ Titan X GPU with 12 GB of memory. If your GPU has less memory, you may run out of memory. If this happens, lower the `'MiniBatchSize'` using the `trainingOptions` function. Training this network took approximately 7 minutes using this setup. Training time varies depending on the hardware you use.

As a quick test, run the detector on one test image. Make sure you resize the image to the same size as the training images.

```
I = imread(testDataTbl.imageFilename{1});
I = imresize(I,inputSize(1:2));
[bboxes,scores] = detect(detector,I);
```

Display the results.

```
I = insertObjectAnnotation(I, 'rectangle', bboxes, scores);
figure
imshow(I)
```

Evaluate Detector Using Test Set

Evaluate the trained object detector on a large set of images to measure the performance. Computer Vision Toolbox™ provides object detector evaluation functions to measure common metrics such as average precision (`evaluateDetectionPrecision`) and log-average miss rates (`evaluateDetectionMissRate`). For this example, use the average precision metric to evaluate performance. The average precision provides a single number that incorporates the ability of the detector to make correct classifications (precision) and the ability of the detector to find all relevant objects (recall).

Apply the same preprocessing transform to the test data as for the training data. Note that data augmentation is not applied to the test data. Test data should be representative of the original data and be left unmodified for unbiased evaluation.

```
preprocessedTestData = transform(testData,@(data)preprocessData(data,inputSize));
```

Run the detector on all the test images.

```
detectionResults = detect(detector, preprocessedTestData);
```

Evaluate the object detector using average precision metric.

```
[ap,recall,precision] = evaluateDetectionPrecision(detectionResults, preprocessedTestD
```

The precision/recall (PR) curve highlights how precise a detector is at varying levels of recall. The ideal precision is 1 at all recall levels. The use of more data can help improve the average precision but might require more training time. Plot the PR curve.

```
figure
plot(recall,precision)
xlabel('Recall')
ylabel('Precision')
grid on
title(sprintf('Average Precision = %.2f',ap))
```

Code Generation

Once the detector is trained and evaluated, you can generate code for the yolov2objectDetector using GPU Coder™. See “Code Generation for Object Detection by Using YOLO v2” (GPU Coder) example for more details.

Supporting Functions

```
function B = augmentData(A)
% Apply random horizontal flipping, and random X/Y scaling. Boxes that get
% scaled outside the bounds are clipped if the overlap is above 0.25. Also,
% jitter image color.
B = cell(size(A));

I = A{1};
sz = size(I);
if numel(sz)==3 && sz(3) == 3
    I = jitterColorHSV(I,...
        'Contrast',0.2,...
        'Hue',0,...
        'Saturation',0.1,...
        'Brightness',0.2);
end

% Randomly flip and scale image.
tform = randomAffine2d('XReflection',true,'Scale',[1 1.1]);
rout = affineOutputView(sz,tform,'BoundsStyle','CenterOutput');
B{1} = imwarp(I,tform,'OutputView',rout);

% Apply same transform to boxes.
[B{2},indices] = bboxwarp(A{2},tform,rout,'OverlapThreshold',0.25);
B{3} = A{3}(indices);

% Return original data only when all boxes are removed by warping.
if isempty(indices)
    B = A;
end
end

function data = preprocessData(data,targetSize)
% Resize image and bounding boxes to the targetSize.
scale = targetSize(1:2)./size(data{1},[1 2]);
data{1} = imresize(data{1},targetSize(1:2));
```

```
data{2} = bboxresize(data{2},scale);  
end
```

Create YOLO v2 Object Detection Network

This example shows how to modify a pretrained MobileNet v2 network to create a YOLO v2 object detection network. This approach offers additional flexibility compared to the `yoloV2Layers` function, which returns a canonical YOLO v2 object detector.

The procedure to convert a pretrained network into a YOLO v2 network is similar to the transfer learning procedure for image classification:

- 1 Load the pretrained network.
- 2 Select a layer from the pretrained network to use for feature extraction.
- 3 Remove all the layers after the feature extraction layer.
- 4 Add new layers to support the object detection task.

You can also implement this procedure using the `deepNetworkDesigner` app.

Load Pretrained Network

Load a pretrained MobileNet v2 network using `mobilenetv2`. This requires the Deep Learning Toolbox Model for MobileNet v2 Network™.

```
% Load a pretrained network.
net = mobilenetv2();

% Convert network into a layer graph object
% in order to manipulate the layers.
lgraph = layerGraph(net);
```

Update Network Image Size

Change the image size of the network based on the training data requirements. To illustrate this step, assume the required image size is [300 300 3] for RGB images.

```
% Input size for detector.
imageInputSize = [300 300 3];

% Create new image input layer. Set the new layer name
% to the original layer name.
imgLayer = imageInputLayer(imageInputSize, "Name", "input_1")

imgLayer =
    ImageInputLayer with properties:
```

```
        Name: 'input_1'  
        InputSize: [300 300 3]  
  
Hyperparameters  
    DataAugmentation: 'none'  
    Normalization: 'zerocenter'  
    NormalizationDimension: 'auto'  
    Mean: []
```

```
% Replace old image input layer.  
lgraph = replaceLayer(lgraph, "input_1", imgLayer);
```

Select Feature Extraction Layer

A good feature extraction layer for YOLO v2 is one where the output feature width and height is between 8 and 16 times smaller than the input image. This amount of downsampling is a trade-off between spatial resolution and quality of output features. The `analyzeNetwork` app or `deepNetworkDesigner` app can be used to determine the output sizes of layers within a network. Note that selecting an optimal feature extraction layer requires empirical evaluation.

Set the feature extraction layer to “`block_12_add`” from MobileNet v2. Because the required input size was previously set to [300 300], the output feature size is [19 19]. This results in a downsampling factor of about 16.

```
featureExtractionLayer = "block_12_add";
```

Remove Layers After Feature Extraction Layer

To easily remove layers from a deep network, such as MobileNet v2, use the `deepNetworkDesigner` app. Import the network into the app to manually remove the layers after “`block_12_add`”. Export the modified network to your workspace. This example uses a pre-saved version of MobileNet v2 which was exported from the app.

```
% Load a network modified using Deep Network Designer.  
modified = load("mobilenetv2Block12Add.mat");  
lgraph = modified.mobilenetv2Block12Add;
```

Alternatively, if you have a list of layers to remove, you can use the `removeLayers` function to remove them manually.

Create YOLO v2 Detection Sub-Network

The detection subnetwork consists of groups of serially connected convolution, ReLU, and batch normalization layers. These layers are followed by a yolov2TransformLayer and a yolov2OutputLayer.

Create the convolution, ReLU, and batch normalization portion of the detection sub-network.

```
% Set the convolution layer filter size to [3 3].
% This size is common in CNN architectures.
filterSize = [3 3];

% Set the number of filters in the convolution layers
% to match the number of channels in the
% feature extraction layer output.
numFilters = 96;

% Create the detection subnetwork.
% * The convolution layer uses "same" padding
%   to preserve the input size.
detectionLayers = [
    % group 1
    convolution2dLayer(filterSize,numFilters,"Name","yolov2Conv1",...
        "Padding","same","WeightsInitializer",@(sz)randn(sz)*0.01)
    batchNormalizationLayer("Name","yolov2Batch1");
    reluLayer("Name","yolov2Relu1");

    % group 2
    convolution2dLayer(filterSize,numFilters,"Name","yolov2Conv2",...
        "Padding","same","WeightsInitializer",@(sz)randn(sz)*0.01)
    batchNormalizationLayer("Name","yolov2Batch2");
    reluLayer("Name","yolov2Relu2");
]
```

detectionLayers =
6x1 Layer array with layers:

1	'yolov2Conv1'	Convolution	96 3x3 convolutions with stride [1 1]
2	'yolov2Batch1'	Batch Normalization	Batch normalization
3	'yolov2Relu1'	ReLU	ReLU
4	'yolov2Conv2'	Convolution	96 3x3 convolutions with stride [1 1]
5	'yolov2Batch2'	Batch Normalization	Batch normalization
6	'yolov2Relu2'	ReLU	ReLU

The remaining layers are configured based on application specific details such as number of object classes and anchor boxes.

```
% Define the number of classes to detect.
numClasses = 5;

% Define the anchor boxes.
anchorBoxes = [
    16 16
    32 16
];

% Number of anchor boxes.
numAnchors = size(anchorBoxes,1);

% There are five predictions per anchor box:
% * Predict the x, y, width, and height offset
%   for each anchor.
% * Predict the intersection-over-union with ground
%   truth boxes.
numPredictionsPerAnchor = 5;

% Number of filters in last convolution layer.
outputSize = numAnchors*(numClasses+numPredictionsPerAnchor);
```

Create the convolution2dLayer, yolov2Transform, and yolov2Output layers.

```
% Final layers in detection sub-network.
finalLayers = [
    convolution2dLayer(1,outputSize,"Name","yolov2ClassConv",...
        "WeightsInitializer", @(sz)randn(sz)*0.01)
    yolov2TransformLayer(numAnchors,"Name","yolov2Transform")
    yolov2OutputLayer(anchorBoxes,"Name","yolov2OutputLayer")
];
```

Add the last layers to the network.

```
% Add the last layers to network.
detectionLayers = [
    detectionLayers
    finalLayers
];

detectionLayers =
    9x1 Layer array with layers:
```

1	'yolov2Conv1'	Convolution	96 3x3 convolutions with stri
2	'yolov2Batch1'	Batch Normalization	Batch normalization
3	'yolov2Relu1'	ReLU	ReLU
4	'yolov2Conv2'	Convolution	96 3x3 convolutions with stri
5	'yolov2Batch2'	Batch Normalization	Batch normalization
6	'yolov2Relu2'	ReLU	ReLU
7	'yolov2ClassConv'	Convolution	20 1x1 convolutions with stri
8	'yolov2Transform'	YOLO v2 Transform Layer	YOLO v2 Transform Layer with 2
9	'yolov2OutputLayer'	YOLO v2 Output	YOLO v2 Output with 2 anchors

Complete YOLO v2 Detection Network

Attach the detection subnetwork to the feature extraction network.

```
% Add the detection subnetwork to the feature extraction network.
```

```
lgraph = addLayers(lgraph,detectionLayers);
```

```
% Connect the detection subnetwork to the feature extraction layer.
```

```
lgraph = connectLayers(lgraph,featureExtractionLayer,"yolov2Conv1");
```

Use `analyzeNetwork(lgraph)` to check the network and then train a YOLO v2 object detector using the `trainYOLOv2ObjectDetector` function.

Semantic Segmentation Using Dilated Convolutions

Train a semantic segmentation network using dilated convolutions.

A semantic segmentation network classifies every pixel in an image, resulting in an image that is segmented by class. Applications for semantic segmentation include road segmentation for autonomous driving and cancer cell segmentation for medical diagnosis. To learn more, see “Getting Started With Semantic Segmentation Using Deep Learning” on page 7-32.

Semantic segmentation networks like DeepLab [1] make extensive use of dilated convolutions (also known as atrous convolutions) because they can increase the receptive field of the layer (the area of the input which the layers can see) without increasing the number of parameters or computations.

Load Training Data

The example uses a simple dataset of 32-by-32 triangle images for illustration purposes. The dataset includes accompanying pixel label ground truth data. Load the training data using an `imageDatastore` and a `pixelLabelDatastore`.

```
dataFolder = fullfile(toolboxdir('vision'),'visiondata','triangleImages');  
imageFolderTrain = fullfile(dataFolder,'trainingImages');  
labelFolderTrain = fullfile(dataFolder,'trainingLabels');
```

Create an `imageDatastore` for the images.

```
imdsTrain = imageDatastore(imageFolderTrain);
```

Create a `pixelLabelDatastore` for the ground truth pixel labels.

```
classNames = ["triangle" "background"];  
labels = [255 0];  
pxdsTrain = pixelLabelDatastore(labelFolderTrain,classNames,labels)
```

```
pxdsTrain =
```

```
PixelLabelDatastore with properties:
```

```
Files: {200x1 cell}  
ClassNames: {2x1 cell}  
ReadSize: 1  
ReadFcn: @readDatastoreImage  
AlternateFileSystemRoots: {}
```

Create Semantic Segmentation Network

This example uses a simple semantic segmentation network based on dilated convolutions.

Create a data source for training data and get the pixel counts for each label.

```
pximdsTrain = pixelLabelImageDatastore(imdsTrain,pxdsTrain);
tbl = countEachLabel(pximdsTrain)
```

```
tbl=2x3 table
      Name      PixelCount      ImagePixelCount
      _____      _____      _____
      'triangle'      10326      2.048e+05
      'background'      1.9447e+05      2.048e+05
```

The majority of pixel labels are for background. This class imbalance biases the learning process in favor of the dominant class. To fix this, use class weighting to balance the classes. You can use several methods to compute class weights. One common method is inverse frequency weighting where the class weights are the inverse of the class frequencies. This method increases the weight given to under represented classes. Calculate the class weights using inverse frequency weighting.

```
numberPixels = sum(tbl.PixelCount);
frequency = tbl.PixelCount / numberPixels;
classWeights = 1 ./ frequency;
```

Create a network for pixel classification by using an image input layer with an input size corresponding to the size of the input images. Next, specify three blocks of convolution, batch normalization, and ReLU layers. For each convolutional layer, specify 32 3-by-3 filters with increasing dilation factors and pad the inputs so they are the same size as the outputs by setting the 'Padding' option to 'same'. To classify the pixels, include a convolutional layer with K 1-by-1 convolutions, where K is the number of classes, followed by a softmax layer and a `pixelClassificationLayer` with the inverse class weights.

```
inputSize = [32 32 1];
filterSize = 3;
numFilters = 32;
numClasses = numel(classNames);

layers = [
    imageInputLayer(inputSize)
```

```
convolution2dLayer(filterSize,numFilters,'DilationFactor',1,'Padding','same')
batchNormalizationLayer
reluLayer

convolution2dLayer(filterSize,numFilters,'DilationFactor',2,'Padding','same')
batchNormalizationLayer
reluLayer

convolution2dLayer(filterSize,numFilters,'DilationFactor',4,'Padding','same')
batchNormalizationLayer
reluLayer

convolution2dLayer(1,numClasses)
softmaxLayer
pixelClassificationLayer('Classes',classNames,'ClassWeights',classWeights)];
```

Train Network

Specify the training options.

```
options = trainingOptions('sgdm', ...
    'MaxEpochs', 100, ...
    'MiniBatchSize', 64, ...
    'InitialLearnRate', 1e-3);
```

Train the network using `trainNetwork`.

```
net = trainNetwork(pximdsTrain, layers, options);
```

Training on single GPU.
Initializing image normalization.

Epoch	Iteration	Time Elapsed (hh:mm:ss)	Mini-batch Accuracy	Mini-batch Loss	Base Learning Rate
1	1	00:00:00	67.54%	0.7098	0.00
17	50	00:00:03	84.60%	0.3851	0.00
34	100	00:00:06	89.85%	0.2536	0.00
50	150	00:00:09	93.39%	0.1959	0.00
67	200	00:00:11	95.89%	0.1559	0.00
84	250	00:00:14	97.29%	0.1188	0.00
100	300	00:00:18	98.28%	0.0970	0.00

Test Network

Load the test data. Create an `imageDatastore` for the images. Create a `pixelLabelDatastore` for the ground truth pixel labels.

```
imageFolderTest = fullfile(dataFolder, 'testImages');
imdsTest = imageDatastore(imageFolderTest);
labelFolderTest = fullfile(dataFolder, 'testLabels');
pxdsTest = pixelLabelDatastore(labelFolderTest, classNames, labels);
```

Make predictions using the test data and trained network.

```
pxdsPred = semanticseg(imdsTest, net, 'WriteLocation', tempdir);
```

```
Running semantic segmentation network
```

```
-----
* Processing 100 images.
* Progress: 100.00%
```

Evaluate the prediction accuracy using `evaluateSemanticSegmentation`.

```
metrics = evaluateSemanticSegmentation(pxdsPred, pxdsTest);
```

```
Evaluating semantic segmentation results
```

```
-----
* Selected metrics: global accuracy, class accuracy, IoU, weighted IoU, BF score.
* Processing 100 images...
[=====] 100%
Elapsed time: 00:00:00
Estimated time remaining: 00:00:00
* Finalizing... Done.
* Data set metrics:
```

GlobalAccuracy	MeanAccuracy	MeanIoU	WeightedIoU	MeanBFScore
0.98334	0.99107	0.85869	0.97109	0.68197

For more information on evaluating semantic segmentation networks, see `evaluateSemanticSegmentation`.

Segment New Image

Read and display the test image `triangleTest.jpg`.

```
imgTest = imread('triangleTest.jpg');  
figure  
imshow(imgTest)
```

Segment the test image using `semanticseg` and display the results using `labeloverlay`.

```
C = semanticseg(imgTest,net);  
B = labeloverlay(imgTest,C);  
figure  
imshow(B)
```

Define Custom Pixel Classification Layer with Dice Loss

Define and create a custom pixel classification layer that uses Dice loss.

You can use this layer to train semantic segmentation networks. To learn more about creating custom deep learning layers, see “Define Custom Deep Learning Layers” (Deep Learning Toolbox).

Dice Loss

The Dice loss is based on the Sørensen-Dice similarity coefficient for measuring the overlap between two segmented images. The generalized Dice loss [1,2] L for between one image Y and the corresponding ground truth T is given by

$$L = 1 - \frac{2 \sum_{k=1}^K w_k \sum_{m=1}^M Y_{km} T_{km}}{\sum_{k=1}^K w_k \sum_{m=1}^M Y_{km}^2 + T_{km}^2},$$

where K is the number of classes, M is the number of elements along the first two dimensions of Y , and w_k is a class-specific weighting factor that controls the contribution each class makes to the loss. w_k is typically the inverse area of the expected region:

$$w_k = \frac{1}{\left(\sum_{m=1}^M T_{km}\right)^2}$$

This weighting helps counter the influence of larger regions on the Dice score and makes it easier for the network to learn how to segment smaller regions.

Classification Layer Template

Copy the classification layer template into a new file in MATLAB®. This template outlines the structure of a classification layer and includes the functions that define the layer behavior. The rest of the example shows how to complete the `dicePixelClassificationLayer`.

```
classdef dicePixelClassificationLayer < nnet.layer.ClassificationLayer

    properties
        % Optional properties
    end

    methods
```

```

function loss = forwardLoss(layer, Y, T)
    % Layer forward loss function goes here.
end

function dLdY = backwardLoss(layer, Y, T)
    % Layer backward loss function goes here.
end
end
end

```

Declare Layer Properties

By default, custom output layers have the following properties:

- **Name** — Layer name, specified as a character vector or a string scalar. To include this layer in a layer graph, you must specify a nonempty unique layer name. If you train a series network with this layer and `Name` is set to `''`, then the software automatically assigns a name at training time.
- **Description** — One-line description of the layer, specified as a character vector or a string scalar. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays the layer class name.
- **Type** — Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays `'Classification layer'` or `'Regression layer'`.

Custom classification layers also have the following property:

- **Classes** — Classes of the output layer, specified as a categorical vector, string array, cell array of character vectors, or `'auto'`. If `Classes` is `'auto'`, then the software automatically sets the classes at training time. If you specify a string array or cell array of character vectors `str`, then the software sets the classes of the output layer to `categorical(str, str)`. The default value is `'auto'`.

If the layer has no other properties, then you can omit the `properties` section.

The Dice loss requires a small constant value to prevent division by zero. Specify the property, `Epsilon`, to hold this value.

```
classdef dicePixelClassificationLayer < nnet.layer.ClassificationLayer
```

```
properties(Constant)
    % Small constant to prevent division by zero.
    Epsilon = 1e-8;

end

...
end
```

Create Constructor Function

Create the function that constructs the layer and initializes the layer properties. Specify any variables required to create the layer as inputs to the constructor function.

Specify an optional input argument name to assign to the `Name` property at creation.

```
function layer = dicePixelClassificationLayer(name)
    % layer = dicePixelClassificationLayer(name) creates a Dice
    % pixel classification layer with the specified name.

    % Set layer name.
    layer.Name = name;

    % Set layer description.
    layer.Description = 'Dice loss';
end
```

Create Forward Loss Function

Create a function named `forwardLoss` that returns the weighted cross entropy loss between the predictions made by the network and the training targets. The syntax for `forwardLoss` is `loss = forwardLoss(layer, Y, T)`, where `Y` is the output of the previous layer and `T` represents the training targets.

For semantic segmentation problems, the dimensions of `T` match the dimension of `Y`, where `Y` is a 4-D array of size `H-by-W-by-K-by-N`, where `K` is the number of classes, and `N` is the mini-batch size.

The size of `Y` depends on the output of the previous layer. To ensure that `Y` is the same size as `T`, you must include a layer that outputs the correct size before the output layer. For example, to ensure that `Y` is a 4-D array of prediction scores for `K` classes, you can include a fully connected layer of size `K` or a convolutional layer with `K` filters followed by a softmax layer before the output layer.

```

function loss = forwardLoss(layer, Y, T)
    % loss = forwardLoss(layer, Y, T) returns the Dice loss between
    % the predictions Y and the training targets T.

    % Weights by inverse of region size.
    W = 1 ./ sum(sum(T,1),2).^2;

    intersection = sum(sum(Y.*T,1),2);
    union = sum(sum(Y.^2 + T.^2, 1),2);

    numer = 2*sum(W.*intersection,3) + layer.Epsilon;
    denom = sum(W.*union,3) + layer.Epsilon;

    % Compute Dice score.
    dice = numer./denom;

    % Return average Dice loss.
    N = size(Y,4);
    loss = sum((1-dice))/N;
end

```

Create Backward Loss Function

Create the backward loss function that returns the derivatives of the Dice loss with respect to the predictions Y. The syntax for `backwardLoss` is `loss = backwardLoss(layer, Y, T)`, where Y is the output of the previous layer and T represents the training targets.

The dimensions of Y and T are the same as the inputs in `forwardLoss`.

```

function dLdY = backwardLoss(layer, Y, T)
    % dLdY = backwardLoss(layer, Y, T) returns the derivatives of
    % the Dice loss with respect to the predictions Y.

    % Weights by inverse of region size.
    W = 1 ./ sum(sum(T,1),2).^2;

    intersection = sum(sum(Y.*T,1),2);
    union = sum(sum(Y.^2 + T.^2, 1),2);

    numer = 2*sum(W.*intersection,3) + layer.Epsilon;
    denom = sum(W.*union,3) + layer.Epsilon;

```

```
N = size(Y,4);  
dLdY = (2*W.*Y.*numer./denom.^2 - 2*W.*T./denom)./N;  
end
```

Completed Layer

The completed layer is provided in `dicePixelClassificationLayer.m`.

```
classdef dicePixelClassificationLayer < nnet.layer.ClassificationLayer  
    % This layer implements the generalized Dice loss function for training  
    % semantic segmentation networks.  
  
    properties(Constant)  
        % Small constant to prevent division by zero.  
        Epsilon = 1e-8;  
    end  
  
    methods  
  
        function layer = dicePixelClassificationLayer(name)  
            % layer = dicePixelClassificationLayer(name) creates a Dice  
            % pixel classification layer with the specified name.  
  
            % Set layer name.  
            layer.Name = name;  
  
            % Set layer description.  
            layer.Description = 'Dice loss';  
        end  
  
        function loss = forwardLoss(layer, Y, T)  
            % loss = forwardLoss(layer, Y, T) returns the Dice loss between  
            % the predictions Y and the training targets T.  
  
            % Weights by inverse of region size.  
            W = 1 ./ sum(sum(T,1),2).^2;  
  
            intersection = sum(sum(Y.*T,1),2);  
            union = sum(sum(Y.^2 + T.^2, 1),2);  
  
            numer = 2*sum(W.*intersection,3) + layer.Epsilon;  
            denom = sum(W.*union,3) + layer.Epsilon;
```

```

    % Compute Dice score.
    dice = numer./denom;

    % Return average Dice loss.
    N = size(Y,4);
    loss = sum((1-dice))/N;

end

function dLdY = backwardLoss(layer, Y, T)
    % dLdY = backwardLoss(layer, Y, T) returns the derivatives of
    % the Dice loss with respect to the predictions Y.

    % Weights by inverse of region size.
    W = 1 ./ sum(sum(T,1),2).^2;

    intersection = sum(sum(Y.*T,1),2);
    union = sum(sum(Y.^2 + T.^2, 1),2);

    numer = 2*sum(W.*intersection,3) + layer.Epsilon;
    denom = sum(W.*union,3) + layer.Epsilon;

    N = size(Y,4);

    dLdY = (2*W.*Y.*numer./denom.^2 - 2*W.*T./denom)./N;
end
end
end

```

GPU Compatibility

For GPU compatibility, the layer functions must support inputs and return outputs of type `gpuArray`. Any other functions used by the layer must do the same.

The MATLAB functions used in `forwardLoss` and `backwardLoss` in `dicePixelClassificationLayer` all support `gpuArray` inputs, so the layer is GPU compatible.

Check Output Layer Validity

Create an instance of the layer.

```
layer = dicePixelClassificationLayer('dice');
```

Check the layer validity of the layer using `checkLayer`. Specify the valid input size to be the size of a single observation of typical input to the layer. The layer expects a H-by-W-by-K-by-N array inputs, where K is the number of classes and N is the number of observations in the mini-batch.

```
numClasses = 2;
validInputSize = [4 4 numClasses];
checkLayer(layer,validInputSize, 'ObservationDimension',4)
```

```
Running nnet.checklayer.OutputLayerTestCase
.....
Done nnet.checklayer.OutputLayerTestCase
```

```
-----
Test Summary:
    17 Passed, 0 Failed, 0 Incomplete, 0 Skipped.
    Time elapsed: 1.6227 seconds.
```

The test summary reports the number of passed, failed, incomplete, and skipped tests.

Use Custom Layer in Semantic Segmentation Network

Create a semantic segmentation network that uses the `dicePixelClassificationLayer`.

```
layers = [
    imageInputLayer([32 32 1])
    convolution2dLayer(3,64,'Padding',1)
    reluLayer
    maxPooling2dLayer(2,'Stride',2)
    convolution2dLayer(3,64,'Padding',1)
    reluLayer
    transposedConv2dLayer(4,64,'Stride',2,'Cropping',1)
    convolution2dLayer(1,2)
    softmaxLayer
    dicePixelClassificationLayer('dice')]
```

```
layers =
    10x1 Layer array with layers:
```

1	''	Image Input	32x32x1 images with 'zerocenter' normalizat
2	''	Convolution	64 3x3 convolutions with stride [1 1] and p
3	''	ReLU	ReLU
4	''	Max Pooling	2x2 max pooling with stride [2 2] and padd
5	''	Convolution	64 3x3 convolutions with stride [1 1] and p

```

6 '' ReLU ReLU
7 '' Transposed Convolution 64 4x4 transposed convolutions with stride
8 '' Convolution 2 1x1 convolutions with stride [1 1] and pa
9 '' Softmax softmax
10 'dice' Classification Output Dice loss

```

Load training data for semantic segmentation using `imageDatastore` and `pixelLabelDatastore`.

```

dataSetDir = fullfile(toolboxdir('vision'),'visiondata','triangleImages');
imageDir = fullfile(dataSetDir,'trainingImages');
labelDir = fullfile(dataSetDir,'trainingLabels');

```

```
imds = imageDatastore(imageDir);
```

```

classNames = ["triangle" "background"];
labelIDs = [255 0];
pxds = pixelLabelDatastore(labelDir, classNames, labelIDs);

```

Associate the image and pixel label data using `pixelLabelImageDatastore`.

```
ds = pixelLabelImageDatastore(imds,pxds);
```

Set the training options and train the network.

```

options = trainingOptions('sgdm', ...
    'InitialLearnRate',1e-2, ...
    'MaxEpochs',100, ...
    'LearnRateDropFactor',1e-1, ...
    'LearnRateDropPeriod',50, ...
    'LearnRateSchedule','piecewise', ...
    'MiniBatchSize',128);

```

```
net = trainNetwork(ds, layers, options);
```

Training on single GPU.

Initializing image normalization.

Epoch	Iteration	Time Elapsed (hh:mm:ss)	Mini-batch Accuracy	Mini-batch Loss	Base Learning Rate
1	1	00:00:03	27.89%	0.8346	0.01
50	50	00:00:34	89.67%	0.6384	0.01
100	100	00:01:09	94.35%	0.5024	0.00

Evaluate the trained network by segmenting a test image and displaying the segmentation result.

```
I = imread('triangleTest.jpg');  
[C,scores] = semanticseg(I,net);  
B = labeloverlay(I,C);  
figure  
imshow(imtile({I,B}))
```

Track a Face in Scene

Create System objects for reading and displaying video and for drawing a bounding box of the object.

```
videoFileReader = vision.VideoFileReader('visionface.avi');  
videoPlayer = vision.VideoPlayer('Position',[100,100,680,520]);
```

Read the first video frame, which contains the object, define the region.

```
objectFrame = videoFileReader();  
objectRegion = [264,122,93,93];
```

As an alternative, you can use the following commands to select the object region using a mouse. The object must occupy the majority of the region:

```
figure; imshow(objectFrame);  
  
objectRegion=round(getPosition(imrect))
```

Show initial frame with a red bounding box.

```
objectImage = insertShape(objectFrame,'Rectangle',objectRegion,'Color','red');  
figure;  
imshow(objectImage);  
title('Red box shows object region');
```

Red box shows object region

Detect interest points in the object region.

```
points = detectMinEigenFeatures(rgb2gray(objectFrame), 'ROI', objectRegion);
```

Display the detected points.

```
pointImage = insertMarker(objectFrame, points.Location, '+', 'Color', 'white');  
figure;  
imshow(pointImage);  
title('Detected interest points');
```

Detected interest points

Create a tracker object.

```
tracker = vision.PointTracker('MaxBidirectionalError',1);
```

Initialize the tracker.

```
initialize(tracker,points.Location,objectFrame);
```

Read, track, display points, and results in each video frame.

```
while ~isDone(videoFileReader)  
    frame = videoFileReader();  
    [points,validity] = tracker(frame);  
    out = insertMarker(frame,points(validity, :),'+');
```

1 Featured Examples

```
    videoPlayer(out);  
end
```

Release the video reader and player.

```
release(videoPlayer);  
release(videoFileReader);
```

Create 3-D Stereo Display

Load parameters for a calibrated stereo pair of cameras.

```
load('webcamsSceneReconstruction.mat')
```

Load a stereo pair of images.

```
I1 = imread('sceneReconstructionLeft.jpg');  
I2 = imread('sceneReconstructionRight.jpg');
```

Rectify the stereo images.

```
[J1, J2] = rectifyStereoImages(I1, I2, stereoParams);
```

Create the anaglyph.

```
A = stereoAnaglyph(J1, J2);
```

Display the anaglyph. Use red-blue stereo glasses to see the stereo effect.

```
figure; imshow(A);
```

Measure Distance from Stereo Camera to a Face

Load stereo parameters.

```
load('webcamsSceneReconstruction.mat');
```

Read in the stereo pair of images.

```
I1 = imread('sceneReconstructionLeft.jpg');  
I2 = imread('sceneReconstructionRight.jpg');
```

Undistort the images.

```
I1 = undistortImage(I1, stereoParams.CameraParameters1);  
I2 = undistortImage(I2, stereoParams.CameraParameters2);
```

Detect a face in both images.

```
faceDetector = vision.CascadeObjectDetector;  
face1 = faceDetector(I1);  
face2 = faceDetector(I2);
```

Find the center of the face.

```
center1 = face1(1:2) + face1(3:4)/2;  
center2 = face2(1:2) + face2(3:4)/2;
```

Compute the distance from camera 1 to the face.

```
point3d = triangulate(center1, center2, stereoParams);  
distanceInMeters = norm(point3d)/1000;
```

Display the detected face and distance.

```
distanceAsString = sprintf('%0.2f meters', distanceInMeters);  
I1 = insertObjectAnnotation(I1, 'rectangle', face1, distanceAsString, 'FontSize', 18);  
I2 = insertObjectAnnotation(I2, 'rectangle', face2, distanceAsString, 'FontSize', 18);  
I1 = insertShape(I1, 'FilledRectangle', face1);  
I2 = insertShape(I2, 'FilledRectangle', face2);  
  
imshowpair(I1, I2, 'montage');
```

Reconstruct 3-D Scene from Disparity Map

Load the stereo parameters.

```
load('webcamsSceneReconstruction.mat');
```

Read in the stereo pair of images.

```
I1 = imread('sceneReconstructionLeft.jpg');  
I2 = imread('sceneReconstructionRight.jpg');
```

Rectify the images.

```
[J1, J2] = rectifyStereoImages(I1,I2, stereoParams);
```

Display the images after rectification.

```
figure  
imshow(cat(3,J1(:,:,1),J2(:,:,2:3)),'InitialMagnification',50);
```

Compute the disparity.

```
disparityMap = disparitySGM(rgb2gray(J1),rgb2gray(J2));
figure
imshow(disparityMap,[0,64], 'InitialMagnification',50);
```

Reconstruct the 3-D world coordinates of points corresponding to each pixel from the disparity map.

```
xyzPoints = reconstructScene(disparityMap, stereoParams);
```

Segment out a person located between 3.2 and 3.7 meters away from the camera.

```
Z = xyzPoints(:,:,3);
mask = repmat(Z > 3200 & Z < 3700,[1,1,3]);
J1(~mask) = 0;
imshow(J1, 'InitialMagnification',50);
```

Visualize Stereo Pair of Camera Extrinsic Parameters

Specify calibration images.

```
imageDir = fullfile(toolboxdir('vision'),'visiondata', ...  
    'calibration','stereo');  
leftImages = imageDatastore(fullfile(imageDir,'left'));  
rightImages = imageDatastore(fullfile(imageDir,'right'));
```

Detect the checkerboards.

```
[imagePoints,boardSize] = detectCheckerboardPoints(...  
    leftImages.Files,rightImages.Files);
```

Specify world coordinates of checkerboard keypoints. Square size is in millimeters.

```
squareSize = 108;  
worldPoints = generateCheckerboardPoints(boardSize,squareSize);
```

Calibrate the stereo camera system. Both cameras have the same resolution.

```
I = readimage(leftImages,1);  
imageSize = [size(I, 1), size(I, 2)];  
cameraParams = estimateCameraParameters(imagePoints,worldPoints, ...  
    'ImageSize',imageSize);
```

Visualize pattern locations.

```
figure;  
showExtrinsics(cameraParams);
```

Visualize camera locations.

```
figure;  
showExtrinsics(cameraParams, 'patternCentric');
```

Remove Distortion from an Image Using the Camera Parameters Object

Use the camera calibration functions to remove distortion from an image. This example creates a `vision.cameraParameters` object manually, but in practice, you would use the `estimateCameraParameters` or the Camera Calibrator app to derive the object.

Create a `vision.cameraParameters` object manually.

```
IntrinsicMatrix = [715.2699 0 0; 0 711.5281 0; 565.6995 355.3466 1];  
radialDistortion = [-0.3361 0.0921];  
cameraParams = cameraParameters('IntrinsicMatrix',IntrinsicMatrix,'RadialDistortion',radialDistortion);
```

Remove distortion from the images.

```
I = imread(fullfile(matlabroot,'toolbox','vision','visiondata','calibration','mono','image1.png'));  
J = undistortImage(I,cameraParams);
```

Display the original and the undistorted images.

```
figure; imshowpair(imresize(I,0.5),imresize(J,0.5),'montage');  
title('Original Image (left) vs. Corrected Image (right)');
```

Point Cloud Processing

- “Point Cloud Registration Overview” on page 2-2
- “The PLY Format” on page 2-7

Point Cloud Registration Overview

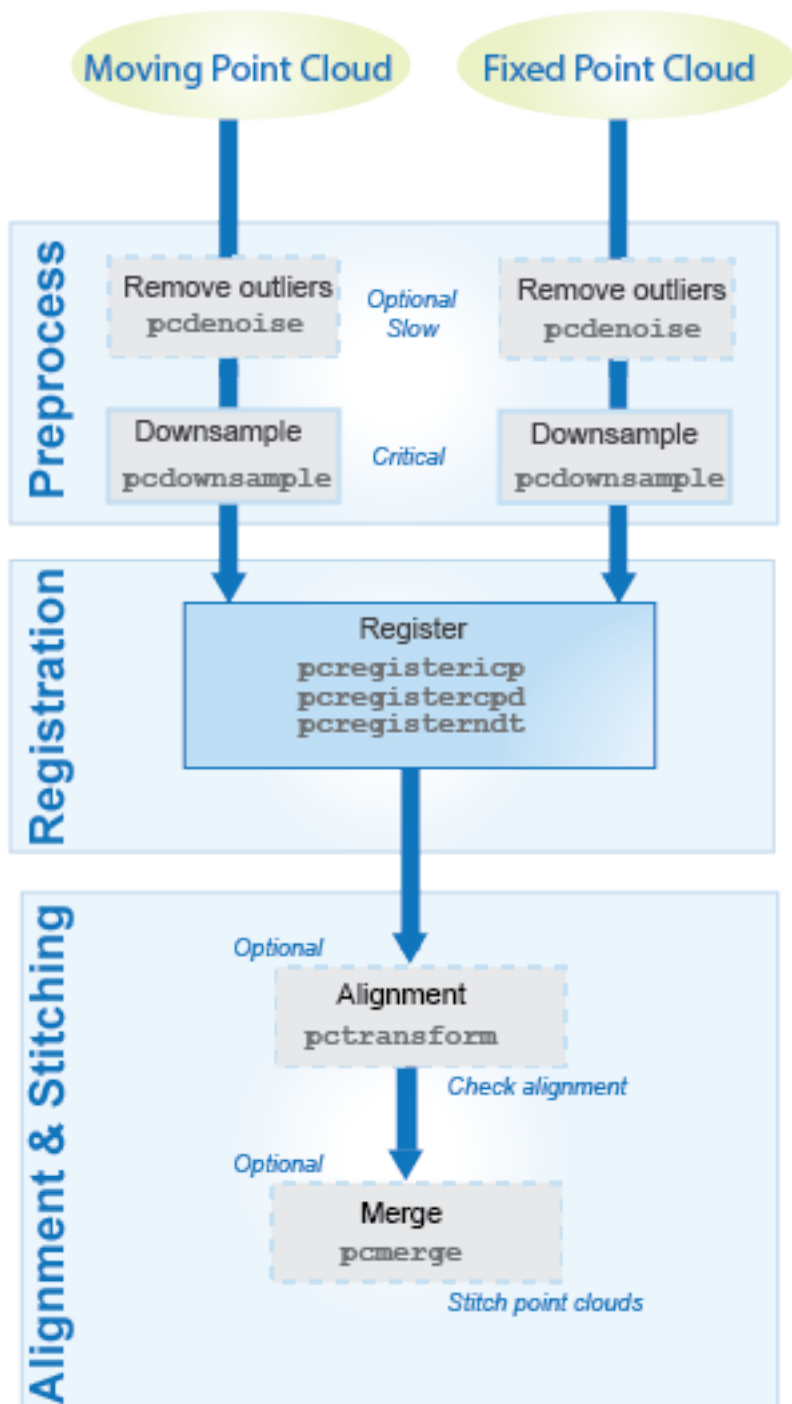

A point cloud is a set of points in 3-D space. Point clouds are typically obtained from 3-D scanners, such as a lidar or Kinect® device. They have applications in robot navigation and perception, depth estimation, stereo vision, visual registration, and in advanced driver assistance systems (ADAS). Computer Vision Toolbox algorithms provide functions that are integral to the point cloud registration workflow. The workflow includes the use of point cloud functions `pcmerge`, `pcdownsample`, `pctransform`, and `pcdenoise` and multiple registration functions `pcregistericp`, `pcregistercpd`, and `pcregisterndt`.

Point cloud registration is the process of aligning two or more 3-D point clouds of the same scene. For example, the process can include reconstructing a 3-D scene from a Kinect device, building a map of a roadway for automobiles, and deformable motion tracking.

Point Cloud Registration Process

The point cloud registration process includes these three steps.

- 1** Preprocessing — Remove noise or unwanted objects in each point cloud. Downsample the point clouds for a faster and more accurate registration.
- 2** Registration — Register two or more point clouds.
- 3** Alignment and stitching — Optionally stitch the point clouds by transforming and merging them.

Point Cloud Registration Methods

You can use the `pregistericp`, `pregistercpd`, or `pregisterndt` function to register a moving point cloud to a fixed point cloud. The registration algorithms used by these functions are based on the iterative closest point (ICP) algorithm, the coherent point drift (CPD) algorithm, and the normal-distributions transform (NDT) algorithm, respectively. For more information on these algorithms, see “References” on page 2-6.

When registering a point cloud you can choose the type of transformation that represents how objects in the scene change between point clouds.

Transformation	Description
Rigid	The rigid transformation preserves the shape and size of objects in the scene. Objects in the scene can undergo translations, rotations, or both. The same transformation is applied to all points.
Affine	The Affine transformation allows the objects to shear and change scale in addition to translations and rotations.
Non-rigid	The non-rigid transformation allows the shape of objects in the scene to change. Points are transformed differently. A displacement field is used to represent the transformation.

This table compares the point cloud registration function options, their transformation types, and their performance characteristics. Use this table to select the appropriate registration function based on your case..

Registration Method (function)	Transformation Type	Description	Performance Characteristics
<code>pcregisterndt</code>	Rigid	<ul style="list-style-type: none"> Local registration method that relies on an initial transform estimate Robust to outliers Better with point clouds of differing resolutions and densities 	Fast registration method, but generally slower than ICP
<code>pcregistericp</code>	Rigid	Local registration method that relies on an initial transform estimate	Fastest registration method
<code>pcregistercpd</code>	Rigid, affine, and non-rigid	Global method that does not rely on an initial transformation estimate	Slowest registration method

Tips

- To improve the accuracy and computation speed of registration, downsample the point clouds using the `pcdownsample` function before registration.
- Remove unnecessary features from the point cloud by using functions such as:
 - `segmentGroundFromLidarData` — Segment ground points from organized lidar data
 - `pcsegdist` — Segment point cloud into clusters based on Euclidean distance
 - `pcfitplane` — Fit plane to 3-D point cloud
 - `select` — Select points in a point cloud
- Local registration methods, such as those that use NDT or ICP (`pcregisterndt` or `pcregistericp`, respectively), require initial estimates. To obtain an initial estimate use another sensor, such as an inertial measurement unit (IMU) or other forms of odometry. Improving the initial estimate helps the registration algorithm converge faster.

- Increase the 'MaxIterations' property or decrease the 'Tolerance' property for more accurate registration results, but slower registration speeds.

The PLY Format

In this section...

"File Header" on page 2-7

"Data" on page 2-9

"Common Elements and Properties" on page 2-10

The version 1.0 PLY format, also known as the Stanford Triangle Format, defines a flexible and systematic scheme for storing 3D data. The ASCII header specifies what data is in the file by defining "elements" each with a set of "properties." Many PLY files only have vertex and face data, however, it is possible to also include other data such as color information, vertex normals, or application-specific properties.

Note The Computer Vision Toolbox point cloud data functions only support the (x,y,z) coordinates, normals, and color properties.

File Header

An example header (italicized text is comment):

```
ply                                     file ID
format binary_big_endian 1.0          specify data format and version
element vertex 9200                   define "vertex" element
property float x
property float y
property float z
element face 18000                    define "face" element
property list uchar int vertex_indices
end_header                             data starts after this line
```

The file begins with "ply," identifying that it is a PLY file. The header must also include a format line with the syntax

```
format <data format> <PLY version>
```

Supported data formats are "ascii" for data stored as text and "binary_little_endian" and "binary_big_endian" for binary data (where little/big endian refers to the byte ordering of multi-byte data). Element definitions begin with an "element" line followed by element property definitions

```
element <element name><number in file>
property <data type><property name 1>
property <data type><property name 2>
property <data type><property name 3>
...
```

For example, "element vertex 9200" defines an element "vertex" and specifies that 9200 vertices are stored in the file. Each element definition is followed by a list of properties of that element. There are two kinds of properties, scalar and list. A scalar property definition has the syntax

```
property <data type><property name>
```

where <data type> is

Name	Type
char	(8-bit) character
uchar	(8-bit) unsigned character
short	(16-bit) short integer
ushort	(16-bit) unsigned short integer
int	(32-bit) integer
uint	(32-bit) unsigned integer
float	(32-bit) single-precision float
double	(64-bit) double-precision float

For compatibility between systems, note that the number of bits in each data type must be consistent. A list type is stored with a count followed by a list of scalars. The definition syntax for a list property is

```
property list <count data type><data type><property name>
```

For example,

```
property list uchar int vertex_index
```

defines `vertex_index` properties are stored starting with a byte count followed by integer values. This is useful for storing polygon connectivity as it has the flexibility to specify a variable number of vertex indices in each face.

The header can also include comments. The syntax for a comment is simply a line beginning with "comment" followed by a one-line comment:

```
comment<comment text>
```

Comments can provide information about the data like the file's author, data description, data source, and other textual data.

Data

Following the header, the element data is stored as either ASCII or binary data (as specified by the format line in the header). After the header, the data is stored in the order the elements and properties were defined. First, all the data for the first element type is stored. In the example header, the first element type is "vertex" with 9200 vertices in the file, and with float properties "x," "y," and "z."

float vertex[1].x
float vertex[1].y
float vertex[1].z
float vertex[2].x
float vertex[2].y
float vertex[2].z
...
float vertex[9200].x
float vertex[9200].y
float vertex[9200].z

In general, the properties data for each element is stored one element at a time.

```
<property 1><property 2> ... <property N> element[1]
```

<property 1><property 2> ... <property N> element[2]
--

...

The list type properties are stored beginning with a count and followed by a list of scalars. For example, the "face" element type has the list property "vertex_indices" with uchar count and int scalar type.

uchar count

int face[1].vertex_indices[1]

int face[1].vertex_indices[2]

int face[1].vertex_indices[3]

...

int face[1].vertex_indices[count]

uchar count

int face[2].vertex_indices[1]

int face[2].vertex_indices[2]

int face[2].vertex_indices[3]

...

int face[2].vertex_indices[count]

...

Common Elements and Properties

While the PLY format has the flexibility to define many types of elements and properties, a common set of elements are understood between programs to communicate common 3-D data types. Turk suggests elements and property names that programs should try to make standard.

Required Core Property	Element	Property	Data Type	Property Description
✓	vertex	x	float	x,y,z coordinates
✓		y	float	
✓		z	float	
		nx	float	x,y,z of normal
		ny	float	
		nz	float	
		red	uchar	vertex color
		green	uchar	
		blue	uchar	
		alpha	uchar	amount of transparency
		material_index	int	index to list of materials
	face	vertex_indices	list of int	indices to vertices
		back_red	uchar	backside color
		back_green	uchar	
		back_blue	uchar	
	edge	vertex1	int	index to vertex
		vertex2	int	index to other vertex
		crease_tag	uchar	crease in subdivision surface
	material	red	uchar	material color
		green	uchar	
		blue	uchar	
		alpha	uchar	amount of transparency
		reflect_coeff	float	amount of light reflected

Required Core Property	Element	Property	Data Type	Property Description
		refract_coeff	float	amount of light refracted
		refract_index	float	index of refraction
		extinct_coeff	float	extinction coefficient

Using the Installer for Computer Vision System Toolbox Product

- “Install Computer Vision Toolbox Add-on Support Files” on page 3-2
- “Install OCR Language Data Files” on page 3-3
- “Install and Use Computer Vision Toolbox OpenCV Interface” on page 3-7

Install Computer Vision Toolbox Add-on Support Files

After you install third-party support files, you can use the data with the Computer Vision Toolbox product. To install the Add-on support files, use one of the following methods:

-  **Get Support Package Now**
- Select **Get Add-ons** from the **Add-ons** drop-down menu from the MATLAB® desktop. The Add-on files are in the “MathWorks Features” section.
- Type `visionSupportPackages` in a MATLAB Command Window and follow the prompts.

Note You must have write privileges for the installation folder.

When a new version of MATLAB software is released, repeat this process to check for updates. You can also check for updates between releases.

Install OCR Language Data Files

In this section...

“Installation” on page 3-3

“Pretrained Language Data and the ocr function” on page 3-3

OCR Language Data files contain pretrained language data from the OCR Engine, tesseract-ocr, to use with the `ocr` function.

Installation

After you install third-party support files, you can use the data with the Computer Vision Toolbox product. To install the Add-on support files, use one of the following methods:

-  **Get Support Package Now**
- Select **Get Add-ons** from the **Add-ons** drop-down menu from the MATLAB desktop. The Add-on files are in the “MathWorks Features” section.
- Type `visionSupportPackages` in a MATLAB Command Window and follow the prompts.

Note You must have write privileges for the installation folder.

When a new version of MATLAB software is released, repeat this process to check for updates. You can also check for updates between releases.

Pretrained Language Data and the ocr function

After you install the pretrained language data files, you can specify one or more additional languages using the `Language` property of the `ocr` function. Use the appropriate language character vector with the property.

```
txt = ocr(img,'Language','Finnish');
```

List of OCR language data in support package

- 'Afrikaans'

Install and Use Computer Vision Toolbox OpenCV Interface

Use the OpenCV Interface files to integrate your OpenCV C++ code into MATLAB and build MEX-files that call OpenCV functions. The support package also contains graphics processing unit (GPU) support.

In this section...

“Installation” on page 3-7

“Support Package Contents” on page 3-8

“Create MEX-File from OpenCV C++ file” on page 3-8

“Use the OpenCV Interface C++ API” on page 3-9

“Create Your Own OpenCV MEX-files” on page 3-10

“Run OpenCV Examples” on page 3-10

Installation

After you install third-party support files, you can use the data with the Computer Vision Toolbox product. To install the Add-on support files, use one of the following methods:

-  **Get Support Package Now**
- Select **Get Add-ons** from the **Add-ons** drop-down menu from the MATLAB desktop. The Add-on files are in the “MathWorks Features” section.
- Type `visionSupportPackages` in a MATLAB Command Window and follow the prompts.

Note You must have write privileges for the installation folder.

When a new version of MATLAB software is released, repeat this process to check for updates. You can also check for updates between releases.

Support Package Contents

The OpenCV Interface support files are installed in the `visionopencv` folder. To find the path to this folder, type the following command:

```
fileparts(which('mexOpenCV'))
```

The `visionopencv` folder contain these files and folder.

Files	Contents
example folder	Template Matching, Foreground Detector, and Oriented FAST and Rotated BRIEF (ORB) examples, including a GPU version. Each subfolder in the example folder contains a <code>README.txt</code> file with step-by-step instructions.
registry folder	Registration files.
mexOpenCV.m file	Function to build MEX-files.
README.txt file	Help file.

The `mex` function uses prebuilt OpenCV libraries, which ship with the Computer Vision Toolbox product. Your compiler must be compatible with the one used to build the libraries. The following compilers are used to build the OpenCV libraries for MATLAB host:

Operating System	Compatible Compiler
Windows® 64 bit	Microsoft® Visual Studio® 2015 Professional or Visual Studio 2017
Linux® 64 bit	gcc-4.9.3 (g++)
Mac 64 bit	Xcode 6.2.0 (Clang++)

Create MEX-File from OpenCV C++ file

This example creates a MEX-file from a wrapper C++ file and then tests the newly created file. The example uses the OpenCV template matching algorithm wrapped in a C++ file, which is located in the `example/TemplateMatching` folder.

- 1 Change your current working folder to the example/TemplateMatching folder:

```
cd(fullfile(fileparts(which('mexOpenCV')), 'example', filesep, 'TemplateMatching'))
```
- 2 Create the MEX-file from the source file:

```
mexOpenCV matchTemplate0CV.cpp
```
- 3 Run the test script, which uses the generated MEX-file:

```
testMatchTemplate
```

Use the OpenCV Interface C++ API

The `mexOpenCV` interface utility functions convert data between OpenCV and MATLAB. These functions support CPP-linkage only. GPU support is available on `glnxa64`, `win64`, and Mac platforms. The GPU-specific utility functions support CUDA enabled NVIDIA GPU with compute capability 2.0 or higher. See the Parallel Computing Toolbox™ System Requirements, The GPU utility functions require the Parallel Computing Toolbox software.

Function	Description
<code>ocvCheckFeaturePointsStruct</code>	Check that MATLAB struct represents feature points
<code>ocvStructToKeyPoints</code>	Convert MATLAB feature points struct to OpenCV <code>KeyPoint</code> vector
<code>ocvKeyPointsToStruct</code>	Convert OpenCV <code>KeyPoint</code> vector to MATLAB struct
<code>ocvMxArrayToCvRect</code>	Convert a MATLAB struct representing a rectangle to an OpenCV <code>CvRect</code>
<code>ocvCvRectToMxArray</code>	Convert OpenCV <code>CvRect</code> to a MATLAB struct
<code>ocvCvBox2DToMxArray</code>	Convert OpenCV <code>CvBox2D</code> to a MATLAB struct
<code>ocvCvRectToBoundingBox_{DataType}</code>	Convert <code>vector<cv::Rect></code> to <i>M</i> -by-4 <code>mxAarray</code> of bounding boxes
<code>ocvMxArrayToSize_{DataType}</code>	Convert 2-element <code>mxAarray</code> to <code>cv::Size</code>
<code>ocvMxArrayToImage_{DataType}</code>	Convert column major <code>mxAarray</code> to row major <code>cv::Mat</code> for image
<code>ocvMxArrayToMat_{DataType}</code>	Convert column major <code>mxAarray</code> to row major <code>cv::Mat</code> for generic matrix

Function	Description
<code>ocvMxArrayFromImage_{DataType}</code>	Convert row major <code>cv::Mat</code> to column major <code>mxArray</code> for image
<code>ocvMxArrayFromMat_{DataType}</code>	Convert row major <code>cv::Mat</code> to column major <code>mxArray</code> for generic matrix.
<code>ocvMxArrayFromVector</code>	Convert numeric <code>vectorT</code> to <code>mxArray</code>
<code>ocvMxArrayFromPoints2f</code>	Converts <code>vector<cv::Point2f></code> to <code>mxArray</code>

GPU Function	Description
<code>ocvMxGpuArrayToGpuMat_{DataType}</code>	Create <code>cv::gpu::GpuMat</code> from <code>gpuArray</code>
<code>ocvMxGpuArrayFromGpuMat_{DataType}</code>	Create <code>gpuArray</code> from <code>cv::gpu::GpuMat</code>

Create Your Own OpenCV MEX-files

Call the `mxArray` function with your source file.

```
mexOpenCV yourfile.cpp
```

For help creating MEX files, at the MATLAB command prompt, type:

```
help mexOpenCV
```

Run OpenCV Examples

Each example subfolder in the OpenCV Interface support package contains all the files you need to run the example. To run an example, you must call the `mexOpenCV` function with one of the supplied source files.

Run Template Matching Example

- 1 Change your current working folder to the `example/TemplateMatching` folder:

```
cd(fullfile(fileparts(which('mexOpenCV')), 'example', filesep, 'TemplateMatching'))
```
- 2 Create the MEX-file from the source file:

```
mexOpenCV matchTemplate0CV.cpp
```
- 3 Run the test script, which uses the generated MEX-file:

```
testMatchTemplate
```

Run Foreground Detector Example

- 1 Change your current working folder to the example/ForegroundDetector folder:

```
cd(fullfile(fileparts(which('mexOpenCV')),'example',filesep,'ForegroundDetector'))
```

- 2 Create the MEX-file from the source file:

```
mexOpenCV backgroundSubtractorOCV.cpp
```

- 3 Run the test script that uses the generated MEX-file:

```
testBackgroundSubtractor.m
```

Run Oriented FAST and Rotated BRIEF (ORB) Detector Example

- 1 Change your current working folder to the example/ORB folder:

```
cd(fullfile(fileparts(which('mexOpenCV')),'example',filesep,'ORB'))
```

- 2 Create the MEX-file for the detector from the source file:

```
mexOpenCV detectORBFeaturesOCV.cpp
```

- 3 Create the MEX-file for the extractor from the source file:

```
mexOpenCV extractORBFeaturesOCV.cpp
```

- 4 Run the test script, which uses the generated MEX-files:

```
testORBFeaturesOCV.m
```

Run Detect ORB Features (GPU Version) Example

- 1 Change your current working folder to the example/ORB_GPU folder:

```
cd(fullfile(fileparts(which('mexOpenCV')),'example',filesep,'ORB_GPU'))
```

- 2 Create the MEX-file for the detector from the source file.

PC:

```
mexOpenCV detectORBFeaturesOCV_GPU.cpp -lgpu -lmwocvcpumex -largeArrayDims
```

Linux/Mac:

```
mexOpenCV detectORBFeaturesOCV_GPU.cpp -lmwgpu -lmwocvcpumex -largeArrayDims
```

- 3 Run the test script, which uses the generated MEX-file:

testORBFeatures0CV_GPU.m

Input, Output, and Conversions

Learn how to import and export videos, and perform color space and video image conversions.

- “Export to Video Files” on page 4-2
- “Import from Video Files” on page 4-4
- “Batch Process Image Files” on page 4-6
- “Convert R'G'B' to Intensity Images” on page 4-8
- “Process Multidimensional Color Video Signals” on page 4-12
- “Video Formats” on page 4-15
- “Image Formats” on page 4-17

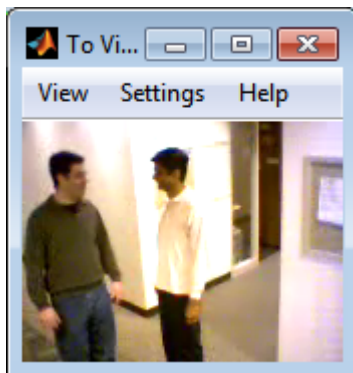

Export to Video Files

The Computer Vision Toolbox blocks enable you to export video data from your Simulink® model. In this example, you use the To Multimedia File block to export a multimedia file from your model. This example also uses Gain blocks from the **Math Operations** Simulink library.

You can open the example model by typing at the MATLAB command line.

```
ex_export_to_mmf
```

- 1 Run your model.
- 2 You can view your video in the To Video Display window.

By increasing the red, green, and blue color values, you increase the contrast of the video. The To Multimedia File block exports the video data from the Simulink model to a multimedia file that it creates in your current folder.

This example manipulated the video stream and exported it from a Simulink model to a multimedia file. For more information, see the To Multimedia File block reference page.

Setting Block Parameters for this Example

The block parameters in this example were modified from default values as follows:

Block	Parameter
Gain	<p>The Gain blocks are used to increase the red, green, and blue values of the video stream. This increases the contrast of the video:</p> <ul style="list-style-type: none"> • Main pane, Gain = 1.2 • Signal Attributes pane, Output data type = Inherit: Same as input
To Multimedia File	<p>The To Multimedia File block exports the video to a multimedia file:</p> <ul style="list-style-type: none"> • File name = my_output.avi • Write = Video only • Image signal = Separate color signals

Configuration Parameters

You can locate the **Model Configuration Parameters** by selecting **Model Configuration Parameters** from the **Simulation** menu. For this example, the parameters on the **Solver** pane, are set as follows:

- **Stop time** = 20
- **Type** = Fixed-step
- **Solver** = Discrete (no continuous states)

Import from Video Files

In this example, you use the From Multimedia File source block to import a video stream into a Simulink model and the To Video Display sink block to view it. This procedure assumes you are working on a Windows platform.

You can open the example model by typing at the MATLAB command line.

```
ex_import_mmf
```

- 1 Run your model.
- 2 View your video in the To Video Display window that automatically appears when you start your simulation.

You have now imported and displayed a multimedia file in the Simulink model. In the "Export to Video Files" on page 4-2 example you can manipulate your video stream and export it to a multimedia file.

For more information on the blocks used in this example, see the From Multimedia File and To Video Display block reference pages.

Setting Block Parameters for this Example

The block parameters in this example were modified from default values as follows:

Block	Parameter
From Multimedia File	<p>Use the From Multimedia File block to import the multimedia file into the model:</p> <ul style="list-style-type: none"> • If you do not have your own multimedia file, use the default <code>vipmen.avi</code> file, for the File name parameter. • If the multimedia file is on your MATLAB path, enter the filename for the File name parameter. • If the file is not on your MATLAB path, use the Browse button to locate the multimedia file. • Set the Image signal parameter to <code>Separate color signals</code>. <p>By default, the Number of times to play file parameter is set to <code>inf</code>. The model continues to play the file until the simulation stops.</p>
To Video Display	<p>Use the To Video Display block to view the multimedia file.</p> <ul style="list-style-type: none"> • Image signal: <code>Separate color signals</code> <p>Set this parameter from the Settings menu of the display viewer.</p>

Configuration Parameters

You can locate the **Model Configuration Parameters** by selecting **Model Configuration Parameters** from the **Simulation** menu. For this example, the parameters on the **Solver** pane, are set as follows:

- **Stop time** = 20
- **Type** = Fixed-step
- **Solver** = Discrete (no continuous states)

Batch Process Image Files

A common image processing task is to apply an image processing algorithm to a series of files. In this example, you import a sequence of images from a folder into the MATLAB workspace.

Note In this example, the image files are a set of 10 microscope images of rat prostate cancer cells. These files are only the first 10 of 100 images acquired.

- 1 Specify the folder containing the images, and use this information to create a list of the file names, as follows:

```
fileFolder = fullfile(matlabroot, 'toolbox', 'images', 'imdata');  
dirOutput = dir(fullfile(fileFolder, 'AT3_lm4_*.tif'));  
fileNames = {dirOutput.name}'
```

- 2 View one of the images, using the following command sequence:

```
I = imread(fileNames{1});  
imshow(I);  
text(size(I,2),size(I,1)+15, ...  
      'Image files courtesy of Alan Partin', ...  
      'FontSize',7,'HorizontalAlignment','right');  
text(size(I,2),size(I,1)+25, ...  
      'Johns Hopkins University', ...  
      'FontSize',7,'HorizontalAlignment','right');
```

- 3 Use a for loop to create a variable that stores the entire image sequence. You can use this variable to import the sequence into Simulink.

```
for i = 1:length(fileNames)  
    my_video(:,:,i) = imread(fileNames{i});  
end
```

For additional information about batch processing, see the “Image Sequences and Batch Processing” (Image Processing Toolbox) section for the Image Processing Toolbox™.

Configuration Parameters

You can locate the **Model Configuration Parameters** by selecting **Model Configuration Parameters** from the **Simulation** menu. For this example, the parameters on the **Solver** pane, are set as follows:

- **Stop time** = 10
- **Type** = Fixed-step
- **Solver** = Discrete (no continuous states)

Convert R'G'B' to Intensity Images

The Color Space Conversion block enables you to convert color information from the R'G'B' color space to the Y'CbCr color space and from the Y'CbCr color space to the R'G'B' color space as specified by Recommendation ITU-R BT.601-5. This block can also be used to convert from the R'G'B' color space to intensity. The prime notation indicates that the signals are gamma corrected.

Some image processing algorithms are customized for intensity images. If you want to use one of these algorithms, you must first convert your image to intensity. In this topic, you learn how to use the Color Space Conversion block to accomplish this task. You can use this procedure to convert any R'G'B' image to an intensity image:

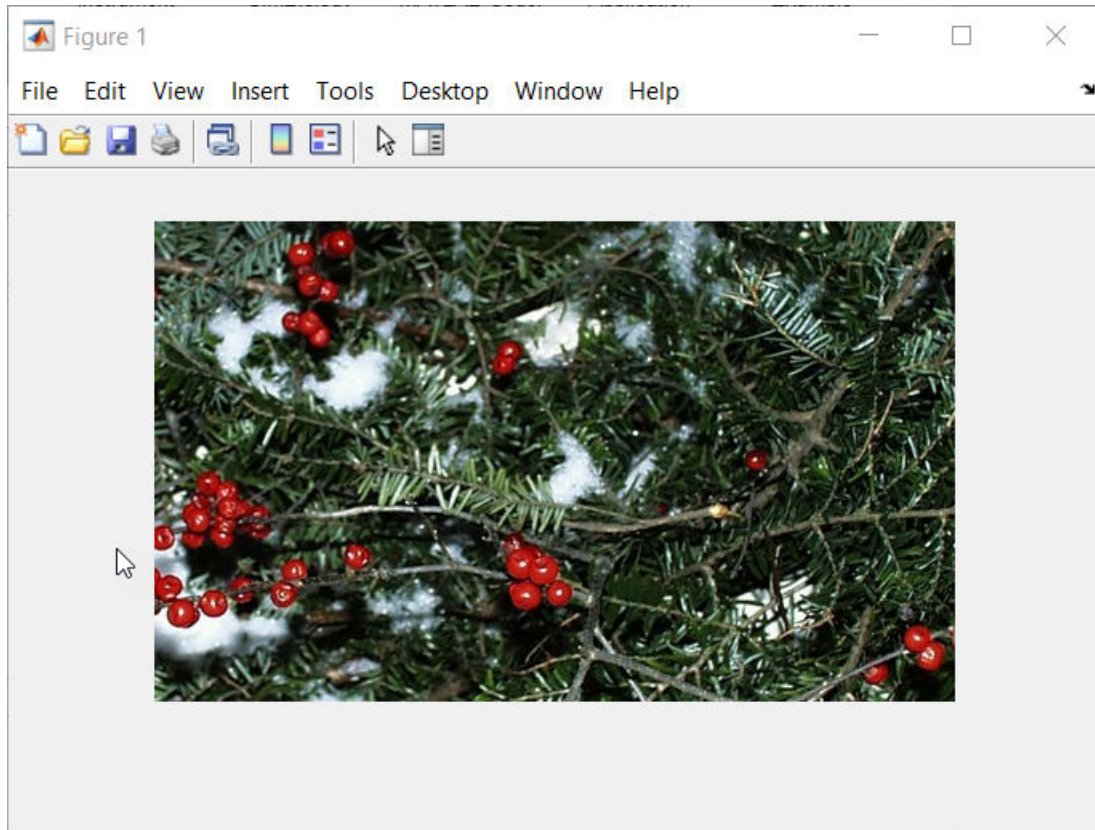

`ex_vision_convert_rgb`

- 1 Define an R'G'B' image in the MATLAB workspace. To read in an R'G'B' image from a JPG file, at the MATLAB command prompt, type

```
I = imread('greens.jpg');
```

I is a 300-by-500-by-3 array of 8-bit unsigned integer values. Each plane of this array represents the red, green, or blue color values of the image.

- 2 To view the image this matrix represents, at the MATLAB command prompt, type
`imshow(I)`

- 3 Create a new Simulink model, and add to it the blocks shown in the following table.

Block	Library	Number of Blocks
Image From Workspace	Computer Vision Toolbox > Sources	1
Color Space Conversion	Computer Vision Toolbox > Conversions	1
Video Viewer	Computer Vision Toolbox > Sinks	2

- 4 Use the Image from Workspace block to import your image from the MATLAB workspace. Set the **Value** parameter to **I**.
- 5 Use the Color Space Conversion block to convert the input values from the R'G'B' color space to intensity. Set the **Conversion** parameter to R'G'B' to intensity.

- 6 View the modified image using the Video Viewer block. View the original image using the Video Viewer1 block. Accept the default parameters.
- 7 Connect the blocks so that your model is similar to the following figure.

- 8 Set the configuration parameters. Open the Configuration dialog box by selecting **Model Settings** from the **Setup** menu on the **Modeling** tab. Set the parameters as follows:
 - **Solver** pane, **Stop time** = 0
 - **Solver** pane, **Type** = Fixed-step
 - **Solver** pane, **Solver** = Discrete (no continuous states)
- 9 Run your model.

The image displayed in the Video Viewer window is the intensity version of the greens .jpg image.

Process Multidimensional Color Video Signals

The Computer Vision Toolbox software enables you to work with color images and video signals as multidimensional arrays. For example, the following model passes a color image from a source block to a sink block using a 384-by-512-by-3 array.

`ex_vision_process_multidimensional`

You can choose to process the image as a multidimensional array by setting the **Image signal** parameter to `One multidimensional signal` in the Image From File block dialog box.

The blocks that support multidimensional arrays meet at least one of the following criteria:

- They have the **Image signal** parameter on their block mask.
- They have a note in their block reference pages that says, “This block supports intensity and color images on its ports.”
- Their input and output ports are labeled “Image”.

You can also choose to work with the individual color planes of images or video signals. For example, the following model passes a color image from a source block to a sink block using three separate color planes.

```
ex_vision_process_individual
```

To process the individual color planes of an image or video signal, set the **Image signal** parameter to **Separate color signals** in both the Image From File and Video Viewer block dialog boxes.

Note The ability to output separate color signals is a legacy option. It is recommend that you use multidimensional signals to represent color data.

If you are working with a block that only outputs multidimensional arrays, you can use the Selector block to separate the color planes. If you are working with a block that only accepts multidimensional arrays, you can use the Matrix Concatenation block to create a multidimensional array.

Video Formats

Defining Intensity and Color

Video data is a series of images over time. Video in binary or intensity format is a series of single images. Video in RGB format is a series of matrices grouped into sets of three, where each matrix represents an R, G, or B plane.

The values in a binary, intensity, or RGB image can be different data types. The data type of the image values determines which values correspond to black and white as well as the absence or saturation of color. The following table summarizes the interpretation of the upper and lower bound of each data type. To view the data types of the signals at each port, from the **Display** menu, point to **Signals & Ports**, and select **Port Data Types**.

Data Type	Black or Absence of Color	White or Saturation of Color
Fixed point	Minimum data type value	Maximum data type value
Floating point	0	1

Note The Computer Vision Toolbox software considers any data type other than double-precision floating point and single-precision floating point to be fixed point.

For example, for an intensity image whose image values are 8-bit unsigned integers, 0 is black and 255 is white. For an intensity image whose image values are double-precision floating point, 0 is black and 1 is white. For an intensity image whose image values are 16-bit signed integers, -32768 is black and 32767 is white.

For an RGB image whose image values are 8-bit unsigned integers, 0 0 0 is black, 255 255 255 is white, 255 0 0 is red, 0 255 0 is green, and 0 0 255 is blue. For an RGB image whose image values are double-precision floating point, 0 0 0 is black, 1 1 1 is white, 1 0 0 is red, 0 1 0 is green, and 0 0 1 is blue. For an RGB image whose image values are 16-bit signed integers, -32768 -32768 -32768 is black, 32767 32767 32767 is white, 32767 -32768 -32768 is red, -32768 32767 -32768 is green, and -32768 -32768 32767 is blue.

Video Data Stored in Column-Major Format

The MATLAB technical computing software and Computer Vision Toolbox blocks use column-major data organization. The blocks' data buffers store data elements from the first column first, then data elements from the second column second, and so on through the last column.

If you have imported an image or a video stream into the MATLAB workspace using a function from the MATLAB environment or the Image Processing Toolbox, the Computer Vision Toolbox blocks will display this image or video stream correctly. If you have written your own function or code to import images into the MATLAB environment, you must take the column-major convention into account.

Image Formats

In the Computer Vision Toolbox software, images are real-valued ordered sets of color or intensity data. The blocks interpret input matrices as images, where each element of the matrix corresponds to a single pixel in the displayed image. Images can be binary, intensity (grayscale), or RGB. This section explains how to represent these types of images.

Binary Images

Binary images are represented by a Boolean matrix of 0s and 1s, which correspond to black and white pixels, respectively.

For more information, see “Binary Images” (Image Processing Toolbox).

Intensity Images

Intensity images are represented by a matrix of intensity values. While intensity images are not stored with colormaps, you can use a gray colormap to display them.

For more information, see “Grayscale Images” (Image Processing Toolbox).

RGB Images

RGB images are also known as a true-color images. With Computer Vision Toolbox blocks, these images are represented by an array, where the first plane represents the red pixel intensities, the second plane represents the green pixel intensities, and the third plane represents the blue pixel intensities. In the Computer Vision Toolbox software, you can pass RGB images between blocks as three separate color planes or as one multidimensional array.

For more information, see “Truecolor Images” (Image Processing Toolbox).

Display and Graphics

Display, Stream, and Preview Videos

In this section...
“View Streaming Video in MATLAB” on page 5-2
“Preview Video in MATLAB” on page 5-2
“View Video in Simulink” on page 5-3

View Streaming Video in MATLAB

Basic Video Streaming

Use the video player `vision.VideoPlayer` System object when you require a simple video display in MATLAB for streaming video.

Code Generation Supported Video Streaming Object

Use the deployable video player `vision.DeployableVideoPlayer` System object as a basic display viewer designed for optimal performance. This object supports code generation on all platforms.

Preview Video in MATLAB

Use the Image Processing Toolbox `implay` function to view and represent videos as variables in the MATLAB workspace. It is a full featured video player with toolbar controls. The `implay` player enables you to view videos directly from files without having to load all the video data into memory at once.

You can open several instances of the `implay` function simultaneously to view multiple video data sources at once. You can also dock these `implay` players in the MATLAB desktop. Use the figure arrangement buttons in the upper-right corner of the Sinks window to control the placement of the docked players.

View Video in Simulink

Code Generation Supported Video Streaming Block

Use the To Video Display block in your Simulink model as a simple display viewer designed for optimal performance. This block supports code generation for the Windows platform.

Simulation Control and Video Analysis Block

Use the Video Viewer block when you require a wired-in video display with simulation controls in your Simulink model. The Video Viewer block provides simulation control buttons directly from the player interface. The block integrates play, pause, and step features while running the model and also provides video analysis tools such as pixel region viewer.

View Video Signals Without Adding Blocks

The `implay` function enables you to view video signals in Simulink models without adding blocks to your model. You can open several instances of the `implay` player simultaneously to view multiple video data sources at once. You can also dock these players in the MATLAB desktop. Use the figure arrangement buttons in the upper-right corner of the Sinks window to control the placement of the docked players.

Set Simulink simulation mode to Normal to use `implay`. `implay` does not work when you use “Accelerating Simulink Models” on page 13-10.

Example 5.1. Use `implay` to view a Simulink signal:

- 1 Open a Simulink model.
- 2 Open an `implay` player by typing `implay` on the MATLAB command line.
- 3 Run the Simulink model.
- 4 Select the signal line you want to view.
- 5 On the `implay` toolbar, select **File > Connect to Simulink Signal** .

The video appears in the player window.

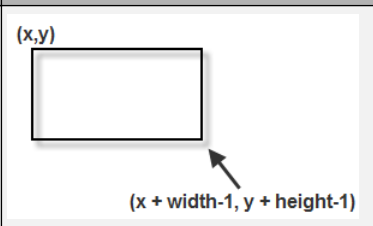

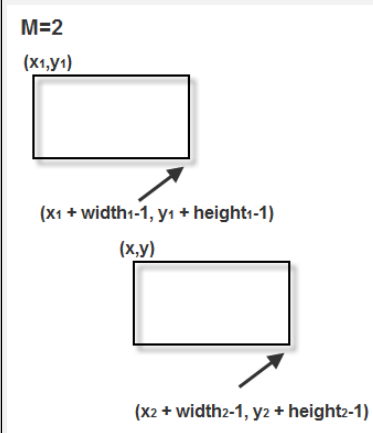

- 6 You can use multiple `implay` players to display different Simulink signals.

Note During code generation, the Simulink Coder™ does not generate code for the `implay` player.

Draw Shapes and Lines

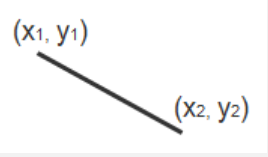

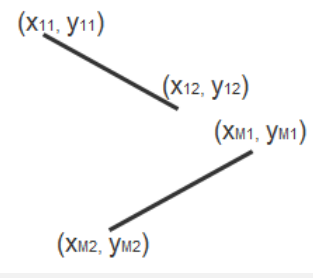

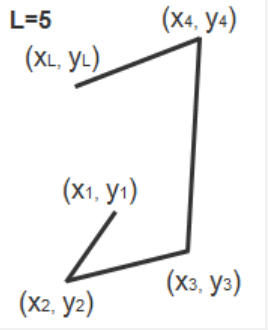

When you specify the type of shape to draw, you must also specify it's location on the image. The table shows the format for the points input for the different shapes.

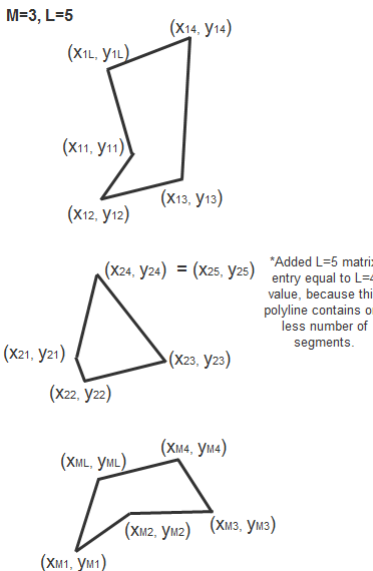

Rectangle

Shape	PTS input	Drawn Shape
Single Rectangle	<p>Four-element row vector $[x \ y \ width \ height]$ where</p> <ul style="list-style-type: none"> x and y are the one-based coordinates of the upper-left corner of the rectangle. $width$ and $height$ are the width, in pixels, and height, in pixels, of the rectangle. The values of $width$ and $height$ must be greater than 0. 	 <p>The diagram shows a single rectangle. An arrow points to the top-left corner, labeled (x,y). Another arrow points to the bottom-right corner, labeled $(x + width-1, y + height-1)$.</p>
M Rectangles	<p>M-by-4 matrix</p> $\begin{bmatrix} x_1 & y_1 & width_1 & height_1 \\ x_2 & y_2 & width_2 & height_2 \\ \vdots & \vdots & \vdots & \vdots \\ x_M & y_M & width_M & height_M \end{bmatrix}$ <p>where each row of the matrix corresponds to a different rectangle and is of the same form as the vector for a single rectangle.</p>	 <p>The diagram shows two rectangles. The first rectangle has its top-left corner labeled (x_1, y_1) and its bottom-right corner labeled $(x_1 + width_1 - 1, y_1 + height_1 - 1)$. The second rectangle has its top-left corner labeled (x, y) and its bottom-right corner labeled $(x_2 + width_2 - 1, y_2 + height_2 - 1)$. The text $M=2$ is written above the first rectangle.</p>

Line and Polyline

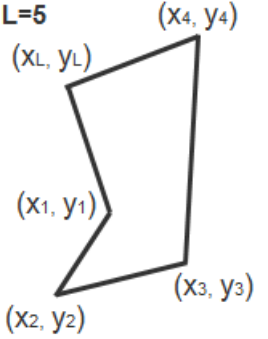

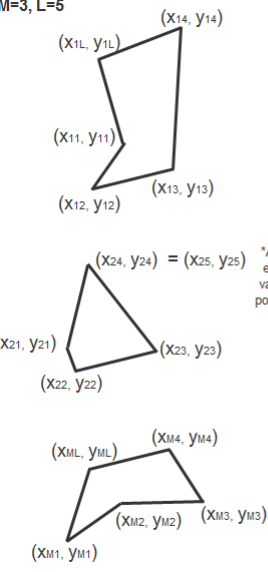

You can draw one or more lines, and one or more polylines. A polyline contains a series of connected line segments.

Shape	PTS input	Drawn Shape
Single Line	<p>Four-element row vector $[x_1 \ y_1 \ x_2 \ y_2]$ where</p> <ul style="list-style-type: none"> x_1 and y_1 are the coordinates of the beginning of the line. x_2 and y_2 are the coordinates of the end of the line. 	
M Lines	<p>M-by-4 matrix</p> $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} \\ x_{21} & y_{21} & x_{22} & y_{22} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} \end{bmatrix}$ <p>where each row of the matrix corresponds to a different line and is of the same form as the vector for a single line.</p>	
Single Polyline with (L-1) Segments	<p>Vector of size $2L$, where L is the number of vertices, with format, $[x_1, \ y_1, \ x_2, \ y_2, \ \dots, \ x_L, \ y_L]$.</p> <ul style="list-style-type: none"> x_1 and y_1 are the coordinates of the beginning of the first line segment. x_2 and y_2 are the coordinates of the end of the first line segment and the beginning of the second line segment. x_L and y_L are the coordinates of the end of the $(L-1)^{th}$ line segment. <p>The polyline always contains $(L-1)$ number of segments because the first and last vertex points do not connect. The block produces an error message when the number of rows is less than two or not a multiple of two.</p>	<p>L=5</p> 

Shape	PTS input	Drawn Shape
<p>M Polylines with $(L-1)$ Segments</p>	<p>$2L$-by-N matrix</p> $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} & \cdots & x_{1L} & y_{1L} \\ x_{21} & y_{21} & x_{22} & y_{22} & \cdots & x_{2L} & y_{2L} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} & \cdots & x_{ML} & y_{ML} \end{bmatrix}$ <p>where each row of the matrix corresponds to a different polyline and is of the same form as the vector for a single polyline. When you require one polyline to contain less than $(L-1)$ number of segments, fill the matrix by repeating the coordinates of the last vertex.</p> <p>The block produces an error message if the number of rows is less than two or not a multiple of two.</p>	<p>$M=3, L=5$</p> 

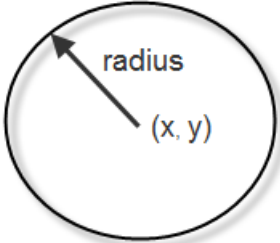

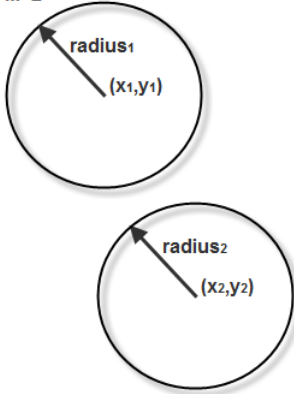

Polygon

You can draw one or more polygons.

Shape	PTS input	Drawn Shape
<p>Single Polygon with L line segments</p>	<p>Row vector of size $2L$, where L is the number of vertices, with format, $[x_1 \ y_1 \ x_2 \ y_2 \ \dots \ x_L \ y_L]$ where</p> <ul style="list-style-type: none"> x_1 and y_1 are the coordinates of the beginning of the first line segment. x_2 and y_2 are the coordinates of the end of the first line segment and the beginning of the second line segment. x_L and y_L are the coordinates of the end of the $(L-1)^{\text{th}}$ line segment and the beginning of the L^{th} line segment. <p>The block connects $[x_1 \ y_1]$ to $[x_L \ y_L]$ to complete the polygon. The block produces an error if the number of rows is negative or not a multiple of two.</p>	<p>$L=5$</p> 
<p>M Polygons with the largest number of line segments in any line being L</p>	<p>M-by-$2L$ matrix</p> $\begin{bmatrix} x_{11} & y_{11} & x_{12} & y_{12} & \dots & x_{1L} & y_{1L} \\ x_{21} & y_{21} & x_{22} & y_{22} & \dots & x_{2L} & y_{2L} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ x_{M1} & y_{M1} & x_{M2} & y_{M2} & \dots & x_{ML} & y_{ML} \end{bmatrix}$ <p>where each row of the matrix corresponds to a different polygon and is of the same form as the vector for a single polygon. If some polygons are shorter than others, repeat the ending coordinates to fill the polygon matrix.</p> <p>The block produces an error message if the number of rows is less than two or is not a multiple of two.</p>	<p>$M=3, L=5$</p>  <p>*Added $L=5$ matrix entry equal to $L=4$ value, because this polyline contains one less number of segments.</p>

Circle

You can draw one or more circles.

Shape	PTS input	Drawn Shape
Single Circle	Three-element row vector $[x \ y \ radius]$ where <ul style="list-style-type: none"> x and y are coordinates for the center of the circle. $radius$ is the radius of the circle, which must be greater than 0. 	 <p>A diagram showing a single circle. A point at the center is labeled (x, y). A line segment with an arrow pointing from the center to the circumference is labeled $radius$.</p>
M Circles	M -by-3 matrix $\begin{bmatrix} x_1 & y_1 & radius_1 \\ x_2 & y_2 & radius_2 \\ \vdots & \vdots & \vdots \\ x_M & y_M & radius_M \end{bmatrix}$ <p>where each row of the matrix corresponds to a different circle and is of the same form as the vector for a single circle.</p>	$M=2$  <p>A diagram showing two circles. The top circle has center (x_1, y_1) and radius $radius_1$. The bottom circle has center (x_2, y_2) and radius $radius_2$. The label $M=2$ is positioned above the circles.</p>

- “Stereo Camera Calibrator App” on page 6-32
- “What Is Camera Calibration?” on page 6-51
- “Structure from Motion” on page 6-59

Fisheye Calibration Basics

Camera calibration is the process of computing the extrinsic and intrinsic parameters of a camera. Once you calibrate a camera, you can use the image information to recover 3-D information from 2-D images. You can also undistort images taken with a fisheye camera.

Fisheye cameras are used in odometry and to solve the simultaneous localization and mapping (SLAM) problems visually. Other applications include, surveillance systems, GoPro, virtual reality (VR) to capture 360 degree field of view (fov), and stitching algorithms. These cameras use a complex series of lenses to enlarge the camera's field of view, enabling it to capture wide panoramic or hemispherical images. However, the lenses achieve this extremely wide angle view by distorting the lines of perspective in the images

Fisheye image

Undistorted fisheye image

Because of the extreme distortion a fisheye lens produces, the pinhole model cannot model a fisheye camera.

Pinhole

Fisheye

Fisheye Camera Model

The Computer Vision Toolbox calibration algorithm uses the fisheye camera model proposed by Scaramuzza[1]. You can use this model with cameras up to a field of view (FOV) of 150 degrees. The model uses an omnidirectional camera model. The process treats the imaging system as a compact system. In order to relate a 3-D world point on to a 2-D image, you must obtain the camera extrinsic and intrinsic parameters. World points are transformed to camera coordinates using the extrinsics parameters. The camera coordinates are mapped into the image plane using the intrinsics parameters.

Extrinsic Parameters

The extrinsic parameters consist of a rotation, R , and a translation, t . The origin of the camera's coordinate system is at its optical center and its x - and y -axis define the image plane.

The transformation from world points to camera points is:

$$\underbrace{\begin{pmatrix} X_c \\ Y_c \\ Z_c \end{pmatrix}}_{\text{Camera points}} = \underbrace{R}_{\text{Rotation}} \underbrace{\begin{pmatrix} X_w \\ Y_w \\ Z_w \end{pmatrix}}_{\text{World points}} + \underbrace{T}_{\text{Translation}}$$

Intrinsic Parameters

For the fisheye camera model, the intrinsic parameters include the polynomial mapping coefficients of the projection function. The alignment coefficients are related to sensor alignment and the transformation from the sensor plane to a pixel location in the camera image plane.

The following equation maps an image point into its corresponding 3-D vector.

$$\begin{pmatrix} X_c \\ Y_c \\ Z_c \end{pmatrix} = \lambda \begin{pmatrix} u \\ v \\ a_0 + a_2\rho^2 + a_3\rho^3 + a_4\rho^4 \end{pmatrix}$$

- (u, v) are the ideal image projections of the real-world points.
- λ represents a scalar factor.
- a_0, a_2, a_3, a_4 are polynomial coefficients described by the Scaramuzza model, where $a_1 = 0$.
- ρ is a function of (u, v) and depends only on the distance of a point from the image center:
center: $\rho = \sqrt{u^2 + v^2}$.

The intrinsic parameters also account for stretching and distortion. The stretch matrix compensates for the sensor-to-lens misalignment, and the distortion vector adjusts the $(0,0)$ location of the image plane.

The following equation relates the real distorted coordinates (u'', v'') to the ideal distorted coordinates (u, v) .

$$\begin{pmatrix} u'' \\ v'' \end{pmatrix} = \begin{pmatrix} c & d \\ e & 1 \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} + \begin{pmatrix} c_x \\ c_y \end{pmatrix}$$

The diagram shows the equation $\begin{pmatrix} u'' \\ v'' \end{pmatrix} = \begin{pmatrix} c & d \\ e & 1 \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} + \begin{pmatrix} c_x \\ c_y \end{pmatrix}$. Blue arrows point from text labels to the corresponding parts of the equation: 'Image pixels' points to the left vector, 'Stretch matrix' points to the middle matrix, 'Hypothetical image plane' points to the middle vector, and 'Distortion center' points to the right vector.

Fisheye Camera Calibration in MATLAB

To remove lens distortion from a fisheye image, you can detect a checkerboard calibration pattern and then calibrate the camera. You can find the checkerboard points using the `detectCheckerboardPoints` and `generateCheckerboardPoints` functions. The `estimateFisheyeParameters` function uses the detected points and returns the `fisheyeParameters` object that contains the intrinsic and extrinsic parameters of a fisheye camera. You can use the `fisheyeCalibrationErrors` to check the accuracy of the calibration.

Correct Fisheye Image for Lens Distortion

Remove lens distortion from a fisheye image by detecting a checkerboard calibration pattern and calibrating the camera. Then, display the results.

Gather a set of checkerboard calibration images.

```
images = imageDatastore(fullfile(toolboxdir('vision'),'visiondata', ...
    'calibration','gopro'));
```

Detect the calibration pattern from the images.

```
[imagePoints,boardSize] = detectCheckerboardPoints(images.Files);
```

Generate world coordinates for the corners of the checkerboard squares.

```
squareSize = 29; % millimeters
worldPoints = generateCheckerboardPoints(boardSize,squareSize);
```

Estimate the fisheye camera calibration parameters based on the image and world points. Use the first image to get the image size.

```
I = readimage(images,1);
imageSize = [size(I,1) size(I,2)];
params = estimateFisheyeParameters(imagePoints,worldPoints,imageSize);
```

Remove lens distortion from the first image I and display the results.

```
J1 = undistortFisheyeImage(I,params.Intrinsics);
figure
imshowpair(I,J1,'montage')
title('Original Image (left) vs. Corrected Image (right)')
```

```
J2 = undistortFisheyeImage(I,params.Intrinsics,'OutputView','full');
figure
imshow(J2)
title('Full Output View')
```

Camera Calibrator Overview

You can use the **Camera Calibrator** app to estimate camera intrinsics, extrinsics, and lens distortion parameters. You can use these camera parameters for various computer vision applications. These applications include removing the effects of lens distortion from an image, measuring planar objects, or reconstructing 3-D scenes from multiple cameras.

The suite of calibration functions used by the **Camera Calibrator** app provide the workflow for camera calibration. You can use these functions directly in the MATLAB workspace. For a list of functions, see “Single and Stereo Camera Calibration”.

Single Camera Calibration

Follow this workflow to calibrate your camera using the app:

- 1 Prepare images, camera, and calibration pattern.
- 2 Add images and select standard or fisheye camera model.
- 3 Calibrate the camera.
- 4 Evaluate calibration accuracy.
- 5 Adjust parameters to improve accuracy (if necessary).
- 6 Export the parameters object.

In some cases, the default values work well, and you do not need to make any improvements before exporting parameters. You can also make improvements using the camera calibration functions directly in the MATLAB workspace. For a list of functions, see “Single and Stereo Camera Calibration”.

Open the Camera Calibrator

- MATLAB Toolstrip: On the **Apps** tab, in the **Image Processing and Computer Vision** section, click the **Camera Calibrator** icon.
- MATLAB command prompt: Enter `cameraCalibrator`

Prepare the Pattern, Camera, and Images

To better the results, use between 10 and 20 images of the calibration pattern. The calibrator requires at least three images. Use uncompressed images or lossless compression formats such as PNG. The calibration pattern and the camera setup must satisfy a set of requirements to work with the calibrator. For greater calibration accuracy, follow these instructions for preparing the pattern, setting up the camera, and capturing the images.

Note The Camera Calibrator app supports only checkerboard patterns. If you are using a different type of calibration pattern, you can still calibrate your camera using the `estimateCameraParameters` function. Using a different type of pattern requires that you supply your own code to detect the pattern points in the image.

Prepare the Checkerboard Pattern

The **Camera Calibrator** app uses a checkerboard pattern. A checkerboard pattern is a convenient calibration target. If you want to use a different pattern to extract key points,

you can use the camera calibration MATLAB functions directly. See “Single and Stereo Camera Calibration” for the list of functions.

You can print (from MATLAB) and use the checkerboard pattern provided. The checkerboard pattern you use must not be square. One side must contain an even number of squares and the other side must contain an odd number of squares. Therefore, the pattern contains two black corners along one side and two white corners on the opposite side. This criteria enables the app to determine the orientation of the pattern. The calibrator assigns the longer side to be the x -direction.

To prepare the checkerboard pattern:

- 1 Attach the checkerboard printout to a flat surface. Imperfections on the surface can affect the accuracy of the calibration.
- 2 Measure one side of the checkerboard square. You need this measurement for calibration. The size of the squares can vary depending on printer settings.

- 3 To improve the detection speed, set up the pattern with as little background clutter as possible.

Camera Setup

To calibrate your camera, follow these rules:

- Keep the pattern in focus, but do not use autofocus.
- If you change zoom settings between images, the focal length changes.

Capture Images

For better results, use at least 10 to 20 images of the calibration pattern. The calibrator requires at least three images. Use uncompressed images or images in lossless compression formats such as PNG. For greater calibration accuracy:

- Capture the images of the pattern at a distance roughly equal to the distance from your camera to the objects of interest. For example, if you plan to measure objects from 2 meters, keep your pattern approximately 2 meters from the camera.
- Place the checkerboard at an angle less than 45 degrees relative to the camera plane.

- Do not modify the images, (for example, do not crop them).
- Do not use autofocus or change the zoom settings between images.
- Capture the images of a checkerboard pattern at different orientations relative to the camera.

- Capture a variety of images of the pattern so that you have accounted for as much of the image frame as possible. Lens distortion increases radially from the center of the image and sometimes is not uniform across the image frame. To capture this lens distortion, the pattern must appear close to the edges of the captured images.

The Calibrator works with a range of checkerboard square sizes. As a general rule, your checkerboard should fill at least 20% of the captured image. For example, the preceding images were taken with a checkerboard square size of 108 mm, as the following montage shows:

Add Images and Select Camera Model

To begin calibration, you must add images. You can add saved images from a folder or add images directly from a camera. The calibrator analyzes the images to ensure they meet the calibrator requirements. The calibrator then detects the points on the checkerboard.

Add Images from File

On the **Calibration** tab, in the **File** section, click **Add images**, and then select From file. You can add images from multiple folders by clicking **Add images** for each folder.

Acquire Live Images

To begin calibration, you must add images. You can acquire live images from a webcam using the MATLAB Webcam support. To use this feature, you must install MATLAB Support Package for USB Webcams. See “Install the MATLAB Support Package for USB Webcams” (Image Acquisition Toolbox) for information on installing the support package. To add live images, follow these steps.

- 1 On the **Calibration** tab, in the **File** section, click **Add Images**, then select From camera.

This action opens the **Camera** tab opens. If you have only one webcam connected to your system, it is selected by default and a live preview window opens. If you have

multiple cameras connected and want to use one different from the default, select that specific camera in the **Camera** list.

- 2 Set properties for the camera to control the image (optional). Click the **Camera Properties** to open a menu of the properties for the selected camera. This list varies depending on your device.

Use the sliders or drop-down list to change any available property settings. The Preview window updates dynamically when you change a setting. When you are done setting properties, click anywhere outside of the menu box to dismiss the properties list.

- 3 Enter a location for the acquired image files in the **Save Location** box by typing the path to the folder or using the **Browse** button. You must have permission to write to the folder you select.
- 4 Set the capture parameters.
 - To set the number of seconds between image captures, use the **Capture Interval** box or slider. The default is 5 seconds, the minimum is 1 second, and the maximum is 60 seconds.
 - To set the number of image captures, use the **Number of images to capture** box or slider. The default is 20 images, the minimum is 2 images, and the maximum is 100 images.

In the default configuration, a total of 20 images are captured, one every 5 seconds.

- 5 The Preview window shows the live images streamed as RGB data. After you adjust any device properties and capture settings, use the Preview window as a guide to line up the camera to acquire the checkerboard pattern image you want to capture.
- 6 Click the **Capture** button. The number of images you set are captured and the thumbnails of the snapshots appear in the **Data Browser** pane. They are automatically named incrementally and are captured as `.png` files.

You can optionally stop the image capture before the designated number of images are captured by clicking **Stop Capture**.

When you are capturing images of a checkerboard, after the designated number of images are captured, a Checkerboard Square Size dialog box displays. Specify the size of the checkerboard square, then click **OK**.

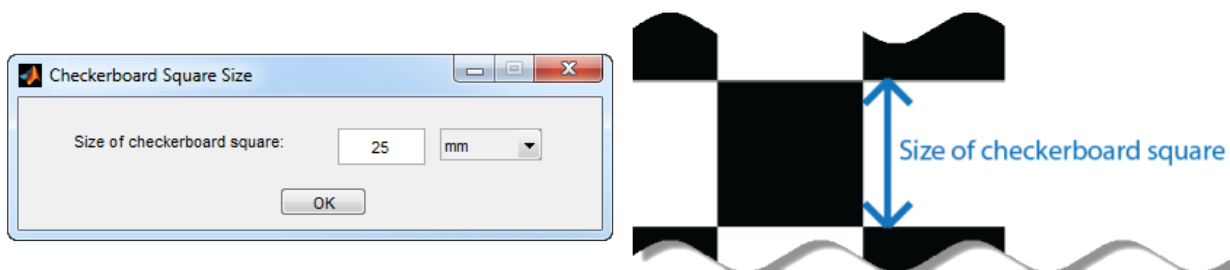

The detection results are then calculated and displayed. For example:

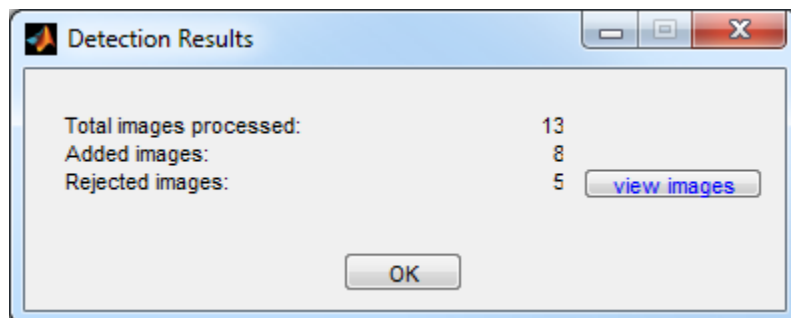

- 7 Click **OK** to dismiss the Detection Results dialog box.
- 8 When you have finished acquiring live images, click **Close Image Capture** to close the **Camera** tab.

Analyze Images

After you add the images, the Checkerboard Square Size dialog box appears. Specify size of the checkerboard square by entering the length of one side of a square from the checkerboard pattern.

The calibrator attempts to detect a checkerboard in each of the added images, displaying an Analyzing Images progress bar window, indicating detection progress. If any of the images are rejected, the Detection Results dialog box appears, which contains diagnostic information. The results indicate how many total images were processed, and of those processed, how many were accepted, rejected, or skipped. The calibrator skips duplicate images.

To view the rejected images, click **View images**. The calibrator rejects duplicate images. It also rejects images where the entire checkerboard could not be detected. Possible reasons for no detection are a blurry image or an extreme angle of the pattern. Detection takes longer with larger images and with patterns that contain a large number of squares.

View Images and Detected Points

The **Data Browser** pane displays a list of images with IDs. These images contain a detected pattern. To view an image, select it from the **Data Browser** pane.

The **Image** window displays the selected checkerboard image with green circles to indicate detected points. You can verify that the corners were detected correctly using the zoom controls. The yellow square indicates the $(0,0)$ origin. The X and Y arrows indicate the checkerboard axes orientation.

Calibrate

Once you are satisfied with the accepted images, click the **Calibrate** button on the **Calibration** tab. The default calibration settings assume the minimum set of camera parameters. Start by running the calibration with the default settings. After evaluating

the results, you can try to improve calibration accuracy by adjusting the settings and adding or removing images and then calibrating again. If you switch between standard and fisheye camera model, you must recalibrate.

Select Camera Model

You can select either a standard or fisheye camera model on the **Calibration** tab, in the **Camera Model** section, select **Standard** or **Fisheye**.

You can switch camera models at any point in the session. You must calibrate again after any changes you make to the app's settings. Click **Options** to access settings and optimizations for either camera model.

Standard Model Options

When the camera has severe lens distortion, the app can fail to compute the initial values for the camera intrinsics. If you have the manufacturer's specifications for your camera and know the pixel size, focal length, or lens characteristics, you can manually set initial guesses for camera intrinsics and radial distortion. To set initial guesses, click **Options** > **Optimization Options**.

- Select the top checkbox and then enter a 3-by-3 matrix to specify initial intrinsics. If you do not specify an initial guess, the function computes the initial intrinsic matrix using linear least squares.
- Select the bottom checkbox and then enter a 2- or 3-element vector to specify the initial radial distortion. If you do not provide a value, the function uses θ as the initial value for all the coefficients.

Fisheye Model Options

In the **Camera Model** section, with **Fisheye** selected, click **Options**. Select **Estimate Alignment** to enable estimation of the axes alignment when the optical axis of the fisheye lens is not perpendicular to the image plane.

Calibration Algorithm

See "Fisheye Calibration Basics" on page 6-2 for the fisheye camera model calibration algorithm.

The standard camera model calibration algorithm assumes a pinhole camera model:

$$w[x \ y \ 1] = [X \ Y \ Z \ 1] \begin{bmatrix} R \\ t \end{bmatrix} K$$

- (X,Y,Z) : world coordinates of a point.
- (x,y) : image coordinates of the corresponding image point in pixels.
- w : arbitrary homogeneous coordinates scale factor.
- K : camera intrinsic matrix, defined as.

$$\begin{bmatrix} f_x & 0 & 0 \\ s & f_y & 0 \\ c_x & c_y & 1 \end{bmatrix}$$

The coordinates (c_x, c_y) represent the optical center (the principal point), in pixels. When the x - and y -axes are exactly perpendicular, the skew parameter, s , equals 0 . The matrix elements are defined as:

$$f_x = F \cdot s_x$$

$$f_y = F \cdot s_y$$

F is the focal length in world units, typically expressed in millimeters.

$[s_x, s_y]$ are the number of pixels per world unit in the x and y direction respectively.

f_x and f_y are expressed in pixels.

- R : matrix representing the 3-D rotation of the camera .
- t : translation of the camera relative to the world coordinate system.

The camera calibration algorithm estimates the values of the intrinsic parameters, the extrinsic parameters, and the distortion coefficients. Camera calibration involves these steps:

- 1 Solve for the intrinsics and extrinsics in closed form, assuming that lens distortion is zero. [1]
- 2 Estimate all parameters simultaneously, including the distortion coefficients, using nonlinear least-squares minimization (Levenberg-Marquardt algorithm). Use the closed-form solution from the preceding step as the initial estimate of the intrinsics and extrinsics. Set the initial estimate of the distortion coefficients to zero. [1][2]

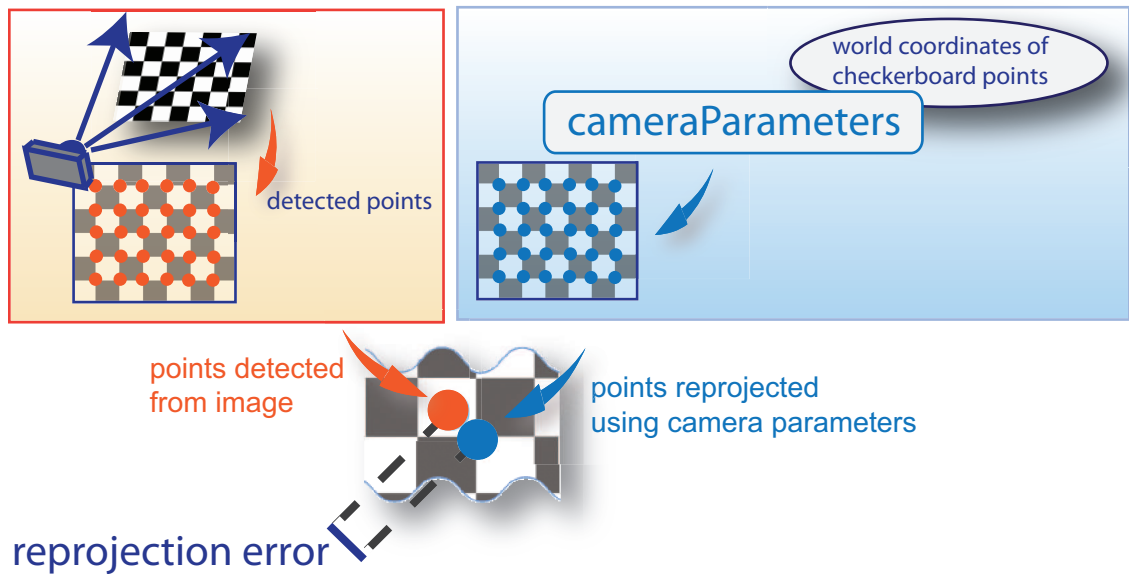

Evaluate Calibration Results

You can evaluate calibration accuracy by examining the reprojection errors, examining the camera extrinsics, or viewing the undistorted image. For best calibration results, use all three methods of evaluation.

Examine Reprojection Errors

The reprojection errors are the distances, in pixels, between the detected and the reprojected points. The **Camera Calibrator** app calculates reprojection errors by projecting the checkerboard points from world coordinates, defined by the checkerboard, into image coordinates. The app then compares the reprojected points to the corresponding detected points. As a general rule, mean reprojection errors of less than one pixel are acceptable.

The **Camera Calibrator** app displays, in pixels, the reprojection errors as a bar graph. The graph helps you to identify which images that adversely contribute to the calibration. Select the bar graph entry and remove the image from the list of images in the **Data Browser** pane.

Reprojection Errors Bar Graph

The bar graph displays the mean reprojection error per image, along with the overall mean error. The bar labels correspond to the image IDs. The highlighted bars correspond to the selected images.

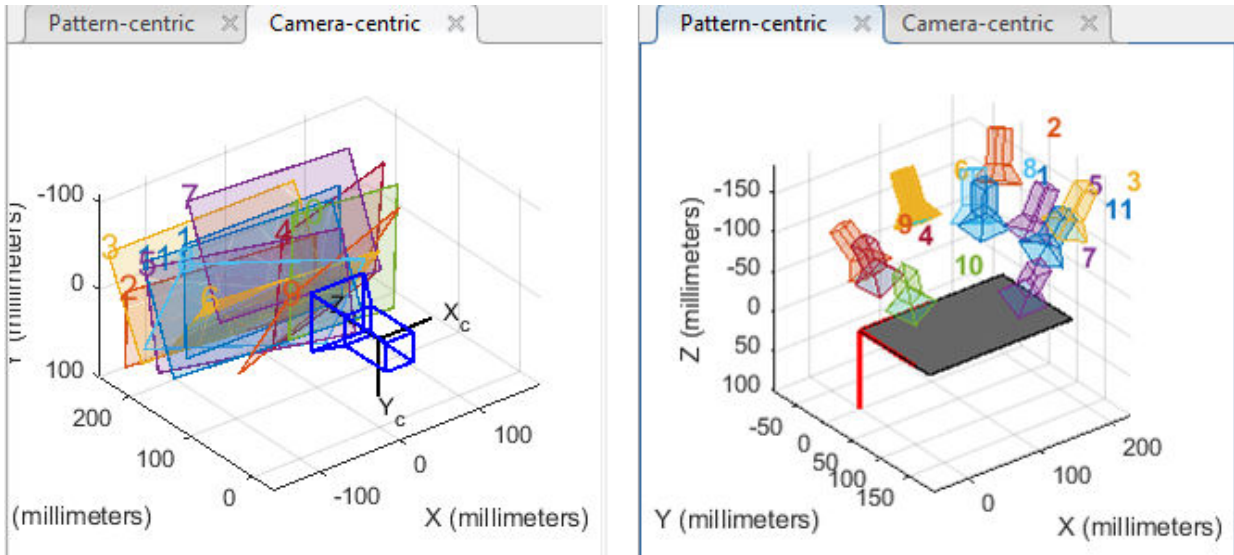

Select an image in one of these ways:

- Click a corresponding bar in the graph.
- Select an image from the list of images in the **Data Browser** pane.
- Adjust the overall mean error. Click and slide the red line up or down to select outlier images.

Examine Extrinsic Parameter Visualization

The 3-D extrinsic parameters plot provides a camera-centric view of the patterns and a pattern-centric view of the camera. The camera-centric view is helpful if the camera was stationary when the images were captured. The pattern-centric view is helpful if the pattern was stationary. You can click the cursor and hold down the mouse button with the rotate icon to rotate the figure. Click a checkerboard (or camera) to select it. The highlighted data in the visualizations correspond to the selected image in the list. Examine the relative positions of the pattern and the camera to determine if they match what you expect. For example, a pattern that appears behind the camera indicates a calibration error.

View Undistorted Image

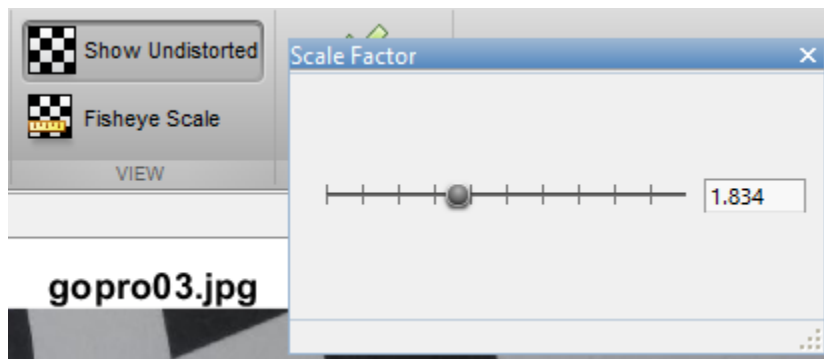

To view the effects of removing lens distortion, click **Show Undistorted** in the **View** section of the **Calibration** tab. If the calibration was accurate, the distorted lines in the image become straight.

Checking the undistorted images is important even if the reprojection errors are low. For example, if the pattern covers only a small percentage of the image, the distortion estimation might be incorrect, even though the calibration resulted in few reprojection errors. The following image shows an example of this type of incorrect estimation for a single camera calibration.

While viewing the undistorted images, you can examine the fisheye images more closely by selecting **Fisheye Scale** in the **View** section of the **Calibration** tab. Use the slider in the Scale Factor window to adjust the scale of the image.

Improve Calibration

To improve the calibration, you can remove high-error images, add more images, or modify the calibrator settings.

Add or Remove Images

Consider adding more images if:

- You have less than 10 images.
- The patterns do not cover enough of the image frame.
- The patterns do not have enough variation in orientation with respect to the camera.

Consider removing images if the images:

- The images have a high mean reprojection error.
- The images are blurry.
- The images contain a checkerboard at an angle greater than 45 degrees relative to the camera plane.

- The images contain incorrectly detected checkerboard points.

Standard Model: Change the Number of Radial Distortion Coefficients

You can specify two or three radial distortion coefficients. On the **Calibrations** tab, in the **Camera Model** section, with **Standard** selected, click **Options**. Select the **Radial Distortion** as either **2 Coefficients** or **3 Coefficients**. Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion.

The radial distortion coefficients model this type of distortion. The distorted points are denoted as $(x_{\text{distorted}}, y_{\text{distorted}})$:

$$x_{\text{distorted}} = x(1 + k_1*r^2 + k_2*r^4 + k_3*r^6)$$

$$y_{\text{distorted}} = y(1 + k_1*r^2 + k_2*r^4 + k_3*r^6)$$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- $k_1, k_2,$ and k_3 — Radial distortion coefficients of the lens.
- $r^2: x^2 + y^2$

Typically, two coefficients are sufficient for calibration. For severe distortion, such as in wide-angle lenses, you can select 3 coefficients to include k_3 .

The undistorted pixel locations are in normalized image coordinates, with the origin at the optical center. The coordinates are expressed in world units.

Standard Model: Compute Skew

When you select the **Compute Skew** check box, the calibrator estimates the image axes skew. Some camera sensors contain imperfections that cause the x - and y -axes of the image to not be perpendicular. You can model this defect using a skew parameter. If you do not select the check box, the image axes are assumed to be perpendicular, which is the case for most modern cameras.

Standard Model: Compute Tangential Distortion

Tangential distortion occurs when the lens and the image plane are not parallel. The tangential distortion coefficients model this type of distortion.

The distorted points are denoted as $(x_{\text{distorted}}, y_{\text{distorted}})$:

$$x_{\text{distorted}} = x + [2 * p_1 * x * y + p_2 * (r^2 + 2 * x^2)]$$

$$y_{\text{distorted}} = y + [p_1 * (r^2 + 2 * y^2) + 2 * p_2 * x * y]$$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- p_1 and p_2 — Tangential distortion coefficients of the lens.
- r^2 : $x^2 + y^2$

When you select the **Compute Tangential Distortion** check box, the calibrator estimates the tangential distortion coefficients. Otherwise, the calibrator sets the tangential distortion coefficients to zero.

Fisheye Model: Estimate Alignment

In the **Camera Model** section, with **Fisheye** selected, click **Options**. Select **Estimate Alignment** to enable estimation of the axes alignment when the optical axis of the fisheye lens is not perpendicular to the image plane.

Export Camera Parameters

When you are satisfied with calibration accuracy, click **Export Camera Parameters**. You can either save and export the camera parameters to an object by selecting **Export Camera Parameters** or generate the camera parameters as a MATLAB script.

Export Camera Parameters

Select **Export Camera Parameters > Export Parameters to Workspace** to create a `cameraParameters` object in your workspace. The object contains the intrinsic and extrinsic parameters of the camera and the distortion coefficients. You can use this object for various computer vision tasks, such as image undistortion, measuring planar objects, and 3-D reconstruction. See “Measuring Planar Objects with a Calibrated Camera”. You can optionally export the `cameraCalibrationErrors` object, which contains the standard errors of estimated camera parameters, by selecting the **Export estimation errors** check box.

Generate MATLAB Script

Select **Export Camera Parameters > Generate MATLAB script** to save your camera parameters to a MATLAB script, enabling you to reproduce the steps from your calibration session.

Stereo Camera Calibrator Overview

You can use the **Stereo Camera Calibrator** app to calibrate a stereo camera, which you can then use to recover depth from images. A stereo system consists of two cameras: camera 1 and camera 2. The app can either estimate or import the parameters of individual cameras. The app also calculates the position and orientation of camera 2, relative to camera 1.

The **Stereo Camera Calibrator** app produces an object containing the stereo camera parameters. You can use this object to

- Rectify stereo images using the `rectifyStereoImages` function.
- Reconstruct the 3-D scene using the `reconstructScene` function.
- Compute 3-D locations corresponding to matching pairs of image points using the `triangulate` function.

The suite of calibration functions used by the **Stereo Camera Calibrator** app provide the workflow for stereo system calibration. You can use these functions directly in the MATLAB workspace. For a list of calibration functions, see “Single and Stereo Camera Calibration”.

Note You can use the Camera Calibrator app with cameras up to a field of view (FOV) of 95 degrees.

Stereo Camera Calibration

Follow this workflow to calibrate your stereo camera using the app:

- 1 Prepare images, camera, and calibration pattern.
- 2 Add image pairs.
- 3 Calibrate the stereo camera.
- 4 Evaluate calibration accuracy.
- 5 Adjust parameters to improve accuracy (if necessary).
- 6 Export the parameters object.
- 7 In some cases, the default values work well, and you do not need to make any improvements before exporting parameters. You can also make improvements using the camera calibration functions directly in the MATLAB workspace. For a list of functions, see “Single and Stereo Camera Calibration”.

Open the Stereo Camera Calibrator

- MATLAB Toolstrip: On the **Apps** tab, in the **Image Processing and Computer Vision** section, click the **Stereo Camera Calibrator** icon.
- MATLAB command prompt: Enter `stereoCameraCalibrator`

Prepare Pattern, Camera, and Images

To improve the results, use between 10 and 20 images of the calibration pattern. The calibrator requires at least three images. Use uncompressed images or lossless compression formats such as PNG. The calibration pattern and the camera setup must satisfy a set of requirements to work with the calibrator. For greater calibration accuracy, follow these instructions for preparing the pattern, setting up the camera, and capturing the images.

Prepare the Checkerboard Pattern

The **Camera Calibrator** app uses a checkerboard pattern. A checkerboard pattern is a convenient calibration target. If you want to use a different pattern to extract key points, you can use the camera calibration MATLAB functions directly. See “Single and Stereo Camera Calibration” for the list of functions.

You can print (from MATLAB) and use the checkerboard pattern provided. The checkerboard pattern you use must not be square. One side must contain an even number of squares and the other side must contain an odd number of squares. Therefore, the pattern contains two black corners along one side and two white corners on the opposite side. This criteria enables the app to determine the orientation of the pattern. The calibrator assigns the longer side to be the x-direction.

To prepare the checkerboard pattern:

- 1 Attach the checkerboard printout to a flat surface. Imperfections on the surface can affect the accuracy of the calibration.
- 2 Measure one side of the checkerboard square. You need this measurement for calibration. The size of the squares can vary depending on printer settings.

- 3 To improve the detection speed, set up the pattern with as little background clutter as possible.

Camera Setup

To calibrate your camera, follow these rules:

- Keep the pattern in focus, but do not use autofocus.
- If you change zoom settings between images, the focal length changes.

Capture Images

For best results, use at least 10 to 20 images of the calibration pattern. The calibrator requires at least three images. Use uncompressed images or images in lossless compression formats such as PNG. For greater calibration accuracy:

- Capture the images of the pattern at a distance roughly equal to the distance from your camera to the objects of interest. For example, if you plan to measure objects from 2 meters, keep your pattern approximately 2 meters from the camera.
- Place the checkerboard at an angle less than 45 degrees relative to the camera plane.

- Do not modify the images, (for example, do not crop them).
- Do not use autofocus or change the zoom settings between images.
- Capture the images of a checkerboard pattern at different orientations relative to the camera.
- Capture a variety of images of the pattern so that you have accounted for as much of the image frame as possible. Lens distortion increases radially from the center of the image and sometimes is not uniform across the image frame. To capture this lens distortion, the pattern must appear close to the edges of the captured images.

- Make sure the checkerboard pattern is fully visible in both images of each stereo pair.

- Keep the pattern stationary for each image pair. Any motion of the pattern between taking image 1 and image 2 of the pair negatively affects the calibration.
- Create a stereo display, or anaglyph, by positioning the two cameras approximately 55 mm apart. This distance represents the average distance between human eyes.
- For greater reconstruction accuracy at longer distances, position your cameras farther apart.

Add Image Pairs

To begin calibration, click **Add Images**, specifically two sets of stereo images of the checkerboard, one set from each camera.

Load Images

You can add images from multiple folders by clicking **Add images** in the **File** section of the **Calibration** tab. Select the location for the images corresponding to camera 1 using the **Browse** button, then do the same for camera 2. Specify **Size of checkerboard square** by entering the length of one side of a square from the checkerboard pattern.

Analyze Images

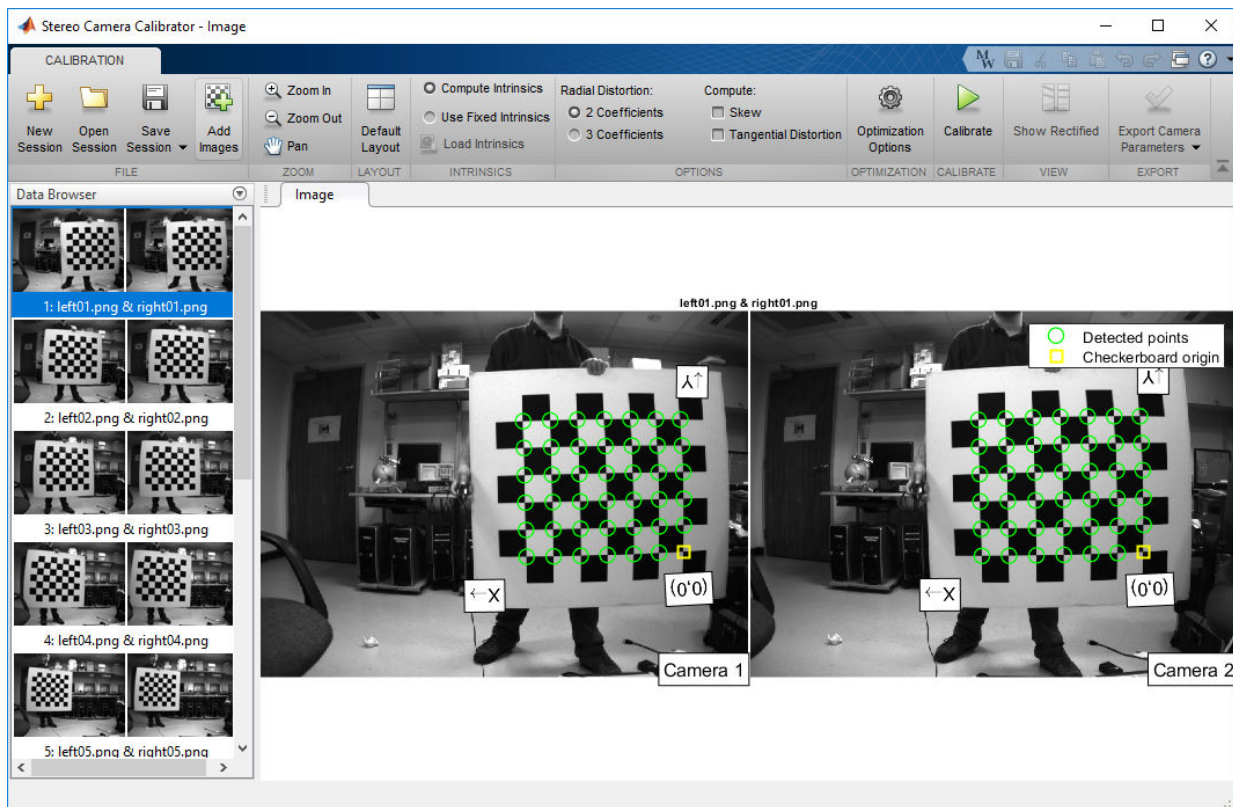

The calibrator attempts to detect a checkerboard in each of the added images, displaying an Analyzing Images progress bar window, indicating detection progress. If any of the images are rejected, the Detection Results dialog box appears, which contains diagnostic information. The results indicate how many total images were processed, and of those processed, how many were accepted, rejected, or skipped. The calibrator skips duplicate images.

To view the rejected images, click **View images**. The calibrator rejects duplicate images. It also rejects images where the entire checkerboard could not be detected. Possible reasons for no detection are a blurry image or an extreme angle of the pattern. Detection takes longer with larger images and with patterns that contain a large number of squares.

View Images and Detected Points

The **Data Browser** pane displays a list of image pairs with IDs. These image pairs contain a detected pattern. To view an image, select it from the **Data Browser** pane.

The **Image** pane displays the selected checkerboard image pair with green circles to indicate detected points. You can verify that the corners were detected correctly using the zoom controls. The yellow square indicates the (0,0) origin. The X and Y arrows indicate the checkerboard axes orientation.

Intrinsics

You can choose for the app to compute camera intrinsics or you can load pre-computed fixed intrinsics. To load intrinsics into the app, select **Use Fixed Intrinsics** in the Intrinsic section of the **Calibration** tab. The **Radial Distortion** and **Compute** options in the **Options** section are disabled when you load intrinsics.

To load intrinsics as variables from your workspace, click **Load Intrinsics**. For example, if the `wideBaselineStereo` struct contains the intrinsics for both cameras.

```
ld = load('wideBaselineStereo');  
int1 = ld.intrinsics1  
int2 = ld.intrinsics2
```

Then, click **Load Intrinsic**s to specify these variables in the dialog box, as shown.

Calibrate

Once you are satisfied with the accepted image pairs, click the **Calibrate** button on the **Calibration** tab. The default calibration settings assume the minimum set of camera parameters. Start by running the calibration with the default settings. After evaluating the results, you can try to improve calibration accuracy by adjusting the settings and adding or removing images, and then calibrate again.

Optimization

When the camera has severe lens distortion, the app can fail to compute the initial values for the camera intrinsics. If you have the manufacturer's specifications for your camera and know the pixel size, focal length, or lens characteristics, you can manually set initial guesses for camera intrinsics and radial distortion. To set initial guesses, click **Options > Optimization Options**.

Note These options are not available for preloaded intrinsics.

- Select the top checkbox and then enter a 3-by-3 matrix to specify initial intrinsics. If you do not specify an initial guess, the function computes the initial intrinsic matrix using linear least squares.
- Select the bottom checkbox and then enter a 2- or 3-element vector to specify the initial radial distortion. If you do not provide a value, the function uses $\mathbf{0}$ as the initial value for all the coefficients.

Evaluate Calibration Results

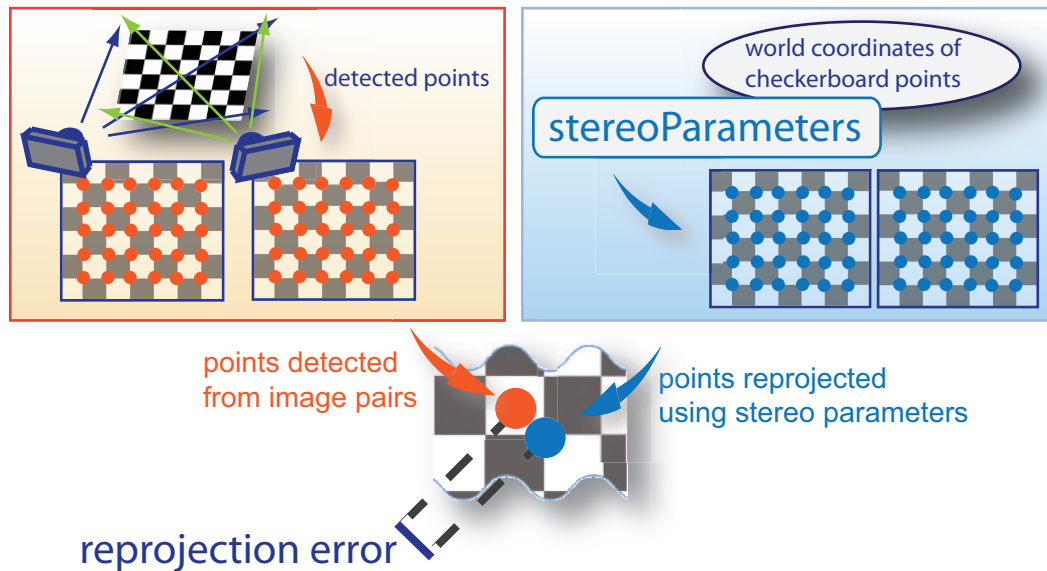

You can evaluate calibration accuracy by examining the reprojection errors, examining the camera extrinsics, or viewing the undistorted image. For best calibration results, use all three methods of evaluation.

The screenshot displays the Stereo Camera Calibrator software interface. The main window is titled "Stereo Camera Calibrator - Camera-centric". The interface is divided into several sections:

- Top Panel:** Contains various toolbars and options. The "INTRINSICS" section includes radio buttons for "Compute Intrinsics" (selected) and "Use Fixed Intrinsics", and options for "Radial Distortion" (2 or 3 Coefficients) and "Compute" (Skew, Tangential Distortion).
- Data Browser:** On the left, it lists five pairs of image files (e.g., "1: left01.png & right01.png") with corresponding thumbnail images.
- Image View:** The central area shows two side-by-side images of a person holding a checkerboard. The left image is labeled "Camera 1" and the right "Camera 2". Both images have a grid of green and red dots overlaid, representing detected and reprojected points. Labels include $\lambda \uparrow$, $\leftarrow X$, and $(0'0)$.
- Reprojection Errors:** A bar chart at the bottom left shows the "Mean Error in Pixels" for 10 image pairs. The y-axis ranges from 0 to 0.08. The legend indicates "Camera 1" (blue bars) and "Camera 2" (orange bars). A dashed line represents the "Overall Mean Error: 0.06 pixels". A red box highlights the top of the chart with the text "Drag to select outliers".
- Pattern-centric / Camera-centric:** A 3D plot at the bottom right shows the camera extrinsics. The axes are labeled "X (millimeters)", "Y (millimeters)", and "Z (millimeters)". The plot shows a 3D coordinate system with a camera model overlaid.

Examine Reprojection Errors

The reprojection errors are the distances, in pixels, between the detected and the reprojected points. The **Stereo Camera Calibrator** app calculates reprojection errors by projecting the checkerboard points from world coordinates, defined by the checkerboard, into image coordinates. The app then compares the reprojected points to the corresponding detected points. As a general rule, mean reprojection errors of less than one pixel are acceptable.

The **Stereo Calibration App** displays, in pixels, the reprojection errors as a bar graph. The graph helps you to identify which images that adversely contribute to the calibration. Select the bar graph entry and remove the image from the list of images in the **Data Browser** pane.

Reprojection Errors Bar Graph

The bar graph displays the mean reprojection error per image, along with the overall mean error. The bar labels correspond to the image IDs. The highlighted bars correspond to the selected image pair.

Select an image pair in one of these ways:

- Clicking the corresponding bar in the graph.
- Select the image pair from the list in the **Data Browser** pane.
- Adjust the overall mean error. Click and slide the red line up or down to select outlier images.

Examine Extrinsic Parameter Visualization

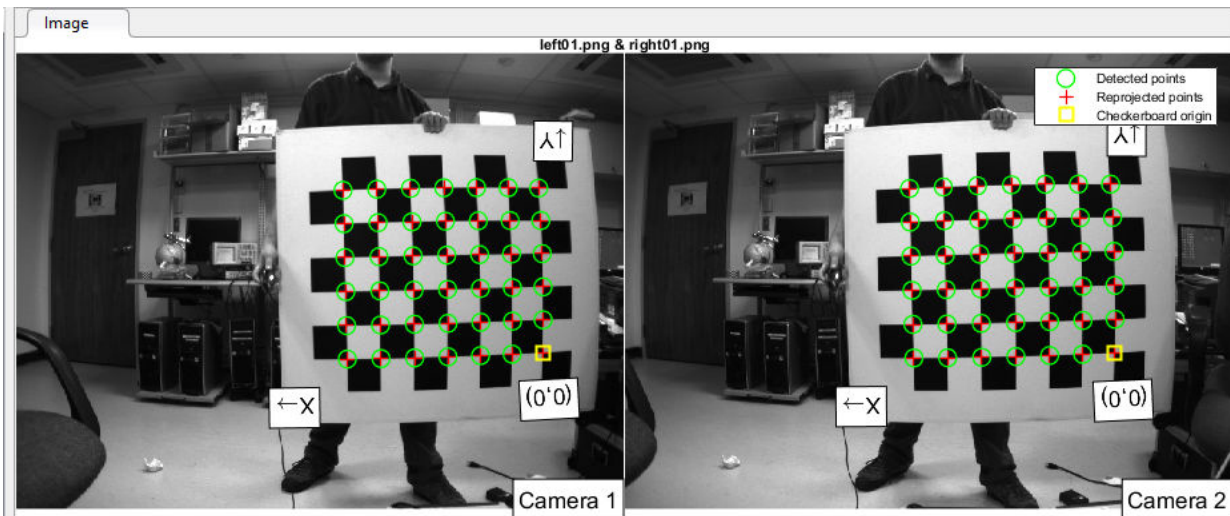

The 3-D extrinsic parameters plot provides a camera-centric view of the patterns and a pattern-centric view of the camera. The camera-centric view is helpful if the camera was stationary when the images were captured. The pattern-centric view is helpful if the pattern was stationary. You can click the cursor and hold down the mouse button with the rotate icon to rotate the figure. Click a checkerboard (or camera) to select it. The highlighted data in the visualizations correspond to the selected image in the list. Examine the relative positions of the pattern and the camera to determine if they match

what you expect. For example, a pattern that appears behind the camera indicates a calibration error.

Show Rectified Images

To view the effects of stereo rectification, click **Show Rectified** in the **View** section of the **Calibration** tab. If the calibration was accurate, the images become undistorted and row-aligned.

Checking the rectified images is important even if the reprojection errors are low. For example, if the pattern covers only a small percentage of the image, the distortion estimation might be incorrect, even though the calibration resulted in few reprojection errors. The following image shows an example of this type of incorrect estimation for a single camera calibration.

Improve Calibration

To improve the calibration, you can remove high-error image pairs, add more image pairs, or modify the calibrator settings.

Add or Remove Images

Consider adding more images if:

- You have less than 10 images.
- The patterns do not cover enough of the image frame.
- The patterns do not have enough variation in orientation with respect to the camera.

Consider removing images if the images:

- The images have a high mean reprojection error.
- The images are blurry.
- The images contain a checkerboard at an angle greater than 45 degrees relative to the camera plane.

- The images contain incorrectly detected checkerboard points.

Change the Number of Radial Distortion Coefficients

You can specify 2 or 3 radial distortion coefficients by selecting the corresponding radio button from the **Options** section. Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion.

Negative radial distortion
"pincushion"

No distortion

Positive radial distortion
"barrel"

The radial distortion coefficients model this type of distortion. The distorted points are denoted as $(x_{\text{distorted}}, y_{\text{distorted}})$:

$$x_{\text{distorted}} = x(1 + k_1 * r^2 + k_2 * r^4 + k_3 * r^6)$$

$$y_{\text{distorted}} = y(1 + k_1 * r^2 + k_2 * r^4 + k_3 * r^6)$$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- $k_1, k_2,$ and k_3 — Radial distortion coefficients of the lens.
- $r^2: x^2 + y^2$

Typically, two coefficients are sufficient for calibration. For severe distortion, such as in wide-angle lenses, you can select 3 coefficients to include k_3 .

Compute Skew

When you select the **Compute Skew** check box, the calibrator estimates the image axes skew. Some camera sensors contain imperfections that cause the x - and y -axes of the image to not be perpendicular. You can model this defect using a skew parameter. If you do not select the check box, the image axes are assumed to be perpendicular, which is the case for most modern cameras.

Compute Tangential Distortion

Tangential distortion occurs when the lens and the image plane are not parallel. The tangential distortion coefficients model this type of distortion.

The distorted points are denoted as $(x_{\text{distorted}}, y_{\text{distorted}})$:

$$x_{\text{distorted}} = x + [2 * p_1 * x * y + p_2 * (r^2 + 2 * x^2)]$$

$$y_{\text{distorted}} = y + [p_1 * (r^2 + 2 * y^2) + 2 * p_2 * x * y]$$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- p_1 and p_2 — Tangential distortion coefficients of the lens.
- r^2 : $x^2 + y^2$

When you select the **Compute Tangential Distortion** check box, the calibrator estimates the tangential distortion coefficients. Otherwise, the calibrator sets the tangential distortion coefficients to zero.

Export Camera Parameters

When you are satisfied with calibration accuracy, click **Export Camera Parameters**. You can either save and export the camera parameters to an object by selecting **Export Camera Parameters** or generate the camera parameters as a MATLAB script.

Export Camera Parameters

Select **Export Camera Parameters > Export Parameters to Workspace** to create a `stereoParameters` object in your workspace. The object contains the intrinsic and extrinsic parameters of the camera and the distortion coefficients. You can use this object for various computer vision tasks, such as image undistortion, measuring planar objects, and 3-D reconstruction. See “Measuring Planar Objects with a Calibrated Camera”. You can optionally export the `stereoCalibrationErrors` object, which contains the standard errors of estimated stereo camera parameters, by selecting the **Export estimation errors** check box.

Generate MATLAB Script

Select **Export Camera Parameters > Generate MATLAB script** to save your camera parameters to a MATLAB script, enabling you to reproduce the steps from your calibration session.

What Is Camera Calibration?

Geometric camera calibration, also referred to as camera resectioning, estimates the parameters of a lens and image sensor of an image or video camera. You can use these parameters to correct for lens distortion, measure the size of an object in world units, or determine the location of the camera in the scene. These tasks are used in applications such as machine vision to detect and measure objects. They are also used in robotics, for navigation systems, and 3-D scene reconstruction.

Examples of what you can do after calibrating your camera:

Remove Lens Distortion

Estimate 3-D Structure from Camera Motion

Estimate Depth
Using a Stereo Camera

Measure Planar Objects

Camera parameters include intrinsics, extrinsics, and distortion coefficients. To estimate the camera parameters, you need to have 3-D world points and their corresponding 2-D image points. You can get these correspondences using multiple images of a calibration pattern, such as a checkerboard. Using the correspondences, you can solve for the camera parameters. After you calibrate a camera, to evaluate the accuracy of the estimated parameters, you can:

- Plot the relative locations of the camera and the calibration pattern
- Calculate the reprojection errors.
- Calculate the parameter estimation errors.

Use the **Camera Calibrator** to perform camera calibration and evaluate the accuracy of the estimated parameters.

Camera Model

The Computer Vision Toolbox calibration algorithm uses the camera model proposed by Jean-Yves Bouguet [3]. The model includes:

- The pinhole camera model [1].
- Lens distortion [2].

The pinhole camera model does not account for lens distortion because an ideal pinhole camera does not have a lens. To accurately represent a real camera, the full camera model used by the algorithm includes the radial and tangential lens distortion.

Pinhole Camera Model

A pinhole camera is a simple camera without a lens and with a single small aperture. Light rays pass through the aperture and project an inverted image on the opposite side of the camera. Think of the virtual image plane as being in front of the camera and containing the upright image of the scene.

The pinhole camera parameters are represented in a 4-by-3 matrix called the camera matrix. This matrix maps the 3-D world scene into the image plane. The calibration algorithm calculates the camera matrix using the extrinsic and intrinsic parameters. The extrinsic parameters represent the location of the camera in the 3-D scene. The intrinsic parameters represent the optical center and focal length of the camera.

$$w [x \ y \ 1] = [X \ Y \ Z \ 1] P$$

Scale factor
Image points
World points

$$P = \begin{bmatrix} R \\ t \end{bmatrix} K$$

Camera matrix
Extrinsics
Intrinsic matrix

Rotation and translation

The world points are transformed to camera coordinates using the extrinsics parameters. The camera coordinates are mapped into the image plane using the intrinsics parameters.

Camera Calibration Parameters

The calibration algorithm calculates the camera matrix using the extrinsic and intrinsic parameters. The extrinsic parameters represent a rigid transformation from 3-D world coordinate system to the 3-D camera's coordinate system. The intrinsic parameters represent a projective transformation from the 3-D camera's coordinates into the 2-D image coordinates.

Extrinsic Parameters

The extrinsic parameters consist of a rotation, R , and a translation, t . The origin of the camera's coordinate system is at its optical center and its x - and y -axis define the image plane.

Intrinsic Parameters

The intrinsic parameters include the focal length, the optical center, also known as the principal point, and the skew coefficient. The camera intrinsic matrix, K , is defined as:

$$\begin{bmatrix} f_x & 0 & 0 \\ s & f_y & 0 \\ c_x & c_y & 1 \end{bmatrix}$$

The pixel skew is defined as:

$[c_x, c_y]$ — Optical center (the principal point), in pixels.

(f_x, f_y) — Focal length in pixels.

$$f_x = F/p_x$$

$$f_y = F/p_y$$

F — Focal length in world units, typically expressed in millimeters.

(p_x, p_y) — Size of the pixel in world units.

s — Skew coefficient, which is non-zero if the image axes are not perpendicular.

$$s = f_x \tan \alpha$$

Distortion in Camera Calibration

The camera matrix does not account for lens distortion because an ideal pinhole camera does not have a lens. To accurately represent a real camera, the camera model includes the radial and tangential lens distortion.

Radial Distortion

Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion.

Negative radial distortion
"pincushion"

No distortion

Positive radial distortion
"barrel"

The radial distortion coefficients model this type of distortion. The distorted points are denoted as $(x_{\text{distorted}}, y_{\text{distorted}})$:

$$x_{\text{distorted}} = x(1 + k_1*r^2 + k_2*r^4 + k_3*r^6)$$

$$y_{\text{distorted}} = y(1 + k_1*r^2 + k_2*r^4 + k_3*r^6)$$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- $k_1, k_2,$ and k_3 — Radial distortion coefficients of the lens.
- $r^2: x^2 + y^2$

Typically, two coefficients are sufficient for calibration. For severe distortion, such as in wide-angle lenses, you can select 3 coefficients to include k_3 .

Tangential Distortion

Tangential distortion occurs when the lens and the image plane are not parallel. The tangential distortion coefficients model this type of distortion.

The distorted points are denoted as $(x_{\text{distorted}}, y_{\text{distorted}})$:

$$x_{\text{distorted}} = x + [2 * p_1 * x * y + p_2 * (r^2 + 2 * x^2)]$$

$$y_{\text{distorted}} = y + [p_1 * (r^2 + 2 * y^2) + 2 * p_2 * x * y]$$

- x, y — Undistorted pixel locations. x and y are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, x and y are dimensionless.
- p_1 and p_2 — Tangential distortion coefficients of the lens.
- r^2 : $x^2 + y^2$

Structure from Motion

In this section...

“Structure from Motion from Two Views” on page 6-59

“Structure from Motion from Multiple Views” on page 6-61

Structure from motion (SfM) is the process of estimating the 3-D structure of a scene from a set of 2-D images. SfM is used in many applications, such as 3-D scanning and augmented reality.

SfM can be computed in many different ways. The way in which you approach the problem depends on different factors, such as the number and type of cameras used, and whether the images are ordered. If the images are taken with a single calibrated camera, then the 3-D structure and camera motion can only be recovered up to scale. up to scale means that you can rescale the structure and the magnitude of the camera motion and still maintain observations. For example, if you put a camera close to an object, you can see the same image as when you enlarge the object and move the camera far away. If you want to compute the actual scale of the structure and motion in world units, you need additional information, such as:

- The size of an object in the scene
- Information from another sensor, for example, an odometer.

Structure from Motion from Two Views

For the simple case of structure from two stationary cameras or one moving camera, one view must be considered camera 1 and the other one camera 2. In this scenario, the algorithm assumes that camera 1 is at the origin and its optical axis lies along the z-axis.

- 1 SfM requires point correspondences between images. Find corresponding points either by matching features or tracking points from image 1 to image 2. Feature

tracking techniques, such as Kanade-Lucas-Tomasi (KLT) algorithm, work well when the cameras are close together. As cameras move further apart, the KLT algorithm breaks down, and feature matching can be used instead.

Distance Between Cameras (Baseline)	Method for Finding Point Correspondences	Example
Wide	Match features using <code>matchFeatures</code>	“Find Image Rotation and Scale Using Automated Feature Matching”
Narrow	Track features using <code>vision.PointTracker</code>	“Face Detection and Tracking Using the KLT Algorithm”

- To find the pose of the second camera relative to the first camera, you must compute the fundamental matrix. Use the corresponding points found in the previous step for the computation. The fundamental matrix describes the epipolar geometry of the two cameras. It relates a point in one camera to an epipolar line in the other camera. Use the `estimateFundamentalMatrix` function to estimate the fundamental matrix.

- 3 Input the fundamental matrix to the `relativeCameraPose` function. `relativeCameraPose` returns the orientation and the location of the second camera in the coordinate system of the first camera. The location can only be computed up to scale, so the distance between two cameras is set to 1. In other words, the distance between the cameras is defined to be 1 unit.
- 4 Determine the 3-D locations of the matched points using `triangulate`. Because the pose is up to scale, when you compute the structure, it has the right shape but not the actual size.

The `triangulate` function takes two camera matrices, which you can compute using `cameraMatrix`.

- 5 Use `pcshow` to display the reconstruction, and use `plotCamera` to visualize the camera poses.

To recover the scale of the reconstruction, you need additional information. One method to recover the scale is to detect an object of a known size in the scene. The “Structure From Motion From Two Views” example shows how to recover scale by detecting a sphere of a known size in the point cloud of the scene.

Structure from Motion from Multiple Views

For most applications, such as robotics and autonomous driving, SfM uses more than two views.

The approach used for SfM from two views can be extended for multiple views. The set of multiple views used for SfM can be ordered or unordered. The approach taken here assumes an ordered sequence of views. SfM from multiple views requires point

correspondences across multiple images, called tracks. A typical approach is to compute the tracks from pairwise point correspondences. You can use `viewSet` to manage the pairwise correspondences and find the tracks. Each track corresponds to a 3-D point in the scene. To compute 3-D points from the tracks, use `triangulateMultiview`.

Using the approach in SfM from two views, you can find the pose of camera 2 relative to camera 1. To extend this approach to the multiple view case, find the pose of camera 3 relative to camera 2, and so on. The relative poses must be transformed into a common coordinate system. Typically, all camera poses are computed relative to camera 1 so that all poses are in the same coordinate system. You can use `viewSet` to manage camera poses. The `viewSet` object stores the views and connections between the views.

Every camera pose estimation from one view to the next contains errors. The errors arise from imprecise point localization in images, and from noisy matches and imprecise calibration. These errors accumulate as the number of views increases, an effect known as drift. One way to reduce the drift, is to refine camera poses and 3-D point locations. The nonlinear optimization algorithm, called bundle adjustment, implemented by the `bundleAdjustment` function, can be used for the refinement.

The “Structure From Motion From Two Views” example shows how to reconstruct a 3-D scene from a sequence of 2-D views. The example uses the **Camera Calibrator** app to calibrate the camera that takes the views. It uses a `viewSet` object to store and manage the data associated with each view.

Getting Started with Object Detection Using Deep Learning

Object detection using deep learning provides a fast and accurate means to predict the location of an object in an image. Deep learning is a powerful machine learning technique in which the object detector automatically learns image features required for detection tasks. Several techniques for object detection using deep learning are available such as Faster R-CNN and you only look once (YOLO) v2.

Applications for object detection include:

- Image classification
- Scene understanding
- Self-driving vehicles
- Surveillance

Create Training Data for Object Detection

Use a labeling app to interactively label ground truth data in a video, image sequence, image collection, or custom data source. You can label object detection ground truth using rectangle labels, which define the position and size of the object in the image.

- “Choose an App to Label Ground Truth Data” on page 7-75
- “Training Data for Object Detection and Semantic Segmentation” on page 7-35

Augment and Preprocess Data

Using data augmentation provides a way to use limited data sets for training. Minor changes, such as translation, cropping, or transforming an image, provide new, distinct, and unique images that you can use to train a robust detector. Datastores are a convenient way to read and augment collections of data. Use `imageDatastore` and the `boxLabelDatastore` to create datastores for images and labeled bounding box data.

- “Augment Bounding Boxes for Object Detection” (Deep Learning Toolbox)
- “Preprocess Images for Deep Learning” (Deep Learning Toolbox)
- “Preprocess Data for Domain-Specific Deep Learning Applications” (Deep Learning Toolbox)

For more information about augmenting training data using datastores, see “Datastores for Deep Learning” (Deep Learning Toolbox), and “Perform Additional Image Processing Operations Using Built-In Datastores” (Deep Learning Toolbox).

Create Object Detection Network

Each object detector contains a unique network architecture. For example, the Faster R-CNN detector uses a two-stage network for detection, whereas the YOLO v2 detector uses a single stage. Use functions like `fasterRCNNLayers` or `yoloV2Layers` to create a network. You can also design a network layer by layer using the **Deep Network Designer**.

- “Pretrained Deep Neural Networks” (Deep Learning Toolbox)
- “Design a YOLO v2 Detection Network” on page 7-21
- “Design an R-CNN, Fast R-CNN, and a Faster R-CNN Model” on page 7-28

Train Detector and Evaluate Results

Use the `trainFasterRCNNObjectDetector` or `trainYOLOv2ObjectDetector` functions to train an object detector. Use the `evaluateDetectionMissRate` and `evaluateDetectionPrecision` functions to evaluate the training results.

- “Train Faster R-CNN Vehicle Detector”
- “Object Detection Using YOLO v2 Deep Learning” on page 1-68

Detect Objects Using Deep Learning Detectors

Detect objects in an image using the trained detector. For example, the partial code shown below uses the trained detector on an image `I`. Use the `detect` object function on `fasterRCNNObjectDetector` or `yoloV2ObjectDetector` objects to return bounding boxes, detection scores, and categorical labels assigned to the bounding boxes.

```
I = imread(input_image)
[bboxes,scores,labels] = detect(detector,I)
```

Image Labeler | Video Labeler

How Labeler Apps Store Exported Pixel Labels

When you create and export pixel labels from the **Image Labeler**, **Video Labeler**, or **Ground Truth Labeler** (requires Automated Driving Toolbox™) app, two sets of data are saved.

- A folder named `PixellabelData`, which contains the PNG files of pixel label information. These labels are encoded as indexed values.
- A MAT-file containing a `groundTruth` object, which stores correspondences between image or video frames and the PNG files. The object also contains any marked rectangles or polylines.

The PNG files within the `PixellabelData` folder are stored as a categorical matrix. The `categorical` matrices contain values assigned to categories. `Categorical` is a data type. A categorical matrix provides efficient storage and convenient manipulation of nonnumeric data, while also maintaining meaningful names for the values. These matrices are natural representations for semantic segmentation ground truth, where each pixel is one of a predefined category of labels.

Location of Pixel Label Data Folder

The `groundTruth` object stores the folder path and name for the pixel label data folder. The ground truth `LabelData` property of this object contains the information in the 'PixelLabelData' column. If you change the location of the pixel data file, you must also update the related information in the `groundTruth` object. You can use the `changeFilePaths` function to update the information.

View Exported Pixel Label Data

The labeler apps store the semantic segmentation ground truth as lossless PNG files, with a `uint8` value representing each category. The app uses the `categorical` function to associate the `uint8` values to a category. To view your pixel data, you can either overlay the categories on images or create a datastore from the labeled images.

View Exported Pixel Label Data By Overlaying Categories on Images

Use the `imread` function with the `categorical` and `labeloverlay` functions. You cannot view the pixel data directly from the categorical matrix. See “View Exported Pixel Label Data” on page 7-7.

View Exported Pixel Label Data from Datastore of Labeled Images

Use the `pixelLabelDatastore` function to create a datastore from a set of labeled images. Use the `read` function to read the pixel label data. See “Read and Display Pixel Label Data” on page 7-8.

Examples

View Exported Pixel Label Data

Read image and corresponding pixel label data that was exported from a labeler app.

```
visiondatadir = fullfile(toolboxdir('vision'),'visiondata');  
  
buildingImage = imread(fullfile(visiondatadir,'building','building1.JPG'));  
buildingLabels = imread(fullfile(visiondatadir,'buildingPixelLabels','Label_1.png'));
```

Define categories for each pixel value in `buildingLabels`.

```
labelIDs = [1,2,3,4];  
labelcats = ["sky" "grass" "building" "sidewalk"];
```

Construct a categorical matrix using the image and the definitions.

```
buildingLabelCats = categorical(buildingLabels,labelIDs,labelcats);
```

Display the categories overlaid on the image.

```
figure  
imshow(labeloverlay(buildingImage,buildingLabelCats))
```

Read and Display Pixel Label Data

Overlay pixel label data on an image.

Set the location of the image and pixel label data.

```
dataDir = fullfile(toolboxdir('vision'),'visiondata');  
imDir = fullfile(dataDir,'building');  
pxDir = fullfile(dataDir,'buildingPixelLabels');
```

Create an image datastore.

```
imds = imageDatastore(imDir);
```

Create a pixel label datastore.

```
classNames = ["sky" "grass" "building" "sidewalk"];  
pixelLabelID = [1 2 3 4];  
pxds = pixelLabelDatastore(pxDir,classNames,pixelLabelID);
```

Read the image and pixel label data. `read(pxds)` returns a categorical matrix, `C`. The element $C(i,j)$ in the matrix is the categorical label assigned to the pixel at the location $l(i,j)$.

```
I = read(imds);  
C = read(pxds);
```

Display the label categories in `C`.

```
categories(C{1})
```

```
ans = 4x1 cell array  
    {'sky'    }  
    {'grass'  }  
    {'building'}  
    {'sidewalk'}
```

Overlay and display the pixel label data onto the image.

```
B = labeloverlay(I,C{1});  
figure  
imshow(B)
```

Anchor Boxes for Object Detection

Object detection using deep learning neural networks provide a fast and accurate means to predict the location and size of an object in an image. Ideally, the network returns valid objects in a timely matter, regardless of the scale of the objects. The use of anchor boxes improves the speed and efficiency for the detection portion of a deep learning neural network framework.

What Is an Anchor Box?

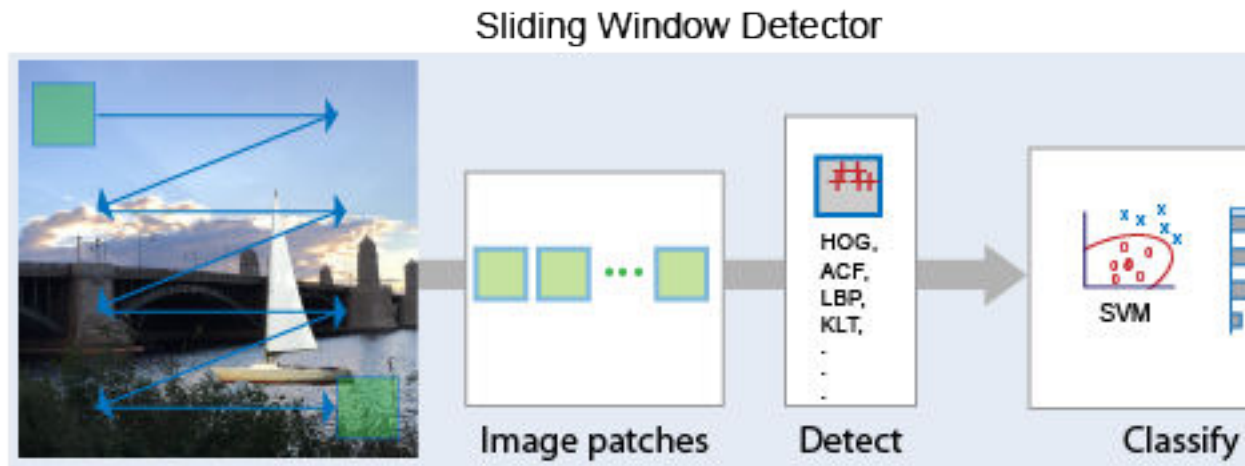

Anchor boxes are a set of predefined bounding boxes of a certain height and width. These boxes are defined to capture the scale and aspect ratio of specific object classes you want to detect and are typically chosen based on object sizes in your training datasets. During detection, the predefined anchor boxes are tiled across the image. The network predicts the probability and other attributes, such as background, intersection over union (IoU) and offsets for every tiled anchor box. The predictions are used to refine each individual anchor box. You can define several anchor boxes, each for a different object size.

The network does not directly predict bounding boxes, but rather predicts the probabilities and refinements that correspond to the tiled anchor boxes. The network returns a unique set of predictions for every anchor box defined. The final feature map represents object detections for each class. The use of anchor boxes enables a network to detect multiple objects, objects of different scales, and overlapping objects.

Advantage of Using Anchor Boxes

When using anchor boxes, you can evaluate all object predictions at once. Anchor boxes eliminate the need to scan an image with a sliding window that computes a separate prediction at every potential position. Examples of detectors that use a sliding window are those that are based on aggregate channel features (ACF) or histogram of gradients (HOG) features. An object detector that uses anchor boxes can process an entire image at once, making real-time object detection systems possible.

Because a convolutional neural network (CNN) can process an input image in a convolutional manner, a spatial location in the input can be related to a spatial location in the output. This convolutional correspondence means that a CNN can extract image features for an entire image at once. The extracted features can then be associated back to their location in that image. The use of anchor boxes replaces and drastically reduces the cost of the sliding window approach for extracting features from an image. Using anchor boxes, you can design efficient deep learning object detectors to encompass all three stages (detect, feature encode, and classify) of a sliding-window based object detector.

How Do Anchor Boxes Work?

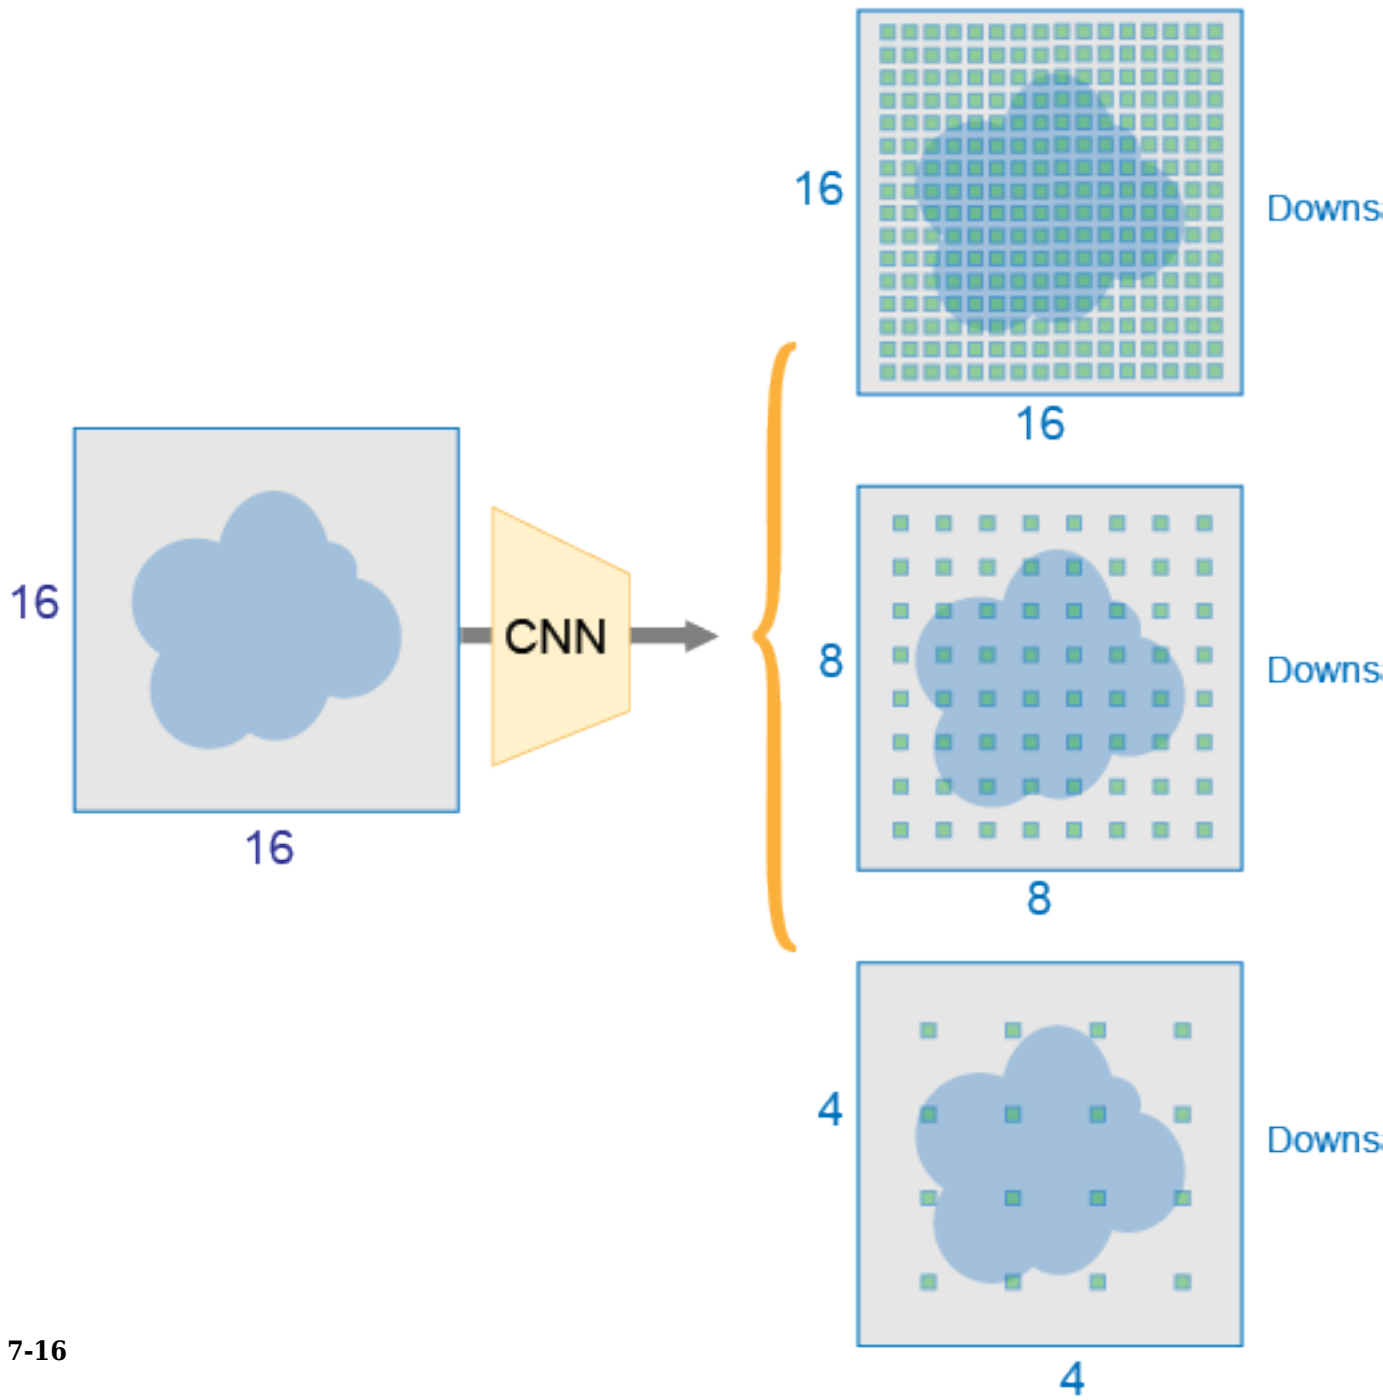

The position of an anchor box is determined by mapping the location of the network output back to the input image. The process is replicated for every network output. The result produces a set of tiled anchor boxes across the entire image.

Each anchor box is tiled across the image. The number of network outputs equals the number of tiled anchor boxes. The network produces predictions for all outputs.

Localization Errors and Refinement

The distance, or stride, between the tiled anchor boxes is a function of the amount of downsampling present in the CNN. Downsampling factors between 4 and 16 are common. These downsampling factors produce coarsely tiled anchor boxes, which can lead to localization errors.

To fix localization errors, deep learning object detectors learn offsets to apply to each tiled anchor box refining the anchor box position and size.

Downsampling can be reduced by removing downsampling layers. To reduce downsampling, lower the 'Stride' property of the convolution or max pooling layers, (such as `convolution2dLayer` and `convolution2dLayer`.) You can also choose a feature extraction layer earlier in the network. Feature extraction layers from earlier in the network have higher spatial resolution but may extract less semantic information compared to layers further down the network

Generate Object Detections

To generate the final object detections, tiled anchor boxes that belong to the background class are removed, and the remaining ones are filtered by their confidence score. Anchor boxes with the greatest confidence score are selected using nonmaximum suppression (NMS). For more details about NMS, see the `selectStrongestBboxMulticlass` function.

Anchor Box Size

Multiscale processing enables the network to detect objects of varying size. To achieve multiscale detection, you must specify anchor boxes of varying size, such as 64-by-64, 128-by-128, and 256-by-256. Specify sizes that closely represent the scale and aspect

ratio of objects in your training data. For an example of estimating sizes, see [Estimate Anchor Boxes From Training Data](#) on page 1-33.

Getting Started with YOLO v2

The you-only-look-once (YOLO) v2 object detector uses a single stage object detection network. YOLO v2 is faster than other two-stage deep learning object detectors, such as regions with convolutional neural networks (Faster R-CNNs).

The YOLO v2 model runs a deep learning CNN on an input image to produce network predictions. The object detector decodes the predictions and generates bounding boxes.

Predicting Objects in the Image

YOLO v2 uses anchor boxes to detect classes of objects in an image. For more details, see “Anchor Boxes for Object Detection” on page 7-12. The YOLO v2 predicts these three attributes for each anchor box:

- Intersection over union (IoU) — Predicts the objectness score of each anchor box.
- Anchor box offsets — Refine the anchor box position
- Class probability — Predicts the class label assigned to each anchor box.

The figure shows the predefined anchor box (the dotted line) and the refined location after offsets are applied.

Transfer Learning

With transfer learning, you can use a pretrained CNN as the feature extractor in a YOLO v2 detection network. Use the `yoloV2Layers` function to create a YOLO v2 detection network from any pretrained CNN, for example `MobileNet_v2`. For a list of pretrained CNNs, see “Pretrained Deep Neural Networks” (Deep Learning Toolbox)

You can also design a custom model based on a pretrained image classification CNN. For more details, see “Design a YOLO v2 Detection Network” on page 7-21.

Design a YOLO v2 Detection Network

You can design a custom YOLO v2 model layer by layer. The model starts with a feature extractor network, which can be initialized from a pretrained CNN or trained from scratch. The detection subnetwork contains a series of Conv, Batch norm, and ReLu layers, followed by the transform and output layers, `yoloV2TransformLayer` and `yoloV2OutputLayer` objects, respectively. `yoloV2TransformLayer` transforms the raw CNN output into a form required to produce object detections. `yoloV2OutputLayer` defines the anchor box parameters and implements the loss function used to train the detector.

You can also use the **Deep Network Designer** app to manually create a network. The designer incorporates Computer Vision Toolbox YOLO v2 features.

Design a YOLO v2 Detection Network with a Reorg Layer

The reorganization layer (created using the `yoloV2ReorgLayer` object) and the depth concatenation layer (created using the `depthConcatenationLayer` object) are used to combine low-level and high-level features. These layers improve detection by adding low-level image information and improving detection accuracy for smaller objects. Typically, the reorganization layer is attached to a layer within the feature extraction network whose output feature map is larger than the feature extraction layer output.

Tip

- Adjust the 'Stride' property of the `yoloV2ReorgLayer` object such that its output size matches the input size of the `depthConcatenationLayer` object.
 - To simplify designing a network, use the interactive **Deep Network Designer** app and the `analyzeNetwork` function.
-

For more details on how to create this kind of network, see “Create YOLO v2 Object Detection Network” on page 1-81.

Train an Object Detector and Detect Objects with a YOLO v2 Model

To learn how to train an object detector by using the YOLO deep learning technique with a CNN, see the “Object Detection Using YOLO v2 Deep Learning” on page 1-68 example.

Code Generation

To learn how to generate CUDA[®] code using the YOLO v2 object detector (created using the `yolov2ObjectDetector` object) see “Code Generation for Object Detection by Using YOLO v2” on page 1-38.

Label Training Data for Deep Learning

You can use the **Image Labeler**, **Video Labeler**, or **Ground Truth Labeler** (available in Automated Driving Toolbox) apps to interactively label pixels and export label data for training. The apps can also be used to label rectangular regions of interest (ROIs) for object detection, scene labels for image classification, and pixels for semantic segmentation.

Getting Started with R-CNN, Fast R-CNN, and Faster R-CNN

Object detection is the process of finding and classifying objects in an image. One deep learning approach, regions with convolutional neural networks (R-CNN), combines rectangular region proposals with convolutional neural network features. R-CNN is a two-stage detection algorithm. The first stage identifies a subset of regions in an image that might contain an object. The second stage classifies the object in each region.

Applications for R-CNN object detectors include:

- Autonomous driving
- Smart surveillance systems
- Facial recognition

Computer Vision Toolbox provides object detectors for the R-CNN, Fast R-CNN, and Faster R-CNN algorithms.

Object Detection Using R-CNN Algorithms

Models for object detection using regions with CNNs are based on the following three processes:

- Find regions in the image that might contain an object. These regions are called region proposals.
- Extract CNN features from the region proposals.
- Classify the objects using the extracted features.

There are three variants of an R-CNN. Each variant attempts to optimize, speed up, or enhance the results of one or more of these processes.

R-CNN

The R-CNN detector [2] first generates region proposals using an algorithm such as Edge Boxes[1]. The proposal regions are cropped out of the image and resized. Then, the CNN classifies the cropped and resized regions. Finally, the region proposal bounding boxes are refined by a support vector machine (SVM) that is trained using CNN features.

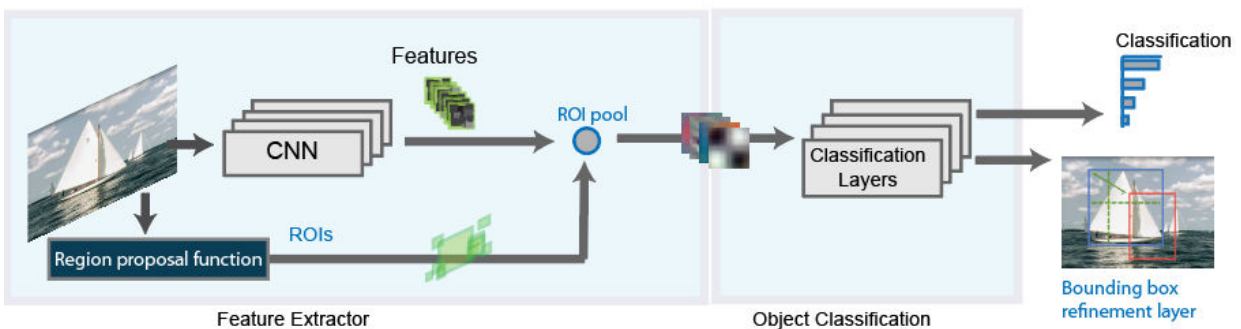

Use the `trainRCNNObjectDetector` function to train an R-CNN object detector. The function returns an `rcnnObjectDetector` object that detects objects in an image.

Fast R-CNN

As in the R-CNN detector, the Fast R-CNN[3] detector also uses an algorithm like Edge Boxes to generate region proposals. Unlike the R-CNN detector, which crops and resizes region proposals, the Fast R-CNN detector processes the entire image. Whereas an R-CNN detector must classify each region, Fast R-CNN pools CNN features corresponding to each region proposal. Fast R-CNN is more efficient than R-CNN, because in the Fast R-CNN detector, the computations for overlapping regions are shared.

Use the `trainFastRCNNObjectDetector` function to train a Fast R-CNN object detector. The function returns a `fastRCNNObjectDetector` that detects objects from an image.

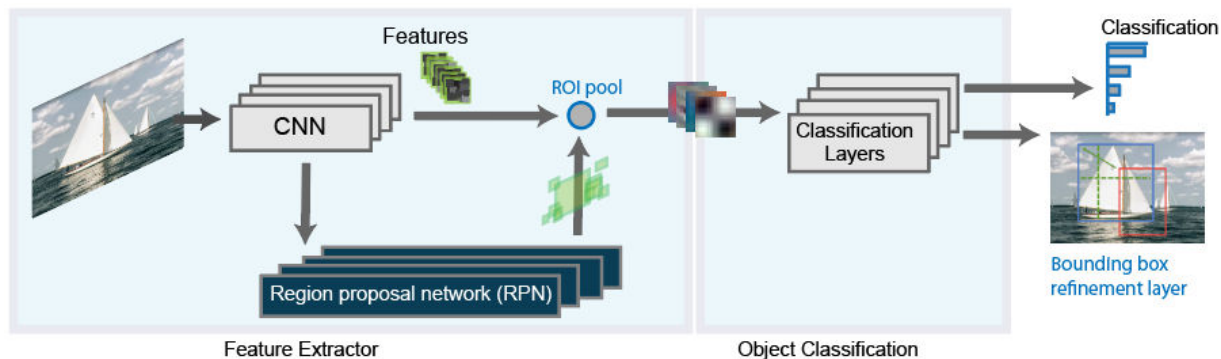

Faster R-CNN

The Faster R-CNN[4] detector adds a region proposal network (RPN) to generate region proposals directly in the network instead of using an external algorithm like Edge Boxes.

The RPN uses “Anchor Boxes for Object Detection” on page 7-12. Generating region proposals in the network is faster and better tuned to your data.

Use the `trainFasterRCNNObjectDetector` function to train a Faster R-CNN object detector. The function returns a `fasterRCNNObjectDetector` that detects objects from an image.

Comparison of R-CNN Object Detectors

This family of object detectors uses region proposals to detect objects within images. The number of proposed regions dictates the time it takes to detect objects in an image. The Fast R-CNN and Faster R-CNN detectors are designed to improve detection performance with a large number of regions.

R-CNN Detector	Description
<code>trainRCNNObjectDetector</code>	<ul style="list-style-type: none"> • Slow training and detection • Allows custom region proposal
<code>trainFastRCNNObjectDetector</code>	<ul style="list-style-type: none"> • Allows custom region proposal
<code>trainFasterRCNNObjectDetector</code>	<ul style="list-style-type: none"> • Optimal run-time performance • Does not support a custom region proposal

Transfer Learning

You can use a pretrained convolution neural network (CNN) as the basis for an R-CNN detector, also referred to as transfer learning. See “Pretrained Deep Neural Networks”

(Deep Learning Toolbox). Use one of the following networks with the `trainRCNNObjectDetector`, `trainFasterRCNNObjectDetector`, or `trainFastRCNNObjectDetector` functions. To use any of these networks you must install the corresponding Deep Learning Toolbox™ model:

- 'alexnet'
- 'vgg16'
- 'vgg19'
- 'resnet50'
- 'resnet101'
- 'inceptionv3'
- 'googlenet'
- 'inceptionresnetv2'
- 'squeezenet'

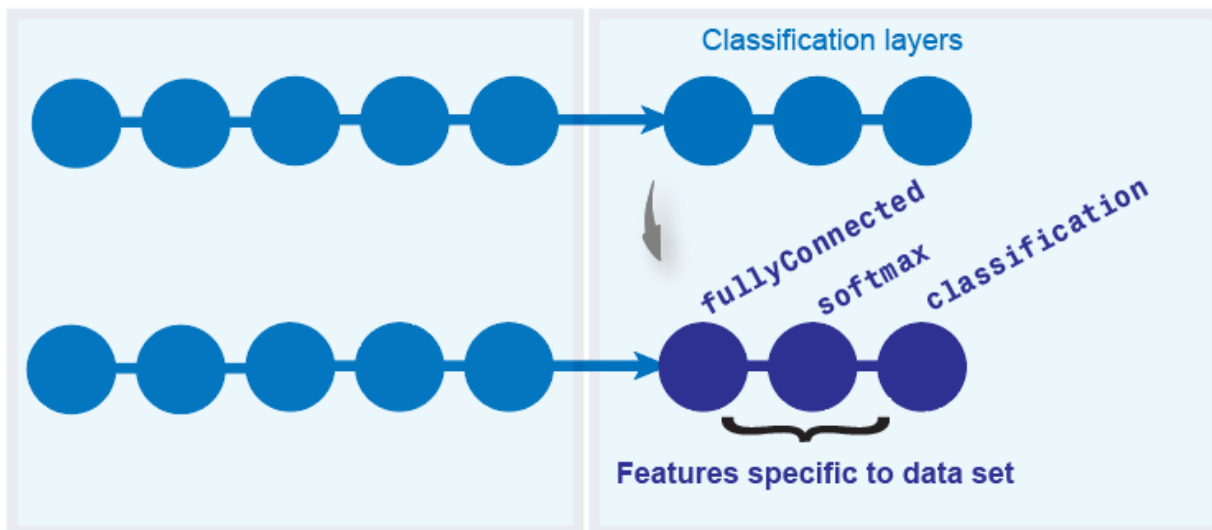

You can also design a custom model based on a pretrained image classification CNN. See the “Design an R-CNN, Fast R-CNN, and a Faster R-CNN Model” on page 7-28 section and the **Deep Network Designer** app.

Design an R-CNN, Fast R-CNN, and a Faster R-CNN Model

You can design custom R-CNN models based on a pretrained image classification CNN. You can also use the **Deep Network Designer** to build, visualize, and edit a deep learning network.

- 1 The basic R-CNN model starts with a pretrained network. The last three classification layers are replaced with new layers that are specific to the object classes you want to detect.

For an example of how to create an R-CNN object detection network, see “Create R-CNN Object Detection Network”

- 2 The Fast R-CNN model builds on the basic R-CNN model. A box regression layer is added to improve on the position of the object in the image by learning a set of box offsets. An ROI pooling layer is inserted into the network to pool CNN features for each region proposal.

For an example of how to create a Fast R-CNN object detection network, see “Create Fast R-CNN Object Detection Network”

- 3 The Faster R-CNN model builds on the Fast R-CNN model. A region proposal network is added to produce the region proposals instead of getting the proposals from an external algorithm.

For an example of how to create a Faster R-CNN object detection network, see “Create Faster R-CNN Object Detection Network”

Label Training Data for Deep Learning

You can use the **Image Labeler**, **Video Labeler**, or **Ground Truth Labeler** (available in Automated Driving Toolbox) apps to interactively label pixels and export label data for training. The apps can also be used to label rectangular regions of interest (ROIs) for object detection, scene labels for image classification, and pixels for semantic segmentation.

Getting Started With Semantic Segmentation Using Deep Learning

Segmentation is essential for image analysis tasks. Semantic segmentation describes the process of associating each pixel of an image with a class label, (such as *flower*, *person*, *road*, *sky*, *ocean*, or *car*).

Applications for semantic segmentation include:

- Autonomous driving
- Industrial inspection
- Classification of terrain visible in satellite imagery
- Medical imaging analysis

Train a Semantic Segmentation Network

The steps for training a semantic segmentation network are as follows:

1. “Analyze Training Data for Semantic Segmentation”
2. “Create a Semantic Segmentation Network”

3. “Train A Semantic Segmentation Network”
4. “Evaluate and Inspect the Results of Semantic Segmentation”

Label Training Data for Semantic Segmentation

Large datasets enable faster and more accurate mapping to a particular input (or input aspect). Using data augmentation provides a means of leveraging limited datasets for training. Minor changes, such as translation, cropping, or transforming an image provides new distinct and unique images. See “Augment Images for Deep Learning Workflows Using Image Processing Toolbox” (Deep Learning Toolbox)

You can use the **Image Labeler** app to interactively label pixels and export the label data for training. The app can also be used to label rectangular regions of interest (ROIs) and scene labels for image classification.

Training Data for Object Detection and Semantic Segmentation

You can use the **Image Labeler** app, **Video Labeler** app, or the **Ground Truth Labeler** app (requires Automated Driving Toolbox), along with Computer Vision Toolbox objects and functions, to train algorithms from ground truth data. Use the labeling app to interactively label ground truth data in a video, image sequence, image collection, or custom data source. Use the labeled data to create training data to train an object detector or to train a semantic segmentation network.

1 Load data for labeling

- **Image Labeler** — Load an image collection from a file or `ImageDatastore` object into the app.
- **Video Labeler** or **Ground Truth Labeler** — Load a video, image sequence, or a custom data source into the app.

2 Label data and select an automation algorithm: Create ROI and scene labels within the app. For more details, see:

- **Image Labeler** — “Get Started with the Image Labeler” on page 7-55
- **Video Labeler** — “Get Started with the Video Labeler” on page 7-77
- **Ground Truth Labeler** — “Get Started with the Ground Truth Labeler” (Automated Driving Toolbox)

You can choose from one of the built-in algorithms or create your own custom algorithm to label objects in your data. To learn how to create your own automation algorithm, see “Create Automation Algorithm for Labeling” on page 7-39.

3 Export labels: After labeling your data, you can export the labels to the workspace or save them to a file. The labels are exported as a `groundTruth` object. If your data source consists of multiple image collections, label the entire set of image collections to obtain an array of `groundTruth` objects. For details about sharing `groundTruth` objects, see “Share and Store Labeled Ground Truth Data” on page 7-115.

4 Create training data: To create training data from the `groundTruth` object, use one of these functions:

- Training data for object detectors — Use the `objectDetectorTrainingData` function.
- Training data for semantic segmentation networks — Use the `pixelLabelTrainingData` function.

For objects created using a video file or custom data source, the `objectDetectorTrainingData` and `pixelLabelTrainingData` functions write images to disk for `groundTruth`. Sample the ground truth data by specifying a sampling factor. Sampling mitigates overtraining an object detector on similar samples.

5 Train algorithm:

- Object detectors — Use one of several Computer Vision Toolbox object detectors. For a list of detectors, see “Object Detection Using Features” and “Object

Detection using Deep Learning”. For object detectors specific to automated driving, see the Automated Driving Toolbox object detectors listed in “Visual Perception” (Automated Driving Toolbox).

- Semantic segmentation network — For details on training a semantic segmentation network, see “Getting Started With Semantic Segmentation Using Deep Learning” on page 7-32.

Create Automation Algorithm for Labeling

The **Image Labeler**, **Video Labeler**, and **Ground Truth Labeler** (requires Automated Driving Toolbox) apps enable you to label ground truth data in an image collection, video, or image sequence. You can use an automation algorithm to automatically label your data by creating and importing a custom automation algorithm.

Create Custom Label Automation Algorithm for Labeling App

The `vision.labeler.AutomationAlgorithm` class enables you to define a custom label automation algorithm for use in the labeling apps. You can use the class to define the interface used by the app to run an automation algorithm.

To define and use a custom automation algorithm with your loaded data source:

- 1 Create the automation folder:** Create a `+vision/+labeler/` folder within a folder that is on the MATLAB path. For example, if the folder `/local/MyProject` is on the MATLAB path, then create the `+vision/+labeler/` folder hierarchy as follows:

```
projectFolder = fullfile('local','MyProject');
automationFolder = fullfile('+vision','+labeler');
mkdir(projectFolder,automationFolder)
```
- 2 Define a class that inherits from the AutomationAlgorithm class:** At the MATLAB command prompt, enter the appropriate command to open the labeling app you want: `imageLabeler`, `videoLabeler`, or `groundTruthLabeler`. Then click **Select Algorithm > Add Algorithm > Create new algorithm** to open the `vision.labeler.AutomationAlgorithm` class template. Define your algorithm by following the instructions in the header and comments in the class.
- 3 Save the file:** Save the file to the `+vision/+labeler` package folder to use your custom algorithm from within the app. To add a folder to the path, use the `addpath` function.
- 4 Refresh the algorithm list:** To start using your custom algorithm, refresh the algorithm list for it to display in the list of algorithms. In the app, click **Select Algorithm > Refresh list** in the app.

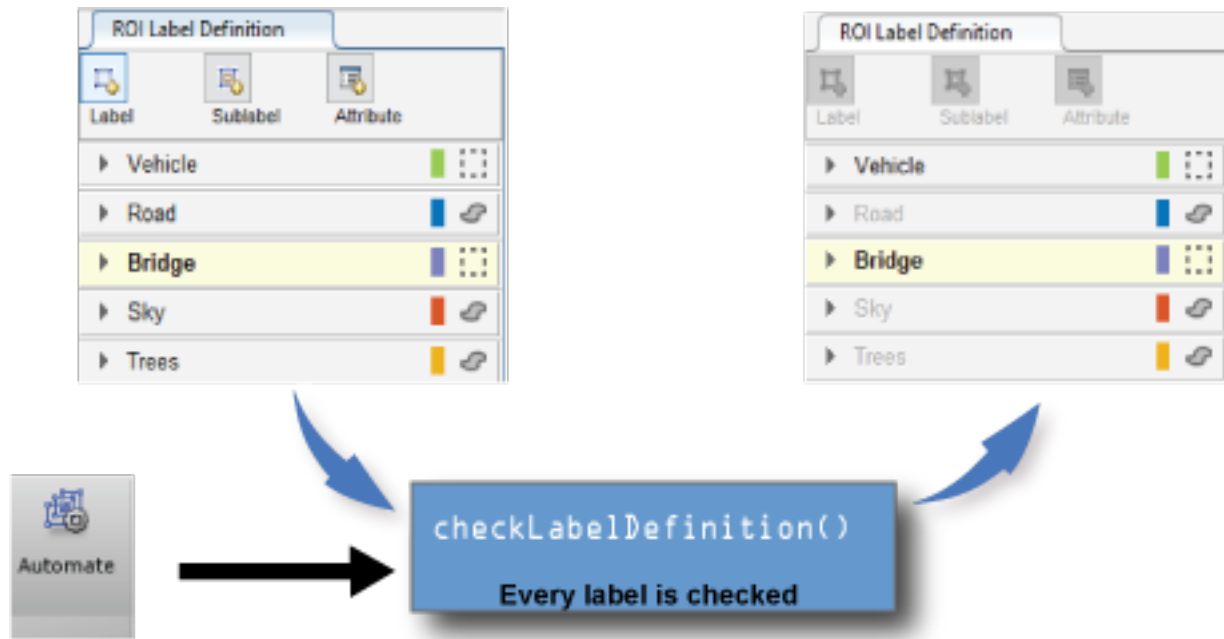

Import Custom Algorithm into Labeling App

Alternatively, to import your custom algorithm, click **Select Algorithm > Add Algorithm > Import Algorithm** and then refresh the list.

Custom Algorithm Execution

The properties and methods in your automation algorithm class define how the class interacts with the **Automate** button in the labeler app.

When you click **Automate**, the app checks each label definition in the **ROI Label Definition** and **Scene Label Definition** panes by using the `checkLabelDefinition` method defined in your custom algorithm. Label definitions that return `true` are retained for automation. Label definitions that return `false` are disabled and not included. Use the `checkLabelDefinition` method to choose a subset of label definitions that are valid for your custom algorithm. For example, if your custom algorithm is a semantic segmentation algorithm, use this method to return `false` for label definitions that are not of type `PixelLabel`.

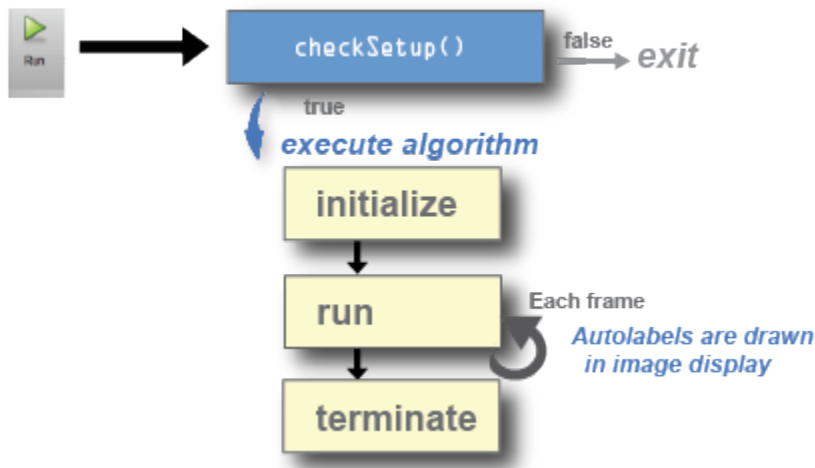

After you select the algorithm, click **Automate** to start an automation session. Then, click **Settings**, which enables you to modify custom app settings. To control the **Settings** options, use the `settingsDialog` method.

When you first run the algorithm, the app calls the `checkSetup` method to check if it is ready for execution. If the method returns `true`, the app calls the `initialize` method and then the `run` method on every image selected for automation. Then, the app calls the `terminate` method.

Use the `checkSetup` method to check whether all conditions needed for your custom algorithm are set up correctly. For example, before running the algorithm, check that the scene contains at least one ROI label before running the algorithm. Use the `initialize` method to initialize the state for your custom algorithm by using the image. Use the `run` method to implement the core of the algorithm that computes and returns labels for each image. Use the `terminate` method to clean up or terminate the state after the algorithm runs.

Label Pixels for Semantic Segmentation

The **Image Labeler**, **Video Labeler**, and **Ground Truth Labeler** (requires Automated Driving Toolbox) apps enable you to assign pixel labels manually. Each pixel can have at most one pixel label. The labels are used to create ground truth data for training semantic segmentation algorithms.

Start Pixel Labeling

Begin by loading an image, video, or image sequence into a labeling app and defining pixel ROI labels. For more details, see:

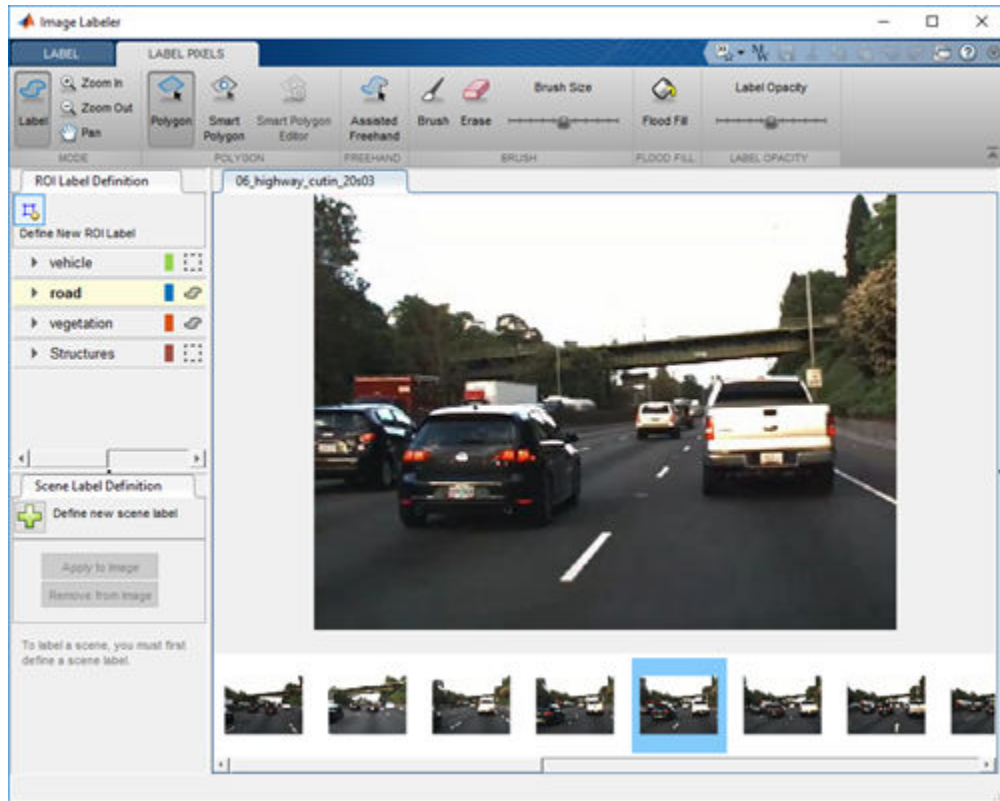

- **Image Labeler** — “Get Started with the Image Labeler” on page 7-55
- **Video Labeler** — “Get Started with the Video Labeler” on page 7-77
- **Ground Truth Labeler** — “Get Started with the Ground Truth Labeler” (Automated Driving Toolbox)

This example shows pixel labeling with the **Image Labeler**. You use the same tools to label videos and image sequences with the **Video Labeler** or **Ground Truth Labeler**.

Select a pixel label definition from the **ROI Label Definition** pane. A **Label Pixels** tab opens, containing tools to label pixels manually using polygons, brushes, or flood fill. You can use the labeling tools in any order. This tab also has controls to adjust the display of the image by zooming and panning and to adjust the opacity of the labels.

This example uses two general strategies to label pixels in the highway image:

- First use the semi-automated tools, such as **Flood Fill** and **Smart Polygon**. Then, refine the labels using tools that offer more direct control, such as **Polygon, Assisted Freehand** and **Brush**.
- First label distant objects with a rough estimation of object borders. Then, label nearer objects with more precise object borders.

Label Pixels Using Flood Fill Tool

The **Flood Fill** tool labels a group of connected pixels that have a similar color. In this image, the sky is a good candidate for flood fill because the boundary of the bright sky is clear against the dark vegetation and overpass. In contrast, flood fill cannot isolate the vegetation because the color of the vegetation is too similar to the adjacent barriers, roads, and vehicles.

To label pixels using **Flood Fill**:

- 1 Select the tool and a label. The pointer changes to a paint can .
- 2 Click a starting pixel in the image.

You can undo the flood fill, or any other labeling operation, by pressing **Ctrl+Z**.

Label Pixels Using Smart Polygon Tool

The **Smart Polygon** tool estimates the shape of an object of interest within a polygon that you draw. The tool is useful when the shape of the object is not a simple polygon. This example uses **Smart Polygon** to label the vegetation, which has a complicated boundary with the sky.

To label pixels using **Smart Polygon**:

- 1 Select the tool and a label. The pointer changes to a crosshair \dagger .
- 2 Click to add polygon vertices. Completely surround the object of interest, with some space between the object and the polygon.
- 3 Close the polygon by clicking the first vertex after placing the other vertices. Alternatively, you can double-click to add the last vertex and close the polygon in one step.

After you close the polygon, the tool draws an initial label.

- 4 Adjust the shape and position of the polygon. When the object of interest extends to the edge of the image, drag vertices to the edge of the image to ensure that the smart polygon completely encloses the object. For instance, this example shows the two leftmost vertices placed at the left edge of the image.

Smart Polygon Actions

Goal	Control
Move vertex	Click and drag the vertex.
Add vertex	<ul style="list-style-type: none"> Right-click the polygon boundary at the position of the new vertex, and select Add Point. Double-click the point on the boundary.
Delete vertex	Right-click the vertex and select Delete Vertex .
Move polygon	Click and drag any point on the polygon boundary (excluding vertices).
Delete polygon	Right-click the polygon boundary and select Delete Polygon .

- Use the **Smart Polygon Editor** tools to refine the label.
 - Select **Mark Foreground** to mark areas inside the region that you want to label. Foreground marks appear in green.
 - Select **Mark Background** to mark areas inside the region that you do not want to label. Background marks appear in red.
 - Select **Erase Marks** to remove foreground or background marks that are no longer needed.
 - See Tips on page 7-53 for additional suggestions on using the **Smart Polygon** tool.

- To finalize the label, press **Enter** or select a new **ROI Label Definition**. You can no longer edit the polygon vertices or mark foreground and background regions.

Label Pixels Using Polygon Tool

The **Polygon** tool labels all pixels within a polygon that you draw. The controls for defining and adjusting the vertices of a polygon are similar to the controls of the **Smart Polygon** tool.

Add additional polygons over structures such as barriers and the road. Many vehicle pixels are incorrectly labeled. The next step shows how to replace the erroneous labels with the correct label.

Label Pixels Using Assisted Freehand Tool

The **Assisted Freehand** tool enables you to draw an ROI that automatically follows the edge of the subject in the underlying image. You can also adjust the size and position of the ROI by using your mouse.

Replace Pixel Labels

Each pixel can have at most one pixel label. When you apply a label to a pixel, the new label replaces the previous label.

This example uses the **Smart Polygon** tool to label pixels belonging to the truck. Foreground marks assign the *vehicle* label to subregions. Background marks revert subregions to their prior label. For instance, in the first pair of images, background marks revert subregions to the *sky* and *vegetation* labels. Similarly, in the second pair of images, background marks revert subregions to the *road* label.

The border of the truck is jagged because **Smart Polygon** labels entire subregions, not individual pixels. The next step shows how to refine the labels along the border of the truck.

Refine Labels Using Brush Tool

The **Brush** tool labels pixels when you draw over the image with the mouse. This example uses **Brush** to remove spurs from the road and to make the edges of the truck smoother.

To label pixels using **Brush**:

- 1 Select the tool and a label. The pointer changes to a pen , and a square appears to indicate the size of the brush.
- 2 Adjust the size of the brush by using the **Brush Size** slider.
- 3 Click and drag the mouse to label pixels.

The **Erase** tool removes pixel labels when you draw over the image with the mouse.

Visualize Pixel Labels

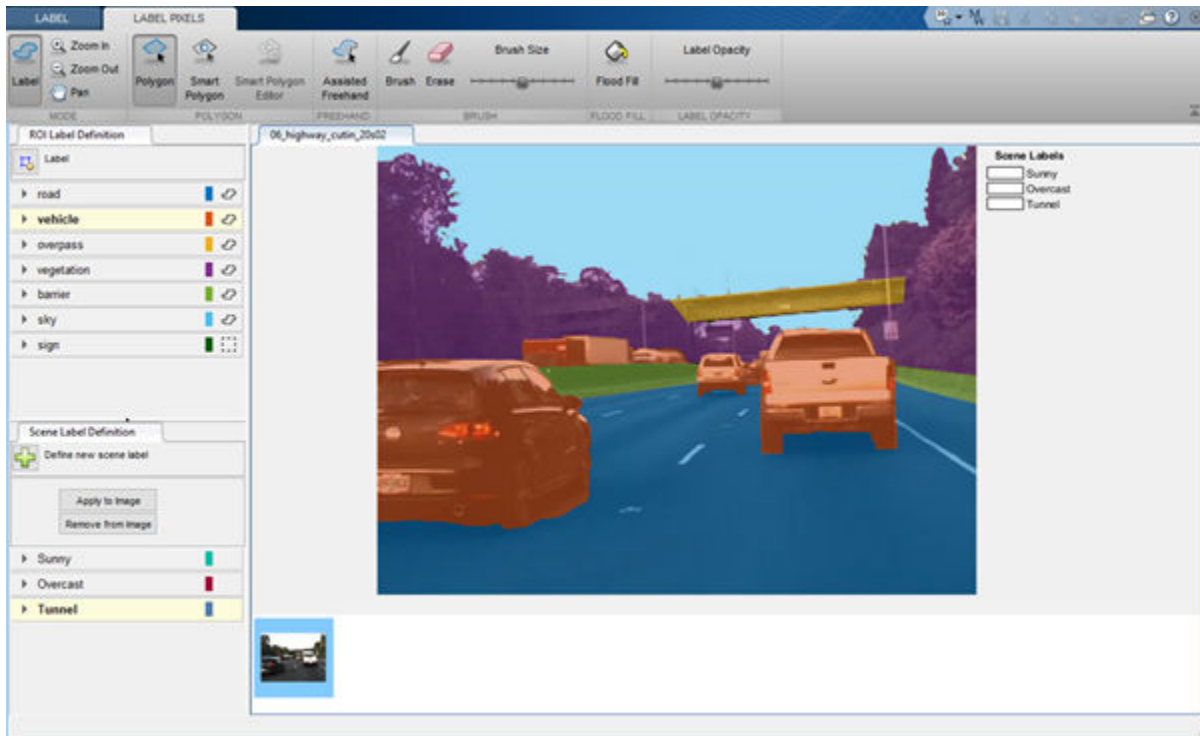

You can modify the view of the image to facilitate pixel labeling. The **Zoom In**, **Zoom Out**, and **Pan** options enable you to zoom and pan the image with the mouse. To resume pixel labeling, click the **Label** icon.

The **Label Opacity** slider adjusts the opacity of all pixel labels.

- Decrease the opacity to see the image more clearly. For instance, decrease the opacity to make it easier to find the border between the bottom of the car and the road.
- Increase the opacity to see the segmentation more clearly. For instance, increase the opacity to see that edge along the front bumper of the car should be smoothed. Also, observe that the barrier and some distant vehicles have unlabeled pixels.

This is the final pixel-labeled image.

Tips

- The **Smart Polygon** tool identifies an object of interest by using regional graph-based segmentation ("GrabCut") [1]. The **Smart Polygon** tool divides the image into subregions. The tool treats all subregions that are fully or partially outside the polygon as belonging to the background. Therefore, to get an optimal segmentation, make sure the object to be labeled is fully contained within the polygon, surrounded by a few background pixels.

All pixels within a subregion have the same label. Marking pixels outside the polygon has no effect on the label.

- To delete the most recently labeled ROI, press **Ctrl+Z**.
- Each pixel can have at most one pixel label. When you apply a label to a pixel, the new label replaces the previous label.

- Pixel labeling is disabled when you pan and zoom the image. You must click the **Label** button to resume pixel labeling.
- To ensure that all pixels in an image are labeled, begin by labeling the entire image with a single label. Pick a label that represents a predominant ROI in the image, such as *sky*, *road*, or *background*. Then, use the labeling tools to relabel objects with their correct label.
- To fill all or all remaining pixels, select an ROI label from your list and press **Shift +Click** (you can use left- or right-click).

- "Get Started with the Video Labeler" on page 7-77
- "Get Started with the Ground Truth Labeler" (Automated Driving Toolbox)
- "How Labeler Apps Store Exported Pixel Labels" on page 7-6

Get Started with the Image Labeler

The **Image Labeler** app provides an easy way to mark rectangular region of interest (ROI) labels, polyline ROI labels, pixel ROI labels, and scene labels in a video or image sequence. This example gets you started using the app by showing you how to:

- Manually label an image frame from an image collection.
- Automatically label across image frames using an automation algorithm.
- Export the labeled ground truth data.

ROI and Scene Label Definitions

- An ROI label corresponds to either a rectangular, polyline, or pixel region of interest. These labels contain two components: the label name, such as "cars," and the region you create.
- A Scene label describes the nature of a scene, such as "sunny." You can associate this label with a frame.

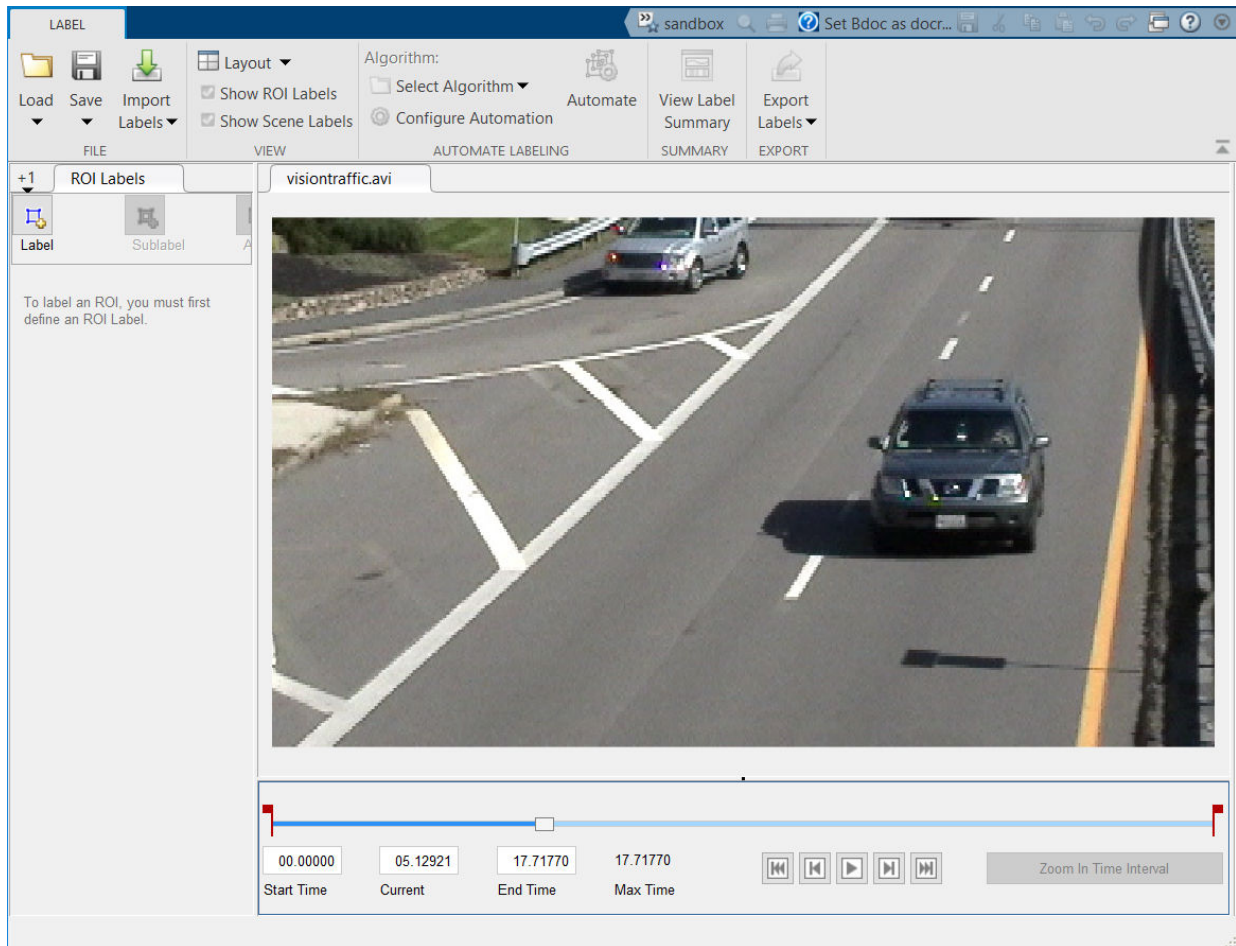

Load Unlabeled Data

Open the app and load a collection of images. You can load images stored in a datastore, from a folder, or load a previous labeler session. The images must be readable by `imread`.

```
imageFolder = fullfile(toolboxdir('vision'),'visiondata','stopSignImages')
imds = imageDatastore(imageFolder)
imageLabeler(imds)
```

```
imageFolder = fullfile(toolboxdir('vision'),'visiondata','stopSignImages')
imageLabeler(imageFolder)
```

Alternatively, open the app from the **Apps** tab, under **Image Processing and Computer Vision**. Then, from the **Load** menu, load an images data source.

Create Label Definitions

Define the labels you intend to draw. In this example, you define labels directly within the app. To define labels from the MATLAB command line instead, use the `labelDefinitionCreator`.

Create ROI Labels

An ROI label is a label that corresponds to a region of interest (ROI). You can define these types of ROI labels.

ROI Label	Description	Example: Driving Scene
Rectangle	Draw rectangular ROI labels (bounding boxes) around objects.	<p data-bbox="970 447 1307 510">Vehicles, pedestrians, road signs</p> 
Line	Draw linear ROI labels to represent lines. To draw a polyline ROI, use two or more points.	<p data-bbox="970 890 1262 953">Lane boundaries, guard rails, road curbs</p> 

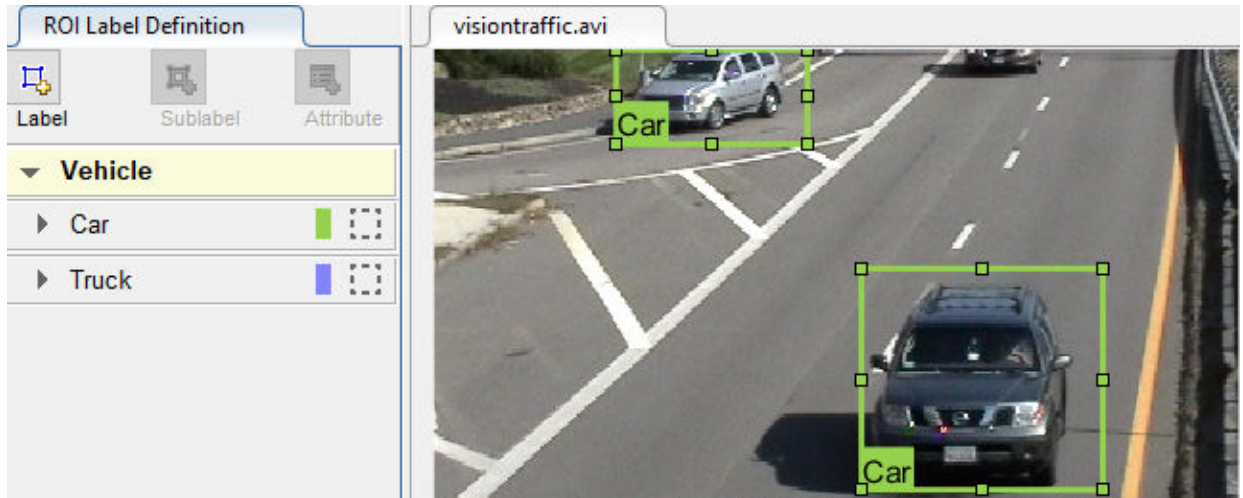

ROI Label	Description	Example: Driving Scene
Pixel label	Assign labels to pixels for semantic segmentation. You can label pixels manually using polygons, brushes, or flood fill. See “Label Pixels for Semantic Segmentation” on page 7-43.	Vehicles, road surface, trees, pavement 

In this example, you define a **vehicle** group for labeling types of vehicles, and then create a **Rectangle** ROI label for a **Car** and a **Truck**.

- 1 In the **ROI Label Definition** pane on the left, click **Label**.
- 2 Create a **Rectangle** label named **Car**.
- 3 From the **Group** drop-down menu, select **New Group** and name the group **Vehicle**.
- 4 Click **OK**.

The **Vehicle** group name appears in the **ROI Label Definition** pane with the label **Car** created. You can move a labels to a different position or group by left-clicking and dragging the label.

- 5 Add a second label. Click **Label**. Name the label **Truck** and make sure the **Vehicle** group is selected. Click **OK**.
- 6 In the first video frame within the time interval, use the mouse to draw rectangular **Car** ROIs around the two vehicles.

Create Sublabels

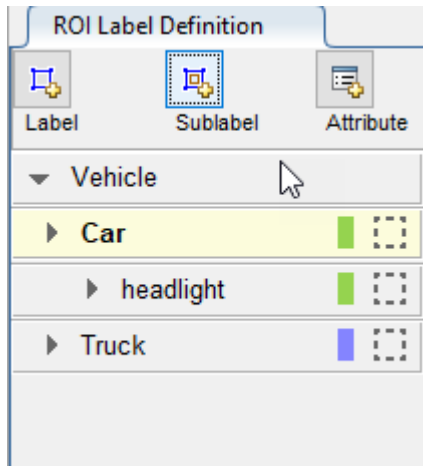

A sublabel is a type of ROI label that corresponds to a parent ROI label. Each sublabel must belong to, or be a child of, a specific label defined in the **ROI Label Definition** pane. For example, in a driving scene, a vehicle label might have sublabels for headlights, license plates, or wheels.

Define a sublabel for headlights.

- 1 In the **ROI Label Definition** pane on the left, click the **Car** label.
- 2 Click **Sublabel**.
- 3 Create a **Rectangle** sublabel named **headlight** and optionally write a description. Click **OK**.

The **headlight** sublabel appears in the **ROI Label Definition** pane. The sublabel is nested under the selected ROI label, **Car**, and has the same color as its parent label.

You can add multiple sublabels under a label. You can also drag-and-drop the sublabels to reorder them in the list. Right-click any label for additional edits.

- 4 In the **ROI Label Definition** pane, select the **headlight** sublabel.
- 5 In the video frame, select the **Car** label. The label turns yellow when selected. You must select the **Car** label (parent ROI) before you can add a sublabel to it.

Draw **headlight** sublabels for each of the cars.

- 6 Repeat the previous steps to label the headlights of the other car. To draw the labels more precisely, use the **Pan**, **Zoom In**, and **Zoom Out** options available from the toolbar.

Sublabels can only be used with rectangular or polyline ROI labels and cannot have their own sublabels. For more details on working with sublabels, see “Use Sublabels and Attributes to Label Ground Truth Data” on page 7-102.

Create Attributes

An attribute provides further categorization of an ROI label or sublabel. Attributes specify additional information about a drawable label. For example, in a driving scene, attributes might include the type or color of a vehicle.

You can define these types of attributes.

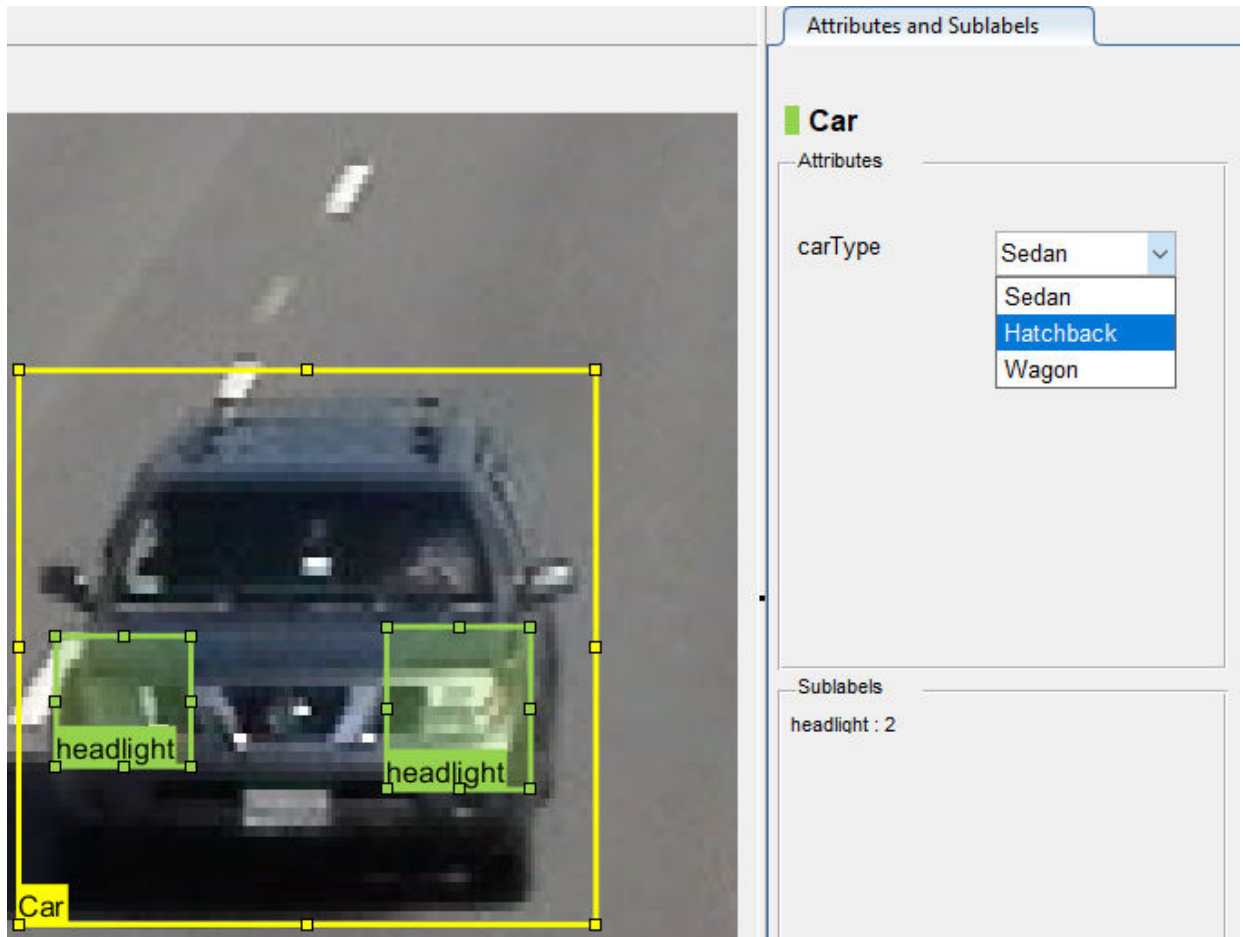

Attribute Type	Sample Attribute Definition	Sample Default Values
Numeric Value	<p>Attribute Name</p> <input type="text" value="numDoors"/> <p>Default Scalar Value (Optional)</p> <input type="text" value="4"/>	
String	<p>Attribute Name</p> <input type="text" value="color"/> <p>Default Value (Optional)</p> <input type="text"/>	<p>String</p> <input type="text"/>
Logical	<p>Attribute Name</p> <input type="text" value="inMotion"/> <p>Default Value (Optional)</p> <input type="text" value="True"/>	<p>Logical</p> <input type="text"/>

Attribute Type	Sample Attribute Definition	Sample Default Values
List	<p>Attribute Name</p> <input data-bbox="635 388 946 427" type="text" value="carType"/> <p>List Items (Each item must appear)</p> <input data-bbox="635 493 946 649" type="text" value="Sedan
Hatchback
Wagon"/>	<p>Attributes and Sublabels</p> <p>Car</p> <p>Attributes</p> <p>carMake <input data-bbox="1228 583 1426 621" type="text" value="Nissan"/></p> <p>inMotion <input data-bbox="1228 666 1426 704" type="text" value="True"/> ▼</p> <p>color <input data-bbox="1228 749 1426 788" type="text" value="Blue"/></p> <p>numDoors <input data-bbox="1228 833 1426 871" type="text" value="4"/></p> <p>carType <input data-bbox="1228 916 1426 1078" type="text" value="Sedan"/> ▼</p> <p>Sedan</p> <p>Hatchback</p> <p>Wagon</p>

Add an attribute for the vehicle type.

- 1 In the **ROI Label Definition** pane on the left, select the **Car** label and click **Attribute**.
- 2 In the **Attribute Name** box, type carType. Set the attribute type to List.
- 3 In the **List Items** section, type different types of cars, such as Sedan, Hatchback, and Wagon, each on its own line. Optionally give the attribute a description, and click **OK**.

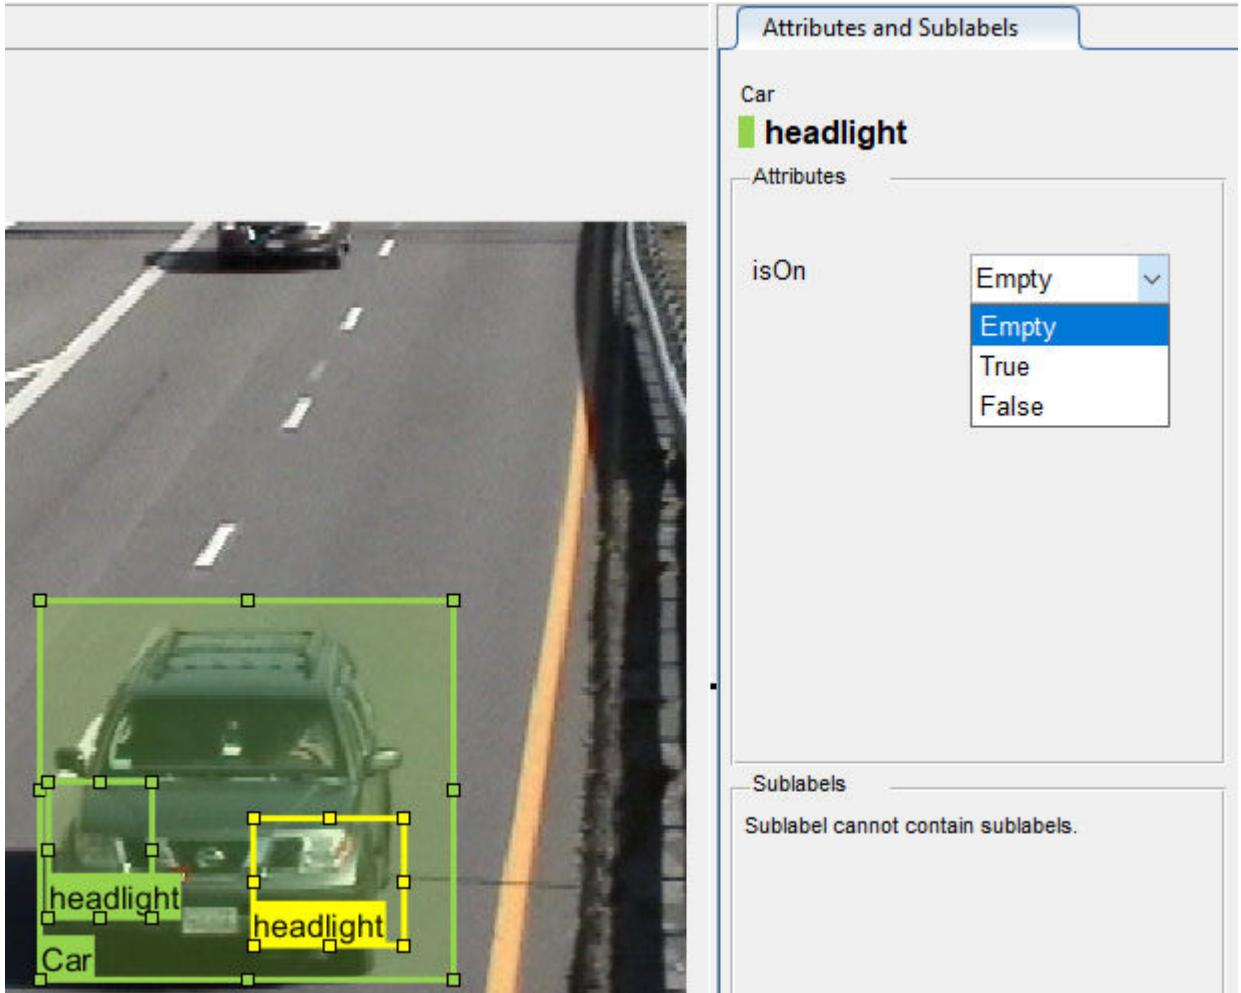

- 4 In the first frame of the video, select a **Car** ROI label. In the **Attributes and Sublabels** pane, select the appropriate **carType** attribute value for that vehicle.
- 5 Repeat the previous step to assign a **carType** attribute to the other vehicle.

You can also add attributes to sublabels. Add an attribute for the **headlight** sublabel that tells whether the headlight is on.

- 1 In the **ROI Label Definition** pane on the left, select the **headlight** sublabel and click **Attribute**.

- 2 In the **Attribute Name** box, type `isOn`. Set the attribute type to `Logical`. Leave the **Default Value** set to `Empty`, optionally write a description, and click **OK**.
- 3 Select a headlight in the video frame. Set the appropriate **isOn** attribute value, or leave the attribute value set to `Empty`.
- 4 Repeat the previous step to set the **isOn** attribute for the other headlights.

The image shows a software interface for object detection. On the left, a video frame of a car on a road is displayed. A green bounding box labeled 'Car' encompasses the entire vehicle. Two yellow bounding boxes labeled 'headlight' are positioned over the front headlights of the car. On the right, a panel titled 'Attributes and Sublabels' is visible. Under the 'Car' category, the 'headlight' sublabel is selected. The 'Attributes' section for 'headlight' shows a dropdown menu for the 'isOn' attribute, with 'Empty' selected. The 'Sublabels' section contains the text 'Sublabel cannot contain sublabels.'

To delete an attribute, right-click an ROI label or sublabel, and select the attribute to delete. Deleting the attribute removes attribute information from all previously created ROI label annotations.

Create Scene Labels

A scene label defines additional information for the entire scene. Use scene labels to describe conditions, such as lighting and weather, or events, such as lane changes.

Create a scene label to use in the video.

- 1 In the **Scene Label Definition** pane on the left, click the **Define new scene label** button, and create a scene label named **sunny**. Make sure **Group** is set to **None**. Click **OK**.

The **Scene Label Definition** pane shows the scene label definition. The scene labels that are applied to the current frame appear in the **Scene Labels** pane on the right. The **sunny** scene label is empty (white), because the scene label has not yet been applied to the frame.

- 2 The entire scene is sunny, so specify to apply the **sunny** scene label over the entire time interval. With the **sunny** scene label definition still selected in the **Scene Label Definition** pane, select **Time Interval**.
- 3 Click **Add Label**.

The **sunny** label now applies to all frames in the time interval.

Label Ground Truth

So far, you have labeled only one frame in the video. To label the remaining frames, choose one of these options.

Label Ground Truth Manually

When you click the right arrow key to advance to the next frame, the ROI labels from the previous frame do not carry over. Only the **sunny** scene label applies to each frame, because this label was applied over the entire time interval.

Advance frame by frame and draw the label and sublabel ROIs manually. Also update the attribute information for these ROIs.

Label Ground Truth Using Automation Algorithm

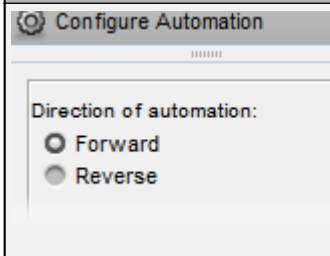

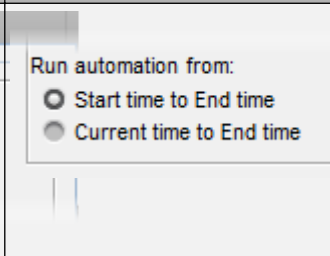

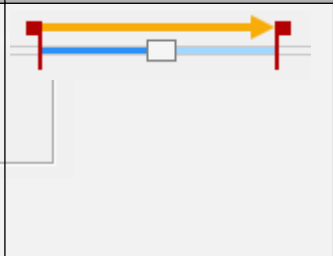

To speed up the labeling process, you can use an automation algorithm within the app. You can either define your own automation algorithm, see “Create Automation Algorithm for Labeling” on page 7-39 and “Temporal Automation Algorithms” on page 7-107, or use a built-in automation algorithm. In this example, you label the ground truth using a built-in point tracking algorithm.

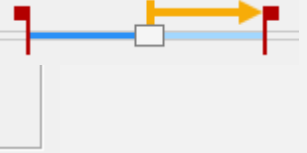

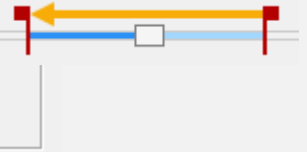

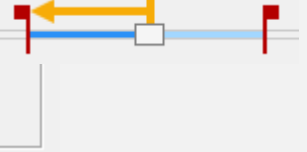

In this example, you automate the labeling of only the **Car** ROI labels. The built-in automation algorithms do not support sublabel and attribute automation.

- 1 Select the labels you want to automate. In the first frame of the video, press **Ctrl** and click to select the two **Car** label annotations. The labels are highlighted in yellow.

- 2 From the app toolstrip, select **Select Algorithm > Point Tracker**. This algorithm tracks one or more rectangle ROIs over short intervals using the Kanade-Lucas-Tomasi (KLT) algorithm.
- 3 (optional) Configure the automation settings. Click **Configure Automation**. By default, the automation algorithm applies labels from the start of the time interval to the end. To change the direction and start time of the algorithm, choose one of the options shown in this table.

Direction of automation	Run automation from	Example
		

Direction of automation	Run automation from	Example
	Run automation from: <input type="radio"/> End time to Start time <input checked="" type="radio"/> Current time to Start time	
Direction of automation: <input type="radio"/> Forward <input checked="" type="radio"/> Reverse	Run automation from: <input checked="" type="radio"/> Start time to End time <input type="radio"/> Current time to End time	
	Run automation from: <input type="radio"/> End time to Start time <input checked="" type="radio"/> Current time to Start time	

The **Import selected ROIs** must be selected so that the **Car** labels you selected are imported into the automation session.

- 4 Click **Automate** to open an automation session. The algorithm instructions appear in the right pane, and the selected labels are available to automate.

- 5 Click **Run** to track the selected ROIs over the interval.
- 6 Examine the results of running the algorithm.

The vehicles that enter the scene later are unlabeled. The unlabeled vehicles did not have an initial ROI label, so the algorithm did not track them. Click **Undo Run**. Use the slider to find the frames where each vehicle first appears. Draw **vehicle** ROIs around each vehicle, and then click **Run** again.

- 7 Advance frame by frame and manually move, resize, delete, or add ROIs to improve the results of the automation algorithm.

When you are satisfied with the algorithm results, click **Accept**. Alternatively, to discard labels generated during the session and label manually instead, click **Cancel**. The **Cancel** button cancels only the algorithm session, not the app session.

Optionally, you can now manually label the remaining frames with sublabel and attribute information.

To further evaluate your labels, you can view a visual summary of the labeled ground truth. From the app toolbar, select **View Label Summary**. Use this summary to compare the frames, frequency of labels, and scene conditions. For more details, see “View Summary of Ground Truth Labels” on page 7-109. This summary does not support sublabels or attributes.

Export Labeled Ground Truth

You can export the labeled ground truth to a MAT-file or to a variable in the MATLAB workspace. In both cases, the labeled ground truth is stored as a `groundTruth` object. You can use this object to train a deep-learning-based computer vision algorithm. For more details, see “Training Data for Object Detection and Semantic Segmentation” on page 7-35.

Note If you export pixel data, the pixel label data and ground truth data are saved in separate files but in the same folder. For considerations when working with exported pixel labels, see “How Labeler Apps Store Exported Pixel Labels” on page 7-6.

In this example, you export the labeled ground truth to the MATLAB workspace. From the app toolstrip, select **Export Labels > To Workspace**. The exported MATLAB variable, `gTruth`, is a `groundTruth` object.

Display the properties of the exported `groundTruth` object. The information in your exported object might differ from the information shown here.

```
gTruth
```

```
gTruth =
```

```
groundTruth with properties:
```

```
DataSource: [1x1 groundTruthDataSource]  
LabelDefinitions: [3x5 table]  
LabelData: [531x3 timetable]
```

Data Source

`DataSource` is a `groundTruthDataSource` object containing the path to the video and the video timestamps. Display the properties of this object.

```
gTruth.DataSource
```

```
ans =
```

```
groundTruthDataSource for a video file with properties
```

```
Source: ...matlab\toolbox\vision\visiondata\visiontraffic.avi  
TimeStamps: [531x1 duration]
```

Label Definitions

`LabelDefinitions` is a table containing information about the label definitions. This table does not contain information about the labels that are drawn on the video frames. To save the label definitions in their own MAT-file, from the app toolstrip, select **Save > Label Definitions**. You can then import these label definitions into another app session by selecting **Import Files**.

Display the label definitions table. Each row contains information about an ROI label definition or a scene label definition. If you exported pixel label data, the `LabelDefinitions` table also includes a `PixelLabelID` column containing the ID numbers for each pixel label definition.

```
gTruth.LabelDefinitions
```

```
ans =
```

```
3x5 table
```

Name	Type	Group	Description	Hierarchy
'Car'	Rectangle	'Vehicle'	''	[1x1 struct]
'Truck'	Rectangle	'Vehicle'	''	[]
'sunny'	Scene	'None'	''	[]

Within `LabelDefinitions`, the `Hierarchy` column stores information about the sublabel and attribute definitions of a parent ROI label.

Display the sublabel and attribute information for the `Car` label.

```
gTruth.LabelDefinitions.Hierarchy{1}
```

```
ans =
```

```
struct with fields:
```

```
    carType: [1x1 struct]
    headlight: [1x1 struct]
        Type: Rectangle
    Description: ''
```

Display information about the `headlight` sublabel.

```
gTruth.LabelDefinitions.Hierarchy{1}.headlight
```

```
ans =  
  
  struct with fields:  
  
      Type: Rectangle  
  Description: ''  
      isOn: [1x1 struct]
```

Display information about the `carType` attribute.

```
gTruth.LabelDefinitions.Hierarchy{1}.carType
```

```
ans =  
  
  struct with fields:  
  
      ListItems: {3x1 cell}  
  Description: ''
```

Label Data

`LabelData` is a timetable containing information about the ROI labels drawn at each timestamp, across the entire video. The timetable contains one column per label.

Display the first few rows of the timetable. The first few timestamps indicate that no vehicles were detected and that the `sunny` scene label is `false`. These results are because this portion of the video was not labeled. Only the time interval of 5-10 seconds was labeled.

```
labelData = gTruth.labelData;  
head(labelData)
```

```
ans =  
  
  8x3 timetable  
  
      Time           Car           Truck           sunny  
      -----  
  5.005 sec   [1x2 struct]   [1x0 struct]   true  
  5.0384 sec  [1x2 struct]   [1x0 struct]   true  
  5.0717 sec  [1x2 struct]   [1x0 struct]   true  
  5.1051 sec  [1x2 struct]   [1x0 struct]   true  
  5.1385 sec  [1x2 struct]   [1x0 struct]   true  
  5.1718 sec  [1x2 struct]   [1x0 struct]   true
```

```

5.2052 sec    [1x2 struct]    [1x0 struct]    true
5.2386 sec    [1x2 struct]    [1x0 struct]    true

```

Display the first few timetable rows from the 5-10 second interval that contains labels.

```

gTruthInterval = labelData(timerange('00:00:05','00:00:10'),:);
head(gTruthInterval)

```

```
ans =
```

```
8x3 timetable
```

Time	Car	Truck	sunny
5.005 sec	[1x2 struct]	[1x0 struct]	true
5.0384 sec	[1x2 struct]	[1x0 struct]	true
5.0717 sec	[1x2 struct]	[1x0 struct]	true
5.1051 sec	[1x2 struct]	[1x0 struct]	true
5.1385 sec	[1x2 struct]	[1x0 struct]	true
5.1718 sec	[1x2 struct]	[1x0 struct]	true
5.2052 sec	[1x2 struct]	[1x0 struct]	true
5.2386 sec	[1x2 struct]	[1x0 struct]	true

For each Car label, the structure includes the position of the bounding box and information about its sublabels and attributes.

Display the bounding box positions for the vehicles at the start of the time interval. Your bounding box positions might differ from the ones shown here.

```
gTruthInterval(1,:).Car{1}.Position % [x y width height], in pixels
```

```
ans =
```

```
1x4 single row vector
```

```
415.8962    82.4737   130.8474   129.3805
```

```
ans =
```

```
1x4 single row vector
```

```
235.2182     1.0000   117.0611    55.3500
```

Save App Session

From the app toolbar, select **Save** and save a MAT-file of the app session. The saved session includes the data source, label definitions, and labeled ground truth. It also includes your session preferences, such as the layout of the app. To change layout options, select **Layout**.

The app session MAT-file is separate from the ground truth MAT-file that is exported when you select **Export > From File**. To share labeled ground truth data, as a best practice, share the ground truth MAT-file containing the `groundTruth` object, not the app session MAT-file. For more details, see “Share and Store Labeled Ground Truth Data” on page 7-115.

Choose an App to Label Ground Truth Data

Computer Vision Toolbox and Automated Driving Toolbox provide several apps for labeling ground truth data. You can use this labeled data to validate algorithms or to train algorithms such as image classifiers, object detectors, and semantic segmentation networks. The choice of labeling app depends on several factors, including the supported data sources, labels, and types of automation.

One key consideration is the type of data that you want to label.

- If your data is an image collection, use the **Image Labeler** app. An image collection is an unordered set of images that can vary in size. For example, you can use the app to label images of books to train a classifier.
- If your data is a video or image sequence, use the **Video Labeler** or **Ground Truth Labeler** app. An image sequence is an ordered set of images that resemble a video. For example, you can use these apps to label a video or image sequence of cars driving on a highway to train an object detector.

The table summarizes the key features of all three labeling apps.

Labeling App	Data Sources	Label Support	Automation	Additional Features
Image Labeler (Computer Vision Toolbox)	<ul style="list-style-type: none"> • Image collections 	<ul style="list-style-type: none"> • Rectangle regions of interest (ROIs) • Line ROIs • Pixel ROIs • Sublabels • Attributes • Scenes 	<ul style="list-style-type: none"> • Built-in automation algorithms • Custom automation algorithms 	<ul style="list-style-type: none"> • View visual summary of labeled data

Labeling App	Data Sources	Label Support	Automation	Additional Features
Video Labeler (Computer Vision Toolbox)	<ul style="list-style-type: none"> • Video • Image sequences • Custom data sources 	<ul style="list-style-type: none"> • Rectangle ROIs • Line ROIs • Pixel ROIs • Sublabels • Attributes • Scenes 	<ul style="list-style-type: none"> • Built-in automation algorithms • Custom automation algorithms • Temporal automation algorithms 	<ul style="list-style-type: none"> • View visual summary of labeled data
Ground Truth Labeler (Automated Driving Toolbox)	<ul style="list-style-type: none"> • Video • Image sequences • Custom data sources 	<ul style="list-style-type: none"> • Rectangle ROIs • Line ROIs • Pixel ROIs • Sublabels • Attributes • Scenes 	<ul style="list-style-type: none"> • Built-in automation algorithms, including vehicle and lane detection algorithms • Custom automation algorithms • Temporal automation algorithms 	<ul style="list-style-type: none"> • View visual summary of labeled data • Connect external tool to app, for displaying time-synchronized signals such as lidar or CAN bus data

More About

- “Get Started with the Image Labeler” on page 7-55
- “Get Started with the Video Labeler” on page 7-77
- “Get Started with the Ground Truth Labeler” (Automated Driving Toolbox)

Get Started with the Video Labeler

The **Video Labeler** app provides an easy way to mark rectangular region of interest (ROI) labels, polyline ROI labels, pixel ROI labels, and scene labels in a video or image sequence. This example gets you started using the app by showing you how to:

- Manually label an image frame from a video.
- Automatically label across image frames using an automation algorithm.
- Export the labeled ground truth data.

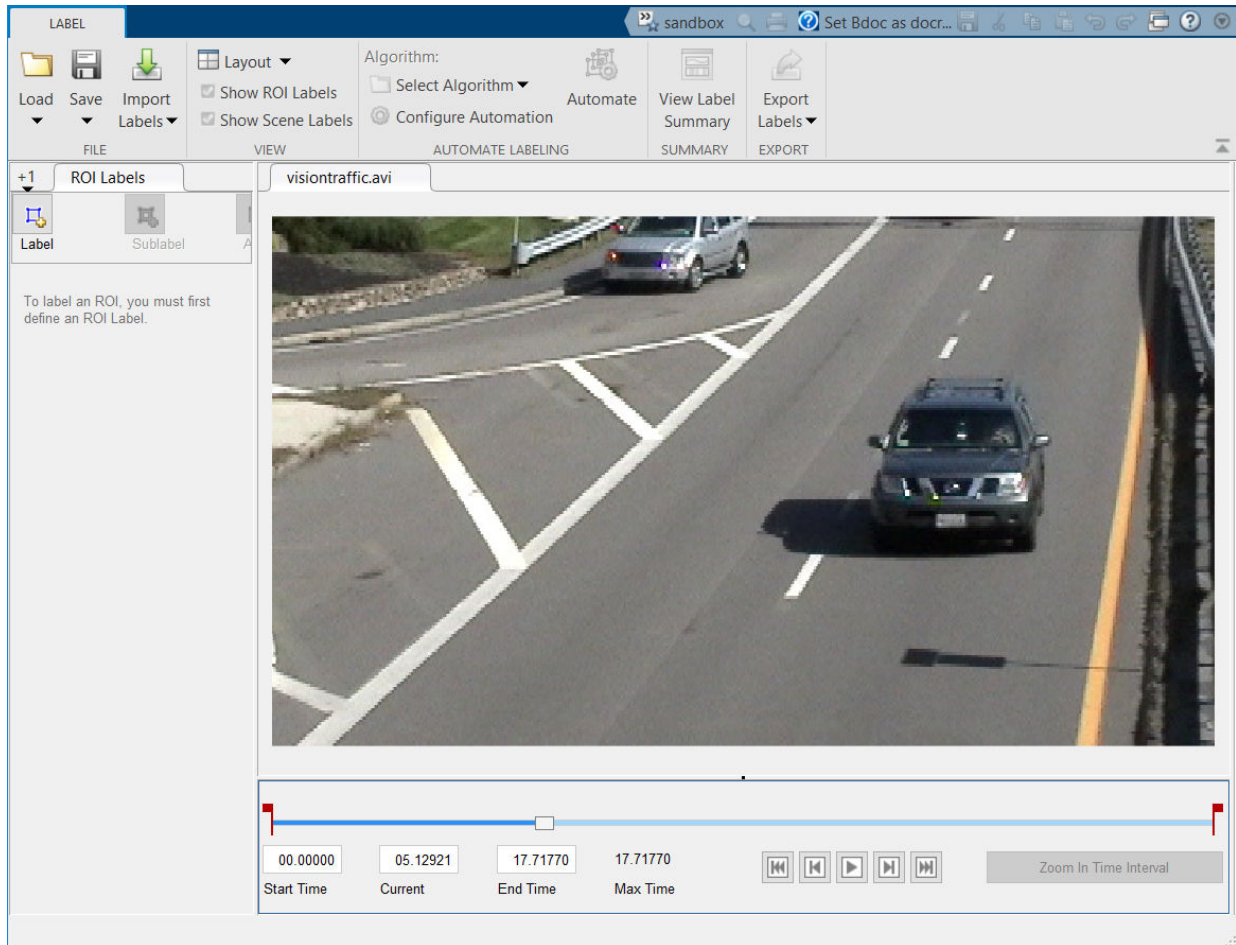

Load Unlabeled Data

Open the app and load a video of vehicles driving on a highway. Videos must be in a file format readable by `VideoReader`.

```
videoLabeler('visiontraffic.avi')
```

Alternatively, open the app from the **Apps** tab, under **Image Processing and Computer Vision**. Then, from the **Load** menu, load a video data source.

Explore the video. Click the Play button  to play the entire video, or use the slider  to navigate between frames.

The app also enables you to load image sequences, with corresponding timestamps, by selecting **Load > Image Sequence**. The images must be readable by `imread`.

To load a custom data source that is readable by `VideoReader` or `imread`, see “Use Custom Data Source Reader for Ground Truth Labeling” on page 7-98.

Set Time Interval to Label

You can label the entire video or start with a portion of the video. In this example, you label a five-second time interval within the loaded video. In the text boxes below the video, enter these times in seconds:

- 1 In the **Current Time** box, type 5 and press **Enter**.
- 2 In the **Start Time** box, type 5 so that the slider is at the start of the time interval.
- 3 In the **End Time** box, type 10.

05.00000	05.00000	10.00000
Start Time	Current	End Time

Optionally, to make adjustments to the time interval, click and drag the red interval flags.

The entire app is now set up to focus on this specific time interval. The video plays only within this interval, and labeling and automation algorithms apply only to this interval. You can change the interval at any time by moving the flags.

To expand the time interval to fill the entire playback section, click **Zoom in Time Interval**.

Create Label Definitions

Define the labels you intend to draw. In this example, you define labels directly within the app. To define labels from the MATLAB command line instead, use the `labelDefinitionCreator`.

Create ROI Labels

An ROI label is a label that corresponds to a region of interest (ROI). You can define these types of ROI labels.

ROI Label	Description	Example: Driving Scene
Rectangle	Draw rectangular ROI labels (bounding boxes) around objects.	<p>Vehicles, pedestrians, road signs</p> 
Line	Draw linear ROI labels to represent lines. To draw a polyline ROI, use two or more points.	<p>Lane boundaries, guard rails, road curbs</p> 

ROI Label	Description	Example: Driving Scene
Pixel label	Assign labels to pixels for semantic segmentation. You can label pixels manually using polygons, brushes, or flood fill. See “Label Pixels for Semantic Segmentation” on page 7-43.	Vehicles, road surface, trees, pavement 

In this example, you define a **vehicle** group for labeling types of vehicles, and then create a **Rectangle** ROI label for a **Car** and a **Truck**.

- 1 In the **ROI Label Definition** pane on the left, click **Label**.
- 2 Create a **Rectangle** label named **Car**.
- 3 From the **Group** drop-down menu, select **New Group** and name the group **Vehicle**.
- 4 Click **OK**.

The **Vehicle** group name appears in the **ROI Label Definition** pane with the label **Car** created. You can move a labels to a different position or group by left-clicking and dragging the label.

- 5 Add a second label. Click **Label**. Name the label **Truck** and make sure the **Vehicle** group is selected. Click **OK**.
- 6 In the first video frame within the time interval, use the mouse to draw rectangular **Car** ROIs around the two vehicles.

Create Sublabels

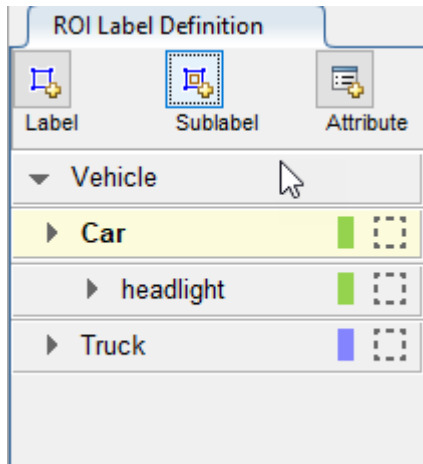

A sublabel is a type of ROI label that corresponds to a parent ROI label. Each sublabel must belong to, or be a child of, a specific label defined in the **ROI Label Definition** pane. For example, in a driving scene, a vehicle label might have sublabels for headlights, license plates, or wheels.

Define a sublabel for headlights.

- 1 In the **ROI Label Definition** pane on the left, click the **Car** label.
- 2 Click **Sublabel**.
- 3 Create a **Rectangle** sublabel named **headlight** and optionally write a description. Click **OK**.

The **headlight** sublabel appears in the **ROI Label Definition** pane. The sublabel is nested under the selected ROI label, **Car**, and has the same color as its parent label.

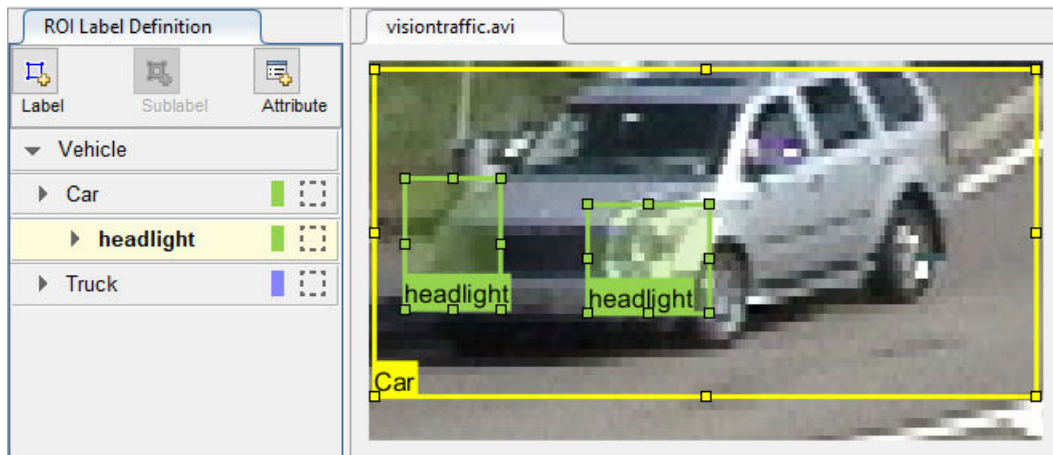

You can add multiple sublabels under a label. You can also drag-and-drop the sublabels to reorder them in the list. Right-click any label for additional edits.

- 4 In the **ROI Label Definition** pane, select the **headlight** sublabel.
- 5 In the video frame, select the **Car** label. The label turns yellow when selected. You must select the **Car** label (parent ROI) before you can add a sublabel to it.

Draw **headlight** sublabels for each of the cars.

- 6 Repeat the previous steps to label the headlights of the other car. To draw the labels more precisely, use the **Pan**, **Zoom In**, and **Zoom Out** options available from the toolbar.

Sublabels can only be used with rectangular or polyline ROI labels and cannot have their own sublabels. For more details on working with sublabels, see “Use Sublabels and Attributes to Label Ground Truth Data” on page 7-102.

Create Attributes

An attribute provides further categorization of an ROI label or sublabel. Attributes specify additional information about a drawable label. For example, in a driving scene, attributes might include the type or color of a vehicle.

You can define these types of attributes.

Attribute Type	Sample Attribute Definition	Sample Default Values
Numeric Value	<p>Attribute Name</p> <input type="text" value="numDoors"/> <p>Default Scalar Value (Optional)</p> <input type="text" value="4"/>	
String	<p>Attribute Name</p> <input type="text" value="color"/> <p>Default Value (Optional)</p> <input type="text"/>	<p>String</p> <input type="text"/>
Logical	<p>Attribute Name</p> <input type="text" value="inMotion"/> <p>Default Value (Optional)</p> <input type="text" value="True"/>	<p>Logical</p> <input type="text"/>

Attribute Type	Sample Attribute Definition	Sample Default Values
List	<p>Attribute Name</p> <input data-bbox="635 388 946 427" type="text" value="carType"/> <p>List Items (Each item must appear)</p> <input data-bbox="635 493 946 649" type="text" value="Sedan"/> <input data-bbox="635 522 946 548" type="text" value="Hatchback"/> <input data-bbox="635 552 946 578" type="text" value="Wagon"/>	<p>Attributes and Sublabels</p> <p>Car</p> <p>Attributes</p> <p>carMake <input data-bbox="1228 586 1426 621" type="text" value="Nissan"/></p> <p>inMotion <input data-bbox="1228 666 1426 710" type="text" value="True"/></p> <p>color <input data-bbox="1228 748 1426 782" type="text" value="Blue"/></p> <p>numDoors <input data-bbox="1228 826 1426 861" type="text" value="4"/></p> <p>carType <input data-bbox="1228 909 1426 1078" type="text" value="Sedan"/></p>

Add an attribute for the vehicle type.

- 1 In the **ROI Label Definition** pane on the left, select the **Car** label and click **Attribute**.
- 2 In the **Attribute Name** box, type carType. Set the attribute type to List.
- 3 In the **List Items** section, type different types of cars, such as Sedan, Hatchback, and Wagon, each on its own line. Optionally give the attribute a description, and click **OK**.

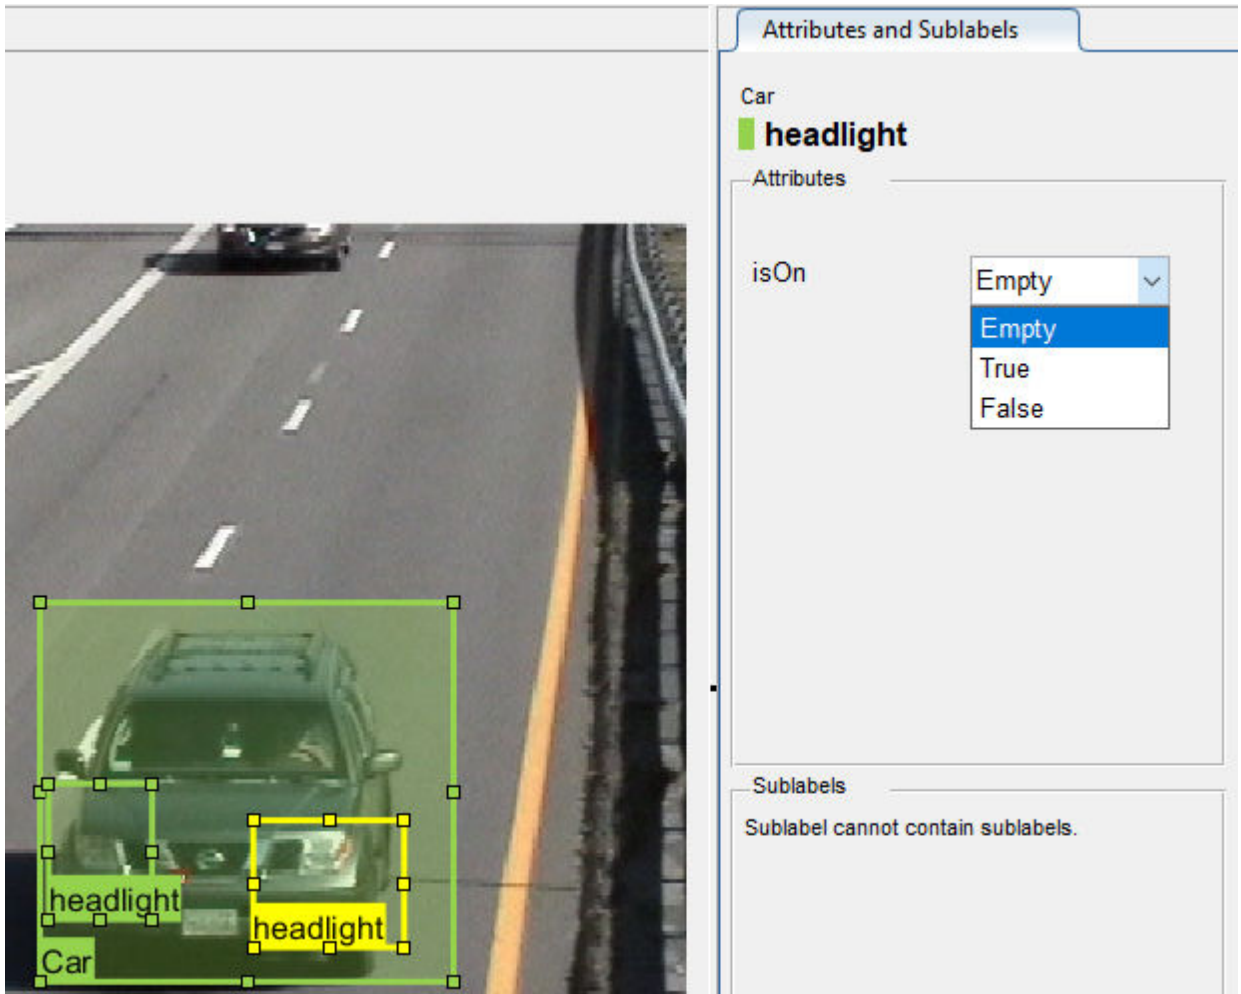

- 4 In the first frame of the video, select a **Car** ROI label. In the **Attributes and Sublabels** pane, select the appropriate **carType** attribute value for that vehicle.
- 5 Repeat the previous step to assign a **carType** attribute to the other vehicle.

You can also add attributes to sublabels. Add an attribute for the **headlight** sublabel that tells whether the headlight is on.

- 1 In the **ROI Label Definition** pane on the left, select the **headlight** sublabel and click **Attribute**.

- 2 In the **Attribute Name** box, type `isOn`. Set the attribute type to `Logical`. Leave the **Default Value** set to `Empty`, optionally write a description, and click **OK**.
- 3 Select a headlight in the video frame. Set the appropriate **isOn** attribute value, or leave the attribute value set to `Empty`.
- 4 Repeat the previous step to set the **isOn** attribute for the other headlight.

The screenshot displays the Video Labeler interface. On the left, a video frame shows a car on a road. A green bounding box labeled 'Car' encompasses the entire vehicle. Two yellow bounding boxes labeled 'headlight' are positioned over the front left and right headlights of the car. On the right, the 'Attributes and Sublabels' panel is visible. The 'Car' label is selected, and the 'headlight' sublabel is active. The 'Attributes' section shows the 'isOn' attribute with a dropdown menu open, displaying options: 'Empty', 'Empty', 'True', and 'False'. The 'Sublabels' section indicates 'Sublabel cannot contain sublabels.'

To delete an attribute, right-click an ROI label or sublabel, and select the attribute to delete. Deleting the attribute removes attribute information from all previously created ROI label annotations.

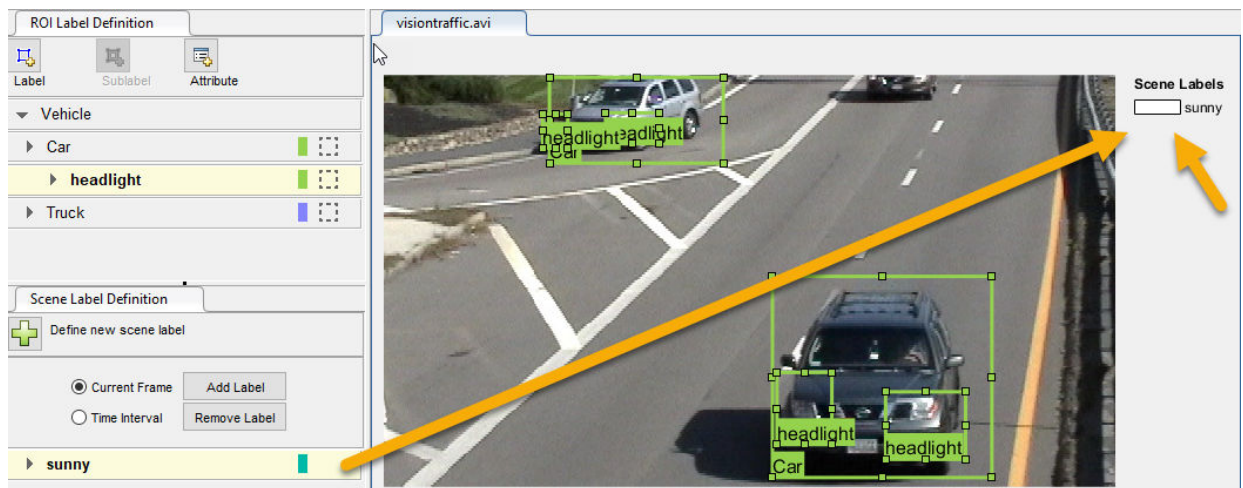

Create Scene Labels

A scene label defines additional information for the entire scene. Use scene labels to describe conditions, such as lighting and weather, or events, such as lane changes.

Create a scene label to use in the video.

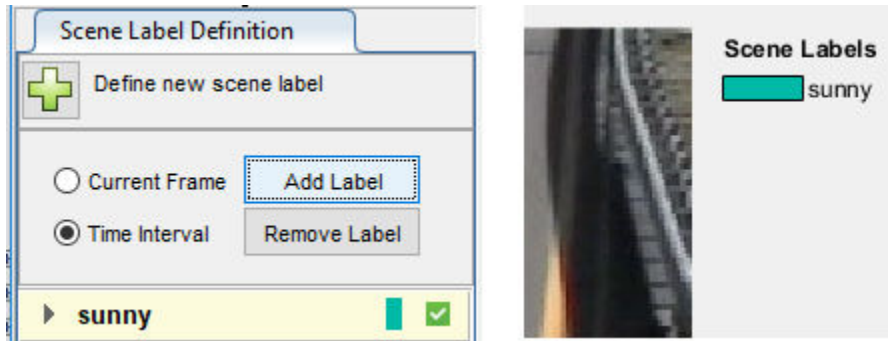

- 1 In the **Scene Label Definition** pane on the left, click the **Define new scene label** button, and create a scene label named **sunny**. Make sure **Group** is set to **None**. Click **OK**.

The **Scene Label Definition** pane shows the scene label definition. The scene labels that are applied to the current frame appear in the **Scene Labels** pane on the right. The **sunny** scene label is empty (white), because the scene label has not yet been applied to the frame.

- 2 The entire scene is sunny, so specify to apply the **sunny** scene label over the entire time interval. With the **sunny** scene label definition still selected in the **Scene Label Definition** pane, select **Time Interval**.
- 3 Click **Add Label**.

The **sunny** label now applies to all frames in the time interval.

Label Ground Truth

So far, you have labeled only one frame in the video. To label the remaining frames, choose one of these options.

Label Ground Truth Manually

When you click the right arrow key to advance to the next frame, the ROI labels from the previous frame do not carry over. Only the **sunny** scene label applies to each frame, because this label was applied over the entire time interval.

Advance frame by frame and draw the label and sublabel ROIs manually. Also update the attribute information for these ROIs.

Label Ground Truth Using Automation Algorithm

To speed up the labeling process, you can use an automation algorithm within the app. You can either define your own automation algorithm, see “Create Automation Algorithm for Labeling” on page 7-39 and “Temporal Automation Algorithms” on page 7-107, or use a built-in automation algorithm. In this example, you label the ground truth using a built-in point tracking algorithm.

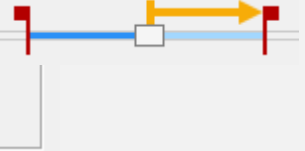

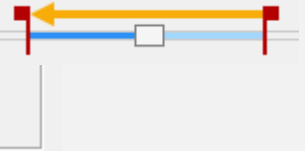

In this example, you automate the labeling of only the **Car** ROI labels. The built-in automation algorithms do not support sublabel and attribute automation.

- 1 Select the labels you want to automate. In the first frame of the video, press **Ctrl** and click to select the two **Car** label annotations. The labels are highlighted in yellow.

- 2 From the app toolstrip, select **Select Algorithm > Point Tracker**. This algorithm tracks one or more rectangle ROIs over short intervals using the Kanade-Lucas-Tomasi (KLT) algorithm.
- 3 (optional) Configure the automation settings. Click **Configure Automation**. By default, the automation algorithm applies labels from the start of the time interval to the end. To change the direction and start time of the algorithm, choose one of the options shown in this table.

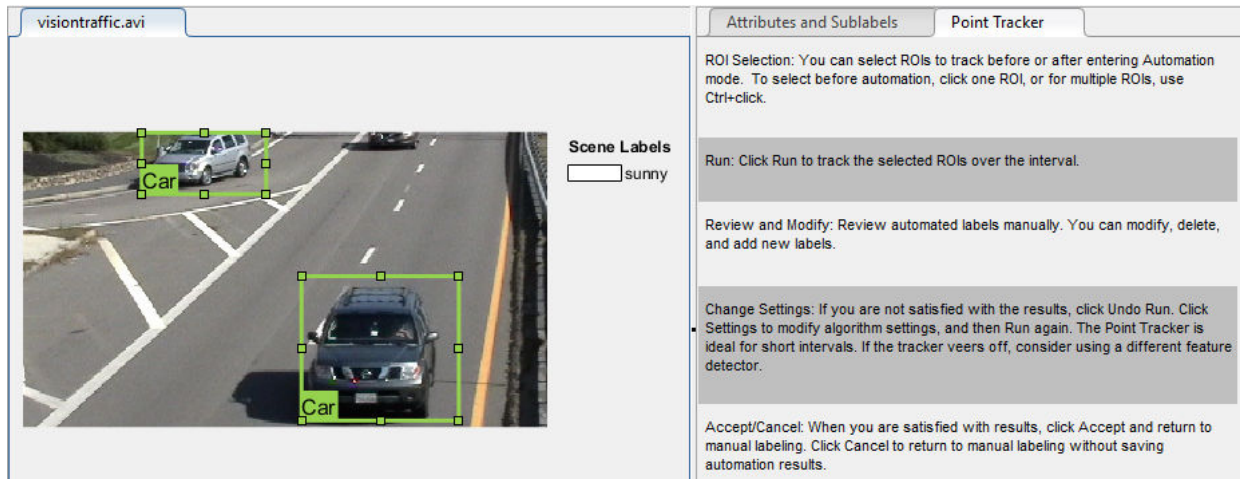

Direction of automation	Run automation from	Example

Direction of automation	Run automation from	Example
	Run automation from: <input type="radio"/> End time to Start time <input checked="" type="radio"/> Current time to Start time	
Direction of automation: <input type="radio"/> Forward <input checked="" type="radio"/> Reverse	Run automation from: <input checked="" type="radio"/> Start time to End time <input type="radio"/> Current time to End time	
	Run automation from: <input type="radio"/> End time to Start time <input checked="" type="radio"/> Current time to Start time	

The **Import selected ROIs** must be selected so that the **Car** labels you selected are imported into the automation session.

- 4 Click **Automate** to open an automation session. The algorithm instructions appear in the right pane, and the selected labels are available to automate.

- 5 Click **Run** to track the selected ROIs over the interval.
- 6 Examine the results of running the algorithm.

The vehicles that enter the scene later are unlabeled. The unlabeled vehicles did not have an initial ROI label, so the algorithm did not track them. Click **Undo Run**. Use the slider to find the frames where each vehicle first appears. Draw **vehicle** ROIs around each vehicle, and then click **Run** again.

- 7 Advance frame by frame and manually move, resize, delete, or add ROIs to improve the results of the automation algorithm.

When you are satisfied with the algorithm results, click **Accept**. Alternatively, to discard labels generated during the session and label manually instead, click **Cancel**. The **Cancel** button cancels only the algorithm session, not the app session.

Optionally, you can now manually label the remaining frames with sublabel and attribute information.

To further evaluate your labels, you can view a visual summary of the labeled ground truth. From the app toolbar, select **View Label Summary**. Use this summary to compare the frames, frequency of labels, and scene conditions. For more details, see “View Summary of Ground Truth Labels” on page 7-109. This summary does not support sublabels or attributes.

Export Labeled Ground Truth

You can export the labeled ground truth to a MAT-file or to a variable in the MATLAB workspace. In both cases, the labeled ground truth is stored as a `groundTruth` object. You can use this object to train a deep-learning-based computer vision algorithm. For more details, see “Training Data for Object Detection and Semantic Segmentation” on page 7-35.

Note If you export pixel data, the pixel label data and ground truth data are saved in separate files but in the same folder. For considerations when working with exported pixel labels, see “How Labeler Apps Store Exported Pixel Labels” on page 7-6.

In this example, you export the labeled ground truth to the MATLAB workspace. From the app toolstrip, select **Export Labels > To Workspace**. The exported MATLAB variable, `gTruth`, is a `groundTruth` object.

Display the properties of the exported `groundTruth` object. The information in your exported object might differ from the information shown here.

```
gTruth
```

```
gTruth =
```

```
groundTruth with properties:
```

```
DataSource: [1x1 groundTruthDataSource]
LabelDefinitions: [3x5 table]
LabelData: [531x3 timetable]
```

Data Source

`DataSource` is a `groundTruthDataSource` object containing the path to the video and the video timestamps. Display the properties of this object.

```
gTruth.DataSource
```

```
ans =
```

```
groundTruthDataSource for a video file with properties
```

```
Source: ...matlab\toolbox\vision\visiondata\visiontraffic.avi
TimeStamps: [531x1 duration]
```

Label Definitions

`LabelDefinitions` is a table containing information about the label definitions. This table does not contain information about the labels that are drawn on the video frames. To save the label definitions in their own MAT-file, from the app toolstrip, select **Save > Label Definitions**. You can then import these label definitions into another app session by selecting **Import Files**.

Display the label definitions table. Each row contains information about an ROI label definition or a scene label definition. If you exported pixel label data, the `LabelDefinitions` table also includes a `PixelLabelID` column containing the ID numbers for each pixel label definition.

```
gTruth.LabelDefinitions
```

```
ans =
```

```
3x5 table
```

Name	Type	Group	Description	Hierarchy
'Car'	Rectangle	'Vehicle'	''	[1x1 struct]
'Truck'	Rectangle	'Vehicle'	''	[]
'sunny'	Scene	'None'	''	[]

Within `LabelDefinitions`, the `Hierarchy` column stores information about the sublabel and attribute definitions of a parent ROI label.

Display the sublabel and attribute information for the `Car` label.

```
gTruth.LabelDefinitions.Hierarchy{1}
```

```
ans =
```

```
struct with fields:
```

```
    carType: [1x1 struct]
    headlight: [1x1 struct]
    Type: Rectangle
    Description: ''
```

Display information about the `headlight` sublabel.

```
gTruth.LabelDefinitions.Hierarchy{1}.headlight
```

```
ans =
  struct with fields:
    Type: Rectangle
    Description: ''
    isOn: [1x1 struct]
```

Display information about the `carType` attribute.

```
gTruth.LabelDefinitions.Hierarchy{1}.carType
```

```
ans =
  struct with fields:
    ListItems: {3x1 cell}
    Description: ''
```

Label Data

`LabelData` is a timetable containing information about the ROI labels drawn at each timestamp, across the entire video. The timetable contains one column per label.

Display the first few rows of the timetable. The first few timestamps indicate that no vehicles were detected and that the `sunny` scene label is `false`. These results are because this portion of the video was not labeled. Only the time interval of 5-10 seconds was labeled.

```
labelData = gTruth.labelData;
head(labelData)
```

```
ans =
  8x3 timetable

    Time          Car          Truck          sunny
  _____  _____  _____  _____
  5.005 sec    [1x2 struct]  [1x0 struct]  true
  5.0384 sec   [1x2 struct]  [1x0 struct]  true
  5.0717 sec   [1x2 struct]  [1x0 struct]  true
  5.1051 sec   [1x2 struct]  [1x0 struct]  true
  5.1385 sec   [1x2 struct]  [1x0 struct]  true
  5.1718 sec   [1x2 struct]  [1x0 struct]  true
```

```

5.2052 sec    [1x2 struct]    [1x0 struct]    true
5.2386 sec    [1x2 struct]    [1x0 struct]    true

```

Display the first few timetable rows from the 5-10 second interval that contains labels.

```

gTruthInterval = labelData(timerange('00:00:05', '00:00:10'), :);
head(gTruthInterval)

```

```
ans =
```

```
8x3 timetable
```

Time	Car	Truck	sunny
5.005 sec	[1x2 struct]	[1x0 struct]	true
5.0384 sec	[1x2 struct]	[1x0 struct]	true
5.0717 sec	[1x2 struct]	[1x0 struct]	true
5.1051 sec	[1x2 struct]	[1x0 struct]	true
5.1385 sec	[1x2 struct]	[1x0 struct]	true
5.1718 sec	[1x2 struct]	[1x0 struct]	true
5.2052 sec	[1x2 struct]	[1x0 struct]	true
5.2386 sec	[1x2 struct]	[1x0 struct]	true

For each Car label, the structure includes the position of the bounding box and information about its sublabels and attributes.

Display the bounding box positions for the vehicles at the start of the time interval. Your bounding box positions might differ from the ones shown here.

```
gTruthInterval(1,:).Car{1}.Position % [x y width height], in pixels
```

```
ans =
```

```
1x4 single row vector
```

```
415.8962    82.4737   130.8474   129.3805
```

```
ans =
```

```
1x4 single row vector
```

```
235.2182    1.0000   117.0611    55.3500
```

Save App Session

From the app toolbar, select **Save** and save a MAT-file of the app session. The saved session includes the data source, label definitions, and labeled ground truth. It also includes your session preferences, such as the layout of the app. To change layout options, select **Layout**.

The app session MAT-file is separate from the ground truth MAT-file that is exported when you select **Export > From File**. To share labeled ground truth data, as a best practice, share the ground truth MAT-file containing the `groundTruth` object, not the app session MAT-file. For more details, see “Share and Store Labeled Ground Truth Data” on page 7-115.

Use Custom Data Source Reader for Ground Truth Labeling

In this section...
“Import Data Source Using Custom Reader Dialog Box” on page 7-98
“Import Data Source Using Custom Reader Function” on page 7-99

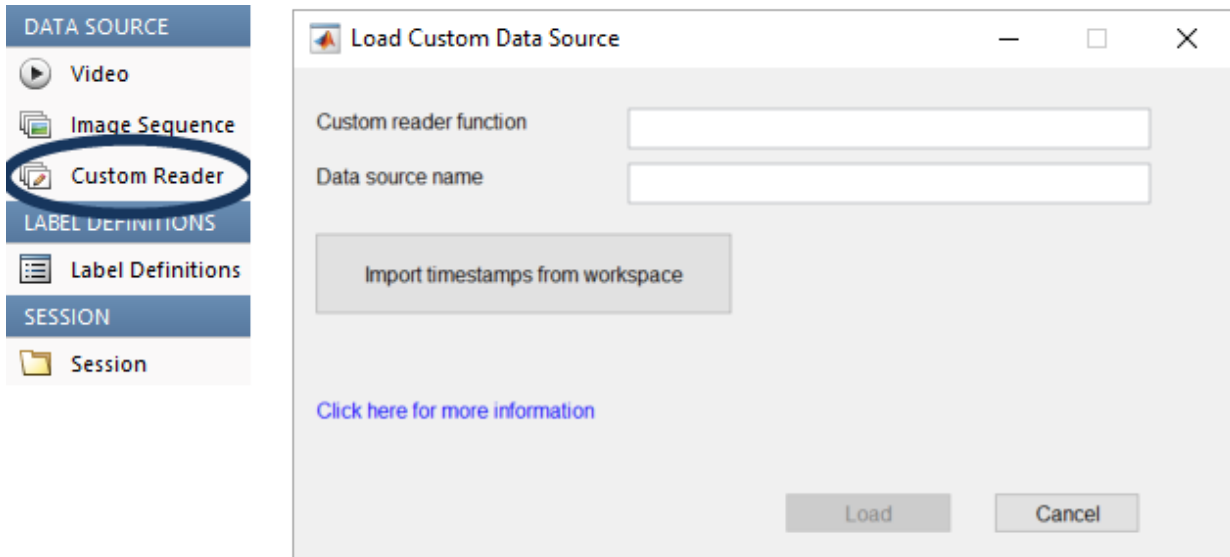

The **Ground Truth Labeler** (requires Automated Driving Toolbox) and **Video Labeler** apps enable you to label ground truth data in a video or in a sequence of images.

You can use a custom reader to import any video or sequence of images that is supported by `VideoReader` or `imread`. You can either use the custom reader dialog box in the app or open the app and specify a custom reader source.

The **Image Labeler** app does not support custom data source readers.

Import Data Source Using Custom Reader Dialog Box

In your app, **Load > Custom Reader** to load your data by using a custom reader function. You must provide the **Custom reader function** handle and the **Data source name**. In addition, you must import corresponding timestamps from the MATLAB workspace.

Import Data Source Using Custom Reader Function

Specify the Custom Reader

Specify a custom reader as a function handle. The custom reader must have the syntax:

```
outputImage = readerFcn(sourceName,currentTimeStamp)
```

where `readerFcn` is the name of your custom reader function.

The custom reader function loads an image from `sourceName`, which corresponds to the current timestamp specified by `currentTimeStamp`.

```
currentTimeStamp = timestamps(currIdx);
```

The `outputImage` from the custom function must be a grayscale or RGB image in any format supported by `imshow`. `currentTimeStamp` is a scalar value that corresponds to the current frame that the algorithm is executing.

Read Ground Truth Data Using Custom Reader

Use the `groundTruthDataSource` function to read the custom source data with the custom reader function handle:

```
gtSource = groundTruthDataSource(sourceName, readerFcn, timeStamps)
```

The syntax returns a `groundTruthDataSource` object with the custom reader function handle, `readerFcn`. The app uses the handle to load the custom data source specified by `sourceName`. The custom reader function loads an image from `sourceName` that corresponds to the current timestamp specified by the indexed value in the `timeStamps` vector.

The syntax returns a `groundTruthDataSource` object, which the app uses to read data from the custom source.

Read Ground Truth Data Using Custom Reader

Use the `groundTruthDataSource` function to read the custom source data with the custom reader function handle:

```
gtSource = groundTruthDataSource(sourceName, readerFcn, timeStamps)
```

The syntax returns a `groundTruthDataSource` object with the custom reader function handle, `readerFcn`. The app uses the handle to load the custom data source specified by `sourceName`. The custom reader function loads an image from `sourceName` that corresponds to the current timestamp specified by the indexed value in the `timeStamps` vector.

The syntax returns a `groundTruthDataSource` object, which the app uses to read data from the custom source.

Import Ground Truth Data into App

You can import the returned `groundTruthDataSource` object into the **Ground Truth Labeler** or **Video Labeler** app. For example:

```
groundTruthLabeler(gtSource)
```

```
videoLabeler(gtSource)
```

More About

- “Get Started with the Ground Truth Labeler” (Automated Driving Toolbox)
- “Get Started with the Video Labeler” on page 7-77

Use Sublabels and Attributes to Label Ground Truth Data

In the **Video Labeler** and **Ground Truth Labeler** (requires Automated Driving Toolbox) apps, a sublabel is a type of label for drawing regions of interest (ROIs) around objects that belong to a parent label. You can use sublabels to provide a greater level of detail about the ROIs in your labeled ground truth data. For example:

- For a **bird** label, you can define **wing** or **beak** sublabels.
- For a **vehicle** label, you can define **headlight**, **licensePlate**, and **wheel** sublabels.

When to Use Sublabels vs. Attributes

A sublabel can be anything that is drawable and is part of a parent label. An attribute provides information about labels. However, attributes are not drawable and they can be associated with either a label or a sublabel.

Consider the possible sublabel and attribute candidates for the label **vehicle**:

- A **wheel** is a good candidate for a *sublabel*. A wheel is part of a vehicle, and you can draw a label around a wheel.

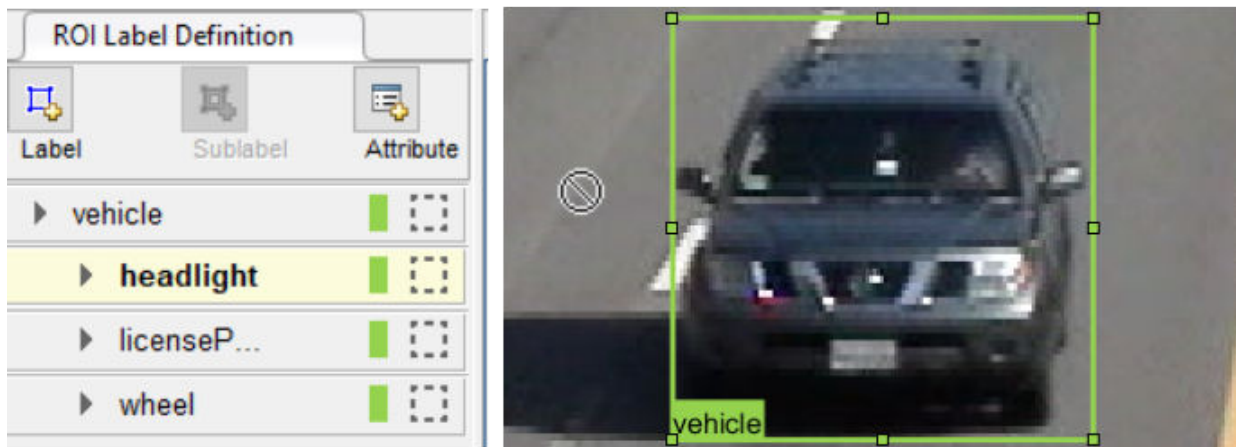

- **Vehicle color** is a good candidate for an *attribute*. You cannot draw a label around the color of a vehicle.
- **Vehicle type** (car, truck, and so on) is a good candidate for an *attribute*. Although you can draw a label around cars and trucks, they are not part of a vehicle. Instead, you can define a list attribute with types `car` and `truck`, or define logical attributes named `isCar`, `isTruck`, and so on.

Draw Sublabels

Within each frame, each sublabel that you draw must be associated with a parent label. Therefore, before you can draw a sublabel on a frame, you must:

- 1 From the **ROI Label Definition** pane, select the type of sublabel that you want to draw.
- 2 Within the frame, select a parent ROI label.

For example, to label the headlights of a vehicle, you must first select the **headlight** sublabel definition. On the frame, however, you cannot yet create a sublabel.

After you select a vehicle label on the frame, you can draw a sublabel that is associated with that vehicle. Once you create a sublabel, you cannot add another sublabel to the vehicle unless you select the vehicle label again.

Notice that sublabels do not have to be completely enclosed within the parent label. You can drag sublabels outside the bounds of the parent label and the parent-child relationship remains unchanged.

Copy and Paste Sublabels

When labeling, it is common to copy (**Ctrl+C**) and paste (**Ctrl+V**) labels from one frame into another.

If you copy a sublabel into another frame, the parent label is copied over as well. That way, the parent-child relationship is maintained between frames. Any sublabels that you did not select to copy do not appear in the new frame.

Copy Sublabel

Paste to Next Frame

If you copy a parent label, however, the associated sublabels are not copied over.

Copy Label

Paste to Next Frame

Delete Sublabels

To delete an ROI sublabel from a frame, right-click the sublabel and select the **Delete** option for the sublabel shape.

To delete an ROI sublabel definition, from the **ROI Label Definition** pane, right-click the sublabel and select **Delete**.

Caution If you delete a sublabel, all ROI sublabel annotations currently on the frames are deleted as well. Attribute definitions for that sublabel are deleted as well.

Sublabel Limitations

- Sublabels can be used only with rectangle and polyline labels.
- Sublabels cannot have their own sublabels.
- The built-in automation algorithms do not support sublabel automation.
- When you click **View Label Summary**, the Label Summary window does not display sublabel information.

- “Label Pixels for Semantic Segmentation” on page 7-43
- “Automate Attributes of Labeled Objects” (Automated Driving Toolbox)

Temporal Automation Algorithms

The **Video Labeler** and **Ground Truth Labeler** (requires Automated Driving Toolbox) apps enable you to create and import a custom automation algorithm to automatically label your data. Automation algorithms can be time-independent or time-dependent. Time-independent (nontemporal) algorithms can operate independently on each time stamp (or image). For example, a detection algorithm, such as the built-in People Detector, is a time-independent algorithm. In time-dependent (temporal) algorithms, there is a dependence on the time stamp of execution. For example, a tracking algorithm, such as the temporal built-in Point Tracker, uses tracking from a previous time stamp to track objects in the current time stamp.

Class Inheritance

If your algorithm is time-based, you must inherit from the `vision.labeler.AutomationAlgorithm` and `vision.labeler.mixin.Temporal` classes. For example:

```
classdef MyCustomTemporalAlg < vision.labeler.AutomationAlgorithm && vision.labeler.mixin.Temporal
```

If your algorithm is time-independent, you only need to inherit from the `vision.labeler.AutomationAlgorithm` class. For example:

```
classdef MyCustomNonTemporalAlg < vision.labeler.AutomationAlgorithm
```

Enable Temporal Properties

Inheriting from the temporal mixin class enables you to access properties such as `StartTime`, `CurrentTime` and `EndTime` to design time-based algorithms. See the `vision.labeler.mixin.Temporal` interface for details.

Create a Temporal Automation Algorithm to use with the Ground Truth Labeler

Only the **Video Labeler** and **Ground Truth Labeler** apps support both temporal and nontemporal automation algorithms. The **Image Labeler** app only supports nontemporal automation algorithms.

To create a temporal automation algorithm to use with the **Ground Truth Labeler**, open the app by typing `groundTruthLabeler` at the MATLAB command prompt. Click **Select Algorithm > Add Algorithm > Create new algorithm** to open the template.

View Summary of Ground Truth Labels

In this section...

“View Label Summary” on page 7-109

“Compare Selected Labels” on page 7-112

You can use the **Image Labeler**, **Video Labeler**, and **Ground Truth Labeler** (requires Automated Driving Toolbox) apps to interactively label ground truth data in an image collection, video, image sequence, or from a custom data source. For details about the supported data sources, see “Choose an App to Label Ground Truth Data” on page 7-75.

You can use the **View Label Summary** option in the app to view and compare the session distribution of ROI and scene labels over either time or frames.

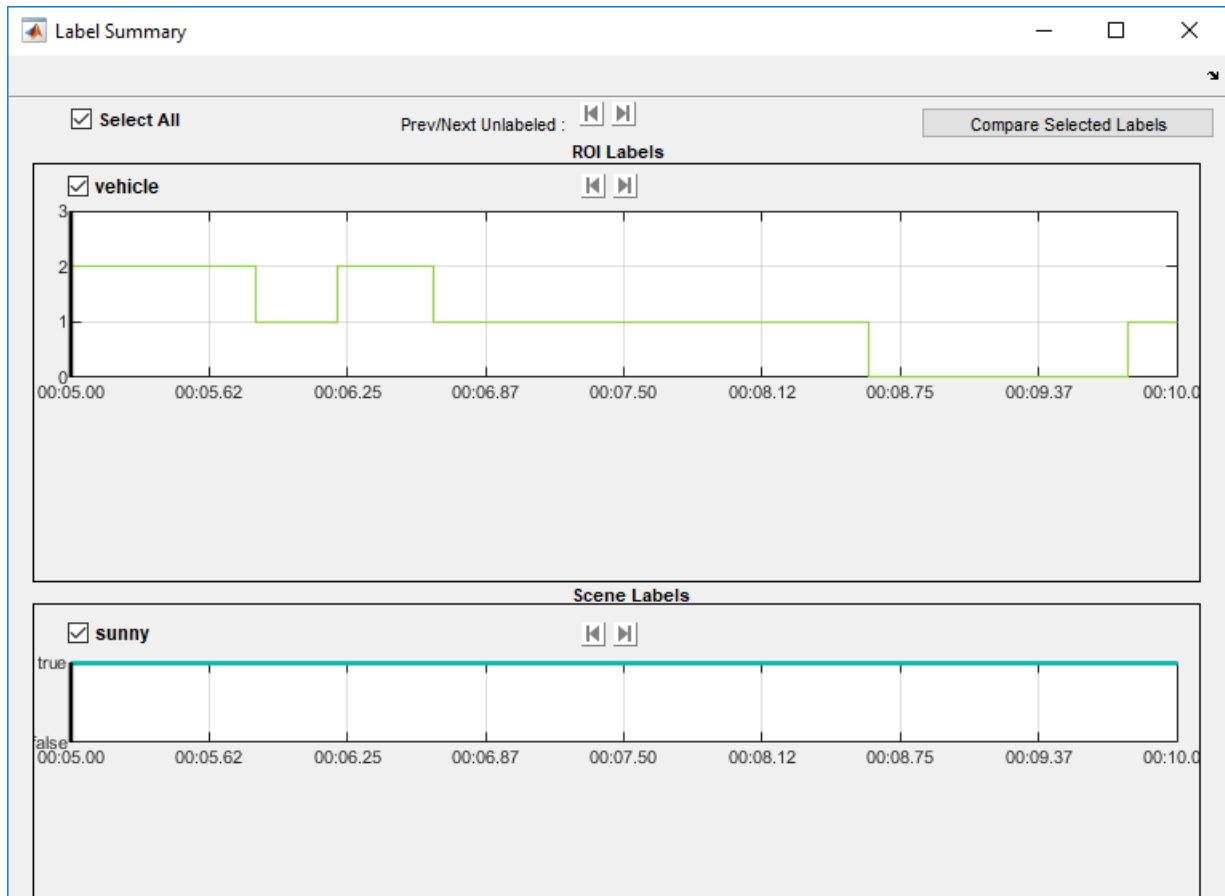

View Label Summary

View Label Summary creates dockable distribution graphs for the ROI labels and scene labels.

For ROI labels, the graph displays the number of ROIs on the y-axis, at each time stamp on the x-axis. The visual summary does not include information about sublabels or label attributes.

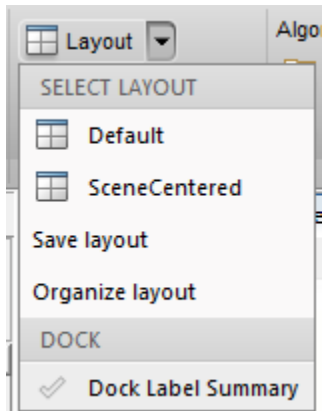

For scene labels, the graph displays the presence or absence of a scene label at each timestamp. For video, the x-axis represents the time in seconds. For images or for a custom sequence of images, the x-axis represents frames. Use the graphs to examine the occurrence of labels over time in relation to each other. Drag the black vertical line in any graph to move the video to a different timestamp.

For pixel labels, the graph displays the percentage of the frame that is labeled with each pixel label.

To dock the Label Summary window in your workspace, select **Layout > Dock Label Summary**.

Compare Selected Labels

Use the **Compare Selected Labels** option and the check boxes to selectively compare labels. ROI labels selected for comparison are displayed on a single graph.

- “Create Automation Algorithm for Labeling” on page 7-39
- “Training Data for Object Detection and Semantic Segmentation” on page 7-35

Share and Store Labeled Ground Truth Data

The **Image Labeler**, **Video Labeler**, and **Ground Truth Labeler** (requires Automated Driving Toolbox) apps enable you to label images, videos, and other ground truth data sources. You can then export the labeled ground truth as a `groundTruth` object. This object contains information about the:

- Data source
- Label definitions
- Marked ground truth labels

You can share this object with:

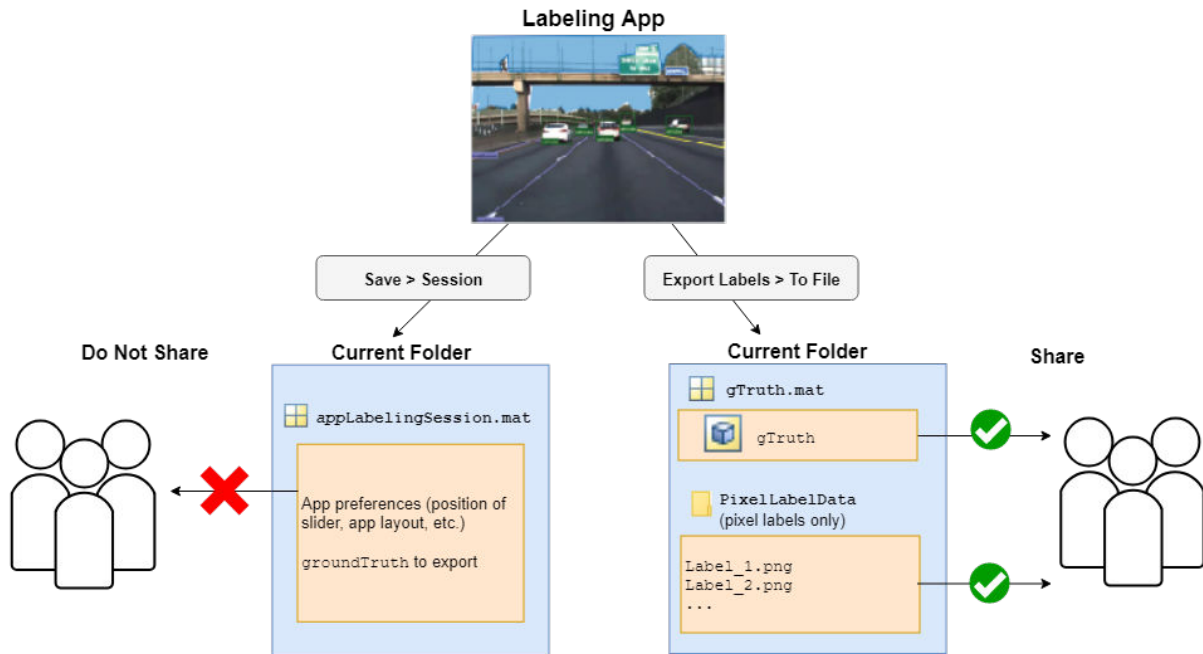

- Other labeling colleagues, who can use it to continue labeling
- Algorithm developers, who can use it to train algorithms, such as an object detector or semantic segmentation network
- Validation engineers, who can use it to validate algorithms

Share Ground Truth

To export and share labeled ground truth data from one of the labeling apps, select **Export Labels > To File**. Then either share the exported MAT-file directly with individuals on your team or place it in a shared network location.

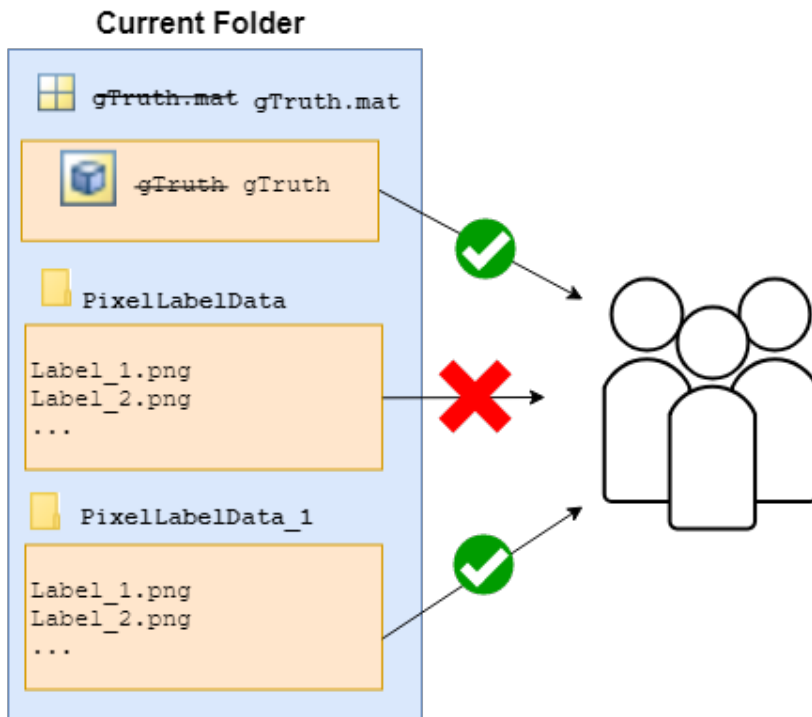

If the exported ground truth contains pixel labels, the app also generates a `PixelLabelData` folder containing the pixel label data. The `LabelData` table stored in the `groundTruth` object references the path to this folder. Share this folder along with the `groundTruth` object.

The labeling apps also enable you to save a MAT-file of the entire app session. Do not share this file. This file contains app preferences that are specific to your local machine, and it might not work on other machines.

If you re-export a ground truth object containing pixel label data, the app generates a new `PixelLabelData` folder. Even if you are overwriting the original `groundTruth` object, the app generates a new `PixelLabelData` folder. The generated folders are named `PixelLabelData_1`, `PixelLabelData_2`, and so on, depending on how many times you re-export the `groundTruth` object to the same folder.

When sharing a `groundTruth` object, be sure to share the correct `PixelLabelData` folder associated with it. For example, if you overwrite the original `groundTruth` object, share the overwritten object and the newly created `PixelLabelData_1` folder.

In addition to sharing the `groundTruth` object, you must also share the data source, and any additional files associated with that data source.

App	Data Source	Files to Share
Image Labeler	Image collection	<ul style="list-style-type: none"> • groundTruth object MAT-file • PixelLabelData folder (pixel labels only) • Folders containing image collections (if not in shared location)
Video Labeler or Ground Truth Labeler	Video	<ul style="list-style-type: none"> • groundTruth object MAT-file • PixelLabelData folder (pixel labels only) • Video source file (if not in shared location)
	Image sequence	<ul style="list-style-type: none"> • groundTruth object MAT-file • PixelLabelData folder (pixel labels only) • Folder containing image sequence (if not in shared location) • Timestamps duration vector (if specified)
	Custom data source reader	<ul style="list-style-type: none"> • groundTruth object MAT-file • PixelLabelData folder (pixel labels only) • Data source files (if not in shared location) • Custom reader function

Move Ground Truth

In the exported `groundTruth` object, the `DataSource` property contains the absolute paths to the data source files. For example:

```
gTruth.DataSource
```

```
ans =
```

```
groundTruthDataSource for an image collection with properties
```

```
Source: {
    '...\matlab\toolbox\vision\visiondata\imageSets\cup\big
    '...\matlab\toolbox\vision\visiondata\imageSets\cup\bl
    '...\matlab\toolbox\vision\visiondata\imageSets\cup\har
    ... and 9 more
}
```

If you move the `groundTruth` object to a new location, you might need to change the file paths stored in the `groundTruthDataSource` object. Even if the data source files are on a shared network, if other people map a different drive letter to their network folder, the file paths can be incorrect.

To update these paths, use the `changeFilePaths` function. Specify the `groundTruth` object as an input argument to this function. Also specify a cell array of string vectors containing the old paths and new paths. For example: `{ ["C:\Shared\ImgFolder\Img1.png" "D:\Shared\ImgFolder\Img1.png"]; ["C:\Shared\ImgFolder\Img2.png" "D:\Shared\ImgFolder\Img2.png"]; ...}`.

If your `groundTruth` object contains pixel label data, the `changeFilePaths` function also updates the path names to the pixel data stored in the `PixelLabelData` folder.

Store Ground Truth

Store the `groundTruth` object in a location that is on the MATLAB search path. For more details, see “What Is the MATLAB Search Path?” (MATLAB).

For a video, an image sequence, or an image collection containing images from a single folder, consider storing the `groundTruth` object in the parent folder of the data source. For image collections containing images from different folders, no specific recommendations exist for where to store the object. You can label image collections using the **Image Labeler** only.

Keyboard Shortcuts and Mouse Actions for Image Labeler

Note On Macintosh platforms, use the **Command (⌘)** key instead of **Ctrl**.

Label Definitions

Task	Action
In the ROI Label Definition pane, navigate through ROI labels and their groups	Up arrow or down arrow
In the Scene Label Definition pane, navigate through scene labels and their groups	Hold Alt and press the up arrow or down arrow
Reorder labels within a group or move labels between groups	Click and drag labels
Reorder groups	Click and drag groups

Image Browsing and Selection

Browse and select images from the image browser, which is located in the bottom pane of the app.

Task	Action
Browse through images one at a time	Left arrow and right arrow
Browse to the next set of images that is viewable in the image browser	<ul style="list-style-type: none"> • PC: Page Up and Page Down • Mac: Hold Fn and press the up and down arrows
Go to the first image	<ul style="list-style-type: none"> • PC: Home • Mac: Hold Fn and press the left arrow
Go to the last image	<ul style="list-style-type: none"> • PC: End • Mac: Hold Fn and press the right arrow

Task	Action
Select all images from the current image to the first image	<ul style="list-style-type: none">• PC: Shift+Home• Mac: Hold Fn+Shift and press the left arrow
Select all images from the current image to the last image	<ul style="list-style-type: none">• PC: Shift+End• Mac: Hold Fn+Shift and press the right arrow
Select all images from the current image to a specific image	Hold Shift and click the final image in the range
Select a specific set of images	Hold Ctrl and click the images you want to select

Labeling Window

Perform labeling actions, such as adding, moving, and deleting regions of interest (ROIs).

Task	Action
Undo labeling action	Ctrl+Z
Redo labeling action	Ctrl+Y
Select all rectangle and line ROIs	Ctrl+A
Select specific rectangle and line ROIs	Hold Ctrl and click the ROIs you want to select
Cut selected rectangle and line ROIs	Ctrl+X
Copy selected rectangle and line ROIs to clipboard	Ctrl+C

Task	Action
Paste copied rectangle and line ROIs <ul style="list-style-type: none"> • If a sublabel was copied, both the sublabel and its parent label are pasted. • If a parent label was copied, only the parent label is pasted, not its sublabels. For more details, see “Use Sublabels and Attributes to Label Ground Truth Data” on page 7-102.	Ctrl+V
Delete selected rectangle and line ROIs	Delete
Copy all pixel ROIs	Ctrl+shift+C
Paste copied pixel ROIs	Ctrl+shift+V
Fill all or all remaining pixels	Shift+click

Polygon Drawing

Draw polygons to label pixels on a frame.

Task	Action
Commit a polygon to the frame, excluding the currently active line segment	Press Enter or right-click while drawing the polygon The polygon closes up by forming a line between the previously committed point and the first point in the polygon.
Commit a polygon to the frame, including the currently active line segment	Double-click while drawing polygon The polygon closes up by forming a line between the point where you double-clicked and the first point in the polygon.
Remove the previously created line segment from a polygon	Backspace
Cancel drawing and delete the entire polygon	Escape

Zooming

Task	Action
Zoom in or out of frame	Move the scroll wheel up (zoom in) or down (zoom out) The scroll wheel works in Zoom In , Zoom Out , and Label mode but not Pan mode.
Zoom in on specific section of frame	From the app toolstrip, under Modes , select Zoom In . Then, draw a box around the section of the frame you want to zoom in on.

App Sessions

Task	Action
Save current session	Ctrl+S

Copy all pixel ROIs	Ctrl+shift+C
Paste copied pixel ROIs	Ctrl+shift+V
Fill all or all remaining pixels	Shift+click

Polyline Drawing

Draw ROI line labels on a frame. ROI line labels are polylines, meaning that they are composed of one or more line segments.

Task	Action
Commit a polyline to the frame, excluding the currently active line segment	Press Enter or right-click while drawing the polyline
Commit a polyline to the frame, including the currently active line segment	Double-click while drawing the polyline A new line segment is committed at the point where you double-click.
Delete the previously created line segment in a polyline	Backspace
Cancel drawing and delete the entire polyline	Escape

Polygon Drawing

Draw polygons to label pixels on a frame.

Task	Action
Commit a polygon to the frame, excluding the currently active line segment	Press Enter or right-click while drawing the polygon The polygon closes up by forming a line between the previously committed point and the first point in the polygon.
Commit a polygon to the frame, including the currently active line segment	Double-click while drawing polygon The polygon closes up by forming a line between the point where you double-clicked and the first point in the polygon.
Remove the previously created line segment from a polygon	Backspace

Task	Action
Cancel drawing and delete the entire polygon	Escape

Zooming

Task	Action
Zoom in or out of frame	Move the scroll wheel up (zoom in) or down (zoom out) The scroll wheel works in Zoom In or Zoom Out mode but not Label or Pan modes.
Zoom in on specific section of frame	From the app toolbar, under Modes , select Zoom In . Then, draw a box around the section of the frame you want to zoom in on.

App Sessions

Task	Action
Save current session	Ctrl+S

Point Feature Types

Image feature detection is a building block of many computer vision tasks, such as image registration, tracking, and object detection. The Computer Vision Toolbox includes a variety of functions for image feature detection. These functions return points objects that store information specific to particular types of features, including (x,y) coordinates (in the `Location` property). You can pass a points object from a detection function to a variety of other functions that require feature points as inputs. The algorithm that a detection function uses determines the type of points object it returns.

Functions That Return Points Objects

Points Object	Returned By	Type of Feature
cornerPoints	detectFASTFeatures Features from accelerated segment test (FAST) algorithm Uses an approximate metric to determine corners. [1]	 <p>Corners Single-scale detection Point tracking, image registration with little or no scale change, corner detection in scenes of human origin, such as streets and indoor scenes.</p>
	detectMinEigenFeatures Minimum eigenvalue algorithm Uses minimum eigenvalue metric to determine corner locations. [4]	
	detectHarrisFeatures Harris-Stephens algorithm More efficient than the minimum eigenvalue algorithm. [3]	

Points Object	Returned By	Type of Feature
BRISKPoints	detectBRISKFeatures Binary Robust Invariant Scalable Keypoints (BRISK) algorithm [6]	 <p>Corners Multiscale detection Point tracking, image registration, handles changes in scale and rotation, corner detection in scenes of human origin, such as streets and indoor scenes</p>
SURFPoints	detectSURFFeatures Speeded-up robust features (SURF) algorithm [11]	 <p>Blobs Multiscale detection Object detection and image registration with scale and rotation changes</p>
ORBPoints	detectORBFeatures Oriented FAST and Rotated BRIEF (ORB) method [13]	 <p>Corners Multi-scale detection Point tracking, image registration, handles changes in rotation, corner detection in scenes of human origin, such as streets and indoor scenes</p>

Points Object	Returned By	Type of Feature
KAZEPoints	detectKAZEFeatures KAZE is not an acronym, but a name derived from the Japanese word <i>kaze</i> , which means wind. The reference is to the flow of air ruled by nonlinear processes on a large scale. [12]	 <p>Multi-scale blob features</p> <p>Reduced blurring of object boundaries</p>
MSERRegions	detectMSERFeatures Maximally stable extremal regions (MSER) algorithm [7] [8] [9] [10]	 <p>Regions of uniform intensity</p> <p>Multi-scale detection</p> <p>Registration, wide baseline stereo calibration, text detection, object detection. Handles changes to scale and rotation. More robust to affine transforms in contrast to other detectors.</p>

Functions That Accept Points Objects

Function	Description			
relativeCameraPose	Compute relative rotation and translation between camera poses			
estimateFundamentalMatrix	Estimate fundamental matrix from corresponding points in stereo images			
estimateGeometricTransform	Estimate geometric transform from matching point pairs			
estimateUncalibratedRectification	Uncalibrated stereo rectification			
extractFeatures	Extract interest point descriptors			
	<table border="1"> <thead> <tr> <th>Method</th> <th>Feature Vector</th> </tr> </thead> <tbody> <tr> <td></td> <td></td> </tr> </tbody> </table>	Method	Feature Vector	
Method	Feature Vector			

Function	Description	
	BRISK	The function sets the Orientation property of the validPoints output object to the orientation of the extracted features, in radians.
	FREAK	The function sets the Orientation property of the validPoints output object to the orientation of the extracted features, in radians.
	SURF	<p>The function sets the Orientation property of the validPoints output object to the orientation of the extracted features, in radians.</p> <p>When you use an MSERRegions object with the SURF method, the Centroid property of the object extracts SURF descriptors. The Axes property of the object selects the scale of the SURF descriptors such that the circle representing the feature has an area proportional to the MSER ellipse area. The scale is calculated as $1/4 * \sqrt{(\text{majorAxes}/2) * (\text{minorAxes}/2)}$ and saturated to 1.6, as required by the SURFPoints object.</p>

Function	Description	
	KAZE	<p>Non-linear pyramid-based features.</p> <p>The function sets the Orientation property of the validPoints output object to the orientation of the extracted features, in radians.</p> <p>When you use an MSERRegions object with the KAZE method, the Location property of the object is used to extract KAZE descriptors.</p> <p>The Axes property of the object selects the scale of the KAZE descriptors such that the circle representing the feature has an area proportional to the MSER ellipse area.</p>
	ORB	<p>The function does not set the Orientation property of the validPoints output object to the orientation of the extracted features. By default, the Orientation property of validPoints is set to the Orientation property of the input ORBPoints object.</p>
	Block	<p>Simple square neighborhood.</p> <p>The Block method extracts only the neighborhoods fully contained within the image boundary. Therefore, the output, validPoints, can contain fewer points than the input POINTS.</p>

Function	Description
	<p>Auto</p> <p>The function selects the Method based on the class of the input points and implements:</p> <p>The FREAK method for a <code>cornerPoints</code> input object.</p> <p>The SURF method for a <code>SURFPoints</code> or <code>MSERRegions</code> input object.</p> <p>The FREAK method for a <code>BRISKPoints</code> input object.</p> <p>The ORB method for a <code>ORBPoints</code> input object.</p> <p>For an M-by-2 input matrix of $[x\ y]$ coordinates, the function implements the <code>Block</code> method.</p>
<code>extractHOGFeatures</code>	Extract histogram of oriented gradients (HOG) features
<code>insertMarker</code>	Insert markers in image or video
<code>showMatchedFeatures</code>	Display corresponding feature points
<code>triangulate</code>	3-D locations of undistorted matching points in stereo images
<code>undistortPoints</code>	Correct point coordinates for lens distortion

Local Feature Detection and Extraction

Local features and their descriptors, which are a compact vector representations of a local neighborhood, are the building blocks of many computer vision algorithms. Their applications include image registration, object detection and classification, tracking, and motion estimation. Using local features enables these algorithms to better handle scale changes, rotation, and occlusion. The Computer Vision Toolbox provides the FAST, Harris, ORB, and Shi & Tomasi methods for detecting corner features, and the SURF, KAZE, and MSER methods for detecting blob features. The toolbox includes the SURF, KAZE, FREAK, BRISK, ORB, and HOG descriptors. You can mix and match the detectors and the descriptors depending on the requirements of your application.

What Are Local Features?

Local features refer to a pattern or distinct structure found in an image, such as a point, edge, or small image patch. They are usually associated with an image patch that differs from its immediate surroundings by texture, color, or intensity. What the feature actually represents does not matter, just that it is distinct from its surroundings. Examples of local features are blobs, corners, and edge pixels.

Example 7.1. Example of Corner Detection

```
I = imread('circuit.tif');  
corners = detectFASTFeatures(I, 'MinContrast', 0.1);  
J = insertMarker(I, corners, 'circle');  
imshow(J)
```

Benefits and Applications of Local Features

Local features let you find image correspondences regardless of occlusion, changes in viewing conditions, or the presence of clutter. In addition, the properties of local features make them suitable for image classification, such as in “Image Classification with Bag of Visual Words” on page 7-186.

Local features are used in two fundamental ways:

- To localize anchor points for use in image stitching or 3-D reconstruction.
- To represent image contents compactly for detection or classification, without requiring image segmentation.

Application	MATLAB Examples
Image registration and stitching	“Feature Based Panoramic Image Stitching”
Object detection	“Object Detection in a Cluttered Scene Using Point Feature Matching”
Object recognition	“Digit Classification Using HOG Features”

Application	MATLAB Examples
Object tracking	"Face Detection and Tracking Using the KLT Algorithm"
Image category recognition	"Image Category Classification Using Bag of Features"
Finding geometry of a stereo system	"Uncalibrated Stereo Image Rectification"
3-D reconstruction	"Structure From Motion From Two Views" "Structure From Motion From Two Views"
Image retrieval	"Image Retrieval Using Customized Bag of Features"

What Makes a Good Local Feature?

Detectors that rely on gradient-based and intensity variation approaches detect good local features. These features include edges, blobs, and regions. Good local features exhibit the following properties:

- **Repeatable detections:**
When given two images of the same scene, most features that the detector finds in both images are the same. The features are robust to changes in viewing conditions and noise.
- **Distinctive:**
The neighborhood around the feature center varies enough to allow for a reliable comparison between the features.
- **Localizable:**
The feature has a unique location assigned to it. Changes in viewing conditions do not affect its location.

Feature Detection and Feature Extraction

Feature detection selects regions of an image that have unique content, such as corners or blobs. Use feature detection to find points of interest that you can use for further processing. These points do not necessarily correspond to physical structures, such as the corners of a table. The key to feature detection is to find features that remain locally invariant so that you can detect them even in the presence of rotation or scale change.

Feature extraction involves computing a descriptor, which is typically done on regions centered around detected features. Descriptors rely on image processing to transform a

local pixel neighborhood into a compact vector representation. This new representation permits comparison between neighborhoods regardless of changes in scale or orientation. Descriptors, such as SIFT or SURF, rely on local gradient computations. Binary descriptors, such as BRISK, ORB or FREAK, rely on pairs of local intensity differences, which are then encoded into a binary vector.

Choose a Feature Detector and Descriptor

Select the best feature detector and descriptor by considering the criteria of your application and the nature of your data. The first table helps you understand the general criteria to drive your selection. The next two tables provide details on the detectors and descriptors available in Computer Vision Toolbox.

Considerations for Selecting a Detector and Descriptor

Criteria	Suggestion
Type of features in your image	Use a detector appropriate for your data. For example, if your image contains an image of bacteria cells, use the blob detector rather than the corner detector. If your image is an aerial view of a city, you can use the corner detector to find man-made structures.
Context in which you are using the features: <ul style="list-style-type: none"> • Matching key points • Classification 	The HOG, SURF, and KAZE descriptors are suitable for classification tasks. In contrast, binary descriptors, such as ORB, BRISK and FREAK, are typically used for finding point correspondences between images, which are used for registration.
Type of distortion present in your image	Choose a detector and descriptor that addresses the distortion in your data. For example, if there is no scale change present, consider a corner detector that does not handle scale. If your data contains a higher level of distortion, such as scale and rotation, then use SURF, ORB or KAZE feature detector and descriptor. The SURF and the KAZE methods are computationally intensive.
Performance requirements: <ul style="list-style-type: none"> • Real-time performance required • Accuracy versus speed 	Binary descriptors are generally faster but less accurate than gradient-based descriptors. For greater accuracy, use several detectors and descriptors at the same time.

Choose a Detection Function Based on Feature Type

Detector	Feature Type	Function	Scale Independent
FAST [1]	Corner	detectFASTFeatures	No
Minimum eigenvalue algorithm [4]	Corner	detectMinEigenFeatures	No
Corner detector [3]	Corner	detectHarrisFeatures	No
SURF [11]	Blob	detectSURFFeatures	Yes
KAZE [12]	Blob	detectKAZEFeatures	Yes
BRISK [6]	Corner	detectBRISKFeatures	Yes
MSER [8]	Region with uniform intensity	detectMSERFeatures	Yes
ORB [13]	Corner	detectORBFeatures	No

Note Detection functions return objects that contain information about the features. The `extractHOGFeatures` and `extractFeatures` functions use these objects to create descriptors.

Choose a Descriptor Method

Descriptor	Binary	Function and Method	Invariance		Typical Use	
			Scale	Rotation	Finding Point Correspondences	Classification
HOG	No	<code>extractHOGFeatures(I, ...)</code>	No	No	No	Yes
LBP	No	<code>extractLBPFeatures(I, ...)</code>	No	Yes	No	Yes
SURF	No	<code>extractFeatures(I,points,'Method','SURF')</code>	Yes	Yes	Yes	Yes
KAZE	No	<code>extractFeatures(I,points,'Method','KAZE')</code>	Yes	Yes	Yes	Yes
FREAK	Yes	<code>extractFeatures(I,points,'Method','FREAK')</code>	Yes	Yes	Yes	No
BRISK	Yes	<code>extractFeatures(I,points,'Method','BRISK')</code>	Yes	Yes	Yes	No
ORB	Yes	<code>extractFeatures(I,points,'Method','ORB')</code>	No	Yes	Yes	No
<ul style="list-style-type: none"> • Block • Simple pixel neighborhood around a keypoint 	No	<code>extractFeatures(I,points,'Method','Block')</code>	No	No	Yes	Yes

Note

- The `extractFeatures` function provides different extraction methods to best match the requirements of your application. When you do not specify the 'Method' input for the `extractFeatures` function, the function automatically selects the method based on the type of input point class.
- Binary descriptors are fast but less precise in terms of localization. They are not suitable for classification tasks. The `extractFeatures` function returns a

binaryFeatures object. This object enables the Hamming-distance-based matching metric used in the matchFeatures function.

Use Local Features

Registering two images is a simple way to understand local features. This example finds a geometric transformation between two images. It uses local features to find well-localized anchor points.

Display two images

The first image is the original image.

```
original = imread('cameraman.tif');  
figure;  
imshow(original);
```

The second image is the original image rotated and scaled.

```
scale = 1.3;  
J = imresize(original, scale);  
theta = 31;  
distorted = imrotate(J, theta);  
figure  
imshow(distorted)
```

Detect matching features between the original and distorted image

Detecting the matching SURF features is the first step in determining the transform needed to correct the distorted image.

```
ptsOriginal = detectSURFFeatures(original);  
ptsDistorted = detectSURFFeatures(distorted);
```

Extract features and compare the detected blobs between the two images

The detection step found several roughly corresponding blob structures in both images. Compare the detected blob features. This process is facilitated by feature extraction, which determines a local patch descriptor.

```
[featuresOriginal, validPtsOriginal] = ...  
    extractFeatures(original, ptsOriginal);
```

```
[featuresDistorted,validPtsDistorted] = ...  
    extractFeatures(distorted,ptsDistorted);
```

It is possible that not all of the original points were used to extract descriptors. Points might have been rejected if they were too close to the image border. Therefore, the valid points are returned in addition to the feature descriptors.

The patch size used to compute the descriptors is determined during the feature extraction step. The patch size corresponds to the scale at which the feature is detected. Regardless of the patch size, the two feature vectors, `featuresOriginal` and `featuresDistorted`, are computed in such a way that they are of equal length. The descriptors enable you to compare detected features, regardless of their size and rotation.

Find candidate matches

Obtain candidate matches between the features by inputting the descriptors to the `matchFeatures` function. Candidate matches imply that the results can contain some invalid matches. Two patches that match can indicate like features but might not be a correct match. A table corner can look like a chair corner, but the two features are obviously not a match.

```
indexPairs = matchFeatures(featuresOriginal,featuresDistorted);
```

Find point locations from both images

Each row of the returned `indexPairs` contains two indices of candidate feature matches between the images. Use the indices to collect the actual point locations from both images.

```
matchedOriginal = validPtsOriginal(indexPairs(:,1));  
matchedDistorted = validPtsDistorted(indexPairs(:,2));
```

Display the candidate matches

```
figure  
showMatchedFeatures(original,distorted,matchedOriginal,matchedDistorted)  
title('Candidate matched points (including outliers)')
```

Analyze the feature locations

If there are a sufficient number of valid matches, remove the false matches. An effective technique for this scenario is the RANSAC algorithm. The `estimateGeometricTransform` function implements M-estimator sample consensus

(MSAC), which is a variant of the RANSAC algorithm. MSAC finds a geometric transform and separates the inliers (correct matches) from the outliers (spurious matches).

```
[tform, inlierDistorted,inlierOriginal] = ...
    estimateGeometricTransform(matchedDistorted,...
        matchedOriginal,'similarity');
```

Display the matching points

```
figure
showMatchedFeatures(original,distorted,inlierOriginal,inlierDistorted)
title('Matching points (inliers only)')
legend('ptsOriginal','ptsDistorted')
```

Verify the computed geometric transform

Apply the computed geometric transform to the distorted image.

```
outputView = imref2d(size(original));
recovered = imwarp(distorted,tform,'OutputView',outputView);
```

Display the recovered image and the original image.

```
figure
imshowpair(original,recovered,'montage')
```

Image Registration Using Multiple Features

This example builds on the results of the "Use Local Features" example. Using more than one detector and descriptor pair enables you to combine and reinforce your results. Multiple pairs are also useful for when you cannot obtain enough good matches (inliers) using a single feature detector.

Load the original image.

```
original = imread('cameraman.tif');
figure;
imshow(original);
text(size(original,2),size(original,1)+15, ...
    'Image courtesy of Massachusetts Institute of Technology', ...
    'FontSize',7,'HorizontalAlignment','right');
```

Image courtesy of Massachusetts Institute of Technology

Scale and rotate the original image to create the distorted image.

```
scale = 1.3;  
J = imresize(original, scale);  
  
theta = 31;  
distorted = imrotate(J,theta);  
figure  
imshow(distorted)
```

Detect the features in both images. Use the BRISK detectors first, followed by the SURF detectors.

```
ptsOriginalBRISK = detectBRISKFeatures(original, 'MinContrast', 0.01);  
ptsDistortedBRISK = detectBRISKFeatures(distorted, 'MinContrast', 0.01);
```

```
ptsOriginalSURF = detectSURFFeatures(original);
ptsDistortedSURF = detectSURFFeatures(distorted);
```

Extract descriptors from the original and distorted images. The BRISK features use the FREAK descriptor by default.

```
[featuresOriginalFREAK,validPtsOriginalBRISK] = ...
    extractFeatures(original,ptsOriginalBRISK);
[featuresDistortedFREAK,validPtsDistortedBRISK] = ...
    extractFeatures(distorted,ptsDistortedBRISK);

[featuresOriginalSURF,validPtsOriginalSURF] = ...
    extractFeatures(original,ptsOriginalSURF);
[featuresDistortedSURF,validPtsDistortedSURF] = ...
    extractFeatures(distorted,ptsDistortedSURF);
```

Determine candidate matches by matching FREAK descriptors first, and then SURF descriptors. To obtain as many feature matches as possible, start with detector and matching thresholds that are lower than the default values. Once you get a working solution, you can gradually increase the thresholds to reduce the computational load required to extract and match features.

```
indexPairsBRISK = matchFeatures(featuresOriginalFREAK,...
    featuresDistortedFREAK,'MatchThreshold',40,'MaxRatio',0.8);

indexPairsSURF = matchFeatures(featuresOriginalSURF,featuresDistortedSURF);
```

Obtain candidate matched points for BRISK and SURF.

```
matchedOriginalBRISK = validPtsOriginalBRISK(indexPairsBRISK(:,1));
matchedDistortedBRISK = validPtsDistortedBRISK(indexPairsBRISK(:,2));

matchedOriginalSURF = validPtsOriginalSURF(indexPairsSURF(:,1));
matchedDistortedSURF = validPtsDistortedSURF(indexPairsSURF(:,2));
```

Visualize the BRISK putative matches.

```
figure
showMatchedFeatures(original,distorted,matchedOriginalBRISK,...
    matchedDistortedBRISK)
title('Putative matches using BRISK & FREAK')
legend('ptsOriginalBRISK','ptsDistortedBRISK')
```

Combine the candidate matched BRISK and SURF local features. Use the `Location` property to combine the point locations from BRISK and SURF features.

```
matchedOriginalXY = ...  
    [matchedOriginalSURF.Location; matchedOriginalBRISK.Location];
```

```
matchedDistortedXY = ...  
    [matchedDistortedSURF.Location; matchedDistortedBRISK.Location];
```

Determine the inlier points and the geometric transform of the BRISK and SURF features.

```
[tformTotal,inlierDistortedXY,inlierOriginalXY] = ...  
    estimateGeometricTransform(matchedDistortedXY,...  
        matchedOriginalXY,'similarity');
```

Display the results. The result provides several more matches than the example that used a single feature detector.

```
figure  
showMatchedFeatures(original,distorted,inlierOriginalXY,inlierDistortedXY)  
title('Matching points using SURF and BRISK (inliers only)')  
legend('ptsOriginal','ptsDistorted')
```

Matching points using SURF and BRISK (inliers only)

Compare the original and recovered image.

```
outputView = imref2d(size(original));  
recovered = imwarp(distorted,tformTotal,'OutputView',outputView);
```

```
figure;  
imshowpair(original, recovered, 'montage')
```

Why Train a Detector?

The `vision.CascadeObjectDetector` System object comes with several pretrained classifiers for detecting frontal faces, profile faces, noses, eyes, and the upper body. However, these classifiers are not always sufficient for a particular application. Computer Vision Toolbox provides the `trainCascadeObjectDetector` function to train a custom classifier.

What Kinds of Objects Can You Detect?

The Computer Vision Toolbox cascade object detector can detect object categories whose aspect ratio does not vary significantly. Objects whose aspect ratio remains fixed include faces, stop signs, and cars viewed from one side.

The `vision.CascadeObjectDetector` System object detects objects in images by sliding a window over the image. The detector then uses a cascade classifier to decide

whether the window contains the object of interest. The size of the window varies to detect objects at different scales, but its aspect ratio remains fixed. The detector is very sensitive to out-of-plane rotation, because the aspect ratio changes for most 3-D objects. Thus, you need to train a detector for each orientation of the object. Training a single detector to handle all orientations will not work.

How Does the Cascade Classifier Work?

The cascade classifier consists of stages, where each stage is an ensemble of weak learners. The weak learners are simple classifiers called decision stumps. Each stage is trained using a technique called boosting. Boosting provides the ability to train a highly accurate classifier by taking a weighted average of the decisions made by the weak learners.

Each stage of the classifier labels the region defined by the current location of the sliding window as either positive or negative. Positive indicates that an object was found and negative indicates no objects were found. If the label is negative, the classification of this region is complete, and the detector slides the window to the next location. If the label is positive, the classifier passes the region to the next stage. The detector reports an object found at the current window location when the final stage classifies the region as positive.

The stages are designed to reject negative samples as fast as possible. The assumption is that the vast majority of windows do not contain the object of interest. Conversely, true positives are rare and worth taking the time to verify.

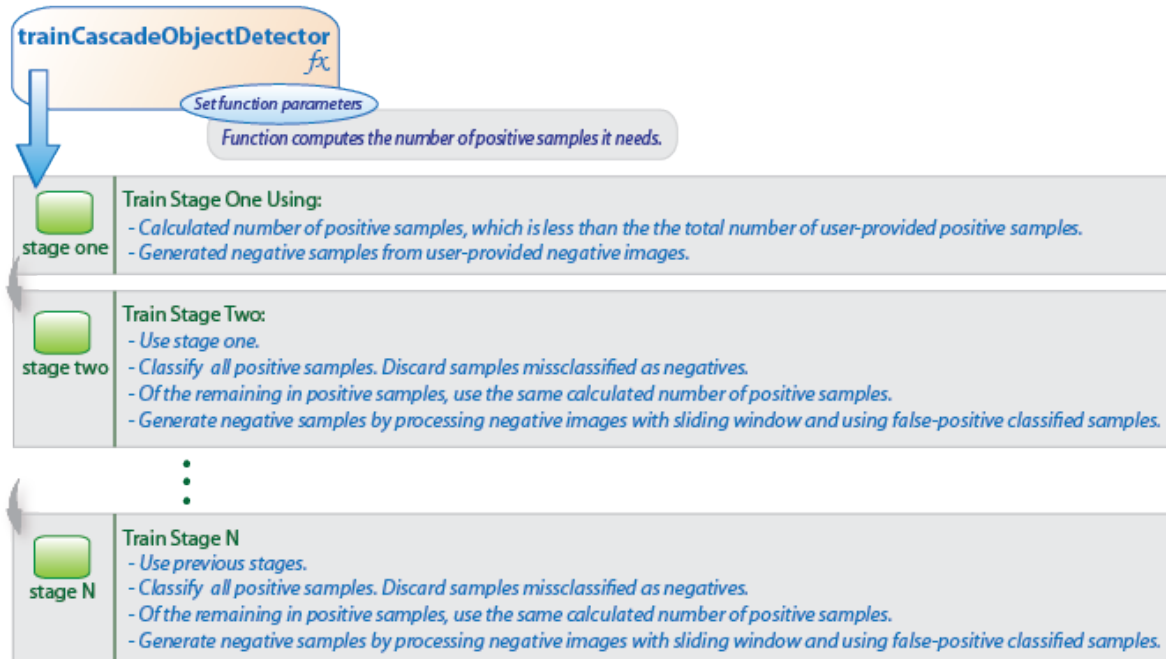

- A true positive occurs when a positive sample is correctly classified.
- A false positive occurs when a negative sample is mistakenly classified as positive.
- A false negative occurs when a positive sample is mistakenly classified as negative.

To work well, each stage in the cascade must have a low false negative rate. If a stage incorrectly labels an object as negative, the classification stops, and you cannot correct the mistake. However, each stage can have a high false positive rate. Even if the detector incorrectly labels a nonobject as positive, you can correct the mistake in subsequent stages.

The overall false positive rate of the cascade classifier is f^s , where f is the false positive rate per stage in the range (0 1), and s is the number of stages. Similarly, the overall true positive rate is t^s , where t is the true positive rate per stage in the range (0 1]. Thus, adding more stages reduces the overall false positive rate, but it also reduces the overall true positive rate.

Create a Cascade Classifier Using the `trainCascadeObjectDetector`

Cascade classifier training requires a set of positive samples and a set of negative images. You must provide a set of positive images with regions of interest specified to be used as positive samples. You can use the **Image Labeler** to label objects of interest with bounding boxes. The Image Labeler outputs a table to use for positive samples. You also must provide a set of negative images from which the function generates negative samples automatically. To achieve acceptable detector accuracy, set the number of stages, feature type, and other function parameters.

Considerations when Setting Parameters

Select the function parameters to optimize the number of stages, the false positive rate, the true positive rate, and the type of features to use for training. When you set the parameters, consider these tradeoffs.

Condition	Consideration
A large training set (in the thousands).	Increase the number of stages and set a higher false positive rate for each stage.
A small training set.	Decrease the number of stages and set a lower false positive rate for each stage.
To reduce the probability of missing an object.	Increase the true positive rate. However, a high true positive rate can prevent you from achieving the desired false positive rate per stage, making the detector more likely to produce false detections.
To reduce the number of false detections.	Increase the number of stages or decrease the false alarm rate per stage.

Feature Types Available for Training

Choose the feature that suits the type of object detection you need. The `trainCascadeObjectDetector` supports three types of features: Haar, local binary patterns (LBP), and histograms of oriented gradients (HOG). Haar and LBP features are often used to detect faces because they work well for representing fine-scale textures. The HOG features are often used to detect objects such as people and cars. They are useful for capturing the overall shape of an object. For example, in the following visualization of the HOG features, you can see the outline of the bicycle.

You might need to run the `trainCascadeObjectDetector` function multiple times to tune the parameters. To save time, you can use LBP or HOG features on a small subset of

your data. Training a detector using Haar features takes much longer. After that, you can run the Haar features to see if the accuracy improves.

Supply Positive Samples

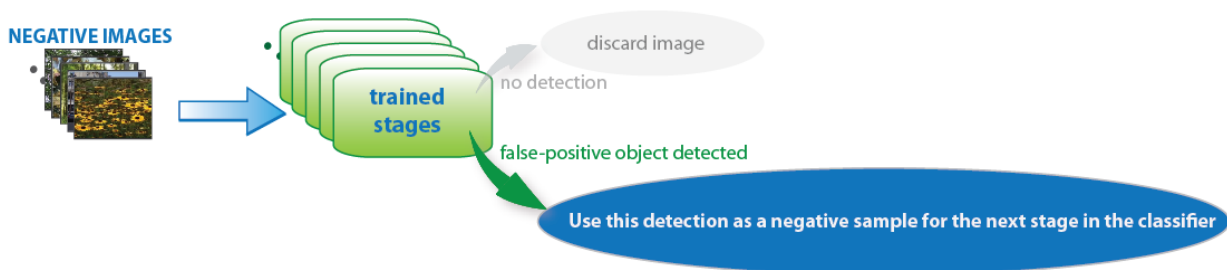

To create positive samples easily, you can use the **Image Labeler** app. The Image Labeler provides an easy way to label positive samples by interactively specifying rectangular regions of interest (ROIs).

You can also specify positive samples manually in one of two ways. One way is to specify rectangular regions in a larger image. The regions contain the objects of interest. The other approach is to crop out the object of interest from the image and save it as a separate image. Then, you can specify the region to be the entire image. You can also generate more positive samples from existing ones by adding rotation or noise, or by varying brightness or contrast.

Supply Negative Images

Negative samples are not specified explicitly. Instead, the `trainCascadeObjectDetector` function automatically generates negative samples from user-supplied negative images that do not contain objects of interest. Before training each new stage, the function runs the detector consisting of the stages already trained on the negative images. Any objects detected from these image are false positives, which are used as negative samples. In this way, each new stage of the cascade is trained to correct mistakes made by previous stages.

As more stages are added, the detector's overall false positive rate decreases, causing generation of negative samples to be more difficult. For this reason, it is helpful to supply as many negative images as possible. To improve training accuracy, supply negative images that contain backgrounds typically associated with the objects of interest. Also, include negative images that contain nonobjects similar in appearance to the objects of interest. For example, if you are training a stop-sign detector, include negative images that contain road signs and shapes similar to a stop sign.

Choose the Number of Stages

There is a trade-off between fewer stages with a lower false positive rate per stage or more stages with a higher false positive rate per stage. Stages with a lower false positive rate are more complex because they contain a greater number of weak learners. Stages with a higher false positive rate contain fewer weak learners. Generally, it is better to have a greater number of simple stages because at each stage the overall false positive rate decreases exponentially. For example, if the false positive rate at each stage is 50%, then the overall false positive rate of a cascade classifier with two stages is 25%. With three stages, it becomes 12.5%, and so on. However, the greater the number of stages, the greater the amount of training data the classifier requires. Also, increasing the number of stages increases the false negative rate. This increase results in a greater chance of rejecting a positive sample by mistake. Set the false positive rate (`FalseAlarmRate`) and the number of stages, (`NumCascadeStages`) to yield an acceptable overall false positive rate. Then you can tune these two parameters experimentally.

Training can sometimes terminate early. For example, suppose that training stops after seven stages, even though you set the number of stages parameter to 20. It is possible that the function cannot generate enough negative samples. If you run the function again and set the number of stages to seven, you do not get the same result. The results between stages differ because the number of positive and negative samples to use for each stage is recalculated for the new number of stages.

Training Time of Detector

Training a good detector requires thousands of training samples. Large amounts of training data can take hours or even days to process. During training, the function displays the time it took to train each stage in the MATLAB Command Window. Training time depends on the type of feature you specify. Using Haar features takes much longer than using LBP or HOG features.

Troubleshooting

What if you run out of positive samples?

The `trainCascadeObjectDetector` function automatically determines the number of positive samples to use to train each stage. The number is based on the total number of positive samples supplied by the user and the values of the `TruePositiveRate` and `NumCascadeStages` parameters.

The number of available positive samples used to train each stage depends on the true positive rate. The rate specifies what percentage of positive samples the function can classify as negative. If a sample is classified as a negative by any stage, it never reaches subsequent stages. For example, suppose you set the `TruePositiveRate` to 0.9, and all of the available samples are used to train the first stage. In this case, 10% of the positive samples are rejected as negatives, and only 90% of the total positive samples are available for training the second stage. If training continues, then each stage is trained with fewer and fewer samples. Each subsequent stage must solve an increasingly more difficult classification problem with fewer positive samples. With each stage getting fewer samples, the later stages are likely to overfit the data.

Ideally, use the same number of samples to train each stage. To do so, the number of positive samples used to train each stage must be less than the total number of available positive samples. The only exception is that when the value of `TruePositiveRate` times the total number of positive samples is less than 1, no positive samples are rejected as negatives.

The function calculates the number of positive samples to use at each stage using the following formula:

$$\text{number of positive samples} = \text{floor}(\text{totalPositiveSamples} / (1 + (\text{NumCascadeStages} - 1) * (1 - \text{TruePositiveRate})))$$

This calculation does not guarantee that the same number of positive samples are available for each stage. The reason is that it is impossible to predict with certainty how

many positive samples will be rejected as negatives. The training continues as long as the number of positive samples available to train a stage is greater than 10% of the number of samples the function determined automatically using the preceding formula. If there are not enough positive samples the training stops and the function issues a warning. The function also outputs a classifier consisting of the stages that it had trained up to that point. If the training stops, you can add more positive samples. Alternatively, you can increase `TruePositiveRate`. Reducing the number of stages can also work, but such reduction can also result in a higher overall false alarm rate.

What to do if you run out of negative samples?

The function calculates the number of negative samples used at each stage. This calculation is done by multiplying the number of positive samples used at each stage by the value of `NegativeSamplesFactor`.

Just as with positive samples, there is no guarantee that the calculated number of negative samples are always available for a particular stage. The `trainCascadeObjectDetector` function generates negative samples from the negative images. However, with each new stage, the overall false alarm rate of the cascade classifier decreases, making it less likely to find the negative samples.

The training continues as long as the number of negative samples available to train a stage is greater than 10% of the calculated number of negative samples. If there are not enough negative samples, the training stops and the function issues a warning. It outputs a classifier consisting of the stages that it had trained up to that point. When the training stops, the best approach is to add more negative images. Alternatively, you can reduce the number of stages or increase the false positive rate.

Examples

Train a Five-Stage Stop-Sign Detector

This example shows you how to set up and train a five-stage, stop-sign detector, using 86 positive samples. The default value for `TruePositiveRate` is 0.995.

Step 1: Load the positive samples data from a MAT-file. In this example, file names and bounding boxes are contained in the array of structures labeled 'data'.

```
load('stopSigns.mat');
```

Step 2: Add the image directory to the MATLAB path.

```
imDir = fullfile(matlabroot,'toolbox','vision','visiondata','stopSignImages');  
addpath(imDir);
```

Step 3: Specify the folder with negative images.

```
negativeFolder = fullfile(matlabroot,'toolbox','vision','visiondata','nonStopSigns');
```

Step 4: Train the detector.

```
trainCascadeObjectDetector('stopSignDetector.xml',data,negativeFolder,'FalseAlarmRate',0.2,'NumCascadeStages',5);
```

Computer Vision Toolbox software returns the following message:

```
Automatically setting ObjectTrainingSize to [ 33, 32 ]  
Using at most 86 of 86 positive samples per stage  
Using at most 172 negative samples per stage  
  
Training stage 1 of 5  
[.....]  
Used 86 positive and 172 negative samples  
  
Training stage 2 of 5  
[.....]  
Used 86 positive and 172 negative samples  
  
Training stage 3 of 5  
[.....]  
Used 86 positive and 172 negative samples  
  
Training stage 4 of 5  
[.....]  
Used 86 positive and 172 negative samples  
  
Training stage 5 of 5  
[.....]  
Used 86 positive and 172 negative samples  
  
Training complete
```

All 86 positive samples were used to train each stage. This high rate occurs because the true positive rate is very high relative to the number of positive samples.

Train a Five-Stage Stop-Sign Detector with a Decreased True Positive Rate

This example shows you how to train a stop-sign detector on the same data set as the first example, (steps 1-3), but with the TruePositiveRate decreased to 0.98.

Step 4: Train the detector.

```
trainCascadeObjectDetector('stopSignDetector_tpr0_98.xml',data,negativeFolder,...
'FalseAlarmRate',0.2,'NumCascadeStages', 5,...
'TruePositiveRate', 0.98);
```

```
Automatically setting ObjectTrainingSize to [ 33, 32 ]
Using at most 79 of 86 positive samples per stage
Using at most 158 negative samples per stage

Training stage 1 of 5
[.....]
Used 79 positive and 158 negative samples

Training stage 2 of 5
[.....]
Used 79 positive and 158 negative samples

Training stage 3 of 5
[.....]
Used 79 positive and 158 negative samples

Training stage 4 of 5
[.....]
Used 79 positive and 158 negative samples

Training stage 5 of 5
[.....]
Used 79 positive and 85 negative samples

Training complete
```

Only 79 of the total 86 positive samples were used to train each stage. This lowered rate occurs because the true positive rate was low enough for the function to start rejecting some of the positive samples as false negatives.

Train a Ten-Stage Stop-Sign Detector

This example shows you how to train a stop-sign detector on the same data set as the first example, (steps 1-3), but with the number of stages increased to 10.

Step 4: Train the detector.

```
trainCascadeObjectDetector('stopSignDetector_10stages.xml', data, negativeFolder, ...  
'FalseAlarmRate', 0.2, 'NumCascadeStages', 10);
```

```
Automatically setting ObjectTrainingSize to [ 33, 32 ]
Using at most 86 of 86 positive samples per stage
Using at most 172 negative samples per stage

Training stage 1 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 2 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 3 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 4 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 5 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 6 of 10
[.....]
Used 86 positive and 33 negative samples

Training stage 7 of 10
[.....Warning:
Unable to generate a sufficient number of negative samples for this stage.
Consider reducing the number of stages, reducing the false alarm rate
or adding more negative images.

Cannot find enough samples for training.
Training will halt and return cascade detector with 6 stages
Training complete
```

In this case, `NegativeSamplesFactor` was set to 2, therefore the number of negative samples used to train each stage was 172. Notice that the function generated only 33 negative samples for stage 6 and was not able to train stage 7 at all. This condition occurs because the number of negatives in stage 7 was less than 17, (roughly half of the previous number of negative samples). The function produced a stop-sign detector with 6 stages, instead of the 10 previously specified. The resulting overall false alarm rate is $0.2^7=1.28e-05$, while the expected false alarm rate is $1.024e-07$.

At this point, you can add more negative images, reduce the number of stages, or increase the false positive rate. For example, you can increase the false positive rate, `FalseAlarmRate`, to 0.5. The expected overall false-positive rate in this case is 0.0039.

Step 4: Train the detector.

```
trainCascadeObjectDetector('stopSignDetector_10stages_far0_5.xml',data,negativeFolder,...  
'FalseAlarmRate',0.5,'NumCascadeStages',10);
```

```
Automatically setting ObjectTrainingSize to [ 33, 32 ]
Using at most 86 of 86 positive samples per stage
Using at most 172 negative samples per stage

Training stage 1 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 2 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 3 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 4 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 5 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 6 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 7 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 8 of 10
[.....]
Used 86 positive and 172 negative samples

Training stage 9 of 10
[.....]
Very low false alarm rate 0.000587108 reached in stage.
Training will halt and return cascade detector with 8 stages
Training complete
```

This time the function trains eight stages before the threshold reaches the overall false alarm rate of 0.000587108 and training stops.

Train Stop Sign Detector

Load the positive samples data from a MAT file. The file contains a table specifying bounding boxes for several object categories. The table was exported from the Training Image Labeler app.

Load positive samples.

```
load('stopSignsAndCars.mat');
```

Select the bounding boxes for stop signs from the table.

```
positiveInstances = stopSignsAndCars(:,1:2);
```

Add the image folder to the MATLAB path.

```
imDir = fullfile(matlabroot,'toolbox','vision','visiondata',...
    'stopSignImages');
addpath(imDir);
```

Specify the folder for negative images.

```
negativeFolder = fullfile(matlabroot,'toolbox','vision','visiondata',...
    'nonStopSigns');
```

Create an imageDatastore object containing negative images.

```
negativeImages = imageDatastore(negativeFolder);
```

Train a cascade object detector called 'stopSignDetector.xml' using HOG features. NOTE: The command can take several minutes to run.

```
trainCascadeObjectDetector('stopSignDetector.xml',positiveInstances, ...
    negativeFolder,'FalseAlarmRate',0.1,'NumCascadeStages',5);
```

```
Automatically setting ObjectTrainingSize to [35, 32]
Using at most 42 of 42 positive samples per stage
Using at most 84 negative samples per stage
```

```
--cascadeParams--
Training stage 1 of 5
```

```
[.....]
Used 42 positive and 84 negative samples
Time to train stage 1: 1 seconds

Training stage 2 of 5
[.....]
Used 42 positive and 84 negative samples
Time to train stage 2: 0 seconds

Training stage 3 of 5
[.....]
Used 42 positive and 84 negative samples
Time to train stage 3: 3 seconds

Training stage 4 of 5
[.....]
Used 42 positive and 84 negative samples
Time to train stage 4: 10 seconds

Training stage 5 of 5
[.....]
Used 42 positive and 17 negative samples
Time to train stage 5: 16 seconds

Training complete
```

Use the newly trained classifier to detect a stop sign in an image.

```
detector = vision.CascadeObjectDetector('stopSignDetector.xml');
```

Read the test image.

```
img = imread('stopSignTest.jpg');
```

Detect a stop sign.

```
bbox = step(detector, img);
```

Insert bounding box rectangles and return the marked image.

```
detectedImg = insertObjectAnnotation(img, 'rectangle', bbox, 'stop sign');
```

Display the detected stop sign.

```
figure; imshow(detectedImg);
```

Remove the image directory from the path.

```
rmpath(imDir);
```

Train Optical Character Recognition for Custom Fonts

In this section...

“Open the OCR Trainer App” on page 7-172

“Train OCR” on page 7-172

“App Controls” on page 7-175

The optical character recognition (OCR) app trains the `ocr` function to recognize a custom language or font. You can use this app to label character data interactively for OCR training and to generate an OCR language data file for use with the `ocr` function.

Open the OCR Trainer App

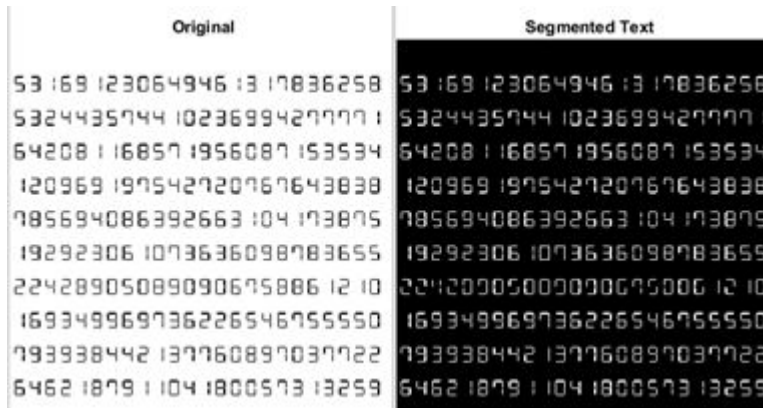

- MATLAB Toolstrip: On the **Apps** tab, under **Image Processing and Computer Vision**, click , the OCR app icon.
- MATLAB command prompt: Enter `ocrTrainer`.

Train OCR

- 1 In the OCR Trainer, click **New Session** to open the OCR Training Session Settings dialog box.
- 2 Under **Output Settings**, enter a name for the OCR language data file and choose the output folder location for the file. The location you specify must be writable.
- 3 Under **Labeling Method**, either label the data manually or pre-label it using optical character recognition. If you use OCR, you can select either the pre-installed English or Japanese language, or you can download additional language support files.

Note To download a language support file, type `visionSupportPackages` in a MATLAB Command Window. Alternatively, on the MATLAB **Home** tab, in the **Environment** section, click **Add-Ons > Get Add-Ons**. Then use the search box to find “Computer Vision System Toolbox OCR Language Data.”

- 4 Add images at any time during the training session. The trainer automatically segments the images for OCR training. Inspect the results to verify expected text segmentation. To improve the segmentation, pre-process your images using the **Image Segmenter** app. Once the images are added, you can inspect segmentation results from the training image view.

To limit the OCR to a specific character set, select the **Character set** check box and add the characters.

Note Use training images that contain text that you want OCR to recognize. Do not use training images with only a few characters. OCR training works best if training images contain blocks of many words. You can use the `insertText` function to automatically generate training images for a known font.

```
I = zeros(500,500,3,'uint8');

textLines = [
    "some training text"
    "even more stuff to learn"easy
]
lineYLocation = 50;

for i = 1:numel(textLines)
    I = insertText(I,[50 lineYLocation],char(textLines(i)), ...
        'Font','LucidaSansRegular',...
        'FontSize',16,'TextColor','white',...
    );
end
```

```

        'BoxOpacity',0);

    % increment to next line
    lineYLocation = lineYLocation + 20;
end
figure
imshow(I)

```

- 5 Remove any noisy images. To improve segmentation results, you can draw a region of interest to select a portion of an image. The display shows the original image on the left and the edited one on the right. When you are done, click **Accept All**.
- 6 Modify the extracted samples from the character view window.
 - To correct samples, select a group of samples from the **Data Browser** pane and change the labels using the **Character Label** field.
 - To exclude a sample from training, right-click the sample and select the option to move that sample to the **Unknown** category. Unknown samples are listed at the top of the **Data Browser** pane and are not used for training.
 - If the bounding box clipped a character, double-click the character and modify it in the image it was extracted from.

- 7 After correcting the samples, click **Train**. When the trainer completes training, the app creates an OCR language data file and saves it to the folder you specified.

App Controls

Sessions

Starts a new session, opens a saved session, or adds a session to the current one. You can also save and name the session. The sessions are saved as MAT files.

Add Images

Adds images. You can add images when you start a new session or after you accept the current collection of images.

Settings

Set or change the font display.

Edit Box

Selects the image that contains the selected character, along with the bounding boxes. You can create additional regions, merge, modify, or delete existing images. To delete an ROI, use the **delete** key.

Train

Creates an OCR data file from the session. To use the `.traineddata` file with the `ocr` function, set the 'Language' property for the `ocr` function, and follow the directions for a custom language.

Generate Function

Creates an autogenerated evaluation function for verification of training results.

Note Before running the OCR Trainer app, check if your machine has only one Tesseract installation. If there are multiple Tesseract installations, remove the extra installations and restart MATLAB to run the OCR Trainer app. Otherwise, the app returns the error "Not enough input arguments" when you click the Train button.

Troubleshoot ocr Function Results

Performance Options with the ocr Function

If your ocr results are not what you expect, try one or more of the following options:

- Increase image size 2-to-4 times larger.
- If the characters in the image are too close together or their edges are touching, use morphology to thin out the characters. Using morphology to thin out the characters separates the characters.
- Use binarization to check for non-uniform lighting issues. Use the `graythresh` and `imbinarize` functions to binarize the image. If the characters are not visible in the results of the binarization, it indicates a potential non-uniform lighting issue. Try top hat, using the `imtophat` function, or other techniques that deal with removing non-uniform illumination.
- Use the region of interest `roi` option to isolate the text. Specify the `roi` manually or use text detection.
- If your image looks like a natural scene containing words, like a street scene, rather than a scanned document, try setting the `TextLayout` property to either 'Block' or 'Word'.

More About

- “Install Computer Vision Toolbox Add-on Support Files” on page 3-2

Create a Custom Feature Extractor

You can use the bag-of-features (BoF) framework with many different types of image features. To use a custom feature extractor instead of the default speeded-up robust features (SURF) feature extractor, use the `CustomExtractor` property of a `bagOfFeatures` object.

Example of a Custom Feature Extractor

This example shows how to write a custom feature extractor function for `bagOfFeatures`. You can open this example function file and use it as a template by typing the following command at the MATLAB command prompt:

```
edit('exampleBagOfFeaturesExtractor.m')
```

- Step 1. Define the image sets.
- Step 2. Create a new extractor function file.
- Step 3. Preprocess the image.
- Step 4. Select a point location for feature extraction.
- Step 5. Extract features.
- Step 6. Compute the feature metric.

Define the set of images and labels

Read the category images and create image sets.

```
setDir = fullfile(toolboxdir('vision'),'visiondata','imageSets');  
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...  
    'foldernames');
```

Create a new extractor function file

The extractor function must be specified as a function handle:

```
extractorFcn = @exampleBagOfFeaturesExtractor;  
bag = bagOfFeatures(imgSets,'CustomExtractor',extractorFcn)
```

`exampleBagOfFeaturesExtractor` is a MATLAB function. For example:

```
function [features,featureMetrics] = exampleBagOfFeaturesExtractor(img)  
...
```

You can also specify the optional location output:

```
function [features,featureMetrics,location] = exampleBagOfFeaturesExtractor(img)
...

```

The function must be on the path or in the current working folder.

Argument	Input/Output	Description
img	Input	<ul style="list-style-type: none"> Binary, grayscale, or truecolor image. The input image is from the image set that was originally passed into <code>bagOfFeatures</code>.
features	Output	<ul style="list-style-type: none"> An M-by-N numeric matrix of image features, where M is the number of features and N is the length of each feature vector. The feature length, N, must be greater than zero and be the same for all images processed during the <code>bagOfFeatures</code> creation process. If you cannot extract features from an image, supply an empty feature matrix and an empty feature metrics vector. Use the empty matrix and vector if, for example, you did not find any keypoints for feature extraction. Numeric, real, and nonsparse.
featureMetrics	Output	<ul style="list-style-type: none"> An M-by-1 vector of feature metrics indicating the strength of each feature vector. Used to apply the 'SelectStrongest' criteria in <code>bagOfFeatures</code> framework. Numeric, real, and nonsparse.
location	Output	<ul style="list-style-type: none"> An M-by-2 matrix of 1-based $[x\ y]$ values. The $[x\ y]$ values can be fractional. Numeric, real, and nonsparse.

Preprocess the image

Input images can require preprocessing before feature extraction. To extract SURF features and to use the `detectSURFFeatures` or `detectMSERFeatures` functions, the images must be grayscale. If the images are not grayscale, you can convert them using the `rgb2gray` function.

```
[height,width,numChannels] = size(I);  
if numChannels > 1  
    grayImage = rgb2gray(I);  
else  
    grayImage = I;  
end
```

Select a point location for feature extraction

Use a regular spaced grid of point locations. Using the grid over the image allows for dense SURF feature extraction. The grid step is in pixels.

```
gridStep = 8;  
gridX = 1:gridStep:width;  
gridY = 1:gridStep:height;  
  
[x,y] = meshgrid(gridX,gridY);  
  
gridLocations = [x(:) y(:)];
```

You can manually concatenate multiple SURFPoints objects at different scales to achieve multiscale feature extraction.

```
multiscaleGridPoints = [SURFPoints(gridLocations,'Scale',1.6);  
    SURFPoints(gridLocations,'Scale',3.2);  
    SURFPoints(gridLocations,'Scale',4.8);  
    SURFPoints(gridLocations,'Scale',6.4)];
```

Alternatively, you can use a feature detector, such as `detectSURFFeatures` or `detectMSERFeatures`, to select point locations.

```
multiscaleSURFPoints = detectSURFFeatures(I);
```

Extract features

Extract features from the selected point locations. By default, `bagOfFeatures` extracts upright SURF features.

```
features = extractFeatures(grayImage,multiscaleGridPoints,'Upright',true);
```

Compute the feature metric

The feature metrics indicate the strength of each feature. Larger metric values are assigned to stronger features. Use feature metrics to identify and remove weak features

before using `bagOfFeatures` to learn the visual vocabulary of an image set. Use the metric that is suitable for your feature vectors.

For example, you can use the variance of the SURF features as the feature metric.

```
featureMetrics = var(features,[],2);
```

If you used a feature detector for the point selection, then use the detection metric instead.

```
featureMetrics = multiscaleSURFPoints.Metric;
```

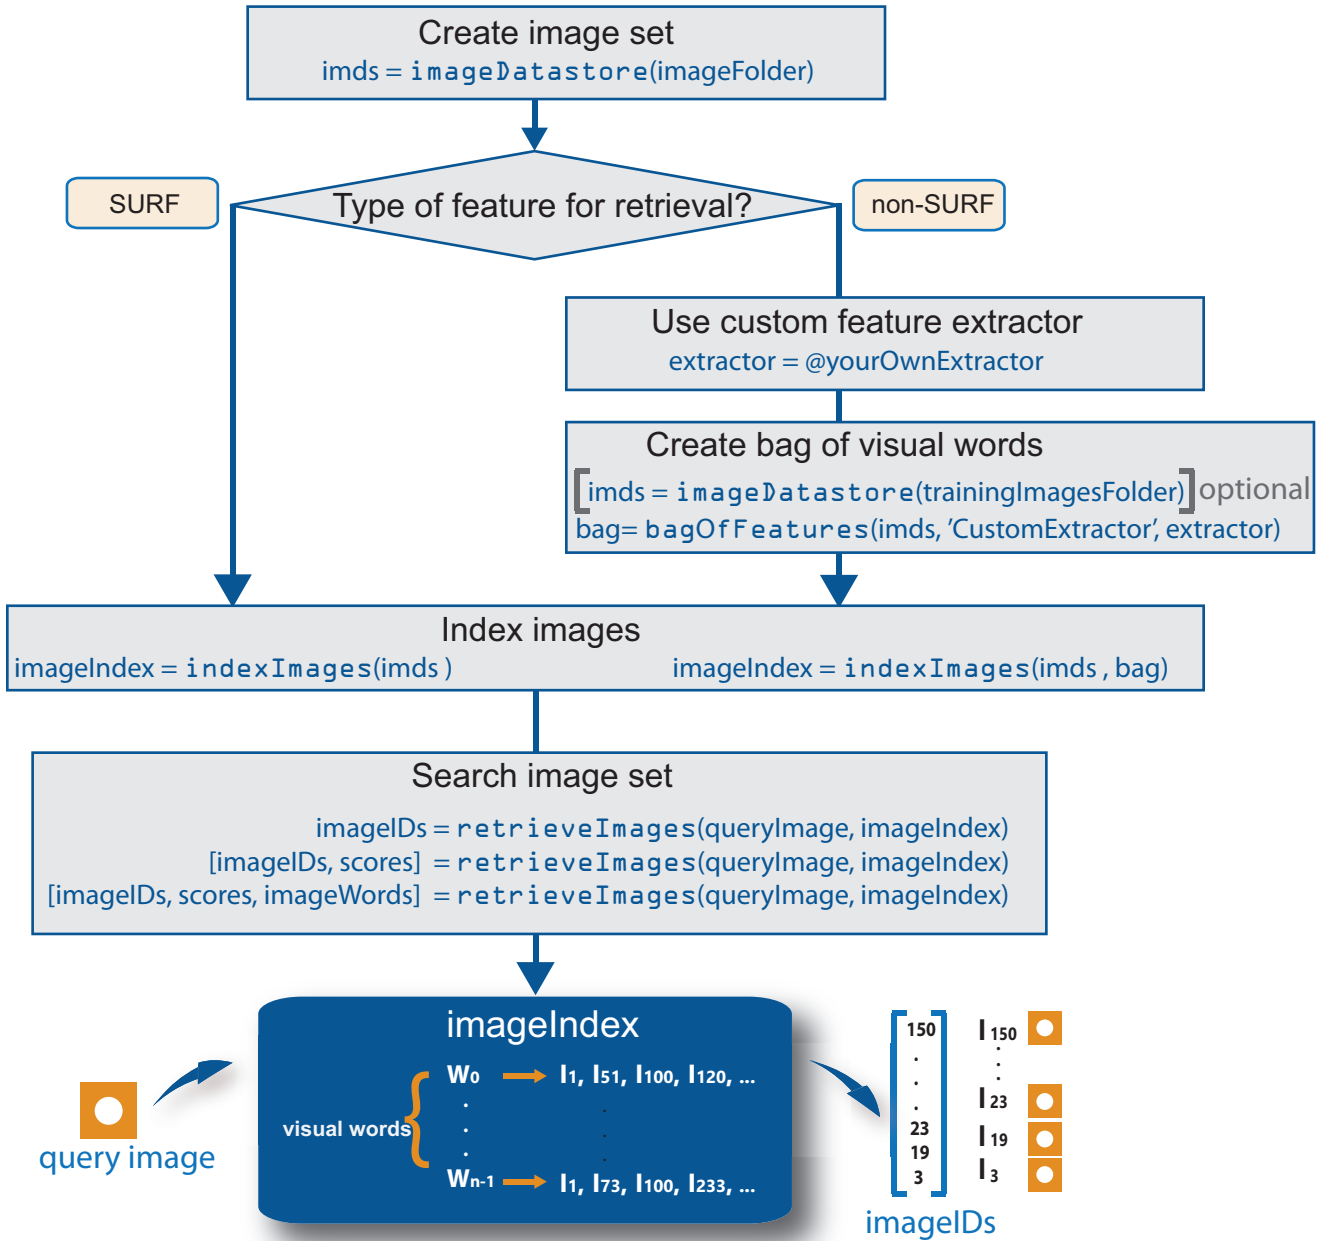

You can optionally return the feature location information. The feature location can be used for spatial or geometric verification image search applications. See the “Geometric Verification Using `estimateGeometricTransform` Function” example. The `retrieveImages` and `indexImages` functions are used for content-based image retrieval systems.

```
if nargin > 2  
    varargout{1} = multiscaleGridPoints.Location;  
end
```

Image Retrieval with Bag of Visual Words

You can use the Computer Vision Toolbox functions to search by image, also known as a content-based image retrieval (CBIR) system. CBIR systems are used to retrieve images from a collection of images that are similar to a query image. The application of these types of systems can be found in many areas such as a web-based product search, surveillance, and visual place identification. First the system searches a collection of images to find the ones that are visually similar to a query image.

The retrieval system uses a bag of visual words, a collection of image descriptors, to represent your data set of images. Images are indexed to create a mapping of visual words. The index maps each visual word to their occurrences in the image set. A comparison between the query image and the index provides the images most similar to the query image. By using the CBIR system workflow, you can evaluate the accuracy for a known set of image search results.

Retrieval System Workflow

- 1 Create image set that represents image features for retrieval.** Use `imageDatastore` to store the image data. Use a large number of images that represent various viewpoints of the object. A large and diverse number of images helps train the bag of visual words and increases the accuracy of the image search.
- 2 Type of feature.** The `indexImages` function creates the bag of visual words using the speeded up robust features (SURF). For other types of features, you can use a custom extractor, and then use `bagOfFeatures` to create the bag of visual words. See the “Create Search Index Using Custom Bag of Features” example.

You can use the original `imgSet` or a different collection of images for the training set. To use a different collection, create the bag of visual words before creating the image index, using the `bagOfFeatures` function. The advantage of using the same set of images is that the visual vocabulary is tailored to the search set. The disadvantage of this approach is that the retrieval system must relearn the visual vocabulary to use on a drastically different set of images. With an independent set, the visual vocabulary is better able to handle the additions of new images into the search index.

- 3 Index the images.** The `indexImages` function creates a search index that maps visual words to their occurrences in the image collection. When you create the bag of visual words using an independent or subset collection, include the bag as an input argument to `indexImages`. If you do not create an independent bag of visual words, then the function creates the bag based on the entire `imgSet` input collection. You can add and remove images directly to and from the image index using the `addImages` and `removeImages` methods.
- 4 Search data set for similar images.** Use the `retrieveImages` function to search the image set for images which are similar to the query image. Use the `NumResults` property to control the number of results. For example, to return the top 10 similar images, set the `ROI` property to use a smaller region of a query image. A smaller region is useful for isolating a particular object in an image that you want to search for.

Evaluate Image Retrieval

Use the `evaluateImageRetrieval` function to evaluate image retrieval by using a query image with a known set of results. If the results are not what you expect, you can modify or augment image features by the bag of visual words. Examine the type of the features retrieved. The type of feature used for retrieval depends on the type of images

within the collection. For example, if you are searching an image collection made up of scenes, such as beaches, cities, or highways, use a global image feature. A global image feature, such as a color histogram, captures the key elements of the entire scene. To find specific objects within the image collections, use local image features extracted around object keypoints instead.

Image Classification with Bag of Visual Words

Use the Computer Vision Toolbox functions for image category classification by creating a bag of visual words. The process generates a histogram of visual word occurrences that represent an image. These histograms are used to train an image category classifier. The steps below describe how to setup your images, create the bag of visual words, and then train and apply an image category classifier.

Step 1: Set Up Image Category Sets

Organize and partition the images into training and test subsets. Use the `imageDatastore` function to store images to use for training an image classifier. Organizing images into categories makes handling large sets of images much easier. You can use the `splitEachLabel` function to split the images into training and test data.

Read the category images and create image sets.

```
setDir = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
    'foldernames');
```

Separate the sets into training and test image subsets. In this example, 30% of the images are partitioned for training and the remainder for testing.

```
[trainingSet,testSet] = splitEachLabel(imds,0.3,'randomize');
```

Step 2: Create Bag of Features

Create a visual vocabulary, or bag of features, by extracting feature descriptors from representative images of each category.

The `bagOfFeatures` object defines the features, or visual words, by using the k-means clustering (Statistics and Machine Learning Toolbox) algorithm on the feature descriptors extracted from `trainingSets`. The algorithm iteratively groups the descriptors into k mutually exclusive clusters. The resulting clusters are compact and separated by similar characteristics. Each cluster center represents a feature, or visual word.

You can extract features based on a feature detector, or you can define a grid to extract feature descriptors. The grid method may lose fine-grained scale information. Therefore, use the grid for images that do not contain distinct features, such as an image containing scenery, like the beach. Using speeded up robust features (or SURF) detector provides greater scale invariance. By default, the algorithm runs the 'grid' method.

This algorithm workflow analyzes images in their entirety. Images must have appropriate labels describing the class that they represent. For example, a set of car images could be labeled cars. The workflow does not rely on spatial information nor on marking the particular objects in an image. The bag-of-visual-words technique relies on detection without localization.

Step 3: Train an Image Classifier With Bag of Visual Words

The `trainImageCategoryClassifier` function returns an image classifier. The function trains a multiclass classifier using the error-correcting output codes (ECOC) framework with binary support vector machine (SVM) classifiers. The `trainImageCategoryClassifier` function uses the bag of visual words returned by the

`bagOfFeatures` object to encode images in the image set into the histogram of visual words. The histogram of visual words are then used as the positive and negative samples to train the classifier.

- 1 Use the `bagOfFeatures` `encode` method to encode each image from the training set. This function detects and extracts features from the image and then uses the approximate nearest neighbor algorithm to construct a feature histogram for each image. The function then increments histogram bins based on the proximity of the descriptor to a particular cluster center. The histogram length corresponds to the number of visual words that the `bagOfFeatures` object constructed. The histogram becomes a feature vector for the image.

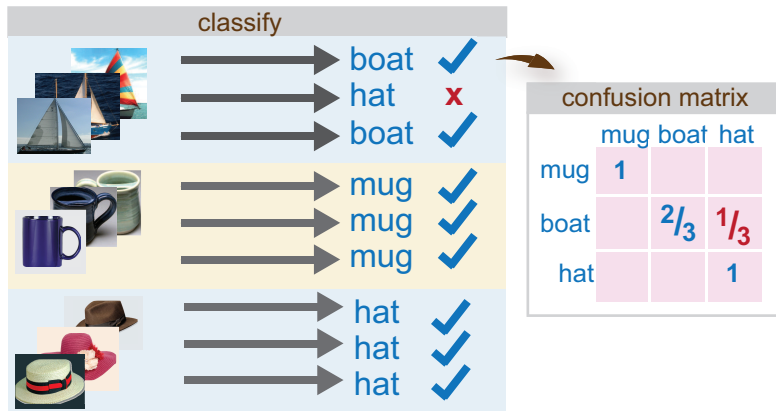

- 2 Repeat step 1 for each image in the training set to create the training data.

- 3 Evaluate the quality of the classifier. Use the `imageCategoryClassifier` `evaluate` method to test the classifier against the validation image set. The output confusion matrix represents the analysis of the prediction. A perfect classification

results in a normalized matrix containing 1s on the diagonal. An incorrect classification results fractional values.

Step 4: Classify an Image or Image Set

Use the `imageCategoryClassifier` `predict` method on a new image to determine its category.

- “Pattern Matching” on page 8-20

Multiple Object Tracking

Tracking is the process of locating a moving object or multiple objects over time in a video stream. Tracking an object is not the same as object detection. Object detection is the process of locating an object of interest in a single frame. Tracking associates detections of an object across multiple frames.

Tracking multiple objects requires detection, prediction, and data association.

- **Detection:** Detect objects of interest in a video frame.
- **Prediction:** Predict the object locations in the next frame.
- **Data association:** Use the predicted locations to associate detections across frames to form *tracks*.

Detection

Selecting the right approach for detecting objects of interest depends on what you want to track and whether the camera is stationary.

Detect Objects Using a Stationary Camera

To detect objects in motion with a stationary camera, you can perform background subtraction using the `vision.ForegroundDetector` System object. The background subtraction approach works efficiently but requires the camera to be stationary.

Detect Objects Using a Moving Camera

To detect objects in motion with a moving camera, you can use a sliding-window detection approach. This approach typically works more slowly than the background subtraction approach. To detect and track a specific category of object, use the System objects or functions described in the table.

Select A Detection Algorithm

Type of Object to Track	Camera	Functionality
Anything that moves	Stationary	<code>vision.ForegroundDetector</code> System object™
Faces, eyes, nose, mouth, upper body	Stationary, Moving	<code>vision.CascadeObjectDetector</code> System object

Type of Object to Track	Camera	Functionality
Pedestrians	Stationary, Moving	<code>vision.PeopleDetector</code> System object
Custom object category	Stationary, Moving	<code>trainCascadeObjectDetector</code> function or custom sliding window detector using <code>extractHOGFeatures</code> and <code>selectStrongestBbox</code>

Prediction

To track an object over time means that you must predict its location in the next frame. The simplest method of prediction is to assume that the object will be near its last known location. In other words, the previous detection serves as the next prediction. This method is especially effective for high frame rates. However, using this prediction method can fail when objects move at varying speeds, or when the frame rate is low relative to the speed of the object in motion.

A more sophisticated method of prediction is to use the previously observed motion of the object. The Kalman filter (`vision.KalmanFilter`) predicts the next location of an object, assuming that it moves according to a motion model, such as constant velocity or constant acceleration. The Kalman filter also takes into account process noise and measurement noise. Process noise is the deviation of the actual motion of the object from the motion model. Measurement noise is the detection error.

To make configuring a Kalman filter easier, use `configureKalmanFilter`. This function sets up the filter for tracking a physical object moving with constant velocity or constant acceleration within a Cartesian coordinate system. The statistics are the same along all dimensions. If you need to configure a Kalman filter with different assumptions, you need to construct the `vision.KalmanFilter` object directly.

Data Association

Data association is the process of associating detections corresponding to the same physical object across frames. The temporal history of a particular object consists of multiple detections, and is called a *track*. A track representation can include the entire history of the previous locations of the object. Alternatively, it can consist only of the object's last known location and its current velocity.

Detection to Track Cost Functions

To match a detection to a track, you must establish criteria for evaluating the matches. Typically, you establish this criteria by defining a cost function. The higher the cost of matching a detection to a track, the less likely that the detection belongs to the track. A simple cost function can be defined as the degree of overlap between the bounding boxes of the predicted and detected objects. The “Tracking Pedestrians from a Moving Car” example implements this cost function using the `bboxOverlapRatio` function. You can implement a more sophisticated cost function, one that accounts for the uncertainty of the prediction, using the `distance` function of the `vision.KalmanFilter` object. You can also implement a custom cost function that can incorporate information about the object size and appearance.

Elimination of Unlikely Matches

Gating is a method of eliminating highly unlikely matches from consideration, such as by imposing a threshold on the cost function. An observation cannot be matched to a track if the cost exceeds a certain threshold value. Using this threshold method effectively results in a circular *gating region* around each prediction, where a matching detection can be found. An alternative gating technique is to make the gating region large enough to include the *k*-nearest neighbors of the prediction.

Assign Detections to Track

Data association reduces to a minimum weight bipartite matching problem, which is a well-studied area of graph theory. A bipartite graph represents tracks and detections as vertices. It also represents the cost of matching a detection and a track as a weighted edge between the corresponding vertices.

The `assignDetectionsToTracks` function implements the Munkres' variant of the Hungarian bipartite matching algorithm. Its input is the *cost matrix*, where the rows correspond to tracks and the columns correspond to detections. Each entry contains the cost of assigning a particular detection to a particular track. You can implement gating by setting the cost of impossible matches to infinity.

Track Management

Data association must take into account the fact that new objects can appear in the field of view, or that an object being tracked can leave the field of view. In other words, in any given frame, some number of new tracks might need to be created, and some number of existing tracks might need to be discarded. The `assignDetectionsToTracks` function

returns the indices of unassigned tracks and unassigned detections in addition to the matched pairs.

One way of handling unmatched detections is to create a new track from each of them. Alternatively, you can create new tracks from unmatched detections greater than a certain size, or from detections that have certain locations or appearance. For example, if the scene has a single entry point, such as a doorway, then you can specify that only unmatched detections located near the entry point can begin new tracks, and that all other detections are considered noise.

Another way of handling unmatched tracks is to delete any track that remain unmatched for a certain number of frames. Alternatively, you can specify to delete an unmatched track when its last known location is near an exit point.

Video Mosaicking

This example shows how to create a mosaic from a video sequence. Video mosaicking is the process of stitching video frames together to form a comprehensive view of the scene. The resulting mosaic image is a compact representation of the video data. The Video Mosaicking block is often used in video compression and surveillance applications.

This example illustrates how to use the Corner Detection block, the Estimate Geometric Transformation block, the Projective Transform block, and the Compositing block to create a mosaic image from a video sequence.

Example Model

The following figure shows the Video Mosaicking model:

The Input subsystem loads a video sequence from either a file, or generates a synthetic video sequence. The choice is user defined. First, the Corner Detection block finds points that are matched between successive frames by the Corner Matching subsystem. Then the Estimate Geometric Transformation block computes an accurate estimate of the transformation matrix. This block uses the RANSAC algorithm to eliminate outlier input points, reducing error along the seams of the output mosaic image. Finally, the Mosaicking subsystem overlays the current video frame onto the output image to generate a mosaic.

Input Subsystem

The Input subsystem can be configured to load a video sequence from a file, or to generate a synthetic video sequence.

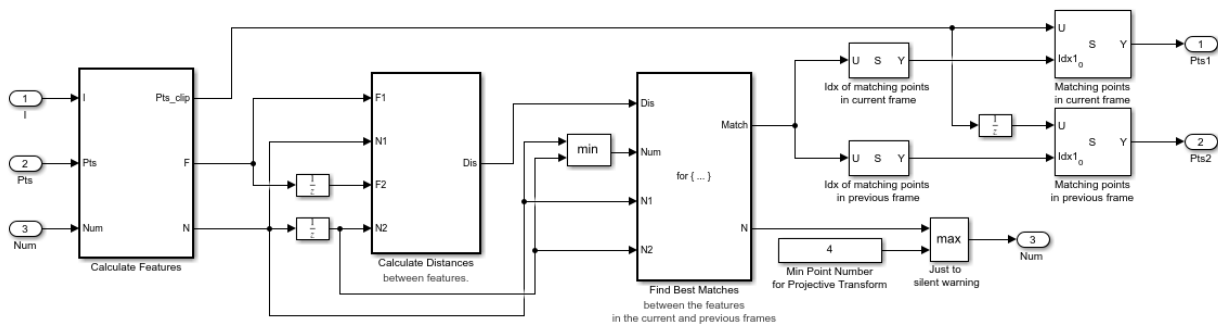

If you choose to use a video sequence from a file, you can reduce computation time by processing only some of the video frames. This is done by setting the downsampling rate in the Frame Rate Downsampling subsystem.

If you choose a synthetic video sequence, you can set the speed of translation and rotation, output image size and origin, and the level of noise. The output of the synthetic video sequence generator mimics the images captured by a perspective camera with arbitrary motion over a planar surface.

Corner Matching Subsystem

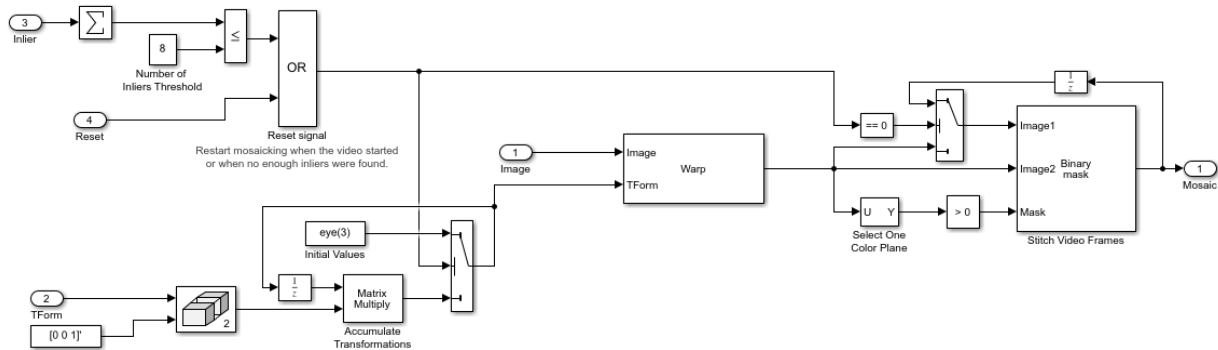

The subsystem finds corner features in the current video frame in one of three methods. The example uses Local intensity comparison (Rosen & Drummond), which is the fastest method. The other methods available are the Harris corner detection (Harris & Stephens) and the Minimum Eigenvalue (Shi & Tomasi).

The Corner Matching Subsystem finds the number of corners, location, and their metric values. The subsystem then calculates the distances between all features in the current frame with those in the previous frame. By searching for the minimum distances, the subsystem finds the best matching features.

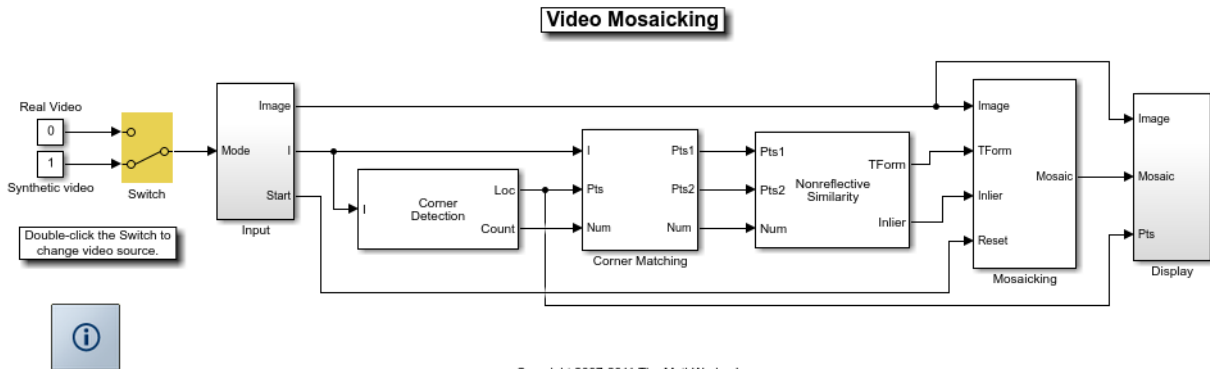

Mosaicking Subsystem

By accumulating transformation matrices between consecutive video frames, the subsystem calculates the transformation matrix between the current and the first video frame. The subsystem then overlays the current video frame on to the output image. By repeating this process, the subsystem generates a mosaic image.

The subsystem is reset when the video sequence rewinds or when the Estimate Geometric Transformation block does not find enough inliers.

Video Mosaicking Using Synthetic Video

The Corners window shows the corner locations in the current video frame.

The Mosaic window shows the resulting mosaic image.

Video Mosaicking Using Captured Video

The Corners window shows the corner locations in the current video frame.

The Mosaic window shows the resulting mosaic image.

Pattern Matching

This example shows how to use the 2-D normalized cross-correlation for pattern matching and target tracking. The example uses predefined or user specified target and number of similar targets to be tracked. The normalized cross correlation plot shows that when the value exceeds the set threshold, the target is identified.

Introduction

In this example you use normalized cross correlation to track a target pattern in a video. The pattern matching algorithm involves the following steps:

- The input video frame and the template are reduced in size to minimize the amount of computation required by the matching algorithm.
- Normalized cross correlation, in the frequency domain, is used to find a template in the video frame.
- The location of the pattern is determined by finding the maximum cross correlation value.

Initialize Parameters and Create a Template

Initialize required variables such as the threshold value for the cross correlation and the decomposition level for Gaussian Pyramid decomposition.

```
threshold = single(0.99);
level = 2;
```

Prepare a video file reader.

```
hVideoSrc = vision.VideoFileReader('vipboard.mp4', ...
    'VideoOutputDataType', 'single', ...
    'ImageColorSpace', 'Intensity');
```

Specify the target image and number of similar targets to be tracked. By default, the example uses a predefined target and finds up to 2 similar patterns. You can set the variable `useDefaultTarget` to false to specify a new target and the number of similar targets to match.

```
useDefaultTarget = true;
[Img, numberOfTargets, target_image] = ...
    videopattern_gettemplate(useDefaultTarget);
```

```
% Downsample the target image by a predefined factor. You do this
% to reduce the amount of computation needed by cross correlation.
target_image = single(target_image);
target_dim_nopyramid = size(target_image);
target_image_gp = multilevelPyramid(target_image, level);
target_energy = sqrt(sum(target_image_gp(:).^2));

% Rotate the target image by 180 degrees, and perform zero padding so that
% the dimensions of both the target and the input image are the same.
target_image_rot = imrotate(target_image_gp, 180);
[rt, ct] = size(target_image_rot);
Img = single(Img);
Img = multilevelPyramid(Img, level);
[ri, ci]= size(Img);
r_mod = 2^nextpow2(rt + ri);
c_mod = 2^nextpow2(ct + ci);
target_image_p = [target_image_rot zeros(rt, c_mod-ct)];
target_image_p = [target_image_p; zeros(r_mod-rt, c_mod)];

% Compute the 2-D FFT of the target image
target_fft = fft2(target_image_p);
```

```
% Initialize constant variables used in the processing loop.
target_size = repmat(target_dim_nopyramid, [numberOfTargets, 1]);
gain = 2^(level);
Im_p = zeros(r_mod, c_mod, 'single'); % Used for zero padding
C_ones = ones(rt, ct, 'single'); % Used to calculate mean using conv
```

Create a System object to calculate the local maximum value for the normalized cross correlation.

```
hFindMax = vision.LocalMaximaFinder( ...
    'Threshold', single(-1), ...
    'MaximumNumLocalMaxima', numberOfTargets, ...
    'NeighborhoodSize', floor(size(target_image_gp)/2)*2 - 1);
```

Create a System object to display the tracking of the pattern.

```
sz = get(0, 'ScreenSize');
pos = [20 sz(4)-400 400 300];
hROIPattern = vision.VideoPlayer('Name', 'Overlay the ROI on the target', ...
    'Position', pos);
```

Initialize figure window for plotting the normalized cross correlation value

```
hPlot = videopatternplots('setup',numberOfTargets, threshold);
```

Search for a Template in Video

Create a processing loop to perform pattern matching on the input video. This loop uses the System objects you instantiated above. The loop is stopped when you reach the end of the input file, which is detected by the VideoFileReader System object.

```
while ~isDone(hVideoSrc)
    Im = step(hVideoSrc);

    % Reduce the image size to speed up processing
    Im_gp = multilevelPyramid(Im, level);

    % Frequency domain convolution.
    Im_p(1:ri, 1:ci) = Im_gp;    % Zero-pad
    img_fft = fft2(Im_p);
    corr_freq = img_fft .* target_fft;
    corrOutput_f = ifft2(corr_freq);
    corrOutput_f = corrOutput_f(rt:ri, ct:ci);

    % Calculate image energies and block run tiles that are size of
    % target template.
    IUT_energy = (Im_gp).^2;
    IUT = conv2(IUT_energy, C_ones, 'valid');
    IUT = sqrt(IUT);

    % Calculate normalized cross correlation.
    norm_Corr_f = (corrOutput_f) ./ (IUT * target_energy);
    xyLocation = step(hFindMax, norm_Corr_f);

    % Calculate linear indices.
    linear_index = sub2ind([ri-rt, ci-ct]+1, xyLocation(:,2),...
        xyLocation(:,1));

    norm_Corr_f_linear = norm_Corr_f(:);
    norm_Corr_value = norm_Corr_f_linear(linear_index);
    detect = (norm_Corr_value > threshold);
    target_roi = zeros(length(detect), 4);
    ul_corner = (gain.*(xyLocation(detect, :)-1))+1;
    target_roi(detect, :) = [ul_corner, fliplr(target_size(detect, :))];

    % Draw bounding box.
    Imf = insertShape(Im, 'Rectangle', target_roi, 'Color', 'green');
    % Plot normalized cross correlation.
```

```
        videopatternplots('update',hPlot,norm_Corr_value);
        step(hROIPattern, Imf);
end

snapnow
release(hVideoSrc);

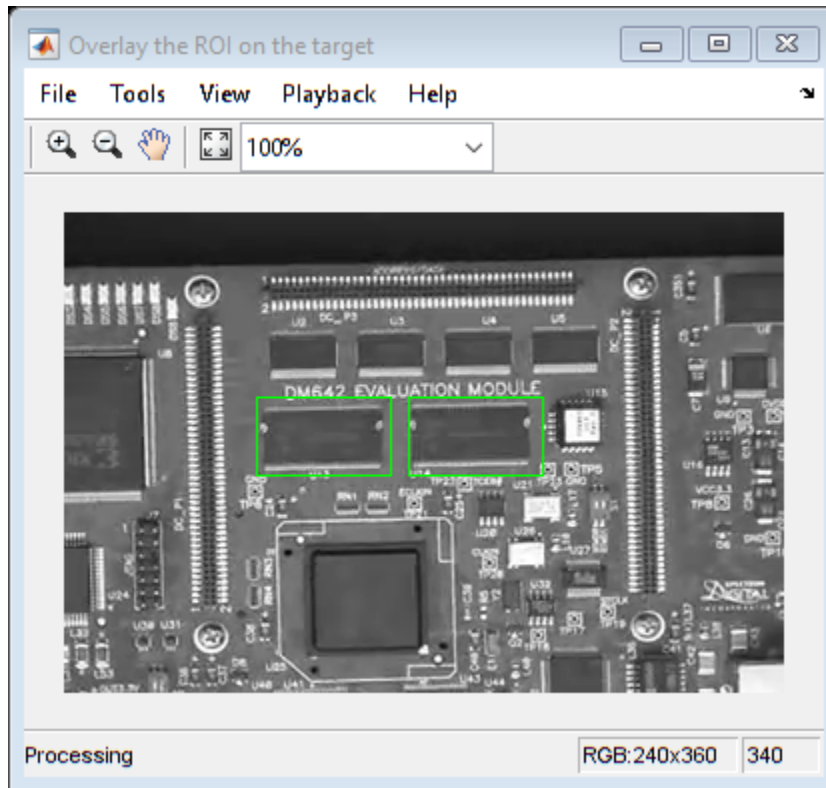

% Function to compute pyramid image at a particular level.
function outI = multilevelPyramid(inI, level)

I = inI;
outI = I;

for i=1:level
    outI = impyramid(I, 'reduce');
    I = outI;
end

end
```

Summary

This example shows use of Computer Vision Toolbox™ to find a user defined pattern in a video and track it. The algorithm is based on normalized frequency domain cross correlation between the target and the image under test. The video player window displays the input video with the identified target locations. Also a figure displays the normalized correlation between the target and the image which is used as a metric to match the target. As can be seen whenever the correlation value exceeds the threshold (indicated by the blue line), the target is identified in the input video and the location is marked by the green bounding box.

Appendix

The following helper functions are used in this example.

- videopattern_gettemplate.m
- videopatternplots.m

Pattern Matching

This example shows how to use the 2-D normalized cross-correlation for pattern matching and target tracking.

Double-click the Edit Parameters block to select the number of similar targets to detect. You can also change the pyramiding factor. By increasing it, you can match the target template to each video frame more quickly. Changing the pyramiding factor might require you to change the Threshold value.

Additionally, you can double-click the Correlation Method switch to specify the domain in which to perform the cross-correlation. The relative size of the target to the input video frame and the pyramiding factor determine which domain computation is faster.

Example Model

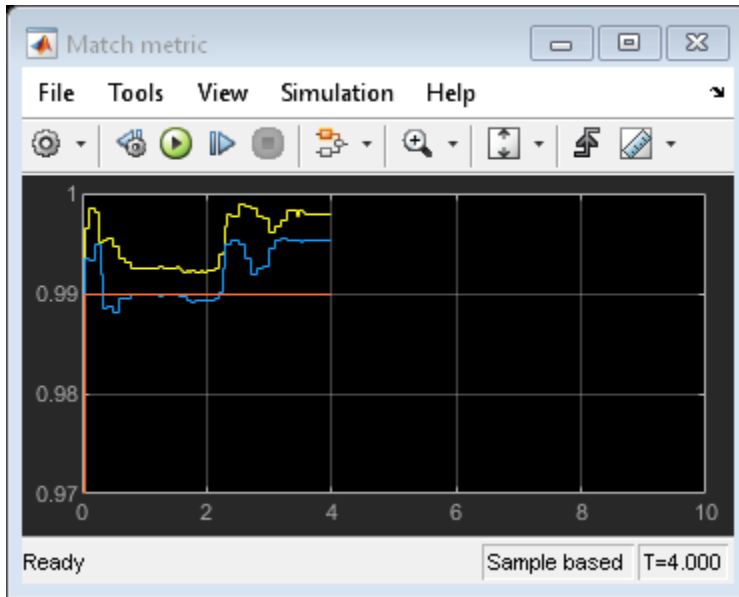

The following figure shows the Pattern Matching model:

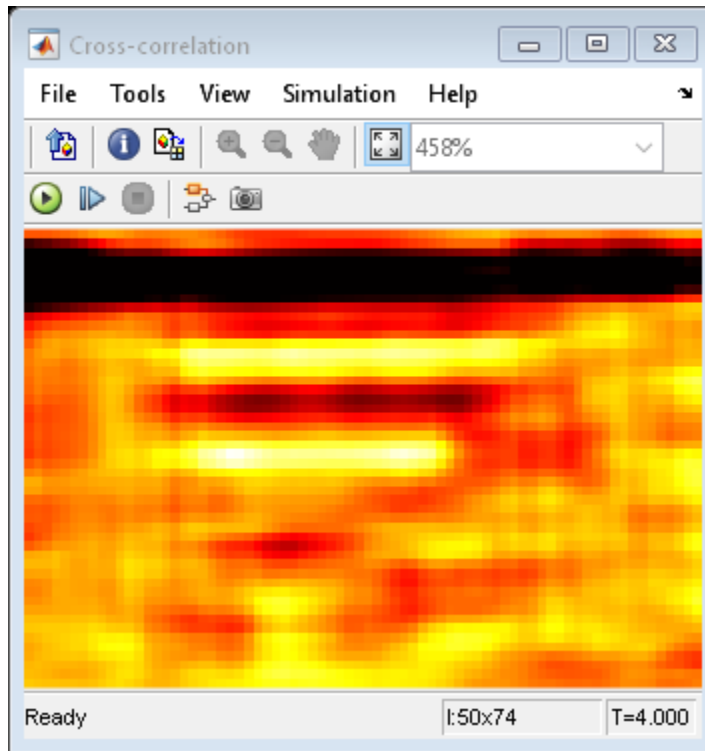

Copyright 2003-2008 The MathWorks, Inc.

Pattern Matching Results

The Match metric window shows the variation of the target match metrics. The model determines that the target template is present in a video frame when the match metric exceeds a threshold (cyan line).

The Cross-correlation window shows the result of cross-correlating the target template with a video frame. Large values in this window correspond to the locations of the targets in the input image.

The Overlay window shows the locations of the targets by highlighting them with rectangular regions of interest (ROIs). These ROIs are present only when the targets are detected in the video frame.

Geometric Transformations

Nearest Neighbor, Bilinear, and Bicubic Interpolation Methods

In this section...

“Nearest Neighbor Interpolation” on page 9-2

“Bilinear Interpolation” on page 9-3

“Bicubic Interpolation” on page 9-4

Nearest Neighbor Interpolation

For nearest neighbor interpolation, the block uses the value of nearby translated pixel values for the output pixel values.

For example, suppose this matrix,

```
1 2 3
4 5 6
7 8 9
```

represents your input image. You want to translate this image 1.7 pixels in the positive horizontal direction using nearest neighbor interpolation. The Translate block's nearest neighbor interpolation algorithm is illustrated by the following steps:

- 1 Zero pad the input matrix and translate it by 1.7 pixels to the right.

- 2 Create the output matrix by replacing each input pixel value with the translated value nearest to it. The result is the following matrix:

```
0 0 1 2 3
0 0 4 5 6
0 0 7 8 9
```

Note You wanted to translate the image by 1.7 pixels, but this method translated the image by 2 pixels. Nearest neighbor interpolation is computationally efficient but not as accurate as bilinear or bicubic interpolation.

Bilinear Interpolation

For bilinear interpolation, the block uses the weighted average of two translated pixel values for each output pixel value.

For example, suppose this matrix,

```
1 2 3
4 5 6
7 8 9
```

represents your input image. You want to translate this image 0.5 pixel in the positive horizontal direction using bilinear interpolation. The Translate block's bilinear interpolation algorithm is illustrated by the following steps:

- 1 Zero pad the input matrix and translate it by 0.5 pixel to the right.

- 2 Create the output matrix by replacing each input pixel value with the weighted average of the translated values on either side. The result is the following matrix where the output matrix has one more column than the input matrix:

```

0.5 1.5 2.5 1.5
 2  4.5 5.5  3
3.5 7.5 8.5 4.5
    
```

Bicubic Interpolation

For bicubic interpolation, the block uses the weighted average of four translated pixel values for each output pixel value.

For example, suppose this matrix,

```

1 2 3
4 5 6
7 8 9
    
```

represents your input image. You want to translate this image 0.5 pixel in the positive horizontal direction using bicubic interpolation. The Translate block's bicubic interpolation algorithm is illustrated by the following steps:

- 1 Zero pad the input matrix and translate it by 0.5 pixel to the right.

- 2 Create the output matrix by replacing each input pixel value with the weighted average of the two translated values on either side. The result is the following matrix where the output matrix has one more column than the input matrix:

```

0.375 1.5  3  1.625
1.875 4.875 6.375 3.125
3.375 8.25  9.75 4.625
    
```

Filters, Transforms, and Enhancements

- “Adjust the Contrast of Intensity Images” on page 10-2
- “Adjust the Contrast of Color Images” on page 10-6
- “Remove Salt and Pepper Noise from Images” on page 10-11
- “Sharpen an Image” on page 10-16

Adjust the Contrast of Intensity Images

This example shows you how to modify the contrast in two intensity images using the Contrast Adjustment and Histogram Equalization blocks.

`ex_vision_adjust_contrast_intensity`

- 1 Create a new Simulink model, and add to it the blocks shown in the following table.

Block	Library	Quantity
Image From File	Computer Vision Toolbox > Sources	2
Contrast Adjustment	Computer Vision Toolbox > Analysis & Enhancement	1
Histogram Equalization	Computer Vision Toolbox > Analysis & Enhancement	1
Video Viewer	Computer Vision Toolbox > Sinks	4

- 2 Place the blocks listed in the table above into your new model.
- 3 Use the Image From File block to import the first image into the Simulink model. Set the **File name** parameter to `pout.tif`.
- 4 Use the Image From File1 block to import the second image into the Simulink model. Set the **File name** parameter to `tire.tif`.
- 5 Use the Contrast Adjustment block to modify the contrast in `pout.tif`. Set the **Adjust pixel values from** parameter to `Range determined by saturating outlier pixels`. This block adjusts the contrast of the image by linearly scaling the pixel values between user-specified upper and lower limits.
- 6 Use the Histogram Equalization block to modify the contrast in `tire.tif`. Accept the default parameters. This block enhances the contrast of images by transforming the values in an intensity image so that the histogram of the output image approximately matches a specified histogram.
- 7 Use the Video Viewer blocks to view the original and modified images. Accept the default parameters.
- 8 Connect the blocks as shown in the following figure.

- 9 Set the configuration parameters. Open the Configuration dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. Set the parameters as follows:
 - **Solver** pane, **Stop time** = 0
 - **Solver** pane, **Type** = Fixed-step
 - **Solver** pane, **Solver** = Discrete (no continuous states)
- 10 Run the model.

The results appear in the Video Viewer windows.

In this example, you used the Contrast Adjustment block to linearly scale the pixel values in `pout.tif` between new upper and lower limits. You used the Histogram Equalization block to transform the values in `tire.tif` so that the histogram of the output image approximately matches a uniform histogram. For more information, see the Contrast Adjustment and Histogram Equalization reference pages.

Adjust the Contrast of Color Images

This example shows you how to modify the contrast in color images using the Histogram Equalization block.

ex_vision_adjust_contrast_color.mdl

- 1 Use the following code to read in an indexed RGB image, `shadow.tif`, and convert it to an RGB image. The model provided above already includes this code in `file > Model Properties > Model Properties > InitFcn`, and executes it prior to simulation.

```
[X map] = imread('shadow.tif');
shadow = ind2rgb(X,map);
```

- 2 Create a new Simulink model, and add to it the blocks shown in the following table.

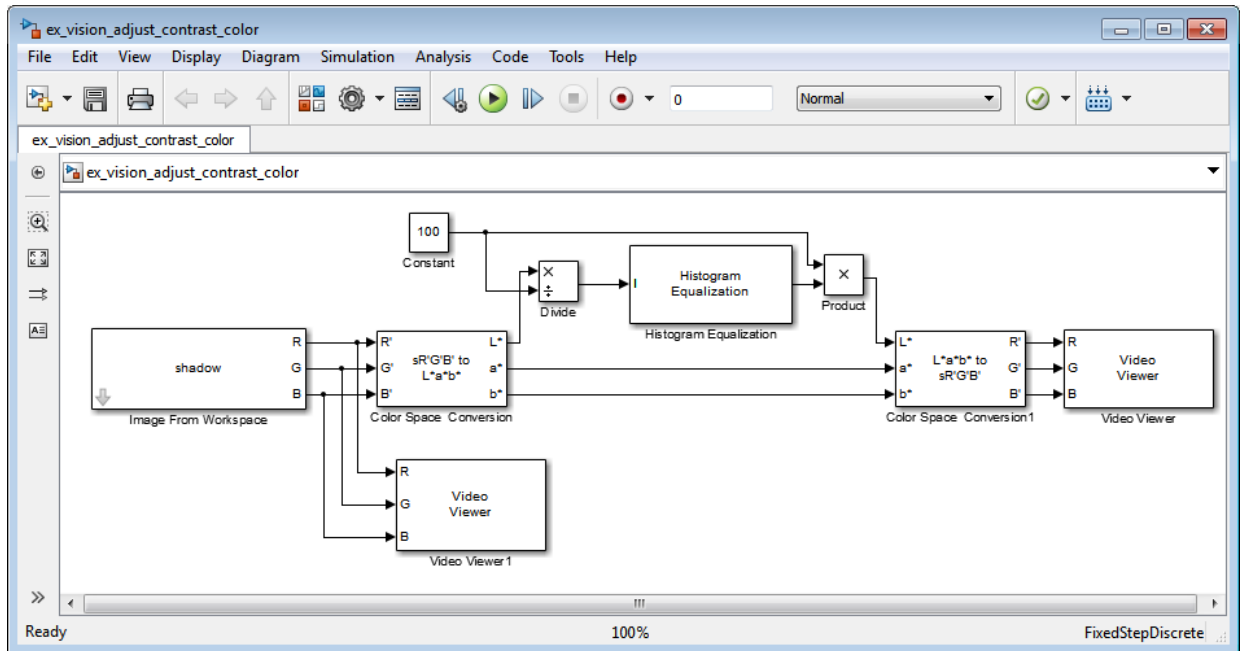

Block	Library	Quantity
Image From Workspace	Computer Vision Toolbox > Sources	1
Color Space Conversion	Computer Vision Toolbox > Conversions	2
Histogram Equalization	Computer Vision Toolbox > Analysis & Enhancement	1
Video Viewer	Computer Vision Toolbox > Sinks	2
Constant	Simulink > Sources	1
Divide	Simulink > Math Operations	1
Product	Simulink > Math Operations	1

- 3 Place the blocks listed in the table above into your new model.
- 4 Use the Image From Workspace block to import the RGB image from the MATLAB workspace into the Simulink model. Set the block parameters as follows:
 - **Value** = `shadow`
 - **Image signal** = `Separate color signals`
- 5 Use the Color Space Conversion block to separate the luma information from the color information. Set the block parameters as follows:

- **Conversion** = sR'G'B' to L*a*b*
- **Image signal** = Separate color signals

Because the range of the L* values is between 0 and 100, you must normalize them to be between zero and one before you pass them to the Histogram Equalization block, which expects floating point input in this range.

- 6 Use the Constant block to define a normalization factor. Set the **Constant value** parameter to 100.
- 7 Use the Divide block to normalize the L* values to be between 0 and 1. Accept the default parameters.
- 8 Use the Histogram Equalization block to modify the contrast in the image. This block enhances the contrast of images by transforming the luma values in the color image so that the histogram of the output image approximately matches a specified histogram. Accept the default parameters.
- 9 Use the Product block to scale the values back to be between the 0 to 100 range. Accept the default parameters.
- 10 Use the Color Space Conversion1 block to convert the values back to the sR'G'B' color space. Set the block parameters as follows:
 - **Conversion** = L*a*b* to sR'G'B'
 - **Image signal** = Separate color signals
- 11 Use the Video Viewer blocks to view the original and modified images. For each block, set the **Image signal** parameter to Separate color signals from the file menu.
- 12 Connect the blocks as shown in the following figure.

13 Set the configuration parameters. Open the Configuration dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. Set the parameters as follows:

- **Solver** pane, **Stop time** = 0
- **Solver** pane, **Type** = Fixed-step
- **Solver** pane, **Solver** = Discrete (no continuous states)

14 Run the model.

As shown in the following figure, the model displays the original image in the Video Viewer1 window.

As the next figure shows, the model displays the enhanced contrast image in the Video Viewer window.

In this example, you used the Histogram Equalization block to transform the values in a color image so that the histogram of the output image approximately matches a uniform histogram. For more information, see the Histogram Equalization reference page.

Remove Salt and Pepper Noise from Images

Median filtering is a common image enhancement technique for removing salt and pepper noise. Because this filtering is less sensitive than linear techniques to extreme changes in pixel values, it can remove salt and pepper noise without significantly reducing the sharpness of an image. In this topic, you use the Median Filter block to remove salt and pepper noise from an intensity image:

`ex_vision_remove_noise`

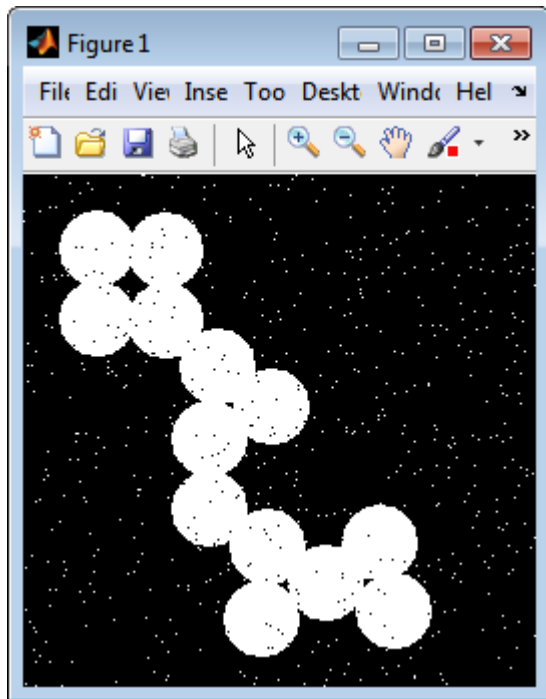

- 1 Define an intensity image in the MATLAB workspace and add noise to it by typing the following at the MATLAB command prompt:

```
I= double(imread('circles.png'));  
I= imnoise(I,'salt & pepper',0.02);
```

I is a 256-by-256 matrix of 8-bit unsigned integer values.

The model provided with this example already includes this code in `file>Model Properties>Model Properties>InitFcn`, and executes it prior to simulation.

- 2 To view the image this matrix represents, at the MATLAB command prompt, type
`imshow(I)`

The intensity image contains noise that you want your model to eliminate.

- 3 Create a Simulink model, and add the blocks shown in the following table.

Block	Library	Quantity
Image From Workspace	Computer Vision Toolbox > Sources	1
Median Filter	Computer Vision Toolbox > Filtering	1
Video Viewer	Computer Vision Toolbox > Sinks	2

- 4 Use the Image From Workspace block to import the noisy image into your model. Set the **Value** parameter to I.
- 5 Use the Median Filter block to eliminate the black and white speckles in the image. Use the default parameters.

The Median Filter block replaces the central value of the 3-by-3 neighborhood with the median value of the neighborhood. This process removes the noise in the image.

- 6 Use the Video Viewer blocks to display the original noisy image, and the modified image. Images are represented by 8-bit unsigned integers. Therefore, a value of 0 corresponds to black and a value of 255 corresponds to white. Accept the default parameters.
- 7 Connect the blocks as shown in the following figure.

- 8 Set the configuration parameters. Open the Configuration dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. Set the parameters as follows:
 - **Solver** pane, **Stop time** = 0
 - **Solver** pane, **Type** = Fixed-step
 - **Solver** pane, **Solver** = Discrete (no continuous states)

- 9 Run the model.

The original and filtered images are displayed.

You have used the Median Filter block to remove noise from your image. For more information about this block, see the Median Filter block reference page in the *Computer Vision Toolbox Reference*.

Sharpen an Image

To sharpen a color image, you need to make the luma intensity transitions more acute, while preserving the color information of the image. To do this, you convert an R'G'B' image into the Y'CbCr color space and apply a highpass filter to the luma portion of the image only. Then, you transform the image back to the R'G'B' color space to view the results. To blur an image, you apply a lowpass filter to the luma portion of the image. This example shows how to use the 2-D FIR Filter block to sharpen an image. The prime notation indicates that the signals are gamma corrected.

ex_vision_sharpen_image

- 1 Define an R'G'B' image in the MATLAB workspace. To read in an R'G'B' image from a PNG file and cast it to the double-precision data type, at the MATLAB command prompt, type

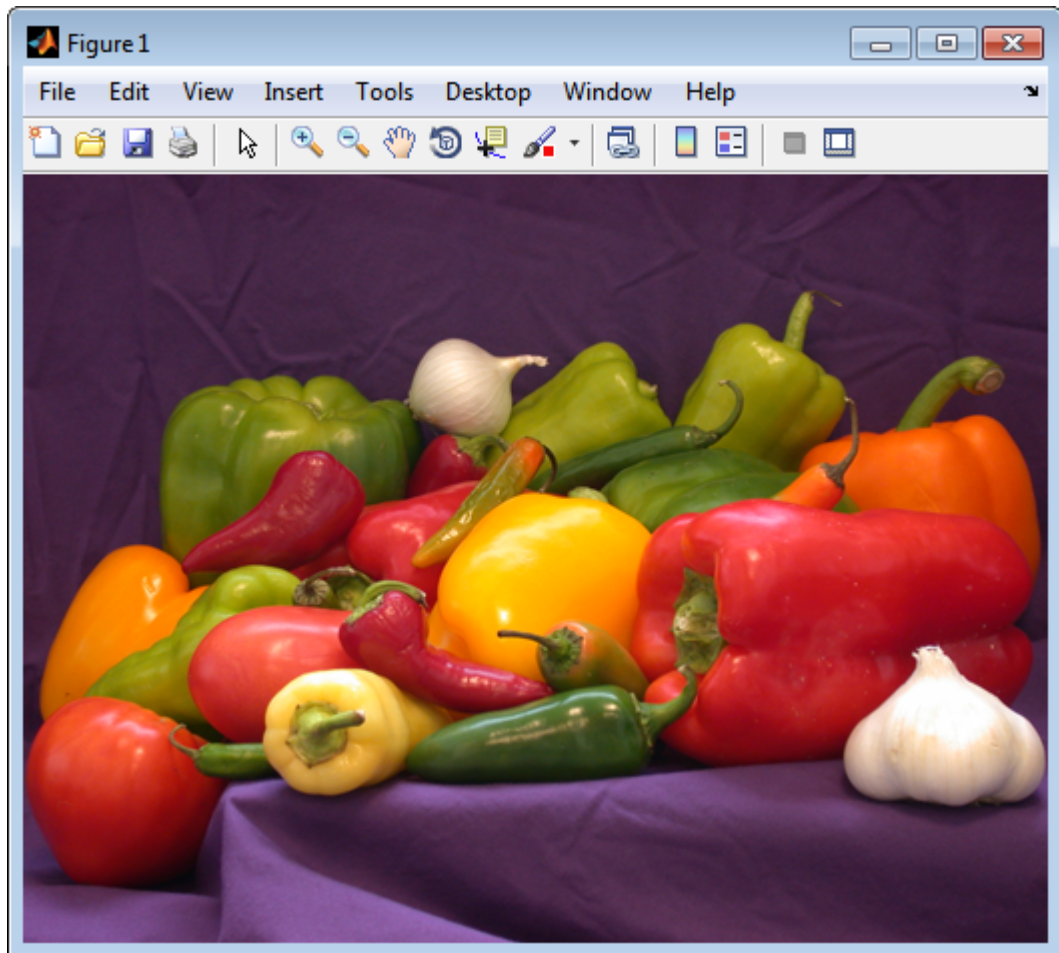

```
I = im2double(imread('peppers.png'));
```

I is a 384-by-512-by-3 array of double-precision floating-point values. Each plane of this array represents the red, green, or blue color values of the image.

The model provided with this example already includes this code in `file>Model Properties>Model Properties>InitFcn`, and executes it prior to simulation.

- 2 To view the image this array represents, type this command at the MATLAB command prompt:

```
imshow(I)
```

Now that you have defined your image, you can create your model.

- 3 Create a new Simulink model, and add to it the blocks shown in the following table.

Block	Library	Quantity
Image From Workspace	Computer Vision Toolbox > Sources	1
Color Space Conversion	Computer Vision Toolbox > Conversions	2

Block	Library	Quantity
2-D FIR Filter	Computer Vision Toolbox > Filtering	1
Video Viewer	Computer Vision Toolbox > Sinks	1

- 4 Use the Image From Workspace block to import the R'G'B' image from the MATLAB workspace. Set the parameters as follows:

- **Main** pane, **Value** = I
- **Main** pane, **Image signal** = Separate color signals

The block outputs the R', G', and B' planes of the I array at the output ports.

- 5 The first Color Space Conversion block converts color information from the R'G'B' color space to the Y'CbCr color space. Set the **Image signal** parameter to Separate color signals

- 6 Use the 2-D FIR Filter block to filter the luma portion of the image. Set the block parameters as follows:

- **Coefficients** = `fspecial('unsharp')`
- **Output size** = Same as input port I
- **Padding options** = Symmetric
- **Filtering based on** = Correlation

The `fspecial('unsharp')` command creates two-dimensional highpass filter coefficients suitable for correlation. This highpass filter sharpens the image by removing the low frequency noise in it.

- 7 The second Color Space Conversion block converts the color information from the Y'CbCr color space to the R'G'B' color space. Set the block parameters as follows:

- **Conversion** = Y'CbCr to R'G'B'
- **Image signal** = Separate color signals

- 8 Use the Video Viewer block to automatically display the new, sharper image in the Video Viewer window when you run the model. Set the **Image signal** parameter to Separate color signals, by selecting **File > Image Signal**.

- 9 Connect the blocks as shown in the following figure.

- 10** Set the configuration parameters. Open the Configuration dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. Set the parameters as follows:
- **Solver** pane, **Stop time** = 0
 - **Solver** pane, **Type** = Fixed-step
 - **Solver** pane, **Solver** = Discrete (no continuous states)
- 11** Run the model.

A sharper version of the original image appears in the Video Viewer window.

To blur the image, double-click the 2-D FIR Filter block. Set **Coefficients** parameter to `fspecial('gaussian',[15 15],7)` and then click **OK**. The `fspecial('gaussian',[15 15],7)` command creates two-dimensional Gaussian lowpass filter coefficients. This lowpass filter blurs the image by removing the high frequency noise in it.

In this example, you used the Color Space Conversion and 2-D FIR Filter blocks to sharpen an image. For more information, see the Color Space Conversion and 2-D FIR Filter, and `fspecial` reference pages.

Statistics and Morphological Operations

- “Correct Nonuniform Illumination” on page 11-2
- “Count Objects in an Image” on page 11-9

Correct Nonuniform Illumination

Global threshold techniques, which are often the first step in object measurement, cannot be applied to unevenly illuminated images. To correct this problem, you can change the lighting conditions and take another picture, or you can use morphological operators to even out the lighting in the image. Once you have corrected for nonuniform illumination, you can pick a global threshold that delineates every object from the background. In this topic, you use the Opening block to correct for uneven lighting in an intensity image:

You can open the example model by typing

```
ex_vision_correct_uniform
```

on the MATLAB command line.

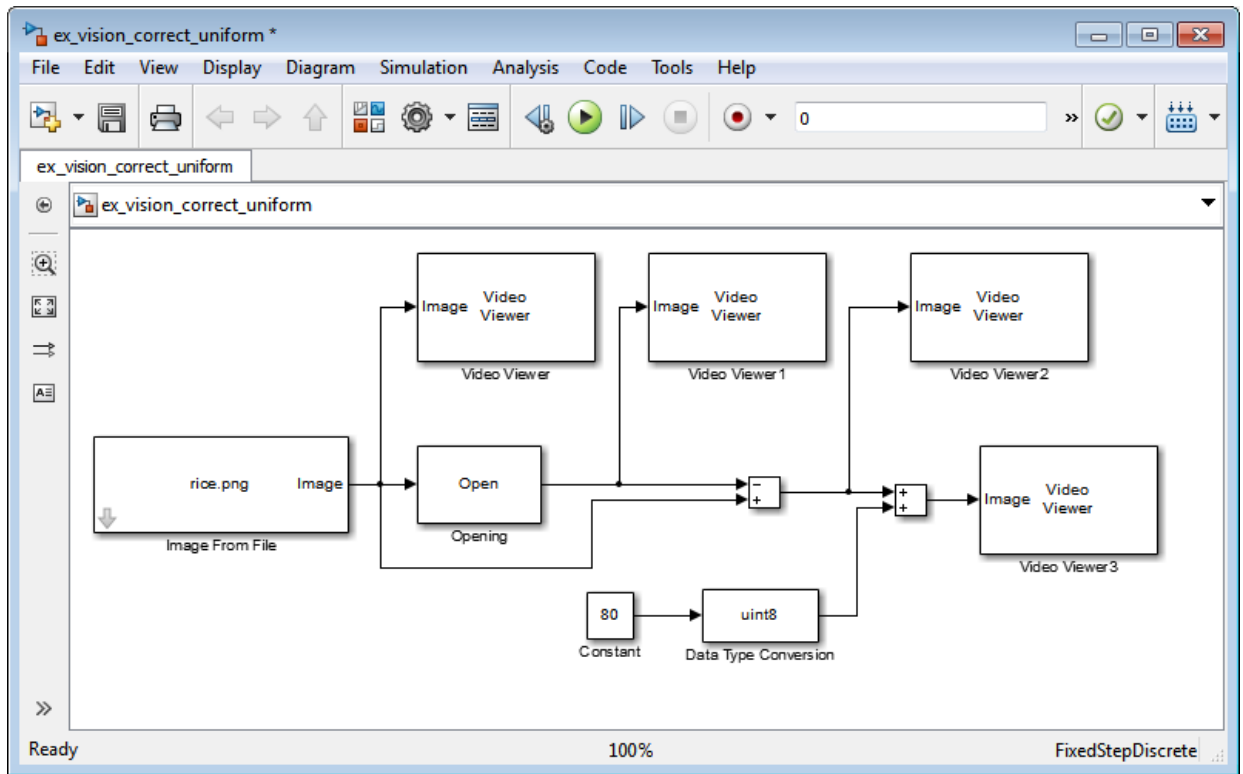

- 1 Create a new Simulink model, and add to it the blocks shown in the following table.

Block	Library	Quantity
Image From File	Computer Vision Toolbox > Sources	1
Opening	Computer Vision Toolbox > Morphological Operations	1
Video Viewer	Computer Vision Toolbox > Sinks	4
Constant	Simulink > Sources	1
Sum	Simulink > Math Operations	2
Data Type Conversion	Simulink > Signal Attributes	1

- 2 Use the Image From File block to import the intensity image. Set the **File name** parameter to `rice.png`. This image is a 256-by-256 matrix of 8-bit unsigned integer values.
- 3 Use the Video Viewer block to view the original image. Accept the default parameters.
- 4 Use the Opening block to estimate the background of the image. Set the **Neighborhood or structuring element** parameter to `strel('disk', 15)`.

The `strel` object creates a circular STREL object with a radius of 15 pixels. When working with the Opening block, pick a STREL object that fits within the objects you want to keep. It often takes experimentation to find the neighborhood or STREL object that best suits your application.

- 5 Use the Video Viewer1 block to view the background estimated by the Opening block. Accept the default parameters.
- 6 Use the first Sum block to subtract the estimated background from the original image. Set the block parameters as follows:
 - **Icon shape** = rectangular
 - **List of signs** = -+
- 7 Use the Video Viewer2 block to view the result of subtracting the background from the original image. Accept the default parameters.
- 8 Use the Constant block to define an offset value. Set the **Constant value** parameter to 80.
- 9 Use the Data Type Conversion block to convert the offset value to an 8-bit unsigned integer. Set the **Output data type mode** parameter to uint8.
- 10 Use the second Sum block to lighten the image so that it has the same brightness as the original image. Set the block parameters as follows:
 - **Icon shape** = rectangular
 - **List of signs** = ++
- 11 Use the Video Viewer3 block to view the corrected image. Accept the default parameters.
- 12 Connect the blocks as shown in the following figure.

13 Set the configuration parameters. Open the Configuration dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. Set the parameters as follows:

- **Solver** pane, **Stop time** = 0
- **Solver** pane, **Type** = Fixed-step
- **Solver** pane, **Solver** = discrete (no continuous states)

14 Run the model.

The original image appears in the Video Viewer window.

The estimated background appears in the Video Viewer1 window.

The image without the estimated background appears in the Video Viewer2 window.

The preceding image is too dark. The Constant block provides an offset value that you used to brighten the image.

The corrected image, which has even lighting, appears in the Video Viewer3 window. The following image is shown at its true size.

In this section, you have used the Opening block to remove irregular illumination from an image. For more information about this block, see the Opening reference page. For related information, see the Top-hat block reference page. For more information about STREL objects, see the `strel` object in the Image Processing Toolbox documentation.

Count Objects in an Image

In this example, you import an intensity image of a wheel from the MATLAB workspace and convert it to binary. Then, using the Opening and Label blocks, you count the number of spokes in the wheel. You can use similar techniques to count objects in other intensity images. However, you might need to use additional morphological operators and different structuring elements.

Note Running this example requires a DSP System Toolbox™ license.

You can open the example model by typing

```
ex_vision_count_objects
```

on the MATLAB command line.

- 1 Create a new Simulink model, and add to it the blocks shown in the following table.

Block	Library	Quantity
Image From File	Computer Vision Toolbox > Sources	1
Opening	Computer Vision Toolbox > Morphological Operations	1
Label	Computer Vision Toolbox > Morphological Operations	1
Video Viewer	Computer Vision Toolbox > Sinks	2
Constant	Simulink > Sources	1
Relational Operator	Simulink > Logic and Bit Operations	1
Display	Simulink > Sinks	1

- 2 Use the Image From File block to import your image. Set the **File name** parameter to `testpat1.png`. This is a 256-by-256 matrix image of 8-bit unsigned integers.
- 3 Use the Constant block to define a threshold value for the Relational Operator block. Set the **Constant value** parameter to `200`.
- 4 Use the Video Viewer block to view the original image. Accept the default parameters.
- 5 Use the Relational Operator block to perform a thresholding operation that converts your intensity image to a binary image. Set the **Relational Operator** parameter to `<`.

If the input to the Relational Operator block is less than 200, its output is 1; otherwise, its output is 0. You must threshold your intensity image because the Label block expects binary input. Also, the objects it counts must be white.

- 6 Use the Opening block to separate the spokes from the rim and from each other at the center of the wheel. Use the default parameters.

The `strel` object creates a circular STREL object with a radius of 5 pixels. When working with the Opening block, pick a STREL object that fits within the objects you want to keep. It often takes experimentation to find the neighborhood or STREL object that best suits your application.

- 7 Use the Video Viewer1 block to view the opened image. Accept the default parameters.
- 8 Use the Label block to count the number of spokes in the input image. Set the **Output** parameter to `Number of labels`.
- 9 The Display block displays the number of spokes in the input image. Use the default parameters.
- 10 Connect the block as shown in the following figure.

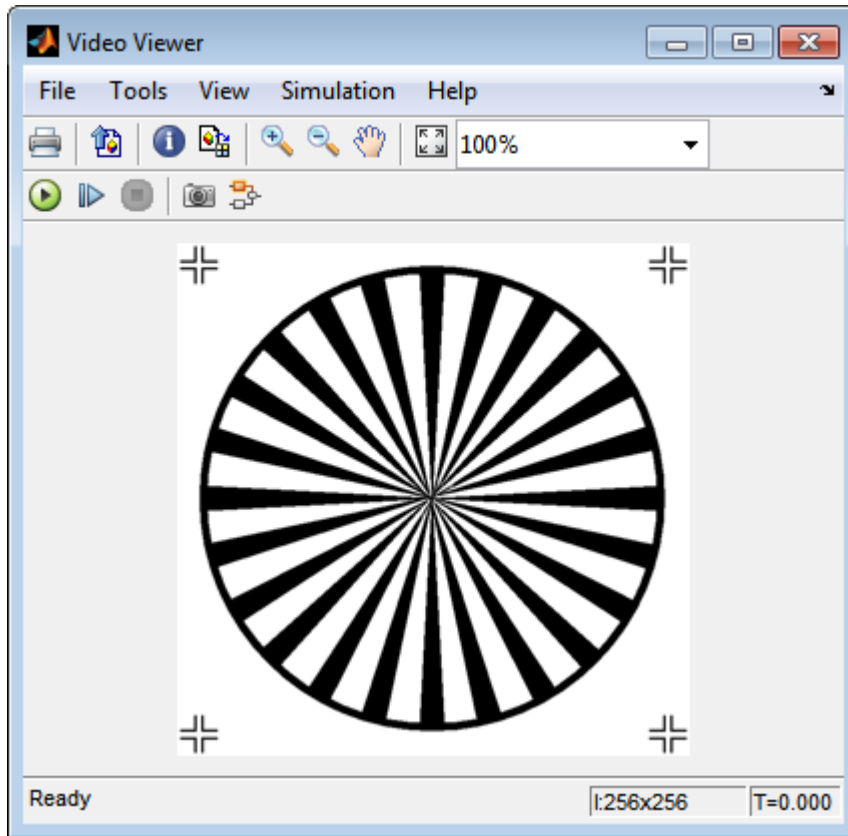

11 Set the configuration parameters. Open the Configuration dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. Set the parameters as follows:

- **Solver** pane, **Stop time** = 0
- **Solver** pane, **Type** = Fixed-step
- **Solver** pane, **Solver** = discrete (no continuous states)

12 Run the model.

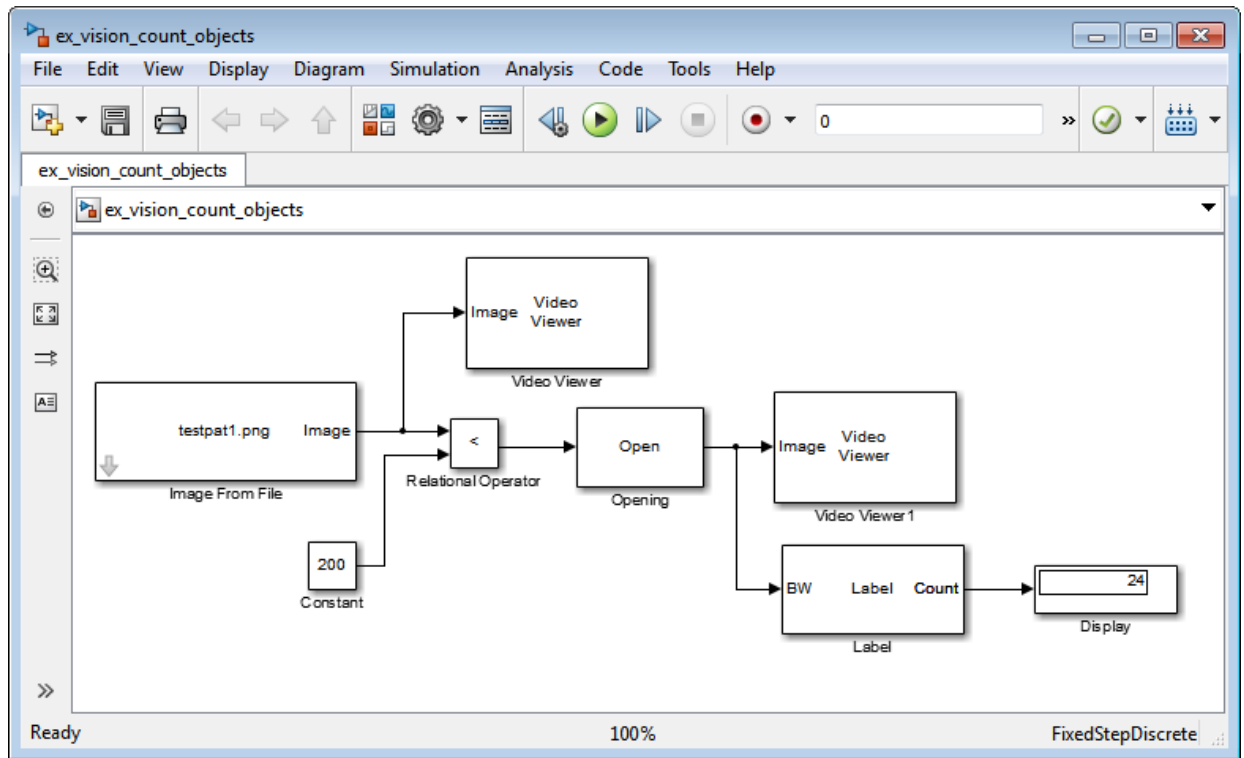

The original image appears in the Video Viewer1 window. To view the image at its true size, right-click the window and select **Set Display To True Size**.

The opened image appears in the Video Viewer window. The following image is shown at its true size.

As you can see in the preceding figure, the spokes are now separate white objects. In the model, the Display block correctly indicates that there are 24 distinct spokes.

You have used the Opening and Label blocks to count the number of spokes in an image. For more information about these blocks, see the Opening and Label block reference pages in the *Computer Vision Toolbox Reference*. If you want to send the number of spokes to the MATLAB workspace, use the To Workspace block in Simulink. For more information about STREL objects, see `strel` in the Image Processing Toolbox documentation.

Fixed-Point Design

Fixed-Point Signal Processing

In this section...
“Fixed-Point Features” on page 12-2
“Benefits of Fixed-Point Hardware” on page 12-2
“Benefits of Fixed-Point Design with System Toolboxes Software” on page 12-3

Note To take full advantage of fixed-point support in System Toolbox software, you must install Fixed-Point Designer™ software.

Fixed-Point Features

Many of the blocks in this product have fixed-point support, so you can design signal processing systems that use fixed-point arithmetic. Fixed-point support in DSP System Toolbox software includes

- Signed two's complement and unsigned fixed-point data types
- Word lengths from 2 to 128 bits in simulation
- Word lengths from 2 to the size of a long on the Simulink Coder C code-generation target
- Overflow handling and rounding methods
- C code generation for deployment on a fixed-point embedded processor, with Simulink Coder code generation software. The generated code uses all allowed data types supported by the embedded target, and automatically includes all necessary shift and scaling operations

Benefits of Fixed-Point Hardware

There are both benefits and trade-offs to using fixed-point hardware rather than floating-point hardware for signal processing development. Many signal processing applications require low-power and cost-effective circuitry, which makes fixed-point hardware a natural choice. Fixed-point hardware tends to be simpler and smaller. As a result, these units require less power and cost less to produce than floating-point circuitry.

Floating-point hardware is usually larger because it demands functionality and ease of development. Floating-point hardware can accurately represent real-world numbers, and

its large dynamic range reduces the risk of overflow, quantization errors, and the need for scaling. In contrast, the smaller dynamic range of fixed-point hardware that allows for low-power, inexpensive units brings the possibility of these problems. Therefore, fixed-point development must minimize the negative effects of these factors, while exploiting the benefits of fixed-point hardware; cost- and size-effective units, less power and memory usage, and fast real-time processing.

Benefits of Fixed-Point Design with System Toolboxes Software

Simulating your fixed-point development choices before implementing them in hardware saves time and money. The built-in fixed-point operations provided by the System Toolboxes software save time in simulation and allow you to generate code automatically.

This software allows you to easily run multiple simulations with different word length, scaling, overflow handling, and rounding method choices to see the consequences of various fixed-point designs before committing to hardware. The traditional risks of fixed-point development, such as quantization errors and overflow, can be simulated and mitigated in software before going to hardware.

Fixed-point C code generation with System Toolbox software and Simulink Coder code generation software produces code ready for execution on a fixed-point processor. All the choices you make in simulation in terms of scaling, overflow handling, and rounding methods are automatically optimized in the generated code, without necessitating time-consuming and costly hand-optimized code.

Fixed-Point Concepts and Terminology

In this section...

“Fixed-Point Data Types” on page 12-4

“Scaling” on page 12-5

“Precision and Range” on page 12-7

Note The Glossary (DSP System Toolbox) defines much of the vocabulary used in these sections. For more information on these subjects, see “Fixed-Point Designer”.

Fixed-Point Data Types

In digital hardware, numbers are stored in binary words. A binary word is a fixed-length sequence of bits (1's and 0's). The way hardware components or software functions interpret this sequence of 1's and 0's is defined by the data type.

Binary numbers are represented as either floating-point or fixed-point data types. In this section, we discuss many terms and concepts relating to fixed-point numbers, data types, and mathematics.

A fixed-point data type is characterized by the word length in bits, the position of the binary point, and the signedness of a number which can be signed or unsigned. Signed numbers and data types can represent both positive and negative values, whereas unsigned numbers and data types can only represent values that are greater than or equal to zero.

The position of the binary point is the means by which fixed-point values are scaled and interpreted.

For example, a binary representation of a generalized fixed-point number (either signed or unsigned) is shown below:

where

- b_i is the i^{th} binary digit.
- wl is the number of bits in a binary word, also known as word length.
- b_{wl-1} is the location of the most significant, or highest, bit (MSB). In signed binary numbers, this bit is the sign bit which indicates whether the number is positive or negative.
- b_0 is the location of the least significant, or lowest, bit (LSB). This bit in the binary word can represent the smallest value. The weight of the LSB is given by:

$$weight_{LSB} = 2^{-fractionlength}$$

where, *fractionlength* is the number of bits to the right of the binary point.

- Bits to the left of the binary point are integer bits and/or sign bits, and bits to the right of the binary point are fractional bits. Number of bits to the left of the binary point is known as the integer length. The binary point in this example is shown four places to the left of the LSB. Therefore, the number is said to have four fractional bits, or a fraction length of four.

Fixed-point data types can be either signed or unsigned.

Signed binary fixed-point numbers are typically represented in one of three ways:

- Sign/magnitude -- Representation of signed fixed-point or floating-point numbers. In the sign/magnitude representation, one bit of a binary word is always the dedicated sign bit, while the remaining bits of the word encode the magnitude of the number. Negation using sign/magnitude representation consists of flipping the sign bit from 0 (positive) to 1 (negative), or from 1 to 0.
- One's complement
- Two's complement -- Two's complement is the most common representation of signed fixed-point numbers. See "Two's Complement" on page 12-11 for more information.

Unsigned fixed-point numbers can only represent numbers greater than or equal to zero.

Scaling

In [Slope Bias] representation, fixed-point numbers can be encoded according to the scheme

$$\text{real-worldvalue} = (\text{slope} \times \text{integer}) + \text{bias}$$

where the slope can be expressed as

$$\text{slope} = \text{slope adjustment} \times 2^{\text{exponent}}$$

The term *slope adjustment* is sometimes used as a synonym for fractional slope.

In the trivial case, slope = 1 and bias = 0. Scaling is always trivial for pure integers, such as int8, and also for the true floating-point types single and double.

The integer is sometimes called the *stored integer*. This is the raw binary number, in which the binary point assumed to be at the far right of the word. In System Toolboxes, the negative of the exponent is often referred to as the *fraction length*.

The slope and bias together represent the scaling of the fixed-point number. In a number with zero bias, only the slope affects the scaling. A fixed-point number that is only scaled by binary point position is equivalent to a number in the Fixed-Point Designer [Slope Bias] representation that has a bias equal to zero and a slope adjustment equal to one. This is referred to as binary point-only scaling or power-of-two scaling:

$$\text{real-world value} = 2^{\text{exponent}} \times \text{integer}$$

or

$$\text{real-world value} = 2^{-\text{fractionlength}} \times \text{integer}$$

In System Toolbox software, you can define a fixed-point data type and scaling for the output or the parameters of many blocks by specifying the word length and fraction length of the quantity. The word length and fraction length define the whole of the data type and scaling information for binary-point only signals.

All System Toolbox blocks that support fixed-point data types support signals with binary-point only scaling. Many fixed-point blocks that do not perform arithmetic operations but merely rearrange data, such as Delay and Matrix Transpose, also support signals with [Slope Bias] scaling.

Precision and Range

You must pay attention to the precision and range of the fixed-point data types and scalings you choose for the blocks in your simulations, in order to know whether rounding methods will be invoked or if overflows will occur.

Range

The range is the span of numbers that a fixed-point data type and scaling can represent. The range of representable numbers for a two's complement fixed-point number of word length wl , scaling S , and bias B is illustrated below:

For both signed and unsigned fixed-point numbers of any data type, the number of different bit patterns is 2^{wl} .

For example, in two's complement, negative numbers must be represented as well as zero, so the maximum value is 2^{wl-1} . Because there is only one representation for zero, there are an unequal number of positive and negative numbers. This means there is a representation for -2^{wl-1} but not for 2^{wl-1} .

For slope = 1 and bias = 0:

The full range is the broadest range for a data type. For floating-point types, the full range is $-\infty$ to ∞ . For integer types, the full range is the range from the smallest to largest integer value (finite) the type can represent. For example, from -128 to 127 for a signed 8-bit integer.

Overflow Handling

Because a fixed-point data type represents numbers within a finite range, overflows can occur if the result of an operation is larger or smaller than the numbers in that range.

System Toolbox software does not allow you to add guard bits to a data type on-the-fly in order to avoid overflows. Guard bits are extra bits in either a hardware register or software simulation that are added to the high end of a binary word to ensure that no information is lost in case of overflow. Any guard bits must be allocated upon model initialization. However, the software does allow you to either *saturate* or *wrap* overflows. Saturation represents positive overflows as the largest positive number in the range being used, and negative overflows as the largest negative number in the range being used. Wrapping uses modulo arithmetic to cast an overflow back into the representable range of the data type. See “Modulo Arithmetic” on page 12-10 for more information.

Precision

The precision of a fixed-point number is the difference between successive values representable by its data type and scaling, which is equal to the value of its least significant bit. The value of the least significant bit, and therefore the precision of the number, is determined by the number of fractional bits. A fixed-point value can be represented to within half of the precision of its data type and scaling. The term resolution is sometimes used as a synonym for this definition.

For example, a fixed-point representation with four bits to the right of the binary point has a precision of 2^{-4} or 0.0625, which is the value of its least significant bit. Any number within the range of this data type and scaling can be represented to within $(2^{-4})/2$ or 0.03125, which is half the precision. This is an example of representing a number with finite precision.

Rounding Modes

When you represent numbers with finite precision, not every number in the available range can be represented exactly. If a number cannot be represented exactly by the specified data type and scaling, it is *rounded* to a representable number. Although precision is always lost in the rounding operation, the cost of the operation and the amount of bias that is introduced depends on the rounding mode itself. To provide you with greater flexibility in the trade-off between cost and bias, DSP System Toolbox software currently supports the following rounding modes:

- **Ceiling** rounds the result of a calculation to the closest representable number in the direction of positive infinity.

- **Convergent** rounds the result of a calculation to the closest representable number. In the case of a tie, **Convergent** rounds to the nearest even number. This is the least biased rounding mode provided by the toolbox.
- **Floor**, which is equivalent to truncation, rounds the result of a calculation to the closest representable number in the direction of negative infinity. The truncation operation results in dropping of one or more least significant bits from a number.
- **Nearest** rounds the result of a calculation to the closest representable number. In the case of a tie, **Nearest** rounds to the closest representable number in the direction of positive infinity.
- **Round** rounds the result of a calculation to the closest representable number. In the case of a tie, **Round** rounds positive numbers to the closest representable number in the direction of positive infinity, and rounds negative numbers to the closest representable number in the direction of negative infinity.
- **Simplest** rounds the result of a calculation using the rounding mode (**Floor** or **Zero**) that adds the least amount of extra rounding code to your generated code. For more information, see “Rounding Mode: Simplest” (Fixed-Point Designer).
- **Zero** rounds the result of a calculation to the closest representable number in the direction of zero.

To learn more about each of these rounding modes, see “Rounding” (Fixed-Point Designer).

For a direct comparison of the rounding modes, see “Choosing a Rounding Method” (Fixed-Point Designer).

Arithmetic Operations

In this section...
“Modulo Arithmetic” on page 12-10
“Two's Complement” on page 12-11
“Addition and Subtraction” on page 12-12
“Multiplication” on page 12-13
“Casts” on page 12-15

Note These sections will help you understand what data type and scaling choices result in overflows or a loss of precision.

Modulo Arithmetic

Binary math is based on modulo arithmetic. Modulo arithmetic uses only a finite set of numbers, wrapping the results of any calculations that fall outside the given set back into the set.

For example, the common everyday clock uses modulo 12 arithmetic. Numbers in this system can only be 1 through 12. Therefore, in the “clock” system, 9 plus 9 equals 6. This can be more easily visualized as a number circle:

Similarly, binary math can only use the numbers 0 and 1, and any arithmetic results that fall outside this range are wrapped "around the circle" to either 0 or 1.

Two's Complement

Two's complement is a common representation of signed fixed-point numbers. In two's complement, positive numbers always start with a 0 and negative numbers always start with a 1. If the leading bit of a two's complement number is 0, the value is obtained by calculating the standard binary value of the number. If the leading bit of a two's complement number is 1, the value is obtained by assuming that the leftmost bit is negative, and then calculating the binary value of the number. For example,

$$01 = (0 + 2^0) = 1$$

$$11 = ((-2^1) + (2^0)) = (-2 + 1) = -1$$

To compute the negative of a binary number using two's complement,

- 1 Take the one's complement. That is, all 0's are flipped to 1's and all 1's are flipped to 0's.

- 2 Add a 1 using binary math.
- 3 Discard any bits carried beyond the original word length.

For example, consider taking the negative of 11010 (-6). First, take the one's complement of the number, or flip the bits:

$$11010 \rightarrow 00101$$

Next, add a 1, wrapping all numbers to 0 or 1:

$$\begin{array}{r} 00101 \\ +1 \quad (6) \\ \hline 00110 \end{array}$$

Addition and Subtraction

The addition of fixed-point numbers requires that the binary points of the addends be aligned. The addition is then performed using binary arithmetic so that no number other than 0 or 1 is used.

For example, consider the addition of 010010.1 (18.5) with 0110.110 (6.75):

$$\begin{array}{r} 010010.1 \quad (18.5) \\ +0110.110 \quad (6.75) \\ \hline 011001.010 \quad (25.25) \end{array}$$

Fixed-point subtraction is equivalent to adding while using the two's complement value for any negative values. In subtraction, the addends must be sign extended to match each other's length. For example, consider subtracting 0110.110 (6.75) from 010010.1 (18.5):

$$\begin{array}{r} 010010.100 \quad (18.5) \\ - 0110.110 \quad (6.75) \\ \hline \end{array} \quad \begin{array}{l} \xrightarrow{\text{two's complement}} \\ \text{and sign extension} \end{array} \quad \begin{array}{r} 010010.100 \quad (18.5) \\ +111001.010 \quad (-6.75) \\ \hline 1001011.110 \quad (11.75) \end{array}$$

Carry bit is discarded.

Most fixed-point DSP System Toolbox blocks that perform addition cast the adder inputs to an accumulator data type before performing the addition. Therefore, no further shifting is necessary during the addition to line up the binary points. See "Casts" on page 12-15 for more information.

Multiplication

The multiplication of two's complement fixed-point numbers is directly analogous to regular decimal multiplication, with the exception that the intermediate results must be sign extended so that their left sides align before you add them together.

For example, consider the multiplication of 10.11 (-1.25) with 011 (3):

$$\begin{array}{r}
 10.11 \text{ (-1.25)} \\
 \underline{011 \text{ (3)}} \\
 11011 \\
 \underline{1011} \\
 1100.01 \text{ (-3.75)}
 \end{array}$$

The extra 1 is the result of necessary sign extension.

The number of fractional bits of the result is the sum of the number of fractional bits of the factors.

Multiplication Data Types

The following diagrams show the data types used for fixed-point multiplication in the System Toolbox software. The diagrams illustrate the differences between the data types used for real-real, complex-real, and complex-complex multiplication. See individual reference pages to determine whether a particular block accepts complex fixed-point inputs.

In most cases, you can set the data types used during multiplication in the block mask. For details, see "Casts" on page 12-15.

Note The following diagrams show the use of fixed-point data types in multiplication in System Toolbox software. They do not represent actual subsystems used by the software to perform multiplication.

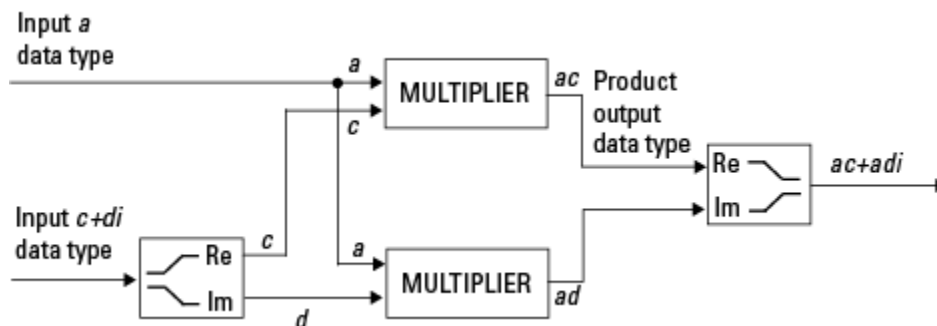

Real-Real Multiplication

The following diagram shows the data types used in the multiplication of two real numbers in System Toolbox software. The software returns the output of this operation in the product output data type, as the next figure shows.

Real-Complex Multiplication

The following diagram shows the data types used in the multiplication of a real and a complex fixed-point number in System Toolbox software. Real-complex and complex-real multiplication are equivalent. The software returns the output of this operation in the product output data type, as the next figure shows.

Complex-Complex Multiplication

The following diagram shows the multiplication of two complex fixed-point numbers in System Toolbox software. Note that the software returns the output of this operation in the accumulator output data type, as the next figure shows.

System Toolbox blocks cast to the accumulator data type before performing addition or subtraction operations. In the preceding diagram, this is equivalent to the C code

```
acc=ac;
acc-=bd;
```

for the subtractor, and

```
acc=ad;
acc+=bc;
```

for the adder, where *acc* is the accumulator.

Casts

Many fixed-point System Toolbox blocks that perform arithmetic operations allow you to specify the accumulator, intermediate product, and product output data types, as

applicable, as well as the output data type of the block. This section gives an overview of the casts to these data types, so that you can tell if the data types you select will invoke sign extension, padding with zeros, rounding, and/or overflow. Sign extension is the addition of bits that have the value of the most significant bit to the high end of a two's complement number. Sign extension does not change the value of the binary number. Padding is extending the least significant bit of a binary word with one or more zeros.

Casts to the Accumulator Data Type

For most fixed-point System Toolbox blocks that perform addition or subtraction, the operands are first cast to an accumulator data type. Most of the time, you can specify the accumulator data type on the block mask. For details, see the description for **Accumulator** data type parameter in “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox). Since the addends are both cast to the same accumulator data type before they are added together, no extra shift is necessary to insure that their binary points align. The result of the addition remains in the accumulator data type, with the possibility of overflow.

Casts to the Intermediate Product or Product Output Data Type

For System Toolbox blocks that perform multiplication, the output of the multiplier is placed into a product output data type. Blocks that then feed the product output back into the multiplier might first cast it to an intermediate product data type. Most of the time, you can specify these data types on the block mask. For details, see the description for **Intermediate Product** and **Product Output** data type parameters in “Specify Fixed-Point Attributes for Blocks” (DSP System Toolbox).

Casts to the Output Data Type

Many fixed-point System Toolbox blocks allow you to specify the data type and scaling of the block output on the mask. Remember that the software does not allow mixed types on the input and output ports of its blocks. Therefore, if you would like to specify a fixed-point output data type and scaling for a System Toolbox block that supports fixed-point data types, you must feed the input port of that block with a fixed-point signal. The final cast made by a fixed-point System Toolbox block is to the output data type of the block.

Note that although you cannot mix fixed-point and floating-point signals on the input and output ports of blocks, you can have fixed-point signals with different word and fraction lengths on the ports of blocks that support fixed-point signals.

Casting Examples

It is important to keep in mind the ramifications of each cast when selecting these intermediate data types, as well as any other intermediate fixed-point data types that are allowed by a particular block. Depending upon the data types you select, overflow and/or rounding might occur. The following two examples demonstrate cases where overflow and rounding can occur.

Cast from a Shorter Data Type to a Longer Data Type

Consider the cast of a nonzero number, represented by a four-bit data type with two fractional bits, to an eight-bit data type with seven fractional bits:

As the diagram shows, the source bits are shifted up so that the binary point matches the destination binary point position. The highest source bit does not fit, so overflow might occur and the result can saturate or wrap. The empty bits at the low end of the destination data type are padded with either 0's or 1's:

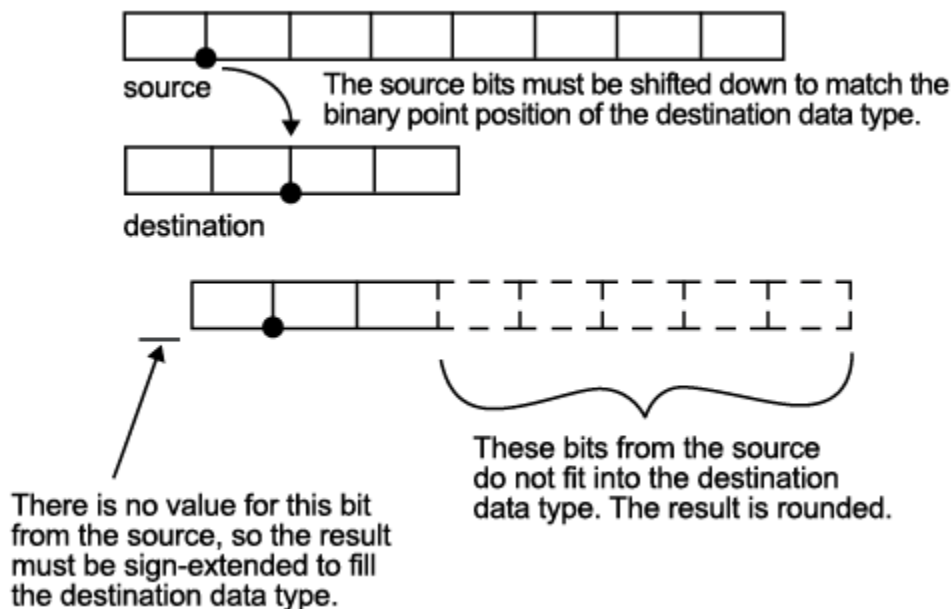

- If overflow does not occur, the empty bits are padded with 0's.
- If wrapping occurs, the empty bits are padded with 0's.
- If saturation occurs,

- The empty bits of a positive number are padded with 1's.
- The empty bits of a negative number are padded with 0's.

You can see that even with a cast from a shorter data type to a longer data type, overflow might still occur. This can happen when the integer length of the source data type (in this case two) is longer than the integer length of the destination data type (in this case one). Similarly, rounding might be necessary even when casting from a shorter data type to a longer data type, if the destination data type and scaling has fewer fractional bits than the source.

Cast from a Longer Data Type to a Shorter Data Type

Consider the cast of a nonzero number, represented by an eight-bit data type with seven fractional bits, to a four-bit data type with two fractional bits:

As the diagram shows, the source bits are shifted down so that the binary point matches the destination binary point position. There is no value for the highest bit from the source, so the result is sign extended to fill the integer portion of the destination data type. The bottom five bits of the source do not fit into the fraction length of the destination. Therefore, precision can be lost as the result is rounded.

In this case, even though the cast is from a longer data type to a shorter data type, all the integer bits are maintained. Conversely, full precision can be maintained even if you cast to a shorter data type, as long as the fraction length of the destination data type is the same length or longer than the fraction length of the source data type. In that case, however, bits are lost from the high end of the result and overflow might occur.

The worst case occurs when both the integer length and the fraction length of the destination data type are shorter than those of the source data type and scaling. In that case, both overflow and a loss of precision can occur.

Fixed-Point Support for MATLAB System Objects

In this section...
“Getting Information About Fixed-Point System Objects” on page 12-20
“Setting System Object Fixed-Point Properties” on page 12-20

For information on working with Fixed-Point features, refer to the “Fixed-Point” topic.

Getting Information About Fixed-Point System Objects

System objects that support fixed-point data processing have fixed-point properties. When you display the properties of a System object, click **Show all properties** at the end of the property list to display the fixed-point properties for that object. You can also display the fixed-point properties for a particular object by typing `vision.<ObjectName>.helpFixedPoint` at the command line.

The following Computer Vision Toolbox objects support fixed-point data processing.

Fixed-Point Data Processing Support

```
vision.AlphaBlender  
vision.BlobAnalysis  
vision.BlockMatcher  
vision.DCT  
vision.Maximum  
vision.Mean  
vision.Median  
vision.Minimum
```

Setting System Object Fixed-Point Properties

Several properties affect the fixed-point data processing used by a System object. Objects perform fixed-point processing and use the current fixed-point property settings when they receive fixed-point input.

You change the values of fixed-point properties in the same way as you change any System object property value. You also use the Fixed-Point Designer `numericType` object to specify the desired data type as fixed point, the signedness, and the word- and fraction-lengths.

In the same way as for blocks, the data type properties of many System objects can set the appropriate word lengths and scalings automatically by using full precision. System objects assume that the target specified on the Configuration Parameters Hardware Implementation target is ASIC/FPGA.

If you have not set the property that activates a dependent property and you attempt to change that dependent property, you will get a warning message.

You must set the property that activates a dependent property before attempting to change the dependent property. If you do not set the activating property, you will get a warning message.

Note System objects do not support fixed-point word lengths greater than 128 bits.

For any System object provided in the Toolbox, the fimath settings for any fimath attached to a fi input or a fi property are ignored. Outputs from a System object never have an attached fimath.

Specify Fixed-Point Attributes for Blocks

In this section...
“Fixed-Point Block Parameters” on page 12-22
“Specify System-Level Settings” on page 12-25
“Inherit via Internal Rule” on page 12-25
“Specify Data Types for Fixed-Point Blocks” on page 12-35

Fixed-Point Block Parameters

Toolbox blocks that have fixed-point support usually allow you to specify fixed-point characteristics through block parameters. By specifying data type and scaling information for these fixed-point parameters, you can simulate your target hardware more closely.

Note Floating-point inheritance takes precedence over the settings discussed in this section. When the block has floating-point input, all block data types match the input.

You can find most fixed-point parameters on the **Data Types** pane of toolbox blocks. The following figure shows a typical **Data Types** pane.

Main Data Types

Fixed-point operational parameters

Rounding mode: Saturate on integer overflow

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

	Data Type		Minimum	Maximum
Sine table:	<input type="text" value="Inherit: Same word length as i"/>	<input type="button" value=">>"/>	N/A	N/A
Product output:	<input type="text" value="Inherit: Inherit via internal rule"/>	<input type="button" value=">>"/>	N/A	N/A
Accumulator:	<input type="text" value="Inherit: Inherit via internal rule"/>	<input type="button" value=">>"/>	N/A	N/A
Output:	<input type="text" value="Inherit: Inherit via internal rule"/>	<input type="button" value=">>"/>	<input type="text" value=""/>	<input type="text" value=""/>

Lock data type settings against changes by the fixed-point tools

All toolbox blocks with fixed-point capabilities share a set of common parameters, but each block can have a different subset of these fixed-point parameters. The following table provides an overview of the most common fixed-point block parameters.

Fixed-Point Data Type Parameter	Description
Rounding Mode	Specifies the rounding mode for the block to use when the specified data type and scaling cannot exactly represent the result of a fixed-point calculation. See “Rounding Modes” on page 12-8 for more information on the available options.
Saturate on integer overflow	When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see “Overflow Handling” on page 12-8 for fixed-point operations.

Fixed-Point Data Type Parameter	Description
Intermediate Product	<p>Specifies the data type and scaling of the intermediate product for fixed-point blocks. Blocks that feed multiplication results back to the input of the multiplier use the intermediate product data type.</p> <p>See the reference page of a specific block to learn about the intermediate product data type for that block.</p>
Product Output	<p>Specifies the data type and scaling of the product output for fixed-point blocks that must compute multiplication results.</p> <p>See the reference page of a specific block to learn about the product output data type for that block. For or complex-complex multiplication, the multiplication result is in the accumulator data type. See “Multiplication Data Types” on page 12-13 for more information on complex fixed-point multiplication in toolbox software.</p>
Accumulator	<p>Specifies the data type and scaling of the accumulator (sum) for fixed-point blocks that must hold summation results for further calculation. Most such blocks cast to the accumulator data type before performing the add operations (summation).</p> <p>See the reference page of a specific block for details on the accumulator data type of that block.</p>
Output	<p>Specifies the output data type and scaling for blocks.</p>

Using the Data Type Assistant

The **Data Type Assistant** is an interactive graphical tool available on the **Data Types** pane of some fixed-point toolbox blocks.

To learn more about using the **Data Type Assistant** to help you specify block data type parameters, see “Specify Data Types Using Data Type Assistant” (Simulink).

Checking Signal Ranges

Some fixed-point toolbox blocks have **Minimum** and **Maximum** parameters on the **Data Types** pane. When a fixed-point data type has these parameters, you can use them to specify appropriate minimum and maximum values for range checking purposes.

To learn how to specify signal ranges and enable signal range checking, see “Signal Ranges” (Simulink).

Specify System-Level Settings

You can monitor and control fixed-point settings for toolbox blocks at a system or subsystem level with the Fixed-Point Tool. For more information, see **Fixed-Point Tool**.

Logging

The Fixed-Point Tool logs overflows, saturations, and simulation minimums and maximums for fixed-point toolbox blocks. The Fixed-Point Tool does not log overflows and saturations when the `Data overflow` line in the **Diagnostics > Data Integrity** pane of the Configuration Parameters dialog box is set to `None`.

Autoscaling

You can use the Fixed-Point Tool autoscaling feature to set the scaling for toolbox fixed-point data types.

Data type override

toolbox blocks obey the `Use local settings`, `Double`, `Single`, and `Off` modes of the **Data type override** parameter in the Fixed-Point Tool. The `Scaled double` mode is also supported for toolboxes source and byte-shuffling blocks, and for some arithmetic blocks such as `Difference` and `Normalization`.

Scaled double is a double data type that retains fixed-point scaling information. Using the data type override, you can convert your fixed-point data types to scaled doubles. You can then simulate to determine the ideal floating-point behavior of your system. After you gather that information, you can turn data type override off to return to fixed-point data types, and your quantities still have their original scaling information because it was held in the scaled double data types.

Inherit via Internal Rule

Selecting appropriate word lengths and scalings for the fixed-point parameters in your model can be challenging. To aid you, an `Inherit via internal` rule choice is often available for fixed-point block data type parameters, such as the **Accumulator** and **Product output** signals. The following sections describe how the word and fraction

lengths are selected for you when you choose `Inherit via internal rule` for a fixed-point block data type parameter in toolbox software:

- “Internal Rule for Accumulator Data Types” on page 12-26
- “Internal Rule for Product Data Types” on page 12-26
- “Internal Rule for Output Data Types” on page 12-27
- “The Effect of the Hardware Implementation Pane on the Internal Rule” on page 12-27
- “Internal Rule Examples” on page 12-29

Note In the equations in the following sections, WL = word length and FL = fraction length.

Internal Rule for Accumulator Data Types

The internal rule for accumulator data types first calculates the ideal, full-precision result. Where N is the number of addends:

$$WL_{idealaccumulator} = WL_{inputtoaccumulator} + \text{floor}(\log_2(N - 1)) + 1$$

$$FL_{idealaccumulator} = FL_{inputtoaccumulator}$$

For example, consider summing all the elements of a vector of length 6 and data type `sfix10_En8`. The ideal, full-precision result has a word length of 13 and a fraction length of 8.

The accumulator can be real or complex. The preceding equations are used for both the real and imaginary parts of the accumulator. For any calculation, after the full-precision result is calculated, the final word and fraction lengths set by the internal rule are affected by your particular hardware. See “The Effect of the Hardware Implementation Pane on the Internal Rule” on page 12-27 for more information.

Internal Rule for Product Data Types

The internal rule for product data types first calculates the ideal, full-precision result:

$$WL_{idealproduct} = WL_{input1} + WL_{input2}$$

$$FL_{idealproduct} = FL_{input1} + FL_{input2}$$

For example, multiplying together the elements of a real vector of length 2 and data type `sfix10_En8`. The ideal, full-precision result has a word length of 20 and a fraction length of 16.

For real-complex multiplication, the ideal word length and fraction length is used for both the complex and real portion of the result. For complex-complex multiplication, the ideal word length and fraction length is used for the partial products, and the internal rule for accumulator data types described above is used for the final sums. For any calculation, after the full-precision result is calculated, the final word and fraction lengths set by the internal rule are affected by your particular hardware. See “The Effect of the Hardware Implementation Pane on the Internal Rule” on page 12-27 for more information.

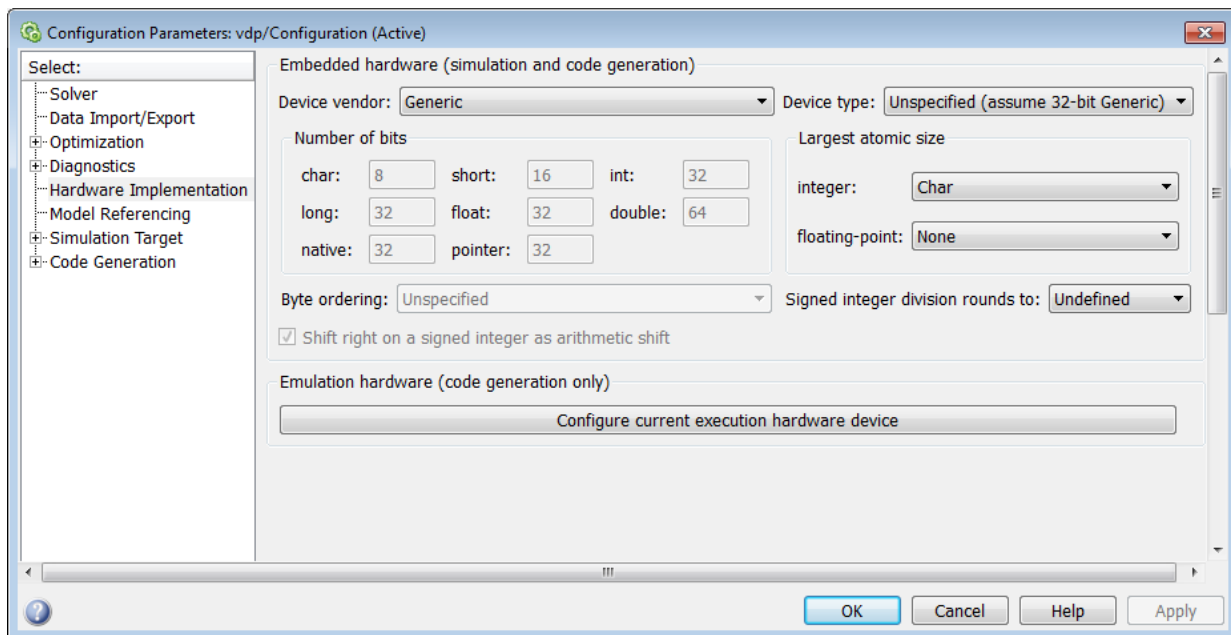

Internal Rule for Output Data Types

A few toolbox blocks have an `Inherit via internal rule` choice available for the block output. The internal rule used in these cases is block-specific, and the equations are listed in the block reference page.

As with accumulator and product data types, the final output word and fraction lengths set by the internal rule are affected by your particular hardware, as described in “The Effect of the Hardware Implementation Pane on the Internal Rule” on page 12-27.

The Effect of the Hardware Implementation Pane on the Internal Rule

The internal rule selects word lengths and fraction lengths that are appropriate for your hardware. To get the best results using the internal rule, you must specify the type of hardware you are using on the **Hardware Implementation** pane of the Configuration Parameters dialog box. You can open this dialog box from the **Simulation** menu in your model.

ASIC/FPGA

On an ASIC/FPGA target, the ideal, full-precision word length and fraction length calculated by the internal rule are used. If the calculated ideal word length is larger than the largest allowed word length, you receive an error.

Other targets

For all targets other than ASIC/FPGA, the ideal, full-precision word length calculated by the internal rule is rounded up to the next available word length of the target. The calculated ideal fraction length is used, keeping the least-significant bits.

If the calculated ideal word length for a product data type is larger than the largest word length on the target, you receive an error. If the calculated ideal word length for an accumulator or output data type is larger than the largest word length on the target, the largest target word length is used.

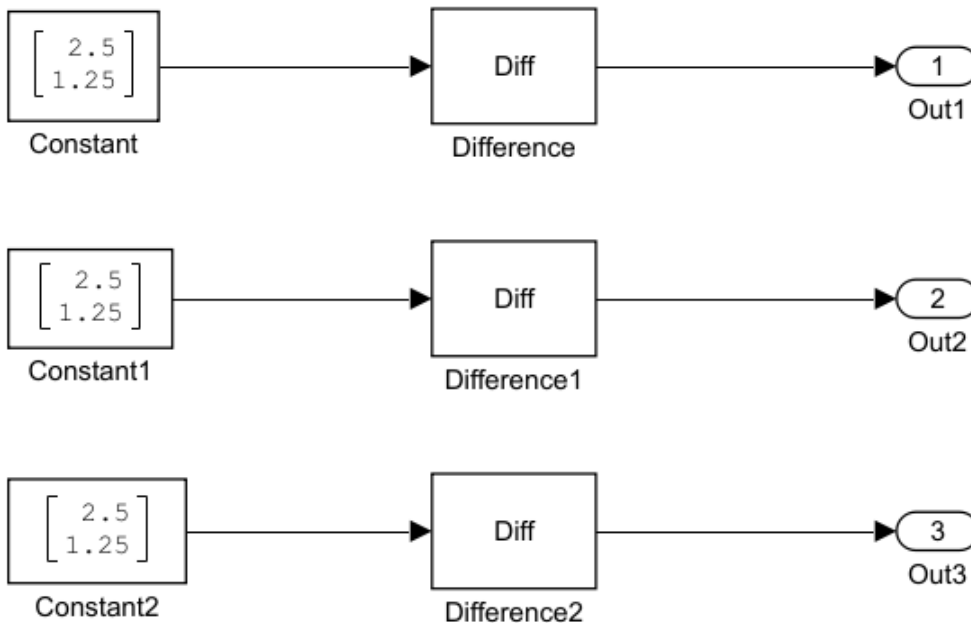

The largest word length allowed for Simulink and toolbox software on any target is 128 bits.

Internal Rule Examples

The following sections show examples of how the internal rule interacts with the **Hardware Implementation** pane to calculate accumulator data types on page 12-29 and product data types on page 12-32.

Accumulator Data Types

Consider the following model `ex_internalRule_accumExp`.

In the Difference blocks, the **Accumulator** parameter is set to `Inherit: Inherit via internal rule`, and the **Output** parameter is set to `Inherit: Same as accumulator`. Therefore, you can see the accumulator data type calculated by the internal rule on the output signal in the model.

In the preceding model, the **Device type** parameter in the **Hardware Implementation** pane of the Configuration Parameters dialog box is set to `ASIC/FPGA`. Therefore, the accumulator data type used by the internal rule is the ideal, full-precision result.

Calculate the full-precision word length for each of the Difference blocks in the model:

$$WL_{idealaccumulator} = WL_{inputtoaccumulator} + \text{floor}(\log_2(\text{numberofaccumulations})) + 1$$

$$WL_{idealaccumulator} = 9 + \text{floor}(\log_2(1)) + 1$$

$$WL_{idealaccumulator} = 9 + 0 + 1 = 10$$

$$WL_{idealaccumulator1} = WL_{inputtoaccumulator1} + \text{floor}(\log_2(\text{numberofaccumulations})) + 1$$

$$WL_{idealaccumulator1} = 16 + \text{floor}(\log_2(1)) + 1$$

$$WL_{idealaccumulator1} = 16 + 0 + 1 = 17$$

$$WL_{idealaccumulator2} = WL_{inputtoaccumulator2} + \text{floor}(\log_2(\text{numberofaccumulations})) + 1$$

$$WL_{idealaccumulator2} = 127 + \text{floor}(\log_2(1)) + 1$$

$$WL_{idealaccumulator2} = 127 + 0 + 1 = 128$$

Calculate the full-precision fraction length, which is the same for each Matrix Sum block in this example:

$$FL_{idealaccumulator} = FL_{inputtoaccumulator}$$

$$FL_{idealaccumulator} = 4$$

Now change the **Device type** parameter in the **Hardware Implementation** pane of the Configuration Parameters dialog box to 32-bit Embedded Processor, by changing the parameters as shown in the following figure.

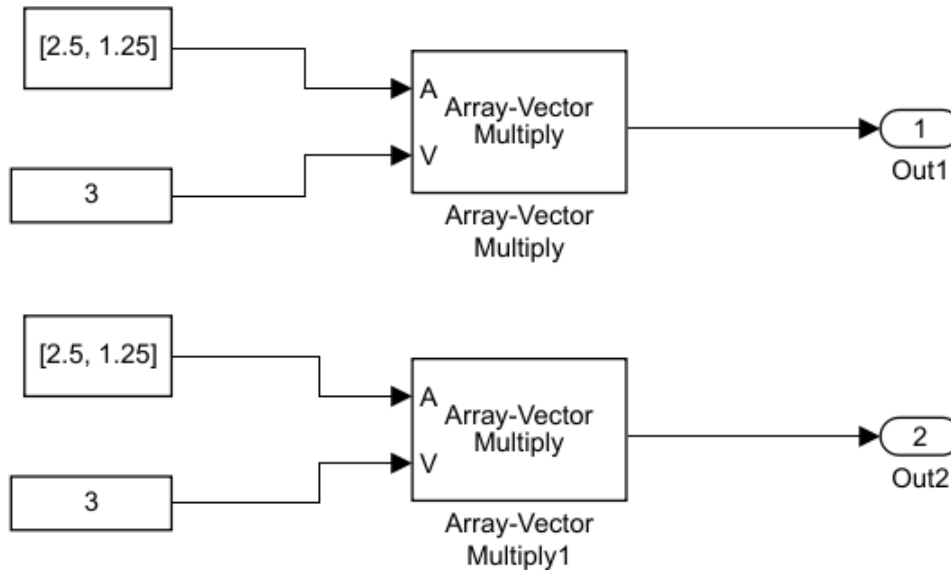

As you can see in the dialog box, this device has 8-, 16-, and 32-bit word lengths available. Therefore, the ideal word lengths of 10, 17, and 128 bits calculated by the internal rule cannot be used. Instead, the internal rule uses the next largest available word length in each case. You can see this if you rerun the model, as shown in the following figure.

Product Data Types

Consider the following model `ex_internalRule_prodExp`.

In the Array-Vector Multiply blocks, the **Product Output** parameter is set to `Inherit: Inherit` via internal rule, and the **Output** parameter is set to `Inherit: Same as product output`. Therefore, you can see the product output data type calculated by the internal rule on the output signal in the model. The setting of the **Accumulator** parameter does not matter because this example uses real values.

For the preceding model, the **Device type** parameter in the **Hardware Implementation** pane of the Configuration Parameters dialog box is set to ASIC/FPGA. Therefore, the product data type used by the internal rule is the ideal, full-precision result.

Calculate the full-precision word length for each of the Array-Vector Multiply blocks in the model:

$$WL_{idealproduct} = WL_{inputa} + WL_{inputb}$$

$$WL_{idealproduct} = 7 + 5 = 12$$

$$WL_{idealproduct1} = WL_{inputa} + WL_{inputb}$$

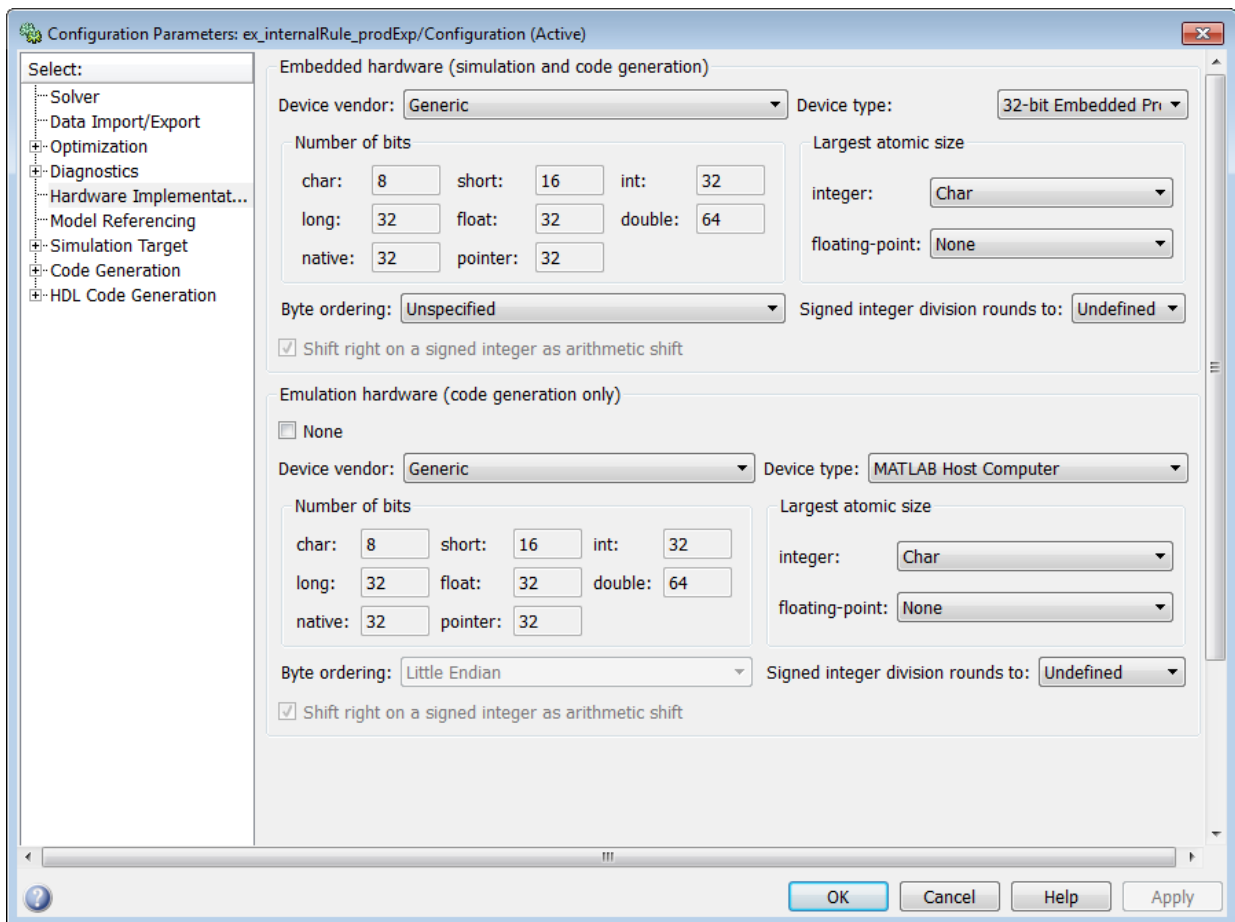

$$WL_{idealproduct1} = 16 + 15 = 31$$

Calculate the full-precision fraction length, which is the same for each Array-Vector Multiply block in this example:

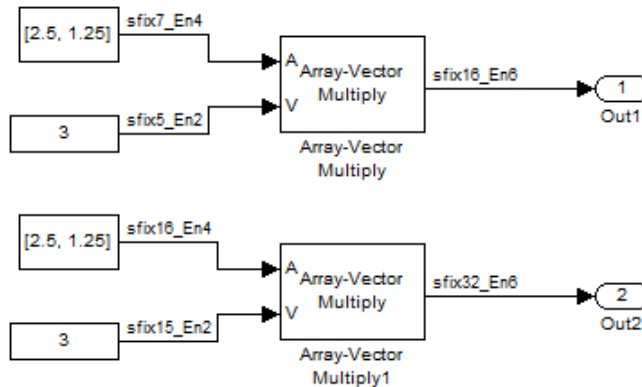

$$FL_{idealaccumulator} = FL_{inputtoaccumulator}$$

$$FL_{idealaccumulator} = 4$$

Now change the **Device type** parameter in the **Hardware Implementation** pane of the Configuration Parameters dialog box to 32-bit Embedded Processor, as shown in the following figure.

As you can see in the dialog box, this device has 8-, 16-, and 32-bit word lengths available. Therefore, the ideal word lengths of 12 and 31 bits calculated by the internal rule cannot be used. Instead, the internal rule uses the next largest available word length in each case. You can see this if you rerun the model, as shown in the following figure.

Specify Data Types for Fixed-Point Blocks

The following sections show you how to use the Fixed-Point Tool to select appropriate data types for fixed-point blocks in the `ex_fixedpoint_tut` model:

- “Prepare the Model” on page 12-35
- “Use Data Type Override to Find a Floating-Point Benchmark” on page 12-40
- “Use the Fixed-Point Tool to Propose Fraction Lengths” on page 12-40
- “Examine the Results and Accept the Proposed Scaling” on page 12-41

Prepare the Model

- 1 Open the model by typing `ex_fixedpoint_tut` at the MATLAB command line.

Copyright 2009-2010 The MathWorks, Inc.

This model uses the Cumulative Sum block to sum the input coming from the Fixed-Point Sources subsystem. The Fixed-Point Sources subsystem outputs two signals with different data types:

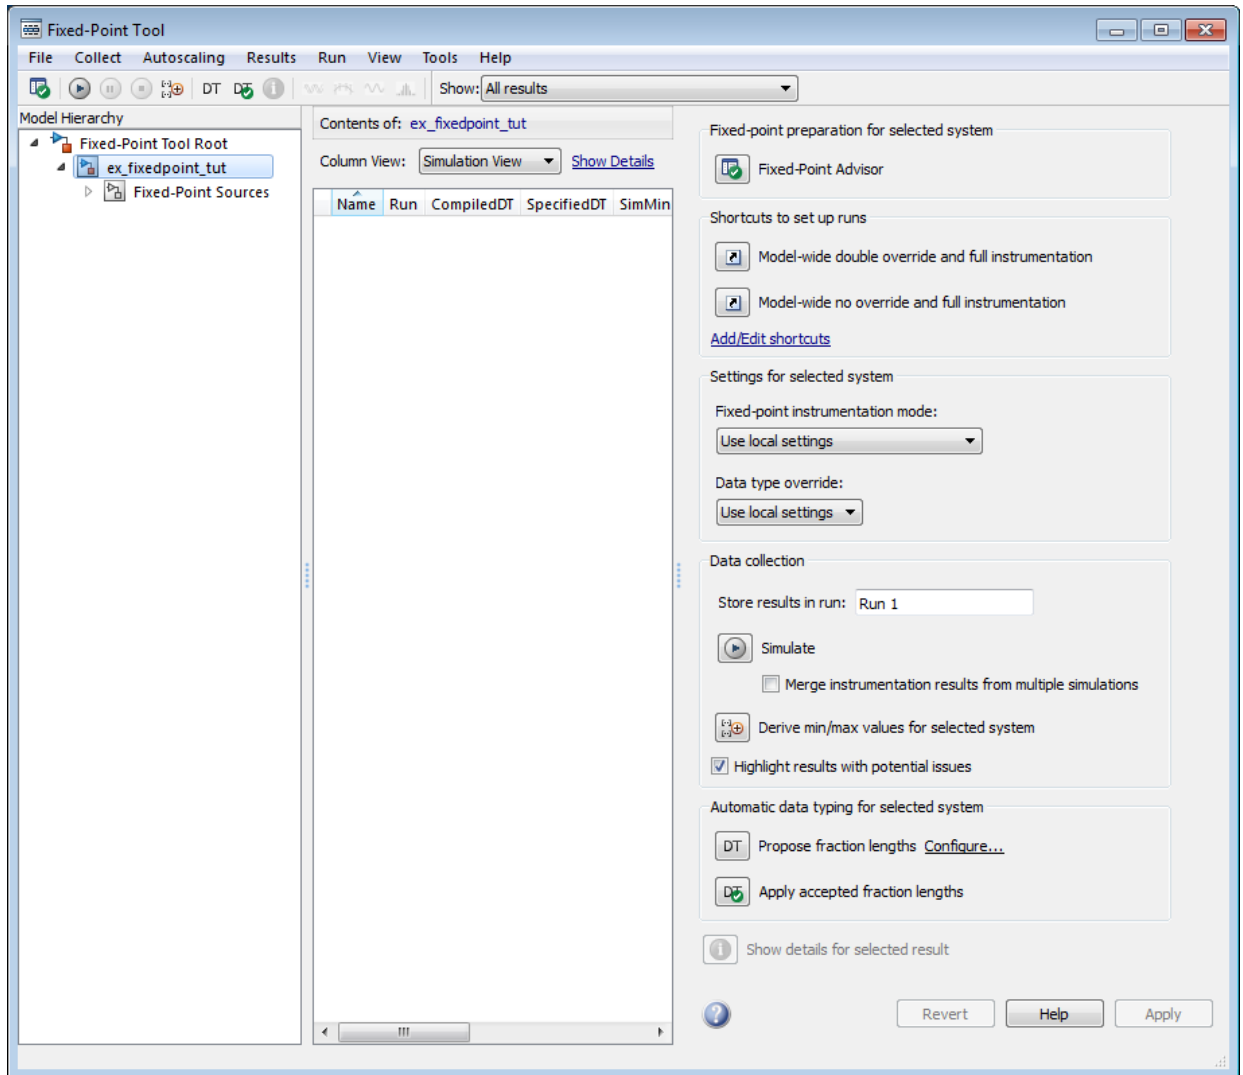

- The Signed source has a word length of 16 bits and a fraction length of 15 bits.
 - The Unsigned source has a word length of 16 bits and a fraction length of 16 bits.
- 2** Run the model to check for overflow. MATLAB displays the following warnings at the command line:

```
Warning: Overflow occurred. This originated from
'ex_fixedpoint_tut/Signed Cumulative Sum'.
```

```
Warning: Overflow occurred. This originated from
'ex_fixedpoint_tut/Unsigned Cumulative Sum'.
```

According to these warnings, overflow occurs in both Cumulative Sum blocks.

- 3** To investigate the overflows in this model, use the Fixed-Point Tool. You can open the Fixed-Point Tool by selecting **Tools > Fixed-Point > Fixed-Point Tool** from the model menu. Turn on logging for all blocks in your model by setting the **Fixed-point instrumentation mode** parameter to **Minimums, maximums and overflows**.
- 4** Now that you have turned on logging, rerun the model by clicking the Simulation button.

- 5 The results of the simulation appear in a table in the central **Contents** pane of the Fixed-Point Tool. Review the following columns:
- **Name** — Provides the name of each signal in the following format: Subsystem Name/Block Name: Signal Name.
 - **SimDT** — The simulation data type of each logged signal.

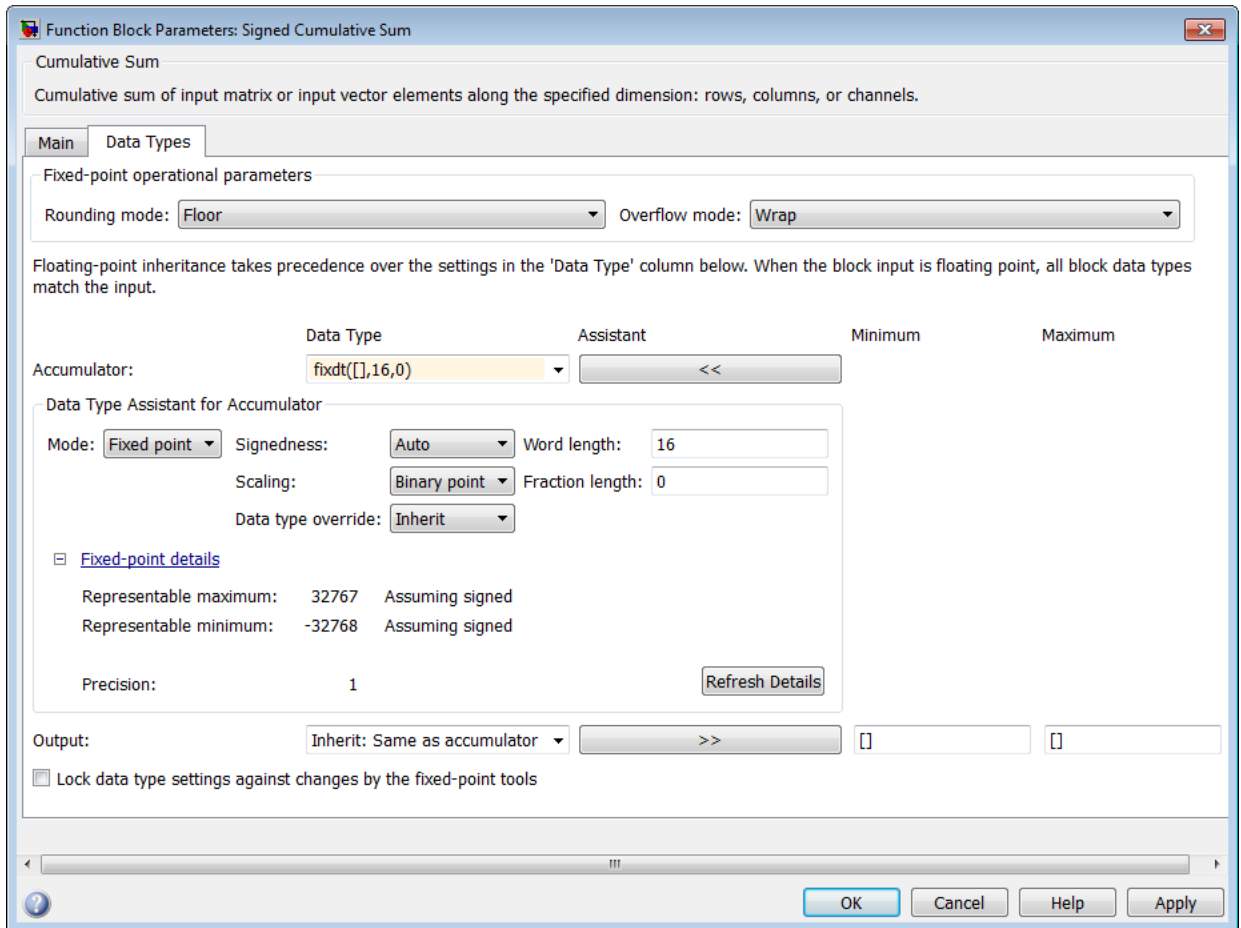

- **SpecifiedDT** — The data type specified on the block dialog for each signal.
- **SimMin** — The smallest representable value achieved during simulation for each logged signal.
- **SimMax** — The largest representable value achieved during simulation for each logged signal.
- **OverflowWraps** — The number of overflows that wrap during simulation.

For more information on each of the columns in this table, see the “Contents Pane” (Simulink) section of the Simulink `fxptdlg` function reference page.

You can also see that the **SimMin** and **SimMax** values for the Accumulator data types range from 0 to .9997. The logged results indicate that 8,192 overflows wrapped during simulation in the Accumulator data type of the Signed Cumulative Sum block. Similarly, the Accumulator data type of the Unsigned Cumulative Sum block had 16,383 overflows wrap during simulation.

To get more information about each of these data types, highlight them in the

- Contents** pane, and click the **Show details for selected result** button ()
- 6** Assume a target hardware that supports 32-bit integers, and set the Accumulator word length in both Cumulative Sum blocks to 32. To do so, perform the following steps:
- 1** Right-click the Signed Cumulative Sum: Accumulator row in the Fixed-Point Tool pane, and select **Highlight Block In Model**.
 - 2** Double-click the block in the model, and select the **Data Types** pane of the dialog box.
 - 3** Open the **Data Type Assistant** for Accumulator by clicking the Assistant button () in the Accumulator data type row.
 - 4** Set the **Mode** to **Fixed Point**. To see the representable range of the current specified data type, click the **Fixed-point details** link. The tool displays the representable maximum and representable minimum values for the current data type.

- 5 Change the **Word length** to 32, and click the **Refresh details** button in the **Fixed-point details** section to see the updated representable range. When you change the value of the **Word length** parameter, the **Data Type** edit box automatically updates.
- 6 Click **OK** on the block dialog box to save your changes and close the window.
- 7 Set the word length of the Accumulator data type of the Unsigned Cumulative Sum block to 32 bits. You can do so in one of two ways:
 - Type the data type `fixdt([],32,0)` directly into **Data Type** edit box for the Accumulator data type parameter.

- Perform the same steps you used to set the word length of the Accumulator data type of the Signed Cumulative Sum block to 32 bits.
- 7 To verify your changes in word length and check for overflow, rerun your model. To do so, click the **Simulate** button in the Fixed-Point Tool.

The **Contents** pane of the Fixed-Point Tool updates, and you can see that no overflows occurred in the most recent simulation. However, you can also see that the **SimMin** and **SimMax** values range from 0 to 0. This underflow happens because the fraction length of the Accumulator data type is too small. The **SpecifiedDT** cannot represent the precision of the data values. The following sections discuss how to find a floating-point benchmark and use the Fixed-Point Tool to propose fraction lengths.

Use Data Type Override to Find a Floating-Point Benchmark

The **Data type override** feature of the Fixed-Point tool allows you to override the data types specified in your model with floating-point types. Running your model in **Double** override mode gives you a reference range to help you select appropriate fraction lengths for your fixed-point data types. To do so, perform the following steps:

- 1 Open the Fixed-Point Tool and set **Data type override** to **Double**.
- 2 Run your model by clicking the **Run simulation and store active results** button.
- 3 Examine the results in the **Contents** pane of the Fixed-Point Tool. Because you ran the model in **Double** override mode, you get an accurate, idealized representation of the simulation minimums and maximums. These values appear in the **SimMin** and **SimMax** parameters.
- 4 Now that you have an accurate reference representation of the simulation minimum and maximum values, you can more easily choose appropriate fraction lengths. Before making these choices, save your active results to reference so you can use them as your floating-point benchmark. To do so, select **Results > Move Active Results To Reference** from the Fixed-Point Tool menu. The status displayed in the **Run** column changes from **Active** to **Reference** for all signals in your model.

Use the Fixed-Point Tool to Propose Fraction Lengths

Now that you have your **Double** override results saved as a floating-point reference, you are ready to propose fraction lengths.

- 1 To propose fraction lengths for your data types, you must have a set of **Active** results available in the Fixed-Point Tool. To produce an active set of results, simply rerun your model. The tool now displays both the **Active** results and the **Reference** results for each signal.

- 2 Select the **Use simulation min/max if design min/max is not available** check box. You did not specify any design minimums or maximums for the data types in this model. Thus, the tool uses the logged information to compute and propose fraction lengths. For information on specifying design minimums and maximums, see “Signal Ranges” (Simulink).
- 3 Click the **Propose fraction lengths** button (). The tool populates the proposed data types in the **ProposedDT** column of the **Contents** pane. The corresponding proposed minimums and maximums are displayed in the **ProposedMin** and **ProposedMax** columns.

Examine the Results and Accept the Proposed Scaling

Before accepting the fraction lengths proposed by the Fixed-Point Tool, it is important to look at the details of that data type. Doing so allows you to see how much of your data the suggested data type can represent. To examine the suggested data types and accept the proposed scaling, perform the following steps:

- 1 In the **Contents** pane of the Fixed-Point Tool, you can see the proposed fraction lengths for the data types in your model.
 - The proposed fraction length for the Accumulator data type of both the Signed and Unsigned Cumulative Sum blocks is 17 bits.
 - To get more details about the proposed scaling for a particular data type, highlight the data type in the **Contents** pane of the Fixed-Point Tool.
 - Open the Autoscale Information window for the highlighted data type by clicking the **Show autoscale information for the selected result** button (.
- 2 When the Autoscale Information window opens, check the **Value** and **Percent Proposed Representable** columns for the **Simulation Minimum** and **Simulation Maximum** parameters. You can see that the proposed data type can represent 100% of the range of simulation data.
- 3 To accept the proposed data types, select the check box in the **Accept** column for each data type whose proposed scaling you want to keep. Then, click the **Apply accepted fraction lengths** button (). The tool updates the specified data types on the block dialog boxes and the **SpecifiedDT** column in the **Contents** pane.
- 4 To verify the newly accepted scaling, set the **Data type override** parameter back to **Use local settings**, and run the model. Looking at **Contents** pane of the Fixed-Point Tool, you can see the following details:

- The **SimMin** and **SimMax** values of the Active run match the **SimMin** and **SimMax** values from the floating-point Reference run.
- There are no longer any overflows.
- The **SimDT** does not match the **SpecifiedDT** for the Accumulator data type of either Cumulative Sum block. This difference occurs because the Cumulative Sum block always inherits its **Signedness** from the input signal and only allows you to specify a **Signedness** of Auto. Therefore, the **SpecifiedDT** for both Accumulator data types is `fixdt([], 32, 17)`. However, because the Signed Cumulative Sum block has a signed input signal, the **SimDT** for the Accumulator parameter of that block is also signed (`fixdt(1, 32, 17)`). Similarly, the **SimDT** for the Accumulator parameter of the Unsigned Cumulative Sum block inherits its **Signedness** from its input signal and thus is unsigned (`fixdt(0, 32, 17)`).

Code Generation

- “Code Generation in MATLAB” on page 13-2

Code Generation in MATLAB

Several Computer Vision Toolbox functions have been enabled to generate C/C++ code. To use code generation with computer vision functions, follow these steps:

- Write your Computer Vision Toolbox function or application as you would normally, using functions from the Computer Vision Toolbox.
- Add the `%#codegen` compiler directive to your MATLAB code.
- Open the MATLAB Coder app, create a project, and add your file to the project. Once in MATLAB Coder, you can check the readiness of your code for code generation. For example, your code may contain functions that are not enabled for code generation. Make any modifications required for code generation.
- Generate code by clicking **Generate** in the Generate Code dialog box. You can choose to build a MEX file, a C/C++ shared library, a C/C++ dynamic library, or a C/C++ executable.

Even if you addressed all readiness issues identified by MATLAB Coder, you might still encounter build issues. The readiness check only looks at function dependencies. When you try to generate code, MATLAB Coder might discover coding patterns that are not supported for code generation. View the error report and modify your MATLAB code until you get a successful build.

For more information about code generation, see the MATLAB Coder documentation and the “Introduction to Code Generation with Feature Matching and Registration” example.

Note To generate code from MATLAB code that contains Computer Vision Toolbox functionality, you must have the MATLAB Coder software.

When working with generated code, note the following:

- For some Computer Vision Toolbox functions, code generation includes creation of a shared library.
- Refer to the “Code Generation Support, Usage Notes, and Limitations” on page 13-3 for supported functionality, usages, and limitations.

Code Generation Support, Usage Notes, and Limitations

Code Generation Support, Usage Notes, and Limitations for Functions, Classes, and System Objects

To generate code from MATLAB code that contains Computer Vision Toolbox functions, classes, or System objects, you must have the MATLAB Coder software.

An asterisk (*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

acfObjectDetector*	Detect objects using aggregate channel features
affine2d*	2-D affine geometric transformation
affine3d*	3-D affine geometric transformation
assignDetectionsToTracks	Assign detections to tracks for multiobject tracking
bbox2points	Convert rectangle to corner points list
bboxOverlapRatio	Compute bounding box overlap ratio
binaryFeatures	Object for storing binary feature vectors
BRISKPoints*	Object for storing BRISK interest points
cameraMatrix*	Camera projection matrix
cameraParameters*	Object for storing camera parameters
cameraPose*	Compute relative rotation and translation between camera poses
cameraPoseToExtrinsics	Convert camera pose to extrinsics
cornerPoints*	Object for storing corner points
detect*	Detect objects using ACF object detector
detectBRISKFeatures*	Detect BRISK features and return BRISKPoints object
detectCheckerboardPoints*	Detect checkerboard pattern in image

detectFASTFeatures*	Detect corners using FAST algorithm and return cornerPoints object
detectHarrisFeatures*	Detect corners using Harris’s Stephens algorithm and return cornerPoints object
detectKAZEFeatures*	Detect KAZE features
detectMinEigenFeatures*	Detect corners using minimum eigenvalue algorithm and return cornerPoints object
detectMSERFeatures*	Detect MSER features and return MSERRegions object
detectORBFeatures	Detect and store ORB keypoints
detectSURFFeatures*	Detect SURF features and return SURFPoints object
disparity*	(Not recommended) Disparity map between stereo images
disparityBM	Compute disparity map using block matching
disparitySGM	Compute disparity map through semi-global matching
epipolarLine	Compute epipolar lines for stereo images
estimateEssentialMatrix*	Estimate essential matrix from corresponding points in a pair of images
estimateFlow	Estimate optical flow
estimateFundamentalMatrix*	Estimate fundamental matrix from corresponding points in stereo images
estimateGeometricTransform*	Estimate geometric transform from matching point pairs
estimateUncalibratedRectification	Uncalibrated stereo rectification
estimateWorldCameraPose*	Estimate camera pose from 3-D to 2-D point correspondences
extractFeatures*	Extract interest point descriptors
extractHOGFeatures	Extract histogram of oriented gradients (HOG) features

<code>extractLBPFeatures*</code>	Extract local binary pattern (LBP) features
<code>extrinsics*</code>	Compute location of calibrated camera
<code>extrinsicsToCameraPose</code>	Convert extrinsics to camera pose
<code>findNearestNeighbors*</code>	Find nearest neighbors of a point in point cloud
<code>findNeighborsInRadius*</code>	Find neighbors within a radius of a point in the point cloud
<code>findPointsInROI</code>	Find points within a region of interest in the point cloud
<code>generateCheckerboardPoints</code>	Generate checkerboard corner locations
<code>imcrop*</code>	Crop image
<code>imresize*</code>	Resize image
<code>imwarp*</code>	Apply geometric transformation to image
<code>insertMarker*</code>	Insert markers in image or video
<code>insertObjectAnnotation*</code>	Annotate truecolor or grayscale image or video stream
<code>insertShape*</code>	Insert shapes in image or video
<code>insertText*</code>	Insert text in image or video
<code>isEpipoleInImage</code>	Determine whether image contains epipole
<code>KAZEPoints*</code>	Object for storing KAZE interest points
<code>lineToBorderPoints</code>	Intersection points of lines in image and image border
<code>matchFeatures*</code>	Find matching features
<code>MSERRegions*</code>	Object for storing MSER regions
<code>ocr*</code>	Recognize text using optical character recognition
<code>ocrText*</code>	Object for storing OCR results
<code>opticalFlow</code>	Object for storing optical flow matrices
<code>opticalFlowFarneback</code>	Object for estimating optical flow using Farneback method

<code>opticalFlowHS</code>	Object for estimating optical flow using Horn-Schunck method
<code>opticalFlowLK</code>	Object for estimating optical flow using Lucas-Kanade method
<code>opticalFlowLKDoG</code>	Object for estimating optical flow using Lucas-Kanade derivative of Gaussian method
<code>ORBPoints*</code>	Object for storing ORB keypoints
<code>pcdenoise*</code>	Remove noise from 3-D point cloud
<code>pcdownsample*</code>	Downsample a 3-D point cloud
<code>pcfitcylinder*</code>	Fit cylinder to 3-D point cloud
<code>pcfitplane*</code>	Fit plane to 3-D point cloud
<code>pcfitsphere*</code>	Fit sphere to 3-D point cloud
<code>pcmerge*</code>	Merge two 3-D point clouds
<code>pcnormals*</code>	Estimate normals for point cloud
<code>pcregistercpd*</code>	Register two point clouds using CPD algorithm
<code>pcregisterndt*</code>	Register two point clouds using NDT algorithm
<code>pcsegdist*</code>	Segment point cloud into clusters based on Euclidean distance
<code>pctransform*</code>	Transform 3-D point cloud
<code>pointCloud</code>	Object for storing 3-D point cloud
<code>projective2d*</code>	2-D projective geometric transformation
<code>reconstructScene*</code>	Reconstruct 3-D scene from disparity map
<code>rectifyStereoImages*</code>	Rectify a pair of stereo images
<code>relativeCameraPose*</code>	Compute relative rotation and translation between camera poses
<code>removeInvalidPoints</code>	Remove invalid points from point cloud
<code>reset</code>	Reset the internal state of the optical flow estimation object
<code>rotationMatrixToVector</code>	Convert 3-D rotation matrix to rotation vector
<code>rotationVectorToMatrix</code>	Convert 3-D rotation vector to rotation matrix

<code>segmentLidarData*</code>	Segment organized 3-D range data into clusters
<code>select</code>	Select points in point cloud
<code>selectStrongestBoundingBox</code>	Select strongest bounding boxes from overlapping clusters
<code>selectStrongestBoundingBoxMulticlass*</code>	Select strongest multiclass bounding boxes from overlapping clusters
<code>stereoAnaglyph</code>	Create red-cyan anaglyph from stereo pair of images
<code>stereoParameters*</code>	Object for storing stereo camera system parameters
<code>SURFPoints*</code>	Object for storing SURF interest points
<code>triangulate*</code>	3-D locations of undistorted matching points in stereo images
<code>undistortImage*</code>	Correct image for lens distortion
<code>vision.AlphaBlender*</code>	Combine images, overlay images, or highlight selected pixels
<code>vision.BlobAnalysis*</code>	Properties of connected regions
<code>vision.CascadeObjectDetector*</code>	Detect objects using the Viola-Jones algorithm
<code>vision.ChromaResampler*</code>	Downsample or upsample chrominance components of images
<code>vision.Deinterlacer*</code>	Remove motion artifacts by deinterlacing input video signal
<code>vision.DeployableVideoPlayer*</code>	Display video
<code>vision.ForegroundDetector*</code>	Foreground detection using Gaussian mixture models
<code>vision.GammaCorrector*</code>	Apply or remove gamma correction from images or video streams
<code>vision.HistogramBasedTracker*</code>	Histogram-based object tracking
<code>vision.KalmanFilter*</code>	Correction of measurement, state, and state estimation error covariance

<code>vision.LocalMaximaFinder*</code>	Find local maxima in matrices
<code>vision.Maximum*</code>	Find maximum values in input or sequence of inputs
<code>vision.Mean*</code>	Find mean values in input or sequence of inputs
<code>vision.Median*</code>	Find median values in input or sequence of inputs
<code>vision.Minimum*</code>	Find minimum values in input or sequence of inputs
<code>vision.PeopleDetector*</code>	Detect upright people using HOG features
<code>vision.PointTracker*</code>	Track points in video using Kanade-Lucas-Tomasi (KLT) algorithm
<code>vision.StandardDeviation*</code>	Find standard deviation values in input or sequence of inputs
<code>vision.TemplateMatcher*</code>	Locate template in image
<code>vision.Variance*</code>	Find variance values in input or sequence of inputs
<code>vision.VideoFileReader*</code>	Read video frames and audio samples from video file
<code>vision.VideoFileWriter*</code>	Write video frames and audio samples to video file

Simulink Shared Library Dependencies

In general, the code you generate from Computer Vision Toolbox blocks is portable ANSI® C code. After you generate the code, you can deploy it on another machine. For more information on how to do so, see “Relocate Code to Another Development Environment” (Simulink Coder).

There are a few Computer Vision Toolbox blocks that generate code with limited portability. These blocks use precompiled shared libraries, such as DLLs, to support I/O for specific types of devices and file formats. To find out which blocks use precompiled shared libraries, open the Computer Vision Toolbox Block Support Table. You can identify blocks that use precompiled shared libraries by checking the footnotes listed in the **Code Generation Support** column of the table. All blocks that use shared libraries have the following footnote:

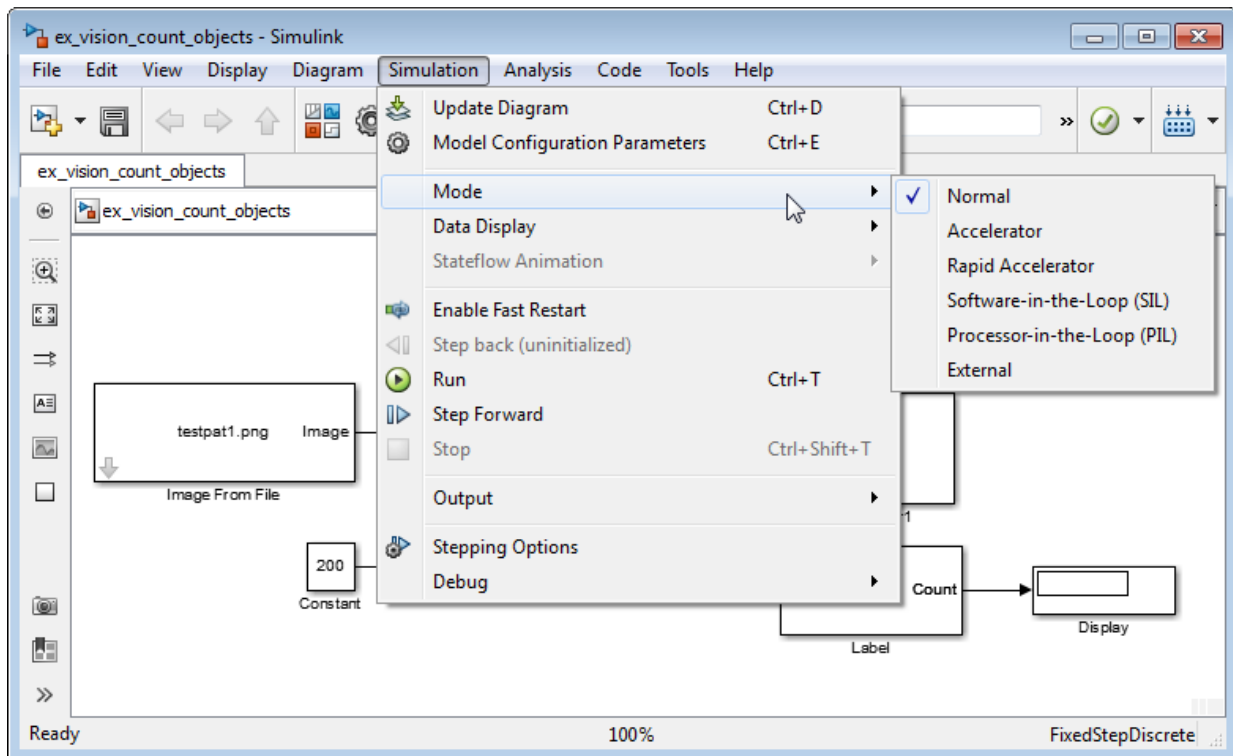

Host computer only. Excludes Simulink Desktop Real-Time™ target.

Simulink Coder provides functions to help you set up and manage the build information for your models. For example, one of the Build Information functions that Simulink Coder provides is `getNonBuildFiles`. This function allows you to identify the shared libraries required by blocks in your model. If your model contains any blocks that use precompiled shared libraries, you can install those libraries on the target system. The folder that you install the shared libraries in must be on the system path. The target system does not need to have MATLAB installed, but it does need to be supported by MATLAB.

Accelerating Simulink Models

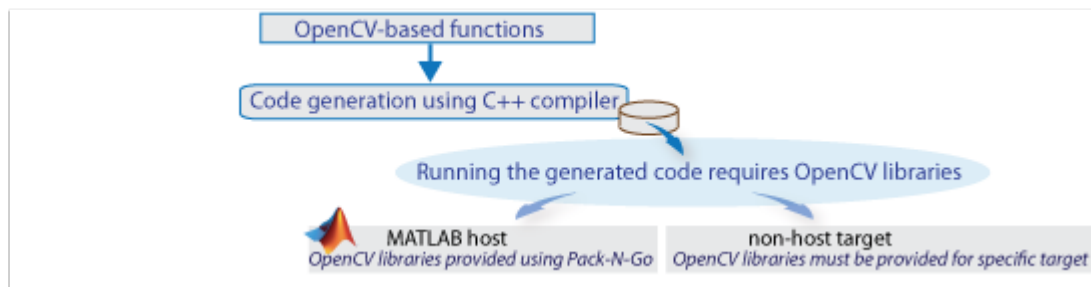

The Simulink software offer Accelerator and Rapid Accelerator simulation modes that remove much of the computational overhead required by Simulink models. These modes compile target code of your model. Through this method, the Simulink environment can achieve substantial performance improvements for larger models. The performance gains are tied to the size and complexity of your model. Therefore, large models that contain Computer Vision Toolbox blocks run faster in Rapid Accelerator or Accelerator mode.

To change between Rapid Accelerator, Accelerator, and Normal mode, use the drop-down list at the top of the model window.

For more information on the accelerator modes in Simulink, see “Choosing a Simulation Mode” (Simulink).

Portable C Code Generation for Functions That Use OpenCV Library

The generated binary uses prebuilt OpenCV libraries that ship with the Computer Vision Toolbox product. Your compiler must be compatible with the one used to build the libraries. The following compilers are used to build the OpenCV libraries for MATLAB host:

Operating System	Compatible Compiler
Windows 64 bit	Microsoft Visual Studio 2015 Professional or Visual Studio 2017
Linux 64 bit	gcc-4.9.3 (g++)
Mac 64 bit	Xcode 6.2.0 (Clang++)

Limitations

Computer Vision Toolbox functions that use the OpenCV library do not support target code generation from Simulink.
