When you clear the **Running RMS** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `rms` function, when it is called as `y = rms(u,D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the RMS value.

The RMS value along the entire input is identical to calling the `rms` function as `y = rms(u(:))`.

When inputs are complex, the block computes the RMS value of the magnitude of the complex input.

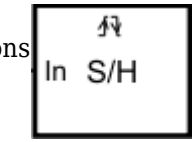
Introduced before R2006a

Sample and Hold

Sample and hold input signal

Library: DSP System Toolbox / Signal Operations
DSP System Toolbox HDL Support / Signal Operations



Description

The Sample and Hold block acquires the input at the signal port whenever it receives a trigger event at the trigger port (marked by). The block then holds the output at the acquired input value until the next triggering event occurs.

Ports

Input

`In` — Signal port

scalar | vector | matrix

The signal port can accept data in the form of a scalar, vector, or matrix.

Dependencies

This port is named **In<Lo>** when you select the **Latch (buffer) input** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Trigger` — Trigger port

scalar

The trigger input must be a sample-based scalar with sample rate equal to the input frame rate at the signal port. You specify the trigger event using the **Trigger type** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Sample and hold value

scalar | vector | matrix

Sample and hold output, returned as a scalar, vector, or a matrix. The block acquires input at the signal port whenever it receives a trigger event at the trigger port. The block then holds the acquired data until the next triggering event occurs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

`Trigger type` — Type of trigger

`Rising edge` (default) | `Falling edge` | `Either edge`

The type of event that triggers the block to acquire the input signal:

- `Rising edge` –– The trigger input rises from a negative value or zero to a positive value.
- `Falling edge` –– The trigger input falls from a positive value or zero to a negative value.
- `Either edge` –– The trigger input either rises from a negative value or zero to a positive value or falls from a positive value or zero to a negative value.

`Initial condition` — Block output prior to first trigger event

`0` (default) | scalar | vector | matrix

Specify the block's output before the first trigger event using the **Initial condition** parameter. When the acquired input is an *M*-by-*N* matrix, the **Initial condition** can be an *M*-by-*N* matrix or a scalar repeated across all elements of the matrix. When the input is a length-*M* unoriented vector, the **Initial condition** can be a length-*M* row or column vector, or a scalar to be repeated across all elements of the vector.

`Latch (buffer) input` — Latch buffer input

`off` (default) | `on`

If you select the **Latch (buffer) input** check box, the block outputs the value of the input from the previous time step until the next triggering event occurs. To use this block in a loop, select this check box.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL code for the Sample and Hold block is generated as a Triggered Subsystem. Similar restrictions apply to both blocks. See “Using Triggered Subsystems for HDL Code Generation” (HDL Coder).

HDL Block Properties

For HDL block property descriptions, see “HDL Block Properties: General” (HDL Coder).

Best Practices

When using the Sample and Hold block in models targeted for HDL code generation, consider the following:

- For synthesis results to match Simulink results, drive the trigger port with registered logic (with a synchronous clock) on the FPGA.
- It is good practice to put a unit delay on the output signal. Doing so prevents the code generator from inserting extra bypass registers in the HDL code.
- The use of triggered subsystems, such as the Sample and Hold block, can affect synthesis results in the following ways:
  - In some cases, the system clock speed can drop by a small percentage.
  - Generated code uses more resources, scaling with the number of triggered subsystem instances.

Restrictions

The Sample and Hold block must meet the following conditions:

- The DUT (i.e., the top-level subsystem for which code is generated) must not be the Sample and Hold block.
- The trigger signal must be a scalar.
- The data type of the trigger signal must be either `boolean` or `ufix1`.
- The output of the Sample and Hold block must have an initial value of 0.
- The input, output, and trigger signal of the Sample and Hold block must run at the same rate. If one of the input or the trigger signals is an output of a Signal Builder block, see “Using the Signal Builder Block” (HDL Coder) for how to match rates.

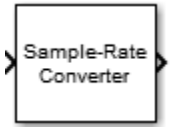
Introduced before R2006a

Sample-Rate Converter

Multistage sample-rate conversion



Library

Signal Operations

`dspsigops`

Description

The Sample-Rate Converter block implements a multistage FIR sample-rate converter. This multistage FIR converter converts the rate of each channel of the input signal from the input sample rate to the output sample rate. Multistage implementations minimize the amount of computation required by the sample-rate conversions by first reducing the sample rate of the input signal. Next, the block determines the optimal number of decimators and interpolators required based on the parameters specified in the block dialog box. Then the block designs filters in the individual stages accordingly.

The input frame size must be a multiple of the decimation factor of the rate converter. The decimation factor depends on the parameter setting of the converter. To determine the decimation factor, in the block dialog box, click **View Info** .

Each column of a two-dimensional input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size), and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel. The inputs to the block can be single or double, and real or complex.

Parameters

Sample rate of input signal (Hz)

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest. The default is `48e3`.

Sample rate of output signal (Hz)

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate must be greater than the bandwidth of interest. The default is `96e3`.

Tolerance for output sample rate

Maximum allowed tolerance for output sample rate, specified as a positive scalar in the range `[0,1]`. The default is `0`.

The actual output sample rate varies but is within the specified range. For example, suppose that you set the **Tolerance for output sample rate**, to 0.01. Then the actual output sample rate is in the range given by sample rate of output signal ± 1%. This flexibility allows for a simpler filter design.

Two-sided bandwidth of interest (Hz)

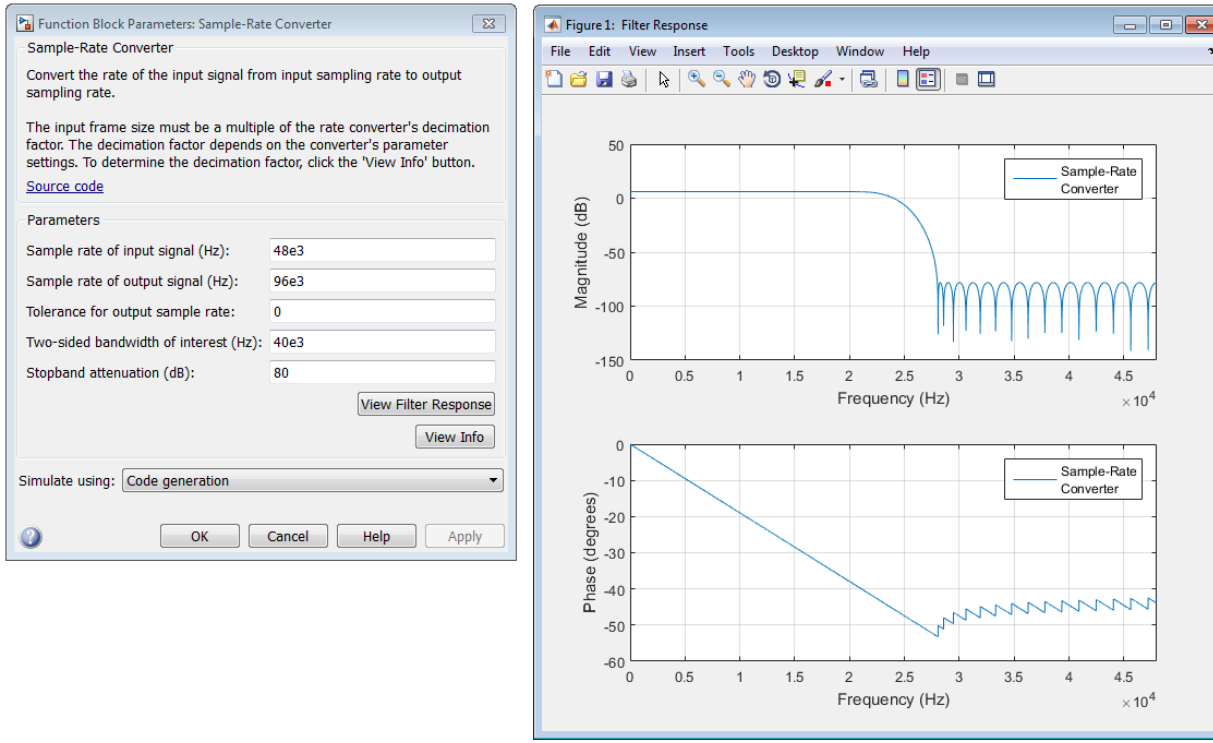
Two-sided bandwidth of interest (after the rate of conversion), specified as a positive scalar in Hz. The default is `40e3`.

Stopband attenuation (dB)

Minimum amount of attenuation for aliased components in the stopband, specified as a positive scalar in dB. The default is `80`. This parameter is the minimum amount by which any aliasing involved in the process is attenuated.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Sample-Rate Converter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

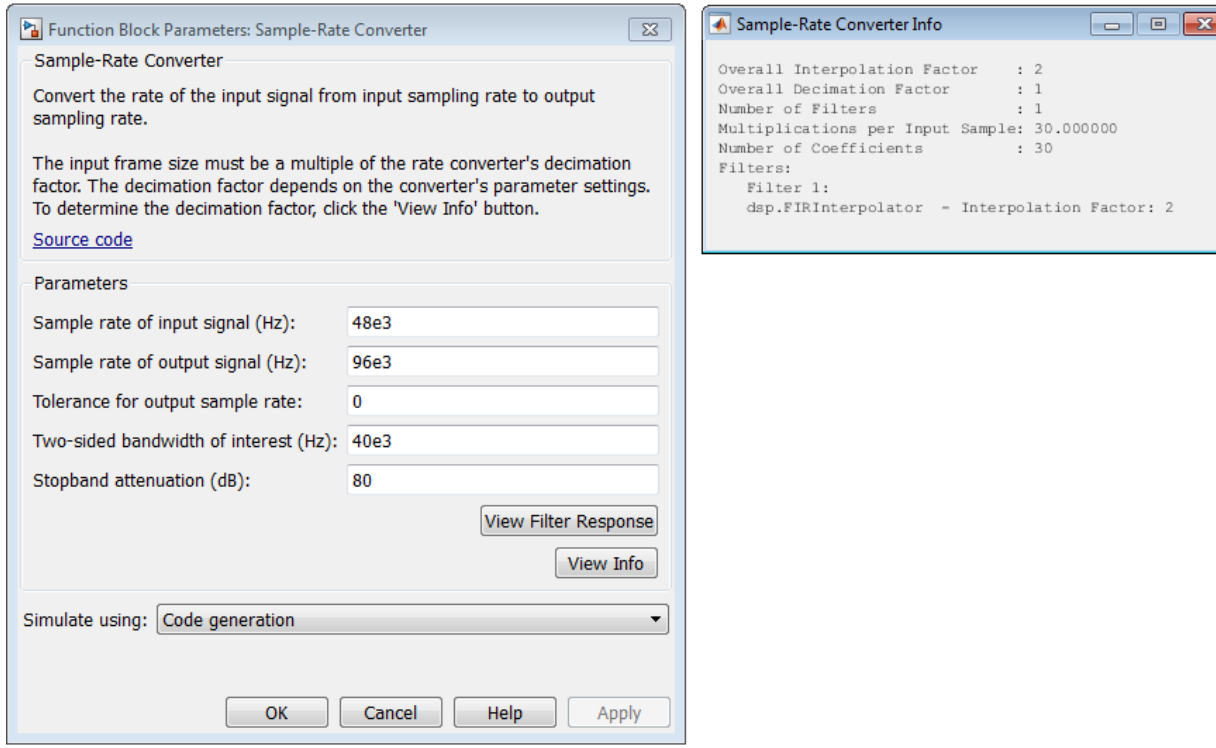


To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

View Info

Displays information about the filter system of the Sample-Rate Converter block:

- `Overall Interpolation Factor`
- `Overall Decimation Factor`
- `Number of Filters`
- `Multiplication per Input Sample`
- `Number of Coefficients`
- `Filters`



The button brings the functionality of the `info` method into the Simulink environment.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

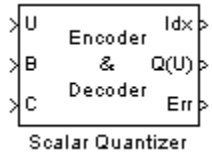
Scalar Quantizer (Obsolete)

Convert input signal into set of quantized output values or index values, or convert set of index values into quantized output signal



Library

`dspobslib`

Description

Note The Scalar Quantizer block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Scalar Quantizer Encoder block or the Scalar Quantizer Decoder block.

The Scalar Quantizer block has three modes of operation. In `Encoder` mode, the block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the index of the associated region. In `Decoder` mode, the block transforms the input index values into quantized output values, defined in the **Codebook** parameter. In the `Encoder and Decoder` mode, the block performs both the encoding and decoding operations. The block outputs the index values and the quantized output values.

You can select how you want to enter the **Boundary points** and/or **Codebook** values using the **Source of quantizer** parameters. When you select `Specify via dialog`, type the parameters into the block parameters dialog box. Select `Input ports`, and port B and/or C appears on the block. In `Encoder` and `Encoder and decoder` mode, the input to port B is used as the **Boundary points**. In `Decoder` and `Encoder and decoder` mode, the input to port C is used as the **Codebook**.

In `Encoder` and `Encoder and decoder` mode, the **Boundary points** are the values used to break up the input signal into regions. Each region is specified by an index number. When your first boundary point is `-inf` and your last boundary point is `inf`, your quantizer is unbounded. When your first and last boundary point is finite, your quantizer is bounded. When only your first or last boundary point is `-inf` or `inf`, your quantizer is semi-bounded.

For instance, when your input signal ranges from 0 to 11, you can create a bounded quantizer using the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The boundary points can have equal or varied spacing. Any input values between 0 and 0.5 would correspond to index 0. Input values between 0.5 and 3.7 would correspond to index 1, and so on.

Suppose you wanted to create an unbounded quantizer with the following boundary points:

```
[-inf 0 2 5.5 7.1 10 inf]
```

When your input signal has values less than 0, these values would be assigned to index 0. When your input signal has values greater than 10, these values would be assigned to index 6.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter defines the index to which the value is assigned. When you want the input value to be assigned to the lower index value, select `Choose the lower index`. To assign the input value with the higher index, select `Choose the higher index`.

In `Decoder` and `Encoder and decoder` mode, the **Codebook** is a vector of quantized output values that correspond to each index value.

In `Encoder` and `Encoder and decoder` mode, the **Searching method** determines how the appropriate quantizer index is found. Select `Linear` and the Scalar Quantizer block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P, where P is the number of boundary points.

Select `Binary` for the **Searching method** and the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this

boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the `Binary` option is faster than the `Linear` option.

In `Decoder` mode, the input to this block is a vector of index values, where $0 \le \text{index} < N$ and N is the length of the codebook vector. Use the **Action for out of range input** parameter to determine what happens when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to N -1, select `Clip`. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to N -1, select `Clip and warn`. When you want the simulation to stop and display an error when the index values are out of range, select `Error`.

In `Encoder and decoder` mode, you can select the **Output the quantization error** check box. The quantization error is the difference between the input value and the quantized output value. Select this check box to output the quantization error for each input value from the Err port on this block.

Data Type Support

In `Encoder` mode, the input data values and the boundary points can be the input to the block at ports U and B. Similarly, in `Encoder and decoder` mode, the codebook values can also be the input to the block at port C. The data type of the input data values, boundary points, and codebook values can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. In `Decoder` mode, the input to the block can be the index values and the codebook values. The data type of the index input to the block at port Idx can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

In `Encoder` mode, the output of the block is the index values. In `Encoder and decoder` mode, the output can also include the quantized output values and the quantization error. In `Encoder` and `Encoder and decoder` mode, use the **Output index data type** parameter to specify the data type of the index output from the block at port Idx. The data type of the index output can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the quantized output and the quantization error can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. In `Decoder` mode, the output of the block is the quantized output values. Use the **Output data type** parameter to specify the

data type of the quantized output values. The data type can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`.

Note The input data, codebook values, boundary points, quantization error, and the quantized output values must have the same data type whenever they are present in any of the quantizer modes.

Parameters

Quantizer mode

Specify `Encoder`, `Decoder`, or `Encoder and decoder` as a mode of operation.

Source of quantizer parameters

Choose `Specify via dialog` to type the parameters into the block parameters dialog box. Select `Input ports` to specify the parameters using the block's input ports. In `Encoder` and `Encoder and decoder` mode, input the **Boundary points** using port B. In `Decoder` and `Encoder and decoder` mode, input the **Codebook** values using port C.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. Tunable (Simulink).

Codebook

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

Searching method

Select `Linear` and the block finds the region in which the input value is located using a linear search. Select `Binary` and the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower index value. When you select `Choose the higher index`, the value is assigned to the higher index.

Action for out of range input

Choose the block's behavior when an input index value is out of range, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Select `Clip`, when you want any

index values less than 0 to be set to 0 and any index values greater than or equal to *N* to be set to *N* -1. Select `Clip and warn`, when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to *N* are set to *N* -1. Select `Error`, when you want the simulation to stop and display an error when the index values are out of range.

Output the quantization error

In `Encoder and decoder` mode, select this check box to output the quantization error from the Err port on this block.

Output index data type

In `Encoder` and `Encoder and decoder` mode, specify the data type of the index output from the block at port Idx. The data type can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. This parameter becomes visible when you select the **Show additional parameters** check box.

Output data type

In `Decoder` mode, specify the data type of the quantized output. The data type can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`, `single`, or `double`. This parameter becomes visible when you select `Specify via dialog` for the **Source of quantizer parameters** and you select the **Show additional parameters** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

For more information on what data types are supported for each quantizer mode, see “Data Type Support” on page 2-1606.

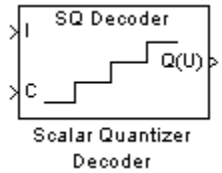
Scalar Quantizer Decoder

Convert each index value into quantized output value



Library

Quantizers

`dspquant2`

Description

The Scalar Quantizer Decoder block transforms the zero-based input index values into quantized output values. The set of all possible quantized output values is defined by the **Codebook values** parameter.

Use the **Codebook values** parameter to specify a matrix containing all possible quantized output values. You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, type the codebook values into the block parameters dialog box. When you select `Input port`, port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The input to this block is a vector of integer index values, where 0 ≤ index <*N* and *N* is the number of distinct codeword vectors in the codebook matrix. Use the **Action for out of range index value** parameter to determine what happens when an input index value is outside this range. When you want any index value less than 0 to be set to 0 and any index value greater than or equal to *N* to be set to *N* -1, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

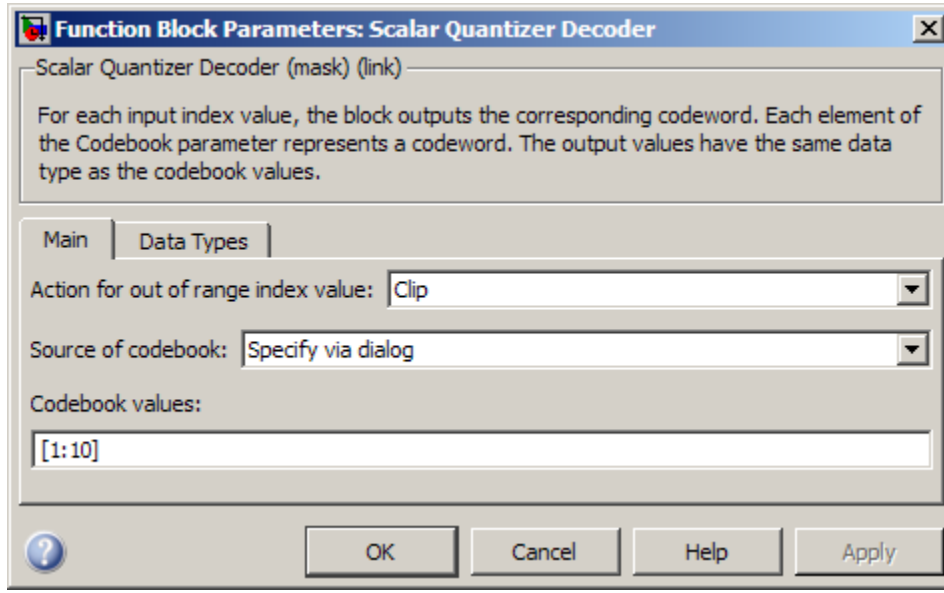
Data Type Support

The data type of the index values input at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values input at port C can be `double`, `single`, or Fixed-point.

The output of the block is the quantized output values. If, for the **Source of codebook** parameter, you select `Specify via dialog`, the **Codebook and output data type** parameter appears. You can use this parameter to specify the data type of the codebook and quantized output values. In this case, the data type of the output values can be `Same as input`, `double`, `single`, `Fixed-point`, or `User-defined`. If, for the **Source of codebook** parameter you select `Input port`, the quantized output values have the same data type as the codebook values input at port C.

Dialog Box

The **Main** pane of the Scalar Quantizer Decoder block dialog appears as follows.



Action for out of range index value

Use this parameter to determine the block's behavior when an input index value is out of range, where 0 ≤ index <*N* and *N* is the length of the codebook vector. Select `Clip`, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to *N* to be set to *N* -1. Select `Clip and warn`, when you want to be warned when clipping occurs. Select `Error`, when you want the simulation to stop and the block to display an error when the index values are outside the range.

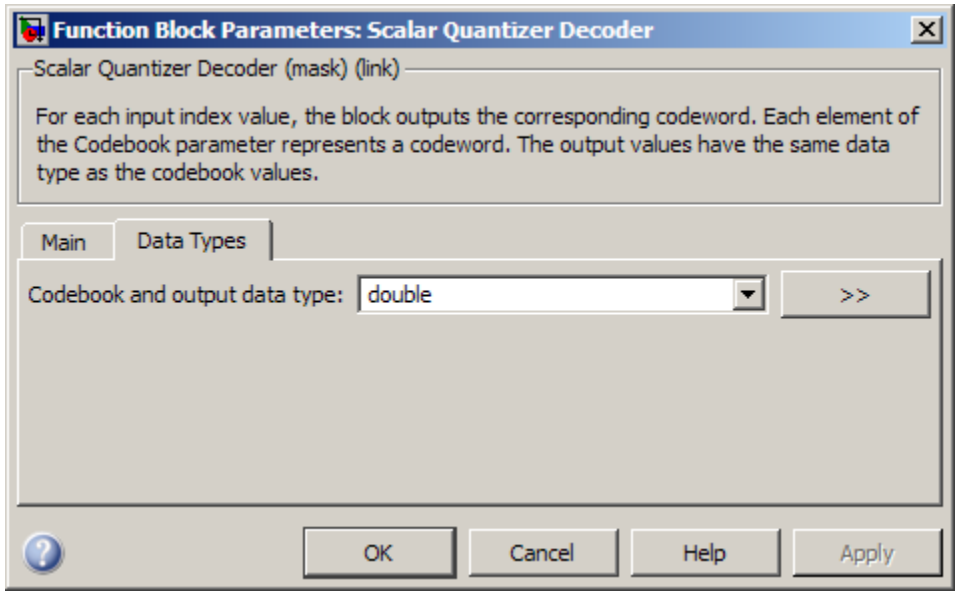
Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook using input port C.

Codebook values

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

The **Data Types** pane of the Scalar Quantizer Decoder block dialog appears as follows.



Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

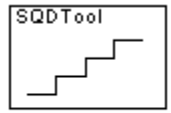
Scalar Quantizer Design

Start Scalar Quantizer Design Tool (SQDTool) to design scalar quantizer using Lloyd algorithm



Library

Quantizers

`dspquant2`

Description

Double-click on the Scalar Quantizer Design block to start SQDTool, a GUI that allows you to design and implement a scalar quantizer. Based on your input values, SQDTool iteratively calculates the codebook values that minimize the mean squared error until the stopping criteria for the design process is satisfied. The block uses the resulting quantizer codebook values and boundary points to implement your scalar quantizer encoder and/or decoder.

For the **Training Set** parameter, enter a set of observations, or samples, of the signal you want to quantize. This data can be any variable defined in the MATLAB workspace including a variable created using a MATLAB function, such as the default value `randn(10000,1)`.

You have two choices for the **Source of initial codebook** parameter. Select `Auto-generate` to have the block choose the values of the initial codebook vector. In this case, the minimum training set value becomes the first codeword, and the maximum training set value becomes the last codeword. Then, the remaining initial codewords are equally spaced between these two values to form a codebook vector of length N, where N is the **Number of levels** parameter. When you select `User defined`, enter the initial

codebook values in the **Initial codebook** field. Then, set the **Source of initial boundary points** parameter. You can select `Mid-points` to locate the boundary points at the midpoint between the codewords. To calculate the mid-points, the block internally arranges the initial codebook values in ascending order. You can also choose `User defined` and enter your own boundary points in the **Initial boundary points (unbounded)** field. Only one boundary point can be located between two codewords. When you select `User defined` for the **Source of initial boundary points** parameter, the values you enter in the **Initial codebook** and **Initial boundary points (unbounded)** fields must be arranged in ascending order.

Note This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary points are always `-inf` and `inf` regardless of any other boundary point values you might enter.

After you have specified the quantization parameters, the block performs an iterative process to design the optimal scalar quantizer. Each step of the design process involves using the Lloyd algorithm to calculate codebook values and quantizer boundary points. Then, the block calculates the squared quantization error and checks whether the stopping criteria has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared quantization error is below a certain value, select `Relative threshold`. Then, for **Relative threshold**, type the maximum acceptable fractional drop. When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter a **Relative threshold** and **Maximum iteration** value. The block stops iterating as soon as one of these conditions is satisfied.

With each iteration, the block quantizes the training set values based on the newly calculated codebook values and boundary points. When the training point lies on a boundary point, the algorithm uses the **Tie-breaking rules** parameter to determine which region the value is associated with. When you want the training point to be assigned to the lower indexed region, select `Lower indexed codeword`. To assign the training point with the higher indexed region, select `Higher indexed codeword`.

The **Searching methods** parameter determines how the block compares the training points to the boundary points. Select `Linear search` and SQDTool compares each training point to each quantization region sequentially. This process continues until all the training points are associated with the appropriate regions.

Select `Binary search` for the **Searching methods** parameter and the block compares the training point to the middle value of the boundary points vector. When the training point is larger than this boundary point, the block discards the lower boundary points. The block then compares the training point to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the training point is associated with the appropriate region.

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the staircase character of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool dialog box.

SQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file. The **Error** values represent the mean squared error for each iteration.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select `Current model` to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Scalar Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Scalar Quantizer Decoder block. When you have a Scalar Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block(s)** check box to replace the block's parameters with the current parameters. When you do not select this check

box, a new Scalar Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is `1e6`.

Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Select `User defined` to enter your own initial codebook values.

Number of levels

Enter the length of the codebook vector. For a b-bit quantizer, the length should be $N = 2^b$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter.

Source of initial boundary points

Select `Mid-points` to locate the boundary points at the midpoint between the codebook values. Choose `User defined` to enter your own boundary points. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter.

Initial boundary points (unbounded)

Enter your initial boundary points. This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary point are `-inf` and `inf`, regardless of any other boundary point values you might enter. From the **Source of initial boundary points** list, select `User defined` in order to activate this parameter.

Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number

of iterations at which to stop. Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

Type the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

Enter the maximum number of iterations you want the block to perform. From the **Stopping criteria** list, select `Maximum iteration` in order to activate this parameter.

Searching methods

Choose `Linear search` to use a linear search method when comparing the training points to the boundary points. Choose `Binary search` to use a binary search method when comparing the training points to the boundary points.

Tie-breaking rules

When a training point lies on a boundary point, choose `Lower indexed codeword` to assign the training point to the lower indexed quantization region. Choose `Higher indexed codeword` to assign the training point to the higher indexed region.

Design and Plot

Click this button to display the performance curve and the staircase character of the quantizer in the figures on the right side of the GUI. These plots are based on the current parameter settings.

You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file.

Destination

Choose `Current model` to create a Scalar Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type

Select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

Encoder block name

Enter a name for the Scalar Quantizer Encoder block.

Decoder block name

Enter a name for the Scalar Quantizer Decoder block.

Overwrite target block(s)

When you do not select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Scalar Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

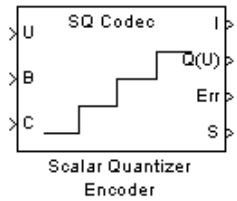
Scalar Quantizer Encoder

Encode each input value by associating it with index value of quantization region



Library

Quantizers

`dspquant2`

Description

The Scalar Quantizer Encoder block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the zero-based index of the associated region.

You can select how you want to enter the **Boundary points** using the **Source of quantizer parameters**. When you select `Specify via dialog`, type the boundary points into the block parameters dialog box. When you select `Input port`, port B appears on the block. The block uses the input to port B as the **Boundary points** parameter.

Use the **Boundary points** parameter to specify the boundary points for your quantizer. These values are used to break up the set of input numbers into regions. Each region is specified by an index number.

Let `N` be the number of quantization regions. When the codebook is defined as `[c1 c2 c3 ... cN]`, and the **Boundary points** parameter is defined as `[p0 p1 p2 p3 ... pN]`, then `p0<c1<p1<c2 ... p(N-1)<cN<pN` for a regular quantizer. When your quantizer is bounded, from the **Partitioning** list, select `Bounded`. You need to specify N

+1 boundary points, or `[p0 p1 p2 p3 ... pN]`. When your quantizer is unbounded, from the **Partitioning** list, select `Unbounded`. You need to specify N-1 boundary points, or`[p1 p2 p3 ... p(N-1)]`; the block sets `p0` equal to -`inf` and `pN` equal to `inf`.

The block uses the **Partitioning** parameter to interpret the boundary points you enter. For instance, to create a bounded quantizer, from the **Partitioning** list, select `Bounded` and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 0, input values between 0.5 and 3.7 to index 1, and so on. The block assigns any values that are less than 0 to index 0, the lowest index value. The block assigns any values that are greater than 11 to index 4, the highest index value.

To create an unbounded quantizer, from the **Partitioning** list, select `Unbounded` and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 1, input values between 0.5 and 3.7 to index 2, and so on. The block assigns any input values less than 0 to index 0 and any values greater than 11 to index 6.

The **Searching method** parameter determines how the appropriate quantizer index is found. When you select `Linear`, the Scalar Quantizer Encoder block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P, where P is the number of boundary points.

When you select `Binary` for the **Searching method**, the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the `Binary` option is faster than the `Linear` option.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter determines the region to which the value is assigned. When you want the input value to

be assigned to the lower indexed region, select `Choose the lower index`. To assign the input value with the higher indexed region, select `Choose the higher index`.

Select the **Output codeword** check box to output the codeword values that correspond to each index value at port Q(U).

Select the **Output the quantization error** check box to output the quantization error for each input value from the Err port on this block. The quantization error is the difference between the input value and the quantized output value.

When you select either the **Output codeword** check box or the **Output quantization error** check box, you must also enter your codebook values. If, from the **Source of quantizer parameters** list, you choose `Specify via dialog`, use the **Codebook** parameter to enter a vector of quantized output values that correspond to each region. If, from the **Source of quantizer parameters** list, you choose `Input port`, use input port C to specify your codebook values.

If, for the **Partitioning** parameter, you select `Bounded`, the **Output clipping status** check box and the **Action for out of range input** parameter appear. When you select the **Output clipping status** check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at the S port. When the value is inside the range, the blocks outputs a 0.

You can use the **Action for out of range input** parameter to determine the block's behavior when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points for a bounded quantizer are defined as `[p0 p1 p2 p3 ... pN]` and the possible index values are defined as `[i0 i1 i2 ... i(N-1)]`, where `i0=0` and `i0<i1<i2<...<i(N-1)`. When you want any input value less than `p0` to be assigned to index value `i0` and any input values greater than `pN` to be assigned to index value `i(N-1)`, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

The Scalar Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1625 or “Supported Data Types” on page 2-1628.

Data Type Support

The input data values, boundary points, and codebook values can be input to the block at ports U, B, and C, respectively. The data type of the inputs can be `double`, `single`, or Fixed-point.

The outputs of the block can be the index values, the quantized output values, the quantization error, and the clipping status. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the quantized output and the quantization error can be `double`, `single`, or Fixed-point. The clipping status values output at port S are Boolean values.

Note The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

Dialog Box

Main Tab

Source of quantizer parameters

Choose `Specify via dialog` to enter the boundary points and codebook values using the block parameters dialog box. Select `Input port` to specify the parameters using the block's input ports. Input the boundary points and codebook values using ports B and C, respectively.

Partitioning

When your quantizer is bounded, select `Bounded`. When your quantizer is unbounded, select `Unbounded`.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. This parameter is visible when you select `Specify via dialog` from the **Source of quantizer parameters** list. Tunable (Simulink).

Searching method

When you select `Linear`, the block finds the region in which the input value is located using a linear search. When you select `Binary`, the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower indexed region. When you select `Choose the higher index`, the value is assigned to the higher indexed region.

Output codeword

Select this check box to output the codeword values that correspond to each index value at port Q(U).

Output quantization error

Select this check box to output the quantization error for each input value at port Err.

Codebook

Enter a vector of quantized output values that correspond to each index value. If, for the **Partitioning** parameter, you select `Bounded` and your boundary points vector has length N, then you must specify a codebook of length N-1. If, for the **Partitioning** parameter, you select `Unbounded` and your boundary points vector has length N, then you must specify a codebook of length N+1.

This parameter is visible when you select `Specify via dialog` from the **Source of quantizer parameters** list and you select either the **Output codeword** or **Output quantization error** check box. Tunable (Simulink).

Output clipping status

When you select this check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at this port. When the value is inside the range, the block outputs a 0. This parameter is visible when you select `Bounded` from the **Partitioning** list.

Action for out of range input

Use this parameter to determine the behavior of the block when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points are defined as `[p0 p1 p2 p3 ... pN]` and the index values are defined as `[i0 i1 i2 ... i(N-1)]`. When you want any input value less than `p0` to be assigned to index value `i0` and any input values greater than `pN` to be assigned to index value `i(N-1)`, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`. This parameter is visible when you select `Bounded` from the **Partitioning** list.

Index output data type

Specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, or `Inherit via back propagation`.

Data Types Tab

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- `Floor`
- `Ceiling`
- `Convergent`
- `Nearest`
- `Round`
- `Simplest`
- `Zero`

For more details, see rounding mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Supported Data Types

Port	Supported Data Types
U	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
C	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
I	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Q(U)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Err	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
S	• Boolean

For more information on what data types are supported for each quantizer mode, see “Data Type Support” on page 2-1625.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is `0`. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see "OutputPipeline" (HDL Coder).

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to `inherit`, `Max`, `Min`, or `Zero` for the floating-point operator. The default is `inherit`. See also "LatencyStrategy" (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

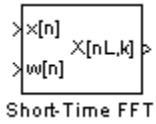
Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Introduced in R2008a

Short-Time FFT

Nonparametric estimate of spectrum using short-time, fast Fourier transform (FFT) method



Library

Transforms

`dspxfrm3`

Description

The Short-Time FFT block computes a nonparametric estimate of the spectrum. The block buffers, applies a window, and zero pads the input signal. The block then takes the FFT of the signal, transforming it into the frequency domain.

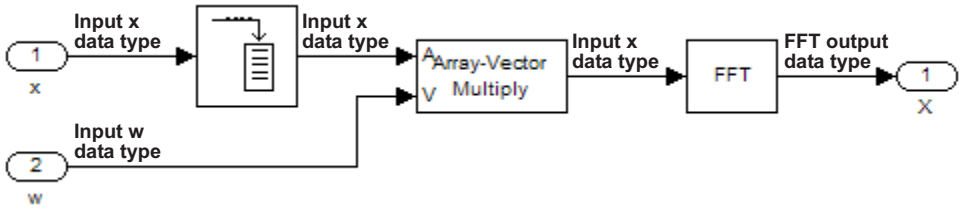
Connect your single-channel analysis window to the w(n) port. For the **Analysis window length** parameter, enter the length of the analysis window, *W*. The block buffers the input signal such that it has a frame length of *W*

Connect your single-channel or multichannel input signal to the x(n) port. After the block buffers and windows this signal, it zero-pads the signal before computing the FFT. For the **FFT length** parameter, enter the length to which the block pads the input signal. For the **Overlap between consecutive windows (in samples)** parameter, enter the number of samples to overlap each frame of the input signal.

The block outputs the complex-valued, single-channel or multichannel short-time FFT at port X(n,k).

Fixed-Point Data Types

The following diagram shows the data types used within the Short-Time FFT subsystem block for fixed-point signals.



The settings for the fixed-point parameters of the Array-Vector Multiply block in the diagram above are as follows:

- **Rounding Mode** — `Floor`
- **Saturate on integer overflow** — `Wrap`
- **Product output** — `Inherit via internal rule`
- **Accumulator** — `Inherit via internal rule`
- **Output** — `Same as first input`

The settings for the fixed-point parameters of the FFT block in the diagram above are as follows:

- **Rounding Mode** — `Floor`
- **Saturate on integer overflow** — `Wrap`
- **Sine table** — `Same word length as input`
- **Product output** — `Inherit via internal rule`
- **Accumulator** — `Inherit via internal rule`
- **Output** — `Inherit via internal rule`

See the FFT and Array-Vector Multiply block reference pages for more information.

Examples

The `dspstsa` example illustrates how to use the Short-Time FFT and Inverse Short-Time FFT blocks to remove the background noise from a speech signal. To open the `dspstsa` model, type `dspstsa` in the MATLAB command prompt.

Parameters

Analysis window length

Specify the frame length of the analysis window. The **Analysis window length** must be a positive integer value greater than one.

Overlap between consecutive windows (in samples)

Enter the number of samples of overlap for each frame of the input signal.

FFT length

Enter the length to which the block pads the input signal.

Supported Data Types

Port	Supported Data Types
x(n)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
w(n)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
X(n,k)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

References

[1] Quatieri, Thomas E. *Discrete-Time Speech Signal Processing.* Englewood Cliffs, NJ: Prentice-Hall, 2001.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on `memcpy` or `memset` functions (string.h) under certain conditions.
- When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

  When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

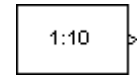
Signal From Workspace

Import signal from MATLAB workspace
Library: DSP System Toolbox / Sources



Description

The Signal From Workspace block imports a signal from the MATLAB workspace into the Simulink model. The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

Unlike the Simulink From Workspace block, the Signal From Workspace block holds the output value constant between successive output frames (that is, no linear interpolation takes place). Also, the initial signal values are always produced immediately at t=0.

Ports

Output

`Port_1` — Signal imported from workspace

scalar | vector | matrix | 3-D array

Signal imported from workspace, as a scalar, vector, matrix, or 3-D array.

When the **Signal** parameter specifies an M-by-N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o. The output is an M_o-by-N matrix containing M_o consecutive samples from each signal channel. You specify the output sample period in the **Sample time** parameter, T_s, and the output frame period is $M_o T_s$. For convenience, an imported row vector (M=1) is treated as a single channel, so the output dimension is M_o-by-1.

When the **Signal** parameter specifies an M-by-N-by-P array, each of the P pages (an M-by-N matrix) is output in sequence with period T_s. The **Samples per frame** parameter must be set to 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Signal` — Signal to import

`1:10` (default) | MATLAB workspace variable | MATLAB expression

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

`Sample time` — Output sample period

`1` (default) | scalar | vector

The sample period, T_s, of the output, specified as a scalar or vector. The output frame period is $M_o T_s$.

`Samples per frame` — Samples per frame

`1` (default) | positive integer

The number of samples, M_o, to buffer into each output frame, specified as a positive integer scalar. This value must be `1` when you specify a 3-D array in the **Signal** parameter.

`Form output after final data value by` — Values to output after final imported signal value

`Setting to zero` (default) | `Holding final value` | `Cyclic repetition`

Specifies the output after all of the specified signal samples have been generated.

- When you specify `Setting To Zero`, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify `Holding Final Value`, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify `Cyclic Repetition`, the block repeats the signal from the beginning after it reaches the last sample in the signal. If the frame size you specify in the **Samples per frame** parameter does not evenly divide the input length, a buffer block is inserted into the Signal From Workspace subsystem, and the model becomes multirate. If you do not want your model to become multirate, make sure that the frame size evenly divides the input signal length.

The block does not extrapolate the imported signal beyond the last sample.

`Warn when frame size does not evenly divide input length` — Warn when input length is not an integer multiple of frame size
`off` (default) | `on`

Select the **Warn when frame size does not evenly divide input length** parameter to be alerted when the input length is not an integer multiple of the frame size. When the input length is not an integer multiple of the frame size, the model becomes multirate. Use the Model Explorer to turn these warnings on or off model-wide:

a In the **Modeling** tab, click **Model Explorer**.

b In the **Search** bar of the Model Explorer, search `by Property Name` for the `ignoreOrWarnInputAndFrameLengths` property. Each block with the **Warn when frame size does not evenly divide input length** check box appears in the list in the **Contents** pane.

c Select each of the blocks for which you want to toggle the warning parameter, and select or clear the check box in the `ignoreOrWarnInputAndFrameLengths` column.

Dependencies

To enable this parameter set **Form output after final data value by** to `Cyclic Repetition`.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`

Signal To Workspace

Write data to MATLAB workspace

Compatibility

Note The Signal To Workspace block has been replaced by the To Workspace block in Simulink. Existing instances of the Signal To Workspace block will continue to operate. For new models, use the To Workspace block.

Library

Sinks

`dspsnks4`

Description

The Signal To Workspace block writes data from your simulation into an array or structure in the main MATLAB workspace. You can specify a name for the workspace variable as well as whether the data is saved as an array, structure, or structure with time.

When the **Save format** is set to `Array` or `Structure`, the dimensions of the output depend on the input dimensions and the setting of the **Save 2-D signals as** parameter. The following table summarizes the output dimensions under various conditions. In the table, *K* represents the value of the **Limit data points to last** parameter.

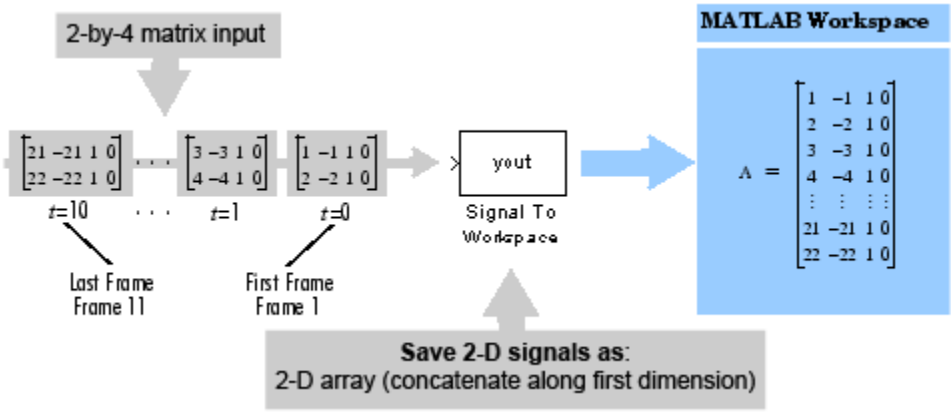
Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
M-by-*N* matrix	`2-D array (concatenate along first dimension)`	*K*-by-*N* matrix. If you set the **Limit data points to last** parameter to `inf`, *K* represents the total number of samples acquired in each column by the end of simulation. This is equivalent to multiplying the input frame size (*M*) by the total number of *M*-by-*N* inputs acquired by the block.
M-by-*N* matrix	`3-D array (concatenate along third dimension)`	*M*-by-*N*-by-*K* array. If you set the **Limit data points to last** parameter to `inf`, *K* represents the total number of *M*-by-*N* inputs acquired by the end of the simulation.
Length-*N* unoriented vector	Any setting	*K*-by-*N* matrix
N-dimensional array where $N > 2$	Any setting	Array with *N+1* dimensions, where the size of the last dimension is equal to *K*. If you set the **Limit data points to last** parameter to `inf`, *K* represents the total number of *M*-by-*N* inputs acquired by the end of simulation

Examples

Example 1: Save 2-D Signals as a 2-D Array

In the ex_signaltoworkspace_ref2 model, the Signal To Workspace block receives a 2-by-4 matrix input and logs 11 frames (two samples per frame) by the end of the simulation. Because the **Save 2-D signals as** parameter is set to `2-D array (concatenate along first dimension)`, the block concatenates the input along the first dimension to create a 22-by-4 matrix, *A*, in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.

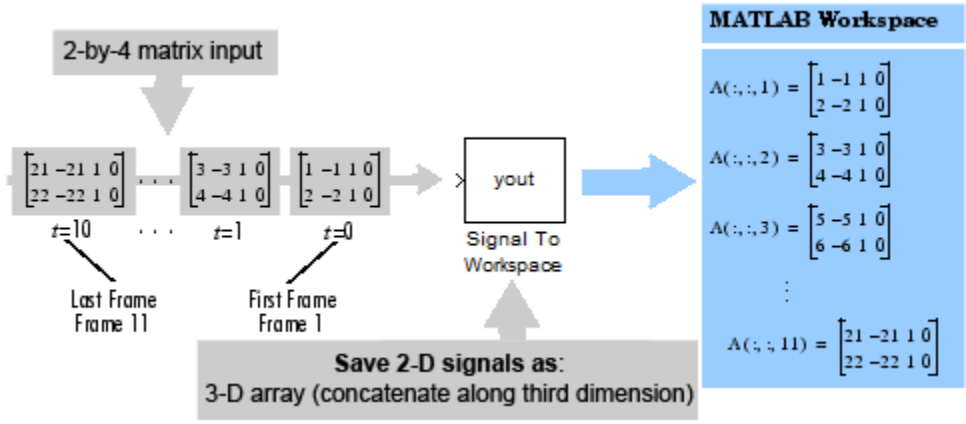


In the 2-D output mode, there is no indication of where one frame ends and another begins. To log input frames separately, set the **Save 2-D signals as** parameter to `3-D array (concatenate along third dimension)`, as shown in Example 2.

Example 2: Save 2-D Signals as a 3-D Array

In the ex_signaltoworkspace_ref1 model, the input to the Signal To Workspace block is a 2-by-4 matrix. The **Save 2-D signals as** parameter is set to `3-D array (concatenate along third dimension)`, so by the end of the simulation the Signal To Workspace block logs 11 frames of data as a 2-by-4-by-11 array, *A*, in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.



Parameters

Variable name

Specify the name of the array or structure into which the block logs the simulation data. The block creates this variable in the MATLAB workspace only after the simulation stops running. When you enter the name of an existing workspace variable, the block overwrites that variable with the simulation data.

Limit data points to last

Specify the maximum number of samples or frames the block will save. When the simulation generates more than the specified maximum number of samples or frames, the simulation saves only the most recently generated data. To capture all data, set this parameter to `inf`. See the table in the Description on page 2-1641 section for more information on how this parameter affects the dimensions of the logged data.

Decimation

Specify a positive integer *d* to determine how often the block writes data to the workspace array or structure. The block writes data to the array or structure every *d*th sample. With the default decimation value of `1`, the block writes data at every time step.

Save format

Specify the format in which to save simulation output to the workspace. You can select one of the following options:

- `Array` — Select this option to save the data as an N-dimensional array. If the input signal is an unoriented vector, the resulting workspace array is 2-D. Each input vector is saved in a row of the output matrix, vertically concatenated onto the previous vector. If the input signal is 2-dimensional, the dimensions of the resulting workspace array depend on the setting of the **Save 2-D signals as** parameter.
- `Structure` — Select this option to save the data as a structure consisting of three fields: `time`, `signals` and `blockName`. In this mode, the `time` field is empty, and the `blockName` field contains the name of the Signal To Workspace block. The `signals` field contains a structure with three additional fields: `values`, `dimensions`, and `label`. The `values` field contains the array of signal values, the `dimensions` field specifies the dimensions of the values array, and the `label` field contains the label of the input line.
- `Structure with time` — This option is the same as `Structure`, except that the `time` field contains a vector of simulation time steps. This is the only output format that can be read directly by a From Workspace block. When you select this option, the **Save 2-D signals as** parameter is not available. In this mode, the block always saves 2-D input arrays as a 3-D array.

The default setting of this parameter is `Array`.

Save 2-D signals as

Specify whether the block outputs 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- `2-D array (concatenate along first dimension)` — When you select this option, the block saves an *M*-by-*N* input signal as a (*K***M*)-by-*N* matrix, where *K***M* is the total number of samples acquired by the end of the simulation. The block vertically concatenates each *M*-by-*N* matrix input with the previous input to produce the 2-D output array. See “Example 1: Save 2-D Signals as a 2-D Array” on page 2-1643 for more information about this mode.
- `3-D array (concatenate along third dimension)` — When you select this option, the block saves an *M*-by-*N* input signal as an *M*-by-*N*-by-*K* array, where *K* is the number of *M*-by-*N* inputs logged by the end of the simulation. *K* has an upper bound equal to the value of the **Limit data points to last** parameter. See “Example 2: Save 2-D Signals as a 3-D Array” on page 2-1643 for more information about this mode.

This parameter is visible only when you set the **Save format** parameter to `Array` or `Structure`. When you set the **Save format** parameter to `Structure with time`, the block outputs the 2-D input signal as a 3-D array.

Note The `Inherit from input (this choice will be removed - see release notes)` option will be removed in a future release. See "Signal To Workspace Block Changes" in the *DSP System Toolbox Release Notes* for more information.

Log fixed-point data as a fi object

Select this check box to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Introduced before R2006a

Sine Wave

Generate continuous or discrete sine wave

Library: DSP System Toolbox / Sources
DSP System Toolbox HDL Support / Sources

Description

The Sine Wave block generates a multichannel real or complex sinusoidal signal, with independent amplitude, frequency, and phase in each output channel. The block supports floating point and signed fixed-point data types.

The block generates a real sinusoidal signal when you set the **Output complexity** parameter to `Real`. The real sinusoidal output is defined by an expression of the type

$$y = A\sin(2\pi ft + \phi)$$

where you specify A in the **Amplitude** parameter, f in hertz in the **Frequency** parameter, and ϕ in radians in the **Phase offset** parameter.

The block generates a complex exponential signal when you set the **Output complexity** parameter to `Complex`. This complex exponential signal is defined by an expression of the type

$$y = Ae^{j(2\pi ft + \phi)} = A\{\cos(2\pi ft + \phi) + j\sin(2\pi ft + \phi)\}$$

Generating Multichannel Outputs

For both real and complex sinusoids, the **Amplitude**, **Frequency**, and **Phase offset** parameter values (A, f, and ϕ) can be scalars or length-N vectors, where N is the desired number of channels in the output. When you specify at least one of these parameters as a length-N vector, scalar values specified for the other parameters are applied to every channel.

For example, to generate the three-channel output containing the following real sinusoids, set the block parameters as shown:

$$y = \begin{cases} \sin(2000\pi t) & \text{(channel 1)} \\ 2\sin(1000\pi t) & \text{(channel 2)} \\ 3\sin\left(500\pi t + \frac{\pi}{2}\right) & \text{(channel 3)} \end{cases}$$

- **Output complexity** = `Real`
- **Amplitude** = `[1 2 3]`
- **Frequency** = `[1000 500 250]`
- **Phase offset** = `[0 0 pi/2]`

Ports

Output

`Port_1` — Sinusoidal signal

scalar | vector | matrix

Output a sinusoidal signal as a scalar or vector. For more information about output complexity, see “Description” on page 2-1647. For information about multichannel support, see “Generating Multichannel Outputs” on page 2-1647.

Tip To output fixed-point data types, you must set **Sample mode** to `Discrete` and **Computation method** to `Table lookup`.

Data Types: `single` | `double` | `fixed point`
Complex Number Support: Yes

Parameters

Main

`Amplitude` — Amplitude of sine waves

1 (default) | scalar | vector

A length-*N* vector containing the amplitudes of the sine waves in each of *N* output channels, or a scalar to be applied to all *N* channels. The vector length must be the same as that specified for the **Frequency** and **Phase offset** parameters.

Tip This parameter is tunable (Simulink) only when the **Computation method** is `Trigonometric fcn` or `Differential`.

Tunable: Yes

`Frequency (Hz)` — Frequency of each sine wave

`100` (default) | scalar | vector

A length-*N* vector containing frequencies, in hertz, of the sine waves in each of *N* output channels, or a scalar to be applied to all *N* channels. The vector length must be the same as that specified for the **Amplitude** and **Phase offset** parameters. You can specify positive, zero, or negative frequencies.

Tip This parameter is tunable (Simulink) when you set either:

- **Sample mode** to `Continuous`.
- **Sample mode** to `Discrete` and **Computation method** to `Trigonometric fcn`.

Tunable: Yes

`Phase offset (rad)` — Phase offset

`0` (default) | scalar | vector

A length-*N* vector containing the phase offsets, in radians, of the sine waves in each of *N* output channels, or a scalar to be applied to all *N* channels. The vector length must be the same as that specified for the **Amplitude** and **Frequency** parameters.

Tip This parameter is tunable (Simulink) when you set either:

- **Sample mode** to `Continuous`.
- **Sample mode** to `Discrete` and **Computation method** to `Trigonometric fcn`.

Tunable: Yes

`Sample mode` — Continuous or discrete sampling mode

`Discrete` (default) | `Continuous`

Specify the sampling mode as `Continuous` or `Discrete`:

- `Continuous`

  In continuous mode, the sinusoid in the *i*th channel, y_i, is computed as a continuous function,

  $y_i = A_i \sin(2\pi f_i t + \phi_i)$ (real)

  or

  $y_i = A_i e^{j(2\pi f_i t + \phi_i)}$ (complex)

  and the block's output is continuous. In this mode, the block operates the same as the Simulink Sine Wave block with **Sample time** set to `0`. This mode offers high accuracy, but requires trigonometric function evaluations at each simulation step, which is computationally expensive. Also, because this method tracks absolute simulation time, a discontinuity will eventually occur when the time value reaches its maximum limit.

  Note also that many DSP System Toolbox blocks do not accept continuous-time inputs.

- `Discrete`

  In discrete mode, the block can generate discrete-time output by directly evaluating the trigonometric function, by table lookup, or by a differential method. For more information on these computation methods, see “Algorithms” on page 2-1653.

`Output complexity` — Real or complex waveform

`Real` (default) | `Complex`

The type of waveform to generate: `Real` specifies a real sine wave, `Complex` specifies a complex exponential.

`Computation method` — Method for computing discrete-time sinusoids

`Trigonometric fcn` (default) | `Table lookup` | `Differential`

The method by which discrete-time sinusoids are generated: `Trigonometric fcn`, `Table lookup`, or `Differential`. For more information on each of the available options, see “Algorithms” on page 2-1653.

Dependencies

This parameter is only visible when you set the **Sample mode** to `Discrete`.

Note To generate fixed-point sinusoids, you must set the **Computation method** to `Table lookup`.

`Optimize table for` — Optimize for speed or memory

`Speed` (default) | `Memory`

Optimizes the table of sine values for `Speed` or `Memory`. When optimized for speed, the table contains k elements, and when optimized for memory, the table contains $k/4$ elements, where k is the number of input samples in one full period of the sine wave.

Dependencies

This parameter is only visible when you set the **Computation method** parameter to `Table lookup`.

`Sample time` — Sample period

`1/1000` (default) | scalar

The period with which the sine wave is sampled, T_s, as a finite scalar, greater than zero. The output frame period of the block is MT_s, where you specify M in the **Samples per frame** parameter.

Dependencies

To enable this parameter, set **Sample mode** to `Discrete`.

`Samples per frame` — Samples per frame

`1` (default) | positive integer

The number of consecutive samples from each sinusoid to buffer into the output frame, M, specified as a positive scalar integer. This parameter is not tunable.

The block output is an M-by-N matrix with frame period MT_s, where you specify T_s in the **Sample time** parameter.

Dependencies

To enable this parameter, set **Sample mode** to `Discrete`.

`Resetting states when re-enabled` — State behavior inside enabled subsystems
`Restart at time zero` (default) | `Catch up to simulation time`

This parameter determines the behavior of the Sine Wave block when an enabled subsystem is reenabled. The block can either reset itself to its starting state (`Restart at time zero`), or resume generating the sinusoid based on the current simulation time (`Catch up to simulation time`).

Dependencies

This parameter only applies when the Sine Wave block is located inside an enabled subsystem and the **States when enabling** parameter of the Enable block is set to `reset`.

Data Types

`Output data type` — Output data type
`double` (default) | `single` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>` | `Inherit:Inherit via back propagation`

Select how you would like to specify the data type properties of the **Output data type**. You can choose:

- `Inherit` — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via back propagation`
- `Built in`— Lets you specify a built in data type, for example, `double`
- `Fixed point` — Lets you specify the fixed-point attributes of the data type.
- `Expression` — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

When you select `Discrete` from the **Sample mode** parameter, the secondary **Computation method** parameter provides three options for generating the discrete sinusoid: `Trigonometric fcn`, `Table lookup`, and `Differential`.

Trigonometric Fcn

The trigonometric function method computes the sinusoid in the *i*th channel, y_i, by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad \text{(real)}$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \quad \text{(complex)}$$

with a period of T_s, where you specify T_s in the **Sample time** parameter. This mode of operation has the same benefits and liabilities as the `Continuous` sample mode.

At each sample time, the block evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the block avoids the imprecision of computing the sine of very large numbers, and eliminates the possibility of discontinuity during extended operations (when an absolute time variable might overflow). This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table

of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/(f_i T_s) = k_i$ must be an integer value for every channel $i = 1, 2, ..., N$.

When the **Optimize table for** parameter is set to `Speed`, the table constructed for each channel contains k_i elements. When the **Optimize table for** parameter is set to `Memory`, the table constructed for each channel contains $k_i/4$ elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods, but can demand considerably more memory, especially for high sample rates (long tables). This method is recommended for models that are intended to emulate or generate code for DSP hardware, and that therefore must be optimized for execution speed.

Note The lookup table for this block is constructed from double-precision floating-point values. Thus, when you use the `Table lookup` computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** or **User-defined** data type to values greater than 53 bits does not improve the precision of your output.

Tip To generate fixed-point sinusoids, you must select `Table Lookup`.

Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by using the following identities.

$$\sin(t + T_s) = \sin(t)\cos(T_s) + \cos(t)\sin(T_s)$$
$$\cos(t + T_s) = \cos(t)\cos(T_s) - \sin(t)\sin(T_s)$$

The update equations for the sinusoid in the ith channel, y_i, can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t + T_s) + \phi_i\} \\ \cos\{2\pi f_i(t + T_s) + \phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t + \phi_i) \\ \cos(2\pi f_i t + \phi_i) \end{bmatrix}$$

where you specify T_s in the **Sample time** parameter. Since T_s is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of

$A_i\sin[2\pi f_i(t+T_s)+\phi_i]$ is then computed from the values of $\sin(2\pi f_i t+\phi_i)$ and $\cos(2\pi f_i t+\phi_i)$ by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations (when an absolute time variable might overflow).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Sine Wave block references absolute simulation time when configured in continuous sample mode.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

Restrictions

For HDL code generation, you must select the following Sine Wave block settings:

- **Computation method**: `Table lookup`
- **Sample mode**: `Discrete`

Output:

- The output port cannot have data types `single` or `double`.

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

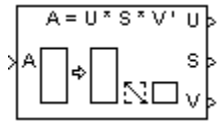
Singular Value Decomposition

Factor matrix using singular value decomposition



Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`

Description

The Singular Value Decomposition block factors the *M*-by-*N* input matrix *A* such that

$$A = U \cdot diag(S) \cdot V^*$$

where

- *U* is an *M*-by-*P* matrix
- *V* is an *N*-by-*P* matrix
- *S* is a length-*P* vector
- *P* is defined as min(*M*,*N*)

When

- *M* = *N*, *U* and *V* are both *M*-by-*M* unitary matrices
- *M* > *N*, *V* is an *N*-by-*N* unitary matrix, and *U* is an *M*-by-*N* matrix whose columns are the first *N* columns of a unitary matrix
- *N* > *M*, *U* is an *M*-by-*M* unitary matrix, and *V* is an *N*-by-*M* matrix whose columns are the first *M* columns of a unitary matrix

In all cases, *S* is an unoriented vector of positive singular values having length *P*.

Length-*N* row inputs are treated as length-*N* columns.

Note that the first (maximum) element of output *S* is equal to the 2-norm of the matrix *A*.

Parameters

Show singular vector ports

Select to enable the `U` and `V` output ports.

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- `0` — The singular value decomposition calculation converges.
- `1` — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at ports U, S, and V are undefined matrices of the correct size.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Interpreted execution` (default)

  Simulate model using the MATLAB interpreter. This option shortens startup time.

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time.

Sort

Sort input elements by value
Library: DSP System Toolbox / Statistics

Description

The Sort block ranks the values of the input elements along each channel (column) in an `Ascending` or a `Descending` order, based on the **Sort order** you specify. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. You can choose the **Sort algorithm** to be either `Quick sort` or `Insertion sort`. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, use the insertion sort algorithm to avoid recursive function calls.

The **Mode** parameter specifies the block's mode of operation, which you can set to `Value`, `Index`, or `Value and Index`.

Ports

Input

`Port_1` — Data input

vector | matrix

The block accepts real-valued or complex-valued multichannel inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Val` — Sorted data

vector | matrix

The block sorts the data along each channel and outputs the sorted data through this port. The size, data type, and complexity of the sorted data matches that of the input data. The block sorts complex inputs according to their magnitude.

Dependencies

To enable this port, set the **Mode** parameter to `Value and index` or `Value`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Idx` — Index of the sorted data

vector | matrix

The output at this port contains the indices of the sorted data.

Dependencies

To enable this port, set the **Mode** parameter to `Value and index` or `Index`.

Data Types: `uint32`

Parameters

Main Tab

`Mode` — Specify whether block returns values, indices, or both

`Value and Index` (default) | `Value` | `Index`

When the **Mode** parameter is set to:

- `Value` — The block sorts the elements in each channel of the *M*-by-*N* input matrix in an ascending or descending order, based on what you specify in the **Sort order** parameter. The output at each sample time, *Val*, is an *M*-by-*N* matrix that contains the sorted columns of the input.

  The block sorts complex inputs according to their magnitude.

- `Index` — The block sorts the elements in each channel of the *M*-by-*N* input matrix, and outputs the index array, *I*. Each element in *I* is an integer of type `uint32` that indexes the sorted value in the corresponding column of the input.
- `Value and index` — The block outputs the sorted values of the input data, *Val*, and the corresponding indices in the index array, *I*.

`Sort order` — Order of sorting
`Ascending` (default) | `Descending`

Specify to sort the input data in either ascending or descending order.

`Sort algorithm` — Sort method
`Quick sort` (default) | `Insertion sort`

The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, to avoid recursive function calls, use the insertion sort algorithm.

Data Types Tab

Note To use these parameters, the data input must be complex and fixedpoint. For all other inputs, the parameters on the **Data Types** tab are ignored.

`Rounding mode` — Method of rounding operation
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

`Saturate on integer overflow` — Method of overflow action
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

`Product output` — Product output data type
`Inherit: Same as input` (default) | `fixdt([],16,0)`

The squares of the real and imaginary parts of the complex input are stored in the **Product output** data type.

You can set this parameter to:

- `Inherit: Same as input` — The product output data type is the same as the input data type.
- `fixdt([],16,0)` — The product output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in *Simulink User's Guide* (Simulink).

`Accumulator` — Accumulator data type

`Inherit: Same as product output` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

The result of the sum of the squares of the real and imaginary parts of the complex input are stored in the **Accumulator** data type.

You can set this parameter to:

- `Inherit: Same as product output` — The accumulator data type is the same as the product output data type.
- `Inherit: Same as input` — The accumulator data type is the same as the input data type.
- `fixdt([],16,0)` — The accumulator data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**.

To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in *Simulink User's Guide* (Simulink).

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

Algorithms

Sort

The block produces results identical to the MATLAB `sort` function.

The output of the block is equivalent to the following MATLAB code, when **Sort order** is set to:

- `Ascending` — `[Val,I] = sort(u,'ascend')`
- `Descending` — `[Val,I] = sort(u,'descend')`

where:

- `u` is the data input.

- `Val` is the sorted output.
- `I` is the index of the sorted output.

When the input is complex, the block sorts the data according to the magnitude. The block computes the magnitude by taking the sum of the squares of the real and imaginary components of the complex input. This is identical to calling the `sort` function as `[Val,I] = sort(u,...,'ComparisonMethod','abs')`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (string.h) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types** tab are used only for complex fixed-point inputs. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. The results of the squares of the real and imaginary parts are stored in the **Product output** data type. The result of the sum of the squares is stored in the **Accumulator** data type. The parameters on the **Data Types** tab are ignored for all other inputs.

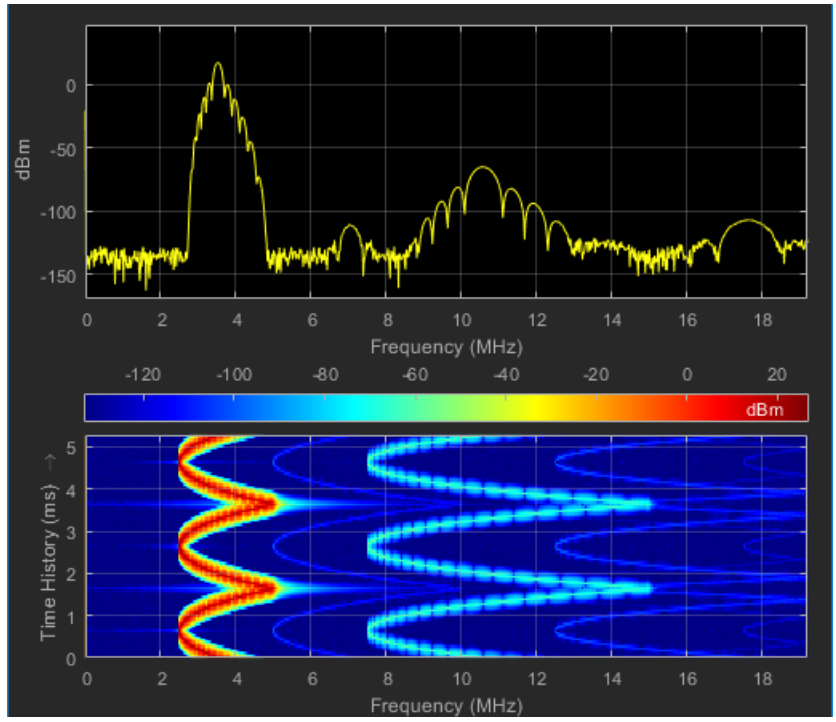
Spectrum Analyzer

Display frequency spectrum
Library: DSP System Toolbox / Sinks
DSP System Toolbox HDL Support / Sinks

Description

The Spectrum Analyzer block, referred to here as the scope, displays the frequency spectra of signals.



You can use the Spectrum Analyzer block in models running in Normal or Accelerator simulation modes. You can also use the Spectrum Analyzer block in models running in Rapid Accelerator or External simulation modes, with some limitations.

You can use the Spectrum Analyzer block inside all subsystems and conditional subsystems. Conditional subsystems include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditionally Executed Subsystems Overview” (Simulink) for more information.

Measurements

- Cursors — Measure signal values using vertical and horizontal cursors.
- Peak Finder — Find maxima, showing the *x*-axis values at which they occur.
- Channel Measurements — Measure the occupied bandwidth or adjacent channel power ratio (ACPR).
- Distortion Measurements — Measure harmonic distortion and intermodulation distortion.
- CCDF Measurements — Measure the complimentary cumulative distribution function. CCDF measurements show the probability of a signal’s instantaneous power being a specified level above the signal’s average power.
- “Spectral Masks” — Visualize spectrum limits and compare spectrum values to specification values.

Programmatic Control

You can configure and display Spectrum Analyzer settings from the command line with the `spbscopes.SpectrumAnalyzerConfiguration` object.

Ports

Input

`Port_1` — Signals to visualize

scalar | vector | matrix | array

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Signal Domain** — Frequency or time signals
- **Type** — Discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink” (Simulink).
- **Dimension** — One dimensional (vector), two dimensional (matrix), or multidimensional (array). Input must have fixed number of channels. See “Signal Dimensions” (Simulink) and “Determine Output Signal Dimensions” (Simulink).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Spectrum Settings

The **Spectrum Settings** pane appears at the right side of the Spectrum Analyzer window. These settings control how the spectrum is calculated. To show the Spectrum Settings, in the Spectrum Analyzer menu, select **View > Spectrum Settings** or use the  button in the toolbar.

Main options

`Input domain` — Domain of the input signal

`Time` (default) | `Frequency`

The domain of the input signal you want to visualize. If you visualize time-domain signals, the signal is transformed to the frequency spectrum based on the algorithm specified by the `Method` parameter.

Programmatic Use

See `InputDomain`.

Type — Type of spectrum to display

`Power` (default) | `Power density` | `RMS`

`Power` — Spectrum Analyzer shows the power spectrum.

`Power density` — Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz.

`RMS` — Spectrum Analyzer shows the root mean squared spectrum.

Tunable: Yes

Dependency

To use this parameter, set "Input domain" on page 2-0 to `Time`.

Programmatic Use

See `SpectrumType`.

`View` — Spectrum view

`Spectrum` (default) | `Spectrogram` | `Spectrum and spectrogram`

`Spectrum` — Spectrum Analyzer shows the spectrum.

`Spectrogram` — Spectrum Analyzer shows the spectrogram, which displays frequency content over time. The most recent spectrogram update is at the bottom of the display, and time scrolls from the bottom to the top of the display.

`Spectrum and spectrogram` — Spectrum Analyzer shows both the spectrum and spectrogram.

Tunable: Yes

Programmatic Use

See `ViewType`.

`Sample rate` — Sample rate of the input signal in hertz

`Inherited` (default) | positive scalar

Select `Inherited` to use the same sample rate as the input signal. To specify a sample rate, delete `Inherited` and enter a sample rate value.

Programmatic Use

See `SampleRate`.

`Method` — Spectrum estimation method

`Welch` (default) | `Filter Bank`

Select `Welch` or `Filter Bank` as the spectrum estimation method. For more details about the two spectrum estimation algorithms, see “Algorithms” on page 2-1693.

Tunable: No

Dependency

To use this parameter, set “Input domain” on page 2-0 to `Time`.

Programmatic Use

See `Method`.

`Full frequency span` — Use entire Nyquist frequency interval

on (default) | off

Select this check box to compute and plot the spectrum over the entire “Nyquist frequency interval” on page 2-1698.

Tunable: Yes

Dependency

To use this parameter, set “Input domain” on page 2-0 to `Time`.

Programmatic Use

See `FrequencySpan`.

`Span (Hz)` — Frequency span in hertz

`10e3` (default) | real positive scalar

Specify the frequency span in hertz. Use this parameter with the `CF (Hz)` parameter to define the frequency span around a center frequency. This parameter defines the range of values shown on the Frequency axis in the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set “Input domain” on page 2-0 to `Time`.
- Clear the “Full frequency span” on page 2-0 check box.

- Set the **Span (Hz)/Fstart (Hz)** dropdown to `Span (Hz)`.

Programmatic Use

See `FrequencySpan` and `Span`.

`CF (Hz)` — Center frequency in hertz

`0` (default) | scalar

Specify the center frequency, in hertz. Use this parameter with the "Span (Hz)" on page 2-0 parameter to define the frequency span around a center frequency. This parameter defines the value shown at the middle point of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set "Input domain" on page 2-0 to `Time`.
- Clear the "Full frequency span" on page 2-0 check box.
- Set the **Span (Hz)/Fstart (Hz)** dropdown to "Span (Hz)" on page 2-0 .

Programmatic Use

See `CenterFrequency`.

`FStart (Hz)` — Start frequency in hertz

`-5e3` (default) | scalar

Specify the start frequency in hertz. Use this parameter with the "FStop (Hz)" on page 2-0 parameter to define the range of frequency-axis values using start frequency and stop frequency. This parameter defines the value shown at the leftmost side of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set "Input domain" on page 2-0 to `Time`.

- Clear the “Full frequency span” on page 2-0 check box.
- Set the **Span (Hz)/FStart (Hz)** dropdown to `FStart (Hz)`.

Programmatic Use

See `StartFrequency`.

`FStop (Hz)` — Stop frequency in hertz

`5e3` (default) | scalar

Specify the stop frequency, in hertz. Use this parameter with the “FStart (Hz)” on page 2-0 parameter to define the range of Frequency axis values. This parameter defines the value shown at the rightmost side of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set “Input domain” on page 2-0 to `Time`.
- Clear the “Full frequency span” on page 2-0 check box.
- Set the **Span (Hz)/FStart (Hz)** dropdown to “FStart (Hz)” on page 2-0 .

Programmatic Use

See `StopFrequency`.

`Frequency (Hz)` — Frequency vector

`Auto` (default) | `Input port` | monotonically increasing vector

Set the frequency vector which determines the *x*-axis of the display.

- `Auto` — The frequency vector is calculated from the length of the input. See “Frequency Vector” on page 4-1653.
- `Input port` — When selected, an input port appears on the block for the frequency vector input.
- Custom vector — Enter a custom vector as the frequency vector. The length of the custom vector must be equal to the frame size of the input signal.

Tunable: No

Dependency

To use this parameter, set "Input domain" on page 2-0 to `Frequency`.

Programmatic Use

See `FrequencyVector`.

`RBW (Hz)` — Resolution bandwidth

`Auto` (default) | `Input port` | positive scalar

The resolution bandwidth in hertz. This parameter defines the smallest positive frequency that can be resolved. By default, this parameter is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span.

If you set this parameter to a numeric value, the value must allow at least two RBW intervals over the specified frequency span. In other words, the ratio of the overall frequency span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

For frequency input only, you can use an input port to set the RBW value.

Tunable: Yes

Dependency

To use this parameter, set either:

- "Input domain" on page 2-0 to `Time` and the **RBW (Hz)/Window length/Number of frequency bands** dropdown to `RBW (Hz)`.
- "Input domain" on page 2-0 to `Frequency`.

Programmatic Use

See `RBW`.

`Input units` — Units of frequency input

`Auto` (default) | `dBm` | `dBV` | `dBW` | `Vrms` | `Watts`

Select the units of the frequency-domain input. This property allows the Spectrum Analyzer to scale frequency data if you choose a different display unit with the “Units” on page 2-0 property.

Tunable: No

Dependency

This option is only available when “Input domain” on page 2-0 is set to `Frequency`.

Programmatic Use

See `InputUnits`.

`Window length` — Length of window in samples

`1024` (default) | integer greater than 2

The length of the window, in samples. The window length used to control the frequency resolution and compute the spectral estimates. The window length must be an integer greater than 2.

Dependencies

To use this parameter, set:

- “Method” on page 2-0 to `Welch`
- Set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to `Window Length`

Dependency

To use this parameter, set “Input domain” on page 2-0 to `Time`.

Programmatic Use

See `WindowLength`.

`Number of frequency bands` — FFT length

`Auto` (default) | positive integer

Specify the fast Fourier transform (FFT) length to control the number of frequency bands. If the value is `Auto`, the Spectrum Analyzer uses the entire frame size to estimate the spectrum. If you specify the number of frequency bands, you set the input buffer size.

Dependencies

To use this parameter, set:

- "Method" on page 2-0 to `Filter Bank`
- Set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to `Number of frequency bands`

Programmatic Use

See `FFTLength`

`Taps per band` — Number of filter taps

12 (default) | positive even integer

Specify the number of filter taps or coefficients for each frequency band. This number must be a positive even integer. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to *Taps Per Band* + *FFT Length*.

Dependency

To use this parameter, you must set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to "Number of frequency bands" on page 2-0 .

Programmatic Use

See `NumTapsPerBand`.

`NFFT` — Number of FFT points

`Auto` (default) | positive integer

Specify the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are `Auto` or a positive integer.

The **NFFT** value must be greater than or equal to the value of the **Window length** parameter. By default, when **NFFT** is set to `Auto`, the Spectrum Analyzer sets **NFFT** equal to the value of **Window length**. When in RBW mode, the specified RBW value is used to calculate an FFT length that equals the window length.

When this parameter is set to a positive integer, this parameter is equivalent to the `n` parameter of the `fft` function.

Dependencies

To use this parameter, you must set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to "Window length" on page 2-0 .

Programmatic Use

See `FFTLength`.

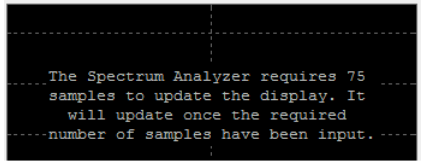
`Samples/update` — Required number of input samples

positive scalar

This property is read-only.

The number of input samples required to compute one spectral update. You cannot modify this parameter; it is shown in the spectrum analyzer for informational purposes only. This parameter is directly related to **RBW (Hz)/Window length/Number of frequency bands**. For more details, see "Algorithms" on page 2-1693.

If the input does not have enough samples to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display.



Spectrogram Settings

`Channel` — Spectrogram channel

channel name

Select the signal channel for which the spectrogram settings apply.

Dependencies

To use this option, set "View" on page 2-0 to `Spectrogram` or `Spectrum and spectrogram`.

Programmatic Use

See `SpectrogramChannel`.

`Time res. (s)` — Time resolution in seconds

`Auto` (default) | positive number

Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current settings.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
`Welch` or `Filter Bank`	`RBW (Hz)`	`Auto`	`Auto`	1/RBW
`Welch` or `Filter Bank`	`RBW (Hz)`	`Auto`	Manually entered	Time Resolution
`Welch` or `Filter Bank`	`RBW (Hz)`	Manually entered	`Auto`	1/RBW
`Welch` or `Filter Bank`	`RBW (Hz)`	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
`Welch`	`Window length`	—	`Auto`	1/RBW

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
`Welch`	`Window length`	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
`Filter Bank`	`Number of frequency bands`	—	`Auto`	1/RBW
`Filter Bank`	`Number of frequency bands`	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW.

Tunable: Yes

Dependency

To use this option, set "View" on page 2-0 to `Spectrogram` or `Spectrum and spectrogram`.

Programmatic Use

See `TimeResolution`.

`Time span` — Time span in seconds

`Auto` (default) | positive scalar

The time span over which the Spectrum Analyzer displays the spectrogram specified in seconds. The time span is the product of the desired number of spectral lines and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to `Auto`, 100 spectral lines are used.

Tunable: Yes

Dependency

To use this option, set "View" on page 2-0 to `Spectrogram` or `Spectrum and spectrogram`.

Programmatic Use

See `TimeSpan`.

Window Options

`Overlap (%)` — Segment overlap percentage

0 (default) | scalar between 0 and 100

This parameter defines the amount of overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

Tunable: Yes

Programmatic Use

See `OverlapPercent`.

`Window` — Windowing method

`Hann` (default) | `Rectangular` | `Blackman-Harris` | `Chebyshev` | `Flat Top` | `Hamming` | `Kaiser` | custom window function name

The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see "Windows" (Signal Processing Toolbox).

Tunable: Yes

Programmatic Use

See `Window`.

`Attenuation` — Sidelobe attenuation

`60` (default) | scalar greater than or equal to `45`

The sidelobe attenuation in decibels (dB). The value must be greater than or equal to `45`.

Dependency

This parameter applies only when you set the **Window** parameter to `Chebyshev` or `Kaiser`.

Programmatic Use

See `SidelobeAttenuation`.

`NENBW` — Normalized effective noise bandwidth

scalar

This property is read-only.

The normalized effective noise bandwidth of the window. You cannot modify this parameter; it is shown for informational purposes only. This parameter is a measure of the noise performance of the window. The value is the width of a rectangular filter that accumulates the same noise power with the same peak power gain.

The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

Trace Options

`Units` — Spectrum units

`dBm` (default) | `dBW` | `Watts` | `Vrms` | `dBV` | `dBFS`

The units of the spectrum. The available values depend on the value of the “Type” on page 2-0 parameter.

Tunable: Yes

Programmatic Use

See `SpectrumUnits`.

`Full scale` — Full scale for dBFS units

`Auto` (default) | positive real scalar

The full scale used for the decibel full scale (dBFS) units. By default, the Spectrum Analyzer uses the entire spectrum scale. Specify a positive real scalar for the dBFS full scale.

Tunable: Yes

Dependencies

To enable this parameter, set:

- "Input domain" on page 2-0 to `Time`
- "Units" on page 2-0 to `dBFS`

Programmatic Use

See `FullScale`.

`Averaging method` — Smoothing method

`Running` (default) | `Exponential`

Specify the smoothing method as:

- `Running` — Running average of the last *n* samples. Use the `Averages` property to specify *n*.
- `Exponential` — Weighted average of samples. Use the `Forgetting factor` property to specify the weighted forgetting factor.

For more information about the averaging methods, see "Averaging Method" on page 2-1704.

Programmatic Use

See `AveragingMethod`.

`Averages` — Number of spectral averages

1 (default) | positive integer

Specify the number of spectral averages as a positive integer. The spectrum analyzer computes the current power spectrum estimate by computing a running average of the last *N* power spectrum estimates. This parameter defines the number of spectral averages, *N*.

Dependencies

This parameter applies only when:

- "View" on page 2-0 is `Spectrum` or `Spectrum and spectrogram`.
- **Averaging method** is `Running`.

Programmatic Use

See `SpectralAverages`.

`Forgetting factor` — Weighting forgetting factor

`0.9` (default) | scalar in the range (0,1]

Specify the exponential weighting as a scalar value greater than 0 and less than or equal to 1.

Dependency

This parameter applies only when the **Averaging method** is `Exponential`.

Programmatic Use

See `ForgettingFactor`.

`Reference load` — Reference load

`1` (default) | positive real scalar

The reference load in ohms that the Spectrum Analyzer uses as a reference to compute power values.

Dependency

To use this parameter, set "Input domain" on page 2-0 to `Time`.

Programmatic Use

See `ReferenceLoad`.

`Scale` — Scale of frequency axis

`Linear` (default) | `Logarithmic`

Choose a linear or logarithm scale for the frequency axis. When the frequency span contains negative frequency values, you cannot choose the logarithmic option.

Programmatic Use

See `FrequencyScale`.

`Offset` — Constant frequency offset

`0` (default) | scalar

The constant frequency offset to apply to the entire spectrum, or a vector of frequencies to apply to each spectrum for multiple inputs. The offset parameter is added to the values on the Frequency axis in the Spectrum Analyzer window. This parameter is not used in any spectral computations. You must take the parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within the "Nyquist frequency interval" on page 2-1698.

Dependency

To use this parameter, set "Input domain" on page 2-0 to `Time`.

Programmatic Use

See `FrequencyOffset`.

`Normal trace` — Normal trace view

on (default) | off

When this check box is selected, the Spectrum Analyzer calculates and plots the power spectrum or power spectrum density. Spectrum Analyzer performs a smoothing operation by averaging several spectral estimates.

Dependencies

To clear this check box, you must first select either the "Max hold trace" on page 2-0 or the "Min hold trace" on page 2-0 parameter. This parameter applies only when "View" on page 2-0 is `Spectrum` or `Spectrum and spectrogram`.

Programmatic Use

See `PlotNormalTrace`.

`Max hold trace` — Maximum hold trace view

off (default) | on

Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained.

Dependency

This parameter applies only when "View" on page 2-0 is `Spectrum` or `Spectrum and spectrogram`.

Programmatic Use

See `PlotMaxHoldTrace`.

`Min hold trace` — Minimum hold trace view
off (default) | on

Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained.

Dependency

This parameter applies only when "View" on page 2-0 is `Spectrum` or `Spectrum and spectrogram`.

Programmatic Use

See `PlotMinHoldTrace`.

`Two-sided spectrum` — Enable two-sided spectrum view
off (default) | on

Select this check box to enable a two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued.

Programmatic Use

See `PlotAsTwoSidedSpectrum`.

Configuration Properties

The **Configuration Properties** dialog box controls visual aspects of the Spectrum Analyzer. To open the Configuration Properties, in the Spectrum Analyzer menu, select **View** > **Configuration Properties** or select the  button in the toolbar dropdown.

`Title` — Display title

character vector | string

Specify the display title. Enter `%<SignalLabel>` to use the signal labels in the Simulink model as the axes titles.

Tunable: Yes

Programmatic Use

See `Title`.

`Show legend` — Display signal legend

off (default) | on

Show signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** parameters. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **ESC**.

Note The legend only shows the first 20 signals. Any additional signals cannot be viewed or controlled from the legend.

Dependency

To enable this parameter, set “View” on page 2-0 to `Spectrum` or `Spectrum and spectrogram`.

Programmatic Use

See `ShowLegend`.

`Show grid` — Show internal grid lines

on (default) | off

Show internal grid lines on the Spectrum Analyzer

Programmatic Use

See `ShowGrid`.

`Y-limits (minimum)` — Y-axis minimum

`-80` (default) | scalar

Specify the minimum value of the *y*-axis.

Programmatic Use

See `YLimits`.

`Y-limits (maximum)` — Y-axis maximum

`20` (default) | scalar

Specify the maximum value of the *y*-axis.

Programmatic Use

See `YLimits`.

`Y-label` — Y-axis label

character vector | string

To display signal units, add `(%<SignalUnits>)` to the label. At the beginning of a simulation, Simulink replaces `(%SignalUnits)` with the units associated with the signals. For example, if you have a signal for velocity with units of m/s enter

```
Velocity (%<SignalUnits>)
```

Programmatic Use

See `YLabel`.

`Color map` — Spectrogram colormap

`jet(256)` (default) | `hot(256)` | `bone(256)` | `cool(256)` | `copper(256)` | `gray(256)` | `parula(256)` | 3-column matrix

Select the colormap for the spectrogram, or enter a three-column matrix expression for the colormap. For more information about colormaps, see `colormap`.

Tunable: Yes

Dependency

To use this parameter, set “View” on page 2-0 to `Spectrogram` or `Spectrum and spectrogram`.

`Color-limits (minimum)` — Spectrogram minimum

`-80` (default) | scalar

Specify the signal power for the minimum color value of the spectrogram.

Tunable: Yes

Dependency

To use this parameter, set “View” on page 2-0 to `Spectrogram` or `Spectrum and spectrogram`.

Programmatic Use

See `ColorLimits`.

`Color-limits (maximum)` — Spectrogram maximum

20 (default) | scalar

Specify the signal power for the maximum color value of the spectrogram.

Tunable: Yes

Dependency

To use this parameter, set “View” on page 2-0 to `Spectrogram` or `Spectrum and spectrogram`.

Programmatic Use

See `ColorLimits`.

Style

The **Style** dialog box controls how to Spectrum Analyzer appears. To open the Style properties, in the Spectrum Analyzer menu, select **View** > **Style** or select the  button in the toolbar dropdown.

`Figure color` — Window background
gray (default) | color picker

Specify the color that you want to apply to the background of the scope figure.

`Plot type` — Plot type
`Line` (default) | `Stem`

Specify whether to display a `Line` or `Stem` plot.

Programmatic Use

See `PlotType`.

`Axes colors` — Axes background color
black (default) | color picker

Specify the color that you want to apply to the background of the axes.

`Properties for line` — Channel for visual property settings
channel names

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

`Visible` — Channel visibility
on (default) | off

Specify whether the selected channel is visible. If you clear this check box, the line disappears. You can also change signal visibility using the scope legend.

`Line` — Line style
line, 0.5, yellow (default)

Specify the line style, line width, and line color for the selected channel.

`Marker` — Data point markers
`none` (default)

Specify marks for the selected channel to show at its data points. This parameter is similar to the 'Marker' property for plots. You can choose any of the marker symbols from the dropdown.

Axes Scaling

The **Axes Scaling** dialog box controls the axes limits of the Spectrum Analyzer. To open the Axes Scaling properties, in the Spectrum Analyzer menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

`Axes scaling/Color scaling` — Automatic axes scaling

`Auto` (default) | `Manual` | `After N Updates`

Specify when the scope automatically scales the y-axis. If the spectrogram is displayed, specify when the scope automatically scales the color axis. By default, this parameter is set to `Auto`, and the scope does not shrink the y-axis limits when scaling the axes or color. You can select one of the following options:

- `Auto` — The scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink**.
- `Manual` — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
  - Select **Tools > Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl+A**.
- `After N Updates` — Selecting this option causes the scope to scale the axes or color after a specified number of updates. This option is useful, and most efficient, when your frequency signal values quickly reach steady-state after a short period. Selecting this option shows the **Number of updates** edit box where you can modify the number of updates to wait before scaling.

Tunable: Yes

Programmatic Use

See `AxesScaling`.

`Do not allow Y-axis/color limits to shrink` — Axes scaling limits

on (default) | off

When you select this parameter, the y-axis is allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this parameter allows the color

limits to grow during axis scaling. If you clear this check box, the y-axis or color limits can shrink during axes scaling operations.

Dependency

This parameter appears only when you select `Auto` for the **Axis scaling** or **Color scaling** parameter. When you set the **Axes scaling** or **Color scaling** parameter to `Manual` or `After N Updates`, the *y*-axis or color limits can shrink.

`Number of updates` — Number of updates before scaling

`10` (default) | positive number

The number of updates after which the axes scale, specified as a positive integer. If the spectrogram is displayed, this parameter specifies the number of updates after which the color axes scales.

Tunable: Yes

Dependency

This parameter appears only when you set "Axes scaling/Color scaling" on page 2-0 to `After N Updates`.

Programmatic Use

See `AxesScalingNumUpdates`.

`Scale limits at stop` — Scale axes at stop

off (default) | on

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

`Data range (%)` — Percent of axes

100 (default) | number in the range [1,100]

Set the percentage of the axis that the scope uses to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the colormap. Valid values are from 1 through 100. For example, if you set this parameter to `100`, the scope scales the axis limits such that your data uses the entire axis range. If you then set this parameter to `30`, the scope increases the *y*-axis or color range such that your data uses only 30% of the axis range.

Tunable: Yes

`Align` — Alignment along axes
`Center` (default) | `Bottom` | `Top` | `Left` | `Right`

Specify where the scope aligns your data along the axis when it scales the axes. If the spectrogram is displayed, specify where the scope aligns your data along the axis when it scales the color. If you are using CCDF Measurements, the x axis is also configurable.

Tunable: Yes

Block Characteristics

Data Types	`Boolean` | `double` | `enumerated` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`yes`
Variable-Size Signals	`yes`
Zero-Crossing Detection	`no`

Algorithms

Welch's Method

When you set the **Method** property to `Welch`, the following algorithms apply. The Spectrum Analyzer uses the `RBW` or the `Window Length` setting in the **Spectrum Settings** pane to determine the data window length. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

Spectrum Analyzer requires that a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation, or to the window length, by the equation shown in step 2.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth, *NENBW*, is a factor that depends on the windowing method. Spectrum Analyzer shows the value of *NENBW* in the **Window Options** pane of the **Spectrum Settings** pane. Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** pane. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

1. When in **RBW (Hz)** mode, the window length required to compute one spectral update, N_{window}, is directly related to the resolution bandwidth and normalized effective noise bandwidth:

   $$N_{window} = \frac{NENBW \times F_s}{RBW}$$

   When in **Window Length** mode, the window length is used as specified.

2. The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

   $$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

   When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100

O_p	$N_{samples}$
50%	50
80%	20

3 The normalized effective noise bandwidth, *NENBW*, is a window parameter determined by the window length, N_{window}, and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then *NENBW* is given by the following equation.

$$NENBW = N_{window} \times \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

4 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

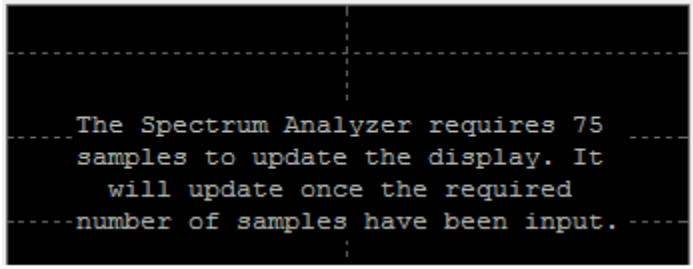
By default, the **RBW (Hz)** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to `Auto`, *RBW* is calculated as:

$$RBW_{auto} = \frac{span}{1024}$$

5 When in **Window Length** mode, you specify N_{window} and the resulting *RBW* is:

$$\frac{NENBW \times F_s}{N_{window}}$$

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:



Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Note The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values if N_{fft} is greater than or equal to N_{window}.

Filter Bank

When you set the **Method** property to `Filter Bank`, the following algorithms apply. The Spectrum Analyzer uses the **RBW (Hz)** or the **Number of frequency band** property in the **Spectrum Settings** pane to determine the input frame length.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation.

$$N_{samples} = \frac{F_s}{RBW}$$

F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

1. When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW** to `Auto`, it is calculated by the following equation.$RBW_{auto} = \frac{span}{1024}$

2 When in **Number of frequency bands** mode, you specify the input frame size. When the number of frequency bands is `Auto`, the resulting RBW is:

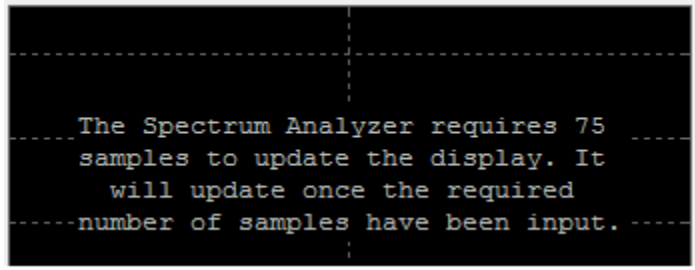
$$RBW = \frac{F_s}{\text{Input Frame Size}}$$

When the number of frequency bands is manually specified, the resulting RBW is:

$$RBW = \frac{F_s}{FFTLength}$$

For more information about the filter bank algorithm, see “Polyphase Implementation” on page 2-208.

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:



Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Nyquist frequency interval

When the PlotAsTwoSidedSpectrum property is set to `true`, the interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

Periodogram and Spectrogram

Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified Periodogram estimator. For more information about the Periodogram method, see `periodogram`.

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$\mathrm{PSD}(f) = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{p}[n]e^{-j2\pi f(n-1)T}\right|^{2}}{F_s \times \sum_{n=1}^{N_{window}} w^{2}[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, with each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{spectrum}(f) = \mathrm{PSD}(f) \times RBW = \mathrm{PSD}(f) \times \frac{F_s \times NENBW}{N_{window}}$$

$$= \frac{1}{P} \sum_{p=1}^{P} \frac{\left| \sum_{n=1}^{N_{FFT}} x^p[n] e^{-j2\pi f(n-1)T} \right|^2}{\left[\sum_{n=1}^{N_{window}} w[n] \right]^2}$$

Spectrogram — You can plot any power as a spectrogram. Each line of the spectrogram is one periodogram. The time resolution of each line is 1/*RBW*, which is the minimum attainable resolution. Achieving the resolution you want may require combining several periodograms. You then use interpolation to calculate noninteger values of 1/*RBW*. In the spectrogram display, time scrolls from top to bottom, so the most recent data is shown at the top of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

Frequency Vector

When set to `Auto`, the frequency vector for frequency-domain input is calculated by the software.

When the PlotAsTwoSidedSpectrum property is set to true, the frequency vector is:

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2} \right]$$

When the PlotAsTwoSidedSpectrum property is set to false, the frequency vector is:

$$\left[0, \frac{SampleRate}{2} \right]$$

Occupied BW

The *Occupied BW* is calculated as follows.

1. Calculate the total power in the measured frequency range.
2. Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this result is

   $$\frac{100 - OccupiedBW\%}{2}$$

   of the total power.
3. Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until the result reaches

   $$\frac{100 - OccupiedBW\%}{2}$$

   of the total power.
4. The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
5. The frequency halfway between the lower and upper frequency values is the center frequency.

Distortion Measurements

The *Distortion Measurements* are computed as follows.

1. Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values. That is, the algorithm treats all these values as if they belong to the peak. Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.
2. The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power near the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power from the fundamental is removed as in step 1.
3. The power and width of the higher-order harmonics (P_2, W_2, P_3, W_3, etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases

monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.

4. Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{remaining}$), peak value ($P_{maxspur}$), and median value ($P_{estnoise}$).
5. The sum of all the removed bandwidth is computed as $W_{sum} = W_0 + W_1 + W_2 + ... + W_n$.

   The sum of powers of the second and higher-order harmonics are computed as $P_{harmonic} = P_2 + P_3 + P_4 + ... + P_n$.
6. The sum of the noise power is estimated as:

   $$P_{noise} = (P_{remaining} \cdot dF + P_{est\,.\,noise} \cdot W_{sum})/RBW$$

   Where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.
7. The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

   $$THD = 10 \cdot \log_{10}\left(\frac{P_{harmonic}}{P_1}\right)$$

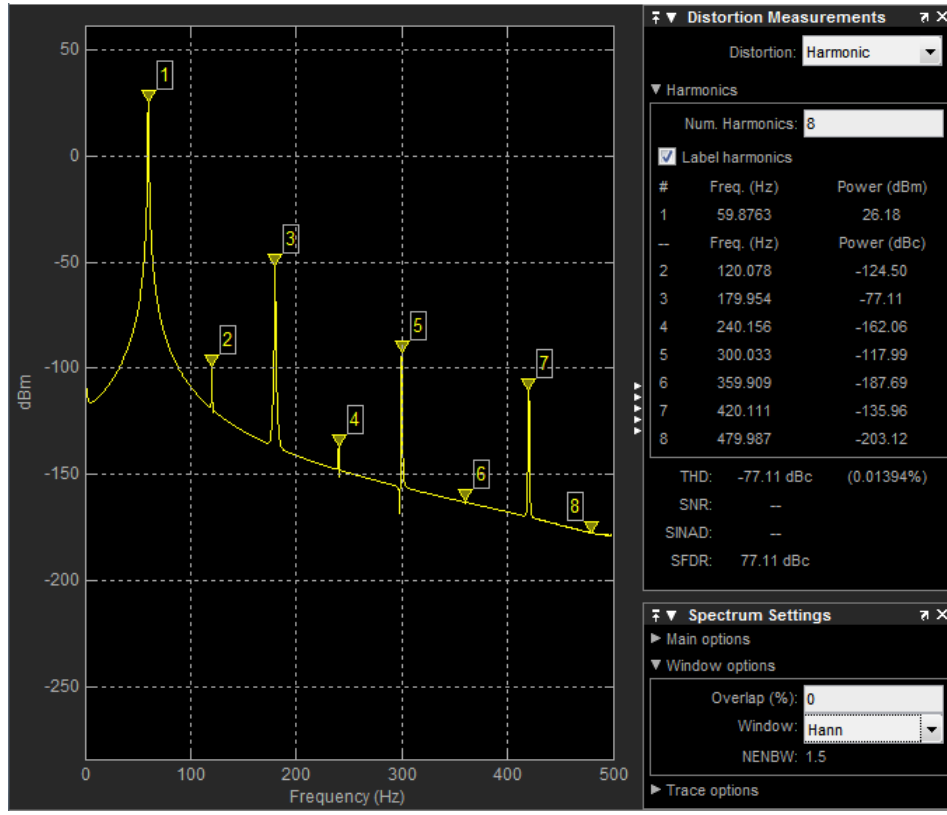
   $$SINAD = 10 \cdot \log_{10}\left(\frac{P_1}{P_{harmonic} + P_{noise}}\right)$$

   $$SNR = 10 \cdot \log_{10}\left(\frac{P_1}{P_{noise}}\right)$$

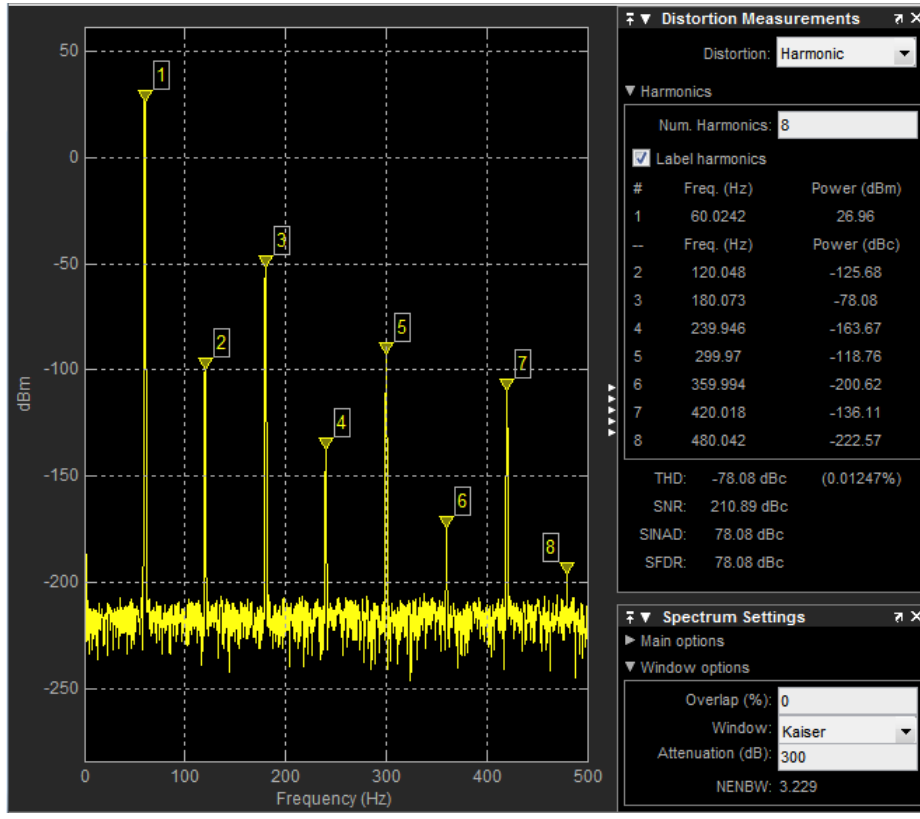
   $$SFDR = 10 \cdot \log_{10}\left(\frac{P_1}{\max\left(P_{maxspur}, \max(P_2, P_3, \ldots, P_n)\right)}\right)$$

Harmonic Measurements

1. The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.



The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (–) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.



2 The DC component is ignored.

3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.

4 N^{th} order intermodulation products occur at $A*F1 + B*F2$,

where $F1$ and $F2$ are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.

5 For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to 1 milliwatt (dBm):

- $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = + (TOI_{lower} + TOI_{upper})/2$

Averaging Method

The moving averaging is done by using one of two methods:

- `Running` — For each frame of input, average the last N scaled Z vectors that are computed by the algorithm. The variable N is the value you specify for the number of spectral averages. If the algorithm does not have enough Z vectors, the algorithm uses zeros to fill the empty elements.
- `Exponential` — The moving average using the exponential weighting method is computed over the current Z vector and the previous Z vector. For details on the computation, see “Exponential Weighting Method” on page 4-1339 in the `dsp.MovingAverage` object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate PLC code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

Spectrum Estimator

Estimate power spectrum or power-density spectrum

Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Spectrum Estimator block outputs the power spectrum or power-density spectrum of a real or complex input signal, using the Welch method of averaged modified periodograms and the filter bank approach.

When you choose the filter bank approach, the block uses an analysis filter bank to estimate the power spectrum. The filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and more precise peaks than the Welch method, with low or no spectral leakage. They come at the expense of increased computation and slower tracking.

When you choose the Welch method, the block computes the averaged modified periodograms to compute the spectral estimate. The block buffers the input data into overlapping segments. Use the block parameters to set the length of the data segments, the amount of data overlap between consecutive segments, and other features of the power spectrum.

For more information on the Welch method and the filter bank method, see “Algorithms” on page 2-1716.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and

the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

Parameters

Main Tab

Method

Specify the spectral estimation method.

- `Filter bank` (default) — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The block computes the power in each narrow frequency band, and the computed value is the spectral estimate over the respective frequency band.
- `Welch` — The block uses the Welch averaged modified periodograms method to compute the power spectrum over the narrow subbands.

Number of taps per band

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to **Number of taps per band** times the FFT length.

This parameter applies when you set **Method** to `Filter bank`. The default is 12.

Spectrum type

Type of spectrum to compute. You can set this parameter to:

- `Power` (default) — Compute the power spectrum.
- `Power density` — Compute the power spectral density.

This parameter is nontunable.

Frequency resolution method

Frequency resolution method. You can set this parameter to:

- `Auto` (default) — The Spectrum Estimator block computes the resolution bandwidth (RBW) so that the frequency span fits 1024 RBW intervals.

- Welch method — The window length, *winLen*, is calculated using $winLen = NENBW \times Fs / RBW$. *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate.
- Filter bank method — The FFT length is the ceiling of the ratio of **Sample rate (Hz)** to the computed resolution bandwidth.

- `RBW` — Specify the resolution bandwidth, which is used to determine the window length (Welch method) or the FFT length (filter bank method). When the block uses the Welch method, the behavior is equivalent to that of the Spectrum Analyzer block. The window length is calculated using $winLen = NENBW \times Fs / RBW$. *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate. The FFT length is equal to the ceiling of the ratio of **Sample rate (Hz)** to **RBW (Hz)**.
- `Window length` — Specify the window or segment length to use in the Welch algorithm. This option appears when you set **Method** to `Welch`.
- `Number of frequency bands` — Specify the number of polyphase branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. This option appears when you set **Method** to `Filter bank`.

This parameter is nontunable.

RBW (Hz)

Resolution bandwidth, specified as a positive scalar in Hz. The default is `5`. This parameter applies when you set **Frequency resolution method** to `RBW`. The ceiling of the ratio of the frequency span to RBW must be greater than `2`.

This parameter is nontunable.

Number of bands source

Source of the number of frequency bands. This parameter applies when you set **Method** to `Filter bank` and **Frequency resolution method** to `Number of frequency bands`. You can set this parameter to:

- `Same as input frame length` (default) — The FFT length is set to the frame size of the input.
- `Specify on dialog` — The FFT length is the value you specify in **Number of bands**.

This parameter is nontunable.

Number of bands

Number of frequency bands, or the FFT length the filter bank uses to compute the power spectral estimate, specified as a positive scalar. The default is `1024`. This parameter applies when you set **Method** to `Filter bank`, **Frequency resolution method** to `Number of frequency bands`, and **Number of bands source** to `Specify on dialog`. This parameter is nontunable.

Window length source

Source of the window length value. This parameter applies when you set **Method** to `Welch` and **Frequency resolution method** to `Window length`. You can set this parameter to:

- `Same as input frame length` (default) — Window length is set to the frame size of the input. Specify this option to obtain behavior equivalent to that of the Periodogram block.
- `Specify on dialog` — Window length is the value you specify in the **Window length** parameter.

This parameter is nontunable.

Window length

Length of the window used to compute the spectrum estimate, specified as a positive integer scalar greater than 2. The default is `1024`. This parameter applies when you set **Method** to `Welch`, **Frequency resolution method** to `Window length`, and **Window length source** to `Specify on dialog`. This parameter is nontunable.

FFT length source

Source of the FFT length value. This parameter applies when you set **Method** to `Welch` and **Frequency resolution method** to `Window length`. You can set this parameter to:

- `Auto` (default) — The block sets the FFT length to the frame size of the input.
- `Property` — The block sets the FFT length to the value you specify in **FFT length**.

This parameter is nontunable.

FFT length

Length of the FFT used to compute the spectrum estimates, specified as a positive integer scalar. This parameter applies when you set **Method** to `Welch`, **Frequency resolution method** to `Window length`, and **FFT length source** to `Property`. The default is `1024`. This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block sample rate is computed as N/T_s, where N is the frame size of the input signal and T_s is the sample time of the input signal.

This check box applies when you do one of the following:

- Set **Method** to `Welch` and **Frequency resolution method** to `Window length`.
- Set **Method** to `Filter bank` and **Frequency resolution method** to `Number of frequency bands`.

When you clear this check box, the block sample rate is the value you specify in **Sample rate (Hz)**. By default, this check box is selected. This parameter is nontunable.

Sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is `44100`. This parameter applies when you do one of the following:

- Set **Frequency resolution method** to `Auto` or `RBW`.
- Set **Method** to `Welch`, **Frequency resolution method** to `Window length`, and clear the **Inherit sample rate from input** check box.
- Set **Method** to `Filter bank`, **Frequency resolution method** to `Number of frequency bands`, and clear the **Inherit sample rate from input** check box.

This parameter is nontunable.

Window function

Window function the Welch algorithm uses, specified as one of `Chebyshev` | `Flat Top` | `Hamming` | `Hann` | `Kaiser` | `Rectangular`. This parameter appears when you set **Method** to `Welch`. The default is `Hann`. This parameter is nontunable.

Sidelobe attenuation of window (dB)

Sidelobe attenuation of the window, specified as a real positive scalar greater than or equal to `45`, in dB. The default is `60`. This parameter appears when you set **Method** to `Welch` and **Window function** to `Chebyshev` or `Kaiser`. This parameter is nontunable.

Averaging method

Specify the averaging method as `Running` or `Exponential`. In the running averaging method, the block computes an equally weighted average of specified number of spectrum estimates defined by **Number of spectral averages** parameter.

In the exponential method, the block computes the average over samples weighted by an exponentially decaying forgetting factor.

Number of spectral averages

Number of spectral averages, specified as a positive integer scalar. The default is `1`. The spectrum estimator computes the current power spectrum estimate by averaging the last *N* power spectrum estimates, where *N* is the number of spectral averages defined in **Number of spectral averages**. This parameter is nontunable.

This parameter applies when **Averaging method** is set to `Running`.

Specify forgetting factor from input port

Select this check box to specify the forgetting factor from an input port. When you do not select this check box, the forgetting factor is specified through the **Forgetting factor** parameter.

This parameter applies when **Averaging method** is set to `Exponential`.

Forgetting factor

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one. The default is `0.9`.

This parameter applies when you set **Averaging method** to `Exponential` and clear the **Specify forgetting factor from input port** parameter.

Advanced Tab

Window overlap (%)

Percentage of overlap between successive data windows, specified as a scalar from `0` and `100`. The default value is `0`. To enable this parameter, on the **Main Tab**, set **Method** to `Welch`. This parameter is nontunable.

Reference load (ohms)

Load used as a reference to compute the power values, specified as a real positive scalar expressed in ohms. The default value is `1`. This parameter is nontunable.

Frequency range

Frequency range of the spectrum estimator. You can set this parameter to:

- `One-sided` — The spectrum estimator computes the one-sided spectrum of a real input signal. When the FFT length, `NFFT`, is even, the spectrum estimate has length (`NFFT/2`) + `1` and is computed over the frequency range

`[0 SampleRate/2]`. `SampleRate` is the sample rate of the input signal. When `NFFT` is odd, the spectrum estimate has length (`NFFT` + 1)/2 and is computed over the frequency range `[0 SampleRate/2)`.

- `Two-sided` — The spectrum estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range `[0 SampleRate)`, where `SampleRate` is the sample rate of the input signal.
- `Centered` (default) — The spectrum estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range `(-SampleRate/2 SampleRate/2]` when the FFT length is even and `(-SampleRate/2 SampleRate/2)` when the FFT length is odd.

This parameter is nontunable.

Power units

Units used to measure power. You can set this parameter to:

- `'Watts'` (default) — The spectrum estimator measures power in watts.
- `'dBw'` — The spectrum estimator measures power in decibel-watts.
- `'dBm'` — The spectrum estimator measures power in decibel-milliwatts.

This parameter is nontunable.

Output max-hold spectrum

When you select this check box, the block computes the max-hold spectrum of the input signal by keeping, at each frequency bin, the maximum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

Output min-hold spectrum

When you select this check box, the block computes the min-hold spectrum of the input signal by keeping, at each frequency bin, the minimum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

Output frequency vector

When you select this check box, the block outputs the frequency vector. By default, this check box is not selected. This parameter is nontunable.

Output effective RBW

When you select this check box, the block computes the effective resolution bandwidth. By default, this check box is not selected. This parameter is nontunable.

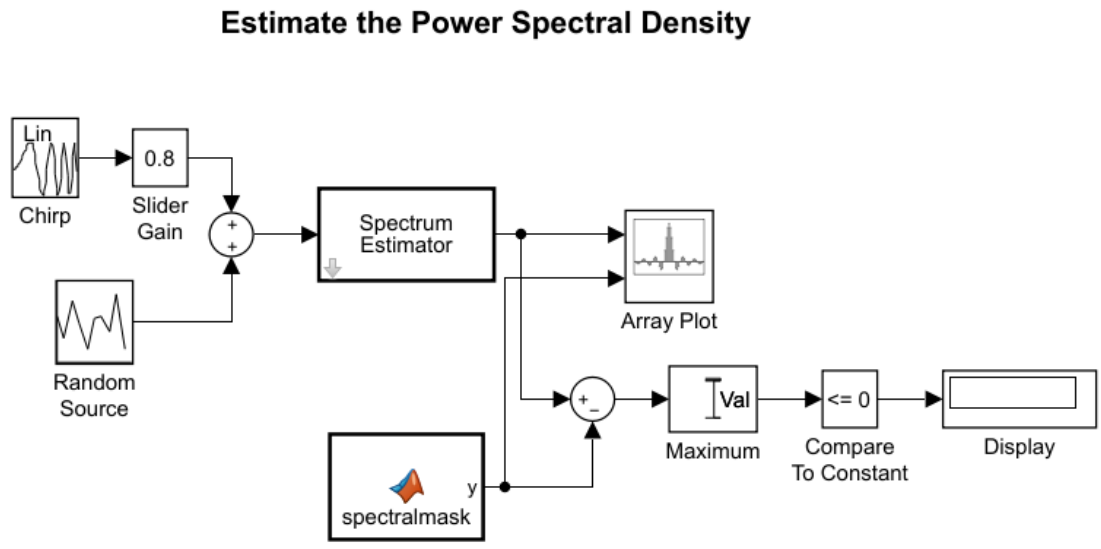
Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default) — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Example

Estimate the Power Spectral Density (PSD) of a chirp signal using the Spectrum Estimator block. Compare the PSD data with a Bluetooth® spectral mask and determine if the PSD data complies with the mask.



To view the complete model, enter `ex_psd_spectralmask` in the MATLAB command prompt.

Input Signal

The input to the Spectrum Estimator block is a chirp signal embedded in Gaussian noise with zero mean and a variance of `0.01`. The chirp signal is amplified with a gain factor in the range `[0 1]`.

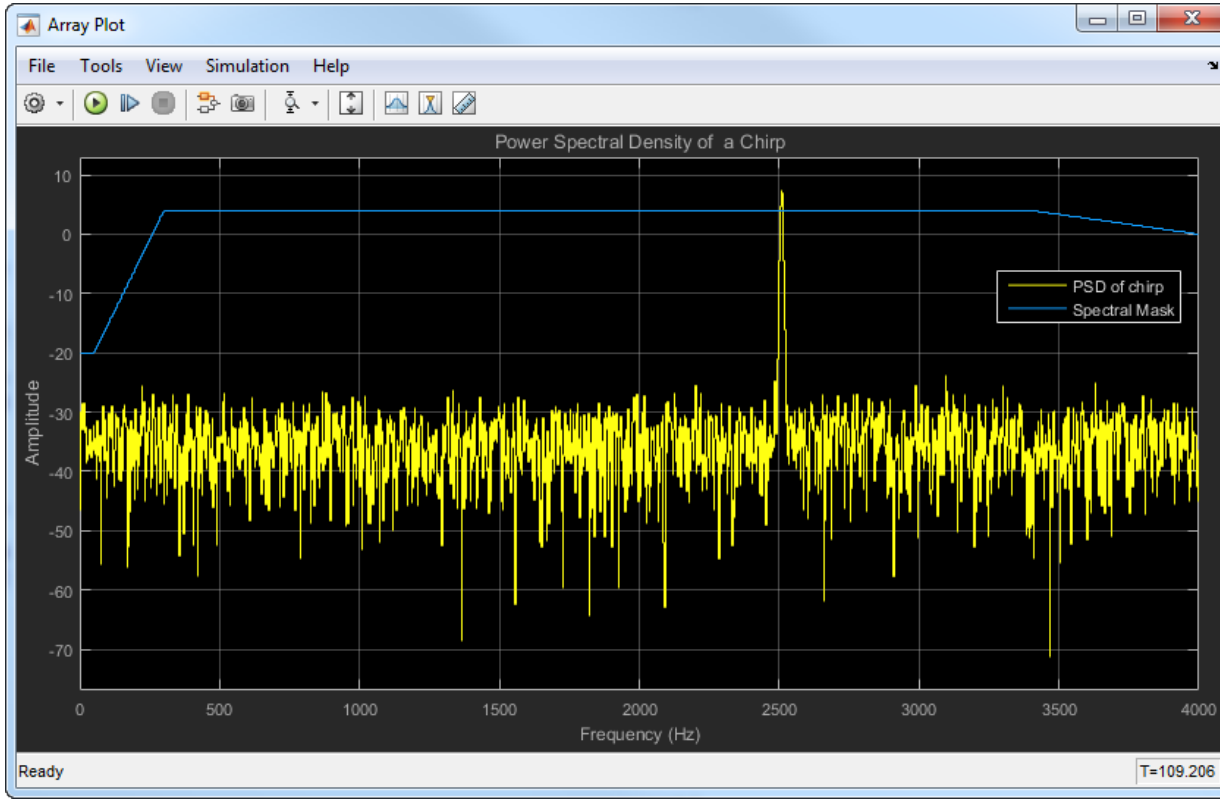
Spectral Mask

The Spectral mask is created using the MATLAB Function block. The mask is based on the Bluetooth standard described in [5].

Live Processing

The Spectrum Estimator block estimates the PSD of the chirp. In this example, the PSD data is compared with the spectral mask. The Display block shows a `1` or `0`, depending on

whether the spectral data is within the mask or not. During simulation, you can change the power in the input signal by moving the slider in the Slider Gain block. Simultaneously, you can view this change in the Array Plot block.



Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Algorithms

Welch's Method of Averaged Modified Periodograms

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

Given the signal input, `x`:

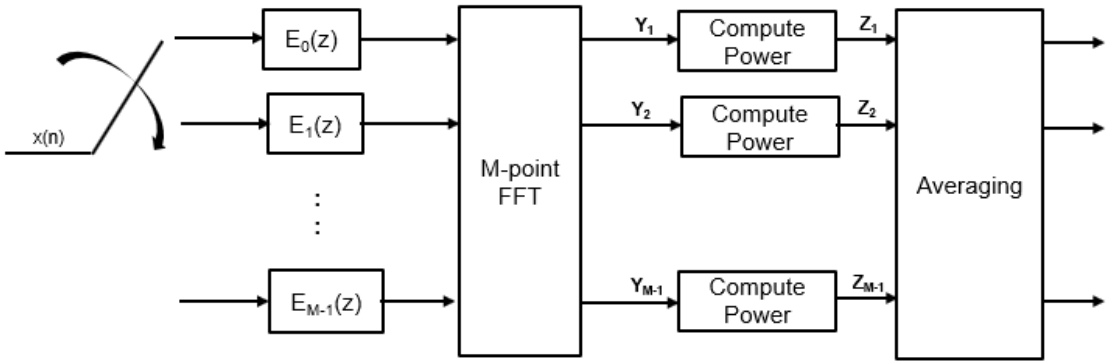
1. Multiply `x` by the window and scale the result by the window power.
2. Compute the FFT of the signal, `Y`, and take the square magnitude using `Z = Y.*conj(Y)`.
3. Compute the current power spectrum estimate by taking the moving average of the last *N* number of *Z*'s, and scaling the answer by the sample rate. For details on the moving average methods, see “Averaging Method” on page 2-1717.

For further information on the algorithms, refer to the “Algorithms” on page 2-1693 section in Spectrum Analyzer.

Filter Bank

The spectrum estimator uses an analysis filter bank to estimate the power spectrum. The number of taps per frequency band specifies the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the FFT length.

The filter-bank-based spectrum estimator splits the broadband input signal, *x(n)*, into multiple narrow bands and computes the power in each band. Each value becomes the estimate of the power over that narrow frequency band. The power in all the narrow bands is averaged by one of the two moving average methods: Running or Exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see “Averaging Method” on page 2-1717.

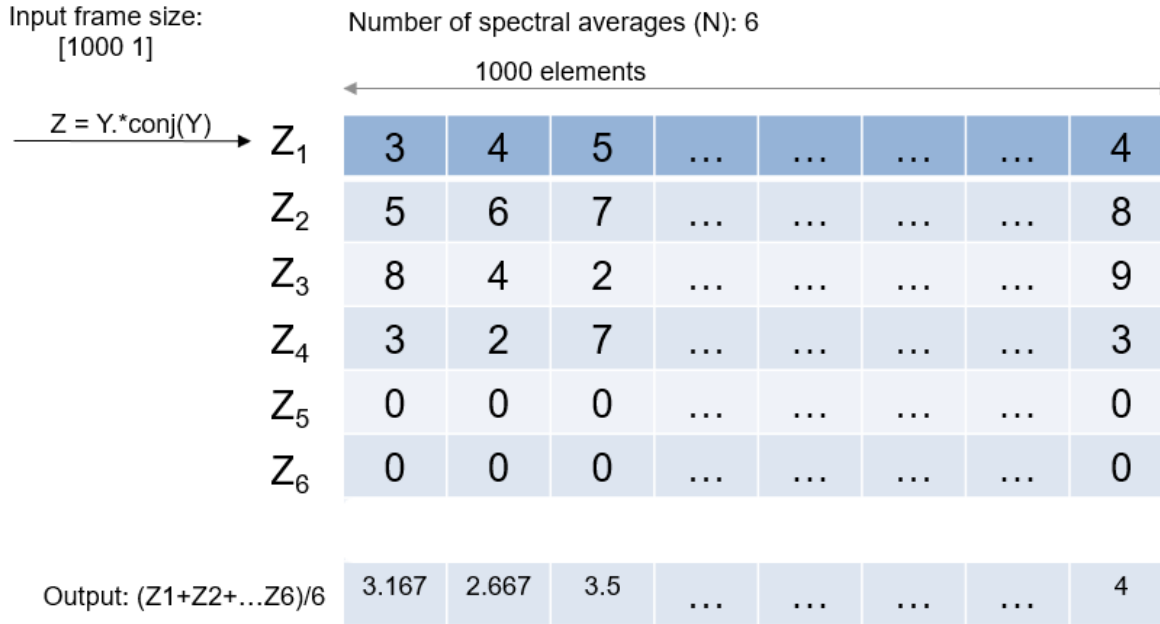


For more information on the analysis filter bank and how it is implemented, see the "More About" on page 4-273 and the "Algorithm" on page 4-276 sections in `dsp.Channelizer`.

Averaging Method

The moving average is calculated using one of two methods:

- `Running` — For each frame of input, average the last N scaled Z vectors, which are computed by the algorithm. The variable N is the value you specify for the number of spectral averages. If the algorithm does not have enough Z vectors, the algorithm uses zeros to fill the empty elements.



- `Exponential` — The moving average using the exponential weighting method is computed over the current *Z* vector and the previous *Z* vector. For details on the computation, see “Exponential Weighting Method” on page 4-1339 in the `dsp.MovingAverage` object.

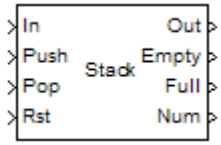
Stack

Store inputs into LIFO register



Library

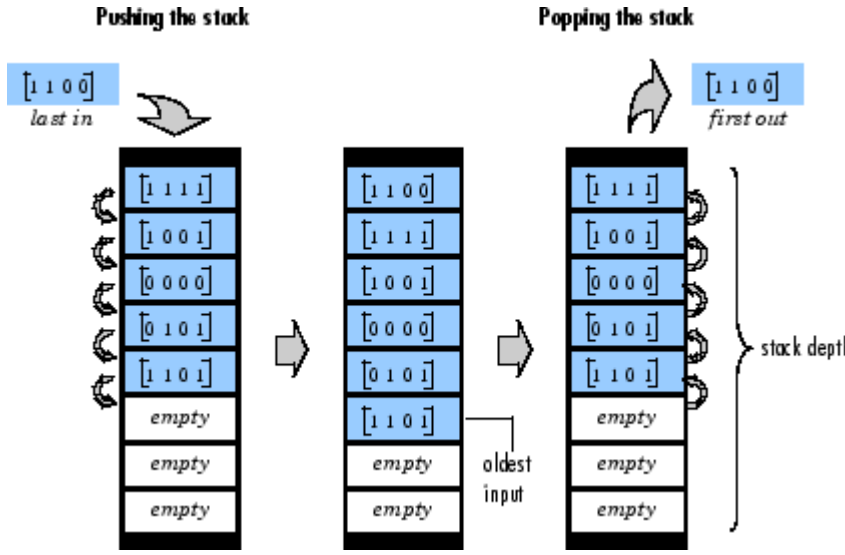
Signal Management / Buffers

`dspbuff3`

Description

The Stack block stores a sequence of input samples in a last in, first out (LIFO) register. The register capacity is set by the **Stack depth** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the `In` port onto the top of the stack when a trigger event is received at the `Push` port. When a trigger event is received at the `Pop` port, the block *pops* the top element off the stack and holds the `Out` port at that value. The last input to be pushed onto the stack is always the first to be popped off.



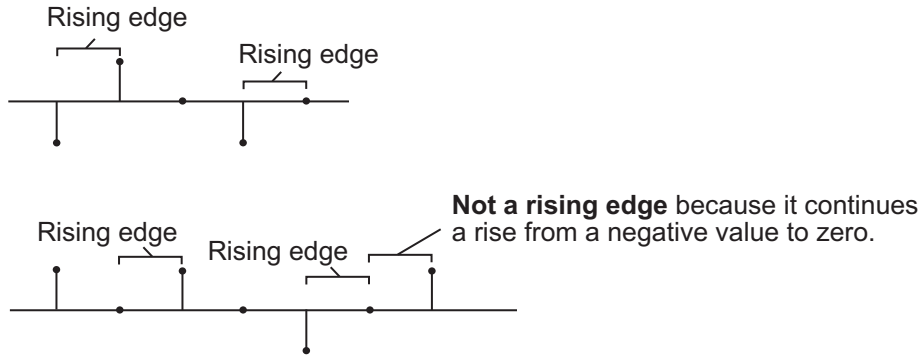
A trigger event at the optional `Rst` port empties the stack contents. When you select **Clear output port on reset**, then a trigger event at the `Rst` port empties the stack *and* sets the value at the `Out` port to zero. This setting also applies when a disabled subsystem containing the Stack block is reenabled; the `Out` port value is only reset to zero in this case when you select **Clear output port on reset**.

When two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

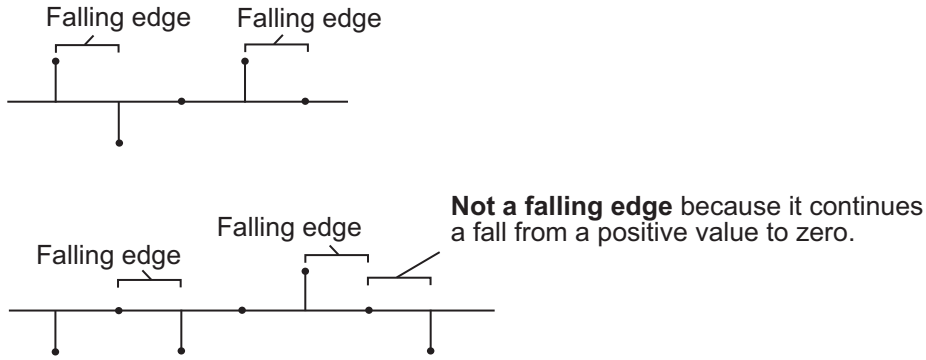
1. `Rst`
2. `Push`
3. `Pop`

The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the `Push`, `Pop`, and `Rst` ports in the **Trigger type** pop-up menu:

- `Rising edge` — Triggers execution of the block when the trigger input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



- `Falling edge` — Triggers execution of the block when the trigger input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



- `Either edge` — Triggers execution of the block when the trigger input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers execution of the block at each sample time that the trigger input is not zero.

Note If your model contains any referenced models that use a Stack block with the **Push full stack** parameter set to `Dynamic reallocation`, you cannot simulate your top-level model in Simulink Accelerator mode.

The **Push full stack** parameter specifies the block's behavior when a trigger is received at the `Push` port but the register is full. The **Pop empty stack** parameter specifies the block's behavior when a trigger is received at the `Pop` port but the register is empty. The following options are available for both cases:

- `Ignore` — Ignore the trigger event, and continue the simulation.
- `Warning` — Ignore the trigger event, but display a warning message in the MATLAB command window.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Push full stack** and **Pop empty stack** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

The **Push full stack** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the stack at a given time, enable the `Num` output port by selecting the **Show number of stack entries port** parameter.

Note When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Examples

Example 1

The table below illustrates the Stack block's operation for a **Stack depth** of 4, **Trigger type** of `Either edge`, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from `1` to `0` or `0` to `1` in the `Push`, `Pop`, and `Rst` columns below represents a distinct trigger event. A `1` in the `Empty` column indicates an empty buffer, while a `1` in the `Full` column indicates a full buffer.

In	Push	Pop	Rst	Stack	Out	Empty	Full	Num
1	0	0	0		0	1	0	0
2	1	0	0		0	0	0	1
3	0	0	0		0	0	0	2
4	1	0	0		0	0	0	3
5	0	0	0		0	0	1	4
6	0	1	0		5	0	0	3
7	0	0	0		4	0	0	2
8	0	1	0		3	0	0	1
9	0	0	0		2	1	0	0
10	1	0	0		2	0	0	1
11	0	0	0		2	0	0	2
12	1	0	1		0	0	0	1

Note that at the last step shown, the `Push` and `Rst` ports are triggered simultaneously. The `Rst` trigger takes precedence, and the stack is first cleared and then pushed.

Example 2

The `dspqdemo` example provides an example of the related Queue block.

Parameters

Stack depth

The number of entries that the LIFO register can hold.

Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

Push full stack

Response to a trigger received at the `Push` port when the register is full. Inputs to this port must have the same built-in data type as inputs to the `Pop` and `Rst` input ports.

When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Pop empty stack

Response to a trigger received at the `Pop` port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the `Push` and `Rst` input ports.

Show empty stack indicator port

Enable the `Empty` output port, which is high (`1`) when the stack is empty, and low (`0`) otherwise.

Show full stack indicator port

Enable the `Full` output port, which is high (`1`) when the stack is full, and low (`0`) otherwise. The `Full` port remains low when you select **Dynamic reallocation** from the **Push full stack** parameter.

Show number of stack entries port

Enable the `Num` output port, which tracks the number of entries currently on the stack. When inputs to the `In` port are double-precision values, the outputs from the `Num` port are double-precision values. Otherwise, the outputs from the `Num` port are 32-bit unsigned integer values.

Show reset port to clear internal stack buffer

Enable the `Rst` input port, which empties the stack when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the `Push` and `Pop` input ports.

Clear output port on reset

Reset the `Out` port to zero (in addition to clearing the stack) when a trigger is received at the `Rst` input port.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Push	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports
Pop	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.

Port	Supported Data Types
Rst	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Empty	• Double-precision floating point • Boolean
Full	• Double-precision floating point • Boolean
Num	• Double-precision floating point The block outputs a double-precision floating-point value at this port when the data type of the In port is double-precision floating-point. • 32-bit unsigned integers The block outputs a 32-bit unsigned integer value at this port when the data type of the In port is anything other than double-precision floating-point.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The following limitations apply:

- Generated code relies on `memcpy` or `memset` functions (string.h) under certain conditions.
- When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Configuration Parameters dialog box must be set to `grt_malloc.tlc - Generic Real-Time Target with dynamic memory allocation`.

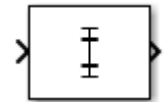
Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Introduced before R2006a

Standard Deviation

Standard deviation of input or sequence of inputs
Library: DSP System Toolbox / Statistics



Description

The Standard Deviation block computes the standard deviation of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input. You can specify the dimension using the **Find the standard deviation value over** parameter. The Standard Deviation block can also track the standard deviation in a sequence of inputs over a period of time. To track the standard deviation in a sequence of inputs, select the **Running standard deviation** parameter.

Note The **Running** mode in the Standard Deviation block will be removed in a future release. To compute the running standard deviation in Simulink, use the Moving Standard Deviation block instead.

Ports

Input

`In` — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double`

`Rst` — Reset port

scalar

Specify the reset event that causes the block to reset the running standard deviation. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Port_1` — Standard deviation along the specified dimension

scalar | vector | matrix | *N*-D array

The data type of the output matches the data type of the input.

When you do not select the **Running standard deviation** parameter, the block computes the standard deviation in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input at each individual sample time. Each element in the output array `y` is the standard deviation of the corresponding column, row, or entire input. The output array `y` depends on the setting of the **Find the standard deviation value over** parameter. Consider a three-dimensional input signal of size *M*-by-*N*-by-*P*. When you set **Find the standard deviation value over** to:

- `Entire input` — The output at each sample time is a scalar that contains the standard deviation of the *M*-by-*N*-by-*P* input matrix.
- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the standard deviation of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the standard deviation of each vector over the first dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.

- `Specified dimension` — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to `1`, the output is the same as when you select `Each column`. If you set the **Dimension** to `2`, the output is the same as when you select `Each row`. If you set the **Dimension** to `3`, the output at each sample time is an M-by-N matrix containing the standard deviation of each vector over the third dimension of the input.

When you select **Running standard deviation**, the block tracks the standard deviation of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M-by-N-by-P, the block outputs an M-by-N-by-P array. Each element y_{ijk} of the output contains the standard deviation of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running standard deviation y_{ijk} in the current frame is reset to the element u_{ijk}.
- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the standard deviation of the elements in the jth column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Data Types: `single` | `double`

Parameters

Main Tab

`Running standard deviation` — Option to select running standard deviation
off (default) | on

When you select the **Running standard deviation** parameter, the block tracks the standard deviation value of each channel in a time sequence of inputs.

`Find the standard deviation value over` — Dimension over which the block computes the standard deviation
`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- `Each column` — The block outputs the standard deviation over each column.
- `Each row` — The block outputs the standard deviation over each row.
- `Entire input` — The block outputs the standard deviation over the entire input.
- `Specified dimension` — The block outputs the standard deviation over the dimension, specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running standard deviation** parameter.

`Dimension` — Custom dimension
1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the standard deviation is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the standard deviation value over** to `Specified dimension`.

`Input processing` — Method to process the input in running mode
`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the standard deviation of the elements in the *j*th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each element y_{ijk} of the output contains the standard deviation of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running standard deviation y_{ijk} in the current frame is reset to the element u_{ijk}.

  Variable-Size Inputs

  When your inputs are of variable size, and you select the **Running standard deviation** parameter, then:

  - If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
  - If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
    - When the input size difference is in the number of channels (number of columns), the state is reset.
    - When the input size difference is in the length of channels (number of rows), no reset occurs and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

`Reset port` — Reset event

`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

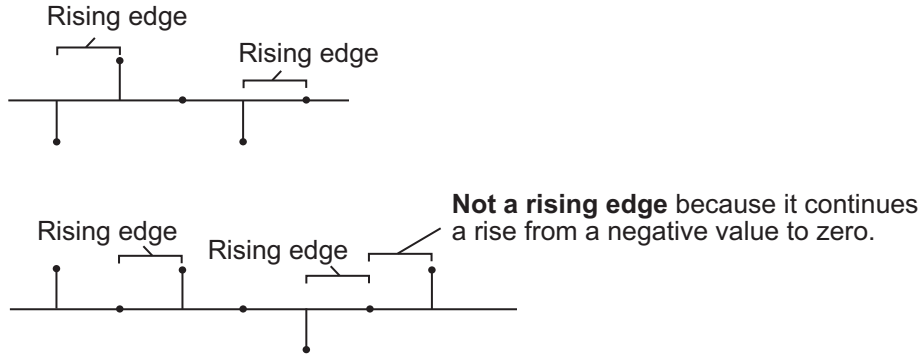
The block resets the running standard deviation whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running standard deviation for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`,

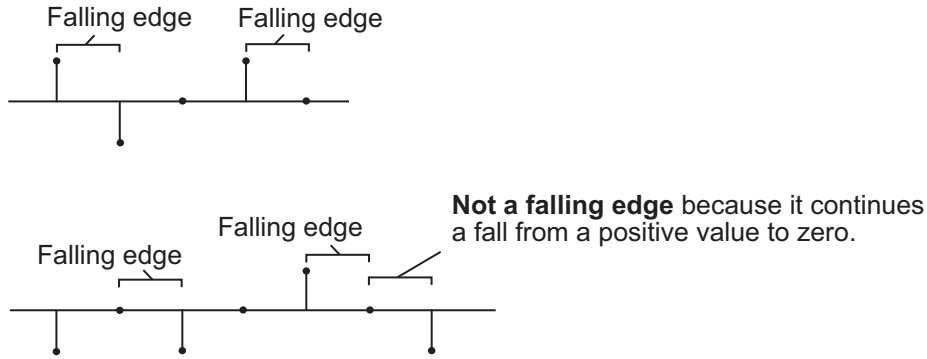
the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.



- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

Block Characteristics

Multidimensional Signals	`no`

Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Standard Deviation

The standard deviation of a discrete-time signal is the square root of the variance of the signal.

Standard deviation gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u, of size M-by-N, the standard deviation is given by the following equation:

$$y = \sigma = \sqrt{\frac{\sum_{i=1}^{M}\sum_{j=1}^{N}\left|u_{ij}\right|^2 - \frac{\left|\sum_{i=1}^{M}\sum_{j=1}^{N}u_{ij}\right|^2}{M*N}}{M*N-1}}$$

- u_{ij} is the input data element at indices i, j.
- M is the length of the jth column.
- N is the number of columns.

For complex inputs, the standard deviation is given by the following equation:

$$\sigma = \sqrt{{\sigma_{\mathrm{Re}}}^2 + {\sigma_{\mathrm{Im}}}^2}$$

- ${\sigma_{Re}}^2$ is the variance of the real part of the complex input.
- ${\sigma_{Im}}^2$ is the variance of the imaginary part of the complex input.

Algorithms

Standard Deviation

When you clear the **Running standard deviation** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `std` function, when it is called as `y = std(u,0,D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the standard deviation along the specified dimension.

The standard deviation along the entire input is identical to calling the `std` function as `y = std(u(:))`.

For a complex input signal, the standard deviation is the square root of the sum of the variances of the real and imaginary parts.

$$\sigma = \sqrt{\sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2}$$

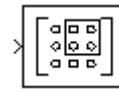
Submatrix

Select subset of elements (submatrix) from matrix input

Library: DSP System Toolbox / Signal Management / Indexing
DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Operations



Description

The Submatrix block extracts a contiguous submatrix, *y*, from the *M*-by-*N* input matrix u. For more information about selecting the rows and columns to extract, see “Range Specification Options” on page 2-1745.

Ports

Input

`Port_1` — Input signal

vector | matrix

Input signal, from which the block extracts the specified submatrix.

This block supports Simulink virtual buses.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Selected submatrix

vector | matrix

Submatrix selected from the input signal. The data type of the output is the same as the input.

This block supports Simulink virtual buses.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

For more information about selecting the subset of elements to form the submatrix, see “Range Specification Options” on page 2-1745.

`Row span` — Range of rows

`All rows` (default) | `One row` | `Range of rows`

The range of input rows to be retained in the output.

`Row` — First row of output

`First` (default) | `Index` | `Offset from last` | `Last` | `Offset from middle` | `Middle`

The input row to be used as the first and only row of the output.

Dependencies

To enable this parameter, set **Row span** to `One row`.

`Starting row` — First row of output

`First` (default) | `Index` | `Offset from last` | `Last` | `Offset from middle` | `Middle`

The input row to be used as the first row of the output.

Dependencies

To enable this parameter, set **Row span** to `Range of rows`.

`Row index` — Index of first row

1 (default) | positive integer

The index of the input row to be used as the first and only row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to `One row` and **Row** to `Index`.

`Starting row index` — Index of first row

1 (default) | positive integer

The index of the input row to be used as the first row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to `Range of rows` and **Starting row** to `Index`.

`Row offset` — Offset of first row

1 (default) | positive integer

The offset of the input row to be used as the first and only row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to `One row` and **Row** to `Offset from last` or `Offset from middle`.

`Starting row offset` — Offset of first row

1 (default) | positive integer

The offset of the input row to be used as the first row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to `Range of rows` and **Starting row** to `Offset from last` or `Offset from middle`.

`Ending row` — Last row

`Last` (default) | `Index` | `Offset from last` | `Offset from middle` | `Middle`

The input row to be used as the last row of the output.

Dependencies

To enable this parameter, set **Row span** to `Range of rows` and set **Starting row** to any value except `Last`.

`Ending row index` — Index of last row

1 (default) | positive integer

The index of the input row to be used as the last row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Ending row** to `Index`.

`Ending row offset` — Offset of last row

1 (default) | positive integer

The offset of the input row to be used as the last row of the output.

Dependencies

To enable this parameter, set **Ending row** to `Offset from middle` or `Offset from last`.

`Column span` — Range of input columns

`All columns` (default) | `One column` | `Range of columns`

The range of input columns to be retained in the output.

`Column` — First column

`First` (default) | `Index` | `Offset from last` | `Last` | `Offset from middle` | `Middle`

The input column to be used as the first and only column of the output.

Dependencies

To enable this parameter, set **Column span** to `One column`.

`Starting column` — First column

`First` (default) | `Index` | `Offset from last` | `Last` | `Offset from middle` | `Middle`

The input column to be used as the first column of the output.

Dependencies

To enable this parameter, set **Column span** to `Range of columns`.

`Starting column index` — Index of first column

1 (default) | positive integer

The index of the input column to be used as the first column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to `Range of columns` and **Starting column** to `Index`.

`Column index` — Index of first column

1 (default) | positive integer

The index of the input column to be used as the first and only column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to `One column` and **Column** to `Index`.

`Column offset` — Offset of first column

1 (default) | positive integer

The offset of the input column to be used as the first and only column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to `One column` and **Column** to `Offset from last` or `Offset from middle`.

`Starting column offset` — Offset of first column

1 (default) | positive integer

The offset of the input column to be used as the first column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to `Range of columns` and **Starting column** to `Offset from last` or `Offset from middle`.

`Ending column` — Last column

`Last` (default) | `Index` | `Offset from last` | `Offset from middle` | `Middle`

The input column to be used as the last column of the output.

Dependencies

To enable this parameter, set **Column span** to `Range of columns` and set **Starting column** to any value except `Last`.

`Ending column index` — Index of last column

1 (default) | positive integer

The index of the input column to be used as the last column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Ending column** to `Index`.

`Ending column offset` — Offset of last column

1 (default) | positive integer

The offset of the input column to be used as the last column of the output.

Dependencies

To enable this parameter, set **Ending column** to `Offset from middle` or `Offset from last`.

Block Characteristics

Data Types	`Boolean` | `double` | `enumerated` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

More About

Range Specification Options

The block treats length-*M* unoriented vector input as an *M*-by-1 matrix. The **Row span** parameter provides three options for specifying the range of rows in `u` to be retained in submatrix output `y`:

- `All rows`

  Specifies that `y` contains all *M* rows of `u`.

- `One row`

  Specifies that `y` contains only one row from `u`. Selecting `One row` enables the **Row** parameter to allow selection of the desired row.

- `Range of rows`

  Specifies that `y` contains a range of rows from `u`. Selecting `Range of rows` enables the **Starting row** and **Ending row** parameters to allow selection of the desired range of rows.

The **Column span** parameter contains a corresponding set of three options for specifying the range of columns in `u` to be retained in submatrix `y`: `All columns`, `One column`, or `Range of columns`. The `One column` option enables the **Column** parameter, and `Range of columns` options enable the **Starting column** and **Ending column** parameters.

When you select `One row` or `Range of rows` from the **Row span** parameter, you specify the desired row or range of rows in the **Row** parameter, or the **Starting row** and **Ending row** parameters. Similarly, when you select `One column` or `Range of columns` from the **Column span** parameter, you specify the desired column or range of columns in the **Column** parameter, or the **Starting column** and **Ending column** parameters.

The **Row**, **Column**, **Starting row**, or **Starting column** can be specified in six ways:

- `First`

  For rows, this specifies that the first row of `u` should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(1,:)`.

For columns, this specifies that the first column of `u` should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,1)`.

- `Index`

  For rows, this specifies that the row of `u`, `firstrow`, forward-indexed by the **Row index** parameter or the **Starting row index** parameter, should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(firstrow,:)`.

  For columns, this specifies that the column of `u`, forward-indexed by the **Column index** parameter or the **Starting column index** parameter, `firstcol`, should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,firstcol)`.

- `Offset from last`

  For rows, this specifies that the row of `u` offset from row *M* by the **Row offset** or **Starting row offset** parameter, `firstrow`, should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(M-firstrow,:)`.

  For columns, this specifies that the column of `u` offset from column *N* by the **Column offset** or **Starting column offset** parameter, `firstcol`, should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,N-firstcol)`.

- `Last`

  For rows, this specifies that the last row of `u` should be used as the only row of `y`. When all columns are to be included, this is equivalent to `y = u(M,:)`.

  For columns, this specifies that the last column of `u` should be used as the only column of `y`. When all rows are to be included, this is equivalent to `y = u(:,N)`.

- `Offset from middle`

  When you select this option, the block selects the first row or column of the output `y` by adding the specified offset to the middle row or column of the input `u`. When the number, *X*, of input rows or columns is even, the block defines the middle as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle as `ceil`(*X*/2).

  When all columns are to be included, the following code defines the starting row: `y(1,:) = u(MiddleRow+Offset,:)`, where `Offset` is the value of the **Row offset**

or **Starting row offset** parameter. When all rows are to be included, the following code defines the starting column: `y(1,:) = u(:,MiddleColumn+Offset)`, where `Offset` is the value of the **Column offset** or **Starting column offset** parameter.

- `Middle`

  When you select this option, the block uses the middle row or column of the input `u` as the first row or column of the output `y`. When the number, *X*, of input rows or columns is even, the block defines the middle as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle as `ceil`(*X*/2).

  When all columns are to be included, the following code defines the starting row: `y = u(MiddleRow,:)`. When all rows are to be included, the following code defines the starting column: `y = u(:,MiddleColumn)`.

The **Ending row** or **Ending column** can similarly be specified in five ways:

- `Index`

  For rows, this specifies that the row of `u` forward-indexed by the **Ending row index** parameter, `lastrow`, should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(lastrow,:)`.

  For columns, this specifies that the column of `u` forward-indexed by the **Ending column index** parameter, `lastcol`, should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,lastcol)`.

- `Offset from last`

  For rows, this specifies that the row of `u` offset from row *M* by the **Ending row offset** parameter, `lastrow`, should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(M-lastrow,:)`.

  For columns, this specifies that the column of `u` offset from column *N* by the **Ending column offset** parameter, `lastcol`, should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,N-lastcol)`.

- `Last`

  For rows, this specifies that the last row of `u` should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(M,:)`.

  For columns, this specifies that the last column of `u` should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,N)`.

- `Offset from middle`

  When you select this option, the block selects the last row or column of the output `y` by adding the specified offset to the middle row or column of the input `u`. When the number, *X*, of input rows or columns is even, the block defines the middle as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle as `ceil`(*X*/2).

  When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow+Offset,:)`, where `Offset` is the value of the **Ending row offset** parameter. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn+Offset)`, where `Offset` is the value of the **Ending column offset** parameter.

- `Middle`

  When you select this option, the block uses the middle row or column of the input `u` as the last row or column of the output `y`. When the number, *X*, of input rows or columns is even, the block defines the middle as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle as `ceil`(*X*/2).

  When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow,:)`. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn)`.

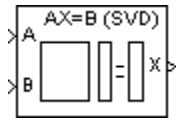
SVD Solver

Solve $AX=B$ using singular value decomposition



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The SVD Solver block solves the linear system $AX=B$, which can be overdetermined, underdetermined, or exactly determined. The system is solved by applying singular value decomposition (SVD) factorization to the M-by-N matrix A, at the A port. The input to the B port is the right side M-by-L matrix, B. The block treats length-M unoriented vector input as an M-by-1 matrix.

The output at the X port is the N-by-L matrix, X. X is chosen to minimize the sum of the squares of the elements of B-AX (the residual). When B is a vector, this solution minimizes the vector 2-norm of the residual. When B is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of X are the solutions to the L corresponding systems $AX_k=B_k$, where B_k is the kth column of B, and X_k is the kth column of X.

X is known as the minimum-norm-residual solution to $AX=B$. The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but it is not unique for underdetermined linear systems. Thus when the SVD Solver block is applied to an underdetermined system, the output X is chosen such that the number of nonzero entries in X is minimized.

Parameters

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- `0` — The singular value decomposition calculation converges.
- `1` — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at port X is an undefined matrix of the correct size.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point
B	• Double-precision floating point • Single-precision floating point
X	• Double-precision floating point • Single-precision floating point
E	• Boolean

Time Scope, Scope

Display and analyze signals generated during simulation and log signal data to MATLAB

Library: DSP System Toolbox / Sinks
DSP System Toolbox HDL Support / Sinks

Description

The Simulink Scope block and DSP System Toolbox Time Scope block display time domain signals.

Triggers
Main
Mode: Auto
Position (%): 50
Source / Type
Levels / Timing

The two blocks have identical functionality, but different default settings. The Time Scope is optimized for discrete time processing. The Scope is optimized for general time-domain simulation. For a side-by-side comparison, see “Simulink Scope Versus DSP System Toolbox Time Scope” (Simulink).

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the *x*-axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

You must have a Simscape™ or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

Scope display features:

- Simulation control — Debug models from a Scope window using **Run**, **Step Forward**, and **Step Backward** toolbar buttons.
- Multiple signals — Plot multiple signals on the same *y*-axis (display) using multiple input ports.
- Multiple y-axes (displays) — Display multiple *y*-axes. All the *y*-axes have a common time range on the *x*-axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscale axes during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.
- Display data after simulation — Scope data is saved during a simulation. If a scope is closed at the start of a simulation, when you open the scope after a simulation, the scope displays simulation results for attached input signals.

Note If you have a high sample rate or long simulation time, you may run into issues with memory or system performance because the scope saves data internally. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

For information on controlling a scope programmatically, see “Control Scope Blocks Programmatically” (Simulink).

Limitations

- Do not use scope blocks in a Library. If you place a scope block inside a library block with a locked link or in a locked library, Simulink displays an error when trying to open the scope window. To display internal data from a library block, add an output port to the library block, and then connect the port to a Scope block in your model.
- If you step through a model, the scope only updates when the scope block runs. This means that the time shown in the status bar may not match the model time.
- When connected to a constant signal, a scope block may plot a single point.
- The scope shows gaps in the display when the signal value is `NaN`.
- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.

Ports

Input

`Port_1` — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink” (Simulink).
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” (Simulink) and “Determine Output Signal Dimensions” (Simulink).

Input Limitations

- When the input is a constant signal, the scope plots a single point.
- The scope shows gaps in the display when the signal value is `NaN`.
- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope. To display the bus signals, use normal or accelerator simulation mode. The scope displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope, set the **Save format** parameter to `Dataset`. You can use any **Save format** to log virtual bus signals.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View > Configuration Properties**.

Main

`Open at simulation start` — Specify when scope window opens
off (default for Scope) | on (default for Time Scope)

Select this check box to open the scope window when simulation starts.

Programmatic Use

See `OpenAtSimulationStart`.

`Display the full path` — Display block path on scope title bar
off (default) | on

Select this check box to display the block path in addition to the block name.

`Number of input ports` — Number of input ports on scope block

1 (default) | integer

Specify number of input ports on a Scope block, specified as an integer. The maximum number of input ports is 96.

Programmatic Use

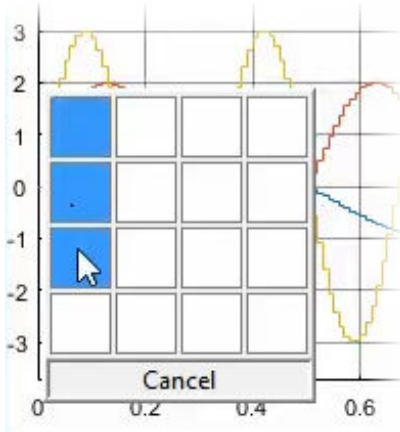
See `NumInputPorts`.

Layout — Number and arrangement of displays

1-by-1 display (default) | an arrangement of `m`-by-`n` axes

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.



If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down then across.

Programmatic Use

See `LayoutDimensions`.

`Sample time` — Simulation interval between scope updates

`-1` (for inherited) (default) | positive real number

Specify the time interval between updates of the scope display. This property does not apply to floating scopes and scope viewers.

Programmatic Use

See `SampleTime`.

`Input processing` — Channel or element signal processing

`Elements as channels (sample based)` (default for Scope) | `Columns as channels (frame based)` (default for Time Scope)

- `Elements as channels (sample based)` - Process each element as a unique sample.
- `Columns as channels (frame based)` - Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See `FrameBasedProcessing`.

`Maximize axes` — Maximize size of plots

`Off` (default for Scope) | `Auto` (default for Time Scope) | `On`

- `Auto` - If “Title” on page 2-0 and “Y-label” on page 2-0 properties are not specified, maximize all plots.
- `On` - Maximize all plots. Values in **Title** and **Y-label** are hidden.
- `Off` - Do not maximize plots.

Programmatic Use

See `MaximizeAxes`.

Time

`Time span` — Length of *x*-axis to display
`Auto` (default) | `User defined`

- `Auto` — Difference between the simulation start and stop times.

  The block calculates the beginning and end times of the time range using the "Time display offset" on page 2-0 and "Time span" on page 2-0 properties. For example, if you set the **Time display offset** to `10` and the **Time span** to `20`, the scope sets the time range from `10` to `30`.
- `User defined` — Enter any value less than the total simulation time.

Programmatic Use

See `TimeSpan`.

`Time span overrun action` — Display data beyond visible *x*-axis
`Wrap` (default) | `Scroll`

Specify how to display data beyond the visible *x*-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- `Wrap` — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.
- `Scroll` — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See `TimeSpanOverrunAction`.

`Time units` — *x*-axis units
`None` (default for Scope) | `Metric` (default for Time Scope) | `Seconds`

- `Metric` — Display time units based on the length of "Time span" on page 2-0 .
- `Seconds` — Display time in seconds.
- `None` — Do not display time units.

Programmatic Use

See `TimeUnits`.

`Time display offset` — *x*-axis offset

`0` (default) | scalar | vector

Offset the *x*-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- Scalar — Offset all channels of an input signal by the same time value.
- Vector — Independently offset the channels.

Programmatic Use

See `TimeDisplayOffset`.

`Time-axis labels` — Display of *x*-axis labels

`Bottom Displays Only` (default for Scope) | `All` (default for Time Scope) | `None`

Specify how *x*-axis (time) labels display:

- `All` — Display *x*-axis labels on all *y*-axes.
- `None` — Do not display labels. Selecting `None` also clears the **Show time-axis label** check box.
- `Bottom displays only` — Display *x*-axis label on the bottom *y*-axis.

Dependencies

To enable this property, set:

- "Show time-axis label" on page 2-0 to on.
- "Maximize axes" on page 2-0 to off.

The "Active display" on page 2-0 property determines which display is affected.

Programmatic Use

See `TimeAxisLabels`.

`Show time-axis label` — Display or hide *x*-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the *x*-axis label for the active display

Dependencies

To enable this property, set "Time-axis labels" on page 2-0 to `All` or `Bottom Displays Only`.

The "Active display" on page 2-0 property determines which display is affected.

Programmatic Use

See `ShowTimeAxisLabel`.

Display

`Active display` — Selected display

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

Programmatic Use

See `ActiveDisplay`.

`Title` — Display name

`%<SignalLabel>` (default) | string

Title for a display. The default value `%<SignalLabel>` uses the input signal name for the title.

Dependency

The "Active display" on page 2-0 property determines which display is affected.

Programmatic Use

See `Title`.

`Show legend` — Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `ShowLegend`.

`Show grid` — Show internal grid lines

on (default) | off

Select this check box to show grid lines.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `ShowGrid`.

`Plot signals as magnitude and phase` — Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same *y*-axis.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `PlotAsMagnitudePhase`.

`Y-limits (Minimum)` — Minimum y-axis value

`-10` (default) | real scalar

Specify the minimum value of the *y*-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The *y*-axis limits of the phase plot are always `[-180 180]`.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `YLimits`.

`Y-limits (Maximum)` — Maximum y-axis value

`10` (default) | real scalar

Specify the maximum value of the *y*-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The *y*-axis limits of the phase plot are always `[-180 180]`.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `YLimits`.

`Y-label` — Y-axis label

none (default for Scope) | `Amplitude` (default for Time Scope) | string

Specify the text to display on the *y*-axis. To display signal units, add `(%<SignalUnits>)` to the label. At the beginning of a simulation, Simulink replaces `(%SignalUnits)` with the units associated with the signals.

Example: For a velocity signal with units of `m/s`, enter `Velocity (%<SignalUnits>)`.

Dependency

If you select **Plot signals as magnitude and phase**, this property does not apply. The *y*-axes are labeled `Magnitude` and `Phase`.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `YLabel`.

Logging

`Limit data points to last` — Limit buffered data values

off and `5000` (default) | on | positive integer

Limit data saved by the scope internally. By default all data points are saved so that you can view the scope visualization after the simulation finishes. For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

Note If you do not select **Limit data points to last** and you have a high sample rate or long simulation time, you may run into issues with memory or system performance.

When you select this property, the scope saves the latest *n* data points, where *n* the specified number of data points.

- Off — Save and plot all data values.

- On — Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

  In some cases, selecting this parameter can have the effect of plotting signals for less than the entire time range of a simulation (for example if your sample time is small). If the scope plots a portion of your signals, consider increasing the number of data points to save.

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 2-0 .

Programmatic Use

See `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

`Decimation` — Reduce amount of scope data to display and save

off, 2 (default) | on | positive integer

- On — Plot and log (save) scope data every `N`th data point, where `N` is the decimation factor entered in the text box. A value of `1` buffers all data values.
- Off — Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 2-0 .

Programmatic Use

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

`Log data to workspace` — Save data to MATLAB workspace

off (default) | on

Select this check box to enable logging and enable the **Variable name**, **Save format**, and **Decimation** properties. This property does not apply to floating scopes and scope viewers.

For an example of saving signals to the MATLAB Workspace using a Scope block, see “Save Simulation Data from Floating Scope” (Simulink).

Programmatic Use

See `DataLogging`.

`Variable name` — Name of saved data variable

`ScopeData` (default) | string

Specify a variable name for saving scope data in the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

Programmatic Use

See `DataLoggingVariableName`.

`Save format` — MATLAB variable format

`Dataset` (default) | `Structure With Time` | `Structure` | `Array`

Select variable format for saving data to the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

- `Dataset` — Save data as a dataset object. Use the **Dataset signal format** configuration parameter to select the dataset object. This format does not support variable-size data, MAT-file logging, or external mode archiving. See `Simulink.SimulationData.Dataset`.
- `Structure With Time` — Save data as a structure with associated time information.
- `Structure` — Save data as a structure.
- `Array` — Save data as an array with associated time information. This format does not support variable-size data.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

Programmatic Use

See `DataLoggingSaveFormat`.

Axes Scaling Properties

The **Axes Scaling** dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

`Axes scaling` — Y-axis scaling mode
`Manual` (default) | `Auto` | `After N Updates`

- `Manual` — Manually scale the *y*-axis range with the **Scale Y-axis Limits** toolbar button.
- `Auto` — Scale the *y*-axis range during and after simulation. Selecting this option displays the "Do not allow Y-axis limits to shrink" on page 2-0 check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to `Auto` and clear the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Scale *y*-axis after the number of time steps specified in the "Number of updates" on page 2-0 text box (`10` by default). Scaling occurs only once during each run.

Programmatic Use

See `AxesScaling`.

`Do not allow Y-axis limits to shrink` — When y-axis limits can change
on (default) | off

Allow *y*-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set "Axes scaling" on page 2-0 to `Auto`.

`Number of updates` — Number of updates before scaling
`10` (default) | integer

Set this property to delay auto scaling the *y*-axis.

Dependency

To use this property, set "Axes scaling" on page 2-0 to `After N Updates`.

Programmatic Use

See `AxesScalingNumUpdates`.

`Scale axes limits at stop` — When y-axis limits can change
on (default) | off

- On — Scale axes when simulation stops.
- Off — Scale axes continually.

Dependency

To use this property, set "Axes scaling" on page 2-0 to `Auto`.

`Y-axis Data range (%)` — Percent of *y*-axis to use for plotting
`80` (default) | integer between [1, 100]

Specify the percentage of the *y*-axis range used for plotting data. If you set this property to `100`, the plotted data uses the entire *y*-axis range.

`Y-axis Align` — Alignment along *y*-axis
`Center` (default) | `Top` | `Bottom`

Specify where to align plotted data along the *y*-axis data range when **Y-axis Data range** is set to less than 100 percent.

- `Top` — Align signals with the maximum values of the *y*-axis range.
- `Center` — Center signals between the minimum and maximum values.
- `Bottom` — Align signals with the minimum values of the *y*-axis range.

`Autoscale X-axis limits` — Scale *x*-axis range limits
off (default) | on

Scale *x*-axis range to fit all signal values. If **Axes scaling** is set to `Auto`, the data currently within the axes is scaled, not the entire signal in the data buffer.

`X-axis Data range (%)` — Percent of *x*-axis to use for plotting
`100` (default) | integer in the range [1, 100]

Specify the percentage of the *x*-axis range to plot data on. For example, if you set this property to `100`, plotted data uses the entire *x*-axis range.

`X-axis Align` — Alignment along *x*-axis
`Center` (default) | `Top` | `Bottom`

Specify where to align plotted data along the *x*-axis data range when **X-axis Data range** is set to less than 100 percent.

- `Top` — Align signals with the maximum values of the *x*-axis range.
- `Center` — Center signals between the minimum and maximum values.
- `Bottom` — Align signals with the minimum values of the *x*-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View > Style**.

`Figure color` — Background color for window
black (default) | color

Background color for the scope.

`Plot type` — How to plot signal
`Auto` (default for Scope) | `Line` (default for Time Scope) | `Stairs` | `Stem`

When you select `Auto`, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

`Axes colors` — Background and axes color for individual displays
black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

`Preserve colors for copy to clipboard` — Copy scope without changing colors
off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

`Properties for line` — Line to change
`Channel 1` (default)

Select active line for setting line style properties.

`Visible` — Line visibility
on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

`Line` — Line style
solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

`Marker` — Data point marker style
`None` (default) | marker shape

Select marker shape.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

Block Characteristics

Data Types	`Boolean` | `bus`[a] | `double` | `enumerated` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`yes`

Variable-Size Signals	yes
Zero-Crossing Detection	no

a. Virtual bus not supported. Nonvirtual bus supported only in normal and accelerator mode simulation. Data logging for nonvirtual bus supported only in the dataset format

Tips

If you run your simulation for a long time, you may run into out-of-memory issues because the scope saves data. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

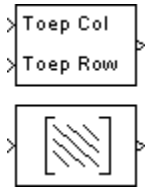
Toeplitz

Generate matrix with Toeplitz symmetry



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Toeplitz block generates a Toeplitz matrix from inputs defining the first column and first row. The top input (`Col`) is a vector containing the values to be placed in the first *column* of the matrix, and the bottom input (`Row`) is a vector containing the values to be placed in the first *row* of the matrix.

```
y = toeplitz(Col,Row)                          % Equivalent MATLAB code
```

The other elements of the matrix obey the relationship

```
y(i,j) = y(i-1,j-1)
```

and the output has dimension `[length(Col) length(Row)]`. The y(1,1) element is inherited from the `Col` input. For example, the following inputs

```
Col = [1 2 3 4 5]
Row = [7 7 3 3 2 1 3]
```

produce the Toeplitz matrix

$$\begin{bmatrix} 1 & 7 & 3 & 3 & 2 & 1 & 3 \\ 2 & 1 & 7 & 3 & 3 & 2 & 1 \\ 3 & 2 & 1 & 7 & 3 & 3 & 2 \\ 4 & 3 & 2 & 1 & 7 & 3 & 3 \\ 5 & 4 & 3 & 2 & 1 & 7 & 3 \end{bmatrix}$$

When you select the **Symmetric** check box, the block generates a symmetric (Hermitian) Toeplitz matrix from a single input, `u`, defining both the first row and first column of the matrix.

```
y = toeplitz(u)                          % Equivalent MATLAB code
```

The output has dimension `[length(u) length(u)]`. For example, the Toeplitz matrix generated from the input vector `[1 2 3 4]` is

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 2 & 3 \\ 3 & 2 & 1 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix}$$

The Toeplitz block supports real and complex floating-point and fixed-point inputs.

Parameters

Symmetric

When selected, enables the single-input configuration for symmetric Toeplitz matrix output.

Saturate on integer overflow

When you generate a symmetric Toeplitz matrix with this block, if the input vector is complex, the output is a symmetric Hermitian matrix whose elements satisfy the relationship

$y(i, j) = \text{conj}(y(j, i))$

For fixed-point signals the conjugate operation could result in an overflow. When you select this parameter, overflows saturate. This parameter is only visible with the **Symmetric** parameter is selected. This parameter is ignored for floating-point signals.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers (real signals only)
Toep Col	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Toep Row	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

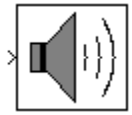
To Audio Device

Write audio data to computer's audio device



Compatibility

Note The To Audio Device block will be removed in a future release. Existing instances of the block continue to run. For new models, use the Audio Device Writer block instead.

Library

Sinks

`dspsnks4`

Description

The To Audio Device block sends audio data to your computer's audio device. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device to which you want to send the audio data. This parameter is automatically populated based on the audio devices installed on your system. If you plug or unplug an audio device from your system, type `clear mex` at the MATLAB command prompt to update the list.

Select the **Inherit sample rate from input** check box if you want the block to inherit the sample rate of the audio signal from the input to the block. If you clear this check box, the **Sample rate (Hz)** parameter appears on the block. Use this parameter to specify the number of samples per second in the signal.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** to specify the data type of the audio data that is sent to the device. You can choose:

- `8-bit integer`
- `16-bit integer`
- `24-bit integer`
- `32-bit float`
- `Determine from input data type`

If you choose `Determine from input data type`, the following table summarizes the block's behavior.

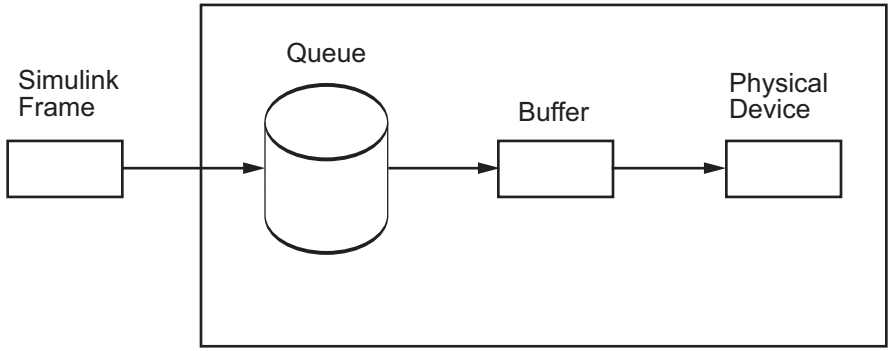
Input Data Type	Device Data Type
Double-precision floating point or single-precision floating point	32-bit floating point
32-bit integer	24-bit integer
16-bit integer	16-bit integer
8-bit integer	8-bit integer

If you choose `Determine from input data type` and the device does not support the input data type, the block uses the next lowest-precision data type supported by the device.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Buffering

The To Audio Device block buffers the data from a Simulink signal using the process illustrated by the following figure.



1. At the start of the simulation, the queue is filled with silence. Specify the size of this queue using the **Queue duration (seconds)** parameter. As Simulink runs, the block appends Simulink frames to the bottom of the queue.
2. At each time step, the blocks sends a buffer of samples from the top of the queue to the audio device. Select the **Automatically determine buffer size** check box to allow the block to use a conservative buffer size. See the From Audio Device block reference page for the equation the block uses to calculate this buffer size. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the size of the buffer in samples.
3. The block writes the buffer of audio data to the device. If the queue did not contain enough data to completely fill the buffer, the block fills the remaining portion of the buffer with zeros. This data has a the data type specified by the **Device data type** parameter.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially full, becomes empty. If the queue is empty, the block sends zeros (silence) to the audio device. You can monitor inserted zeroes using the optional `Underrun` output port. When the simulation throughput rate is higher than the hardware throughput rate, the To Audio Device block waits to write data to the queue.

To minimize the chance of dropouts, the block checks to make sure the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value.

Channel Mapping

The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio device directs input to a specific channel of audio data. You can specify channel mapping as a vector of output channel indices corresponding to each output channel of data being written. The default value in the **Device Output Channels** parameter is 1:MAXOUTPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Output Channels** parameter in the dialog box.

Example: The selected output audio device contains 8 channels. The data being output has dimensions N×3 (3–channel data). You want the output to be redirected as follows:

- First data channel to Audio Device channel 3
- Second data channel to Audio Device channel 1
- Third data channel to Audio Device channel 8

Thus, you would specify the **Device Output Channels** as [3 1 8].

Troubleshooting

Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue becomes empty and gaps occur in the audio data that the block sends to the device. Select the **Output number of samples by which the queue was underrun** check box to add an output port indicating when the queue was empty. Here are several ways to deal with this situation:

- *Increase the queue duration*.

  The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data supply can lag the hardware's data demand.

- *Increase the buffer size*.

  The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the device. If the buffer is too big, Simulink must

wait for the device to empty the buffer before it can write the data to the queue, which introduces latency.

- *Increase the simulation throughput rate*.

  Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

  - Increase frame sizes and use frame-based processing throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
  - Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Optimize Performance” (Simulink).

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Platform	Command

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/ tcsh)`
	
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH = $MATLABROOT\bin \win64;%PATH%`

Channel-to-Speaker Mapping on Windows Operating Systems

The To Audio Device and From Audio Device blocks can support multiple channels. On Windows operating systems, the channel-to-speaker mapping is defined as listed below. This mapping only applies when your sound card is properly configured and capable of receiving the audio data you send. If the number of channels on the card does not match the number of channels on the block, or if you specify a data type for the **Device data type** parameter that is not supported by your device, the Windows mixer intervenes to translate from one format to another. If the Windows mixer does intervene, the channel-to-speaker mapping might differ from what is specified here.

- Single channel input — Front center speaker

  On systems with two speakers, the front center channel is split between the right and left speakers.
- Multichannel input — Channels are assigned to speakers as follows:
  - One channel — Front center
  - Two channels — Front left, front right
  - Four channels — Front left, front right, rear left, rear right
  - Six channels — Front left, front right, front center, low frequency, rear left, rear right
  - Eight channels — Front left, front right, front center, low frequency, rear left, rear right, front left center, front right center
  - For all other channel combinations, the channel assignment is dictated by the audio card.

Audio Hardware API

The To Audio Device and From Audio Device blocks use the open-source PortAudio library in order to communicate with the audio hardware on a given computer. The PortAudio library supports a range of API's designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows: DirectSound, WDM-KS, ASIO
- Linux: ALSA, OSS
- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice.

To determine the audio hardware API currently selected, type the following command in the MATLAB command prompt.

```
getpref('dsp','portaudioHostApi')
```

The output is a scalar indicating the choice of the API.

- 1 — DirectSound
- 3 — ASIO
- 7 — OSS
- 8 — ALSA
- 11 — WDM-KS

To select a particular API, type the following command in the MATLAB command prompt.

```
setpref('dsp','portaudioHostApi',N)
```

where *N* is a scalar. Choose *N* based on the API choice above.

Parameters

Device

Specify which device to send the audio data to.

Inherit sample rate from input

Select this check box if you want the block to inherit the sample rate of the audio signal from the input to the block.

Sample rate (Hz)

Specify the number of samples per second in the signal. This parameter is visible when the **Inherit sample rate from input** check box is cleared.

Device data type

Specify the data type of the audio data sent to the device.

Automatically determine buffer size

Select this check box to allow the block to calculate a conservative buffer size.

Buffer size (samples)

Specify the size of the buffer. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

Queue duration (seconds)

Specify the size of the queue in seconds.

Use default mapping between Data and Device Output Channels

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

Device Output Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

Output number of samples by which the queue was underrun

Select this check box to output the number of zero samples inserted into the audio stream due to queue underrun since the last transfer of a frame to the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see “Troubleshooting” on page 2-1781.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • 32-bit signed integers • 16-bit signed integers • 8-bit unsigned integers
Underrun	32-bit unsigned integer

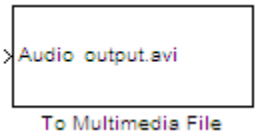
To Multimedia File

Stream video frames and audio samples to multimedia file



Library

Sinks

`dspsnks4`

Description

The To Multimedia File block writes video frames, audio samples, or both to a multimedia (`.avi, .wav, .wma, .mp4, .ogg, .flac, or .wmv`) file.

You can compress the video frames or audio samples by selecting a compression algorithm. You can connect as many of the input ports as you want. Therefore, you can control the type of video and/or audio the multimedia file receives.

Note This block supports code generation for platforms that have file I/O available. You cannot use this block with Simulink Desktop Real-Time software, because that product does not support file I/O.

This block performs best on platforms with Version 11 or later of Windows Media Player software. This block supports only uncompressed RGB24 AVI files on Linux and Mac platforms.

Windows 7 UAC (User Account Control), may require administrative privileges to encode `WMV` and `WMA` files.

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra

library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See “Understanding C Code Generation in DSP System Toolbox” for details.

Cross-Platform Supported File Formats for Audio Files

Audio files can be of the following formats on all platforms:

- WAV
- FLAC
- OGG
- MPEG4 (only on Windows 7 and macOS)

The default format is WAV. This block supports MPEG-4 AAC audio files on Windows 7, and macOS. You can use both M4A and MP4 extensions. The following platform specific restrictions apply when writing these files:

<table>
<tr><th>Windows 7</th><th>macOS</th></tr>
<tr><td>• Only sample rates of 44100 and 48000 Hz are supported.</td><td rowspan="2">• Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.</td></tr>
<tr><td>• Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.</td></tr>
<tr><td>• The output data is padded on both the front and back of the signal, with extra samples of silence.

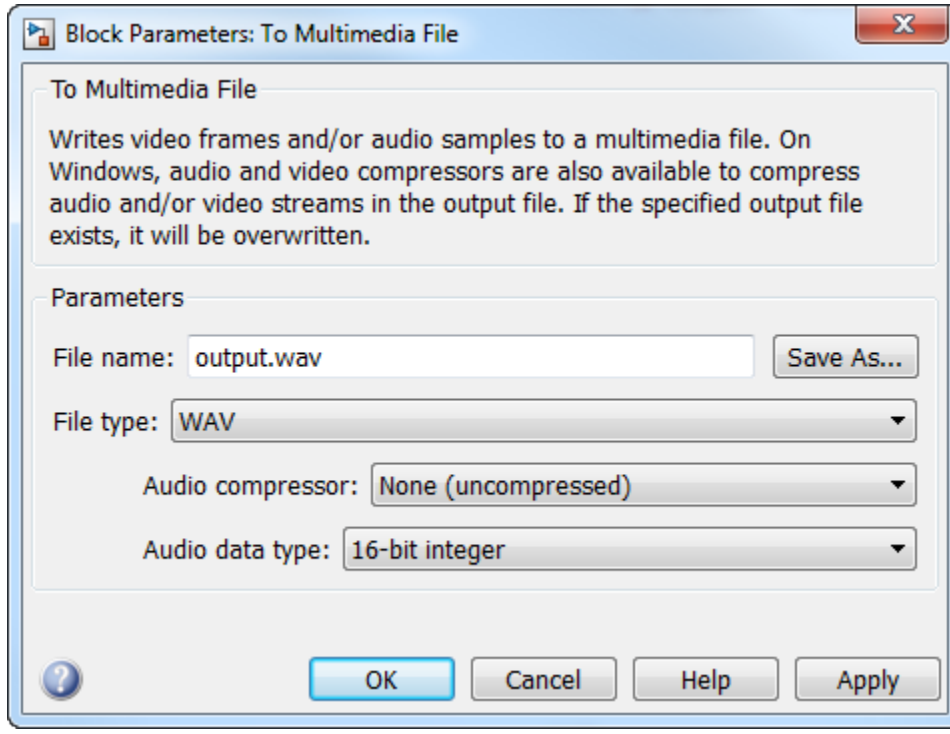
Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.</td><td rowspan="2">• Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.</td></tr>
<tr><td>• A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file.</td></tr>
</table>

Ports

Port	Description
Image	*M*-by-*N*-by-3 matrix RGB, Intensity, or YCbCr 4:2:2 signal.
R, G, B	Matrix that represents one plane of the RGB video stream. Inputs to the R, G, or B port must have the same dimensions and data type.
Audio	*M*-by-*N* matrix. *M* is the number of samples in each channel, and *N* is the number of channels.
Y, Cb, Cr	Matrix that represents one frame of the YCbCr video stream. The Y, Cb, and Cr ports use the following dimensions: Y: M x N Cb: M x$\frac{N}{2}$ Cr: M x$\frac{N}{2}$

Dialog Box

The **Main** pane of the To Multimedia File block dialog appears as follows.



File name

Specify the name of the multimedia file. The block saves the file in your current folder. To specify a different file or location, click the **Save As...** button.

File type

Specify the file type of the multimedia file. You can select `AVI`, `WAV`, `MJ2000`, `WMA`, `WMV`, `MPEG4`, `FLACC`, or `OGG`. By default, the **File type** is set to `WAV`.

Write

Specify whether the block writes video frames, audio samples, or both to the multimedia file. You can select `Video and audio`, `Video only`, or `Audio only`. This parameter is visible only when you set **File type** to `AVI`, `MPEG4`, or `OGG`.

Audio compressor

Select the type of compression algorithm to use to compress the audio data. This compression reduces the size of the multimedia file. Choose `None (uncompressed)` to save uncompressed audio data to the multimedia file.

Note The other items available in this parameter list are the audio compression algorithms installed on your system. For information about a specific audio compressor, see the documentation for that compressor.

Audio data type

Select the audio data type. You can use the **Audio data type** parameter only for uncompressed wave files.

Video compressor

Select the type of compression algorithm to use to compress the video data. This compression reduces the size of the multimedia file. Choose `None (uncompressed)` to save uncompressed video data to the multimedia file.

Note The other items available in this parameter list are the video compression algorithms installed on your system. For information about a specific video compressor, see the documentation for that compressor.

Compression Factor (>1)

Specify the compression factor as an integer scalar greater than `1`. This parameter is applicable only when the **File type** is set to `MJ2000` and **Video compressor** is set to `Lossy`. By default, this parameter is set to `10`.

File color format

Select the color format of the data stored in the file. You can select either `RGB` or `YCbCr 4:2:2`.

Image signal

Specify how the block accepts a color video signal. If you select `One multidimensional signal`, the block accepts an *M*-by-*N*-by-*P* color video signal, where *P* is the number of color planes, at one port. If you select `Separate color signals`, additional ports appear on the block. Each port accepts one *M*-by-*N* plane of an RGB video stream.

Video Quality (0-100)

Quality of the video specified as an integer scalar in the range `[0 100]`. This parameter is applicable only when **File name** is set to `MPEG4` and **Write** is set to `Video only`. By default, this parameter is set to `75`.

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH "$ {DYLD_LIBRARY_PATH}:$MATLABROOT/b in/maci64" (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH= $DYLD_LIBRARY_PATH:$MATLABROOT/bi n/maci64 (Bash)`
	
	For more information, see Append library path to "DYLD_LIBRARY_PATH" in MAC.

Linux	`setenv LD_LIBRARY_PATH $ {LD_LIBRARY_PATH}:$MATLABROOT/bin /glnxa64 (csh/tcsh)`
	
	`export LD_LIBRARY_PATH= $LD_LIBRARY_PATH:$MATLABROOT/bin/ glnxa64 (Bash)`

Windows	`set PATH=%PATH%;%MATLABROOT%\bin \win64`

Supported Data Types

For the block to display video data properly, double- and single-precision floating-point pixel values must be between `0` and `1`. Any other data type requires the pixel values between the minimum and maximum values supported by their data type.

Check the specific codecs you are using for supported audio rates.

Port	Supported Data Types	Supports Complex Values?
Image	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16- 32-bit signed integers • 8-, 16- 32-bit unsigned integers	No
R, G, B	Same as Image port	No
Audio	• Double-precision floating point • Single-precision floating point • 16-bit signed integers • 32-bit signed integers • 8-bit unsigned integers	No
Y, Cb, Cr	Same as Image port	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

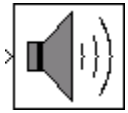
To Wave Device (Obsolete)

Send audio data to standard Windows audio device in real time



Library

`dspwin32`

Description

Note The To Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Audio Device block.

The To Wave Device block sends audio data to a standard Windows audio device in real time. It is compatible with most popular Windows hardware, including Sound Blaster cards. The data is sent to the hardware in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. Some hardware might support other rates in addition to these.

Note Models that contain both the To Wave Device block and the From Wave Device block require a duplex-capable sound card.

The **Use default audio device** check box allows the To Wave Device block to detect and use the system's default audio hardware. You should select this option for systems that have a single sound device installed, or when the default sound device on a multiple-device system is your desired target. When the default sound device is *not* your desired output device, clear **Use default audio device**, and set the desired hardware in the **Audio device** parameter. This parameter lists the names of the installed audio devices.

The block input can contain audio data from a mono or stereo signal. A mono signal is represented as either a sample-based scalar or a frame-based length-*M* vector, where *M* is frame size. A stereo signal is represented as a sample-based length-2 vector or a frame-based *M*-by-2 matrix.

When the input data type is `uint8`, the block conveys the signal samples to the audio device using 8 bits. When the input data type is `double`, `single`, `int16`, or fixed point with a word length of 16 and a fraction length of 15, the block conveys the signal samples to the audio device using 16 bits by default. For inputs of data type `double` and `single`, you can also set the block to convey the signal samples using 24 bits by selecting the **Enable 24-bit output for double- and single-precision input signals** check box. The 24-bit sample width requires more memory but in general yields better fidelity.

The amplitude of the input must be in a valid range that depends on the input data type, as shown in the following table. Amplitudes outside the valid range are clipped to the nearest allowable value.

Input Data Type	Valid Input Amplitude Range
`double`	$-1 \le amplitude < 1$
`single`	$-1 \le amplitude < 1$
`int16`	$-32768 \le amplitude \le 32767$
`uint8`	$0 \le amplitude \le 255$
Fixed point with a word length of 16 and a fraction length of 15	$-1 \le amplitude \le 1 - 2^{-15}$

Buffering

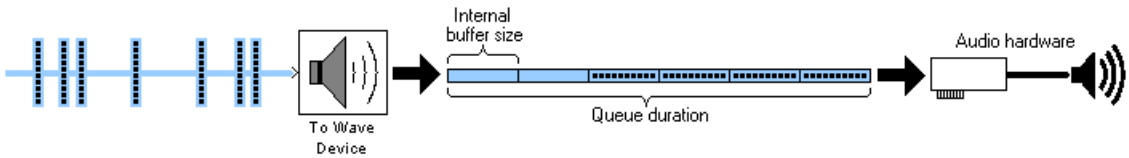
Because audio devices generate real-time audio output, the Simulink environment must maintain a continuous flow of data to a device throughout simulation. Delays in passing data to the audio hardware can result in hardware errors or distortion of the output. This means that the To Wave Device block must in principle supply data to the audio hardware as quickly as the hardware reads the data. However, the To Wave Device block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running within Simulink rather than as generated code. Simulink execution speed can vary during the simulation as the host operating system services other processes. The

block must therefore rely on a buffering strategy to ensure that signal data is available to the hardware on demand.

Note This block requires real-time execution of the parent model for best performance.

The following block parameters control the memory management for this block:

- **Queue duration**
- **Automatically determine internal buffer size** or **User-defined internal buffer size**
- **Initial output delay**



The **Queue duration** parameter defines the overall size of the block's buffer. The block reads in chunks of data in the size of the input dimensions and stores them in the buffer. The internal buffer size defines the dimensions of the block output to the hardware. You can define the internal buffer size yourself in the **User-defined internal buffer size parameter**. If you select **Automatically determine internal buffer size** instead, the internal buffer size is calculated for you according to the following rules:

- If the input to the block has a frame size of 32 samples or larger, the internal buffer size be the same as the input frame size.
- If the input to the block has a frame size smaller than 32 samples, the internal buffer size is based on the input sample rate according to the following table, where

$$F_s = samplingfrequency = \frac{1}{sampletime}$$

F_s (Hz)	Internal Buffer Size (samples)
$F_s < 8000$	$\min(64, 2 * F_s)$
$8000 \le F_s < 22,050$	128

F_s (Hz)	Internal Buffer Size (samples)
$22,050 \le F_S < 44,100$	256
$44,100 \le F_S < 96,000$	512
$F_S \ge 96,000$	1024

To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as big as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

The **Initial output delay** parameter enables you to preload the buffer before the block starts to output data to the audio device, which can be helpful for models that do not run in real time. However, for real-time applications, it is best to set the initial output delay to zero (one frame of delay), or as close to zero as possible.

Troubleshooting

If you are getting undesirable audio output using the To Wave Device block, first determine whether your model can run in real time. Replace the To Wave Device block with a To Wave File block, run the model, and compare the model's simulation stop time to the elapsed time on your watch. If the model simulation stop time is less than the elapsed time on your watch, your model can probably run in real time. Then,

- If your model can run in real time,

  1. Select **Automatically determine internal buffer size**. This alone might solve the problem. If not,
  2. Try increasing the **Queue duration** parameter to a relatively large value, such as 0.5 s.

  If one or both of these options restores desirable audio output, you can try reducing the internal buffer size and/or queue duration until the quality of the audio output again degrades.
- If your model is not running in real time, try to make it run in real time by

  1. Optimizing the model (using a more efficient implementation), or
  2. Using a Simulink “Acceleration” (Simulink) mode, or
  3. Generating stand-alone code

If none of these are possible, but the model only runs for a short period of time, set the **Queue duration** parameter to a size equal to a significant fraction of the model stop time and use a similarly large initial delay. This is not an optimal solution, but might work in some cases.

Parameters

Queue duration (seconds)

Specify the overall buffer size. To minimize the chance of dropouts, the block checks to make sure that the queue duration is as least as large as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

Automatically determine internal buffer size

Select to have the block automatically select the internal buffer size for you. For details, see “Buffering” on page 2-1796.

User-defined internal buffer size (samples)

Define the internal buffer size, or the size of the chunks of data sent by the block to the audio hardware device.

This parameter is only visible when **Automatically determine internal buffer size** is not selected.

Initial output delay (seconds)

Specify the amount of time by which to delay the initial output to the audio device. During this time data accumulates in the block's buffer. Any value less than or equal to the queue duration specifies the smallest possible initial delay, which is a single frame.

Use default audio device

Select to direct audio output to the system's default audio device.

Audio device

This parameter lists the names of the installed audio devices. Specify the name of the audio device to receive the audio output. Select **Use default audio device** when the system has only a single audio card installed.

This parameter is only enabled when the **Use default audio device** check box is not selected.

Enable 24-bit output for double and single precision input signals

Select to output 24-bit data when inputs are double- or single-precision. Otherwise, the block outputs 16-bit data for double- and single-precision inputs.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

To Wave File (Obsolete)	DSP System Toolbox
`audioplayer`	MATLAB
`sound`	MATLAB

Introduced in R2008b

To Wave File (Obsolete)

Write audio data to file in Microsoft Wave (`.wav`) format

Library

`dspwin32`

Description

Note The To Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Multimedia File block.

The To Wave File block streams audio data to a Microsoft Wave (`.wav`) file in the uncompressed pulse code modulation (PCM) format. For compatibility reasons, the sample rate of the discrete-time input signal should typically be one of the standard Windows audio device rates (8000, 11025, 22050, or 44100 Hz), although the block supports arbitrary rates.

The input to the block, *u*, can contain audio data with one or more channels. A signal with *C* channels is represented as a sample-based length-*C* vector or a frame-based *M*-by-*C* matrix. The amplitude of the input should be in the range ±1. Values outside this range are clipped to the nearest allowable value.

```
wavwrite(u,Fs,bits,'filename')    % Equivalent MATLAB code
```

Note AVI files are the only supported file type for non-Windows platforms.

Parameters

File name

Specify the path and name of the file to write. Paths can be relative or absolute. You do not need to specify the `.wav` extension.

Sample width (bits)

Specify the number of bits used to represent the signal samples in the file. The higher sample width settings require more memory but yield better fidelity for double- and single-precision inputs:

- `8` — Allocates 8 bits to each sample, allowing a resolution of 256 levels
- `16` — Allocates 16 bits to each sample, allowing a resolution of 65536 levels
- `24` — Allocates 24 bits to each sample, allowing a resolution of 16777216 levels
- `32` — Allocates 32 bits to each sample, allowing a resolution of 2^{32} levels ranging from -1 to 1

The 8-, 16-, and 24-bit modes output integer data, while the 32-bit mode outputs single-precision floating-point data.

Minimum number of samples for each write to file

Specify the number of consecutive samples, L, to write with each file access. To reduce the required number of file accesses, the block writes L consecutive samples to the file during each access for$L \geq M$. For $L < M$, the block instead writes M consecutive samples during each access. Larger values of L result in fewer file accesses, which reduces run-time overhead.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

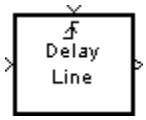
Triggered Delay Line (Obsolete)

Buffer sequence of inputs into frame-based output



Library

`dspobslib`

Description

Note The Triggered Delay Line block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Delay Line block.

The Triggered Delay Line block acquires a collection of M_o input samples into a frame, where you specify M_o in the **Delay line size** parameter. The block buffers a single sample from input 1 whenever it is triggered by the control signal at input 2 (⤒). When the next triggering event occurs, the newly acquired input sample is appended to the output frame so that the new output overlaps the previous output by M_o-1 samples. Between triggering events the block ignores input 1 and holds the output at its last value.

You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

The Triggered Delay Line block has zero latency, so the new input appears at the output in the same simulation time step. The output frame period is the same as the input sample period, $T_{fo}=T_{si}$.

Sample-Based Operation

In sample-based operation, the Triggered Delay Line block buffers a sequence of sample-based length-N vector inputs (1-D, row, or column) into a sequence of overlapping sample-based M_o-by-N matrix outputs, where you specify M_o in the **Delay line size** parameter ($M_o>1$). That is, each input vector becomes a *row* in the sample-based output matrix. When $M_o=1$, the input is simply passed through to the output, and retains the same dimension. Sample-based full-dimension matrix inputs are not accepted.

Frame-Based Operation

In frame-based operation, the Triggered Delay Line block rebuffers a sequence of frame-based M_i-by-N matrix inputs into an sequence of overlapping frame-based M_o-by-N matrix outputs, where M_o is the output frame size specified by the **Delay line size** parameter (that is, the number of consecutive samples from the input frame to rebuffer into the output frame). M_o can be greater or less than the input frame size, M_i. Each of the N input channels is rebuffered independently.

Initial Conditions

The Triggered Delay Line block's buffer is initialized to the value specified by the **Initial condition** parameter. The block always outputs this buffer at the first simulation step ($t=0$). When the block's output is a vector, the **Initial condition** can be a vector of the same size or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial condition** can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

Parameters

Trigger type

The type of event that triggers the block's execution.

Delay line size

The length of the output frame (number of rows in output matrix), M_o.

Initial condition

The value of the block's initial output, a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Trigger	• Any data type supported by the Trigger block
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

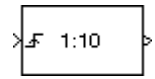
Triggered Signal From Workspace

Import signal samples from MATLAB workspace when triggered
Library: DSP System Toolbox / Signal Operations



Description

The Triggered Signal From Workspace block imports signal samples from the MATLAB workspace into the Simulink model when triggered by the control signal at the input port (). The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

Ports

Input

— Trigger signal

scalar | vector | matrix

Triggering input signal, specified as a scalar, vector, or matrix

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Signal imported from workspace

scalar | vector | matrix | 3-D array

The block outputs the signal imported from the workspace when triggered by the control signal at the input port.

When the **Signal** parameter specifies an M-by-N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame**

parameter, M_o. When triggered, the block outputs an M_o-by-N matrix containing M_o consecutive samples from each signal channel. For convenience, an imported row vector (M=1) is treated as a single channel, so the output dimension is M_o-by-1.

When the **Signal** parameter specifies an M-by-N-by-P array, the block generates a single page of the array (an M-by-N matrix) at each trigger time. The **Samples per frame** parameter must be set to `1`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

`Signal` — Signal to import

`1:10` (default) | MATLAB workspace variable | MATLAB expression

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

When the **Signal** parameter specifies an M-by-N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o. When triggered, the block outputs an M_o-by-N matrix containing M_o consecutive samples from each signal channel. For convenience, an imported row vector (M=1) is treated as a single channel, so the output dimension is M_o-by-1.

When the **Signal** parameter specifies an M-by-N-by-P array, the block generates a single page of the array (an M-by-N matrix) at each trigger time. The **Samples per frame** parameter must be set to `1`.

`Trigger type` — Type of triggering event

`Rising edge` (default) | `Falling edge` | `Either edge`

The type of event that triggers the block to execute.

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge occurs.

`Initial output` — Initial output value
`0` (default) | scalar | vector | matrix

The value to output until the first trigger event is received. Between trigger events, the block holds the output value constant at its most recent value (that is, no linear interpolation takes place). For single-channel signals, the **Initial output** can be a vector of length M_o or a scalar to repeat across the M_o elements of the initial output frames. For matrix outputs (M_o-by-N or M-by-N), the **Initial output** parameter value can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

`Samples per frame` — Samples per frame
1 (default) | positive integer

The number of samples, M_o, to buffer into each output frame specified as a positive integer scalar. This value must be `1` when you specify a 3-D array in the **Signal** parameter.

`Form output after final data value by` — Values to output after final imported signal value
`Setting to zero` (default) | `Holding final value` | `Cyclic repetition`

Specifies the output after all of the specified signal samples have been generated.

- When you specify `Setting To Zero`, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify `Holding Final Value`, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify `Cyclic Repetition`, the block repeats the signal from the beginning after generating the last frame. When there are not enough samples at the end of the signal to fill the final frame, the block zero-pads the final frame as necessary to ensure that the output for each cycle is identical. For example, the *i*th frame of one cycle contains the same samples as the *i*th frame of any other cycle.

The block does not extrapolate the imported signal beyond the last sample.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`

Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

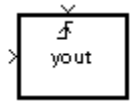
Blocks

Signal From Workspace | To Workspace | Triggered To Workspace

Introduced before R2006a

Triggered To Workspace

Write input sample to MATLAB workspace when triggered



Library

Sinks

`dspsnks4`

Description

The Triggered To Workspace block creates a matrix or array variable in the MATLAB workspace, where it stores the acquired inputs at the end of a simulation. The block overwrites an existing variable with the same name.

When you set the **Save 2-D signals as** parameter to `2-D array (concatenate along first dimension`, the block saves an *M*-by-*N* input as a *P*-by-*N* matrix, where *P* is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than *P* samples, the block stores only the most recent *P* samples. The **Decimation factor**, *D*, allows you to store only every *D*th input matrix.

When you set the **Save 2-D signals as** parameter to `3-D array (concatenate along third dimension`, the block saves an *M*-by-*N* input as a three-dimensional array in which each *M*-by-*N* page represents a single sample from each of the *M***N* channels (the most recent input matrix occupies the last page). The maximum size of this variable is limited to *M*-by-*N*-by-*P*, where *P* is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than *P* inputs, it stores only the last *P* inputs. The **Decimation factor**, *D*, allows you to store only every *D*th input matrix.

The block acquires and buffers a single frame from input 1 whenever it is triggered by the control signal at input 2 (⤒). At all other times, the block ignores input 1. You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

To save a record of the sample time corresponding to each sample value, open the Configuration Parameters dialog box. In the **Select** pane, click **Data Import/Export** and select the **Time** check box.

The nontriggered version of this block is the To Workspace block.

Parameters

Trigger type

The type of event that triggers the block's execution.

Variable name

The name of the workspace variable in which to store the data.

Maximum number of rows

The maximum number of rows (one row per time step) to be saved, *P*.

Decimation

The decimation factor, *D*.

Save 2-D signals as

Specify whether the block saves 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- `2-D array (concatenate along first dimension)` — When you select this option, the block vertically concatenates each *M*-by-*N* matrix input with the previous input to produce a 2-D output array.
- `3-D array (concatenate along third dimension)` — When you select this option, the block saves an *M*-by-*N* input signal as a 3-D array. The maximum size of

this 3-D array is limited to *M*-by-*N*-by-*P*, where *P* is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than *P* inputs, the block stores only the last *P* inputs. The **Decimation factor**, *D*, allows you to store only every *D*th input matrix.

Log fixed-point data as a fi object

Select to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

Port	Supported Data Types
Input	• Any data type supported by the To Workspace block
Trigger	• Any data type supported by the Trigger block

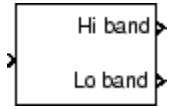
Two-Channel Analysis Subband Filter

Decompose signal into high-frequency and low-frequency subbands



Library

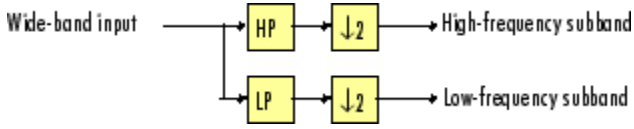
Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Analysis Subband Filter block decomposes the input into high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the input.

The block filters the input with a pair of highpass and lowpass FIR filters, and then downsamples the results by 2, as illustrated in the following figure.



The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward filter-then-decimate algorithm shown in the preceding figure. Each subband is the first phase of the respective polyphase filter. You can implement a multilevel dyadic analysis filter bank by connecting multiple copies of this block or by using the Dyadic Analysis Filter Bank block. See “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1819 for more information.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops.

See the following topics for more information about this block:

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector `[b(1) b(2) ... b(m)]`.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block. To do so, you must design perfect reconstruction filters to use in the synthesis subband filter.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function in to design both the filters both in this block and in the Two-Channel Synthesis Subband Filter block. You can also use other DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Analysis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts an *M*-by-*N* matrix. The block treats each column of the input

as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be an *M*-by-*N* matrix, where *M* is a multiple of two. The block treats each column of the input as an independent channel and decomposes each channel over time. The block outputs two matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. To maintain the input sample rate, the block decreases the output frame size by a factor of two.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i-by-*N* matrix input as *N* independent channels and decomposes each channel over time. The block outputs two *M*-by-*N* matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. The input and output frame *sizes* are the same, but the frame *rate* of the output is half that of the input. Thus, the overall sample rate of the output is half that of the input.

  In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1818 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an *M*-by-*N* matrix input as $M \cdot N$ independent channels. The block decomposes each channel over time and outputs two *M*-by-*N* matrices whose sample rates are half the input sample rate. Each element in the output matrix is the high- or low-frequency subband output of the corresponding element of the input matrix.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1818 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Analysis Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time $t=0$) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Analysis Subband Filter block may exhibit latency. The amount of latency

depends on the setting of the **Input processing** parameter of this block, and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
`Elements as channels (sample based)`	`Off`	None.
	`On`	One sample. The first output sample in each channel always has a value of `0`.
`Columns as channels (frame based)`	`On` or `Off`	One frame. All samples in the first output frame have a value of `0`.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Creating Multilevel Dyadic Analysis Filter Banks

The Two-Channel Analysis Subband Filter block is the basic unit of a dyadic analysis filter bank. You can connect several of these blocks to implement an *n*-level filter bank, as illustrated in the following figure. For a review of dyadic analysis filter banks, see the Dyadic Analysis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1818 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

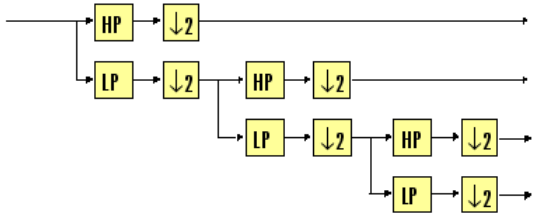
- The frame size of the signal you are decomposing is a multiple of 2^n.

- You are decomposing the signal into $n+1$ or 2^n subbands.

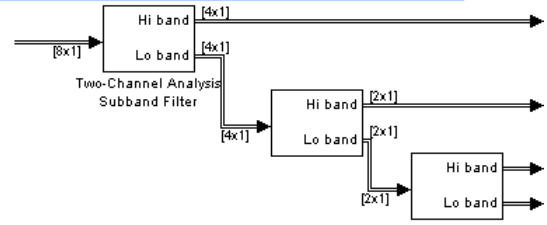
In all other cases, use Two-Channel Analysis Subband Filter blocks to implement your filter banks.

3-Level Dyadic Analysis Filter Banks

Conceptual illustration



Two-Channel Analysis Subband Filter block implementation

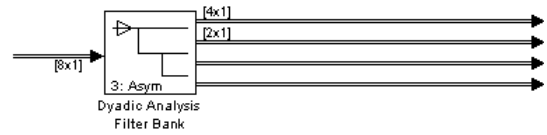


Both implementations of the dyadic analysis filter bank decompose a frame-based signal with frame size a multiple of 2^n into n+1 subbands, where n = 3.

In this case, the Dyadic Analysis Filter Bank block's implementation is more efficient.

Use the Two-Channel Analysis Subband Filter block implementation for other cases, such as to handle sample-based inputs, or to handle frame-based inputs whose frame size is not a multiple of 2^n.

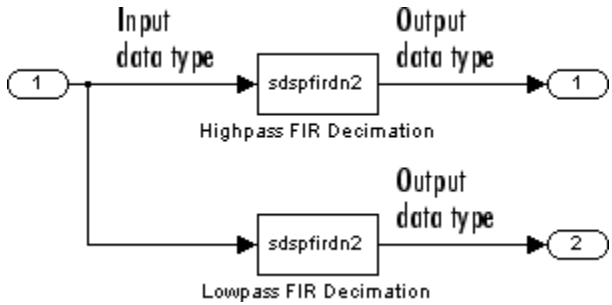
Dyadic Analysis Filter Bank block implementation



The Dyadic Analysis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Analysis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Analysis Subband Filter Bank block is composed of two FIR Decimation blocks as shown in the following diagram.



For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types of the FIR Decimation blocks as discussed in “Parameters” on page 2-1821. For a diagram showing the usage of these data types, see the FIR Decimation block reference page.

Parameters

Main Tab

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 2-1817.

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 2-1817.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and decomposes each channel over time. The output has the same sample rate as the input, but the output frame size is half that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is half that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1818 for more information.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always rounded to `Nearest`.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is `Inherit: Inherit via internal rule`
- **Accumulator** is `Inherit: Inherit via internal rule`
- **Output** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

Coefficients

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1820 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1820 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

  Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1820 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-1820 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)

- 8-, 16-, and 32-bit signed integers

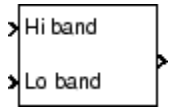
Two-Channel Synthesis Subband Filter

Reconstruct signal from high-frequency and low-frequency subbands



Library

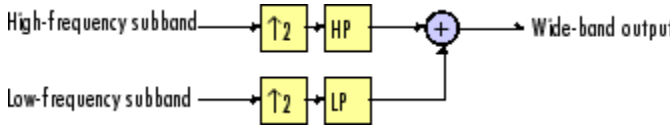
Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Synthesis Subband Filter block reconstructs a signal from its high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the original signal. Use this block to reconstruct signals decomposed by the Two-Channel Analysis Subband Filter block.

The block upsamples the high- and low-frequency subbands by 2, and then filters the results with a pair of highpass and lowpass FIR filters, as illustrated in the following figure.



The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward interpolate-then-filter algorithm shown in the preceding figure. You can implement a multilevel dyadic synthesis filter bank by connecting multiple copies of this block or by using the Dyadic Synthesis Filter Bank block. For more information, see “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1831.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

See the following topics for more information about this block:

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector `[b(1) b(2) ... b(m)]`.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function for the filters in both this block *and* in the corresponding Two-Channel Analysis Subband Filter block. You can also use DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Synthesis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts any two *M*-by-*N* matrices with the same frame rates. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be any two *M*-by-*N* matrices with the same frame rate. The block treats each input column as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of each input matrix. The input and output frame *rates* are the same, but the frame *size* of the output is twice that of the input.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of the input matrices. The input and output frame *sizes* are the same, but the frame *rate* of the output is twice that of the input. Thus, the overall sample rate of the output is twice that of the input sample rate.

  In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1831 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block accepts any two *M*-by-*N* matrices with the same sample rates. The block treats each *M*-by-*N* matrix as $M \cdot N$ independent subbands. Each element of the input matrices is the high- or low-frequency subband of the corresponding channel in the output matrix. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix with the same dimensions as the input matrices, but a sample rate that is twice that of the input. The block reconstructs each element of the output from the corresponding elements in the input matrices.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1831 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Synthesis Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time $t = 0$) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Synthesis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
`Elements as channels (sample based)`	`Off`	None.
	`On`	One sample. The first output sample in each channel always has a value of `0`.
`Columns as channels (frame based)`	`Off` or `On`	One frame. All samples in the first output frame have a value of `0`.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

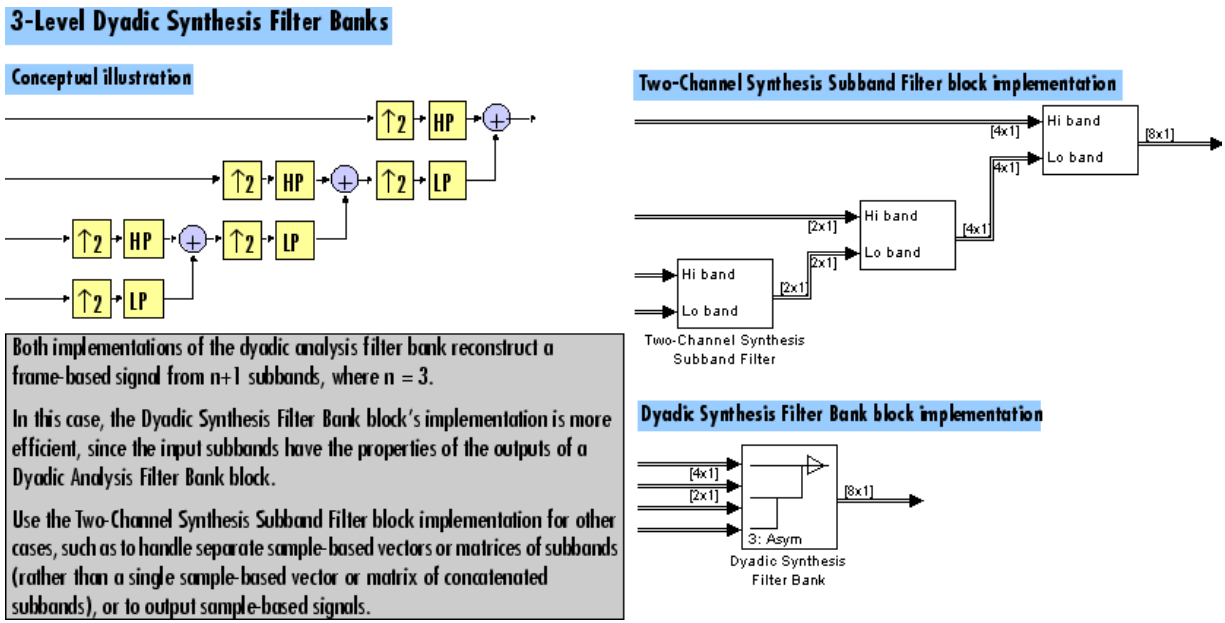
Creating Multilevel Dyadic Synthesis Filter Banks

The Two-Channel Synthesis Subband Filter block is the basic unit of a dyadic synthesis filter bank. You can connect several of these blocks to implement an n-level filter bank, as illustrated in the following figure. For a review of dyadic synthesis filter banks, see the Dyadic Synthesis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1831 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- You are reconstructing a signal from 2^n or $n+1$ subbands.
- The frame size of the signal you are reconstructing is a multiple of 2^n.
- The properties of the subbands you are working with match those of the outputs of the Dyadic Analysis Filter Bank block. These properties are described in the Dyadic Analysis Filter Bank reference page.

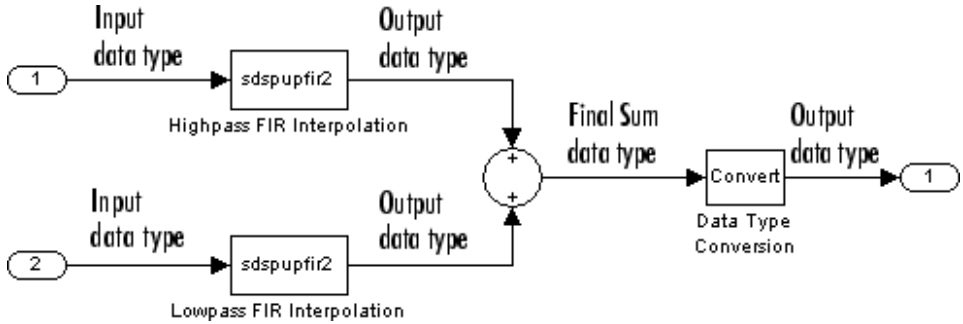


The Dyadic Synthesis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Synthesis Filter

Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Synthesis Subband Filter block is composed of two FIR Interpolation blocks as shown in the following diagram.



For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types used in the FIR Interpolation blocks as discussed in “Parameters” on page 2-1833. For a diagram showing the usage of these data types within the FIR blocks, see the FIR Interpolation block reference page.

In addition, the inputs to the Sum block shown in the previous diagram are accumulated using the accumulator data type. The output of the Sum block is then cast from the accumulator data type to the output data type. Therefore the output of the Two-Channel Synthesis Subband Filter block is in the output data type. You also set these data types in the block dialog box as discussed in the “Parameters” on page 2-1833 section.

Parameters

Main Tab

Lowpass FIR filter coefficients

A vector of lowpass FIR filter coefficients, in descending powers of z. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must

design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specifying the FIR Filters” on page 2-1829.

Highpass FIR filter coefficients

A vector of highpass FIR filter coefficients, in descending powers of z. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specifying the FIR Filters” on page 2-1829.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and reconstructs each channel over time. The output has the same sample rate as the input, but the output frame size is twice that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is twice that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1831 for more information.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is `Inherit: Inherit via internal rule`
- **Accumulator** is `Inherit: Inherit via internal rule`
- **Output** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

Coefficients

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1833 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1833 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

  Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1833 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-1833 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

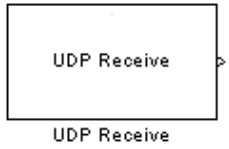
UDP Receive

Receive `uint8` vector as UDP message



Library

Sources

`dspsrcs4`

Description

The UDP Receive block receives UDP packets from an IP network port and saves them to its buffer. With each sample, the block outputs the contents of a single UDP packet as a data vector. The local IP port number on which the block receives the UDP packets is tunable in the C/C++ generated code.

The generated code for this block relies on prebuilt `.dll` files. You can run this code outside the MATLAB environment, or redeploy it, but you must account for these extra `.dll` files when doing so. The `packNGo` function creates a single zip file containing all of the pieces required to run or rebuild this code. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Parameters

Local IP port

Specify the IP port number on which to receive UDP packets. This parameter is tunable in the C/C++ generated code but not tunable during simulation. The default is `25000`. The value can be in the range [1 65535].

Note On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Remote IP address ('0.0.0.0' to accept all)

Specify the IP address from which to accept packets. Entering a specific IP address blocks UDP packets from other addresses. To accept packets from any IP address, enter `'0.0.0.0'`. This value defaults to `'0.0.0.0'`.

Receive buffer size (bytes)

Make the receive buffer large enough to avoid data loss caused by buffer overflows. This value defaults to `8192`.

Maximum length for Message

Specify the maximum length, in vector elements, of the data output vector. Set this parameter to a value equal or greater than the data size of a UDP packet. The system truncates data that exceeds this length. This value defaults to `255`.

If you disable **Output variable-size signal**, the block outputs a fixed-length output the same length as the **Maximum length for Message**.

Data type for Message

Set the data type of the vector elements in the Message output. Match the data type with the data input used to create the UDP packets. This option defaults to `uint8`.

Message is complex

Select this parameter to receive the message as complex data. Clear this parameter if the received message is real. By default, this parameter is not selected.

Output variable-size signal

If your model supports signals of varying length, enable the **Output variable-size signal** parameter. This checkbox defaults to selected (enabled). In that case:

- The output vector varies in length, depending on the amount of data in the UDP packet.
- The block emits the data vector from a single unlabeled output.

If your model does not support signals of varying length, disable the **Output variable-size signal** parameter. In that case:

- The block emits a fixed-length output the same length as the **Maximum length for Message**.
- If the UDP packet contains less data than the fixed-length output, the difference contains invalid data.
- The block emits the data vector from the **Message** output.
- The block emits the length of the valid data from the **Length** output.
- The block dialog box displays the **Data type for Length** parameter.

In both cases, the block truncates data that exceeds the **Maximum length for Message**.

Blocking time (seconds)

For each sample, wait this length of time for a UDP packet before returning control to the scheduler. This value defaults to `inf`, which indicates to wait indefinitely.

Note This parameter appears only in the Embedded Coder® UDP Receive block.

Sample time (seconds)

Specify how often the scheduler runs this block. Enter a value greater than zero. In real-time operation, setting this option to a smaller value reduces the likelihood of dropped UDP messages. This value defaults to a sample time of 0.01 s.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- The **Local IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code through several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. For details, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

UDP Send

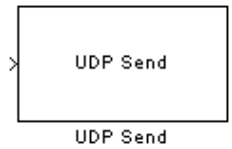
Send UDP message



Library

Sinks

`dspsnks4`

Limitations

The UDP buffer size is fixed at 8192 bytes and is not configurable.

Description

The UDP Send block transmits an input vector as a UDP message over an IP network port. The remote IP port number to which the block sends the UDP packets is tunable in the C/C++ generated code.

Note Some Simulink blocks and `.exe` files built from models that contain those blocks require shared libraries, such as `.dll` files on Windows. The UDP Send block requires the `networkdevice.dll` library file. To meet this requirement, follow the example on the `packNGo` function page to package the code files for your model. The resulting compressed folder contains the `.dll` files that the model requires, including `networkdevice.dll`. To run this type of `.exe` file outside a MATLAB environment, place the required `.dll` files in the same folder as the `.exe` file, or place them in a folder on the Windows system path. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Parameters

Remote IP address ('255.255.255.255' for broadcast)

Specify the IP address or hostname to which the block sends the message. To broadcast the UDP message, retain the default value, `'255.255.255.255'`.

Remote IP port

Specify the port to which the block sends the message. This parameter is tunable in the C/C++ generated code but not tunable during simulation. The default is `25000`. The value can be in the range [1 65535].

Note On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Local IP port source

To let the system automatically assign the port number, select `Automatically determine`. To specify the IP port number using the **Local IP port** parameter, select `Specify via dialog`.

Local IP port

Specify the IP port number from which the block sends the message.

If the receiving address expects messages from a particular port number, enter that number here.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Unbuffer

Unbuffer input frame into sequence of scalar outputs

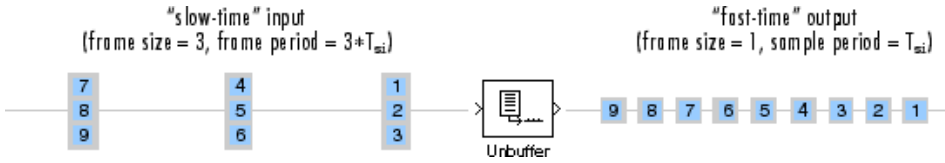
Library

Signal Management / Buffers

`dspbuff3`

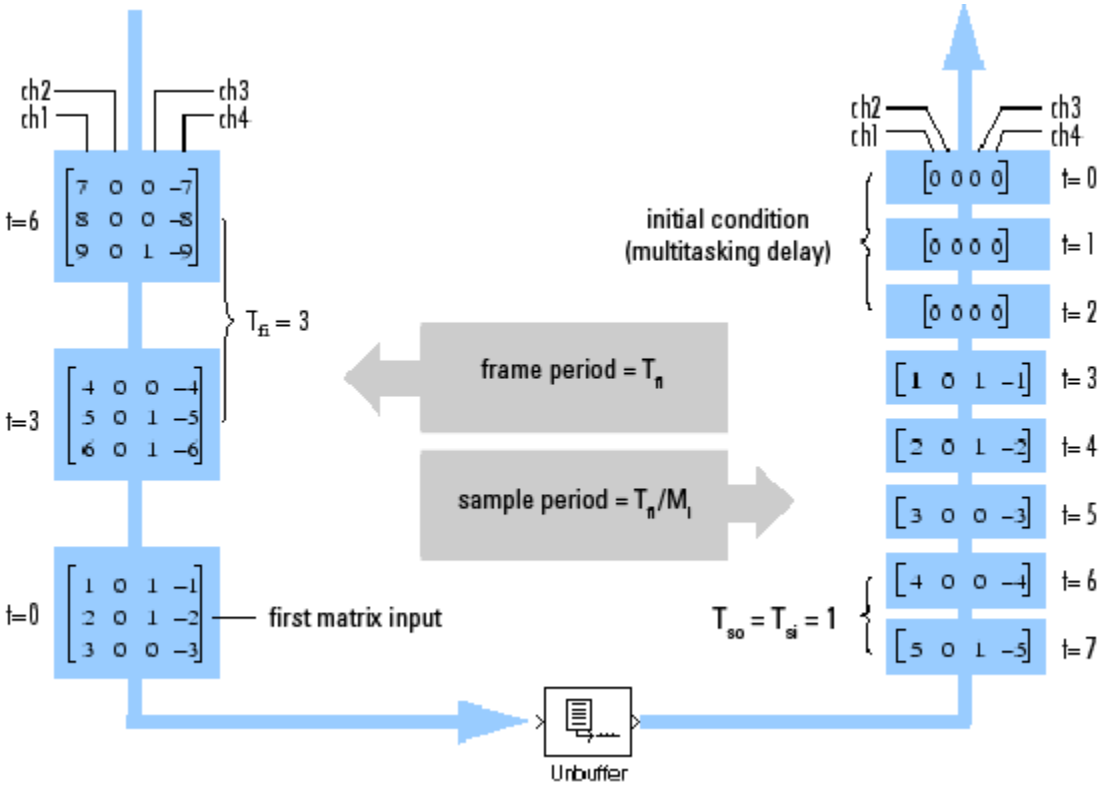
Description

The Unbuffer block unbuffers an M_i-by-N input into a 1-by-N output. That is, inputs are unbuffered *row-wise* so that each matrix row becomes an independent time-sample in the output. The rate at which the block receives inputs is generally less than the rate at which the block produces outputs.



The block adjusts the output rate so that the *sample period* is the same at both the input and output, $T_{so}=T_{si}$. Therefore, the output sample period for an input of frame size M_i and frame period T_{fi} is T_{fi}/M_i, which represents a *rate* M_i times higher than the input frame rate. In the example above, the block receives inputs only once every three sample periods, but produces an output once every sample period. To rebuffer inputs to a larger or smaller frame size, use the Buffer block.

In the model below, the block unbuffers a four-channel input with a frame size of three. The **Initial conditions** parameter is set to zero and the tasking mode is set to multitasking, so the first three outputs are zero vectors.



Zero Latency

The Unbuffer block has *zero-tasking latency* in Simulink single-tasking mode. Zero-tasking latency means that the first input sample (received at t=0) appears as the first output sample.

Nonzero Latency

For *multitasking* operation, the Unbuffer block's buffer is initialized with the value specified by the **Initial conditions** parameter, and the block begins unbuffering this frame at the start of the simulation. Inputs to the block are therefore delayed by one buffer length, or M_i samples.

The **Initial conditions** parameter can be one of the following:

- A scalar to be repeated for the first M_i output samples of every channel
- A length-M_i vector containing the values of the first M_i output samples for every channel
- An M_i-by-N matrix containing the values of the first M_i output samples in each of N channels

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Initial conditions

The value of the block's initial output for cases of nonzero latency. You can specify a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

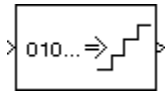
Uniform Decoder

Decode integer input into floating-point output



Library

Quantizers

`dspquant2`

Description

The Uniform Decoder block performs the inverse operation of the Uniform Encoder block, and reconstructs quantized floating-point values from encoded integer input. The block adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

Inputs can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

The block first casts the integer input values to floating-point values, and then uniquely maps (decodes) them to one of 2^B uniformly spaced floating-point values in the range [-V, $(1-2^{1-B})$V], where you specify B in the **Bits** parameter (as an integer between 2 and 32) and V is a floating-point value specified by the **Peak** parameter. The smallest input value representable by B bits (0 for an unsigned input data type; -2^{B-1} for a signed input data type) is mapped to the value -V. The largest input value representable by B bits (2^B-1 for an unsigned input data type; 2^{B-1}-1 for a signed input data type) is mapped to the value $(1-2^{1-B})$V. Intermediate input values are linearly mapped to the intermediate values in the range [-V, $(1-2^{1-B})$V].

To correctly decode values encoded by the Uniform Encoder block, the **Bits** and **Peak** parameters of the Uniform Decoder block should be set to the same values as the **Bits** and **Peak** parameters of the Uniform Encoder block. The **Overflow mode** parameter specifies the Uniform Decoder block's behavior when the integer input is outside the range representable by B bits. When you select **Saturate**, *unsigned* input values greater

than 2^B-1 saturate at 2^B-1; *signed* input values greater than 2^{B-1}-1 or less than -2^{B-1} saturate at those limits. The real and imaginary components of complex inputs saturate independently.

When you select **Wrap**, *unsigned* input values, `u`, greater than 2^B-1 are wrapped back into the range [0, 2^B-1] using mod-2^B arithmetic.

```
u = mod(u,2^B)
```

Signed input values, `u`, greater than 2^{B-1}-1 or less than -2^{B-1} are wrapped back into that range using mod-2^B arithmetic.

```
u = (mod(u+2^B/2,2^B)-(2^B/2))
```

The real and imaginary components of complex inputs wrap independently.

The **Output type** parameter specifies whether the decoded floating-point output is single or double precision. Either level of output precision can be used with any of the six integer input data types.

Examples

See example model ex_uniform_decoder.

In this example, the input to the block is the `uint8` output of a Uniform Encoder block. This block has comparable settings: **Peak** = `2`, **Bits** = `3`, and **Output type** = `Unsigned`. (Comparable settings ensure that inputs to the Uniform Decoder block do not saturate or wrap. See the example on the Uniform Encoder block reference page for more about these settings.)

The real and complex components of each input are independently mapped to one of 2^3 distinct levels in the range `[-2.0,1.5]`.

```
0  is mapped to  -2.0
1  is mapped to  -1.5
2  is mapped to  -1.0
3  is mapped to  -0.5
4  is mapped to   0.0
5  is mapped to   0.5
6  is mapped to   1.0
7  is mapped to   1.5
```

Parameters

Peak

Specify the largest amplitude represented in the encoded input. To correctly decode values encoded with the Uniform Encoder block, set the **Peak** parameters in both blocks to the same value.

Bits

Specify the number of input bits, B, used to encode the data. (This can be less than the total number of bits supplied by the input data type.) To correctly decode values encoded with the Uniform Encoder block, set the **Bits** parameters in both blocks to the same value.

Overflow mode

Specify the block's behavior when the integer input is outside the range representable by B bits. Out-of-range inputs can either saturate at the extreme value, or wrap back into range.

Output type

Specify the precision of the floating-point output, `single` or `double`.

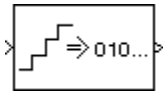
Uniform Encoder

Quantize and encode floating-point input into integer output



Library

Quantizers

`dspquant2`

Description

The Uniform Encoder block performs the following two operations on each floating-point sample in the input vector or matrix:

1. Quantizes the value using the same precision
2. Encodes the quantized floating-point value to an integer value

In the first step, the block quantizes an input value to one of 2^B uniformly spaced levels in the range $[-V, (1-2^{1-B})V]$, where you specify B in the **Bits** parameter and you specify V in the **Peak** parameter. The quantization process rounds both positive and negative inputs *downward* to the nearest quantization level, with the exception of those that fall exactly on a quantization boundary. The real and imaginary components of complex inputs are quantized independently.

The number of bits, B, can be any integer value between 2 and 32, inclusive. Inputs greater than $(1-2^{1-B})V$ or less than $-V$ saturate at those respective values. The real and imaginary components of complex inputs saturate independently.

In the second step, the quantized floating-point value is uniquely mapped (encoded) to one of 2^B integer values. When the **Output type** is set to `Unsigned integer`, the smallest quantized floating-point value, $-V$, is mapped to the integer 0, and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer 2^B-1. Intermediate

quantized floating-point values are linearly (uniformly) mapped to the intermediate integers in the range [0, 2^B-1]. For efficiency, the block automatically selects an *unsigned* output data type (`uint8`, `uint16`, or `uint32`) with the minimum number of bits equal to or greater than *B*.

When the **Output type** is set to `Signed integer`, the smallest quantized floating-point value, -*V*, is mapped to the integer -2^{B-1}, and the largest quantized floating-point value, (1-2^{1-B})*V*, is mapped to the integer 2^{B-1}-1. Intermediate quantized floating-point values are linearly mapped to the intermediate integers in the range [-2^{B-1}, 2^{B-1}-1]. The block automatically selects a *signed* output data type (`int8`, `int16`, or `int32`) with the minimum number of bits equal to or greater than *B*.

Inputs can be real or complex, double or single precision. The output data types that the block uses are shown in the table below. Note that most of the DSP System Toolbox blocks accept only double-precision inputs. Use the Simulink Data Type Conversion block to convert integer data types to double precision. See “About Data Types in Simulink” (Simulink) for a complete discussion of data types, as well as a list of Simulink blocks capable of reduced-precision operations.

Bits	Unsigned Integer	Signed Integer
2 to 8	`uint8`	`int8`
9 to 16	`uint16`	`int16`
17 to 32	`uint32`	`int32`

The Uniform Encoder block operations adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

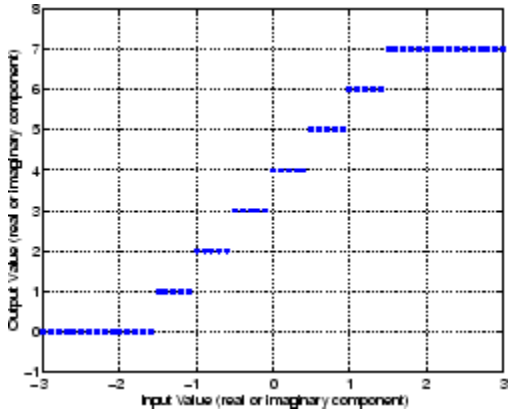
Examples

See example model ex_uniform_encoder.

In this example, the following parameters are set:

- **Peak** = 2
- **Bits** = 3
- **Output type** = `Unsigned`

The following figure illustrates uniform encoding.



The real and complex components of each input (horizontal axis) are independently quantized to one of 2^3 distinct levels in the range `[-2,1.5]`. These components are then mapped to one of 2^3 integer values in the range `[0,7]`.

```
-2.0  is mapped to  0
-1.5  is mapped to  1
-1.0  is mapped to  2
-0.5  is mapped to  3
 0.0  is mapped to  4
 0.5  is mapped to  5
 1.0  is mapped to  6
 1.5  is mapped to  7
```

This table shows the results for a few particular inputs.

Input	Quantized Input	Output	Notes
`1.6`	`1.5+0.0i`	`7+4i`	
`-0.4`	`-0.5+0.0i`	`3+4i`	
`-3.2`	`-2.0+0.0i`	`4i`	Saturation (real)
`0.4-1.2i`	`0.0-1.5i`	`4+i`	
`0.4-6.0i`	`0.0-2.0i`	`4`	Saturation (imaginary)
`-4.2+3.5i`	`-2.0+2.0i`	`7i`	Saturation (real and imaginary)

The output data type is automatically set to `uint8`, the most efficient format for this input range.

Parameters

Peak

The largest input amplitude to be encoded, V. Real or imaginary input values greater than $(1-2^{1-B})V$ or less than $-V$ saturate (independently for complex inputs) at those limits.

Bits

Specify the number of bits, B, needed to represent the integer output. The number of levels at which the block quantizes the floating-point input is 2^B.

Output type

The data type of the block's output, `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, while signed outputs are `int8`, `int16`, or `int32`.

Unwrap

Unwrap signal phase

Library

Signal Operations

`dspsigops`

Description

The Unwrap block unwraps each channel of the input by adding or subtracting appropriate multiples of 2π to each channel element. The input can be a vector or matrix, and must have radian phase entries. The block recognizes phase discontinuities larger than the **Tolerance** parameter setting. For more information about phase unwrapping, see the “Definition of Phase Unwrap” on page 2-1864.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Unwrap Method

The Unwrap block unwraps each channel of its input matrix or input vector by adding 2π*k* to each successive channel element, and updating *k* at each *phase jump*. A phase jump occurs when the difference between two adjacent phase value entries exceeds the value of the **Tolerance** parameter.

The following code illustrates how the block unwraps the data in a given input channel `u`.

```
k=0; % initialize k to 0
i=1; % initialize the counter to 1
alpha=pi; % set alpha to the desired Tolerance. In this case, pi

for i = 1:(size(u)-1)
    yout(i,:)=u(i)+(2*pi*k); % add 2*pi*k to ui
```

```
    if((abs(u(i+1)-u(i)))>(abs(alpha)))  %if diff is greater than alpha, increment or decrement k

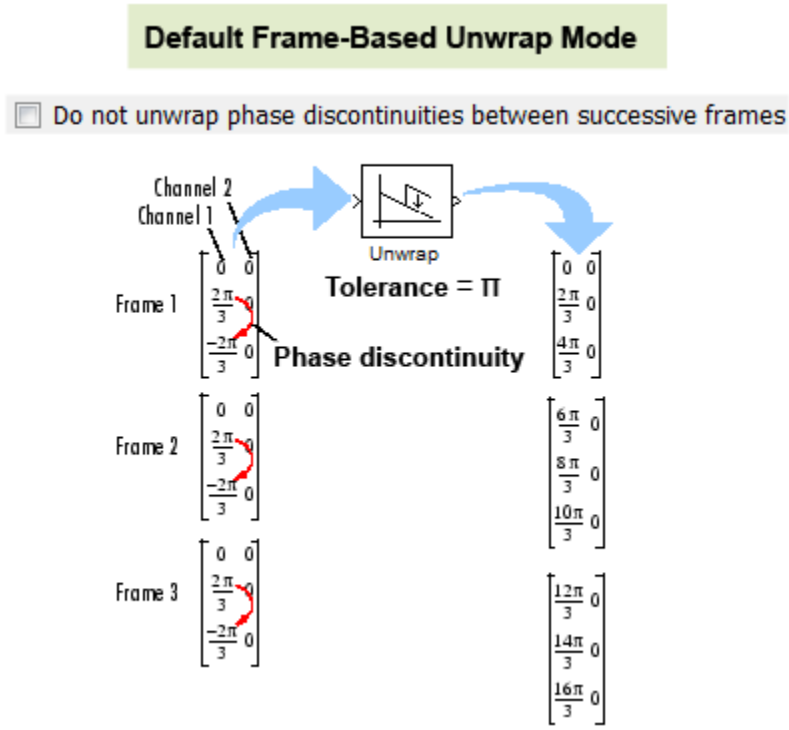
        if u(i+1)<u(i)   % if the phase jump is negative, increment k
            k=k+1;
        else             % if the phase jump is positive, decrement k
            k=k-1;
        end
    end
end
yout((i+1),:)=u(i+1)+(2*pi*k); % add 2*pi*k to the last element of the input
```

Frame-Based Processing

When you configure the block to perform frame-based processing, the block supports two different unwrap modes. In both modes, the block adds $2\pi k$ to each input channel's elements, and updates k at each phase discontinuity. The difference between the two modes is how often the block resets the initial phase value (k) to zero. You can choose to unwrap data across frame boundaries (default), or to unwrap only within input frames, by resetting the initial phase value each time a new input frame is received.

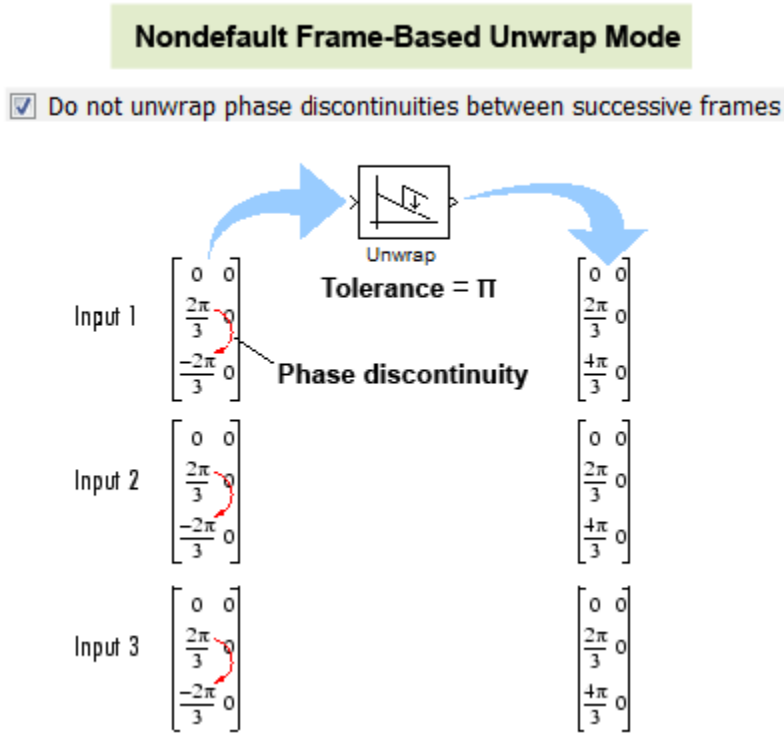
Unwrapping Across Frame Boundaries

In the default mode, the block ignores boundaries between input frames, and continues to unwrap the data in each channel without resetting the initial phase value to zero. To specify this mode, clear the **Do not unwrap phase discontinuities between successive frames** check box. The following figure illustrates how the block unwraps data in this mode.



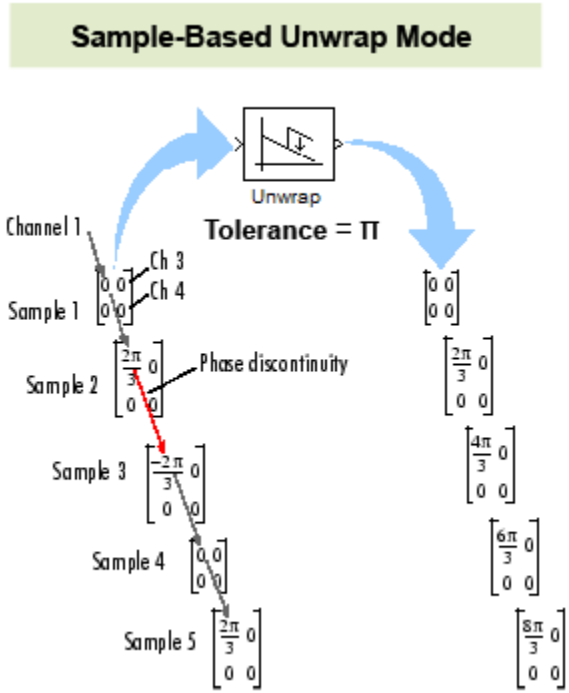
Unwrapping Within Frames

When you select the **Do not unwrap phase discontinuities between successive frames** check box, the block treats each frame of input data independently. In this mode, the block resets the initial phase value to zero each time a new input frame is received. The following figure illustrates how the block unwraps data in this mode.



Sample-Based Processing

When you configure the block to perform sample-based processing, the block treats each element of the input as an individual channel. The block unwraps the data in each channel of the input, and does not reset the initial phase to zero each time a new input is received. The following figure illustrates how the block unwraps data when performing sample-based processing.

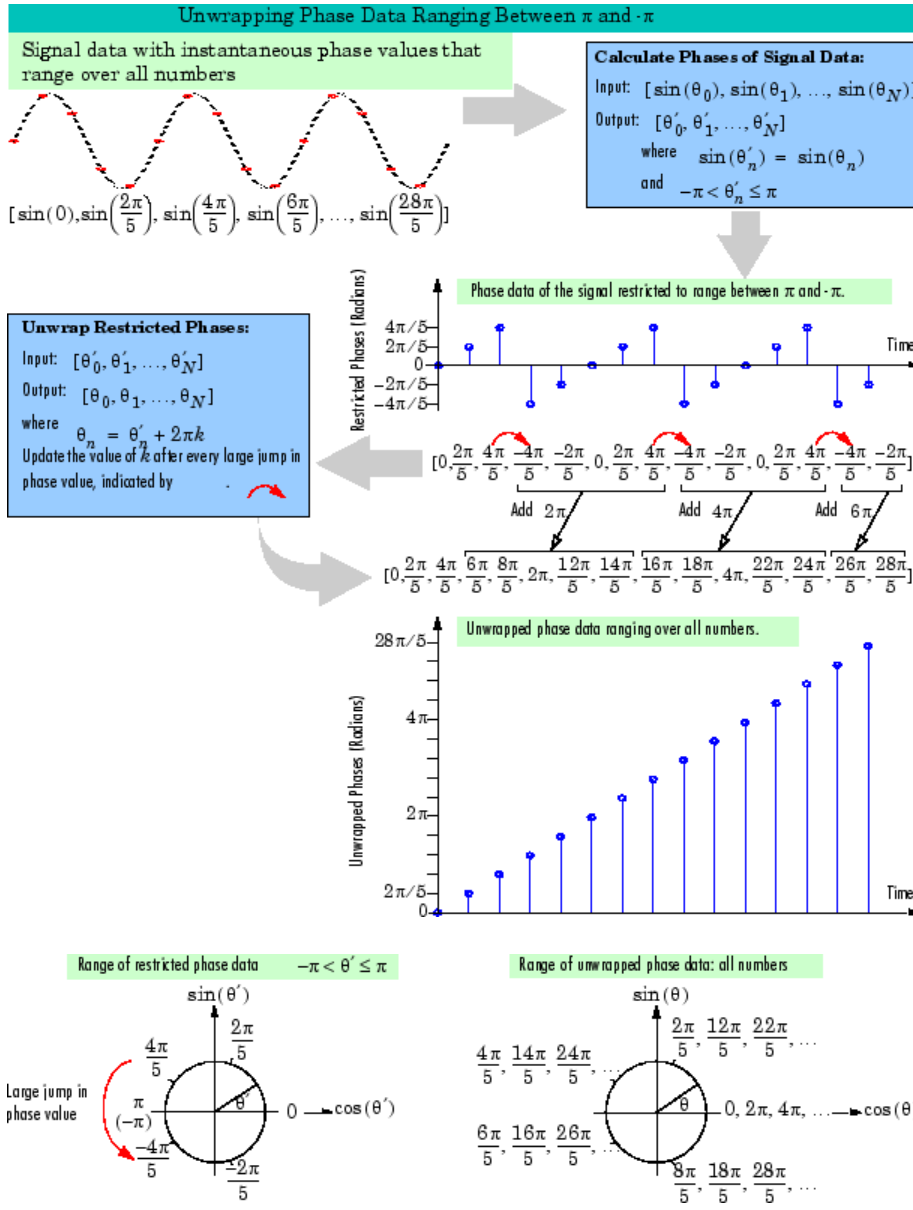


Definition of Phase Unwrap

Algorithms that compute the phase of a signal often only output phases between –π and π. For instance, such algorithms compute the phase of sin(2π + 3) to be 3, since sin(3) = sin(2π + 3), and since the actual phase, 2π + 3, is not between –π and π. Such algorithms compute the phases of sin(–4π + 3) and sin(16π + 3) to be 3 as well.

Phase unwrap or unwrap is a process often used to reconstruct a signal's original phase. Unwrap algorithms add appropriate multiples of 2π to each phase input to restore original phase values, as illustrated in the following diagram. See “Unwrap Method” on page 2-1860 for more information on the unwrap algorithm used by this block.

The following figure illustrates the concept of phase unwrapping.



Unwrapping Phase Data Ranging Between π and -π

Parameters

Tolerance

The jump size that the block recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the block's sensitivity, set the **Tolerance** to a value slightly less than π.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Do not unwrap phase discontinuities between successive frames

When you clear this check box, the block ignores boundaries between input frames and does not reset the initial phase value to zero each time a new input is received. In this mode, the block continuously unwraps the data in each column of the input. When you select this check box, the block treats each frame of input data independently, and resets the initial phase value for each new input frame. See the “Frame-Based Processing” on page 2-1861 section for more information.

This parameter is available only when you configure the block to perform frame-based processing. In sample-based processing mode, the block does not reset the initial phase value to zero for each new input. See “Sample-Based Processing” on page 2-1863 for more information.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Upsample

Resample input at higher rate by inserting zeros

Library

Signal Operations

`dspsigops`

Description

The Upsample block resamples each channel of the M_i-by-N input at a rate L times higher than the input sample rate by inserting L-1 zeros between consecutive samples. You specify the integer L in the **Upsample factor** parameter. The **Sample offset** parameter, D, allows you to delay the output samples by an integer number of sample periods. Doing so enables you to select any of the L possible output phases. The value you specify for the **Sample offset** parameter must be in the range $0 \le D < (L - 1)$.

You can use this block inside of triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame *size* than the input. For upsampling by a factor of L, the output frame size is L times larger than the input frame size ($M_o = M_i*L$), but the input and output frame rates are equal.

For an example of single-rate upsampling, see the **Single-Rate Processing** example.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i-by-N matrix input as N independent channels. The block upsamples each column of the input over time by keeping the frame size constant (M_i=M_o), and making the output frame period (T_{fo}) L times shorter than the input frame period (T_{fo} = T_{fi}/L).

  See the **Multirate, Frame-Based Processing** example to see the Upsample block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as M*N independent channels, and upsamples each channel over time. In this mode, the block always performs multirate processing. The output sample rate is L times higher than the input sample rate (T_{so} = T_{si}/L), and the input and output sizes are identical.

Zero Latency

The Upsample block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Upsample factor** parameter to `1` or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Upsample block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block propagates the first input (received at t=0) immediately following the D consecutive zeros specified by the **Sample offset** parameter. This output (D+1) is followed in turn by the L-1 inserted zeros and the next input sample.

Nonzero Latency

The Upsample block has tasking latency for multirate, multitasking operation:

- In multirate, sample-based processing mode, the initial condition for each channel appears as output sample D+1, and is followed by L-1 inserted zeros. The channel's first input appears as output sample D+L+1. The **Initial conditions** parameter can be

an M_i-by-N matrix containing one value for each channel, or a scalar to be applied to all signal channels.

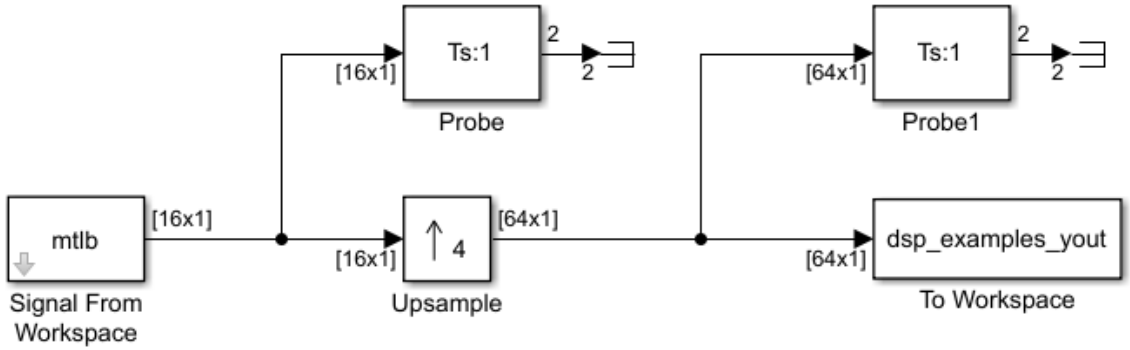
- In multirate, frame-based processing mode, the first row of the initial condition matrix appears as output sample D+1, and is followed by L-1 inserted rows of zeros, the second row of the initial condition matrix, and so on. The first row of the first input matrix appears in the output as sample M_iL+D+1. The **Initial conditions** parameter can be an M_i-by-N matrix, or a scalar to be repeated across all elements of the input matrix.

Note For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Examples

Example 2.5. Example: Single-Rate Processing

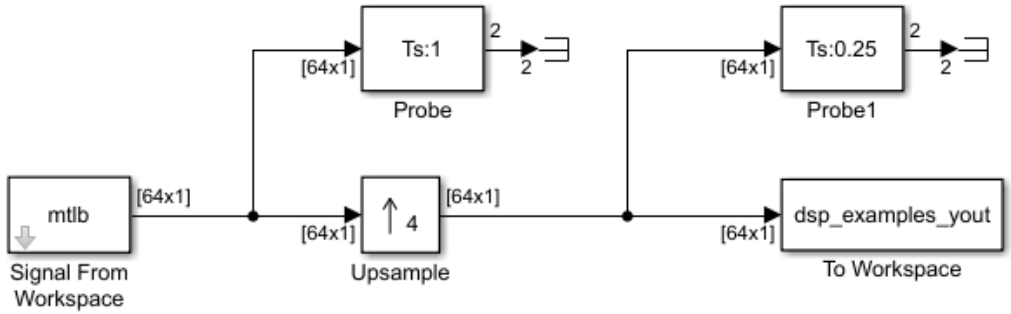
In the ex_upsample_ref2 model, the Upsample block resamples a single-channel input with a frame size of 16. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame size of 64. Because the block is in single-rate processing mode, the input and output frame rates are identical.



Example 2.6. Example: Multirate, Frame-Based Processing

In the ex_upsample_ref1 model, the Upsample block resamples a single-channel input with a frame period of 1 second. The block upsamples the input by a factor of 4. Thus, the

output of the block has a frame period of 0.25 seconds. Because the block is in multirate processing mode, the input and output frame sizes are identical.



Parameters

Upsample factor

The integer factor, *L*, by which to increase the input sample rate.

Sample offset

The sample offset, *D*, which must be an integer in the range [0,*L*-1].

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Rate options

Specify the method by which the block upsamples the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of *L*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is *L* times faster than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency, a scalar or matrix. This value appears in the output as sample *D*+1. This parameter appears only when you configure the block to perform multirate processing.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Variable Bandwidth FIR Filter

Design tunable bandwidth FIR filter

Library

Filtering / Filter Designs

`dspfdesign`

Description

The Variable Bandwidth FIR Filter block filters each channel of the input signal over time using specified FIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the FIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of `dsp.VariableBandwidthFIRFilter` System object to the Simulink environment.

The FIR filter is designed using the window method. For information on the algorithms used by the Variable Bandwidth FIR Filter block, see the “Algorithms” on page 4-1822 section of `dsp.VariableBandwidthFIRFilter`.

Examples

- “System Identification Using RLS Adaptive Filtering”

Parameters

FIR filter order

Order of the FIR filter, specified as a positive integer scalar. The default is `30`. This parameter is nontunable.

Filter type

Type of FIR filter. You can set this parameter to:

- `Lowpass` (default)
- `Highpass`
- `Bandpass`
- `Bandstop`

This parameter is nontunable.

Specify cutoff frequency from input port

When you select this check box, the cutoff frequency is input through the **Fcut** port. When you clear this check box, the cutoff frequency is specified on the block dialog through the **Filter Cutoff frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to `Lowpass` or `Highpass`.

Filter Cutoff frequency (Hz)

Cutoff frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter**

type to `Lowpass` or `Highpass`, and clear the **Specify cutoff frequency from input port** parameter. The default is `1000`. This parameter is tunable.

Specify center frequency from input port

When you select this check box, the center frequency is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Filter center frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`.

Filter center frequency (Hz)

Center frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`, and clear the **Specify center frequency from input port** parameter. The default is `10000`. This parameter is tunable.

Specify bandwidth from input port

When you select this check box, the filter bandwidth is input through the **BW** port. When you clear this check box, the filter bandwidth is specified on the block dialog through the **Filter bandwidth (Hz)** parameter.

This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`.

Filter bandwidth (Hz)

Bandwidth of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`, and clear the **Specify bandwidth from input port** parameter. The default is `2000`. This parameter is tunable.

Window function

Window function used to design the FIR filter. You can set this parameter to:

- `Hann` (default)
- `Hamming`
- `Chebyshev`
- `Kaiser`

This parameter is nontunable.

Chebyshev window sidelobe attenuation (dB)

Sidelobe attenuation of chebyshev window, specified as a real positive scalar. This parameter applies when you set **Window function** to `Chebyshev`. The default is `60`. This parameter is nontunable.

Kaiser window parameter

Kaiser window parameter, specified as a real scalar. This parameter applies when you set **Window function** to `Kaiser`. The default is `0.5`. This parameter is nontunable.

Inherit sample rate from input

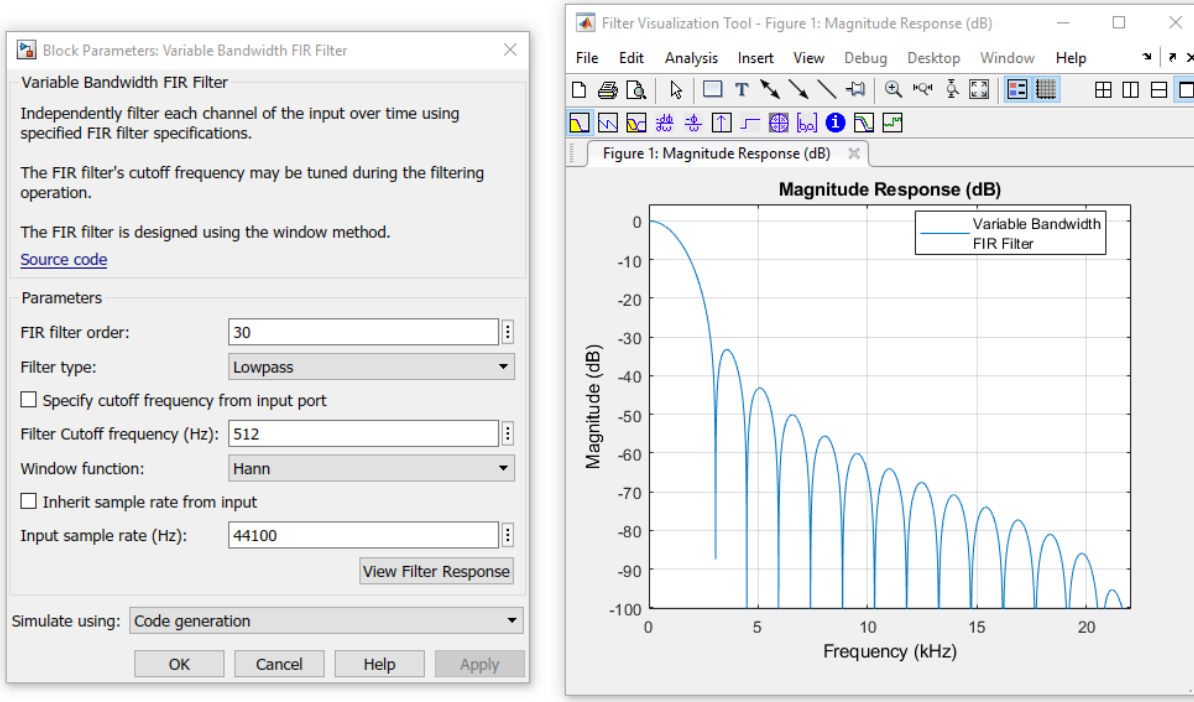
When you select this check box, the block's sample rate is computed as *N* / *Ts*, where *N* is the frame size of the input signal and *Ts* is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is `44100`. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Variable Bandwidth FIR Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.



To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Variable Bandwidth IIR Filter

Design tunable bandwidth IIR filter

Library

Filtering / Filter Designs

`dspfdesign`

Description

The Variable Bandwidth IIR Filter block filters each channel of the input signal over time using specified IIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the IIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of `dsp.VariableBandwidthIIRFilter` System object to the Simulink environment.

The IIR filter is designed using the elliptical method. The IIR filter is tuned using IIR spectral transformations based on allpass filters. For more information on the algorithms used by the Variable Bandwidth IIR Filter block, see the “Algorithms” on page 4-1832 section of `dsp.VariableBandwidthIIRFilter`.

Examples

- “Tunable Lowpass Filtering of Noisy Input in Simulink”

Parameters

Filter type

Type of IIR filter. You can set this parameter to:

- `Lowpass` (default)
- `Highpass`
- `Bandpass`
- `Bandstop`

This parameter is nontunable.

IIR filter order

Order of the IIR filter, specified as a positive integer scalar. The default is `8`. This parameter is nontunable.

Specify passband frequency from input port

When you select this check box, the filter passband frequency is input through the **Fp** port. When you clear this check box, the passband frequency is specified on the block dialog through the **Filter passband frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to `Lowpass` or `Highpass`.

Filter passband frequency (Hz)

Passband frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Lowpass` or `Highpass`, and clear the **Specify passband frequency from input port** parameter. The default is `1000`. This parameter is tunable.

Specify center frequency from input port

When you select this check box, the center frequency of the IIR filter is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Filter center frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`.

Filter center frequency (Hz)

Center frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`, and clear the **Specify center frequency from input port** parameter. The default is `10000`. This parameter is tunable.

Specify bandwidth from input port

When you select this check box, the bandwidth of the IIR filter is input through the **BW** port. When you clear this check box, the filter bandwidth is specified on the block dialog through the **Filter bandwidth (Hz)** parameter.

This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`.

Filter bandwidth (Hz)

Bandwidth of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`, and clear the **Specify bandwidth from input port** parameter. The default is `2000`. This parameter is tunable.

Filter passband ripple (dB)

Passband ripple of the IIR filter, specified as a real positive scalar. The default is `1`. This parameter is nontunable.

Filter Stopband attenuation (dB)

Stopband attenuation of the IIR filter, specified as a real positive scalar. The default is `60`. This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block's sample rate is computed as *N* / *Ts*, where *N* is the frame size of the input signal and *Ts* is the sample time of the input signal.

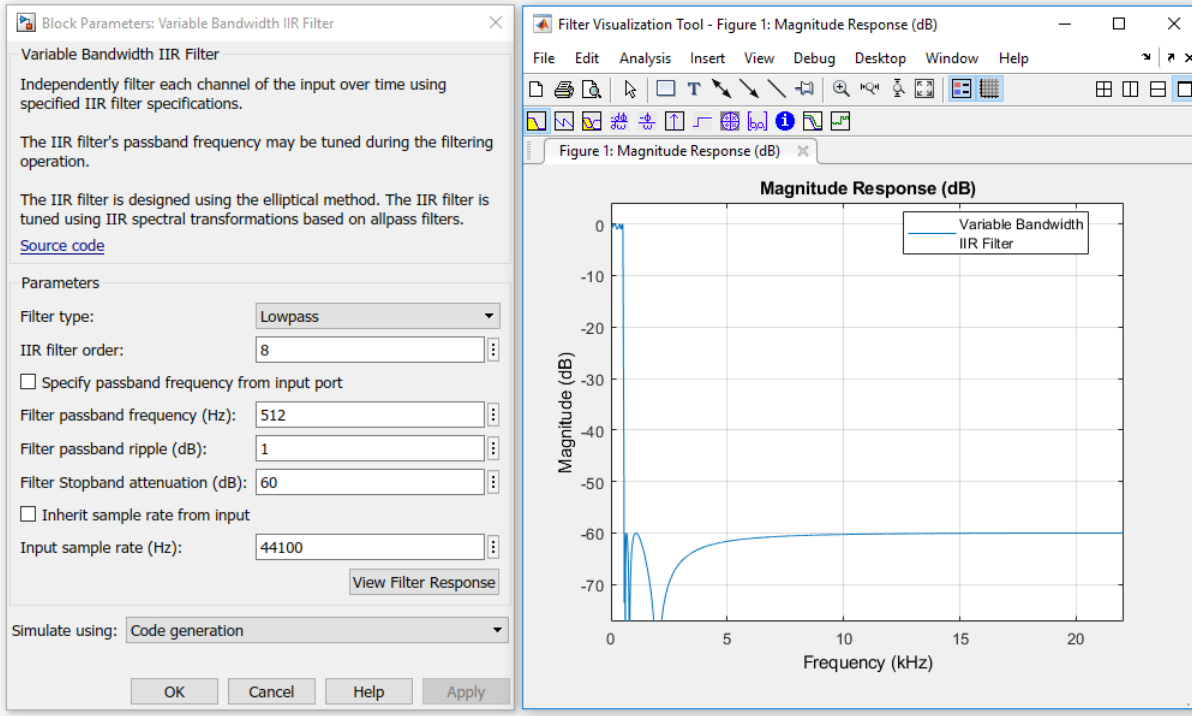
When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is `44100`. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Variable Bandwidth IIR Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.



To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

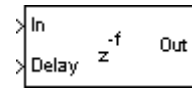
Variable Fractional Delay

Delay input by time-varying fractional number of sample periods
Library: DSP System Toolbox / Signal Operations



Description

The Variable Fractional Delay block delays the input signal by a specified number of fractional samples along each channel of the input. The block can also concurrently compute multiple delayed versions (taps) of the same signal. For an example, see “Delay Signal Using Multitap Fractional Delay”.

When the delay has a fractional value, the block interpolates the input signal to obtain new samples at noninteger sampling intervals. You can set **Interpolation mode** parameter to one of `Linear`, `FIR`, or `Farrow`. The block supports time-varying delay values. That is, the delay value can vary within a frame from sample to sample.

The block assumes that the input values at the **Delay** port are between D_{min} and D_{max}, where D_{min} appears in the `Valid delay range` section on the **Main** tab of the block dialog, and D_{max} is the value of the **Maximum delay (Dmax) in samples** parameter. The block clips delay values less than D_{min} to D_{min} and delay values greater than D_{max} to D_{max}.

You must consider additional factors when selecting valid `Delay` values for the `FIR` and `Farrow` interpolation modes. For details, see “Algorithms” on page 2-1907.

Ports

Input

`In` — Data input

vector | matrix

Specify the data input as a vector or matrix. The data input must have the same data type as the delay input.

This block supports variable-size input signal. That is, you can change the number of input rows during the simulation. However, the number of channels must remain constant.

Example: [1 2 3 4;5 1 4 2;2 6 2 3;1 2 3 2;3 4 5 6;1 2 3 1]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Delay` — Delay input
scalar | vector | matrix | *N*-D array

Specify the delay input as a scalar, vector, matrix, or *N*-D array. The delay can be an integer or a fractional value. The block interpolates the signal to obtain new samples at noninteger sampling intervals. The delay input must have the same data type as the data input.

This block supports variable-size delay signal. That is, you can change one or both of the dimensions of the delay signal during simulation. However, the block must make sure that the resulting number of output channels remains constant throughout the simulation.

When the **Input processing** parameter is set to `Columns as channels (frame based)`, the table below shows the effect of the dimension of the delay input on the data input. For an example, see “Delay Signal Using Multitap Fractional Delay”.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	1-by-*P*	*N*-by-*P*	*P* taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N (unoriented, one channel)	*N*-by-*P*	*N*-by-*P*	*P* taps. In addition, delay varies within each frame from sample to sample.
N-by-1 (one channel with frame size equal to *N*)	scalar	*N*-by-1	One delay value applied to the input channel
N-by-1 (one channel with frame size equal to *N*)	Unoriented (N)	*N*-by-1	Delay value varies within the frame from sample to sample
N-by-1 (one channel with frame size equal to *N*)	*N*-by-1	*N*-by-1	Delay value varies within the frame from sample to sample
N-by-1 (one channel with frame size equal to *N*)	1-by-*P*	*N*-by-*P*	*P* taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N-by-1 (one channel with frame size equal to *N*)	*N*-by-*P*	*N*-by-*P*	*P* taps. In addition, delay varies within each frame from sample to sample.
N-by-*L* (*L* channels with frame size equal to *N*)	scalar	*N*-by-*L*	One delay value applied to all input channels
N-by-*L* (*L* channels with frame size equal to *N*)	1-by-*L*	*N*-by-*L*	Unique delay value for each input channel
N-by-*L* (*L* channels with frame size equal to *N*)	*N*-by-1	*N*-by-*L*	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N-by-*L* (*L* channels with frame size equal to *N*)	*N*-by-*L*	*N*-by-*L*	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
N-by-*L* (*L* channels with frame size equal to *N*)	1-by-1-by-*P*	*N*-by-*L*-by-*P*	*L* channels. *P* taps per channel. Same delay for all channels.
N-by-*L* (*L* channels with frame size equal to *N*)	1-by-*L*-by-*P*	*N*-by-*L*-by-*P*	*L* channels. *P* taps per channel. Taps vary across channels.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N-by-*L* (*L* channels with frame size equal to *N*)	*N*-by-1-by-*P*	*N*-by-*L*-by-*P*	*L* channels. *P* taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.
N-by-*L* (*L* channels with frame size equal to *N*)	*N*-by-*L*-by-*P*	*N*-by-*L*-by-*P*	*L* channels. *P* taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

When the **Input processing** parameter is set to `Elements as channels (sample based)`, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N-by-1 (one channel with frame size equal to *N*)	scalar	*N*-by-1	One delay value applied to the input channel

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N-by-1 (one channel with frame size equal to *N*)	Unoriented (N)	*N*-by-1	Delay value varies within the frame from sample to sample
N-by-1 (one channel with frame size equal to *N*)	*N*-by-1	*N*-by-1	Delay value varies within the frame from sample to sample
N-by-*L* (*L* channels with *N* samples in each channel)	scalar	*N*-by-*L*	One delay value applied to all input channels
N-by-*L* (*L* channels with *N* samples in each channel)	1-by-*L*	*N*-by-*L*	Unique delay value for each input channel
N-by-*L* (*L* channels with *N* samples in each channel)	*N*-by-1	*N*-by-*L*	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N-by-*L* (*L* channels with *N* samples in each channel)	*N*-by-*L*	*N*-by-*L*	Delay value varies within the frame from sample to sample. Different delay values for each input channel.

Example: [2 3 4 5]

Example: [2.5]

Example: [5.6]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The data type and complexity of the output match the data type and complexity of the data input.

When the **Input processing** parameter is set to `Columns as channels (frame based)`, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N (unoriented, one channel)	1-by-*P*	*N*-by-*P*	*P* taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N (unoriented, one channel)	*N*-by-*P*	*N*-by-*P*	*P* taps. In addition, delay varies within each frame from sample to sample.
N-by-1 (one channel with frame size equal to *N*)	scalar	*N*-by-1	One delay value applied to the input channel

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N-by-1 (one channel with frame size equal to *N*)	Unoriented (N)	*N*-by-1	Delay value varies within the frame from sample to sample
N-by-1 (one channel with frame size equal to *N*)	*N*-by-1	*N*-by-1	Delay value varies within the frame from sample to sample
N-by-1 (one channel with frame size equal to *N*)	1-by-*P*	*N*-by-*P*	*P* taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N-by-1 (one channel with frame size equal to *N*)	*N*-by-*P*	*N*-by-*P*	*P* taps. In addition, delay varies within each frame from sample to sample.
N-by-*L* (*L* channels with frame size equal to *N*)	scalar	*N*-by-*L*	One delay value applied to all input channels
N-by-*L* (*L* channels with frame size equal to *N*)	1-by-*L*	*N*-by-*L*	Unique delay value for each input channel
N-by-*L* (*L* channels with frame size equal to *N*)	*N*-by-1	*N*-by-*L*	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N-by-*L* (*L* channels with frame size equal to *N*)	*N*-by-*L*	*N*-by-*L*	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
N-by-*L* (*L* channels with frame size equal to *N*)	1-by-1-by-*P*	*N*-by-*L*-by-*P*	*L* channels. *P* taps per channel. Same delay for all channels.
N-by-*L* (*L* channels with frame size equal to *N*)	1-by-*L*-by-*P*	*N*-by-*L*-by-*P*	*L* channels. *P* taps per channel. Taps vary across channels.
N-by-*L* (*L* channels with frame size equal to *N*)	*N*-by-1-by-*P*	*N*-by-*L*-by-*P*	*L* channels. *P* taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.
N-by-*L* (*L* channels with frame size equal to *N*)	*N*-by-*L*-by-*P*	*N*-by-*L*-by-*P*	*L* channels. *P* taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

When the **Input processing** parameter is set to `Elements as channels (sample based)`, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N-by-1 (one channel with frame size equal to *N*)	scalar	*N*-by-1	One delay value applied to the input channel
N-by-1 (one channel with frame size equal to *N*)	Unoriented (N)	*N*-by-1	Delay value varies within the frame from sample to sample
N-by-1 (one channel with frame size equal to *N*)	*N*-by-1	*N*-by-1	Delay value varies within the frame from sample to sample
N-by-*L* (*L* channels with *N* samples in each channel)	scalar	*N*-by-*L*	One delay value applied to all input channels
N-by-*L* (*L* channels with *N* samples in each channel)	1-by-*L*	*N*-by-*L*	Unique delay value for each input channel
N-by-*L* (*L* channels with *N* samples in each channel)	*N*-by-1	*N*-by-*L*	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N-by-*L* (*L* channels with *N* samples in each channel)	*N*-by-*L*	*N*-by-*L*	Delay value varies within the frame from sample to sample. Different delay values for each input channel.

Example: [0 0 0 0;0 0 0 0;1 0 0 0;5 2 0 0;2 1 3 0;1 6 4 4]

Example: [0 0 0 0;0 0 0 0;0.5 1.0 1.5 2.0;3 1.5 3.5 3.0;3.5 3.5 3.0 2.5;1.5 4.0 2.5 2.5]

Example: [0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0.4 0.8 1.2 1.6]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Interpolation mode` — Method of interpolation

`Linear` (default) | `FIR` | `Farrow`

Specify the method of interpolation. Using this method, the block interpolates the signal to obtain new samples at noninteger sampling intervals.

- `Linear` –– Linear interpolation. In this mode, the block stores the $\mathbf{D_{max}}+1$ most recent samples the **In** port receives for each channel. $\mathbf{D_{max}}$ is the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- `FIR` –– Polyphase FIR interpolation. In this mode, the block stores the $\mathbf{D_{max}}+\mathbf{P}+1$ most recent samples the **In** port receives for each channel. **P** is the value you specify in the **Interpolation filter half-length (P)** parameter.
- `Farrow` –– LaGrange method. In this mode, the block stores the $\mathbf{D_{max}}+\frac{N}{2}+1$ most recent samples the **In** port receives for each channel. **N** is the value you specify in the **Farrow filter length (N)** parameter.

For more details on these methods, see “Algorithms” on page 2-1907.

`Interpolation filter half-length (P)` — Half length of interpolation filter

4 (default) | positive integer in the range [1 65535]

Half-length of the FIR interpolation filter. For periodic signals, a larger value of this property, which indicates a higher order filter, yields a better estimate of the delayed output sample. A property value of 4 to 6, which corresponds to a 7th-order to 11th-order filter, is usually adequate.

Example: `6`

Example: `10`

Dependencies

This parameter applies only when you set **Interpolation mode** to `FIR`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Interpolation points per input sample` — Number of interpolation points per input sample

`10` (default) | positive integer in the range [2, 65,535]

Number of interpolation points per input sample at which a unique FIR interpolation filter is computed.

Example: `20`

Example: `5`

Dependencies

This parameter applies only when you set **Interpolation mode** to `FIR`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Normalized input bandwidth (0 to 1)` — Normalized input bandwidth

1 (default) | real scalar in the range (0, 1]

Normalized input bandwidth at which to constrain the interpolated output samples. A value of `1` equals the Nyquist frequency, or half the sampling frequency, *Fs*. Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above *Fs*/4, you can specify a value of `0.5`.

Example: `0.5`

Example: `0.8`

Dependencies

This parameter applies only when you set **Interpolation mode** to `FIR`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Farrow filter length (N)` — Length of Farrow filter

4 (default) | integer greater than or equal to 2

Length of the FIR filter implemented using the Farrow structure. If the length equals 2, the filter performs linear interpolation.

Example: `4`

Example: `10`

Dependencies

This parameter applies only when you set **Interpolation mode** to `Farrow`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`Maximum delay (Dmax) in samples` — Maximum delay

`100` (default) | integer in the range [0 65535]

Maximum delay the block can produce, $\mathbf{D_{max}}$. Input delay values exceeding this maximum are clipped to $\mathbf{D_{max}}$.

Example: 200

Example: 500

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`Input processing` — Method to process the input

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel. The block treats each of the R input columns as independent channels containing M_i sequential time samples.

  The input to the **Delay** port, v, contains floating-point values that specify the number of sample intervals to delay the current input.

  The input to the **Delay** port can be a scalar value to uniformly delay every sample in every channel. It can also be a length-M column vector, containing one delay for each sample in the input frame. The block applies the set of delays contained in the vector identically to every channel of a multichannel input. The **Delay** port entry can also be a length-R row vector, containing one delay for each channel. Finally, the **Delay** port entry can be an M-by-R matrix, containing a different delay for each corresponding element of the input.

  For example, if v is the M_i-by-1 matrix `[v(1) v(2) ... v(Mi)]'`, the earliest sample in the current frame is delayed by `v(1)` fractional sample intervals, the following sample in the frame is delayed by `v(2)` fractional sample intervals, and so on. The block applies the set of fractional delays contained in v identically to every channel of a multichannel input.
- `Elements as channels (sample based)` –- When you select this option, the block treats each element of the input as a separate channel. The block treats each element of the N-D input array, u, as an independent channel. The input to the **Delay** port, v, must either be an N-D array of the same size and dimension as the input u, or be a scalar value, such that $D_{min} \le v \le D_{max}$.

  For example, consider an M-by-R input matrix. The block treats each of the $M*R$ matrix elements as independent channels. The input to the **Delay** port can be an M-by-R matrix of floating-point values in the range $D_{min} \le v \le D_{max}$ that specifies the number of sample intervals to delay each channel of the input, or it can be a scalar floating-point value, $D_{min} \le v \le D_{max}$, by which to equally delay all channels.

  In sample-based processing mode, the block treats an unoriented vector input as an M-by-1 matrix. In this mode, the output is also an unoriented vector.

`InitialConditions` — Initial values in the memory

`0` (default) | scalar | 1-by-R-by-D array | 1-by-R-by-(D+L) array

Specify the values with in the block's memory at the start of the simulation. The dimensions of this parameter can vary depending on whether you want fixed or time-

varying initial conditions. The block treats each of the *R* input columns as a frame containing *M* sequential time samples from an independent channel.

For an *M*-by-*R* input matrix, *u*, you can set this parameter as follows:

- To specify fixed initial conditions, set this parameter to a scalar value. The block initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the interpolation method. To specify different time-varying initial conditions for each channel, set this parameter as follows:
  - If you set the **Interpolation mode** to `Linear`, set the **Initial conditions** to an array of size 1-by-*R*-by-*D*, where *D* is the value in **Maximum delay (Dmax) in samples** parameter.
  - If you set the **Interpolation mode** to `FIR` or `Farrow`, set the **Initial conditions** to an array of size 1-by-*R*-by-(*D*+*L*), where *D* is the value of the maximum delay. For FIR interpolation, `L` is the value of the interpolation filter half length. For Farrow interpolation, `L` equals `floor` of half the value of the farrow filter length (`floor( farrow filter length/2)`).

Example: 1

Example: randn(1,3,104)

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`Disable direct feedthrough by increasing minimum possible delay by one — Disable direct feedthrough`
`off` (default) | `on`

Select this box to disable direct feedthrough by increasing the minimum possible delay value. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block increases the minimum possible delay value by *`frame size`* – 1. Similarly, when you set the **Input processing** parameter to `Elements as channels (sample based)`, the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Fractional Delay block in feedback loops.

`For small input delay values — Action to take for small input delay values`
`Clip to the minimum value necessary for centered kernel` (default) | `Use off-centered kernel` | `Switch to linear interpolation if kernel cannot be centered`

Specify the block's behavior when the input delay values are too small to center the kernel.

You can specify how the block handles input delay values that are too small for the kernel to be centered using one of the following choices:

- In both `FIR` and `Farrow` interpolation modes, you can select `Clip to the minimum value necessary for centered kernel`. This option forces the block to increase D_{min} to the smallest value necessary to keep the kernel centered.
- In `FIR` interpolation mode, you can select `Switch to linear interpolation if kernel cannot be centered`. This option forces the block to preserve the value of D_{min} and compute all interpolated values using `Linear` interpolation.
- In `Farrow` interpolation mode, you can select `Use off-centered kernel`. This option forces the block to preserve the value of D_{min} and compute the interpolated values using a farrow filter with an off-centered kernel.

Dependencies

This parameter applies only when **Interpolation mode** is set to `FIR` or `Farrow`.

`Valid delay range (in samples)` — Range of valid delay values

[0 100] (default) | [D_{min} D_{max}]

This property is read-only.

The delay range values [D_{min} D_{max}] are calculated (in samples) by the block based on the current parameter settings. D_{min} is the smallest possible valid delay value (in samples). The block clips all input delay values less than D_{min} to D_{min}. D_{max} is the maximum valid delay value (in samples). The block clips all input delay values greater than D_{max} to D_{max}.

When the **Interpolation mode** is set to one of the following:

- `Linear` –– D_{min} equal 0. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- `FIR` –– D_{min} equals P – 1, where P is the value you specify in **Interpolation filter half-length (P)**. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- `Farrow` –– D_{min} equals $N/2$ – 1, where N is the value you specify in **Farrow filter length (N)**. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.

Example: [1 100]

Example: [2 100]

Example: [3 100]

Fixed-Point Properties

Fixed-Point Properties

`Rounding mode` — Rounding method for fixed-point operations
`Zero` (default) | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest`

Specify the rounding mode for fixed-point operations as one of the following:

- `Zero`
- `Ceiling`
- `Convergent`
- `Floor`
- `Nearest`
- `Round`
- `Simplest`

For more details, see rounding mode.

`Saturate on integer overflow` — Method of overflow action
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

`Coefficients` — Data type of the coefficients
`Same word length as input` (default) | `Specify word length`

Specify the data type of the filter coefficients as one of the following:

- `Same word length as input` -– The word length of the filter coefficients matches that of the input to the block. The fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.

- `Specify word length` –– Specify the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.

For more information on the coefficients data type this block uses, see the “Fixed Point” on page 2-1910 section.

`Product output` — Data type of the product output
`Same as first input` (default) | `Binary point scaling`

Specify the data type of the product output as one of the following:

- `Same as first input` –– The block specifies the product output data type to be the same as that of the data input.
- `Binary point scaling` –– Specify the word length and the fraction length of the product output, in bits.

For more information on the product output data type, see “Multiplication Data Types” and the “Fixed Point” on page 2-1910 section.

`Accumulator` — Data type of accumulation operation
`Same as product output` (default) | `Same as first input` | `Binary point scaling`

Specify the data type of an accumulation operation as one of the following:

- `Same as product output` –– The block specifies the accumulator data type to be the same as that of the product output data type.
- `Same as first input` –– The block specifies the accumulator data type to be the same as that of the data input.
- `Binary point scaling` –– Specify the word length and the fraction length of the accumulator output, in bits.

For more information on the accumulator data type this block uses, see the “Fixed Point” on page 2-1910.

`Product output polyval` — Data type of the product polynomial value
`Same as first input` (default) | `Binary point scaling`

Specify the data type of the product polynomial value as one of the following:

- `Same as first input` –– The block specifies the product polynomial value data type to be the same as that of the data input.
- `Binary point scaling` –– Specify the word length and the fraction length of the product output polynomial, in bits.

For more information on the product polynomial value data type this block uses, see the “Fixed Point” on page 2-1910 section.

Dependencies

This property applies when you set **Interpolation mode** to `Farrow`.

`Accumulator polyval` — Data type of the accumulator polynomial value
`Same as first input` (default) | `Binary point scaling`

Specify the data type of the accumulator polynomial value as one of the following:

- `Same as first input` –– The block specifies the accumulator polynomial value data type to be the same as that of the data input.
- `Binary point scaling` –– Specify the word length and the fraction length of the accumulator polynomial value, in bits.

For more information on the accumulator polynomial value data type that this block uses, see the “Fixed Point” on page 2-1910 section.

Dependencies

This property applies when you set **Interpolation mode** to `Farrow`.

`Multiplicand polyval` — Data type of multiplicand polynomial value
`Same as first input` (default) | `Binary point scaling`

Specify the data type of the multiplicand polynomial value as one of the following:

- `Same as first input` –– The block specifies the multiplicand polynomial value data type to be the same as that of the data input.
- `Binary point scaling` –– Specify the word length and the fraction length of the multiplicand polynomial value, in bits.

For more information on the multiplicand polynomial value data type this block uses, see the “Fixed Point” on page 2-1910 section.

Dependencies

This property applies when you set **Interpolation mode** to `Farrow`.

`Output` — Data type of block output
`Same as accumulator` (default) | `Same as first input` | `Binary point scaling`

Specify the data type of the block output as one of the following:

- `Same as accumulator` –– The block specifies the output data type to be the same as that of the accumulator output data type.
- `Same as first input` –– The block specifies the output data type to be the same as that of the data input.
- `Binary point scaling` –– Specify the word length and the fraction length of the block output, in bits.

For more information on the output data type this block uses, see the “Fixed Point” on page 2-1910 section.

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block dialog box.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`
Zero-Crossing Detection	`no`

Algorithms

The delay value specified at the **Delay** port serves as an index into the block's memory, U, which stores, at a minimum, the $\mathbf{D_{max}}$+1 most recent samples received at the **In** port for each channel. For example, an integer delay of 5 on a scalar input sequence retrieves and outputs the fifth most recent input sample from the block's memory, U(6). The block computes fractional delays by interpolating between stored samples. The block uses a linear, FIR, or farrow interpolation method to interpolate signal values at noninteger sample intervals.

Linear Interpolation Mode

For noninteger delays, at each sample time, the linear interpolation method uses the two samples in memory nearest to the specified delay to compute a value for the sample at that time.

For a vector data input, the output vector, *y*, is computed using the following relation:

```
vi = floor(v)
vf = v-vi
y(i) = U(i-vi-1)*vf + U(i-vi)*(1-vf)
```

where,

- *i* –– Index of the current sample
- *v* –– Fractional delay
- *vi* –– Integer part of the delay
- *vf* –– Fractional part of the delay
- *U* –– Input data vector
- *y* –– Output data vector
- *U(i-vi)*, *U(i-vi-1)* –– Two samples in memory nearest to the specified delay
- *i-vi* –– Distance, in samples, between the current index and the nearest point in the interpolation line.

The variable fractional delay stores the *Dmax*+1 most recent samples received at the input for each channel, where *Dmax* is the maximum delay specified. *U* represents the stored samples.

FIR Interpolation Mode

In the FIR interpolation mode, the block stores the *Dmax*+*P*+1 most recent samples received at the input for each channel, where *P* is the specified interpolation filter half-length.

In this mode, the block provides a discrete set of fractional delays:

$$v + \frac{i}{L}, \qquad v \geq P - 1, \;\; i = 0, 1, \ldots, L - 1$$

If *v* is less than *P* – 1, the behavior depends on the **For small input delay values** parameter. You can specify the block's behavior when the input delay value is too small to center the kernel (less than *P*-1), by setting the **For small input delay values** parameter:

- `Clip to the minimum value necessary for centered kernel` –– The FIR interpolation method remains in use. The small input delay values are clipped to the smallest value necessary to center the kernel.
- `Switch to linear interpolation if kernel cannot be centered` –– Fractional delays are computed using linear interpolation when the input delay value is less than *P*-1.

In the FIR interpolation mode, the algorithm implements a polyphase structure to compute a value for each sample at the specified delay. Each arm of the structure corresponds to a different delay value. The output computed for each sample corresponds to the output of the arm with a delay value nearest to the specified input delay. Therefore, only a discrete set of delays is actually possible. The number of coefficients in each of the *L* filter arms of the polyphase structure is 2*P*. In most cases, using values of *P* between 4 and 6 provides you with reasonably accurate interpolation values.

The `designMultirateFIR` function designs the FIR interpolation filter.

For example, when you set the following values:

- Interpolation filter half-length (P) to 4
- Interpolation points per input sample to 10
- Normalized input bandwidth to 1
- Stopband attenuation to 80 dB

The filter coefficients are given by:

```
b = designMultirateFIR(10,1,4,80);
```

The algorithm then implements this filter as a polyphase structure.

Increasing the filter half length (*P*) increases the accuracy of the interpolation, but also increases the number of computations performed per input sample. The amount of memory needed to store the filter coefficients increases too. Increasing the interpolation points per sample (*L*) increases the number of representable discrete delay points, but also increases the simulation's memory requirements. The computational load per sample is not affected.

The normalized input bandwidth from 0 to 1 allows you to take advantage of the bandlimited frequency content of the input. For example, if you know that the input signal does not have frequency content above $F_s/4$, you can specify `0.5` normalized bandwidth to constrain the frequency content of the output to that range.

Note You can consider each of the *L* interpolation filters to correspond to one output phase of an upsample-by-*L* FIR filter. Therefore, the normalized input value improves the stopband in critical regions and relaxes the stopband requirements in frequency regions without signal energy.

Farrow Interpolation Mode

In the farrow interpolation mode, the block stores the *Dmax*+*N/2*+1 most recent samples received at the input for each channel, where *N* is the specified farrow filter length.

The algorithm uses the LaGrange method to interpolate values.

To increase the minimum possible delay value, select the **Disable direct feedthrough by increasing minimum possible delay by one** check box. Checking this box prevents algebraic loops from occurring when you use the block inside a feedback loop.

To specify the behavior when the input delay value is too small to center the kernel (less than $\frac{N}{2} - 1$), use the Farrow small delay action setting.

- `Clip to the minimum value necessary for centered kernel` –– The block clips small input delay values to the smallest value necessary to keep the kernel centered. This increases D_{min} but yields more accurate interpolation values.

- `Use off-centered kernel` –– The fractional delays are computed using a Farrow filter with an off-centered kernel. This mode does not increase D_{min}, but the results for input delay values less than $\frac{N}{2}$ – 1 are less accurate than the results achieved by keeping the kernel centered.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The diagrams in the following sections show the data types used within the Variable Fractional Delay for fixed-point signals.

Although you can specify most of these data types, the following data types are computed internally by the block and cannot be directly specified on the block dialog box.

Data Type	Word Length	Fraction Length
vf data type	Same word length as the coefficients	Same as the word length
HoldInteger data type	Same word length as the input delay value	`0` bits
Integer data type	`32` bits	`0` bits

Note When the input is fixed point, all internal data types are signed fixed point.

To compute the integer (v_i) and fractional (v_f) parts of the input delay value (v), the Variable Fractional Delay block uses the following equations:

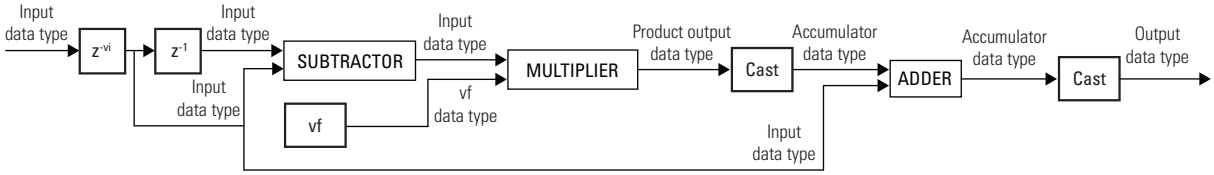
$$D_{min} < v < D_{max} \Rightarrow \begin{cases} v_i = \text{floor}(v) \\ v_f = v - vi \end{cases}$$

$$v \leq D_{min} \Rightarrow \begin{cases} v_i = D_{min} \\ v_f = 0 \end{cases}$$

$$v \geq D_{max} \Rightarrow \begin{cases} v_i = D_{max} \\ v_f = 0 \end{cases}$$

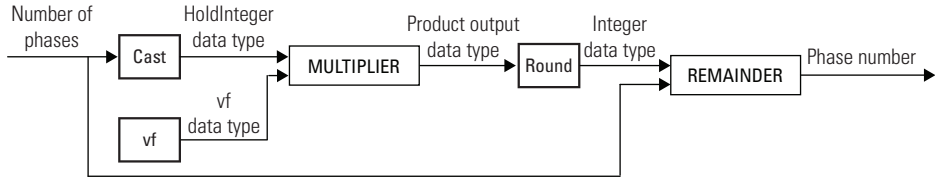
Linear Interpolation Mode

The following diagram shows the fixed-point data types used by the Linear interpolation mode of the Variable Fractional Delay block.

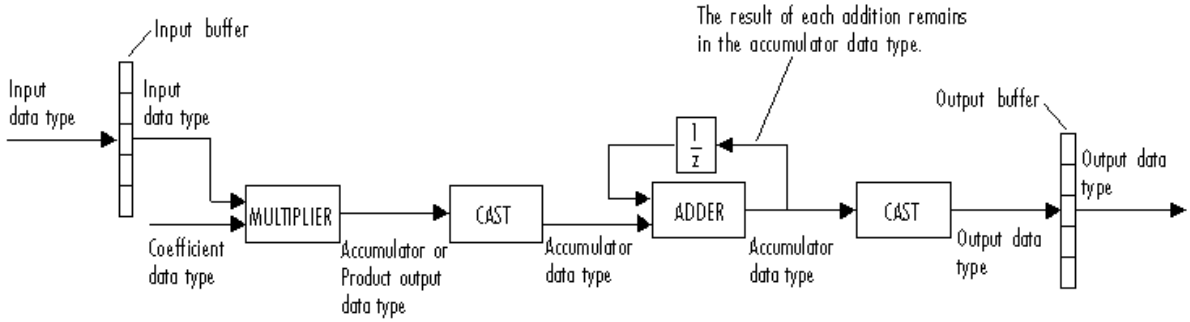


FIR Interpolation Mode

The following diagram illustrates how the Variable Fractional Delay block selects the arm of the polyphase filter structure that most closely matches the fractional delay value (v_f).



The following diagram shows the fixed-point data types used by the variable fractional delay algorithm in the FIR interpolation mode.



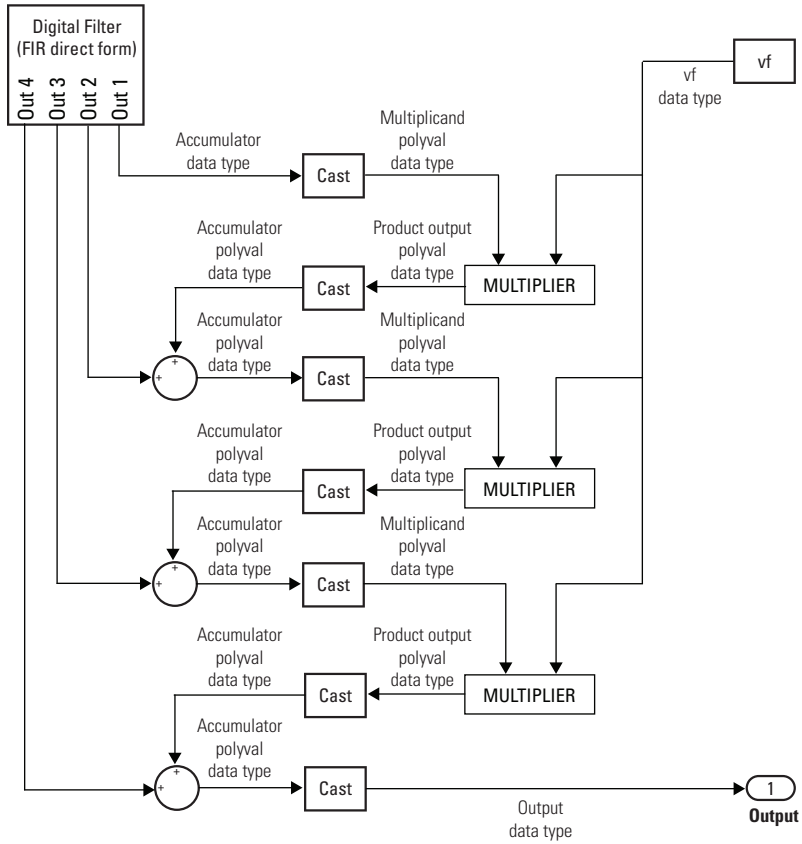
You can set the coefficient, product output, accumulator, and output data types in the block. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication, see “Multiplication Data Types”.

Farrow Interpolation Mode

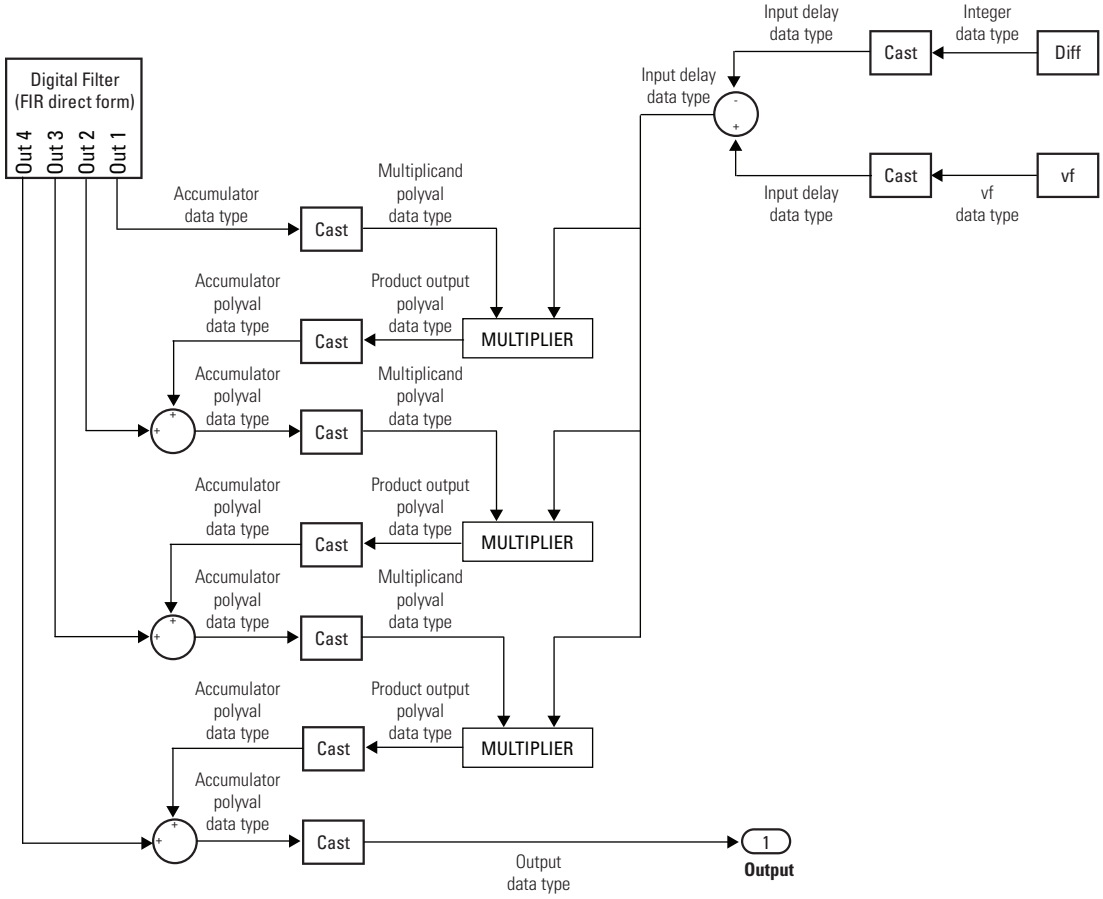
The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to `Clip to the minimum value necessary for centered kernel`



The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to `4`.
- Farrow small delay action is set to `Use off-centered kernel`.



`Diff` is computed from the integer part of the delay value (v_i) and the farrow filter length (N) according to the following equation:

$$Diff = v_i - \left(\frac{N-1}{2}\right)$$

$$Diff \geq 0 \Rightarrow Diff = 0$$

$$Diff < 0 \Rightarrow Diff = -Diff$$

The following diagram shows the fixed-point data types used by the Digital Filter's FIR direct form filter.

Description

Note The Variable Integer Delay block has been replaced with the Simulink Variable Integer Delay block. Existing instances of the DSP block will continue to operate, but certain functionality will be disabled in future releases. See “Functionality being removed or replaced for blocks and System objects”.

The Variable Integer Delay block delays the discrete-time input at the In port by the integer number of sample intervals specified by the input to the Delay port. The sample rate of the input signal at the Delay port must be the same as the sample rate of the input signal at the In port. When these sample rates are not the same, you need to insert a Zero-Order Hold or Rate Transition block in order to make the sample rates identical. When you set the **Input processing** parameter to `Elements as channels (sample based)`, the delay for an N-D input can be a scalar value to uniformly delay every sample in every channel, or a matrix containing one delay value for each channel of the input. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the delay can be a scalar value to uniformly delay every sample in every channel, a vector containing one delay value for each sample in the input frame, or a vector containing one delay value for each channel in the input frame.

The delay values should be in the range of 0 to *D*, where *D* is the **Maximum delay**. Delay values greater than *D* or less than 0 are clipped to those respective values and noninteger delays are rounded to the nearest integer value.

The Variable Integer Delay block differs from the Delay block in the following ways.

Variable Integer Delay Block	Delay Block
The delay is provided as an input to the Delay port.	You specify the delay as a parameter setting in the dialog box.
Delay can vary with time; for example, when the block performs frame-based processing, the *n*th element's delay in the first input frame can differ from the *n*th element's delay in the second input frame.	Delay cannot vary with time; for example, when the block performs frame-based processing, the *n*th element's delay is the same for every input frame.
When you use the Variable Integer Delay block in a feedback loop, you must check the **Disable direct feedthrough by increasing minimum possible delay by one** check box. This prevents the occurrence of an algebraic loop when the delay of the Variable Integer Delay block is driven to zero.	You can use the Delay block to break an algebraic loop.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the Variable Integer Delay block supports N-D input arrays. When the input is an *M*-by-*N*-by-*P* array, the block treats each of the *M***N***P* elements as independent channels, and applies the delay at the Delay port to each channel.

The Variable Integer Delay block stores the D+1 most recent samples received at the In port for each channel. At each sample time the block outputs the stored sample(s) indexed by the input to the Delay port.

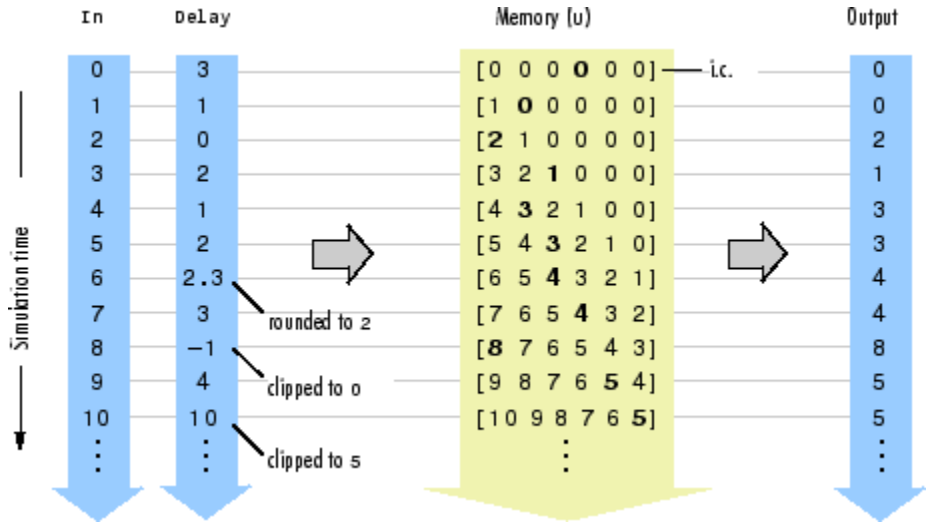
For example, when the input to the In port, `u`, is a scalar signal, the block stores a vector, `U`, of the D+1 most recent signal samples. When the current input sample is `U(1)`, the previous input sample is `U(2)`, and so on, then the block's output is

```
y = U(v+1);                    % Equivalent MATLAB code
```

where `v` is the input to the Delay port. A delay value of 0 (`v=0`) causes the block to pass through the sample at the In port in the same simulation step that it is received. The

block's memory is initialized to the **Initial conditions** value at the start of the simulation (see below).

The next figure shows the block output for a scalar ramp sequence at the In port, a **Maximum delay** of 5, an **Initial conditions** of 0, and a variety of different delays at the Delay port.



The current input at each time step is immediately stored in memory as `U(1)`. This allows the current input to be available at the output for a delay of 0 (`v=0`).

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Unlike the Delay block, the Variable Integer Delay block does not have a fixed initial delay period during which the initial conditions appear at the output. Instead, the initial conditions are propagated to the output only when they are indexed in memory by the value at the Delay port. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input sequence.

Fixed Initial Conditions

The settings in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of *D* samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in sample-based mode can be specified in one of the following ways:

- Scalar value with which to initialize every sample of every channel in memory. For a general *M*-by-*N* input and the parameter settings in this figure,

  the block initializes 100 *M*-by-*N* matrices in memory with zeros.
- Array of size *M*-by-*N*-by-*D*. In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1919 below for details.

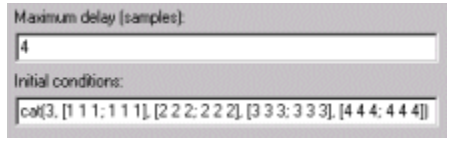
Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For a time-varying initial condition, the block initializes each of *D* samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector containing *D* elements with which to initialize memory samples `U(2:D+1)`, where *D* is the **Maximum delay**. For a scalar input and the parameters in the next figure, the block initializes `U(2:6)` with values `[-1, -1, -1, 0, 1]`.

- Array of dimension *M*-by-*N*-by-*D* with which to initialize memory samples `U(2:D+1)`, where *D* is the **Maximum delay** and *M* and *N* are the number of rows and columns, respectively, in the input matrix. For a 2-by-3 input and the following parameters, the block initializes memory locations `U(2:5)` with values

$$\mathbf{U}(2) = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix},\ \mathbf{U}(3) = \begin{bmatrix} 2 & 2 & 2 \\ 2 & 2 & 2 \end{bmatrix},\ \mathbf{U}(4) = \begin{bmatrix} 3 & 3 & 3 \\ 3 & 3 & 3 \end{bmatrix},\ \mathbf{U}(5) = \begin{bmatrix} 4 & 4 & 4 \\ 4 & 4 & 4 \end{bmatrix}$$



An *M*-by-*N*-by-*P*-by-*D* array can be entered for the **Initial Conditions** parameter when the input is an *M*-by-*N*-by-*P* array. The (*M*,*N*,*P*,*T*)th sample of the **Initial Conditions** matrix provides the initial condition value for the (*M*,*N*,*P*)th channel of the input matrix at delay = *D*–*t*+1 samples.

Frame-Based Processing

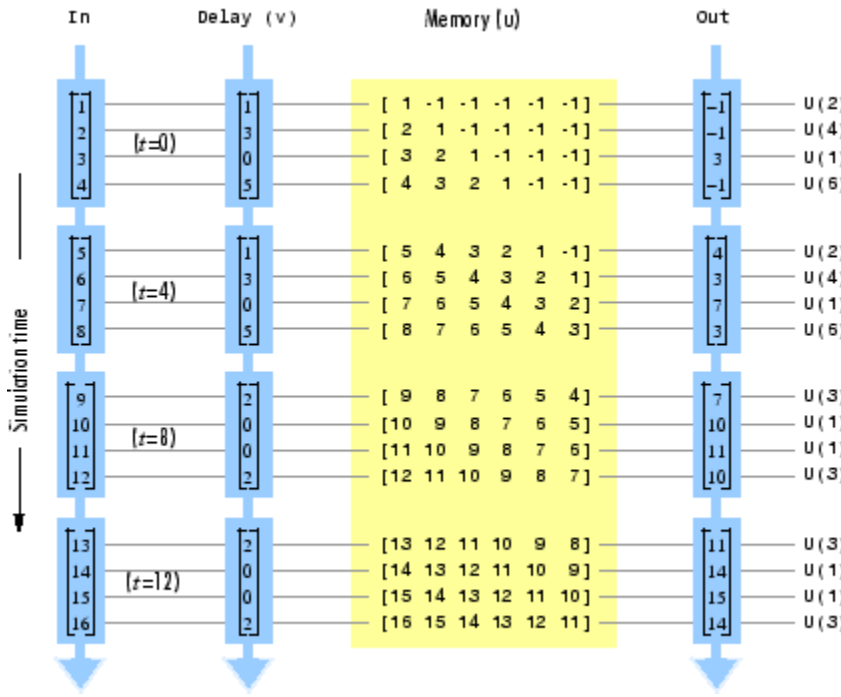
When you set the **Input processing** parameter to `Columns as channels (frame based)`, the input can be an *M*-by-*N* matrix. The block treats each of the *N* input columns as independent channels containing *M* sequential time samples.

In this mode, the input at the Delay port can be a scalar value to uniformly delay every sample in every channel. It can also be a length-*M* column vector containing one delay value for each sample in the input frame(s). The set of delays contained in the vector is applied identically to every channel of a multichannel input. The Delay port entry can also be a length-*N* row vector, containing one delay for each channel. Finally, the Delay port entry can be an *M*-by-*N* matrix, containing a different delay for each corresponding element of the input.

Vector `v` does not specify when the samples in the current input frame will appear in the output. Rather, `v` indicates which previous input samples (stored in memory) should be included in the current output frame. The first sample in the current output frame is the input sample `v(1)` intervals earlier in the sequence, the second sample in the current output frame is the input sample `v(2)` intervals earlier in the sequence, and so on.

The illustration below shows how this works for an input with a sample period of 1 and frame size of 4. The **Maximum delay** (`Dmax`) is `5`, and the **Initial conditions** parameter is set to `-1`. The delay input changes from `[1 3 0 5]` to `[2 0 0 2]` after the second input frame. The samples in each output frame are the values in memory indexed by the elements of `v`:

```
y(1) = U(v(1)+1)
y(2) = U(v(2)+1)
y(3) = U(v(3)+1)
y(4) = U(v(4)+1)
```



The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Both fixed and time-varying initial conditions can be specified.

Fixed Initial Conditions

The settings shown in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of *D* samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value with which to initialize every sample of every channel in memory. For a general *M*-by-*N* input with the parameter settings below, the block initializes five samples in memory with zeros.

- Array of size 1-by-*N*-by-*D*. In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1922 below for details.

Time-Varying Initial Conditions

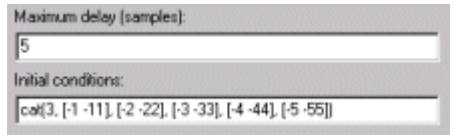
The following setting specifies a time-varying initial condition. For a time-varying initial condition, the block initializes each of *D* samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. When the block is performing frame-based processing, you can specify a time-varying initial condition in the following ways:

- Vector containing *D* elements. In this case, all channels have the same set of time-varying initial conditions specified by the entries of the vector. For the ramp input `[1:100; 1:100]'` with a frame size of `4`, delay of `5`, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -1 \\ -2 & -2 \\ -3 & -3 \\ -4 & -4 \end{bmatrix}, \begin{bmatrix} -5 & -5 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \ldots$$

- Array of size 1-by-*N*-by-*D*. In this case, you can specify different time-varying initial conditions for each channel. For the ramp input `[1:100; 1:100]'` with a frame size of `4`, delay of `5`, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -11 \\ -2 & -22 \\ -3 & -33 \\ -4 & -44 \end{bmatrix}, \begin{bmatrix} -5 & -55 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \ldots$$



By specifying a 1-by-*N*-by-*D* initial condition array such that each 1-by-*N* vector entry is identical, you can implement different fixed initial conditions for each channel.

Examples

See “Basic Algorithmic Delay” in the *DSP System Toolbox User's Guide*.

Parameters

Maximum delay

The maximum delay that the block can produce for any sample. Delay input values exceeding this maximum are clipped at the maximum.

Initial conditions

The values with which the block's memory is initialized.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Disable direct feedthrough by increasing minimum possible delay by one

Select this box to disable direct feedthrough by adding one to the minimum possible delay value. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block increases the minimum possible delay value by *`frame size`* – 1. Similarly, when you set the **Input processing** parameter to `Elements as channels (sample based)`, the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Integer Delay block in feedback loops.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Delay	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

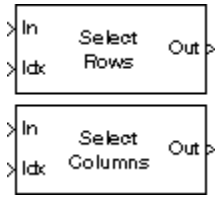
Variable Selector

Select subset of rows or columns from input



Library

Signal Management / Indexing

`dspindex`

Description

The Variable Selector block extracts a subset of rows or columns from the *M*-by-*N* input matrix `u` at each input port. You specify the number of input and output ports in the **Number of input signals** parameter.

When the **Select** parameter is set to `Rows`, the Variable Selector block extracts rows from each input matrix, while if the **Select** parameter is set to `Columns`, the block extracts columns.

When the **Selector mode** parameter is set to `Variable`, the length-*L* vector input to the Idx port selects *L* rows or columns of each input to pass through to the output. The elements of the indexing vector can be updated at each sample time, but the vector length must remain the same throughout the simulation.

When the **Selector mode** parameter is set to `Fixed`, the Idx port is disabled, and the length-*L* vector specified in the **Elements** parameter selects *L* rows or columns of each input to pass through to the output. The **Elements** parameter is tunable, so you can change the values of the indexing vector elements at any time during the simulation; however, the vector length must remain the same.

For both variable and fixed indexing modes, the row selection operation is equivalent to

```
y = u(idx,:)                          % Equivalent MATLAB code
```

and the column selection operation is equivalent to

```
y = u(:,idx)                          % Equivalent MATLAB code
```

where `idx` is the length-*L* indexing vector. The row selection output size is *L*-by-*N* and the column selection output size is *M*-by-*L*. Input rows or columns can appear any number of times in the output, or not at all.

When the input is an unoriented vector, the **Select** parameter is ignored; the output is a unoriented vector of length *L* containing those elements specified by the length-*L* indexing vector.

When an element of the indexing vector references a nonexistent row or column of the input, the block reacts with the action you specify using the **Invalid index** parameter.

When the indexing vector elements are of Boolean data type, the block performs logical indexing. Select **Fill empty spaces in outputs (for logical indexing)** to access the **Fill values** parameter. These values are appended to the output to make it as long as the input elements.

Note The Variable Selector block always copies the selected input rows to a contiguous block of memory (unlike the Simulink Selector block).

Parameters

Number of input signals

Specify the number of input signals. An input port is created on the block for each input signal.

Select

Specify the dimension of the input to select, `Rows` or `Columns`.

Selector mode

Specify the type of indexing operation to perform, `Variable` or `Fixed`. Variable indexing uses the input at the Idx port to select rows or columns from the input at the `In` port. Fixed indexing uses the **Elements** parameter value to select rows from the input at the In port, and disables the Idx port.

Elements

Specify a vector containing the indices of the input rows or columns that will appear in the output matrix. This parameter appears only when you set the **Selector mode** to `Fixed`.

Index mode

When set to `One-based`, an index value of `1` refers to the first row or column of the input. When set to `Zero-based`, an index value of `0` refers to the first row or column of the input.

Invalid index

Specify how the block handles an invalid index value. You can select one of the following options:

- `Clip index` — Clip the index to the nearest valid value, and do not issue an alert.

  For example, if the block receives a `64`-by-`4` input and the **Select** parameter is set to `Rows`, the block clips an index of `72` to `64`. For the same input, if the **Select** parameter is set to `Columns`, the block clips an index of `72` to `4`. In both cases, the block clips an index of `-2` to `1`.
- `Clip and warn` — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- `Generate error` — Display an error dialog box and terminate the simulation.

This parameter is tunable (Simulink).

Fill empty spaces in outputs (for logical indexing)

When the indexing vector elements are of Boolean data type, the block performs logical indexing. This can cause empty spaces in the output. Select this parameter to designate values to be appended to the output in the **Fill values** parameter.

Fill values

Specify the fill values when the block performs logical indexing. This parameter appears only when you select the **Fill empty spaces in outputs (for logical indexing)** check box.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Idx	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (string.h) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is `0`. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see "OutputPipeline" (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Introduced before R2006a

Variance

Variance of input or sequence of inputs
Library: DSP System Toolbox / Statistics

Description

The Variance block computes the unbiased variance of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input. You can specify the dimension using the **Find the variance value over** parameter. The Variance block can also track the variance in a sequence of inputs over a period of time. To track the variance in a sequence of inputs, select the **Running variance** parameter.

Note The **Running** mode in the Variance block will be removed in a future release. To compute the running variance in Simulink, use the Moving Variance block instead.

Ports

Input

`In` — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running variance** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Rst` — Reset port

scalar

Specify the event that causes the block to reset the running variance. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running variance** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Port_1` — Variance along the specified dimension

scalar | vector | matrix | *N*-D array

When you do not select the **Running variance** parameter, the block computes the variance in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input at each individual sample time. Each element in the output array `y` is the variance of the corresponding column, row, or entire input. The output array `y` depends on the setting of the **Find the variance value over** parameter.

Consider a three-dimensional input signal of size *M*-by-*N*-by-*P*. When you set **Find the variance value over** to:

- `Entire input` — The output at each sample time is a scalar that contains the variance of the *M*-by-*N*-by-*P* input matrix.
- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the variance of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the variance of each vector over the first dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is a 1-by-*N* row vector.

  In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.

- `Specified dimension` — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to `1`, the output is the same as when you select `Each column`. If you set the **Dimension** to `2`, the output is the same as when you select `Each row`. If you set the **Dimension** to `3`, the output at each sample time is an *M*-by-*N* matrix containing the variance of each vector over the third dimension of the input.

When you select **Running variance**, the block tracks the variance of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set **Input processing** to:

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk}.
- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the variance of the elements in the *j*th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

The data type of the output matches the data type of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main Tab

`Running variance` — Option to select running variance
off (default) | on

When you select the **Running variance** parameter, the block tracks the variance value of each channel in a time sequence of inputs.

`Find the variance value over` — Dimension over which variance is computed
`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- `Each column` — The block outputs the variance over each column.
- `Each row` — The block outputs the variance over each row.
- `Entire input` — The block outputs the variance over the entire input.
- `Specified dimension` — The block outputs the variance over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running variance** parameter.

`Dimension` — Custom dimension
1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the variance is computed. The value of this parameter must be greater than 0 and less than or equal to the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the variance value over** to `Specified dimension`.

`Input processing` — Method to process the input in running mode
`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the variance of the elements in the *j*th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk}.

  Variable-Size Inputs

  When your inputs are of variable size, and you select the **Running variance** parameter, then:

  - If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
  - If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
    - When the input size difference is in the number of channels (number of columns), the state is reset.
    - When the input size difference is in the length of channels (number of rows), the state is not reset, and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running variance** parameter.

`Reset port` — Reset event

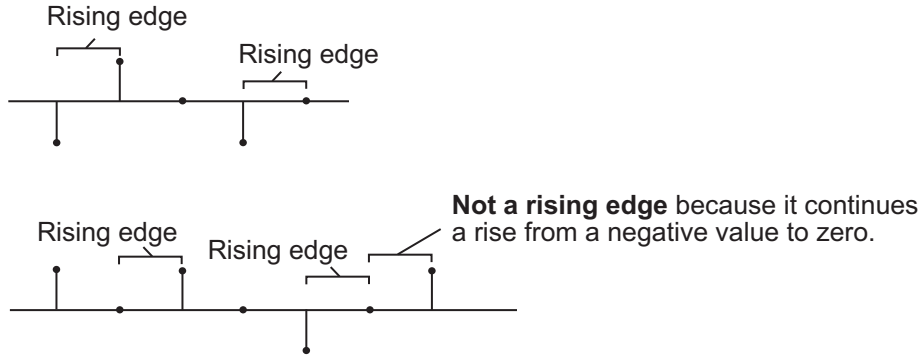
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

The block resets the running variance whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

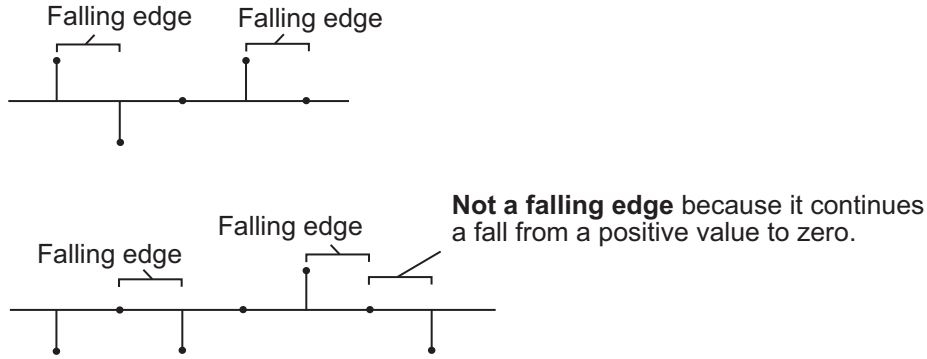
When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running variance for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.



- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.

- `Non-zero sample` — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Dependencies

To enable this parameter, select the **Running variance** parameter.

Data Types Tab

Note To use these parameters, the data input must be fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

`Rounding mode` — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

`Saturate on integer overflow` — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

`Input-squared product output` — Data type of the input-squared term

`Same as input` (default) | `Binary point scaling`

The squares of the input elements are stored in the **Input-squared product output** data type. If the input is complex, the squares of the real and imaginary parts of the input are stored in this data type. For more details, see "Fixed Point" on page 2-1942.

You can set this parameter to:

- `Inherit: Same as input` — The data type is same as the input data type.
- `Binary point scaling` — The **Input-squared product output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

`Input-sum-squared product` — Data type of the input-sum-squared term
`Same as input-squared product` (default) | `Binary point scaling`

The squares of the sum of the input elements are stored in the **Input-sum-squared product** data type. If the input is complex, the squares of the sum of the real parts and the squares of the sum of the imaginary parts are stored in this data type. For more details, see “Fixed Point” on page 2-1942.

You can set this parameter to:

- `Same as input-squared product` — The data type is the same as the input squared-product data type.
- `Binary point scaling` — The **Input-sum-squared product** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

`Accumulator` — Accumulator data type
`Same as input-squared product` (default) | `Same as input` | `Binary point scaling`

Accumulator specifies the data type of the output of an accumulation operation in the Variance block. See “Fixed Point” on page 2-1942 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to:

- `Same as input-squared product` — The accumulator data type is the same as the input-squared product data type.
- `Same as input` — The accumulator data type is the same as the input data type.
- `Binary point scaling` — The **Accumulator** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

`Output` — Output data type
`Same as input-squared product` (default) | `Same as accumulator` | `Same as input` | `Binary point scaling`

Output specifies the data type of the output of the Variance block. See “Fixed Point” on page 2-1942 for information about the use of the output data type in this block. You can set it to:

- `Same as input-squared product` — The output data type is the same as the input-squared product data type.
- `Same as accumulator` — The output data type is the same as the accumulator data type.
- `Same as input` — The output data type is the same as the input data type.
- `Binary point scaling` — The **Output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	`double` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`
Zero-Crossing Detection	`no`

More About

Variance

The variance of a discrete-time signal is the square of the standard deviation of the signal. Variance gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u, of size M-by-N, the variance is given by:

$$y = \sigma^2 = \frac{\sum_{i=1}^{M}\sum_{j=1}^{N}\left|u_{ij}\right|^2 - \frac{\left|\sum_{i=1}^{M}\sum_{j=1}^{N}u_{ij}\right|^2}{M*N}}{M*N-1}.$$

where,

- u_{ij} is the input data element at indices i, j.
- M is the length of the jth column.
- N is the number of columns.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2$$

where,

- $\sigma_{Re}{}^2$ is the variance of the real part of the complex input.
- $\sigma_{Im}{}^2$ is the variance of the imaginary part of the complex input.

Algorithms

Variance

When you clear the **Running variance** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `var` function when it is called as `y = var(u,0,D)`, where,

- `u` is the data input.
- `D` is the dimension.
- `y` is the variance along the specified dimension.

When this block calculates the variance along the entire input, the result is identical to calling the `var` function as `y = var(u(:))`.

For a complex input signal, the variance is the sum of the variances of the real and imaginary parts.

$$\sigma^2 = \sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

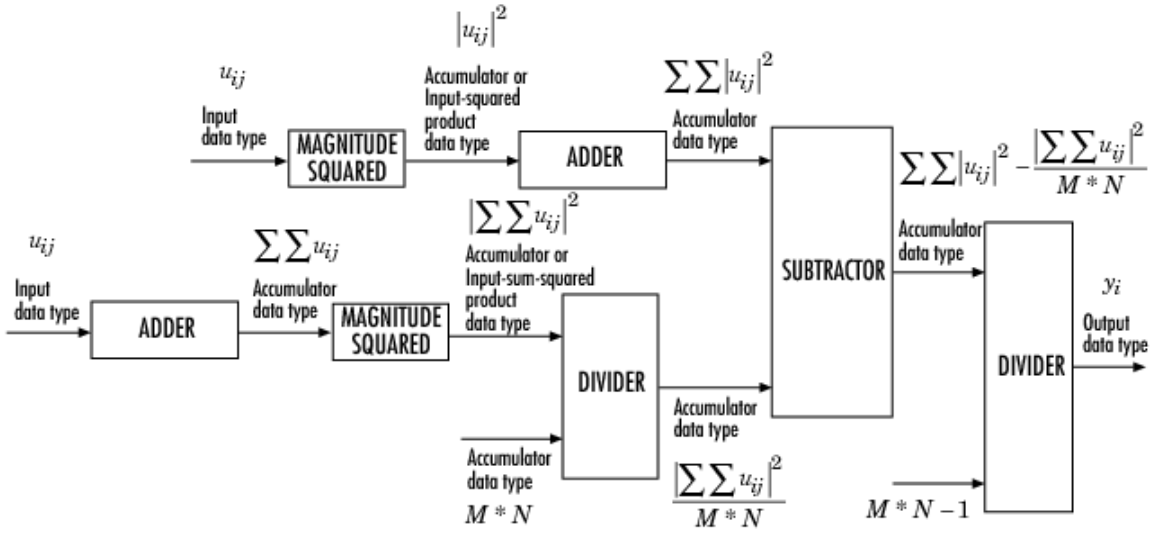
Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

For purely real or imaginary input u of size M-by-N, the variance is given by:

$$y = \sigma^2 = \frac{\sum_{i=1}^{M}\sum_{j=1}^{N}\left|u_{ij}\right|^2 - \frac{\left|\sum_{i=1}^{M}\sum_{j=1}^{N}u_{ij}\right|^2}{M*N}}{M*N-1}.$$

The following diagram shows the data types used within the Variance block when the input is fixed-point.



For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2$$

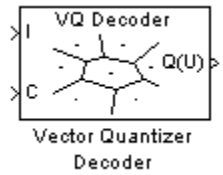
Vector Quantizer Decoder

Find vector quantizer codeword that corresponds to given, zero-based index value



Library

Quantizers

`dspquant2`

Description

The Vector Quantizer Decoder block associates each input index value with a codeword, a column vector of quantized output values defined in the **Codebook values** parameter. When you input multiple index values into this block, the block outputs a matrix of quantized output vectors. This matrix is created by horizontally concatenating the codeword vectors that correspond to each index value.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, you can type the codebook values into the block parameters dialog box. Select `Input port` and port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The **Codebook values** parameter is a k-by-N matrix of values, where $k \geq 1$ and $N \geq 1$. Each column of this matrix is a codeword vector, and each codeword vector corresponds to an index value. The index values are zero based; therefore, the first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on.

The input to this block is a vector of index values, where $0 \leq index < N$ and N is the number of columns of the codebook matrix. Use the **Action for out of range index**

value parameter to determine how the block behaves when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to *N* to be set to *N*-1, select `Clip`. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to *N* are set to *N*-1, select `Clip and warn`. When you want the simulation to stop and display an error when the index values are out of range, select `Error`.

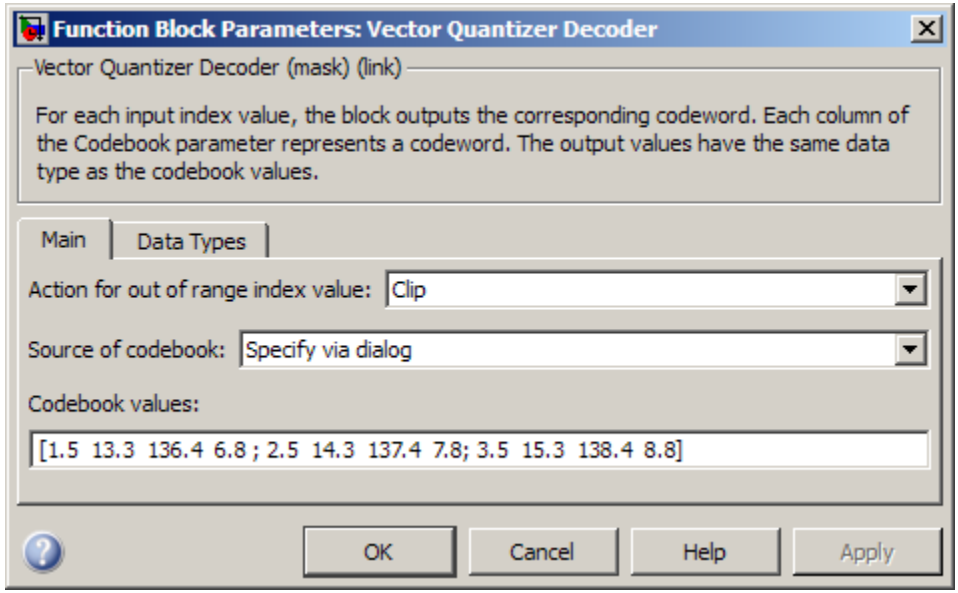
Data Type Support

The input to the block can be the index values and the codebook values. The data type of the index input to the block at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values can be `double`, `single`, or Fixed-point.

The output of the block is the quantized output values. These quantized output values always have the same data type as the codebook values. When the codebook values are specified via an input port, the block assigns the same data type to the Q(U) output port. When the codebook values are specified via the dialog, use the **Codebook and output data type** parameter to specify the data type of the Q(U) output port. The data type of the codebook and quantized output can be `Same as input`, `double`, `single`, `Fixed-point`, `User-defined`, or `Inherit via back propagation`.

Dialog Box

The **Main** pane of the Vector Quantizer Decoder block dialog appears as follows.



Action for out of range index value

Choose the behavior of the block when an input index value is out of range, where $0 \le index < N$ and N is the length of the codebook vector. Select `Clip` when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to N-1. Select `Clip and warn` when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to N-1. Select `Error` when you want the simulation to stop and display an error when the index values are out of range.

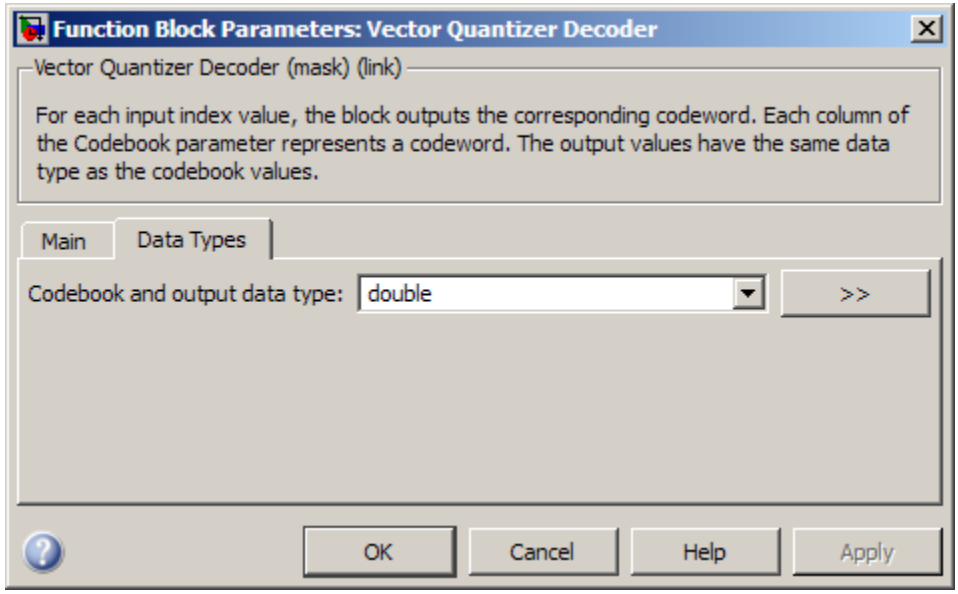
Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, C.

Codebook values

Enter a k-by-N matrix of quantized output values, where $1 \le k$ and $1 \le N$. Each column of your matrix corresponds to an index value. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

The **Data Types** pane of the Vector Quantizer Decoder block dialog appears as follows.



Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

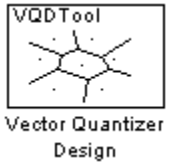
Vector Quantizer Design

Design vector quantizer using Vector Quantizer Design Tool (VQDTool)



Library

Quantizers

`dspquant2`

Description

Double-click on the Vector Quantizer Design block to start VQDTool, a GUI that allows you to design and implement a vector quantizer. You can also start VQDTool by typing `vqdtool` at the MATLAB command prompt. Based on your specifications, VQDTool iteratively calculates the codebook values that minimize the mean squared error between the training set and the codebook until the stopping criteria for the design process is satisfied. The block uses the resulting codebook values to implement your vector quantizer.

For the **Training Set** parameter, enter a *k*-by-*M* matrix of values you want to use to train the quantizer codebook. The variable k, where $k \geq 1$, is the length of each training vector. It also represents the dimension of your quantizer. The variable *M*, where $M \geq 2$, is the number of training vectors. This data can be created using a MATLAB function, such as the default value `randn(10,1000)`, or it can be any variable defined in the MATLAB workspace.

You have two choices for the **Source of initial codebook** parameter. Select `Auto-generate` to have the block choose the values of the initial codebook. In this case, the block picks *N* random training vectors as the initial codebook, where *N* is the **Number of levels** parameter and $N \geq 2$. When you select `User defined`, enter the initial codebook

values in the **Initial codebook** field. The initial codebook matrix must have the same number of rows as the training set. Each column of the codebook is a codeword, and your codebook must have at least two codewords.

For the given training set and initial codebook, the block performs an iterative process, using the Generalized Lloyd Algorithm (GLA), to design a final codebook. For each iteration of the GLA, the block first associates each training vector with its nearest codeword by calculating the distortion. You can specify one of the two possible methods for calculating distortion using the **Distortion measure** parameter.

When you select `Squared error` for the **Distortion measure** parameter, the block finds the nearest codeword by calculating the squared error (unweighted). Consider the codebook $CB = [CW_1\ CW_2\ \ldots\ CW_N]$. This codebook has N codewords; each codeword has k elements. The i-th codeword is defined as $CW_i = [a_{1i}\ a_{2i}\ \ldots\ a_{ki}]$. The training set has M columns and is defined as $U = [U_1\ U_2\ \ldots\ U_M]$, where the p-th training vector is $U_p = [u_{1p}\ u_{2p}\ \ldots\ u_{kp}]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^{k} (a_{ji} - u_{jp})^2$$

When you select `Weighted squared error` for the **Distortion measure** parameter, enter a vector or matrix for the **Weighting factor** parameter. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The block finds the nearest codeword by calculating the weighted squared error. If the weighting factor for the p-th column of the training vector, U_p, is defined as $Wp = [w_{1p}\ w_{2p}\ \ldots\ w_{kp}]'$, then the weighted squared error is defined by the equation

$$D = \sum_{j=1}^{k} w_{jp}(a_{ji} - u_{jp})^2$$

Once the block has associated all the training vectors with their nearest codeword vectors, the block calculates the mean squared error for the codebook and checks to see if the stopping criteria for the process has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared error is below a certain value, select `Relative`

`threshold`. Then, type the maximum acceptable fractional drop in the **Relative threshold** field. The fraction drop in the squared error is defined as

$$\frac{\text{error at previous iteration} - \text{error at current iteration}}{\text{error at previous iteration}}$$

When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter **Relative threshold** and **Maximum iteration** values. The block stops iterating as soon as one of these conditions is satisfied.

When a training vector has the same distortion for two different codeword vectors, the algorithm uses the **Tie-breaking rule** parameter to determine which codeword vector the training vector is associated with. When you want the training vector to be associated with the lower indexed codeword, select `Lower indexed codeword`. To associate the training vector with the higher indexed codeword, select `Higher indexed codeword`.

With each iteration, the block updates the codeword values in order to minimize the distortion. The **Codebook update method** parameter defines the way the block calculates these new codebook values.

Note If, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

If, for the **Distortion measure** parameter, you choose `Weighted squared error` and you choose `Mean` for the **Codebook update method** parameter, the new codeword vector is found as follows. Suppose there are three training vectors associated with one codeword vector. The training vectors are

$$TS_1 = \begin{bmatrix}1\\2\end{bmatrix},\ TS_3 = \begin{bmatrix}10\\12\end{bmatrix},\ \text{and } TS_7 = \begin{bmatrix}11\\12\end{bmatrix}.$$

The new codeword vector is calculated as $CW_{new} = \begin{bmatrix}\frac{1+10+11}{3}\\ \frac{2+12+12}{3}\end{bmatrix}$

where the denominator is the number of training vectors associated with this codeword. If, for the **Codebook update method** parameter, you choose `Centroid` and you specify

the weighting factors $W_1 = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix}$, $W_3 = \begin{bmatrix} 1 \\ 0.6 \end{bmatrix}$, and $W_7 = \begin{bmatrix} 0.3 \\ 0.4 \end{bmatrix}$, the new codeword vector is calculated as

$$CW_{new} = \begin{bmatrix} \frac{(0.1)(1) + (1)(10) + (0.3)(11)}{0.1 + 1 + 0.3} \\ \frac{(0.2)(2) + (0.6)(12) + (0.4)(12)}{0.2 + 0.6 + 0.4} \end{bmatrix}$$

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the entropy of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool dialog box.

The following is an example of how the block calculates the entropy of the quantizer at each iteration. Suppose you have a codebook with four codewords and a training set with 200 training vectors. Also suppose that, at the *i*-th iteration, 40 training vectors are associated with the first codeword, 60 training vectors are associated with the second codeword, 20 training vectors are associated with the third codeword, and 80 training vectors are associated with the fourth codeword. The probability that a training vector is associated with the first codeword is $\frac{40}{200}$. The probabilities that training vectors are associated with the second, third, and fourth codewords are $\frac{60}{200}$, $\frac{20}{200}$, and $\frac{80}{200}$, respectively. The GUI uses these probabilities to calculate the entropy according to the equation

$$H = \sum_{i=1}^{N} -p_i \log_2 p_i$$

where N is the number of codewords. Based on these probabilities, the GUI calculates the entropy of the quantizer at the *i*-th iteration as

$$H = -\left(\frac{40}{200}\log_2\frac{40}{200} + \frac{60}{200}\log_2\frac{60}{200} + \frac{20}{200}\log_2\frac{20}{200} + \frac{80}{200}\log_2\frac{80}{200}\right)$$

$$H = 1.8464$$

VQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Square Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select `Current model` to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Vector Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Vector Quantizer Decoder block. When you have a Vector Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Vector Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is `1e5`.

Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Choose `User defined` to enter your own initial codebook values.

Number of levels

Enter the number of codeword vectors, N, in your codebook matrix, where $N \geq 2$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter. The codebook must have the same number of rows as the training set. You must provide at least two codeword vectors.

Distortion measure

When you select `Squared error`, the block finds the nearest codeword by calculating the squared error (unweighted). When you select `Weighted squared error`, the block finds the nearest codeword by calculating the weighted squared error.

Weighting factor

Enter a vector or matrix. The block uses these values to compute the weighted squared error. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The individual weighting factors cannot be negative. The weighting factor vector or matrix cannot contain all zeros.

Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number of iterations at which to stop. Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

This parameter is available when you choose `Relative threshold` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

This parameter is available when you choose `Maximum iteration` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the maximum number of iterations you want the block to perform.

Tie-breaking rules

When a training vector has the same distortion for two different codeword vectors, select `Lower indexed codeword` to associate the training vector with the lower indexed codeword. Select `Higher indexed codeword` to associate the training vector with the lower indexed codeword.

Codebook update method

When you choose `Mean`, the new codeword vector is calculated by taking the average of all the training vector values that were associated with the original codeword vector. When you choose `Centroid`, the block calculates the new codeword vector by taking the weighted average of all the training vector values that were associated with the original codeword vector Note that if, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

Destination

Choose `Current model` to create a Vector Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type

Select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

Encoder block name

Enter a name for the Vector Quantizer Encoder block.

Decoder block name

Enter a name for the Vector Quantizer Decoder block.

Overwrite target block

When you do not select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Vector Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Design and Plot

Click this button to design a quantizer using the parameters on the left side of the GUI and to update the performance curve and entropy plots on the right side of the GUI.

You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Squared Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

Supported Data Types

- Double-precision floating point

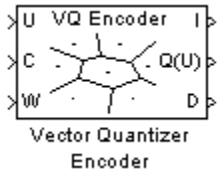
Vector Quantizer Encoder

For given input, find index of nearest codeword based on Euclidean or weighted Euclidean distance measure



Library

Quantizers

`dspquant2`

Description

The Vector Quantizer Encoder block compares each input column vector to the codeword vectors in the codebook matrix. Each column of this codebook matrix is a codeword. The block finds the codeword vector nearest to the input column vector and returns its zero-based index. This block supports real floating-point and fixed-point signals on all input ports.

The block finds the nearest codeword by calculating the distortion. The block uses two methods for calculating distortion: Euclidean squared error (unweighted) and weighted Euclidean squared error. Consider the codebook, $CB = [CW_1\ CW_2\ \ldots\ CW_N]$. This codebook has N codewords; each codeword has k elements. The i-th codeword is defined as a column vector, $CW_i = [a_{1i}\ a_{2i}\ \ldots\ a_{ki}]$. The multichannel input has M columns and is defined as $U = [U_1\ U_2\ \ldots\ U_M]$, where the p-th input column vector is $U_p = [u_{1p}\ u_{2p}\ \ldots\ u_{kp}]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^{k} \left(a_{ji} - u_{jp}\right)^2$$

The weighted squared error is calculated using the equation

$$D = \sum_{j=1}^{k} w_j (a_{ji} - u_{jp})^2$$

where the weighting factor is defined as $W = [w_1\ w_2\ \ldots\ w_k]$. The index of the codeword that is associated with the minimum distortion is assigned to the input column vector.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, you can type the codebook values into the block parameters dialog box. Select `Input port` and port C appears on the block. The block uses the input to port C as the **Codebook** parameter.

The **Codebook** parameter is an *k*-by-*N* matrix of values, where $k \geq 1$ and $N \geq 1$. Each input column vector is compared to this codebook. Each column of the codebook matrix is a codeword, and each codeword has an index value. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. The codeword vectors must have the same number of rows as the input, U.

For the **Distortion measure** parameter, select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want to use a weighting factor to emphasize or deemphasize certain input values.

For the **Source of weighting factor** parameter, select `Specify via dialog` to enter a weighting factor vector in the dialog box. Choose `Input port` to specify the weighting factor using port W.

Use the **Weighting factor** parameter to emphasize or deemphasize certain input values when calculating the distortion measure. For example, consider the *p*-th input column vector, U_p, as previously defined. When you want to neglect the effect of the first element of this vector, enter `[0 1 1 ... 1]` as the **Weighting factor** parameter. This weighting factor is used to calculate the weighted squared error using the equation

$$D = \sum_{j=1}^{k} w_j (a_{ji} - u_{jp})^2$$

Because of the weighting factor used in this example, the weighted squared error is not affected by the first element of the input matrix. Therefore, the first element of the input

column vector no longer impacts the choice of index value output by the Vector Quantizer Encoder block.

Use the **Index output data type** parameter to specify the data type of the index values output at port I. The data type of the index values can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

When an input vector is equidistant from two codewords, the block uses the **Tie-breaking rule** parameter to determine which index value the block chooses. When you want the input vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Select the **Output codeword** check box to output at port Q(U) the codeword vectors that correspond to each index value. When the input is a matrix, the corresponding codeword vectors are horizontally concatenated into a matrix.

Select the **Output quantization error** check box to output at port D the quantization error that results when the block represents the input column vector by its nearest codeword. When the input is a matrix, the quantization error values are horizontally concatenated.

The Vector Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1960 or “Supported Data Types” on page 2-1964.

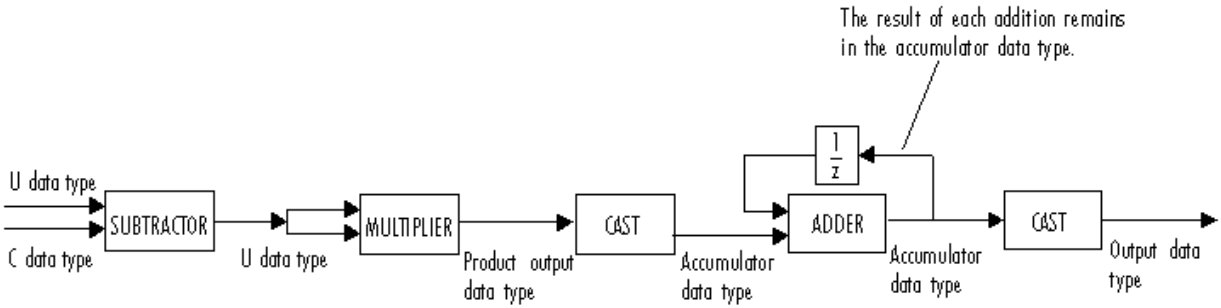
Data Type Support

The input data values, codebook values, and weighting factor values are input to the block at ports U, C, and W, respectively. The data type of the input data values, codebook values, and weighting factor values can be `double`, `single`, or Fixed-point. The input data, codebook values, and weighting factor must be the same data type.

The outputs of the block are the index values, output codewords, and quantization error. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. The data type of the index can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the output codewords and the quantization error can be `double`, `single`, or Fixed-point. The block assigns the data type of the output codewords and the quantization error based on the data type of the input data.

Fixed-Point Data Types

The following diagram shows the data types used within the Vector Quantizer Encoder block for fixed-point signals.



You can set the product output, accumulator, and index output data types in the block dialog as discussed below.

Dialog Box

Main Tab

Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, C.

Codebook

Enter a *k*-by-*N* matrix of values, where $1 \le k$ and $1 \le N$, to which your input column vector or matrix is compared. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

Distortion measure

Select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want the block to calculate the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values.

Source of weighting factor

Select `Specify via dialog` to enter a value for the weighting factor in the dialog box. Choose `Input port` and specify the weighting factor using port W on the block. This parameter is visible if, for the **Distortion measure** parameter, you select `Weighted squared error`.

Weighting factor

Enter a vector of values. This vector must have length equal to the number of rows of the input, U. This parameter is visible if, for the **Source of weighting factor** parameter, you select `Specify via dialog`.

Tie-breaking rule

Set this parameter to determine the behavior of the block when an input column vector is equidistant from two codewords. When you want the input column vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Output codeword

Select this check box to output the codeword vectors nearest to the input column vectors.

Output quantization error

Select this check box to output the quantization error value that results when the block represents the input column vector by the nearest codeword.

Index output data type

Select `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32` as the data type of the index output at port I. To inherit the index output data type, select `Inherit via back propagation`.

Data Types Tab

Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- `Floor`
- `Ceiling`
- `Convergent`
- `Nearest`

- `Round`
- `Simplest`
- `Zero`

For more details, see rounding mode.

Overflow mode

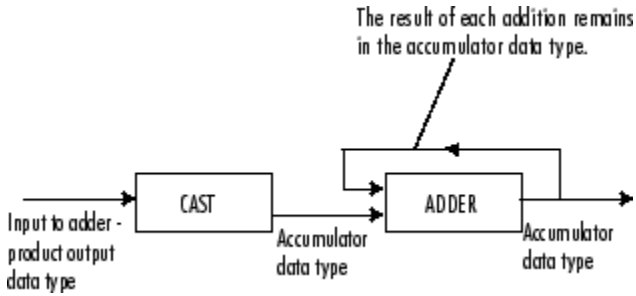
When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Product output

As depicted above, the output of the multiplier is placed into the product output data type and scaling. Use this parameter to specify how you would like to designate this product output word and fraction lengths.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.

Accumulator



As depicted above, inputs to the accumulator are cast to the accumulator data type. The output of the adder remains in the accumulator data type as each element of the

input is added to it. Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.

Introduced before R2006a

Waterfall

View vectors of data over time

Library

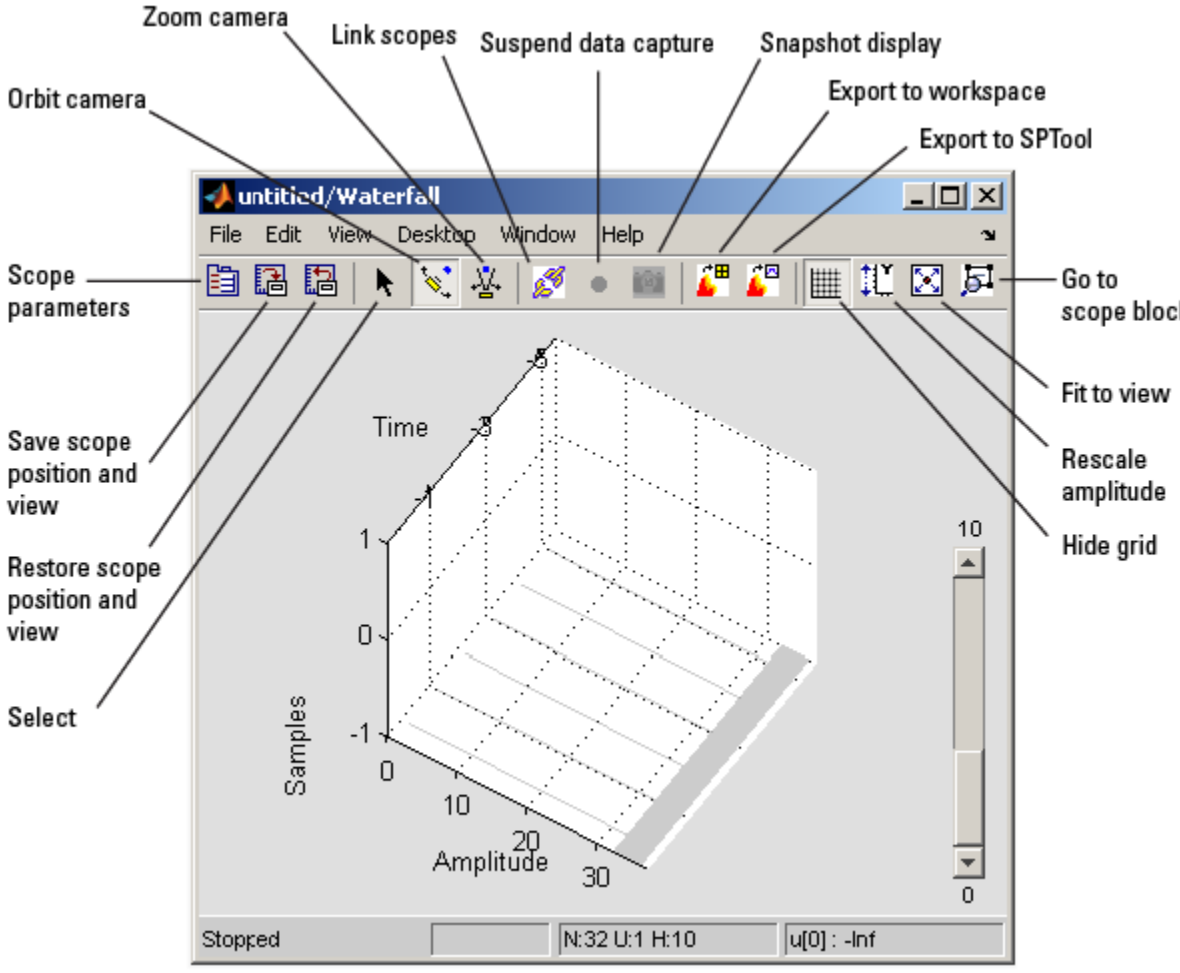
Sinks

`dspsnks4`

Description

The Waterfall block displays multiple vectors of data at one time. These vectors represent the input data at consecutive sample times. The input to the block can be real or complex-valued data vectors of any data type including fixed-point data types. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

The data is displayed in a three-dimensional axis in the Waterfall window. By default, the *x*-axis represents amplitude, the *y*-axis represents samples, and the *z*-axis represents time. You can adjust the number of sample vectors that the block displays, move and resize the Waterfall window, and modify block parameter values during the simulation. The Waterfall window has toolbar buttons that enable you to zoom in on displayed data, suspend data capture, freeze the scope's display, save the scope position, and export data to the workspace. The toolbar buttons are labeled in the following figure, which shows the Waterfall window as it appears when you double-click a Waterfall block.



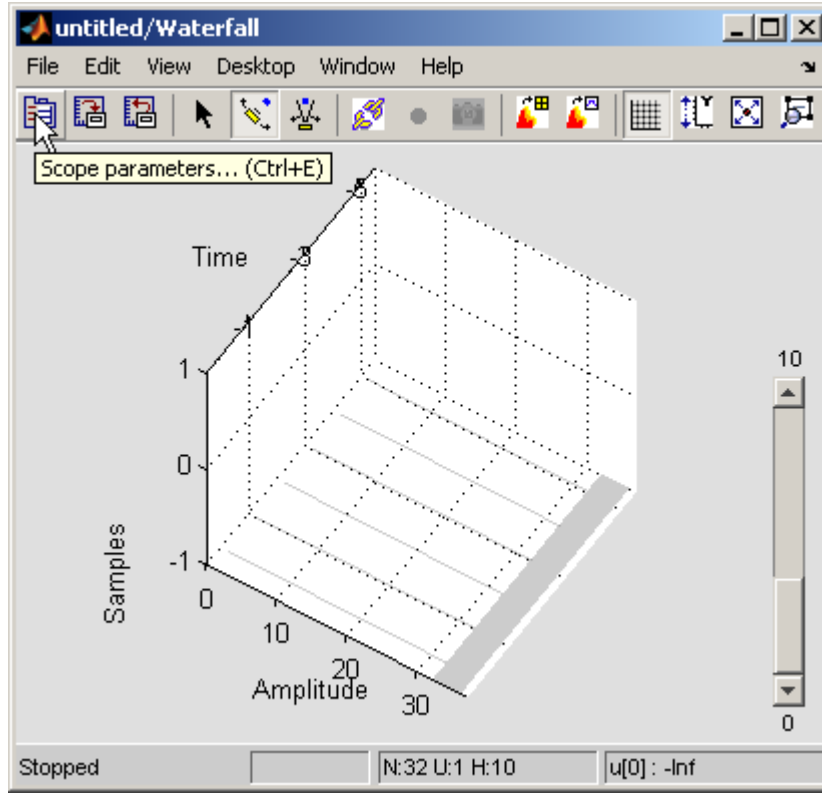
Sections of This Reference Page

Waterfall Parameters

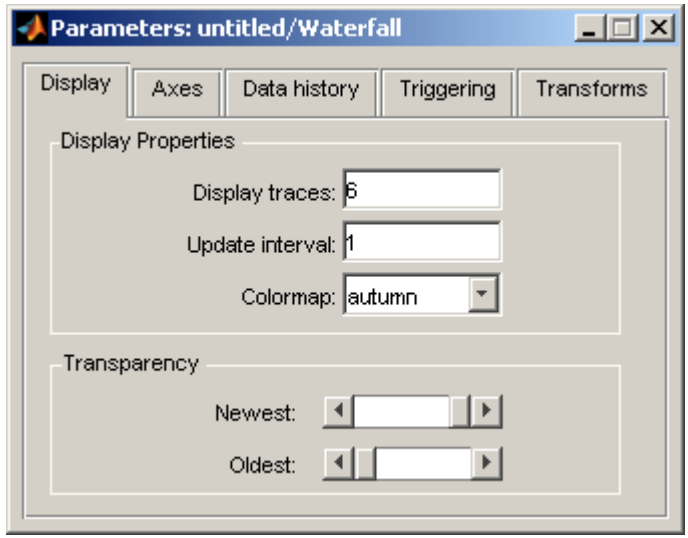
You can control the display and behavior of the Waterfall window using the Parameters dialog box.

Note You can alter the Waterfall parameters while the simulation is running. However, when you make changes to values in text boxes, you must click **Enter** or click outside the text box before the block accepts your changes.

1 To open the Parameters dialog box, click the **Scope parameters** button.



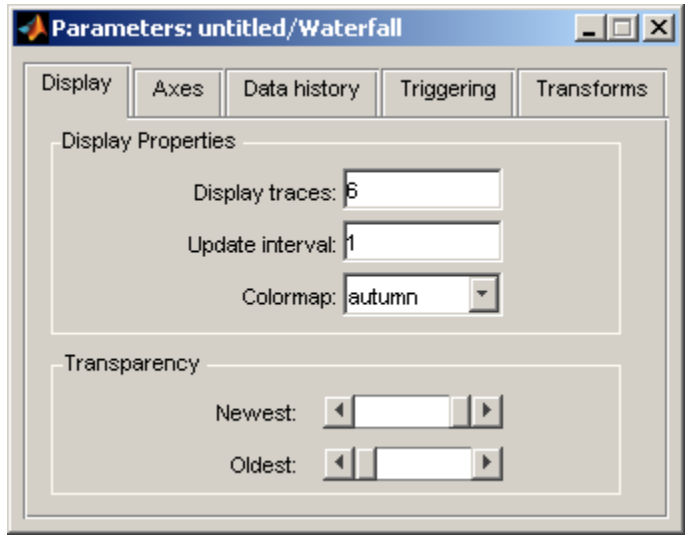
The Parameters dialog box appears.



2 Click on the different panes to enter parameter settings.

Display Parameters

The following parameters control the Waterfall window's display.



Display traces

Enter the number of vectors of data to be displayed in the Waterfall window.

Update interval

Enter the number of vectors the block should store before it displays them to the window.

Colormap

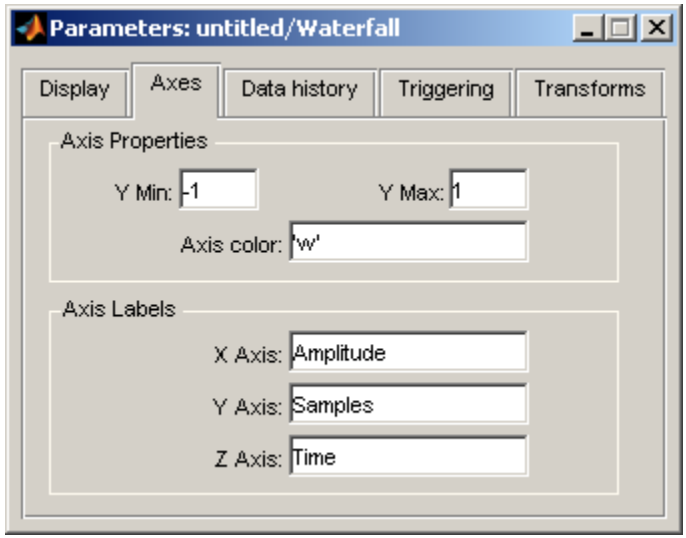
Choose a colormap for the displayed data.

Transparency

Specify the transparency of the newest and oldest data vectors. Placing the slider in the left-most position tells the block to make the data vector transparent. Placing the slider in the right-most position tells the block to make the data vector opaque. The intermediate data vectors transition between the two chosen transparency values.

Axes Parameters

The following parameters control the axes in the Waterfall window.



Y Min

Enter the minimum value of the *y*-axis.

Y Max

Enter the maximum value of the *y*-axis.

Axis color

Enter a background color for the axes. Specify the color using a character vector. For example, to specify black, enter `'k'`.

X Axis

Enter the *x*-axis label.

Y Axis

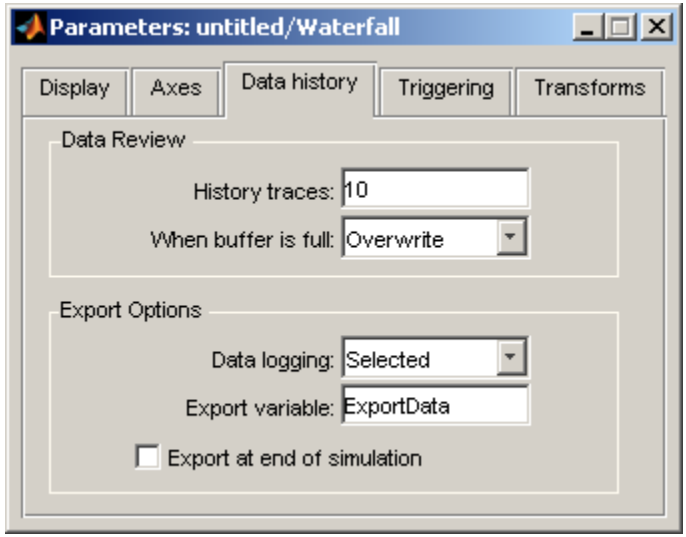
Enter the *y*-axis label.

Z Axis

Enter the *z*-axis label.

Data History Parameters

The following parameters control how many input data vectors the Waterfall block stores. They also control how the data is exported to the MATLAB workspace.



History traces

Enter the number of vectors (traces) that you want the block to store.

When the buffer is full

Use this parameter to control the behavior of the block when the buffer is filled:

- `Overwrite` — The old data is replaced with the new data.
- `Suspend` — The block stops storing data in the buffer; however, the simulation continues to run.
- `Extend` — The block extends the buffer so that it can continue to store all the input data.

Data logging

Use this parameter to control which data is exported from the block:

- `Selected` — The selected data vector is exported.
- `All visible` — All of the data vectors displayed in the Waterfall window are exported.
- `All history` — All of the data vectors stored in the block's history buffer are exported.

Export variable

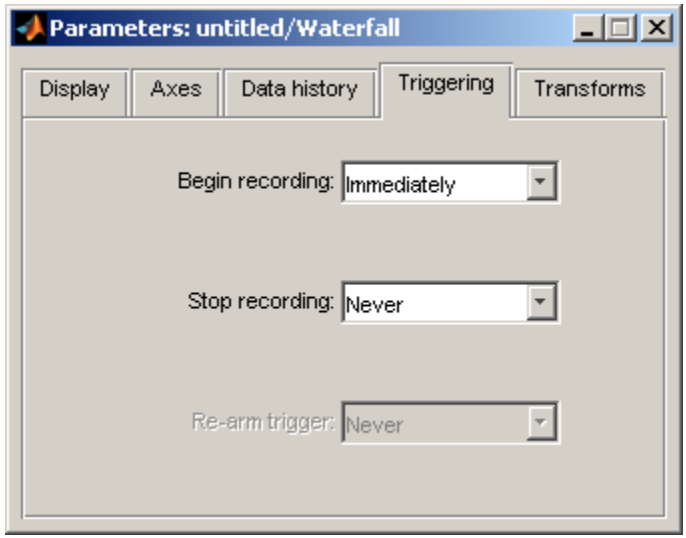
Enter the name of the variable that represents your data in the MATLAB workspace. The default variable name is `ExportData`.

Export at end of simulation

Select this check box to automatically export the data to the MATLAB workspace when the simulation stops.

Triggering Parameters

The following parameters control when the Waterfall block starts and stops capturing data.



Begin recording

This parameter controls when the Waterfall block starts capturing data:

- `Immediately` — The Waterfall window captures the input data as soon as the simulation starts.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins capturing data.
- `After N inputs` — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins capturing data.
- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin capturing data. For more information about how you define this function, see “Scope Trigger Function” on page 2-1977.

Stop recording

This parameter controls when the Waterfall block stops capturing data:

- `Never` — The block captures the input data as long as the simulation is running.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it stops capturing data.

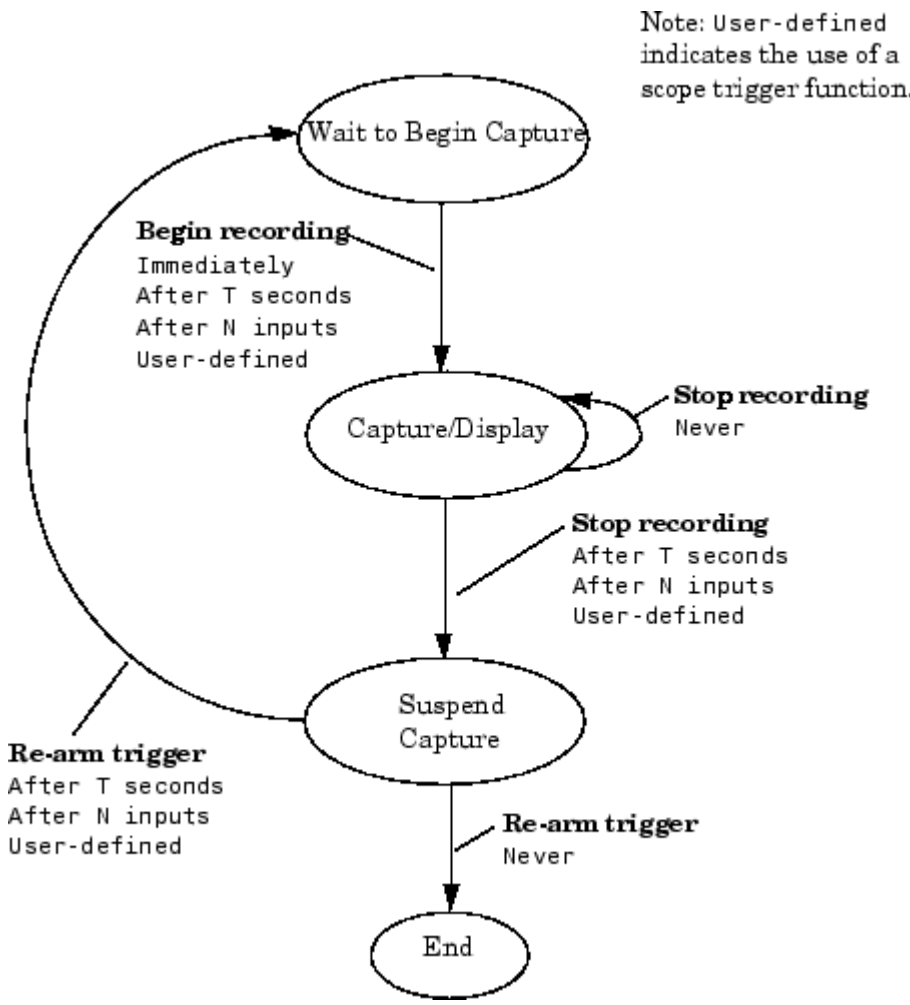
- `After N inputs` —The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it stops capturing data.
- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should stop capturing data. For more information about how you define this function, see “Scope Trigger Function” on page 2-1977.

Re-arm trigger

This parameter controls when the Waterfall block begins waiting to capture data. It is available only when you select `After T seconds`, `After N inputs`, or `User-defined` for the **Stop recording** parameter:

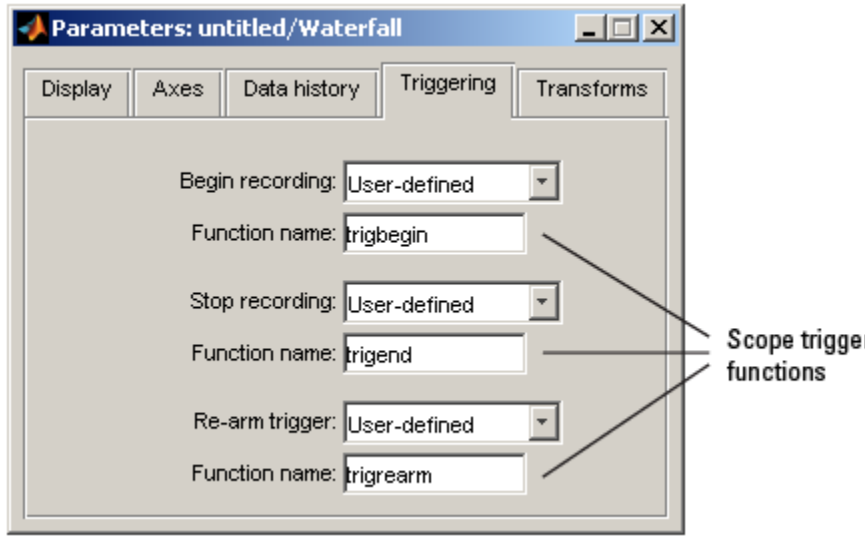
- `Never` — The Waterfall Scope block starts and stops capturing data as defined by the **Begin recording** and **Stop recording** parameters.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins waiting to capture data.
- `After N inputs` — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins waiting to capture data.
- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin waiting to capture data. For more information about how you define this function, see “Scope Trigger Function” on page 2-1977.

The triggering process is illustrated in the state diagram below.



Scope Trigger Function

You can create custom scope trigger functions to control when the scope starts, stops, or begins waiting to capture data.



These functions must be valid MATLAB functions and be located either in the current folder or on the MATLAB path.

Each scope trigger function must have the following form

```
y = functionname(blk,t,u),
```

where `functionname` refers to the name you give your scope trigger function. The variable `blk` is the Simulink block handle. When the scope trigger function is called by the block, Simulink automatically populates this variable with the handle of the Waterfall block. The variable `t` is the current simulation time, represented by a real, double-precision, scalar value. The variable `u` is the vector input to the block. The output of the scope trigger function, `y`, is interpreted as a logical signal. It is either true or false:

- Begin recording scope trigger function
  - When the output of this scope trigger function is true, the Waterfall block starts capturing data.
  - When the output is false, the block remains in its current state.
- Stop recording scope trigger function
  - When the output of this scope trigger function is true, the block stops capturing data.

    - When the output is false, the block remains in its current state.
- Re-arm trigger scope trigger function
    - When the output of this scope trigger function is true, the block waits for a begin recording event.
    - When the output is false, the block remains in its current state.

> **Note** The Waterfall block passes its input data directly to the scope trigger functions. These functions do not use the transformed data defined by the Transform parameters.

The following is an example of a scope trigger function. This function, called `trigPower` detects when the energy in u exceeds a certain threshold.

```
function y = trigPower(blk, t, u)

y = (u'*u > 2300);
```

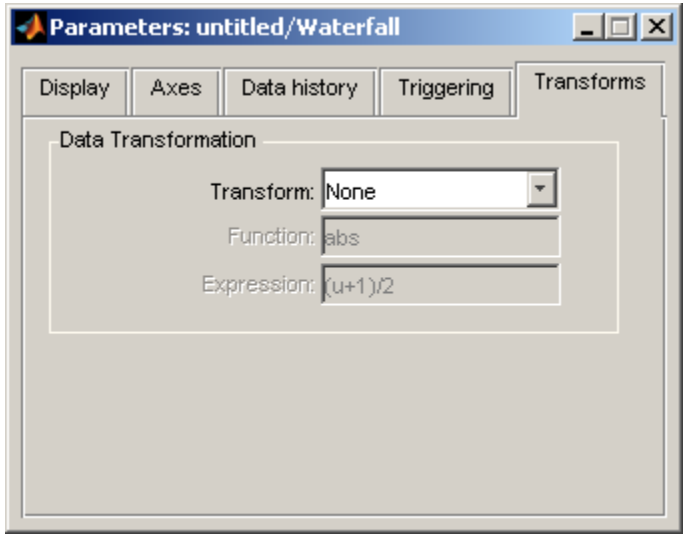
The following is another example of a scope trigger function. This function, called `count3`, triggers the scope once three vectors with positive means are input to the block. Then, the function resets itself and begins searching for the next three input vectors with positive means. This scope trigger function is valid only when one Waterfall block is present in your model.

```
function y = count3(blk, t, u)

persistent state;
if isempty(state); state = 0; end
if mean(u)>0; state = state+1; end
y = (state>=3);
if y; state = 0; end
```

Transform Parameters

The following parameters transform the input data to the Waterfall block. The result of the transform is displayed in the Waterfall window.



Note The block assumes that the input to the block corresponds to the **Transform** parameter you select. For example, when you choose `Complex-> Angle`, the block assumes that the input is complex. The block does not produce an error when the input is not complex. Therefore, you must verify the format of your input data to guarantee that a meaningful result is displayed in the Waterfall window.

Transform

Choose a transform that you would like to apply to the input of the Waterfall block:

- `None` — The input is displayed as it is received by the block.
- `Amplitude-> dB` — The block converts the input amplitude into decibels.
- `Complex-> Mag Lin` — The block converts the complex input into linear magnitude.
- `Complex-> Mag dB` — The block converts the complex input into magnitude in decibels.
- `Complex-> Angle` — The block converts the complex input into phase.
- `FFT-> Mag Lin Fs/2` — The block takes the linear magnitude of the FFT input and plots it from 0 to the Nyquist frequency.

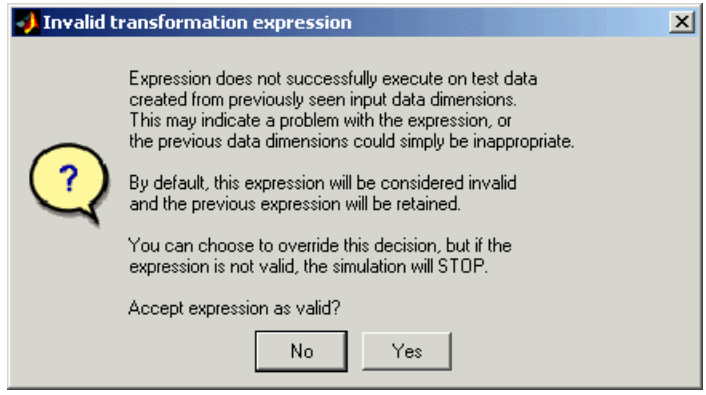
- `FFT-> Mag dB Fs/2` — The block takes the magnitude of the FFT input, converts it to decibels, and plots it from 0 to the Nyquist frequency.
- `FFT-> Angle Fs/2` — The block converts the FFT input into phase and plots it from 0 to the Nyquist frequency.
- `Power-> dB` — The block converts the input power into decibels.

Function

This parameter is only available when you select `User-defined fcn` for the **Transform** parameter. Enter a function that you would like to apply to the input of the Waterfall block. For more information about how you define this function, see “Scope Transform Function” on page 2-1982.

Expression

This parameter is only available when you select `User-defined expr` for the **Transform** parameter. Enter an expression that you would like to apply to the input of the Waterfall block. The result of this expression must be real-valued. When you write the expression, be sure to include only one unknown variable. The block assumes this unknown variable represents the input to the block. When the block believes your expression is invalid, the following window appears.



When you click **No**, your expression is not applied to the input. When you click **Yes** and your expression is invalid, your simulation stops and Simulink displays an error.

Scope Transform Function

You can create a scope transform function to control how the Waterfall block transforms your input data. This function must have a valid MATLAB function name and be located either in the current folder or on the MATLAB path.

Your scope transform function must have the following form

```
y = functionname(u),
```

where `functionname` refers to the name you give your function. The variable `u` is the real or complex vector input to the block. The output of the scope transform function, `y`, must be a double-precision, real-valued vector. When it is not, the simulation stops and Simulink displays an error. Note that the output vector does not need to be the same size as the input vector.

Examples

The following examples illustrate some capabilities of the Waterfall block.

Exporting Data

You can use the Waterfall block to export data to the MATLAB workspace:

1. Open and run the `dspanc` example.
2. While the simulation is running, click the **Export to Workspace** button.
3. Type `whos` at the MATLAB command line.

The variable `ExportData` appears in your MATLAB workspace. `ExportData` is a 40-by-6 matrix. This matrix represents the six data vectors that were present in the Waterfall window at the time you clicked the **Export to Workspace** button. Each column of this matrix contains 40 filter coefficients. The columns of data were captured at six consecutive instants in time.

You can control what data is exported using the **Data logging** parameter in **Data history** pane of the Parameters dialog box. For more information, see “Data History Parameters” on page 2-1973.

Capturing Data

You can use the Waterfall block to interact with your data while it is being captured:

1. Open and run the `dspanc` example.
2. While the simulation is running, click the **Suspend data capture** button.

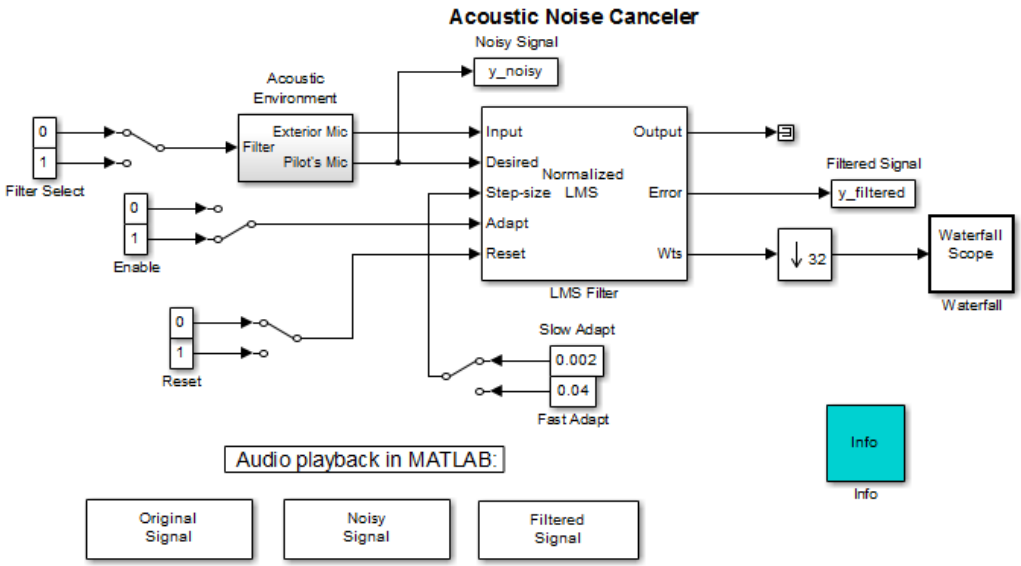
   The Waterfall block no longer captures or displays the data coming from the Downsample block.
3. To continue capturing data, click the **Resume data capture** button.
4. To freeze the data display while continuing to capture data, click the **Snapshot display** button.
5. To view the Waterfall block that the data is coming from, click the **Go to scope block** button.

   In the Simulink model window, the Waterfall block that corresponds to the active Waterfall window flashes. This feature is helpful when you have more than one Waterfall block in a model and you want to clarify which data is being displayed.

Linking Scopes

You can link several Waterfall blocks together in order to capture the effect of a model event in all of the Waterfall windows in the model:

1. Open the `dspanc` example.
2. Drag a second Waterfall block into the example model.
3. Connect this block to the Output port of the LMS Filter block as shown in the figure below.



4 Run the model and view the model behavior in both Waterfall windows.

5 In the dspanc/Waterfall window, click the **Link scopes** button.

6 In the same window, click the **Suspend data capture** button.

   The data capture is suspended in both scope windows.

7 Click the **Resume data capture** button.

   The data capture resumes in both scope windows.

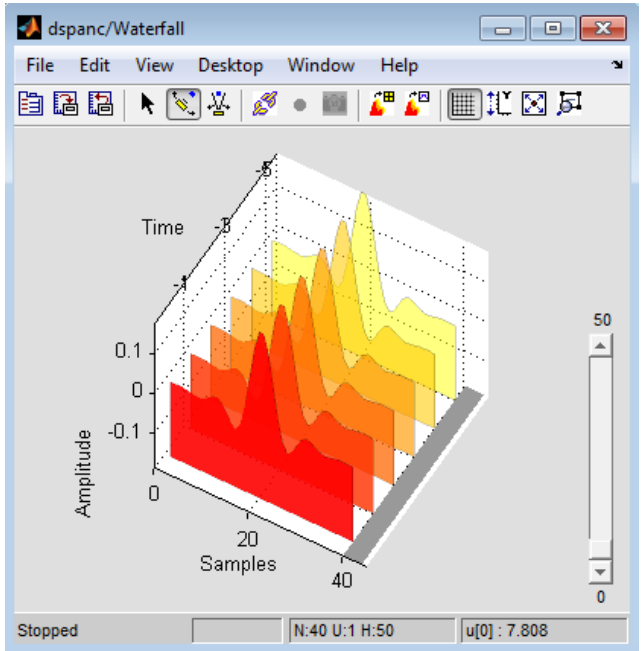
8 In the dspanc/Waterfall window, click the **Snapshot display** button.

   In both scope windows, the data display freezes while the block continues to capture data.

9 To continue displaying the captured data, click the **Resume display** button.

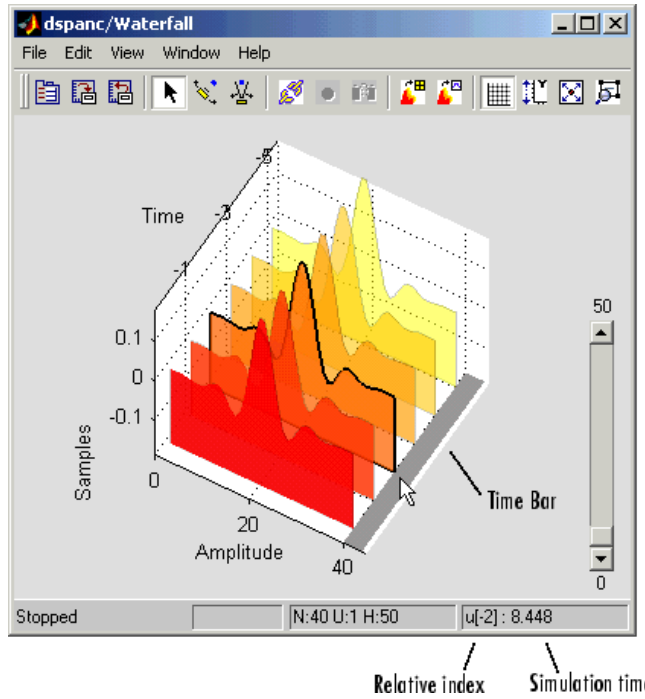
Selecting Data

The following figure shows the Waterfall window displaying the output of the `dspanc` example:



1. To select a particular set of data, click the **Select** button.
2. Click on the Time Bar at the bottom right of the axes to select a vector of data.

   The Waterfall block highlights the selected trace.



While the simulation is running, in the bottom right corner, the Waterfall window displays the relative index of the selected trace. For example, in the previous figure, the selected vector is two sample times away from the most current data vector. When the simulation is stopped, the Waterfall window displays both the relative index and the simulation time associated with the selected trace.

3 To deselect the data vector, click it again.

4 Click-and-drag along the Time Bar.

Your selection follows the movement of the pointer.

You can use this feature to choose a particular vector to export to the MATLAB workspace. For more information, see “Data History Parameters” on page 2-1973.

Zooming

You can use the Waterfall window to zoom in on data:

1. Click the **Zoom camera** button.
2. In the Waterfall window, click and hold down the left mouse button.
3. Move the mouse up and down and side-to-side to move closer and farther away from the axes.
4. To resize the axes to fit the Waterfall window, click the **Fit to view** button.

Rotating the Display

You can rotate the data displayed in the Waterfall window:

1. Click on the **Orbit camera** button.
2. In the Waterfall window, click and hold down the left mouse button.
3. Move the mouse in a circular motion to rotate the axes.
4. To return to the position of the original axes, click the **Restore scope position and view** button.

Scaling the Axes

You can use the Waterfall window to rescale the *y*-axis values:

1. Open and run the `dspanc` example.
2. Click the **Rescale amplitude** button.

   The *y*-axis changes so that its minimum value is zero. The maximum value is scaled to fit the data displayed.

Alternatively, you can scale the *y*-axis using the **Y Min** and **Y Max** parameters in the **Axes** pane of the Parameters dialog box. This is helpful when you want to undo the effects of rescaling the amplitude. For more information, see “Axes Parameters” on page 2-1972.

Saving Scope Settings

The Waterfall block can save the screen position and viewpoint of the Waterfall window:

1. Click the **Save scope position and view** button.
2. Close the Waterfall window.
3. Reopen the Waterfall window.

It reopens at the same place on your screen. The viewpoint of the axes also remains the same.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

The Waterfall block accepts any of these data types as input. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

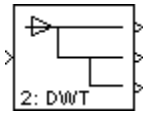
Wavelet Analysis (Obsolete)

Decompose signal into components of logarithmically decreasing frequency intervals and sample rates (requires the Wavelet Toolbox product)



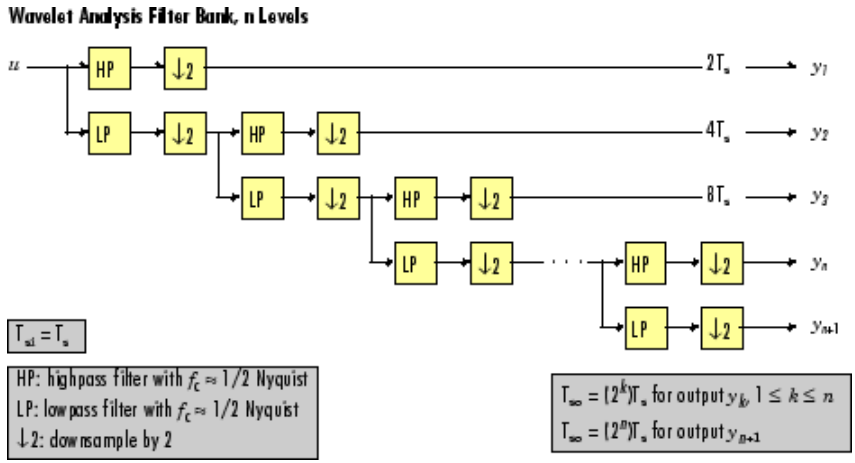
Library

`dspobslib`

Description

Note The Wavelet Analysis block will be removed from the product in a future release. We strongly recommend replacing this block with the DWT block.

The Wavelet Analysis block uses the Wavelet Toolbox `wfilters` function to construct a dyadic analysis filter bank that decomposes a broadband signal into a collection of successively more bandlimited components. An *n*-level filter bank structure is shown below, where *n* is specified by the **Number of levels** parameter.



At each level, the low-frequency output of the previous level is decomposed into adjacent high- and low-frequency subbands by a highpass (HP) and lowpass (LP) filter pair. Each of the two output subbands is half the bandwidth of the input to that level. The bandlimited output of each filter is maximally decimated by a factor of 2 to preserve the bit rate of the original signal.

Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	`wfilters('haar')`
Daubechies	`wfilters('db4')`
Symlets	`wfilters('sym3')`
Coiflets	`wfilters('coif1')`
Biorthogonal	`wfilters('bior3.1')`
Reverse Biorthogonal	`wfilters('rbio3.1')`
Discrete Meyer	`wfilters('dmey')`

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to `6`, the Wavelet Analysis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to `[2 / 6]`, the Wavelet Analysis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the analysis filter bank, use the Dyadic Analysis Filter bank block.

Tree Structure

The wavelet tree structure has n+1 outputs, where n is the number of levels. The sample rate and bandwidth of the top output are half the input sample rate and bandwidth. The sample rate and bandwidth of each additional output (except the last) are half that of the output from the previous level. In general, for an input with sample period $T_{si} = T_s$, and bandwidth BW, output y_k has sample period $T_{so,k}$ and bandwidth BW_k.

$$T_{so,k} = \begin{cases} \left(2^k\right)T_s \ (1 \le k \le n) \\ \left(2^n\right)T_s \ (k = n+1) \end{cases}$$

$$BW_k = \begin{cases} \dfrac{BW}{2^k} \ (1 \le k \le n) \\ \dfrac{BW}{2^n} \ (k = n+1) \end{cases}$$

Note that in frame-based mode, the change in the sample period of output y_k is reflected by its frame size $M_{o,k}$, rather than by its frame rate.

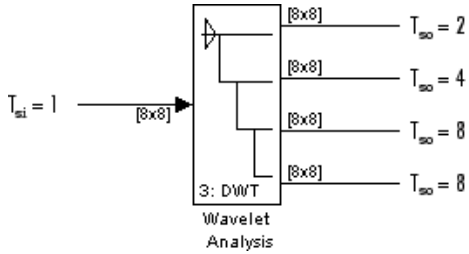
$$M_{o,k} = \begin{cases} \dfrac{M_i}{2^k} \ (1 \le k \le n) \\ \dfrac{M_i}{2^n} \ (k = n+1) \end{cases}$$

The bottom two outputs (y_n and y_{n+1}) share the same sample period, bandwidth, and frame size because they originate at the same tree level.

Sample-Based Operation

An *M*-by-*N* sample-based matrix input is treated as *M***N* independent channels, and the block filters each channel independently over time. The output at each port is the same size as the input, one output channel for each input channel. As described earlier, each output port has a different sample period.

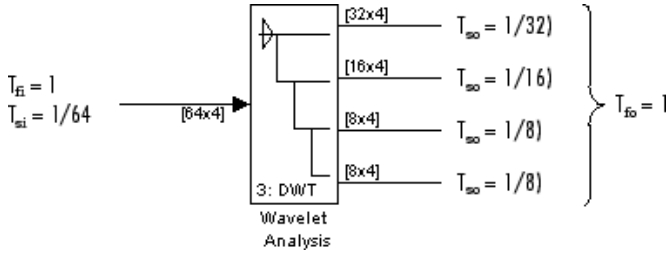
The figure below shows the input and output sample periods for a 64-channel sample-based input to a three-level filter bank. The input has a period of 1, so the fastest output has a period of 2.



Frame-Based Operation

An M_i-by-*N* frame-based matrix input is treated as *N* independent channels, and the block filters each channel independently over time. The input frame size M_i must be a multiple of 2^n, and *n* is the number of filter bank levels. For example, a frame size of 8 would be appropriate for a three-level tree (2^3=8). The number of columns in each output is the same as the number of columns in the input.

Each output port has the same frame period as the input. The reduction in the output sample rates results from the smaller output frame sizes, as shown in the example below for a four-channel input to a three-level filter bank.



Zero Latency

The Wavelet Analysis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore analyzes the first input sample (received at t=0) to produce the first output sample at each port.

Nonzero Latency

For sample-based operation, the Wavelet Analysis block is multirate and has 2^{n-1} samples of latency in both Simulink tasking modes. As a result, the block repeats a zero initial condition in each channel for the first 2^{n-1} output samples, before propagating the first analyzed input sample (computed from the input received at t=0).

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Wavelet name

The wavelet used in the analysis.

Wavelet order

The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

Filter order [synthesis / analysis]

The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, `[2 / 6]` selects a second-order

synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

Number of levels

The number of filter bank levels. An *n*-level structure has *n*+1 outputs.

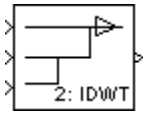
`wfilters`	Wavelet Toolbox

Introduced in R2008b

Wavelet Synthesis (Obsolete)

Reconstruct signal from its multirate bandlimited components (requires the Wavelet Toolbox product)



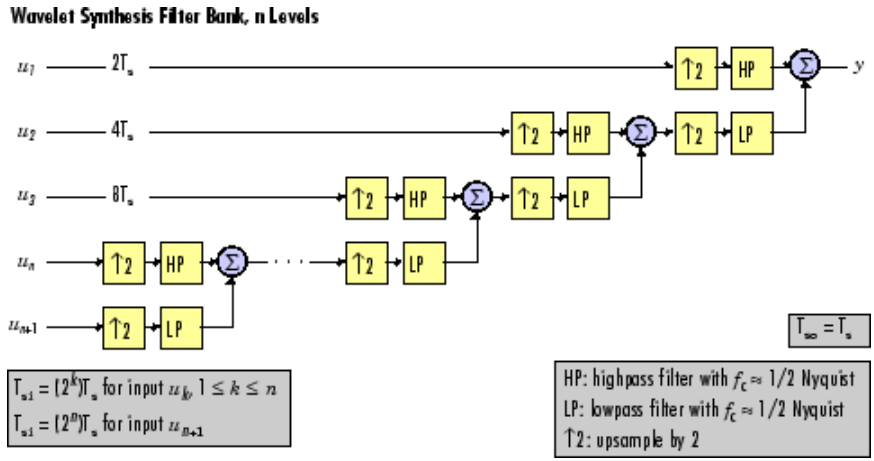
Library

`dspobslib`

Description

Note The Wavelet Synthesis block will be removed from the product in a future release. We strongly recommend replacing this block with the IDWT block.

The Wavelet Synthesis block uses the Wavelet Toolbox `wfilters` function to reconstruct a signal that was decomposed by the Wavelet Analysis (Obsolete) block. The reconstruction or synthesis process is the inverse of the analysis process, and restores the original signal by upsampling, filtering, and summing the bandlimited inputs in stages corresponding to the analysis process. An *n*-level synthesis filter bank structure is shown below, where *n* is specified by the **Number of levels** parameter.



At each level, the two bandlimited inputs (one low-frequency, one high-frequency, both with the same sample rate) are upsampled by a factor of 2 to match the sample rate of the input to the next stage. They are then filtered by a highpass (HP) and lowpass (LP) filter pair with coefficients calculated to cancel (in the subsequent summation) the aliasing introduced in the corresponding analysis filter stage. The output from each (upsample-filter-sum) level has twice the bandwidth and twice the sample rate of the input to that level.

For perfect reconstruction, the Wavelet Synthesis and Wavelet Analysis blocks must have the same parameter settings.

Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	`wfilters('haar')`
Daubechies	`wfilters('db4')`
Symlets	`wfilters('sym3')`
Coiflets	`wfilters('coif1')`

Wavelet Name	Sample Wavelet Function Syntax
Biorthogonal	`wfilters('bior3.1')`
Reverse Biorthogonal	`wfilters('rbio3.1')`
Discrete Meyer	`wfilters('dmey')`

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to `6`, the Wavelet Synthesis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to `[2 / 6]`, the Wavelet Synthesis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the synthesis filter bank, use the Dyadic Synthesis Filter bank block.

Tree Structure

The wavelet tree structure has n+1 inputs, where n is the number of levels. The sample rate and bandwidth of the output are twice the sample rate and bandwidth of the top input. The sample rate and bandwidth of each additional input (except the last) are half that of the input to the previous level.

$$T_{si,k+1} = 2T_{si,k} \quad 1 \le k < n$$

$$BW_{k+1} = \frac{BW_k}{2} \quad 1 \le k < n$$

The bottom two inputs (u_n and u_{n+1}) should have the same sample rate and bandwidth since they are processed by the same level.

$$T_{si,n+1} = T_{si,n}$$

$$BW_{n+1} = BW_n$$

Note that in frame-based mode, the sample period of input u_k is reflected by its frame size$M_{i,k}$, rather than by its frame rate.

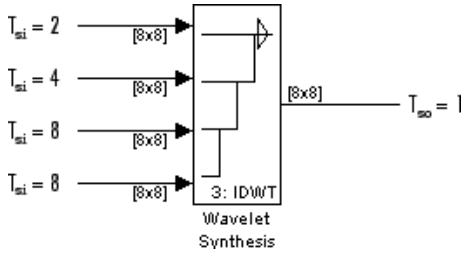
$$M_{i,k+1} = \frac{M_{i,k}}{2} \qquad 1 \le k < n$$

$$M_{i,n+1} = M_{i,n}$$

Sample-Based Operation

An *M*-by-*N* sample-based matrix input is treated as *M***N* independent channels, and the block filters each channel independently over time. The output is the same size as the input at each port, one output channel for each input channel. As described earlier, each input port has a different sample period.

The figure below shows the input and output sample periods for the four 64-channel sample-based inputs to a three-level filter bank. The fastest input has a period of 2, so the output period is 1.

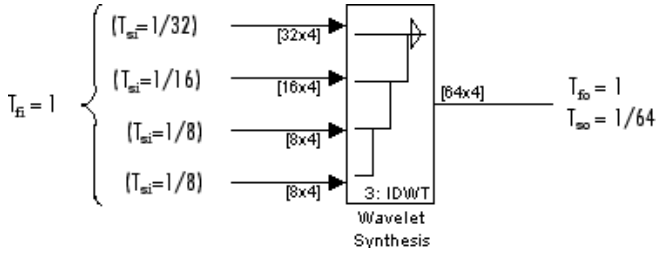


Frame-Based Operation

An M_i-by-*N* frame-based matrix input is treated as *N* independent channels, and the block filters each channel independently over time. The number of columns in the output is the same as the number of columns in the input.

All inputs must have the same frame period, which is also the output frame period. The different input sample rates should be represented by the input frame sizes: If the input to the top port has frame size M_i, the input to the second-from-top port should have frame size $M_i/2$, the input to the third-from-top port should have frame size $M_i/4$, and so on. The input to the bottom port should have the same frame size as the second-from-bottom port. The increase in the sample rate of the output is also represented by its frame size, which is twice the largest input frame size.

The relationship between sample periods, frame periods, and frame sizes is shown below for a four-channel frame-based input to a 3-level filter bank.



Zero Latency

The Wavelet Synthesis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore uses the first input samples (received at t=0) to synthesize the first output sample.

Nonzero Latency

For sample-based operation, the Wavelet Synthesis block is multirate and has the following tasking latencies:

- 2^n-2 samples in Simulink's single-tasking mode
- 2^n samples in Simulink's multitasking mode

In the above cases, the block repeats a zero initial condition in each channel for the first D output samples, where D is the latency shown above. For example, in single-tasking mode the block generates 2^n-2 zero-valued output samples in each channel before propagating the first synthesized output sample (computed from the inputs received at t=0).

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Wavelet name

The wavelet used in the synthesis.

Wavelet order

The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

Filter order [synthesis / analysis]

The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, `[2 / 6]` selects a second-order synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

Number of levels

The number of filter bank levels. An *n*-level structure has *n*+1 outputs.

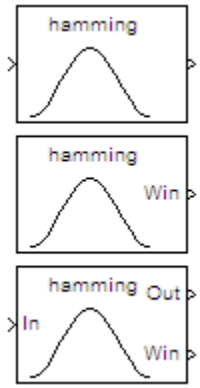
Dyadic Synthesis Filter bank DSP System Toolbox

`wfilters`	Wavelet Toolbox

Introduced in R2008b

Window Function

Compute and/or apply window to input signal



Library

Signal Operations

`dspsigops`

Description

The Window Function block computes a window and/or applies a window to an input signal. The input signal can be a matrix or an N-D array.

Operation Modes

The Window Function block has three modes of operation that you can select via the **Operation** parameter. In each mode, the block first creates a window vector *w* by sampling the window specified in the **Window type** parameter at *M* discrete points. The operation modes are:

- `Apply window to input`

In this mode, the block computes an *M*-by-1 window vector *w* and applies it to the input. The output *y* always has the same dimension as the input.

When the input is an *M*-by-*N* matrix *u*, the window is multiplied element-wise with each of the *N* channels in the input matrix *u*. This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u                                  % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \ldots, k) = w(i) * u(i, j, \ldots, k) \qquad i = 1, \ldots, M, \quad j = 1, \ldots, N, \quad \ldots, \quad k = 1, \ldots, P$$

A length-*M* unoriented vector input is treated as an *M*-by-1 matrix.

- `Generate window`

  In this mode, the block generates an unoriented window vector *w* with length *M* specified by the **Window length** parameter. The In port is disabled for this mode.

- `Generate and apply window`

  In this mode, the block generates an *M*-by-1 window vector *w* and applies it to the input. The block produces two outputs:

  - At the Out port, the block produces the result of the multiplication *y*, which has the same dimension as the input.
  - At the Win port, the block produces the *M*-by-1 window vector *w*.

  When the input is an *M*-by-*N* matrix *u*, the window is multiplied element-wise with each of the *N* channels in the input matrix *u*. This is equivalent to the following MATLAB code:

  ```
  y = repmat(w,1,N) .* u                                  % Equivalent MATLAB code
  ```

  The window is always applied to the first dimension:

  $$y(i, j, \ldots, k) = w(i) * u(i, j, \ldots, k) \qquad i = 1, \ldots, M, \quad j = 1, \ldots, N, \quad \ldots, \quad k = 1, \ldots, P$$

  A length-*M* 1-D vector input is treated as an *M*-by-1 matrix.

Window Type

The following table lists the available window types. For complete information about the window functions, consult the Signal Processing Toolbox documentation.

Window Type	Description
Bartlett	Computes a Bartlett window. `w = bartlett(M)`
Blackman	Computes a Blackman window. `w = blackman(M)`
Boxcar	Computes a rectangular window. `w = rectwin(M)`
Chebyshev	Computes a Chebyshev window with stopband ripple `R`. `w = chebwin(M,R)`
Hamming	Computes a Hamming window. `w = hamming(M)`
Hann	Computes a Hann window (also known as a Hanning window). `w = hann(M)`
Hanning	Obsolete. This window type is included only for compatibility with older models. Use the `Hann` **Window type** instead of `Hanning` whenever possible.
Kaiser	Computes a Kaiser window with the Kaiser parameter `beta`. `w = kaiser(M,beta)`
Taylor	Computes a Taylor window. `w = taylorwin(M)`
Triang	Computes a triangular window. `w = triang(M)`

Window Type	Description

User Defined	Computes the user-defined window function specified by the entry in the **Window function name** parameter, `usrwin`.
	
	`w = usrwin(M) % Window takes no extra parameters`
	`w = usrwin(M,`x_1`,...,`x_n`) % Window takes extra parameters {`x_1` ... `x_n`}`

Window Sampling

For the generalized-cosine windows (`Blackman`, `Hamming`, `Hann`, and `Hanning`), the **Sampling** parameter determines whether the window samples are computed in a periodic or a symmetric manner. For example, when **Sampling** is set to `Symmetric`, a Hamming window of length M is computed as

```
w = hamming(M)                    % Symmetric (aperiodic) window
```

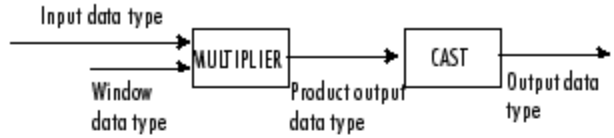
When **Sampling** is set to `Periodic`, the same window is computed as

```
w = hamming(M+1)                    % Periodic (asymmetric) window
w = w(1:M)
```

Fixed-Point Data Types

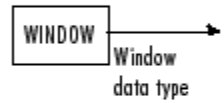
The following diagram shows the data types used within the Window Function block for fixed-point signals for each of the three operating modes.

Apply window to input



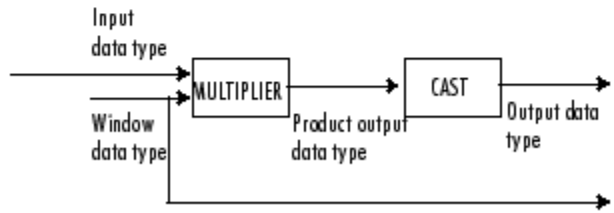
The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is not output from the block.

Generate window



In this mode, the block acts as a source. The window vector is output in the window data type you specify in the block dialog.

Generate and apply window



The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is output from the block.

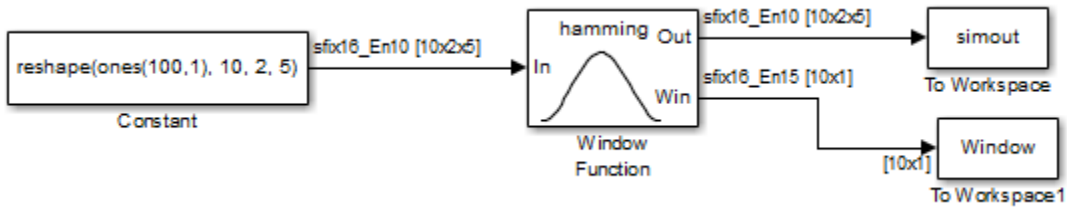
You can set the window, product output, and output data types in the block dialog box. For more information see the “Dialog Box” on page 2-2008 section.

Examples

The following model uses the Window Function block to generate and apply a Hamming window to a 3-dimensional input array.

In this example, set the **Operation** mode of the Window Function block to `Generate and apply window`, so the block provides two outputs: the window vector *Window* at the Win port, and the result of the multiplication *simout* at the Out port.

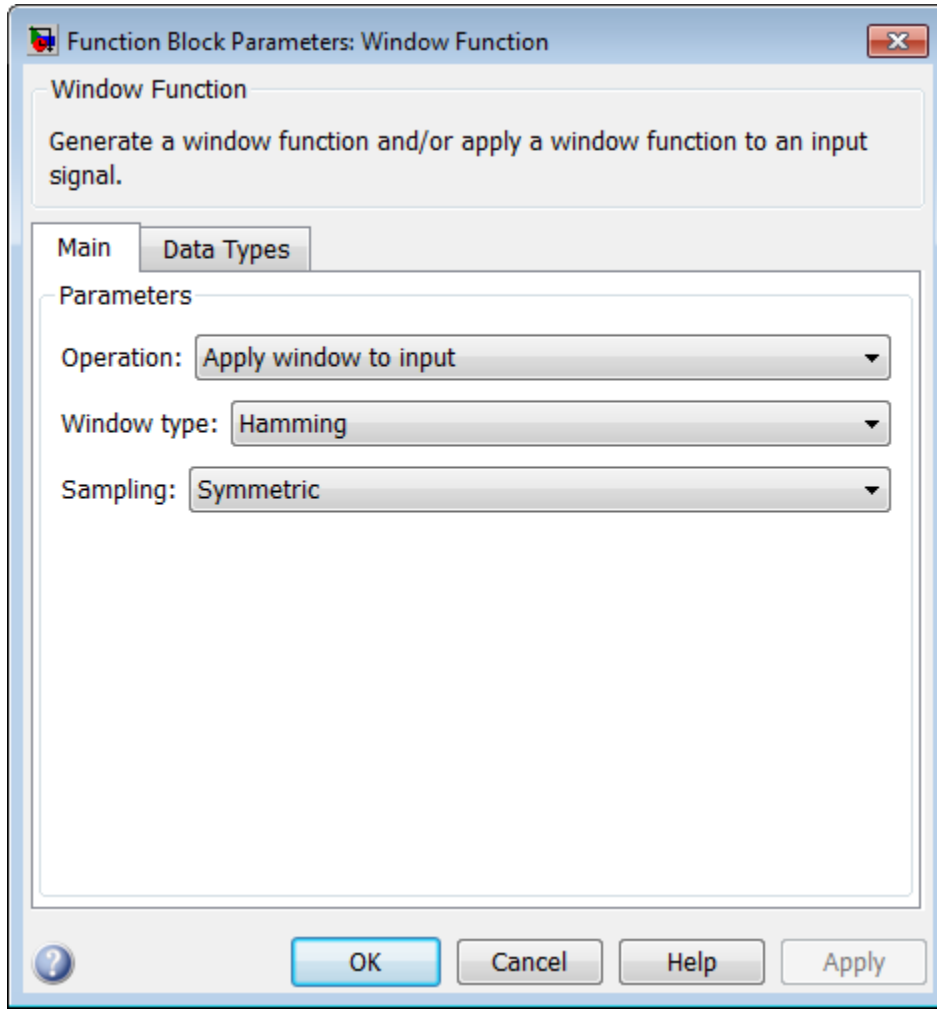
Open the model by typing `ex_windowfunction_ref` at the MATLAB command line, and run it.



- The length of the first dimension of the input array is 10, so the Window Function block generates and outputs a Hamming window vector of length 10. To see the window vector generated by the Window Function block, type `Window` at the MATLAB command line.
- To see the result of the multiplication, type `simout` at the MATLAB command line.

Dialog Box

The **Main** pane of the Window Function block dialog appears as follows.



Operation

Specify the block's operation, as discussed in “Operation Modes” on page 2-2003. The port configuration of the block is updated to match the setting of this parameter.

Window type

Specify the window type to apply, as listed in “Window Type” on page 2-2005. Tunable (Simulink) in simulation only.

Sampling

Specify the window sampling for generalized-cosine windows. This parameter is only visible when you select `Blackman`, `Hamming`, `Hann`, or `Hanning` for the **Window type** parameter. Tunable (Simulink) in simulation only.

Sample Mode

Specify the sample mode for the block, `Continuous` or `Discrete`, when it is in `Generate Window` mode. In the `Apply window to output` and `Generate and apply window` modes, the block inherits the sample time from its driving block. Therefore, this parameter is only visible when you select `Generate window` for the **Operation** parameter.

Sample time

Specify the sample time for the block when it is in `Generate window` and `Discrete` modes. In `Apply window to output` and `Generate and apply window` modes, the block inherits the sample time from its driving block. This parameter is only visible when you select `Discrete` for the **Sample Mode** parameter.

Window length

Specify the length of the window to apply. This parameter is only visible when you select `Generate window` for the **Operation** parameter. Otherwise, the window vector length is computed to match the length of the first dimension of the input.

Stopband attenuation in dB

Specify the level of stopband attenuation, R_s, in decibels. This parameter is only visible when you select `Chebyshev` for the **Window type** parameter. Tunable (Simulink) in simulation only.

Beta

Specify the `Kaiser` window β parameter. Increasing β widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This parameter is only visible when you select `Kaiser` for the **Window type** parameter. Tunable (Simulink) in simulation only.

Number of sidelobes

Specify the number of sidelobes as a scalar integer value greater than zero. This parameter is only visible when you select `Taylor` for the **Window type** parameter.

Maximum sidelobe level relative to mainlobe (dB)

Specify, in decibels, the maximum sidelobe level relative to the mainlobe. This parameter must be a scalar less than or equal to zero. The default value of –30 produces sidelobes with peaks 30 dB down from the mainlobe peak. This parameter is only visible when you select `Taylor` for the **Window type** parameter.

Window function name

Specify the name of the user-defined window function to be calculated by the block. This parameter is only visible when you select `User defined` for the **Window type** parameter.

Specify additional arguments to the hamming function

Select to enable the **Cell array of additional arguments** parameter, when the user-defined window requires parameters other than the window length. This parameter is only visible when you select `User defined` for the **Window type** parameter.

Cell array of additional arguments

Specify the extra parameters required by the user-defined window function, besides the window length. This parameter is only available when you select the **Specify additional arguments to the hamming function** parameter. The entry must be a cell array.

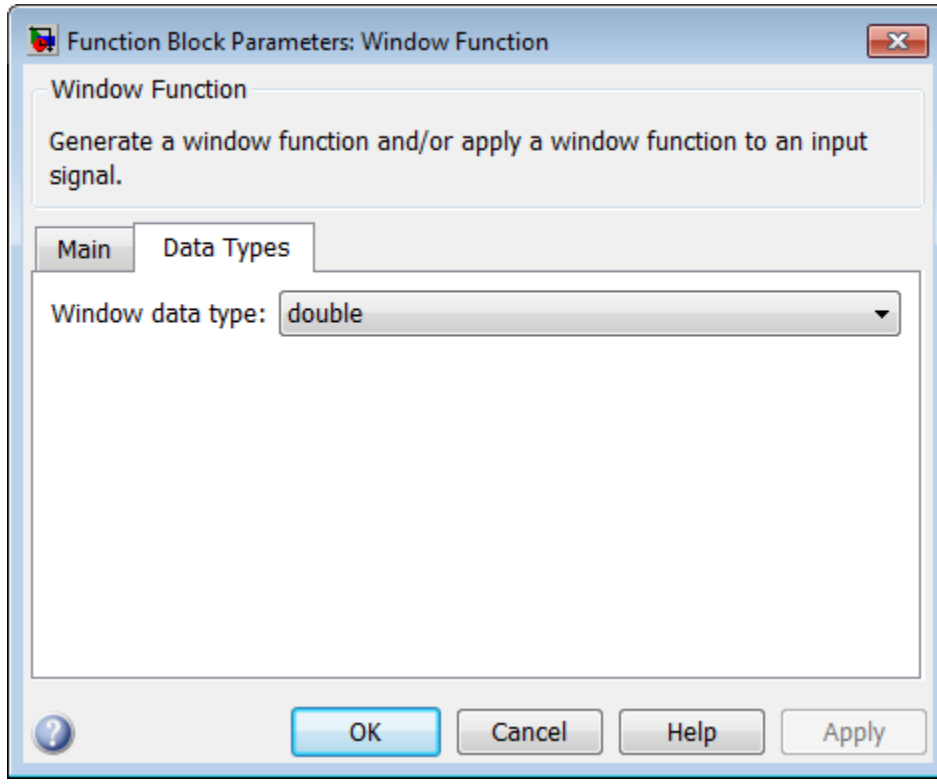
The **Data Types** pane of the Window Function block dialog is discussed in the following sections:

“Parameters for Generate Window Only Mode” on page 2-2011

“Parameters for Apply Window Modes” on page 2-2013

Parameters for Generate Window Only Mode

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to `Generate window`.



Window

Specify the window data type in one of the following ways:

- Choose `double` or `single` from the list.
- Choose `Fixed-point` to specify the window data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose `User-defined` to specify the window data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose `Inherit via back propagation` to set the window data type and scaling to match the following block.

Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned.

Word length

Specify the word length, in bits, of the fixed-point window data type. This parameter is only visible when you select `Fixed-point` for the **Window** parameter.

User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the Fixed-Point Designer functions `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`. This parameter is only visible when you select `User-defined` for the **Window** parameter.

Set fraction length in output to

Specify the scaling of the fixed-point window data type by either of the following two methods:

- Choose `Best precision` to have the window data type scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the window data type scaling in the **Fraction length** parameter.

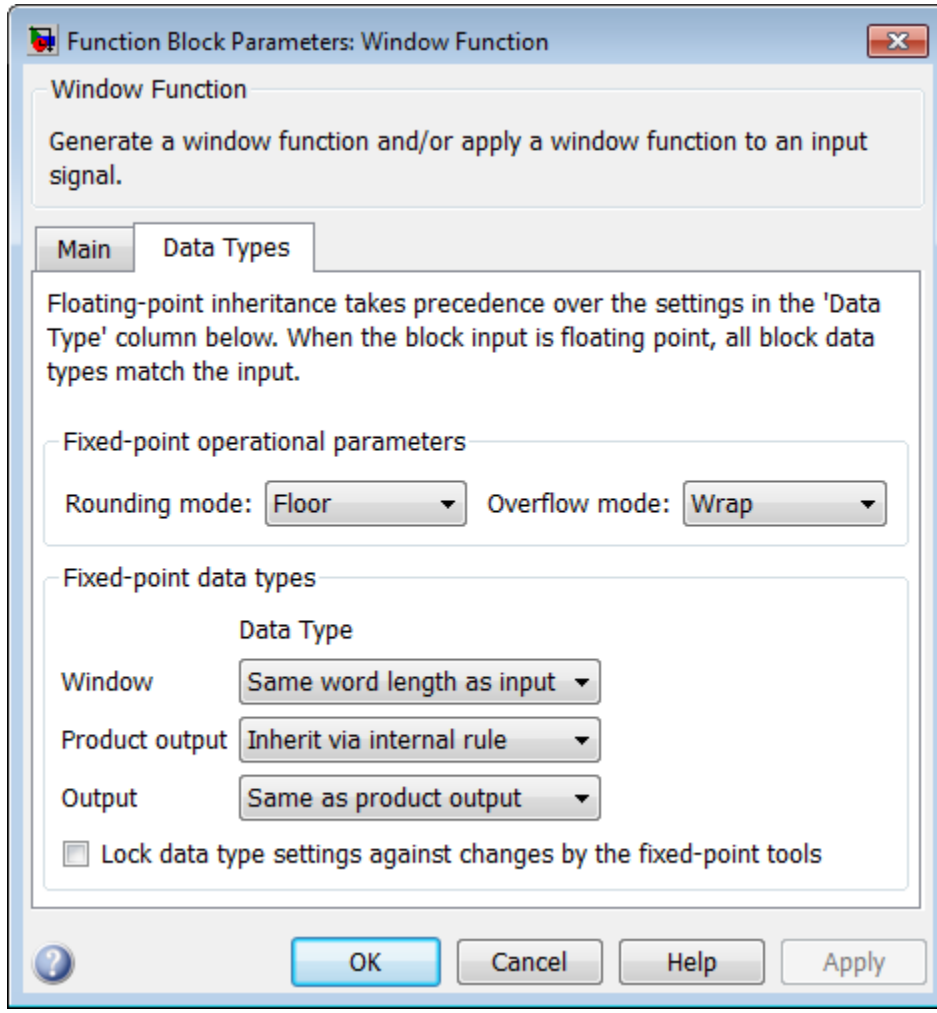
This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Window** parameter, and when the specified window data type is a fixed-point data type.

Fraction length

Specify the fraction length, in bits, of the fixed-point window data type. This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Window** parameter and `User-defined` for the **Set fraction length in output to** parameter.

Parameters for Apply Window Modes

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to either `Apply window to input` or `Generate and apply window`.



Rounding mode

Select the rounding mode for fixed-point operations.

The window vector *w* does not obey this parameter; it always rounds to `Nearest`.

Note The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Product output** is `Inherit via internal rule`
- **Output** is `Same as product output`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the overflow mode for fixed-point operations.

The window vector *w* does not obey this parameter; it is always saturated.

Window

Choose how you specify the word length and fraction length of the window vector *w*.

When you select `Same word length as input`, the word length of the window vector elements is the same as the word length of the input. The fraction length is automatically set to the best precision possible.

When you select `Specify word length`, you can enter the word length of the window vector elements in bits. The fraction length is automatically set to the best precision possible.

When you select `Binary point scaling`, you can enter the word length and the fraction length of the window vector elements in bits.

When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the window vector elements. This block requires power-of-two slope and a bias of zero.

The window vector does not obey the **Rounding mode** and **Overflow mode** parameters; it is always saturated and rounded to `Nearest`.

Product output

Use this parameter to specify how you want to designate the product output word and fraction lengths.

- When you select `Inherit via internal rule`, the product output word length and fraction length are calculated automatically. For information about how the product output word and fraction lengths are calculated when an internal rule is used, see “Inherit via Internal Rule”.
- When you select `Same as input`, these characteristics match those of the input to the block.

- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the word length and fraction length of the output of the block:

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Win	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit integers

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (string.h) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

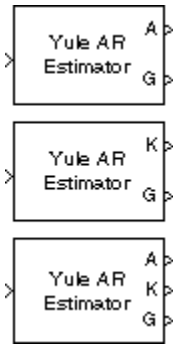
Yule-Walker AR Estimator

Compute estimate of autoregressive (AR) model parameters using Yule-Walker method



Library

Estimation / Parametric Estimation

`dspparest3`

Description

The Yule-Walker AR Estimator block uses the Yule-Walker AR method, also called the autocorrelation method, to fit an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which are solved by the Levinson-Durbin recursion. Block outputs are always nonsingular.

The Yule-Walker AR Estimator block can output the AR model coefficients as polynomial coefficients, reflection coefficients, or both. The input can be a row vector, a column vector, or an unoriented vector which is assumed to be the output of an AR system driven by white noise. The block accepts matrices, and treats each column of the matrix as a channel. If the input is a row vector of length N, the input is treated as N different channels. If the input is an unoriented vector, the input is treated as a single channel. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

When you select **Inherit estimation order from input dimensions**, the order p of the all-pole model is one less than the length of each input channel. Otherwise, the order is the value specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be a scalar less than or equal to half the input channel length. The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

When **Output(s)** is set to `A`, port A is enabled. For each channel, port A outputs a column of length p+1 that contains the normalized estimate of the AR model coefficients in descending powers of z

```
[1 a(2) ... a(p+1)]
```

When **Output(s)** is set to `K`, port K is enabled. For each channel, port K outputs a length-p column whose elements are the AR model reflection coefficients. When **Output(s)** is set to `A and K`, both port A and K are enabled, and each port outputs the respective AR model coefficients for each channel.

The square of the model gain, G, is provided at port G. G is a scalar for each channel.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Output(s)

The type of AR model coefficients output by the block. The block can output polynomial coefficients (`A`), reflection coefficients (`K`), or both (`A and K`).

Inherit estimation order from input dimensions

When selected, sets the estimation order p to one less than the length of each input channel.

Estimation order

The order of the AR model, p. This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

Yule-Walker Method

Power spectral density estimate using Yule-Walker method

Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Yule-Walker Method block estimates the power spectral density (PSD) of the input using the Yule-Walker AR method. This method, also called the autocorrelation method, fits an autoregressive (AR) model to the windowed input data. It does so by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which the Levinson-Durbin recursion solves. Block outputs are always nonsingular.

The input must be a column vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

When you select **Inherit estimation order from input dimensions**, the order of the all-pole model is one less that the input frame size. Otherwise, the **Estimation order** parameter value specifies the order. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from**

estimation order parameter allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker AR Estimator blocks. The Yule-Walker AR Estimator and Burg Method blocks return similar results for large buffer lengths.

Parameters

Inherit estimation order from input dimensions

When you select this option, it sets the estimation order to one less than the length of the input vector.

Estimation order

Specify the order of the AR model. This parameter is only visible when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When you select the **Inherit FFT length from estimation order** check box, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is

smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

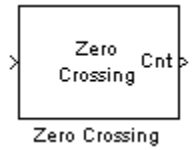
Zero Crossing

Count number of times signal crosses zero in single time step



Library

Signal Operations

`dspsigops`

Description

The Zero Crossing block concludes that a signal in a given channel has passed through zero if it meets any of the following criteria, where x_i is the current signal value, x_{i-1} is the previous signal value, and so on:

- $x_i < 0$ and $x_{i-1} > 0$
- $x_i > 0$ and $x_{i-1} < 0$
- For some positive integer L, $x_i < 0$, $x_{i-l} = 0$, and $x_{i-L-1} > 0$, where $0 \le l \le L$.
- For some positive integer L, $x_i > 0$, $x_{i-l} = 0$, and $x_{i-L-1} < 0$, where $0 \le l \le L$.

For the first input value, x_{i-1} and x_{i-2} are zero. The block outputs the number of times the signal crosses zero in a single time step at the Cnt port.

The input to this block must be a real-valued fixed-point or floating-point signal. If you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input as a time-varying channel. If you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column of the input as an independent channel.

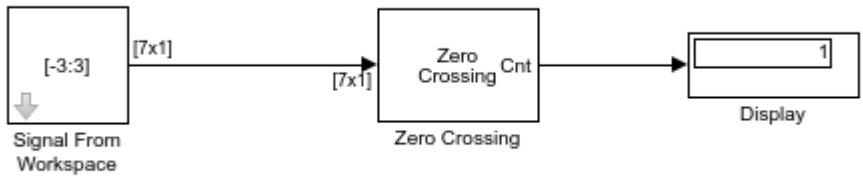
Examples

The following example, ex_zero_crossing illustrates the behavior of the Zero Crossing block.

To run the model for one time step, the **Stop time** is set to `0`.

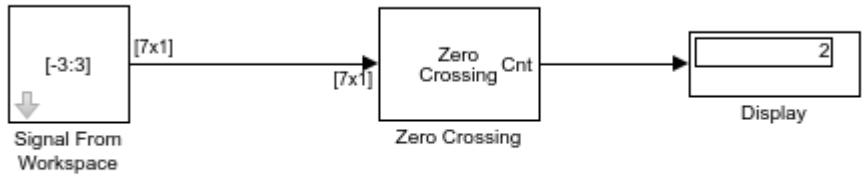
1. Run the model.

   Because the signal passes through zero once during the first time step, the Zero Crossing block finds one zero crossing. The number of detected zero crossings in the first time step is shown in the Display block in the following figure.



2. To run the model for two time steps, change the simulation **Stop time** to `1`. To do so, select **Modeling** tab and click **Model Settings**. In the **Solver** pane, set **Stop time** to `1`.
3. Run the model.

   The Zero Crossing block remembers that the last value of the last frame was 3. Therefore, the signal passes through zero twice during the second time step. It passes through zero while going from 3 to -3, and it passes through zero again while going from -3 to 3. The Zero Crossing block finds two zero crossings in the second time step as shown in the Display block in the following figure.



Parameters

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating-point • Single-precision floating-point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Cnt	• 32-bit unsigned integers

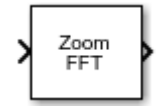
Zoom FFT

High-resolution FFT of a portion of a spectrum
Library: DSP System Toolbox / Transforms



Description

The Zoom FFT block computes the fast Fourier Transform (FFT) of a signal over a portion of frequencies in the Nyquist interval. By setting an appropriate decimation factor *D*, and sampling rate *Fs*, you can choose the bandwidth of frequencies to analyze *BW*, where *BW* = *Fs*/*D*. You can also select a specific range of frequencies to analyze in the Nyquist interval by choosing the center frequency of the desired band.

The resolution of a signal is the ratio of *Fs* and the FFT length (*L*). Using zoom FFT, you can retain the same resolution you would achieve with a full-size FFT on your original signal by computing a small FFT on a shorter signal. The shorter signal comes from decimating the original signal. The savings come from being able to compute a much shorter FFT while achieving the same resolution. For a decimation factor of *D*, the new sampling rate, *Fsd*, is *Fs*/*D*, and the new frame size (and FFT length) is *Ld* = *L*/*D*. The resolution of the decimated signal is *Fsd*/*Ld* = *Fs*/*L*. To achieve a higher resolution of the shorter band, use the original FFT length, *L*, instead of the decimated FFT length, *Ld*.

Ports

Input

x — Data input

vector | matrix

Data input whose zoom FFT the block computes, specified as a vector or a matrix. The number of input rows must be a multiple of the decimation factor.

This block supports variable-size input signals, as long as the input frame size is a multiple of the decimation factor. That is, you can change the input frame size (number of

rows) during the simulation. However, the number of channels (number of columns) must remain constant.

This port is unnamed until you select the **Specify center frequency from input port** parameter and click **Apply**.

Example: `randn(22,2)`

Data Types: `single` | `double`

Fc — Center frequency input

real scalar

Center frequency of the desired band in Hz, passed through this input port as a real scalar in the range (– *SampleRate*/2, *SampleRate*/2). *SampleRate* is the input sample rate either inherited from the input signal or specified through the **Input sample rate (Hz)** parameter. This port appears only when you select the **Specify center frequency from input port** check box.

This port appears only when you select the **Specify center frequency from input port** check box and click **Apply**.

Example: `0`

Example: `1200`

Data Types: `single` | `double`

Output Arguments

Port_1 — Zoom FFT output

vector | matrix

Zoom FFT output, returned as a vector or matrix. If you select the **Inherit FFT Length from input dimensions** check box, the output frame size equals the input frame size divided by the decimation factor. If you clear the **Inherit FFT Length from input dimensions** check box and specify the FFT length, the output frame size equals the specified FFT length. The output data type matches the input data type.

Example: randn(11,2)

Data Types: `single` | `double`

Parameters

`Decimation factor` — Decimation factor

`2` (default) | positive integer

Decimation factor, specified as a positive integer. This value specifies the factor by which the block reduces the bandwidth of the input signal. The number of rows in the input signal must be a multiple of the decimation factor.

Example: `4`

Example: `8`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Specify center frequency from input port` — Flag to specify center frequency from input port

`'off'` (default) | `'on'`

When you select this option and click **Apply**, the input port **Fc** appears on the block icon. You can pass the center frequency through this input port as a scalar.

`Center frequency (Hz)` — Center frequency

`0` (default) | real scalar

Center frequency of the desired band in Hz, specified as a real scalar in the range (–*SampleRate*/2, *SampleRate*/2). *SampleRate* is the input sample rate either inherited from the input or specified through the **Input sample rate (Hz)** parameter.

Example: `0.5`

Example: `10`

Dependencies

This parameter applies when you clear the **Specify center frequency from input port** check box.

Data Types: `single` | `double`

`Inherit FFT Length from input dimensions` — Flag to inherit FFT length from input dimensions

`'on'` (default) | `'off'`

When you select this option, the FFT length is the ratio of the input frame size (number of rows in the input) and the **Decimation factor**.

`FFT length` — FFT length

`64` (default) | positive scalar

FFT length, specified as a positive integer. The FFT length must be greater than or equal to the ratio of the frame size (number of input rows) and the **Decimation factor**.

Example: `24`

Example: `52`

Dependencies

This parameter applies when you clear the **Inherit FFT Length from input dimensions** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Inherit Sample rate from input` — Flag to inherit sample rate from input

`'off'` (default) | `'on'`

When you clear this check box, the block inherits the sample rate from the input signal.

`Input sample rate (Hz)` — Input sample rate

`44100` (default) | positive real scalar

Input sample rate in Hz, specified as positive real scalar.

Example: `44100`

Example: `48000`

`Simulate using` — Type of simulation to run

`Interpreted execution` (default) | `Code generation`

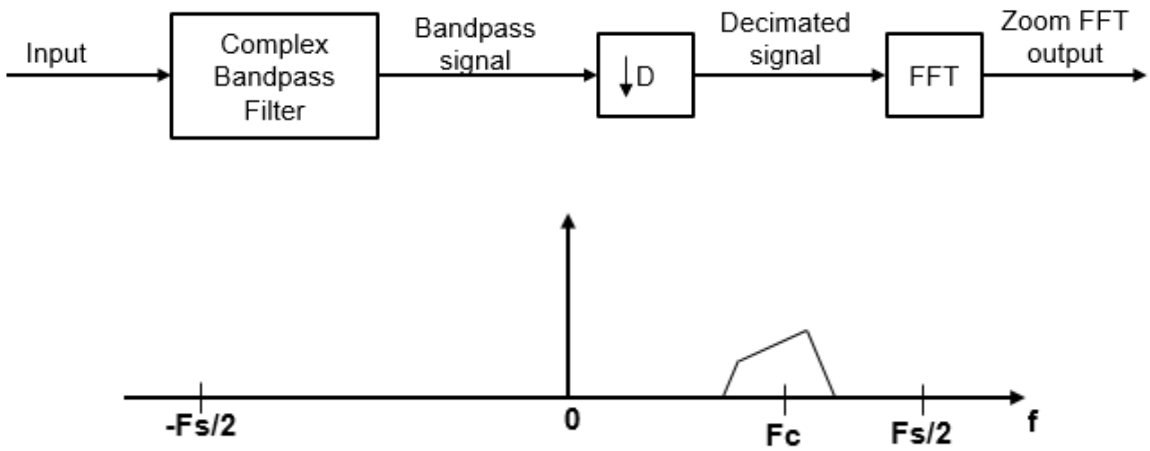
- `Interpreted execution` — Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed than `Code generation`.
- `Code generation` — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time and provides slower simulation speed than `Interpreted execution`.

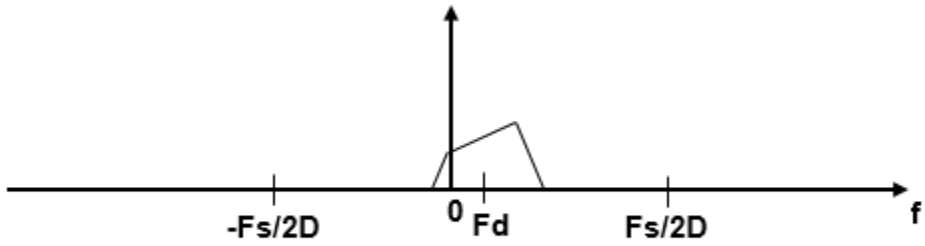
Block Characteristics

Data Types	`double` | `single`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`

Algorithms

The zoom FFT algorithm leverages bandpass filtering before computing the FFT of the signal. The concept of bandpass filtering is that suppose you are interested in the band [*F1*, *F2*] of the original input signal, sampled at the rate *Fs* Hz. If you pass this signal through a complex (one-sided) bandpass filter centered at *Fc* = (*F1*+*F2*)/2, with the bandwidth *BW* = *F2* – *F1*, and then downsample the signal by a factor of *D* = floor(*Fs*/*BW*), the desired band comes down to the baseband.





If *Fc* cannot be expressed in the form of $k \times Fs/D$, where k is an integer, then the shifted, decimated spectrum is not centered at DC. In this case, the center frequency gets translated to *Fd*.

$$F_d = F_c - (F_s/D) \times floor((D \times F_c + F_s/2)/F_s)$$

The complex bandpass filter is obtained by first designing a lowpass filter prototype and then multiplying the lowpass coefficients with a complex exponential. This algorithm uses a multirate, multistage FIR filter as the lowpass filter prototype. To obtain the bandpass filter, the coefficients of each stage are frequency shifted. The decimation factor is the cumulative decimation factor of each stage. The complex bandpass filter followed by the decimator are implemented using an efficient polyphase structure. For more details on the design of the complex bandpass filter from the multirate multistage FIR filter prototype, see “Zoom FFT” and “Complex Bandpass Filter Design”.

Analysis Methods for Filter System Objects

Analysis Methods for Filter System Objects

Method	Description
Single-rate and Multirate Analysis	
`fvtool`	Filter visualization tool
`info`	Filter information
`freqz`	Frequency response of a discrete-time filter
`phasez`	Phase response of a discrete-time filter
`zerophase`	Zero-phase response of a discrete-time filter
`grpdelay`	Group delay of a discrete-time filter
`phasedelay`	Phase delay of a discrete-time filter
`impz`	Impulse response of a discrete-time filter
`impzlength`	Impulse response length
`stepz`	Step response of a discrete-time filter
`zplane`	Pole/Zero plot
`cost`	Cost estimate
`measure`	Measure filter response
`order`	Filter order
`firtype`	Determine the type (1–4) of a linear phase FIR filter
`coeffs`	Return filter coefficients
Multirate Analysis	
`polyphase`	Polyphase decomposition of multirate filters
`gain`	Gain of a Cascaded Integrator-Comb (CIC) filter
Second-order Sections	
`scale`	Scale second-order sections
`scalecheck`	Check scale of second-order sections
`scaleopts`	Create options object for sos scaling

Method	Description
`cumsec`	Vector of cumulative second-order section filters
`reorder`	Reorder second-order sections
`sos`	Convert IIR filter to Biquad filter
Code Generation	
`realizemdl`	Filter realization diagram
Fixed-point (supported by FIRFilter, IIRFilter, AllpoleFilter, and BiquadFilter only)	
`noisepsd`	Power spectral density of filter output due to roundoff noise
`noisepsdopts`	Create options object for noisepsd computation
`freqrespest`	Frequency response estimate via filtering
`freqrespopts`	Create options object for frequency response estimate
Other	
`isallpass`	True for allpass discrete-time filter
`islinphase`	True for linear discrete-time filter
`ismaxphase`	True if maximum phase
`isminphase`	True if minimum phase
`isreal`	True for discrete-time filter with real coefficients
`isstable`	True if the filter is stable
`isfir`	True if the filter is FIR
`issos`	True if filter is in second order sections form
`specifyall`	Specify all fixed-point properties

System Objects — Alphabetical List

dsp.AdaptiveLatticeFilter

Package: `dsp`

Adaptive lattice filter

Description

The `dsp.AdaptiveLatticeFilter` System object computes output, error, and coefficients using a lattice-based FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Create the `dsp.AdaptiveLatticeFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
alf = dsp.AdaptiveLatticeFilter
alf = dsp.AdaptiveLatticeFilter(len)
alf = dsp.AdaptiveLatticeFilter(Name,Value)
```

Description

`alf = dsp.AdaptiveLatticeFilter` returns a lattice-based FIR adaptive filter System object, `alf`. This System object computes the filtered output and the filter error for a given input and desired signal.

`alf = dsp.AdaptiveLatticeFilter(len)` returns an `AdaptiveLatticeFilter` System object with the `Length` property set to `len`.

`alf = dsp.AdaptiveLatticeFilter(Name,Value)` returns an `AdaptiveLatticeFilter` System object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Method` — Method to calculate filter coefficients

`'Least-squares Lattice'` (default) | `'QR-decomposition Least-squares Lattice'` | `'Gradient Adaptive Lattice'`

Specify the method used to calculate filter coefficients as one of `'Least-squares Lattice'`, `'QR-decomposition Least-squares Lattice'`, `'Gradient Adaptive Lattice'`. The default value is `'Least-squares Lattice'`. For algorithms used to implement these three different methods, refer to [1] [2]. This property is nontunable.

`Length` — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ForgettingFactor` — Least-squares lattice forgetting factor

1 (default) | positive scalar

Specify the least-squares lattice forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this value to 1 denotes infinite memory during adaptation.

Tunable: Yes

Dependencies

This property applies only if the Method property is set to `'Least-squares Lattice'` or `'QR-decomposition Least-squares Lattice'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StepSize` — Joint process step size of gradient adaptive filter

`0.1` (default) | positive scalar

Specify the joint process step size of the gradient adaptive lattice filter as a positive numeric scalar less than or equal to 1.

Tunable: Yes

Dependencies

This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`Offset` — Offset for denominator of StepSize normalization term

`1` (default) | nonnegative scalar

Specify an offset value for the denominator of the `StepSize` normalization term as a nonnegative numeric scalar. A nonzero offset helps avoid a divide-by-near-zero condition when the input signal amplitude is very small.

Tunable: Yes

Dependencies

This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ReflectionStepSize` — Reflection process step size

`StepSize` property value (default) | positive scalar

Specify the reflection process step size of the gradient adaptive lattice filter as a scalar numeric value between 0 and 1, both inclusive. The default value is the `StepSize` property value.

Tunable: Yes

Dependencies

Use this property only if the `Method` property is set to `'Gradient Adaptive Lattice'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`AveragingFactor` — Averaging factor of energy estimator

`1 - StepSize` (default) | positive scalar

Specify the averaging factor as a positive numeric scalar less than 1. Use this property to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. The default is the value of `1 - StepSize`.

Tunable: Yes

Dependencies

This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice`.

Data Types: `single` | `double`

`InitialPredictionErrorPower` — Initial prediction error power

`1.0` (default) | positive scalar

Specify the initial values for the prediction error vectors as a scalar positive numeric value.

If the `Method` property is set to `'Least-squares Lattice'` or `'QR-decomposition Least-squares Lattice'`, the default value is `1.0`. If the `Method` property is set to `'Gradient Adaptive Lattice'`, the default value is `0.1`.

Tunable: Yes

Data Types: `single` | `double`

`InitialCoefficients` — Initial coefficients of filter
`0` (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LockCoefficients` — Locked status of coefficient updates
`false` (default) | `true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `'Gradient Adaptive Lattice'`.

Usage

Syntax

```
[y,err] = alf(x,d)
```

Description

`[y,err] = alf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `alf` filter, call `alf.Coefficients` after you pass the input and desired signal to the object.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the adaptive lattice filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The adaptive lattice filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The objective of the adaptive lattice filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the adaptive lattice filter coefficients, call `alf.Coefficients` after you pass the input and desired signal to the object algorithm.

Data Types: `single` | `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AdaptiveLatticeFilter`

msesim Estimated mean squared error for adaptive filters

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

QPSK Adaptive Equalization Using Adaptive Lattice Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create the QPSK signal and the noise, filter them to obtain the received signal, and delay the received signal to obtain the desired signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
```

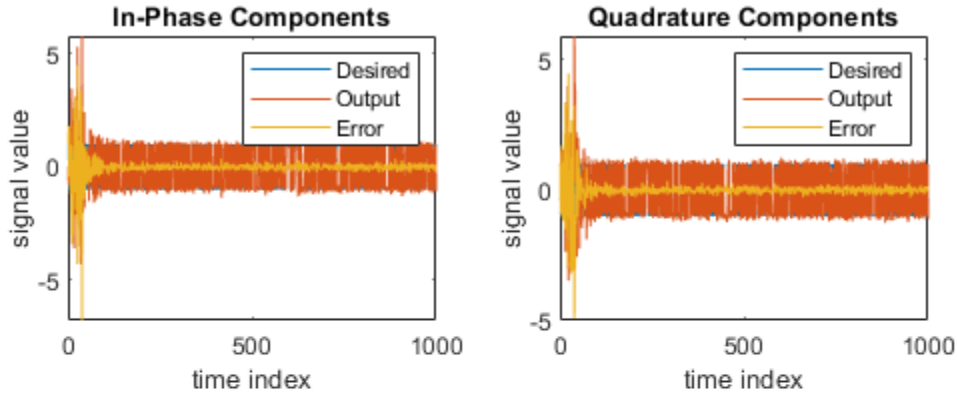
```
a = [1 -0.7];
ntr = 1000;
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);
```

Use the Adaptive Lattice Filter to compute the filtered output and the filter error for the input and desired signal.

```
lam = 0.995;
del = 1;
alf = dsp.AdaptiveLatticeFilter('Length', 32, ...
    'ForgettingFactor', lam, 'InitialPredictionErrorPower', del);
[y,e] = alf(x,d);
```

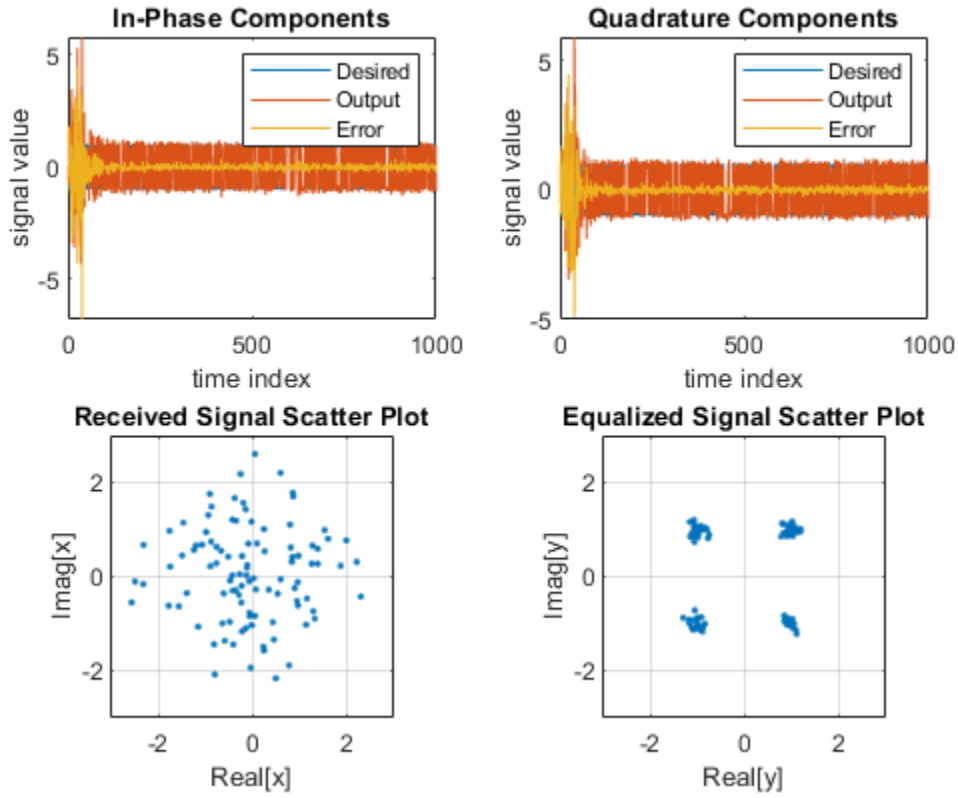
Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
```



Plot the received and equalized signals' scatter plots.

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```



System Identification of FIR Filter Using Adaptive Lattice Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
ha = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));             % Observation noise signal
```

```
d = fir(x)+n;                       % Desired signal
l = 32;                                 % Filter length
m  = 5;                                 % Decimation factor for analysis
                                        % and simulation results

ha = dsp.AdaptiveLatticeFilter(l);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Adaptive Lattice filter used in system identification')
```

dsp.AffineProjectionFilter

Package: dsp

Compute output, error and coefficients using affine projection (AP) Algorithm

Description

The dsp.AffineProjectionFilter System object filters each channel of the input using AP filter implementations.

To filter each channel of the input:

1. Create the dsp.AffineProjectionFilter object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
apf = dsp.AffineProjectionFilter
apf = dsp.AffineProjectionFilter(len)
apf = dsp.AffineProjectionFilter(Name,Value)
```

Description

apf = dsp.AffineProjectionFilter returns an adaptive FIR filter System object, apf. This System object computes the filtered output and the filter error for a given input and desired signal using the affine projection (AP) algorithm.

apf = dsp.AffineProjectionFilter(len) returns an affine projection filter object with the Length property set to len.

`apf = dsp.AffineProjectionFilter(Name,Value)` returns an affine projection filter object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Method` — Method to calculate filter coefficients
`Direct Matrix Inversion` (default) | `Recursive Matrix Update` | `Block Direct Matrix Inversion`

Specify the method used to calculate filter coefficients as `Direct Matrix Inversion`, `Recursive Matrix Update`, `Block Direct Matrix Inversion`. This property is nontunable.

`Length` — Length of filter coefficients vector
32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a scalar positive integer value. This property is nontunable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ProjectionOrder` — Projection order of affine projection algorithm
2 (default) | positive integer

Specify the projection order of the affine projection algorithm as a scalar positive integer value greater than or equal to 2. This property defines the size of the input signal covariance matrix. This property is nontunable.

Data Types: `double`

`StepSize` — Affine projection step size

1 (default) | nonnegative scalar

Specify the affine projection step size factor as a scalar nonnegative numeric value between 0 and 1, both inclusive. Setting the step size equal to one provides the fastest convergence during adaptation.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`InitialCoefficients` — Initial coefficients of filter

`0` (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the `Length` property value.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialOffsetCovariance` — Initial values of offset input covariance matrix

1 (default) | scalar | square matrix

Specify the initial values for the offset input covariance matrix. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `OffsetCovariance` property is initialized to a diagonal matrix with the diagonal elements equal to that scalar value. If it is a square matrix, the `OffsetCovariance` property is initialized to the value of that square matrix.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Direct Matrix Inversion` or `Block Direct Matrix Inversion`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialInverseOffsetCovariance` — Initial values of offset input covariance matrix inverse

`20` (default) | scalar | square matrix

Specify the initial values for the offset input covariance matrix inverse. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `InverseOffsetCovariance` property is initialized to a diagonal matrix with each diagonal element equal to that scalar value. If it is a square matrix, the `InverseOffsetCovariance` property is initialized to the values of that square matrix.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialCorrelationCoefficients` — Initial correlation coefficients

`0` (default) | scalar | vector

Specify the initial values of the correlation coefficients of the FIR filter as a scalar or a vector of length equal to `ProjectionOrder` –1.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LockCoefficients` — Lock coefficient updates

`false` (default) | `true`

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients are continuously updated).

Tunable: Yes

Usage

Syntax

```
[y,err] = apf(x,d)
```

Description

`[y,err] = apf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `apf` filter, call `apf.Coefficients` after you pass the input and desired signal to the object.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the affine projection filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The affine projection filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

`y` — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

`err` — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The objective of the affine projection filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the affine projection filter coefficients, call `apf.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AffineProjectionFilter`

msesim Estimated mean squared error for adaptive filters

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

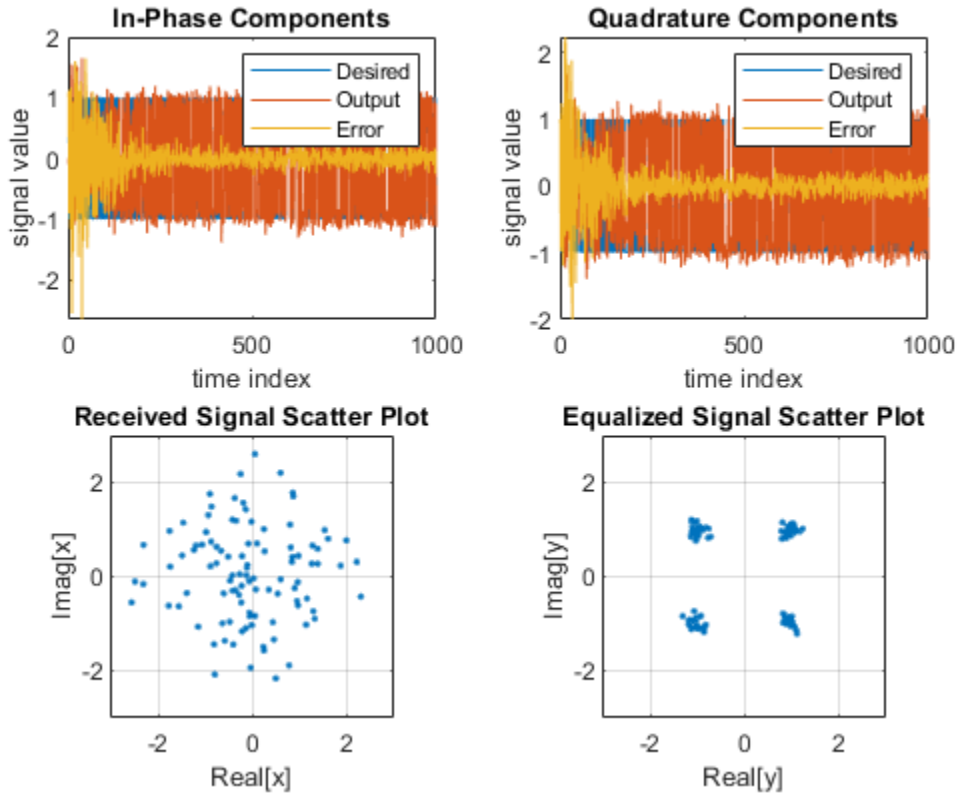
QPSK Adaptive Equalization

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

QPSK Adaptive Equalization Using a 32-Coefficient FIR Filter (1000 Iterations)

```
D = 16;                       % Number of samples of delay
b = exp(1i*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a = [1 -0.7];                 % Denominator coefficients of channel
ntr = 1000;                   % Number of iterations
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D)); % Baseband signal
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));       % Noise signal
r = filter(b,a,s)+n;          % Received signal
x = r(1+D:ntr+D);             % Input signal (received signal)
d = s(1:ntr);                 % Desired signal (delayed QPSK signal)
mu = 0.1;                     % Step size
po = 4;                       % Projection order
offset = 0.05;                % Offset for covariance matrix
apf = dsp.AffineProjectionFilter('Length', 32, ...
    'StepSize', mu, 'ProjectionOrder', po, ...
    'InitialOffsetCovariance',offset);
[y,e] = apf(x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
```

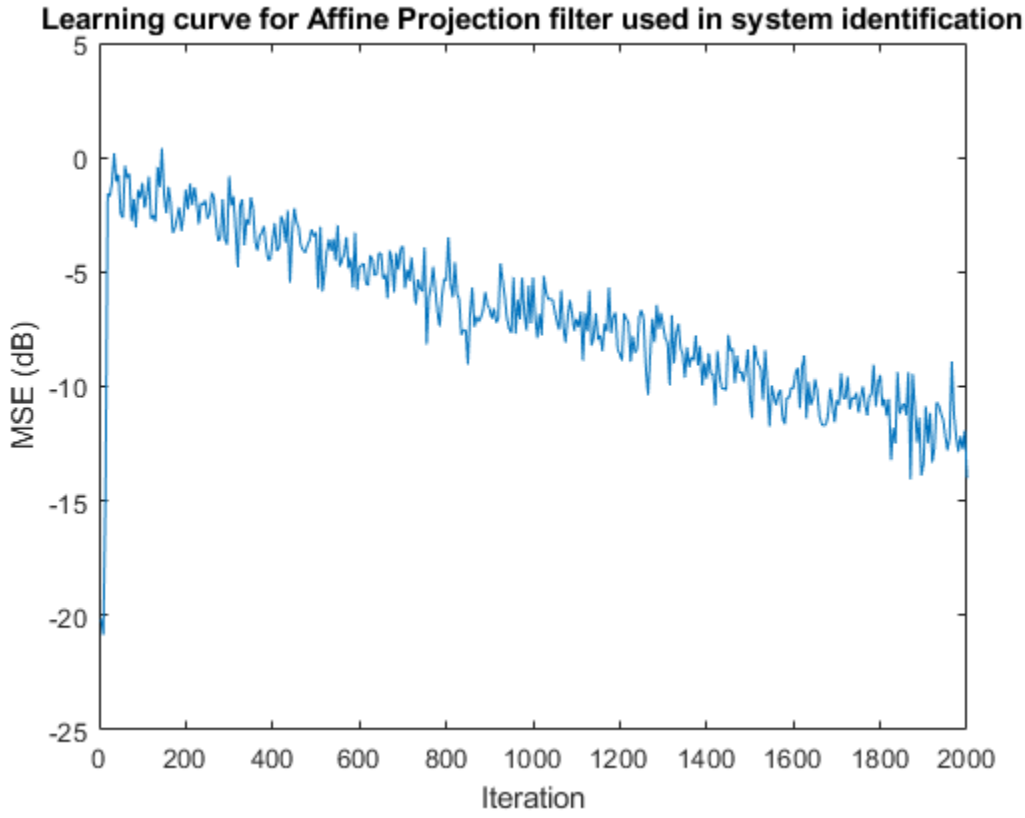
```
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```



System Identification of FIR Filter Using Affine Projection Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
ha = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));             % Observation noise signal
d = fir(x)+n;                    % Desired signal
l = 32;                             % Filter length
mu = 0.008;                         % Affine Projection filter Step size.
m  = 5;                             % Decimation factor for analysis
                                    % and simulation results
apf = dsp.AffineProjectionFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(apf,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Affine Projection filter used in system identification')
```



Algorithms

The affine projection algorithm (APA) is an adaptive scheme that estimates an unknown system based on multiple input vectors [1]. It is designed to improve the performance of other adaptive algorithms, mainly those that are LMS based. The affine projection algorithm reuses old data resulting in fast convergence when the input signal is highly correlated, leading to a family of algorithms that can make trade-offs between computation complexity with convergence speed [2].

The following equations describe the conceptual algorithm used in designing AP filters:

$$\mathbf{U}ap(n) = \begin{pmatrix} u(n) & \dots & u(n-L) \\ \vdots & \ddots & \vdots \\ u(n-N) & \cdots & u(n-L-N) \end{pmatrix} = (\mathbf{u}(n)\ \mathbf{u}(n-1)\ \cdots\ \mathbf{u}(n-L))$$

$$\mathbf{y}ap(n) = \mathbf{U}^{T}ap(n)\mathbf{w}(n) = \begin{pmatrix} y(n) \\ . \\ . \\ . \\ y(n-L) \end{pmatrix}$$

$$\mathbf{d}ap(n) = \begin{pmatrix} d(n) \\ . \\ . \\ . \\ d(n-L) \end{pmatrix}$$

$$\mathbf{e}ap(n) = \mathbf{d}ap(n) - \mathbf{y}ap(n) = \begin{pmatrix} e(n) \\ . \\ . \\ . \\ e(n-L) \end{pmatrix}$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mu\mathbf{U}ap(n)(^{\mathbf{U}}\mathbf{e}ap$$

where **C** is either $\varepsilon\mathbf{I}$ if the initial offset covariance is a scalar ε, or **R** if the initial offset covariance is a matrix **R**. The variables are as follows:

Variable	Description
n	The current time index
u(n)	The input sample at step *n*
$\mathbf{U}_{\text{ap}}$(n)	The matrix of the last *L*+1 input signal vectors
w(n)	The adaptive filter coefficients vector
y(n)	The adaptive filter output
d(n)	The desired signal
e(n)	The error at step *n*

Variable	Description
L	The projection order
N	The filter order (i.e., filter length = N+1)
μ	The step size

System Objects

`dsp.FIRFilter` | `dsp.LMSFilter` | `dsp.RLSFilter`

Introduced in R2013a

dsp.AllpassFilter

Package: `dsp`

Single section or cascaded allpass filter

Description

The `dsp.AllpassFilter` object filters each channel of the input using Allpass filter implementations. To import this object into Simulink, use the MATLAB System block.

Note Cell array support for `AllpassCoefficients`, `WDFCoefficients`, and `LatticeCoefficients` has been removed. Use an *N*-by-1 or *N*-by-2 numeric array instead. For more information, see “Compatibility Considerations” on page 4-36.

To filter each channel of the input:

1. Create the `dsp.AllpassFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
Allpass = dsp.AllpassFilter
Allpass = dsp.AllpassFilter(Name,Value)
```

Description

`Allpass = dsp.AllpassFilter` returns an allpass filter System object, `Allpass`, that filters each channel of the input signal independently using an allpass filter, with the default structure and coefficients.

`Allpass = dsp.AllpassFilter(Name,Value)` returns an allpass filter System object, `Allpass`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Structure` — Internal allpass filter structure

`Minimum multiplier` (default) | `Lattice` | `Wave Digital Filter`

You can specify the internal allpass filter implementation structure as one of | `Minimum multiplier` | `Lattice` | `Wave Digital Filter`. Each structure uses a different set of coefficients, independently stored in the corresponding object property.

`AllpassCoefficients` — Allpass polynomial coefficients

`[-2^(-1/2) 0.5]` (default) | *N*-by-1 | *N*-by-2

Specify the real allpass polynomial filter coefficients. Specify this property as either an *N*-by-1 or *N*-by-2 matrix of *N* first-order or second-order allpass sections. The default value defines a stable second-order allpass filter with poles and zeros located at ±π/3 in the Z plane.

Tunable: Yes

Dependencies

This property is applicable only when the `Structure` property is set to `Minimum multiplier`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WDFCoefficients` — Wave Digital Filter allpass coefficients

`[1/2, -2^(1/2)/3]` (default) | *N*-by-1 | *N*-by-2

Specify the real allpass coefficients in the Wave Digital Filter form. Specify this property as either a *N*-by-1 or *N*-by-2 matrix of *N* first-order or second-order allpass sections. All elements must have absolute values less than or equal to 1. This value is a transformed version of the default value of `AllpassCoefficients`, computed using `allpass2wdf(AllpassCoefficients)`. These coefficients define the same stable second-order allpass filter as when `Structure` is set to `'Minimum multiplier'`.

Tunable: Yes

Dependencies

This property is only applicable when the `Structure` property is set to `Wave Digital Filter`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LatticeCoefficients` — Lattice allpass coefficients

`[-2^(1/2)/3, 1/2]` (default) | vector

Specify the real or complex allpass coefficients as lattice reflection coefficients. Specify this property as either a row vector (single-section configuration) or a column vector. This value is a transformed and transposed version of the default value of `AllpassCoefficients`, computed using `transpose(tf2latc([1 h.AllpassCoefficients]))`. These coefficients define the same stable second-order allpass filter as when `Structure` is set to `'Lattice'`.

Tunable: Yes

Dependencies

This property is applicable only if the `Structure` property is set to `Lattice`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TrailingFirstOrderSection` — Indicate if last section is first order

`false` (default) | `true`

Indicate if last section is first order or second order. When you set `TrailingFirstOrderSection` to `true`, the last section is considered to be first-order, and the second element of the last row of the *N*-by-2 matrix is ignored. When you set `TrailingFirstOrderSection` to `false`, the last section is considered to be second-order.

Usage

Syntax

```
y = Allpass(x)
```

Description

`y = Allpass(x)` filters the input signal `x` using an allpass filter to produce the output `y`. Each column of `x` is filtered independently as a separate channel over time.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AllpassFilter`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Filter coefficients
cost	Estimate cost for implementing filter System objects
grpdelay	Group delay response of discrete-time filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Lowpass Filtering using Two Allpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Construct the Allpass Filters

```
Fs  = 48000;    % in Hz
FL = 1024;
APF1 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.710525516540603   0.208818210000029]);
APF2 =  dsp.AllpassFilter('AllpassCoefficients',...
    [-0.940456403667957   0.6;...
```

```
    -0.324919696232907   0],...
    'TrailingFirstOrderSection',true);
```

Construct the Transfer Function Estimator to estimate the transfer function between the random input and the Allpass filtered output

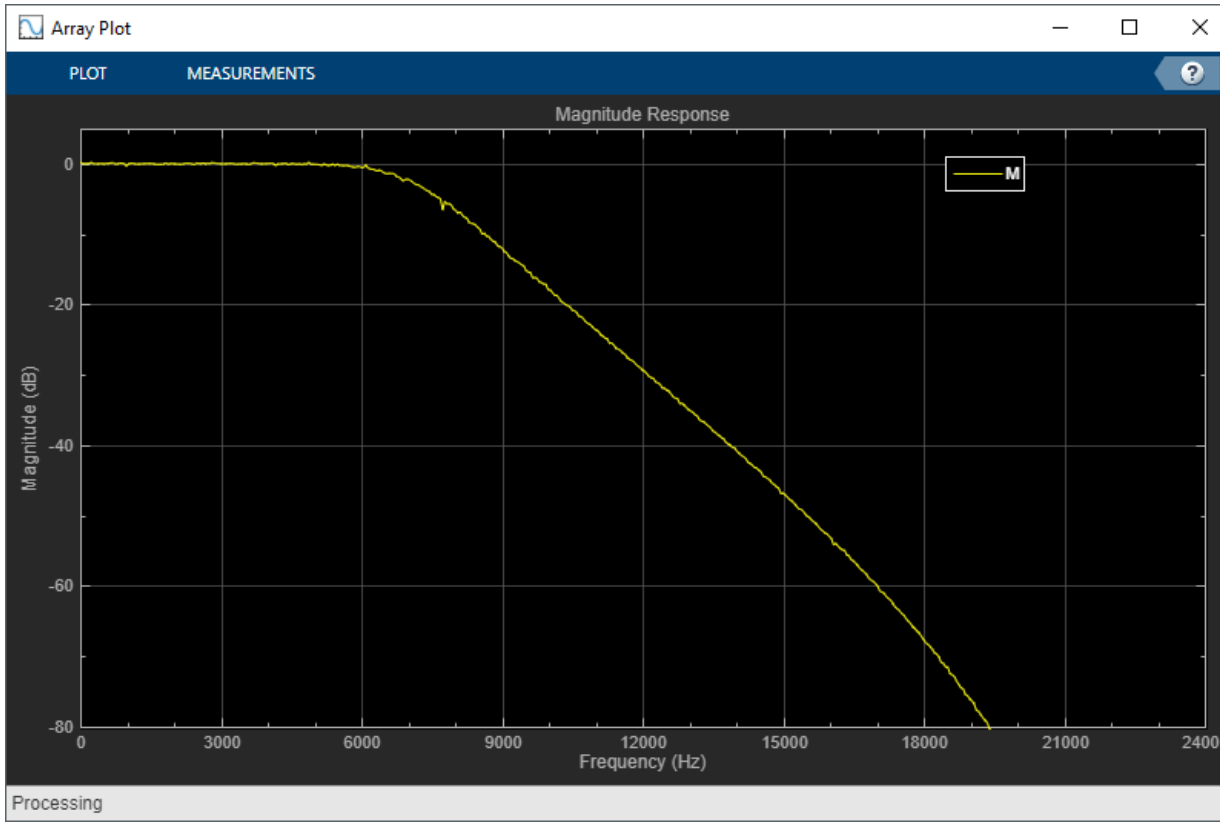
```
TFE = dsp.TransferFunctionEstimator('FrequencyRange',...
    'onesided','SpectralAverages',2);
```

Construct the ArrayPlot to plot the magnitude response

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits', [-80 5],...
    'YLabel','Magnitude (dB)','SampleIncrement', Fs/FL,...
    'XLabel','Frequency (Hz)','Title','Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Magnitude Response'});
```

Filter the Input and show the magnitude response of the estimated transfer function between the input and the filtered output

```
tic;
while toc < 5
    in  = randn(FL,1);
    out = 0.5.*(APF1(in) + APF2(in));
    A = TFE(in, out);
    AP(db(A));
end
```



Algorithms

The transfer function of an allpass filter is given by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \ldots + z^{-n}}{1 + c(1)z^{-1} + \ldots + c(n)z^{-n}}.$$

c is allpass polynomial coefficients vector. The order, n, of the transfer function is the length of vector c.

In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the

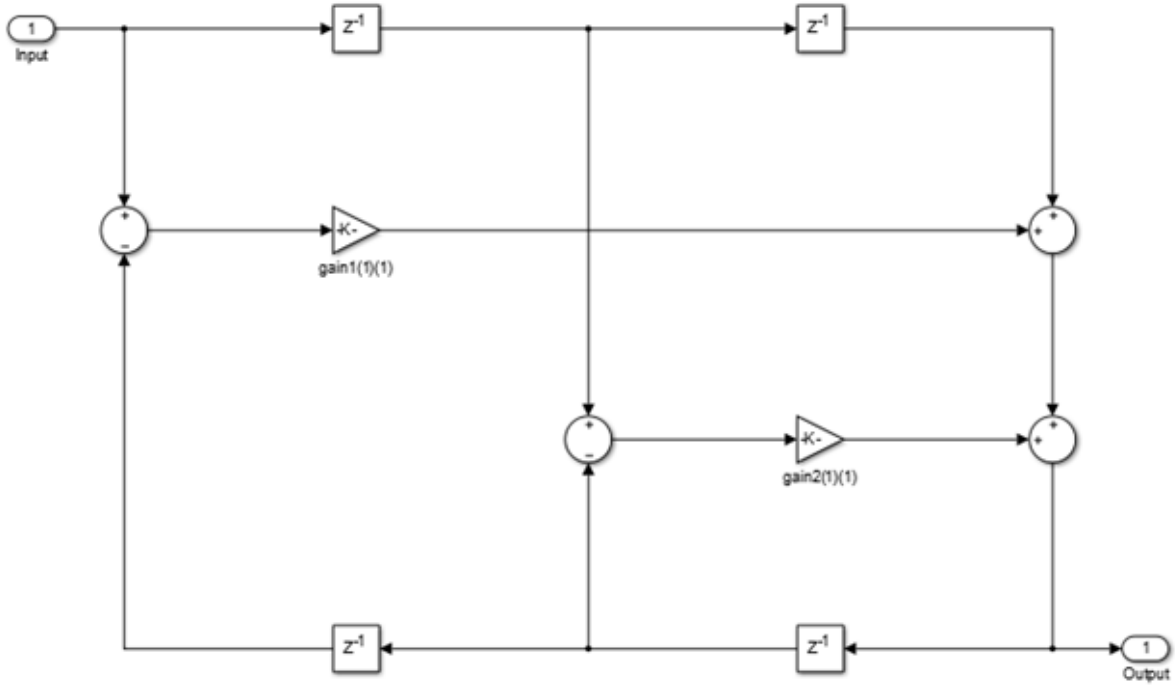
coefficients are specified as an *N*-by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an *N*-by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as df1, df1t, df2, df2t. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

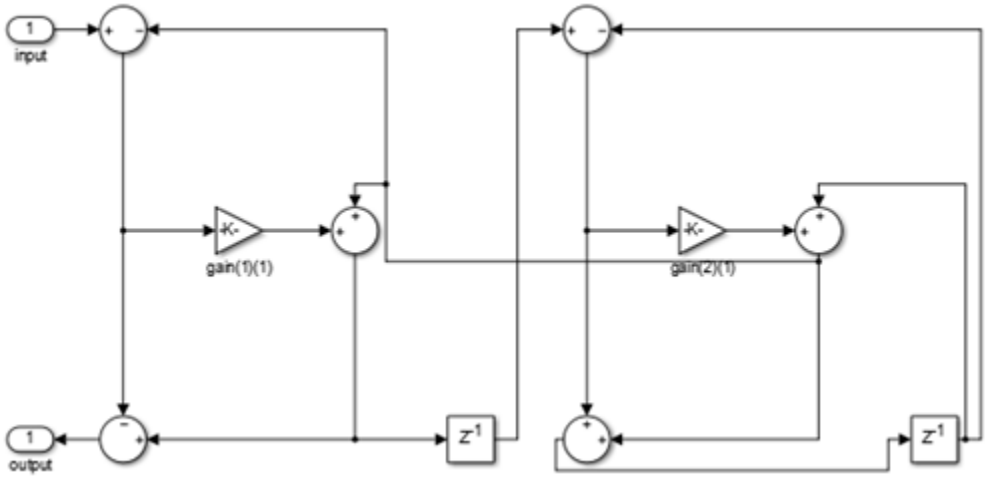
Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order `n`. It also uses `2n` delay units and `2n` adders. The multipliers uses the specified coefficients, which are equal to the polynomial vector *c* in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector, *c*, is equal to `[0.1 -0.7]`.



Wave Digital Filter

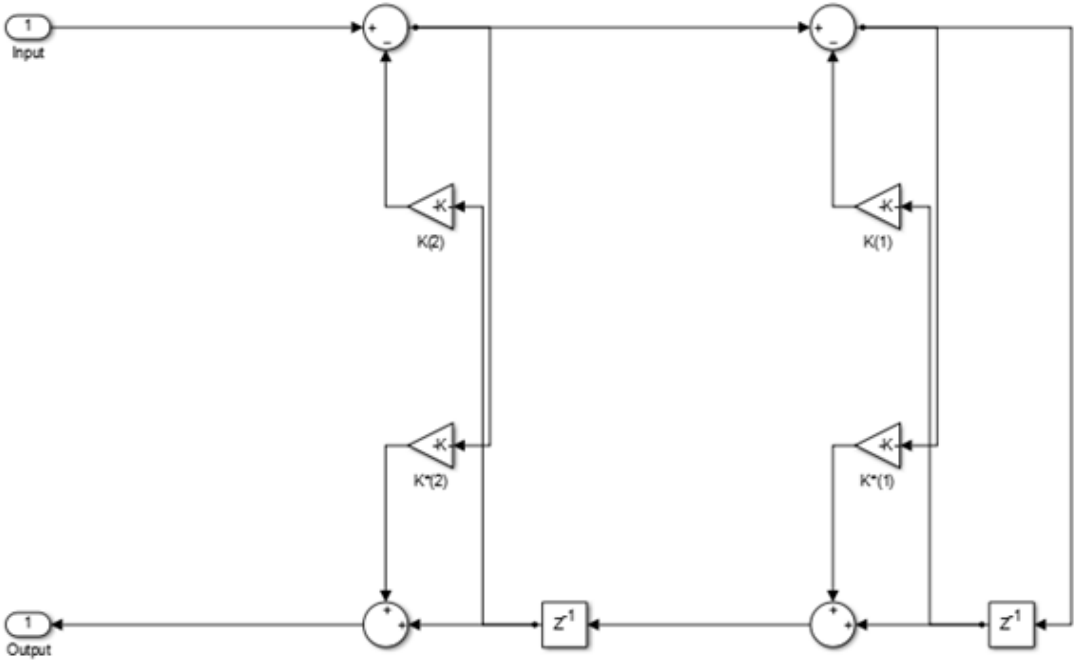
This structure uses `n` multipliers, but only `n` delay units, at the expense of requiring `3n` adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF coefficients)`. In this second-order section of the WDF structure, the coefficients vector *w* is equal to `allpass2wdf([0.1 -0.7])`.



Lattice

This lattice structure uses 2n multipliers, n delay units, and 2n adders. To use this structure, specify the coefficients as a vector.

You can obtain the lattice equivalent of the conventional allpass coefficients using `transpose(tf2latc(1, [1 allpass_coefficients]))`. In the following second-order section of the lattice structure, the coefficients vector is computed using `transpose(tf2latc(1, [1 0.1 -0.7]))`. Use these coefficients for a filter that is functionally equivalent to the minimum multiplier structure with coefficients [0.1 -0.7].



Compatibility Considerations

Cell Array Support for `dsp.AllpassFilter` System object is removed

Errors starting in R2018b

The following properties of `dsp.AllpassFilter` System object have been removed in R2018b:

- `LatticeCoefficients`
- `AllpassCoefficients`
- `WDFCoefficients`

Use an *N*-by-1 or *N*-by-2 numeric array instead.

Update Code

This table shows typical usage of the System object and explains how to update your existing code.

If your code has this form:	Use this code instead:
`allpass = dsp.AllpassFilter;` `allpass.AllpassCoefficients = {0.5 0.7};`	`allpass = dsp.AllpassFilter;` `allpass.AllpassCoefficients = [0.5 0.7]`
`allpass = dsp.AllpassFilter('Structure','Lattice');` `allpass.LatticeCoefficients = {-0.4714 0.5000};`	`allpass = dsp.AllpassFilter('Structure','Lattice` `allpass.LatticeCoefficients = [-0.4714 0.5000]`
`allpass = dsp.AllpassFilter('Structure','Wave Digital Filter');` `allpass.LatticeCoefficients = {0.5000 -0.4714};`	`allpass = dsp.AllpassFilter('Structure','Wave Di` `allpass.LatticeCoefficients = [0.5000 -0.4714]`

Introduced in R2013a

dsp.AllpoleFilter

Package: `dsp`

IIR Filter with no zeros

Description

The `dsp.AllpoleFilter` object filters each channel of the input using allpole filter implementations.

To filter each channel of the input:

1. Create the `dsp.AllpoleFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
allpole = dsp.AllpoleFilter
allpole = dsp.AllpoleFilter(Name,Value)
```

Description

`allpole = dsp.AllpoleFilter` returns an allpole filter System object, `allpole`, which independently filters each channel of the input over successive calls to the algorithm. This System object uses a specified allpole filter implementation.

`allpole = dsp.AllpoleFilter(Name,Value)` returns an allpole filter System object, `allpole`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Structure` — Filter structure

`Direct form` (default) | `Direct form transposed` | `Lattice AR`

Specify the filter structure as one of | `Direct form` | `Direct form transposed` | `Lattice AR`. Analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`. This property is nontunable.

`Denominator` — Filter denominator coefficients

`[1 0.1]` (default) | row vector

Specify the denominator coefficients as a numeric row vector.

Tunable: Yes

Dependencies

This property is applicable when the Structure property is set to one of `Direct form` | `Direct form transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ReflectionCoefficients` — Lattice filter coefficients

`[0.2 0.4]` (default) | row vector

Specify the lattice filter coefficients as a numeric row vector.

Tunable: Yes

Dependencies

This property is applicable when the `Structure` property is set to `Lattice AR`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialConditions` — Initial conditions for the filter states

`0` (default) | scalar | vector | matrix

Specify the initial conditions of the filter states.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CoefficientsDataType` — Denominator coefficients word- and fraction-length designations

`Same word length as input` (default) | `Custom`

Specify the denominator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. This property is nontunable.

`ReflectionCoefficientsDataType` — Reflection coefficients word- and fraction-length designations

`Same word length as input` (default) | `Custom`

Specify the reflection coefficients fixed-point data type as one of `Same word length as input` | `Custom`. This property is nontunable.

Fixed-Point Properties

`ProductDataType` — Product word- and fraction-length designations
`Full precision` (default) | `Same as input` | `Custom`

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. This property is nontunable.

`AccumulatorDataType` — Accumulator word- and fraction-length designations
`Full precision` (default) | `Same as input` | `Same as product` | `Custom`

Specify the accumulator fixed-point data type to one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. This property is nontunable.

`OutputDataType` — Output word- and fraction-length designations
`Same as input` (default) | `Same as accumulator` | `Custom`

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as input` | `Custom` |. This property is nontunable.

`StateDataType` — State word- and fraction-length designations
`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom`. This property is nontunable.

`CustomCoefficientsDataType` — Custom denominator word- and fraction-lengths
`numerictype ([],16,15)` (default) | numerictype

Specify the denominator coefficients fixed-point type as an autosigned `numerictype` object. This property is nontunable.

Dependencies

This property is applicable when the `CoefficientsDataType` property is `Custom`.

`CustomReflectionCoefficientsDataType` — Custom reflection coefficients word- and fraction-lengths
`numerictype ([],16,15)` (default) | numerictype

Specify the denominator coefficients fixed-point type as an autosigned `numerictype` object. This property is nontunable.

Dependencies

This property is applicable when the `ReflectionCoefficientsDataType` property is `Custom`.

`CustomProductDataType` — Custom Product word- and fraction-lengths

`numerictype ([],32,30)` (default) | numerictype

Specify the product fixed-point type as an autosigned scaled `numerictype` object. This property is nontunable.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

`CustomAccumulatorDataType` — Custom accumulator word- and fraction-lengths

`numerictype([],32,30)` (default) | numerictype

Specify the accumulator fixed-point type as an autosigned scaled `numerictype` object. This property is nontunable.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

`CustomStateDataType` — Custom state word- and fraction-lengths

`numerictype([],16,15)` (default) | numerictype

Specify the state fixed-point type as an autosigned scaled `numerictype` object. This property is nontunable.

Dependencies

This property applies when you set the `StateDataType` property to `Custom`.

`CustomOutputDataType` — Custom output word- and fraction-lengths

`numerictype([],16,15)` (default) | numerictype

Specify the output fixed-point type as an autosigned scaled `numerictype` object. This property is nontunable.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage

Syntax

```
y = allpole(x)
```

Description

`y = allpole(x)` filters the real or complex input signal `x` using an allpole filter to produce the output `y`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

When the input data is of a fixed-point type, it must be signed. The allpole filter object operates on each channel of the input signal independently over successive calls to the algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AllpoleFilter`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Filter coefficients
cost	Estimate cost for implementing filter System objects
grpdelay	Group delay response of discrete-time filter System object
phasez	Unwrapped phase response for filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Lowpass filtering a waveform with two frequencies

Use an Allpole filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
t = (0:1000)./8e3;
xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t);

src = dsp.SignalSource(xin', 4);
```

```
sink = dsp.SignalSink;
allpole = dsp.AllpoleFilter;
tt = (-25:25)';
xsinc = 0.4*sinc(0.4*tt);
asinc = lpc(xsinc,51);
allpole.Denominator = asinc;

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
   'PlotAsTwoSidedSpectrum',false,...
   'OverlapPercent', 80,'PowerUnits','dBW',...
   'YLimits', [-150 50]);

while ~isDone(src)
      input = src();
      filteredOutput = allpole(input);
      sink(filteredOutput);
      sa(filteredOutput)
end

filteredResult = sink.Buffer;
fvtool(allpole,'Fs',8000)
```

dsp.AnalyticSignal

Package: `dsp`

Analytic signals of discrete-time inputs

Description

The `dsp.AnalyticSignal` System object computes analytic signals of discrete-time inputs. The real part of the analytic signal in each channel is a replica of the real input in that channel, and the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component. The object computes the Hilbert transform using an equiripple FIR filter.

To compute the analytic signal of a discrete-time input:

1. Create the `dsp.AnalyticSignal` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
anaSig = dsp.AnalyticSignal
anaSig = dsp.AnalyticSignal(order)
anaSig = dsp.AnalyticSignal(Name,Value)
```

Description

`anaSig = dsp.AnalyticSignal` returns an analytic signal object, `anaSig`, that computes the complex analytic signal corresponding to each channel of a real *M*-by-*N* input matrix.

`anaSig = dsp.AnalyticSignal(order)` returns an analytic signal object, `anaSig`, with the "FilterOrder" on page 4-0 property set to `order`.

`anaSig = dsp.AnalyticSignal(Name,Value)` returns an analytic signal object, `anaSig`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`FilterOrder` — Filter order used to compute Hilbert transform
`100` (default) | scalar integer

Order of the equiripple FIR filter used in computing the Hilbert transform, specified as an even integer scalar greater than 3.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
y = anaSig(x)
```

Description

`y = anaSig(x)` computes the analytic signal, `y`, of the *M*-by-*N* input matrix `x`, according to the equation

$$\mathbf{Y} = \mathbf{X} + jH\{\mathbf{X}\}$$

where j is the imaginary unit and $H\{\mathbf{X}\}$ denotes the Hilbert transform.

Each of the N columns in `x` contains M sequential time samples from an independent channel. The method computes the analytic signal for each channel.

Input Arguments

x — Data input
vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double`

Output Arguments

y — Analytic signal output
vector | matrix

Analytic signal output, returned as a vector or a matrix.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Compute The Analytic Signal

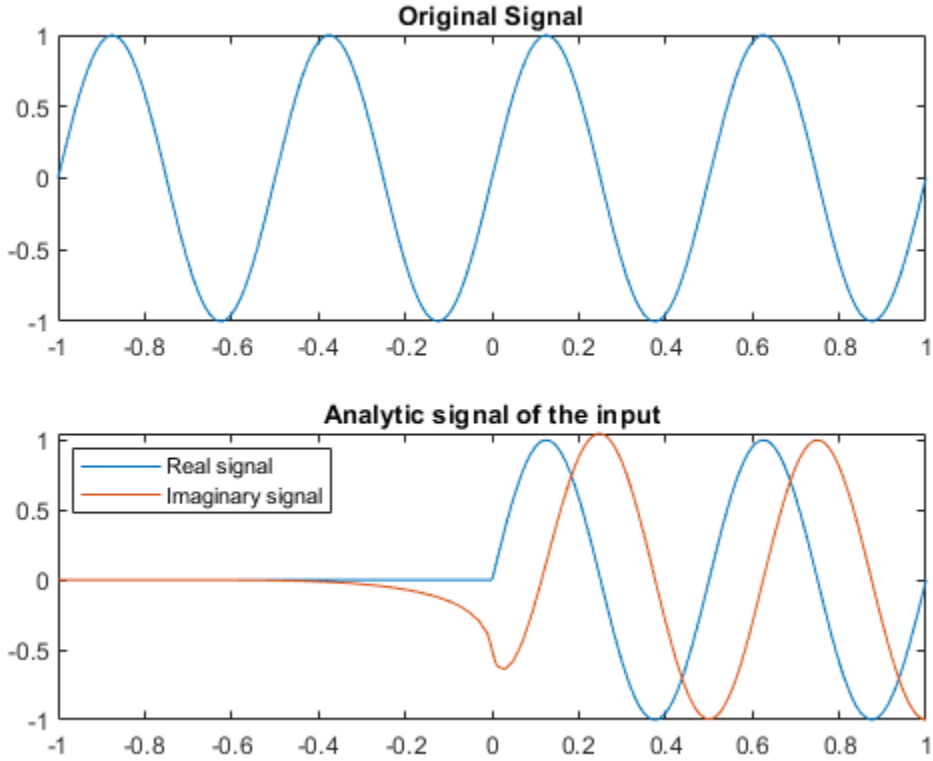
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute the analytic signal of a sinusoidal input.

```
t = (-1:0.01:1)';
x = sin(4*pi*t);
anaSig = dsp.AnalyticSignal(200);
y = anaSig(x);
```

View the analytic signal.

```
subplot(2,1,1);
plot(t, x)
title('Original Signal');
subplot(2,1,2), plot(t, [real(y) imag(y)]);
title('Analytic signal of the input')
legend('Real signal','Imaginary signal',...
    'Location','best');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Analytic Signal block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

System Objects
`dsp.FFT` | `dsp.IFFT`

Introduced in R2012a

dsp.ArrayPlot

Package: `dsp`

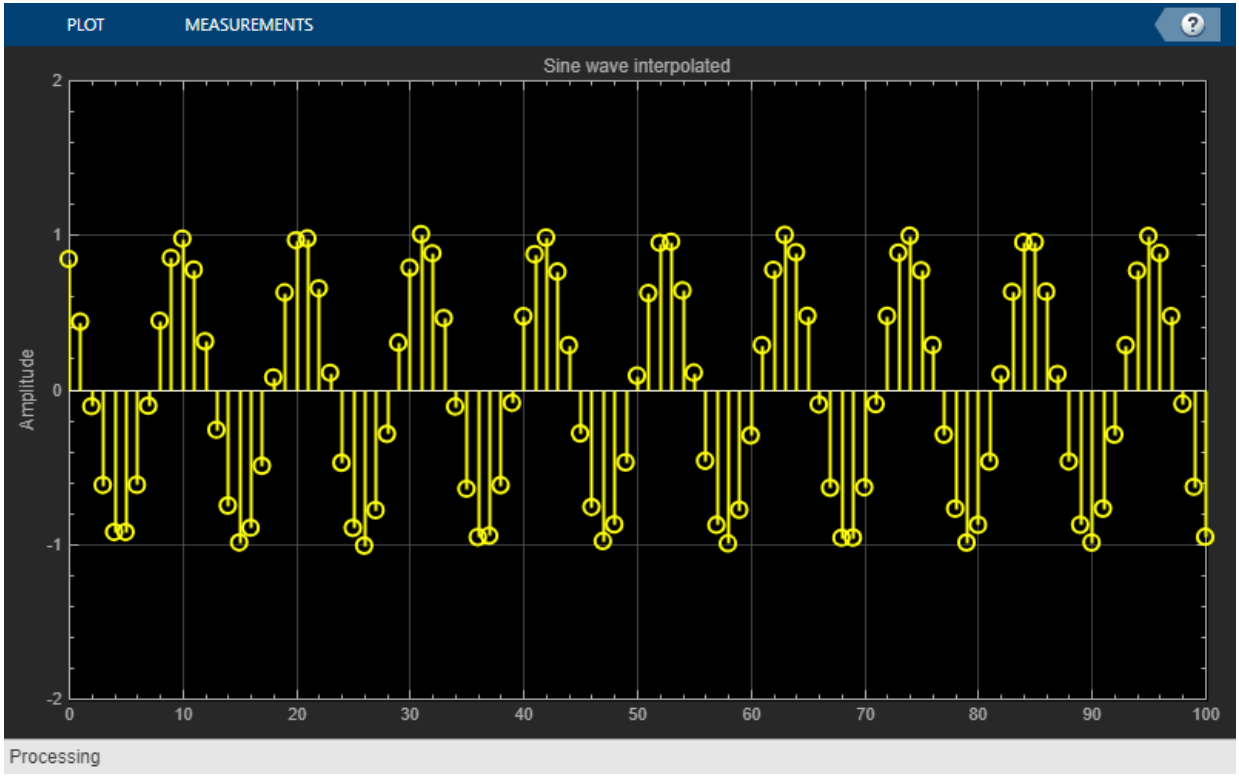
Display vectors or arrays

Description

The dsp.ArrayPlot object displays vectors or arrays where the data is uniformly spaced along the *x*-axis.

To display vectors or array on the Array Plot:

1. Create the `dsp.ArrayPlot` object and set its properties.
2. Call the object with arguments, as if it were a function.



Creation

Syntax

```
scope = dsp.ArrayPlot
scope = dsp.ArrayPlot(Name,Value)
```

Description

`scope = dsp.ArrayPlot` creates an Array Plot object, `scope`.

`scope = dsp.ArrayPlot(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example, `scope = dsp.ArrayPlot("NumInputPorts",3)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

Plot Configuration

`NumInputPorts` — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

`XDataMode` — Source of the *x*-data spacing

`"Sample increment and X-offset"` (default) | `"Custom"`

Specify whether to use the `SampleIncrement` and `XOffset` property values to determine spacing, or specify your own custom spacing. If you specify `"Custom"`, you also must specify the `CustomXData` property values.

UI Use

Open the **Plot** tab, click **Settings**, and set **X-Data Mode**.

Data Types: `char` | `string`

`CustomXData` — X-data values

empty vector (default) | vector

Specify the desired *x*-data values as a row or column vector of length equal to the frame length of the inputs. If you use the default (empty vector) value, the *x*-data is uniformly spaced and set to (0:*L*–1), where *L* is the frame length.

Example: `scope = dsp.ArrayPlot("XDataMode","Custom","CustomXData",logspace(0,log10(44100/2),1024))`

UI Use

Open the **Plot** tab, click **Settings**, and set **X-Data Mode** to **Custom** and specify **Custom X-Data**.

Dependency

To use this property, set `XDataMode` to `"Custom"`.

`SampleIncrement` — Sample increment of input

`1` (default) | finite numeric scalar

Specify the spacing between samples along the *x*-axis as a finite numeric scalar. The input signal is only *y*-axis data. *x*-axis data is set automatically based on the `XOffset` and `SampleIncrement` properties. For example, when `Xoffset` is 0 and `SampleIncrement` is 1, the *x*-data for the input signal is set to 0, 1, 2, 3, 4, etc. If you set `SampleIncrement` to 0.25, the *x*-axis data becomes 0, 0.25, 0.5, 0.75, 1, etc.

Tunable: Yes

UI Use

Open the **Plot** tab, click **Settings**, and set **Sample Increment**.

`XOffset` — Display offset of x-axis

`0` (default) | scalar

Specify the offset to display on the *x*-axis. This property is a scalar

Tunable: Yes

UI Use

Open the **Plot** tab, click **Settings**, and set **X-Offset**.

`XScale` — Scale of x-axis

`"Linear"` (default) | `"Log"`

Specify whether the scale of the *x*-axis is `"Linear"` or `"Log"`. If `XOffset` is a negative value, you cannot set this property to `"Log"`.

Tunable: Yes

UI Use

Open the **Plot** tab, click **Settings**, and set **XScale**.

Data Types: `char` | `string`

`YScale` — Scale of *y*-axis

`"Linear"` (default) | `"Log"`

Specify whether the scale of the *y*-axis is `"Linear"` or `"Log"`.

Tunable: Yes

UI Use

Open the **Plot** tab, click **Settings**, and set **YScale**.

Data Types: `char` | `string`

`PlotType` — Control type of plot

`"Stem"` (default) | `"Line"` | `"Stairs"`

Specify the type of plot to use for all the input signals displayed in the scope window:

- `"Stem"` – The scope displays the input signal as circles with vertical lines extending down to the *x*-axis at each of the sampled values. This option is similar to the `stem` function.
- `"Line"` – The scope displays the input signal as lines connecting each of the sampled values. This option is similar to the `line` or `plot` functions.
- `"Stairs"` – The scope displays the input signal as a stair-step graph. A stair-step graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This option is similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

UI Use

Open the **Settings** and set **Plot Type**.

Data Types: `char` | `string`

`AxesScaling` — Axes scaling mode

`"OnceAtStop"` (default) | `"Auto"` | `"Manual"` | `"Updates"`

Specify when the scope scales the axes. Valid values are:

- `"Auto"` — The scope scales the axes as needed to fit the data, both during and after simulation.
- `"Manual"` — The scope does not scale the axes automatically.
- `"OnceAtStop"` — The scope scales the axes when the simulation stops.
- `"Updates"` — The scope scales the axes once and only once after 10 updates.

UI Use

Hover over the array plot to see the zoom  , pan  , and autoscale  buttons. You can also zoom and pan using your mouse.

Data Types: `char` | `string`

Visualization

`Name` — Window name

`'Array Plot'` (default) | character vector | string scalar

Specify the name of the scope. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the `Title` property.

Data Types: `char` | `string`

`Position` — Scope window position in pixels

screen center (default) | `[left bottom width height]`

Specify, in pixels, the size and location of the scope window as a four-element vector of the form `[left bottom width height]`. By default, the scope window appears in the center of your screen with a width of `800` pixels and height of `450` pixels. The default values for this property may change depending on your screen resolution.

`MaximizeAxes` — Maximize axes control

`"Auto"` (default) | `"On"` | `"Off"`

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `"Auto"` — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `"On"` — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- `"Off"` — None of the axes appear maximized.

Tunable: Yes

UI Use

Hover over the array plot to see the maximize axes button  .

Data Types: `char` | `string`

`Title` — Display title

`''` (default) | character vector | string scalar

Specify the display title as a character vector or string.

Tunable: Yes

UI Use

Open the **Plot** tab, click **Settings**, and set **Title**.

Data Types: `char` | `string`

`ShowLegend` — Show legend

`false` (default) | `true`

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be viewed or controlled from the legend.

Tunable: Yes

UI Use

On the **Plot** tab, click **Legend**.

Data Types: `logical`

`ChannelNames` — Channel names

empty cell (default) | cell array of character vectors

Specify the input channel names as a cell array of character vectors. The names appear in the legend, **Style** dialog box, and **Measurements** panels. If you do not specify names, the channels are labeled as `Channel 1`, `Channel 2`, etc.

Tunable: Yes

Dependency

To see channel names, set `ShowLegend` to `true`.

Data Types: `char`

`ShowGrid` — Display grid

`true` (default) | `false`

Set this property to `true` to show grid lines on the plot.

Tunable: Yes

UI Use

Open the **Plot** tab, click **Settings**, and select **Grid**.

`PlotAsMagnitudePhase` — Plot signal as magnitude and phase

`false` (default) | `true`

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

Tunable: Yes

UI Use

On the Plot tab, select the **Magnitude Phase** button.

`XLabel` — *x*-axis label

`""` (default) | character vector | string scalar

Specify the text for the scope to display below the *x*-axis.

Tunable: Yes

UI Use

Open the **Plot** tab, click **Settings**, and set **XLabel**.

Data Types: `char` | `string`

`YLabel` — *y*-axis label

`"Amplitude"` (default) | character vector | string scalar

Specify the text for the scope to display to the left of the *y*-axis.

Tunable: Yes

Dependencies

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two *y*-axis labels are read-only values. The *y*-axis labels are set to `"Magnitude"` and `"Phase"` for the magnitude plot and the phase plot, respectively.

UI Use

Open the **Plot** tab, click **Settings**, and set **YLabel**.

Data Types: `char` | `string`

`YLimits` — *y*-axis limits

`[-10,10]` (default) | `[ymin, ymax]`

Specify the *y*-axis limits as a two-element numeric vector, `[ymin, ymax]`.

If `PlotAsMagnitudePhase` is `false`, the default is `[-10,10]`. If `PlotAsMagnitudePhase` is `true`, the default is `[0,10]`.

Tunable: Yes

Dependencies

When `PlotAsMagnitudePhase` is `true`, this property specifies the *y*-axis limits of only the magnitude plot. The *y*-axis limits of the phase plot are always `[-180,180]`.

UI Use

Open the **Plot** tab, click **Settings**, and set **Y-Axis Limits** as a two-element numeric vector.

Usage

Syntax

```
scope(signal)
scope(signal1,signal2,...,signalN)
```

Description

`scope(signal)` displays the signal in the Array Plot.

`scope(signal1,signal2,...,signalN)` displays multiple signals in the Array Plot. The signals must have the same frame length, but can vary in number of channels. You must set the `NumInputPorts` property to enable multiple input signals.

Input Arguments

`signal` — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.ArrayPlot`. Signals can have a different number of channels, but they must have the same frame length.

Example: `scope(signal1, signal2)`

UI Customization

To customize the style of signals on the array plot, open the **Settings** and use the bottom row of options to select a signal and modify the style, width, color, and marker type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the object as the first input argument. For example, to release system resources of an object named `obj`, use this syntax:

generateScript Generate MATLAB script to create scope with current settings

show	Display scope window
hide	Hide scope window
isVisible	Determine visibility of scope

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Plot a Gaussian Distribution

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a new Array Plot object.

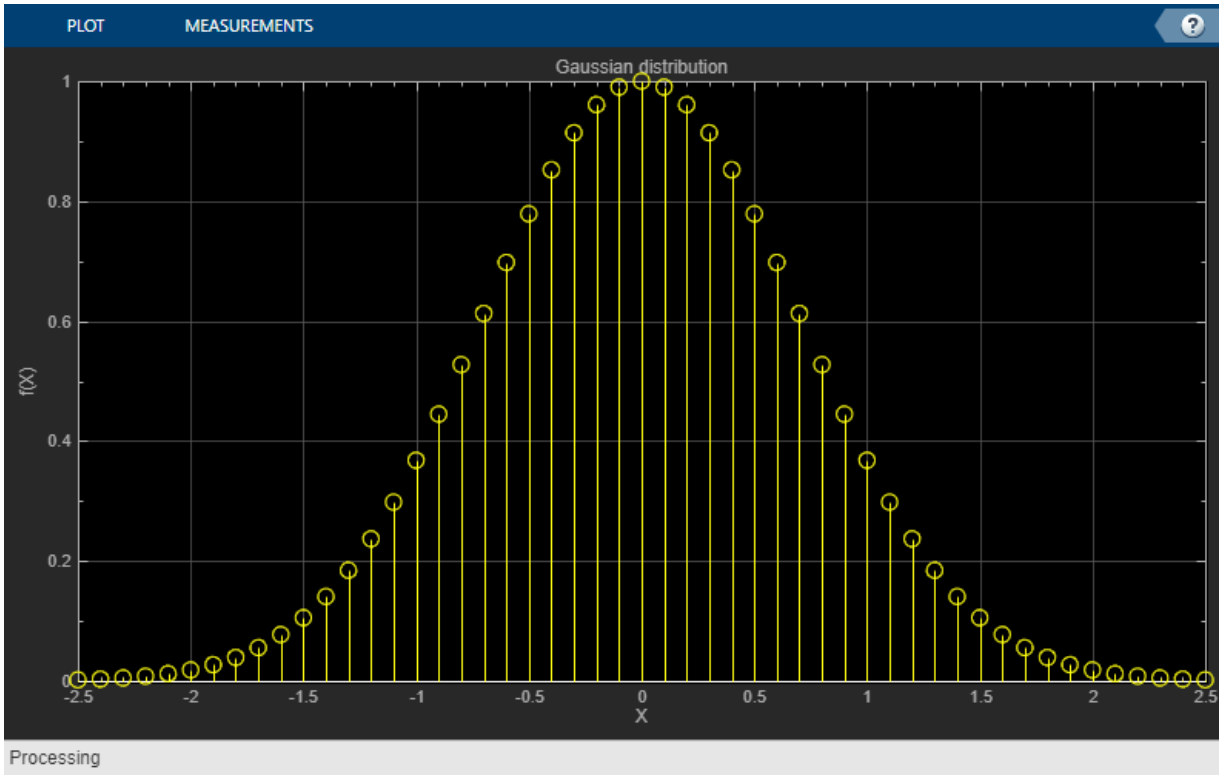
```
scope = dsp.ArrayPlot;
```

Configure the properties of the Array Plot object for a Gaussian distribution.

```
scope.YLimits = [0 1];
scope.XOffset = -2.5;
scope.SampleIncrement = 0.1;
scope.Title = 'Gaussian distribution';
scope.XLabel = 'X';
scope.YLabel = 'f(X)';
```

Call the Array Plot object to plot a Gaussian distribution.

```
scope(exp(-(-2.5:.1:2.5).*(-2.5:.1:2.5))')
```



Plot Changing Filter Weights

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

View least mean squares (LMS) adaptive filter weights on the Array Plot figure. Watch the filter weights change as they adapt to filter a noisy input signal.

Create an LMS adaptive filter System object.

```
lmsFilter = dsp.LMSFilter(40,'Method','Normalized LMS','StepSize',0.002);
```

Create and configure a dsp.AudiFileReader System object to read the input signal from the specified audio file.

```
signalSource = dsp.AudioFileReader('dspafxf_8000.wav',...
    'SamplesPerFrame',40, ...
    'PlayCount',Inf,...
    'OutputDataType','double');
```

Create and configure a dsp.FIRFilter System object to filter random white noise, creating colored noise.

```
firFilter = dsp.FIRFilter('Numerator',fir1(39,0.25));
```

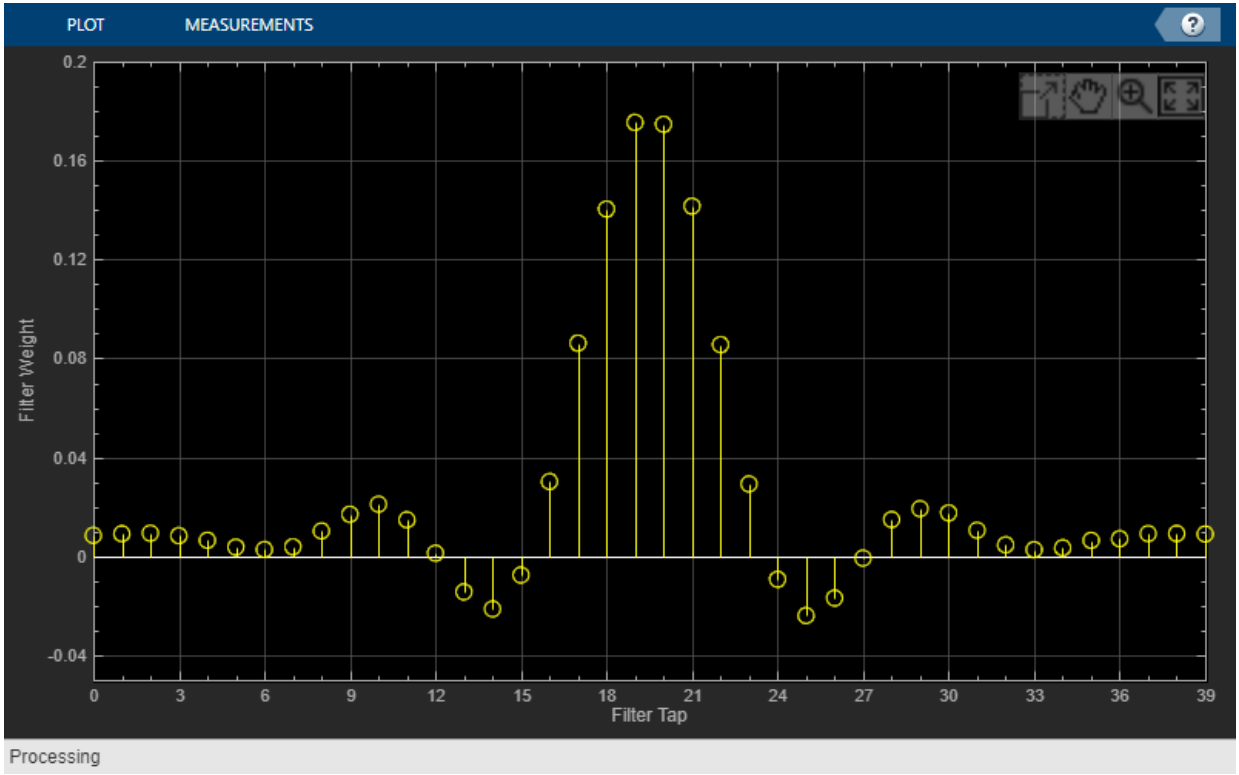
Create and configure an Array Plot System object to display the adaptive filter weights.

```
scope = dsp.ArrayPlot('XLabel','Filter Tap', ...
    'YLabel','Filter Weight', ...
    'YLimits',[-0.05 0.2]');
```

Plot the LMS filter weights as they adapt to a desired signal. Read from the audio file, produce random data, and filter the random data. Update the filter weights and plot the filter weights.

```
numplays = 0;
while numplays < 3
    [y, eof]    = signalSource();
    noise       = rand(40,1);
    noisefilt   = firFilter(noise);
    desired     = y + noisefilt;
    [~, ~, wts] = lmsFilter(noise,desired);
    scope(wts);
```

```
    numplays = numplays + eof;
end
```



Tips

- To close the Array Plot window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the Array Plot window, use the `hide` and `show` functions.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Blocks

Array Plot

Topics

“Configure Array Plot MATLAB Object”
“Visualize Central Limit Theorem in Array Plot”

Introduced in R2013a

dsp.ArrayVectorAdder

Package: `dsp`

Add array to vector along specified dimension

Description

The `ArrayVectorAdder` object adds an N-D array to a vector along a specified dimension. The length of the vector must equal the size of the N-D array along the specified dimension.

To add an N-D array to a vector along a specified dimension:

1. Define and set up your array-vector addition object. See “Construction” on page 4-71.
2. Call `step` to add the N-D array according to the properties of `dsp.ArrayVectorAdder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ava = dsp.ArrayVectorAdder` returns an array-vector addition object, `ava`, that adds a vector to an N-D array along the first dimension.

`ava = dsp.ArrayVectorAdder('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an array-vector addition object, `ava`, with each property set to the specified value.

Properties

`Dimension`

Dimension along which to add vector elements to input

Specify the dimension along which to add the input array to the elements of the vector as a positive integer. The length of the vector must match the size of the N-D array along the specified dimension. The default is `1`.

`VectorSource`

Source of vector

Specify the source of the vector values as |`Input port` | `Property` |. The default is `Input port`.

`Vector`

Vector values

Specify the vector values. This property applies only when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

`VectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point data type as | `Same word length as input` | `Custom` |. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

`CustomVectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as | `Full precision` | `Same as first input` | `Custom` |. The default is `Full precision`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as | `Same as accumulator` | `Same as first input` | `Custom` |.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the “OutputDataType” on page 4-0 property is `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Add vector to N-D array

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Add a Vector To a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Add a 2-by-1 vector to a 2-by-2 matrix along the first dimension of the array.

```
ava = dsp.ArrayVectorAdder;
a = ones(2);
x = [1 2]';
y = ava(a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Add block reference page. The object properties correspond to the block parameters, except:

The array-vector addition object does not have **Minimum** or **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.ArrayVectorDivider` | `dsp.ArrayVectorMultiplier` | `dsp.ArrayVectorSubtractor`

Introduced in R2012a

step

System object: `dsp.ArrayVectorAdder`
Package: `dsp`

Add vector to N-D array

Syntax

```
Y = step(ava,A)
Y = step(ava,A,V)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ava,A)` returns `Y` , the result of adding the input array `A` to the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

`Y = step(ava,A,V)` returns `Y` , the result of adding the input array `A` to the elements of the input vector `V` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorDivider

Package: `dsp`

Divide array by vector along specified dimension

Description

The `ArrayVectorDivider` object divides an array by a vector along a specified dimension.

To divide an array by a vector along a specified dimension:

1. Define and set up your array-vector division object. See “Construction” on page 4-78.
2. Call `step` to divide the array according to the properties of `dsp.ArrayVectorDivider`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avd = dsp.ArrayVectorDivider` returns an array-vector division object, `avd`, that divides an input array by the elements of a vector along the first dimension of the array.

`avd = dsp.ArrayVectorDivider('PropertyName',PropertyValue,...)` returns an array-vector division object, `avd`, with each property set to the specified value.

Properties

`Dimension`

Dimension along which to divide input by vector elements

Specify the dimension along which to divide the input array by the elements of a vector as a positive integer. The default is `1`.

`VectorSource`

Source of vector

Specify the source of the vector values as | `Input port` | `Property` |. The default is `Input port`.

`Vector`

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as | `Wrap` | `Saturate` |. The default is `Wrap`.

`VectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point mode as | `Same word length as input` | `Custom` |. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

`CustomVectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as | `Same as first input` | `Custom` |. The default is `Same as first input`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the “OutputDataType” on page 4-0 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Divide array by vector

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Divide a Matrix By a Vector

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
avd = dsp.ArrayVectorDivider;
a = ones(2)
```

```
a = 2×2

     1     1
     1     1
```

```
x = [2 3]'
```

```
x = 2×1

     2
     3
```

```
y = avd(a, x)
```

```
y = 2×2

    0.5000    0.5000
    0.3333    0.3333
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Divide block reference page. The object properties correspond to the block parameters, except:

The array-vector division object does not have **Minimum** or **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Divide array by vector

Syntax

```
Y = step(avd,A,V)
Y = step(avd,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(avd,A,V)` returns `Y` , the result of dividing the input array `A` by the elements of input vector `V` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

`Y = step(avd,A)` returns `Y` , the result of dividing the input array `A` by the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorMultiplier

Package: `dsp`

Multiply array by vector along specified dimension

Description

The `ArrayVectorMultiplier` object multiplies an array by a vector along a specified dimension.

To multiply an array by a vector along a specified:

1. Define and set up your array-vector multiplication object. See “Construction” on page 4-85.
2. Call `step` to multiply the array according to the properties of `dsp.ArrayVectorMultiplier`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avm = dsp.ArrayVectorMultiplier` returns an array-vector multiplication object, `avm`, that multiplies an input N-D array by the elements of a vector along the second dimension.

`avm = dsp.ArrayVectorMultiplier('PropertyName',PropertyValue,...)` returns an array-vector multiplication object, `avm`, with each property set to the specified value.

Properties

`Dimension`

Dimension along which to multiply input by vector elements

Specify the dimension along which to multiply the input array by the elements of vector as a positive integer. The default is `2`.

`VectorSource`

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

`Vector`

Vector to multiply array

Specify the vector by which to multiply the array. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, Simplest', `Zero`. The default is `floor`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

`VectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` , `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

`CustomVectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

`ProductDataType`

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision` , `Same as first input`, or `Custom`. The default is `Full precision`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision` , `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as `Same as product`, `Same as first input`, or `Custom`. The default is `Same as product`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Multiply array by vector

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Multiply a Matrix by a Vector

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
avm = dsp.ArrayVectorMultiplier;
a = ones(2);
x = [2 3]';
y = avm(a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Multiply block reference page. The object properties correspond to the block parameters, except:

- The array-vector multiplication object does not have **Minimum** or **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

step

System object: `dsp.ArrayVectorMultiplier`
Package: `dsp`

Multiply array by vector

Syntax

```
Y = step(avm,A,V)
Y = step(avm,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(avm,A,V)` returns `Y` , the result of multiplying the input array `A` by the elements of input vector `V` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

`Y = step(avm,A)` returns `Y` , the result of multiplying the input array `A` by the elements of vector specified in `Vector` property along the specified dimension when the `VectorSource` property is set to `Property`. The length of the vector specified in `Vector` property must equal the length of the specified dimension of `A`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorSubtractor

Package: `dsp`

Subtract vector from array along specified dimension

Description

The `ArrayVectorSubtractor` object subtracts a vector from an N-D array along a specified dimension.

To subtract a vector from an N-D array along a specified dimension:

1. Define and set up your array-vector subtraction object. See “Construction” on page 4-92.
2. Call `step` to subtract the vector according to the properties of `dsp.ArrayVectorSubtractor`. The behavior of `step` is specified to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avs = dsp.ArrayVectorSubtractor` returns an array-vector subtraction object, `avs`, that subtracts the elements of a vector from an N-D input array along the first dimension.

`avs = dsp.ArrayVectorSubtractor('PropertyName',PropertyValue,...)` returns an array-vector subtraction object, `avs`, with each property set to the specified value.

Properties

`Dimension`

Dimension along which to subtract vector elements from input

Specify the dimension along which to subtract the elements of the vector from the input array as an integer-valued scalar greater than `0`. The default is `1`.

`VectorSource`

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

`Vector`

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only if the object is not in full precision mode.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

`VectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` or `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

`CustomVectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision` , `Same as first input`, or `Custom`. The default is `Full precision`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the "OutputDataType" on page 4-0 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Subtract vector from array along specified dimension

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Subtract Vector From Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
avs = dsp.ArrayVectorSubtractor;
a = ones(2);
x = [1 2]';
y = avs(a, x)
```

```
y = 2×2

     0     0
    -1    -1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Subtract block reference page. The object properties correspond to the block parameters, except:

The array-vector subtraction object does not have **Minimum** or **Maximum** options for data output.

step

System object: `dsp.ArrayVectorSubtractor`
Package: `dsp`

Subtract vector from array along specified dimension

Syntax

```
Y = step(avs,A,V)
Y = step(avs,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(avs,A,V)` returns `Y`. The value of `Y` results from subtracting the elements of input vector `V` from the input array `A` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

`Y = step(avs,A)` returns `Y`. The value of `Y` results from subtracting the elements of the vector specified in the `Vector` property from the input array `A` along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AsyncBuffer

Package: `dsp`

FIFO buffer

Description

The `dsp.AsyncBuffer` System object writes samples to and reads samples from a first-in, first-out (FIFO) buffer. The `write` method writes data to the buffer, and the `read` method reads data from the buffer. When creating the object, you can set the number of samples (rows) of the buffer using the `Capacity` property. The number of channels (columns) is set during the first call to `write`. Initialize the buffer by calling `write` or `setup` before the first call to `read`.

The data that you write occupies the next available space in the buffer. If the buffer is full and all the data within it is unread (`asyncBuff.NumUnreadSamples == asyncBuff.Capacity`), the object overwrites the oldest data with any new data that comes in. The buffer removes data only when the data is overwritten, so you can reread data from the past. The `dsp.AsyncBuffer` object supports writing and reading variable frame size signals. For examples, see “Read Variable Frame Sizes from Buffer” on page 4-102 and “Write Variable Frame Sizes to Buffer” on page 4-105.

To write and read samples from a FIFO buffer:

- Create a `dsp.AsyncBuffer` object and set the properties of the object.
- Call `write` to write samples to the buffer.
- Call `read` to read samples from the buffer.
- Call `peek` to read samples without changing the number of unread samples in the buffer.

Creation

Syntax

```
asyncBuff = dsp.AsyncBuffer
asyncBuff = dsp.AsyncBuffer(cap)
```

Description

`asyncBuff = dsp.AsyncBuffer` returns an async buffer System object, `asyncBuff`, using the default properties.

`asyncBuff = dsp.AsyncBuffer(cap)` sets the `Capacity` property to `cap`.

Example: `asyncBuff = dsp.AsyncBuffer(200000);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Capacity` — Number of writable/readable rows in buffer
`192000` (default) | positive integer

Number of writable/readable rows in the buffer, specified as a positive integer greater than or equal to 2. The number of rows during each write to the buffer must not exceed the capacity of the buffer. If the buffer is full and all the data within is unread, the object overwrites the oldest data with any new data that comes in. The `CumulativeOverrun` property returned by `info` gives the number of samples overrun per channel since the last call to `reset`. The number of samples overrun is the number of unread samples overwritten.

By default, this property has data type `int32`.

Example: `asyncBuff = dsp.AsyncBuffer(200000);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumUnreadSamples` — Number of unread samples in each channel
`0` (default) | integer

This property is read-only.

Number of unread samples in each channel (column) of the buffer, specified as an integer greater than or equal to 0. The total number of unread samples in the buffer is `NumUnreadSamples` × *numChann*. The variable *numChann* is the number of channels in the buffer. The number of channels in the buffer is the number of data columns in the first call to `write`.

The `CumulativeUnderrun` property returned by the `info` method gives the number of samples underrun per channel since the last call to `reset`. Underrun occurs if you attempt to read more samples than available.

Example: `asyncBuff = dsp.AsyncBuffer; input = randn(512,1); numUnreadSamples = write(asyncBuff,input)`

Data Types: `int32`

Usage

To write and read samples from the async buffer:

- Create a `dsp.AsyncBuffer` object and set the properties of the object.
- Call `write` to write samples to the buffer.
- Call `read` to read samples from the buffer.
- Call `peek` to read samples without changing the number of unread samples in the buffer.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AsyncBuffer`

info	Get cumulative overrun and underrun
read	Read data from buffer
write	Write data to buffer
peek	Read data from buffer without changing number of unread samples

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

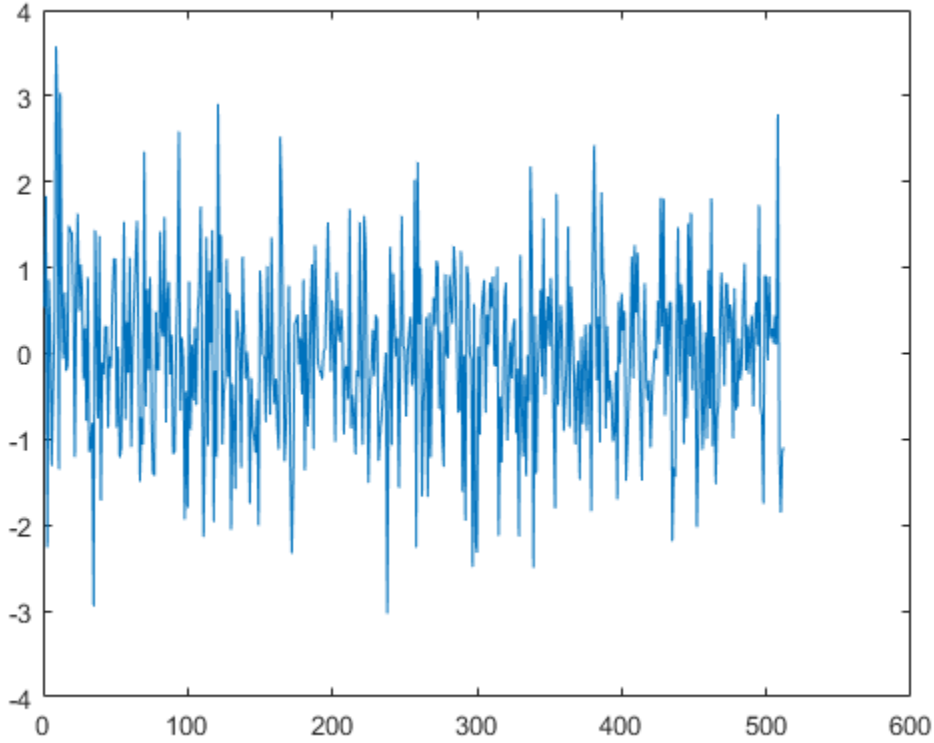
Examples

Read Variable Frame Sizes from Buffer

The `dsp.AsyncBuffer` System object™ supports reading variable frame sizes from the buffer.

Create a `dsp.AsyncBuffer` System object. The input is white Gaussian noise with a mean of 0, a standard deviation of 1, and a frame size of 512 samples. Write the input to the buffer using the `write` method.

```
asyncBuff = dsp.AsyncBuffer;
input = randn(512,1);
write(asyncBuff,input);
plot(input)
hold on
```

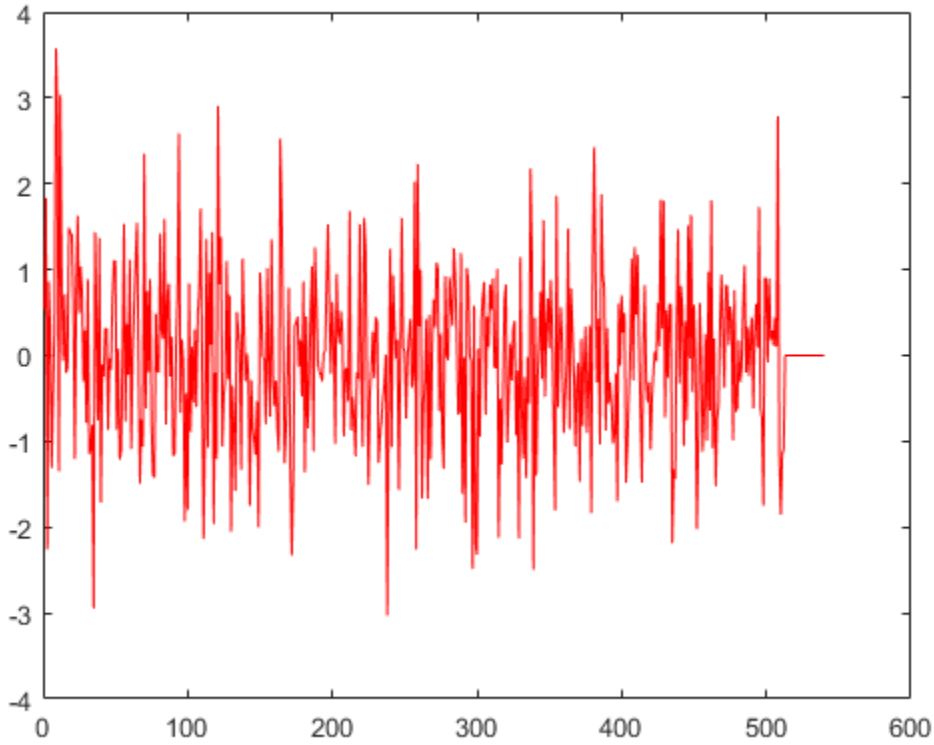


Store the data that is read from the buffer in `outTotal`.

Plot the input signal and data that is read from the buffer in the same plot. Read data from the buffer until all samples are read. In each iteration of the loop, `randi` determines the number of samples to read. Therefore, the signal is read in as a variable-size signal. The `prevIndex` variable keeps track of the previous index value that contains the data.

```
outTotal = zeros(size(input));
prevIndex = 0;
while asyncBuff.NumUnreadSamples ~= 0
    numToRead = randi([1,64]);
    out = read(asyncBuff,numToRead);
    outTotal(prevIndex+1:prevIndex+numToRead) = out;
    prevIndex = prevIndex+numToRead;
```

```
end
plot(outTotal,'r')
hold off
```



Verify that the input data and the data read from the buffer (excluding the underrun samples, if any) are the same. The cumulative number of overrun and underrun samples in the buffer is determined by the `info` function.

```
S = info(asyncBuff)
```

```
S = struct with fields:
     CumulativeOverrun: 0
    CumulativeUnderrun: 28
```

The `CumulativeUnderrun` field shows the number of samples underrun per channel. Underrun occurs if you attempt to read more samples than available.

Write Variable Frame Sizes to Buffer

Write a sine wave of variable frame size to the buffer. Compute the FFT of the sine wave and visualize the result on an array plot.

Initialize the `dsp.AsyncBuffer`, `dsp.ArrayPlot`, and `dsp.FFT` System objects.

```
asynBuff = dsp.AsyncBuffer;
plotter = dsp.ArrayPlot;
fftObj = dsp.FFT('FFTLengthSource','Property','FFTLength',256);
```

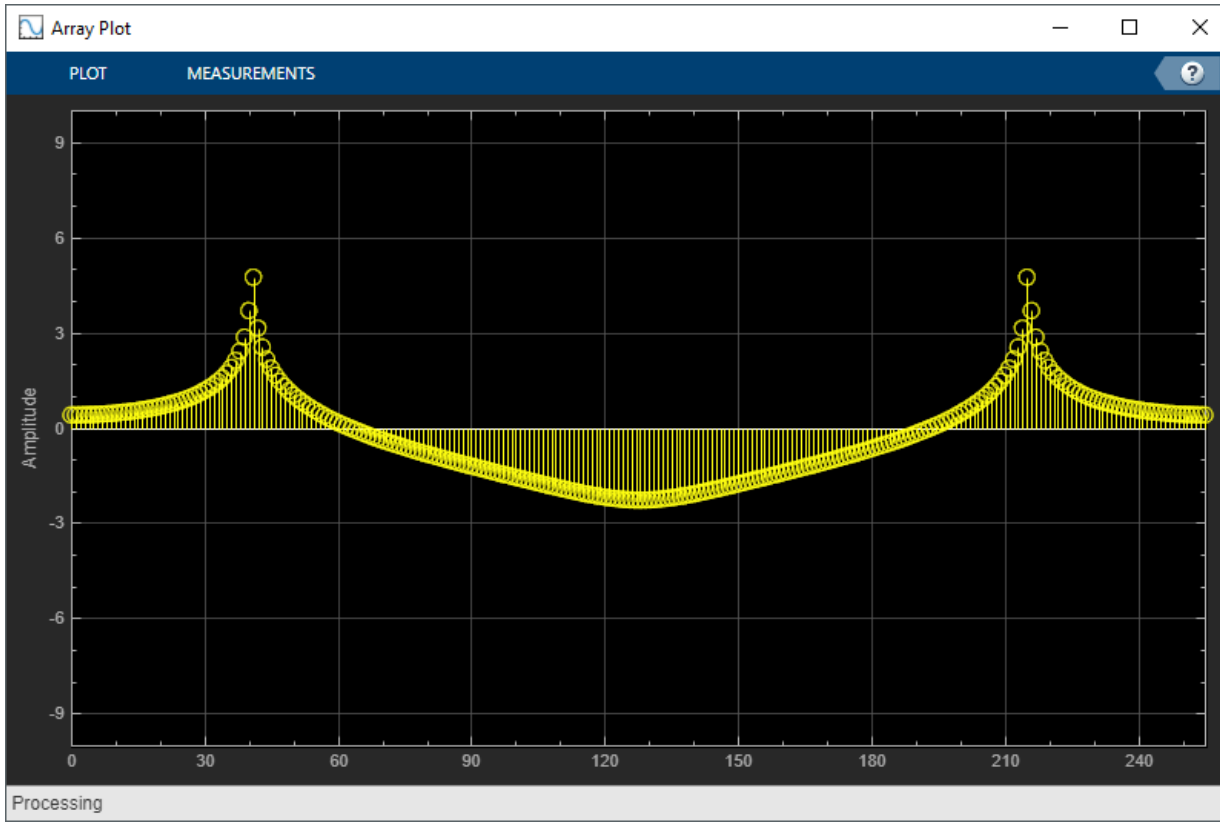
The sine wave is generated using the `sin` function in MATLAB. The `start` and `finish` variables mark the start and finish indices of each frame. If enough data is cached, read from the buffer and perform the FFT. View the FFT on an array plot.

```
start = 1;

for Iter = 1 : 2000
    numToWrite = randi([200,800]);
    finish = start + numToWrite;

    inputData = sin(start:finish)';
    start = finish + 1;

    write(asynBuff,inputData);
    while asynBuff.NumUnreadSamples >= 256
        x = read(asynBuff,256);
        X = abs(fftObj(x));
        plotter(log(X));
    end
end
```



Peek Data from Async Buffer

Read data from the async buffer without changing the number of unread samples using the `peek` function.

Create a `dsp.AsyncBuffer` System object™. The input is a column vector of 100 samples, 1 to 100. Write the data to the buffer.

```
asyncBuff = dsp.AsyncBuffer
```

```
asyncBuff =
  AsyncBuffer with properties:
```

```
            Capacity: 192000
    NumUnreadSamples: 0
```

```
input = (1:100)';
write(asyncBuff,input);
```

Peek at the first three samples. The output is [1 2 3]'.

```
out1  = peek(asyncBuff,3)
```

```
out1 = 3×1

     1
     2
     3
```

The `NumUnreadSamples` is 100, indicating that the `peek` function has not changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
    100
```

After peeking, read 50 samples using the `read` function. The output is [1:50]'.

```
out2  = read(asyncBuff,50)
```

```
out2 = 50×1

     1
     2
     3
     4
     5
     6
     7
     8
     9
    10
     ⋮
```

The `NumUnreadSamples` is 50, indicating that the `read` function has changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
    50
```

Now peek again at the first three samples. The output is [51 52 53]'. Verify that the `NumUnreadSamples` is still 50.

```
out3  = peek(asyncBuff,3)
```

```
out3 = 3×1

    51
    52
    53
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
    50
```

Read 50 samples again. The output now contains the sequence [51:100]'. Verify that `NumUnreadSamples` is 0.

```
out4  = read(asyncBuff)
```

```
out4 = 50×1

    51
    52
    53
    54
    55
    56
    57
    58
    59
    60
     ⋮
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
    0
```

Limitations

Before calling the `read` method, you must initialize the buffer by calling either the `write` or `setup` method. For an example, see "Why Does the dsp.AsyncBuffer Object Error When You Call read Before write?"

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

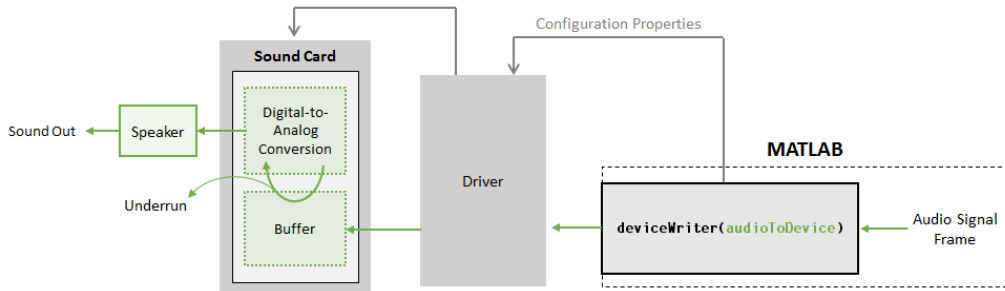
Introduced in R2017a

audioDeviceWriter

Play to sound card

Description

The `audioDeviceWriter` System object writes audio samples to an audio output device. Properties of the audio device writer specify the driver, the device, and device attributes such as sample rate, bit depth, and buffer size.



Data Flow of Audio Device Writer

- Call the object to input an audio signal frame to the `audioDeviceWriter`.
- The `audioDeviceWriter` uses the specified driver to pass the frame (device input) to the buffer of your specified audio device.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

To stream data to an audio device:

1. Create the `audioDeviceWriter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
deviceWriter = audioDeviceWriter
deviceWriter = audioDeviceWriter(sampleRateValue)
deviceWriter = audioDeviceWriter( ___ ,Name,Value)
```

Description

`deviceWriter = audioDeviceWriter` returns a System object, `deviceWriter`, that writes audio samples to an audio output device in real time.

`deviceWriter = audioDeviceWriter(sampleRateValue)` sets the SampleRate property to `sampleRateValue`.

`deviceWriter = audioDeviceWriter( ___ ,Name,Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Example: `deviceWriter = audioDeviceWriter(48000,'BitDepth','8-bit integer')` creates a System object, `deviceWriter`, that operates at a 48 kHz sample rate and an 8-bit integer bit depth.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Driver` — Driver used to access audio device (Windows only)
`'DirectSound'` (default) | `'ASIO'` | `'WASAPI'`

Driver used to access your audio device, specified as `'DirectSound'`, `'ASIO'`, or `'WASAPI'`.

- ASIO drivers do not come pre-installed on Windows machines. To use the `'ASIO'` driver option, install an ASIO driver outside of MATLAB.

  Note If `Driver` is specified as `'ASIO'`, use `asiosettings` to set the sound card buffer size to the buffer size of your `audioDeviceWriter` System object.

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, set `SampleRate` to a sample rate supported by your audio device.

This property applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault `Driver` values, you must have an Audio Toolbox licence. If the toolbox is not installed, specifying nondefault `Driver` values returns an error.

Data Types: `char` | `string`

`Device` — Device used to play audio samples
default audio device (default) | character vector | string scalar

Device used to play audio samples, specified as a character vector or string scalar. Use `getAudioDevices` to list available devices for the selected driver.

Data Types: `char` | `string`

`SampleRate` — Sample rate of signal sent to audio device (Hz)
`44100` (default) | positive integer

Sample rate of signal sent to audio device, in Hz, specified as a positive integer. The range of `SampleRate` depends on your audio hardware.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`BitDepth` — Data type used by the device
`'16-bit integer'` (default) | `'8-bit integer'` | `'24-bit integer'` | `'32-bit float'`

Data type used by the device, specified as a character vector or string scalar. Before performing digital-to-analog conversion, the input data is cast to a data type specified by `BitDepth`.

To specify a nondefault `BitDepth`, you must have an Audio Toolbox licence. If the toolbox is not installed, specifying a nondefault `BitDepth` returns an error.

Data Types: `char` | `string`

`SupportVariableSizeInput` — Support variable frame size
`false` (default) | `true`

Option to support variable frame size, specified as `true` or `false`.

- `false` –– If the `audioDeviceWriter` object is locked, the input must have the same frame size at each call. The buffer size of your audio device is the same as the input frame size.
- `true` –– If the `audioDeviceWriter` object is locked, the input frame size can change at each call. The buffer size of your audio device is specified through the BufferSize property.

Data Types: `char`

`BufferSize` — Buffer size of audio device
`4096` (default) | positive integer

Buffer size of audio device, specified as a positive integer.

Note If `Driver` is specified as `'ASIO'`, open the ASIO UI to set the sound card buffer size to the `BufferSize` value of your `audioDeviceWriter` System object.

Dependencies

To enable this property, set SupportVariableSizeInput to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ChannelMappingSource` — Source of mapping between input matrix and device channels
`'Auto'` (default) | `'Property'`

Source of mapping between columns of input matrix and channels of audio output device, specified as `'Auto'` or `'Property'`.

- `'Auto'` –– Default settings determine the mapping between columns of input matrix and channels of audio output device. For example, suppose that your input is a matrix with four columns, and your audio device has four channels available. Column 1 of your input data writes to channel 1 of your device, column 2 of your input data writes to channel 2 of your device, and so on.
- `'Property'` –– The ChannelMapping property determines the mapping between columns of input matrix and channels of audio output device.

Data Types: `char` | `string`

`ChannelMapping` — Nondefault mapping between input matrix and device channels
`[1:MaximumOutputChannels]` (default) | scalar | vector

Nondefault mapping between columns of input matrix and channels of output device, specified as a scalar or vector of valid channel indices.

To selectively map between columns of the input matrix and your sound card's output channels, you must have an Audio Toolbox licence. If the toolbox is not installed, specifying a nondefault `ChannelMapping` returns an error.

Dependencies

To enable this property, set ChannelMappingSource to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
numUnderrun = deviceWriter(audioToDevice)
```

Description

`numUnderrun = deviceWriter(audioToDevice)` writes one frame of audio samples, `audioToDevice`, to the selected audio device and returns the number of audio samples underrun since the last call to `deviceWriter`.

Note: When you call the `audioDeviceWriter` System object, the audio device specified by the `Device` property is locked. An audio device can be locked by only one `audioDeviceWriter` at a time. To release the audio device, call `release` on your `audioDeviceWriter` System object.

Input Arguments

`audioToDevice` — Audio to device

matrix

Audio signal to write to device, specified as a matrix. The columns of the matrix are treated as independent audio channels.

If `audioToDevice` is of data type `'double'` or `'single'`, the audio device writer clips values outside the range [–1, 1]. For other data types, the allowed input range is [min, max] of the specified data type.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

Output Arguments

`numUnderrun` — Number of samples underrun

scalar

Number of samples by which the audio device writer queue was underrun since the last call to `deviceWriter`.

Data Types: `uint32`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to audioDeviceWriter

getAudioDevices	List available audio devices
info	Characteristic information about audio device writer

Common to All System Objects

clone	Create duplicate System object
isLocked	Determine if System object is in use
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object
step	Run System object algorithm

Examples

Read from File and Write to Audio Device

Read an MP3 audio file and play it through your default audio output device.

Create a `dsp.AudioFileReader` object with default settings. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3')
```

```
fileInfo = struct with fields:
             Filename: 'B:\matlab\toolbox\dsp\dsp\speech_dft.mp3'
    CompressionMethod: 'MP3'
          NumChannels: 1
           SampleRate: 22050
         TotalSamples: 112893
             Duration: 5.1199
                Title: []
              Comment: []
               Artist: []
              BitRate: 64
```

Create an `audioDeviceWriter` object and specify the sample rate.

```
deviceWriter = audioDeviceWriter('SampleRate',fileInfo.SampleRate);
```

Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels))
```

Use the `info` function to obtain the characteristic information about the device writer.

```
info(deviceWriter)
```

```
ans = struct with fields:
                    Driver: 'DirectSound'
                DeviceName: 'Primary Sound Driver'
    MaximumOutputChannels: 2
```

In an audio stream loop, read an audio signal frame from the file, and write the frame to your device.

```
while ~isDone(fileReader)
    audioData = fileReader();
    deviceWriter(audioData);
end
```

Close the input file and release the device.

```
release(fileReader)
release(deviceWriter)
```

Reduce Latency due to Output Device Buffer

Latency due to the output device buffer is the time delay of writing one frame of data. Modify default properties of your `audioDeviceWriter` System object™ to reduce latency due to device buffer size.

Create a `dsp.AudioFileReader` System object to read an audio file with default settings.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object and specify the sample rate to match that of the audio file reader.

```
deviceWriter = audioDeviceWriter(...
    'SampleRate',fileReader.SampleRate);
```

Calculate the latency due to your device buffer, in seconds.

```
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate %#ok
```

```
bufferLatency = 0.0464
```

Set the `SamplesPerFrame` property of your `dsp.AudioFileReader` System object to 256. Calculate the buffer latency in seconds.

```
fileReader.SamplesPerFrame = 256;
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate
```

```
bufferLatency = 0.0116
```

Determine and Decrease Underrun

Underrun refers to output signal silence, which occurs when the audio stream loop does not keep pace with the output device. Determine the underrun of an audio stream loop, add artificial computational load to the audio stream loop, and then modify properties of your `audioDeviceWriter` object to decrease underrun. Your results depend on your computer.

Create a `dsp.AudioFileReader` object, and specify the file to read. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3');
```

Create an `audioDeviceWriter` object. Use the `SampleRate` of the file reader as the `SampleRate` of the device writer. Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
deviceWriter = audioDeviceWriter('SampleRate',fileReader.SampleRate);
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels))
```

Run your audio stream loop with input from file and output to device. Print the total samples underrun and the underrun in seconds.

```
totalUnderrun = 0;
while ~isDone(fileReader)
```

```
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)

Total samples underrun: 0.

fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.Sampl

Total seconds underrun: 0.
```

Release your `dsp.AudioFileReader` and `audioDeviceWriter` objects and set your counter variable to zero.

```
release(fileReader)
release(deviceWriter)
totalUnderrun = 0;
```

Use `pause` to mimic an algorithm that takes 0.075 seconds to process. The pause causes the audio stream loop to go slower than the device, which results in periods of silence in the output audio signal.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)

Total samples underrun: 71680.

fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.Sampl

Total seconds underrun: 3.250794e+00.
```

Release your `audioDeviceReader` and `dsp.AudioFileWriter` and set the counter variable to zero.

```
release(fileReader)
release(deviceWriter)
totalUnderrun = 0;
```

Set the frame size of your audio stream loop to 2048. Because the `SupportVariableSizeInput` property of your `audioDeviceWriter` System object is

set to `false`, the buffer size of your audio device is the same size as the input frame size. Increasing your device buffer size decreases underrun.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileReader.SamplesPerFrame = 2048;
fileInfo = audioinfo('speech_dft.mp3');

deviceWriter = audioDeviceWriter('SampleRate',fileReader.SampleRate);
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels))
```

Calculate the total underrun.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

```
Total samples underrun: 0.
```

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.Samp
```

```
Total seconds underrun: 0.
```

The increased frame size reduces the total underrun of your audio stream loop. However, increasing the frame size also increases latency. Other approaches to reduce underrun include:

- Increasing the buffer size independent of input frame size. To increase buffer size independent of input frame size, you must first set `SupportVariableSizeInput` to `true`. This approach also increases latency.
- Decreasing the sample rate. Decreasing the sample rate reduces both latency and underrun at the cost of signal resolution.
- Choosing an optimal driver and device for your system.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Introduced in R2016a

getAudioDevices

List available audio devices

Syntax

```
devices = getAudioDevices(deviceWriter)
```

Description

`devices = getAudioDevices(deviceWriter)` returns a list of audio devices that are available and compatible with your I/O audio object, `deviceWriter`.

Input Arguments

`deviceWriter` — Audio I/O object
object of `audioDeviceWriter`

Audio I/O object, specified as an object of `audioDeviceWriter`.

Data Types: `object`

Output Arguments

`devices` — List of available and compatible devices
array

List of available and compatible devices. The list of audio devices depends on the specified `Driver` property of your object.

Data Types: `cell`

System Objects
`audioDeviceWriter`

Introduced in R2016a

dsp.AudioFileReader

Package: `dsp`

Stream from audio file

Description

The `dsp.AudioFileReader` System object reads audio samples from an audio file.

To read audio samples from an audio file:

1. Create the `dsp.AudioFileReader` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
afr = dsp.AudioFileReader
afr = dsp.AudioFileReader(File name)
afr = dsp.AudioFileReader(Name,Value)
```

Description

`afr = dsp.AudioFileReader` returns an audio file reader System object, `afr` that reads audio from an audio file.

`afr = dsp.AudioFileReader(File name)` returns an audio file reader object, `afr`, with `Filename` property set to `File name`.

`afr = dsp.AudioFileReader(Name,Value)` returns an audio file reader System object, `afr`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Filename` — Name of audio file from which to read

`'speech_dft.mp3'` (default) | character vector | string scalar

Specify the name of an audio file as a character vector or a string scalar. Specify the full path for the file only if the file is not on the MATLAB path. The file name can be an http web address, like `'http://audio.wgbh.org:8004/'`. For an example, see “Read and Play Back Audio File from http Web Address” on page 4-129.

The following table lists the supported audio file formats:

Platforms	File Name Extensions
Windows	`.wav`, `.wma`, `.avi`, `.aif`, `.aifc`, `.aiff`, `.mp3`, `.au`, `.snd`, `.mp4`, `.m4a`, `.flac`, `.ogg`, `.mov`
Non-Windows	`.avi`, `.mp3`, `.mp4`, `.m4a`, `.wav`, `.flac`, `.ogg`, `.aif`, `.aifc`, `.aiff`, `.au`, `.snd`, `.mov`

`PlayCount` — Number of times to play file

1 (default) | positive integer

Specify a positive integer as the number of times to play the file.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SampleRate` — Sampling rate of audio file
positive scalar

This property is read-only.

This property displays the sampling rate, in Hz, of the audio file.

Data Types: `double`

`SamplesPerFrame` — Number of samples in audio frame
`1024` (default) | positive integer

Specify the number of samples in an audio frame as a positive, scalar integer value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OutputDataType` — Data type of output
`'double'` (default) | `'single'` | `'int16'` | `'uint8'`

Set the data type of the audio data output from the audio file reader object. Specify the data type as `'double'`, `'single'`, `'int16'`, or `'uint8'`.

`ReadRange` — Range of samples to be read
`[1 inf]` (default) | two-element row vector

Specify the sample range from which to read, as a vector in the form of [*StartSample EndSample*], where *StartSample* is the sample at which file reading starts, and *EndSample* is the sample at which file reading stops.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
audio = afr()
[audio,eof] = afr()
```

Description

`audio = afr()` outputs one frame of audio samples, `audio`. You can specify the number of times to play the file using the `PlayCount` property. After playing the file for the number of times you specify, `audio` contains silence.

`[audio,eof] = afr()` returns an end-of-file indicator, `eof`. `eof` is true each time the output `audio` contains the last audio sample in the file.

Output Arguments

`audio` — Audio samples

column vector

One frame of audio samples, returned as a column vector of length equal to the value you specify in the `SamplesPerFrame` property. The data type of the audio output is specified in the `OutputDataType` property.

Data Types: `single` | `double` | `int16` | `uint8`

`eof` — End-of-file indicator

`1` | `0`

End-of-file indicator, returned as either a `1` or a `0`. A value of `1` is output when `audio` contains the last audio sample in the file.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AudioFileReader`

info	Information about specific audio file
isDone	End-of-file status (logical)

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Read and Play Back Audio File

Read and play back an audio file using the standard audio output device.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj()` becomes `step(obj)`.

You can choose to read the entire data or specify a range of data to read from using the ReadRange property. By default, ReadRange is set to [1 inf], indicating the file reader to read the entire data from the source. In this example, set ReadRange to 3Fs, indicating the file reader to read the first 3 seconds of the data.

```
afr = dsp.AudioFileReader('speech_dft.mp3','ReadRange',[1 3*22050]);
adw = audioDeviceWriter('SampleRate', afr.SampleRate);

while ~isDone(afr)
    audio = afr();
    adw(audio);
end
release(afr);
release(adw);
```

Read and Play Back Audio File from http Web Address

Read audio data from an http web address using the `dsp.AudioFileReader` System object™. Play back the data using the `audioDeviceWriter` System object.

Initialization

Create an audio file reader which reads data from http://audio.wgbh.org:8004/. Set the sample rate of the audio device writer to be the same as that of the audio file reader.

```
afr = dsp.AudioFileReader('http://audio.wgbh.org:8004/')
```

```
afr =
  dsp.AudioFileReader with properties:

           Filename: 'http://audio.wgbh.org:8004/'
          PlayCount: 1
    SamplesPerFrame: 1024
     OutputDataType: 'double'
         SampleRate: 44100
          ReadRange: [1 Inf]
```

```
adw = audioDeviceWriter(afr.SampleRate)
```

```
adw =
  audioDeviceWriter with properties:

        Driver: 'DirectSound'
        Device: 'Default'
    SampleRate: 44100

  Show all properties
```

Read and Play Back

Read a specific amount of data from the web address directly and play the data back using the audio device writer.

```
for i = 1:1000
    audio = afr();
    adw(audio);
end
```

Close the input file and the audio output device.

```
release(afr)
release(adw)
```

Limitations

For MP3, MPEG-4 AAC, and AVI audio files on Windows 7 or later and Linux platforms, `dsp.AudioFileReader` object can read fewer samples than expected. On Windows platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs `EOF` as the last output.
- The object has no corresponding property for the **Multimedia Outputs** parameter because audio is the only supported output.
- The object has no corresponding property for the **Image signal** block parameter.
- The object has no corresponding property for the **Output color format** parameter.
- The object has no corresponding property for the **Video output data type** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. Objects
`dsp.AudioFileWriter`

Topics

“How To Run a Generated Executable Outside MATLAB”

Introduced in R2012a

dsp.AudioFileWriter

Package: `dsp`

Stream to audio file

Description

The `dsp.AudioFileWriter` System object writes audio samples to an audio file.

To write audio samples to an audio file:

1. Create the `dsp.AudioFileWriter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
afw = dsp.AudioFileWriter
afw = dsp.AudioFileWriter(File name)
afw = dsp.AudioFileWriter(Name,Value)
```

Description

`afw = dsp.AudioFileWriter` returns an audio file writer System object, `afw`. This object writes audio samples to an audio file.

`afw = dsp.AudioFileWriter(File name)` returns an audio file writer System object, `afw`. This object has the `Filename` property set to `File name`.

`afw = dsp.AudioFileWriter(Name,Value)` returns an audio file writer object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Filename` — Name of audio file to which to write

`'output.wav'` (default) | character vector | string scalar

Specify the name of the audio file as a character vector or a string scalar.

`FileFormat` — Audio file format

`'WAV'` (default) | `'AVI'` | `'FLAC'` | `'OGG'` | `'MPEG4'` | `'WMA'`

Specify which audio file format the object writes. On Microsoft platforms, select one of `'AVI'`, `'WAV'`, `'FLAC'`, `'OGG'`, `'MPEG4'`, `'WMA'`. On Linux platforms, select one of `'AVI'`, `'WAV'`, `'FLAC'`, or `'OGG'`. On macOS platforms, select one of `'AVI'`, `'WAV'`, `'FLAC'`, `'OGG'`, or `'MPEG4'`. These abbreviations correspond to the following file formats:

- `'AVI'`: Audio-Video Interleave
- `'WAV'`: Microsoft WAVE Files
- `'WMA'`: Windows Media Audio
- `'FLAC'`: Free Lossless Audio Codec
- `'OGG'`: Ogg/Vorbis Compressed Audio File
- `'MPEG4'`: MPEG-4 AAC File — You can use both `.m4a` and `.mp4` extensions

The default is `'WAV'`.

`SampleRate` — Sampling rate of audio data stream
`44100` (default) | positive scalar

Specify the sampling rate of the input audio data as a positive, numeric scalar value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Compressor` — Algorithm that compresses audio data
`'None (uncompressed)'` (default) | `'CCITT A-Law'` | `'CCITT u-Law'` | `'GSM 6.10'` | `'IMA ADPCM'` | `'Microsoft ADPCM'` | `'PCM'`

Specify the type of compression algorithm the audio file writer uses to compress the audio data. Compression reduces the size of the audio file. Select `'None (uncompressed)'` to save uncompressed audio data to the file. The other options available reflect the audio compression algorithms installed on your system. You can use tab completion to query valid `Compressor` options for your computer by typing `H.Compressor = '` and then pressing the tab key.

Dependencies

This property applies when writing WAV or AVI files on Windows platforms.

`DataType` — Data type of the uncompressed audio
`'int16'` (default) | `'double'` | `'single'` | `'inherit'` | `'int24'` | `'int32'` | `'uint8'`

Specify the type of uncompressed audio data written to the file as `'int16'`, `'double'`, `'single'`, `'inherit'`, `'int24'`, `'int32'`, or `'uint8'`.

Dependencies

This property only applies when writing uncompressed WAV files.

Usage

Syntax

```
afw(audio)
```

Description

`afw(audio)` writes one frame of audio samples, `audio`, to the output file specified by `Filename`. `audio` is either a vector for mono audio input or an *M*-by-*N* matrix for *N*-channel audio input respectively.

Input Arguments

`audio` — Audio samples

column vector | matrix

One frame of audio samples, returned as a column vector or a matrix. A column vector input indicates a mono audio input. An *M*-by-*N* matrix indicates an *N*-channel audio input.

If the input is fixed-point, the input must be a signed fixed-point input with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int16` | `int32` | `uint8` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Limitations

The following platform-specific restrictions apply when writing these files:

Windows 7	macOS
• Only sample rates of 44100 Hz and 48000 Hz are supported for the MPEG-4 AAC file format. For other file formats, there is no restriction on the sample rate.	• Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
• Only mono or stereo outputs are allowed for the MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.	
• The output data is padded on both the front and back of the signal, with extra samples of silence. Windows AAC encoder places sharp fade-in and fade-out on audio signals, causing the signals to be slightly longer in samples when written to disk.	• Not all sampling rates are supported, although the Mac Audio Toolbox API does not explicitly specify a restriction.
• A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file.	

Examples

Write an Audio Signal to WAV File

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj()` becomes `step(obj)`.

Decimate an audio signal, and write it to disk as a WAV file.

```
afr = dsp.AudioFileReader('OutputDataType',...
   'double');
firdec = dsp.FIRDecimator; % decimate by 2
afw = dsp.AudioFileWriter...
   ('speech_dft.wav', ...
   'SampleRate', afr.SampleRate/2);

while ~isDone(afr)
```

```
    audio = afr();
    audiod = firdec(audio);
    afw(audiod);
end

release(afr);
release(afw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object `FileFormat` property does not support video-only file formats.
- The object has no corresponding property for the **Write** parameter. The object writes only audio content to files.
- The object has no corresponding property for the **Video compressor** parameter.
- The object has no corresponding property for the **File color format** parameter.
- The object has no corresponding property for the **Image signal** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

"How To Run a Generated Executable Outside MATLAB"

Introduced in R2012a

dsp.AudioPlayer

Package: `dsp`

Play audio data using computer's audio device

Compatibility

Note The `dsp.AudioPlayer` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceWriter` object instead.

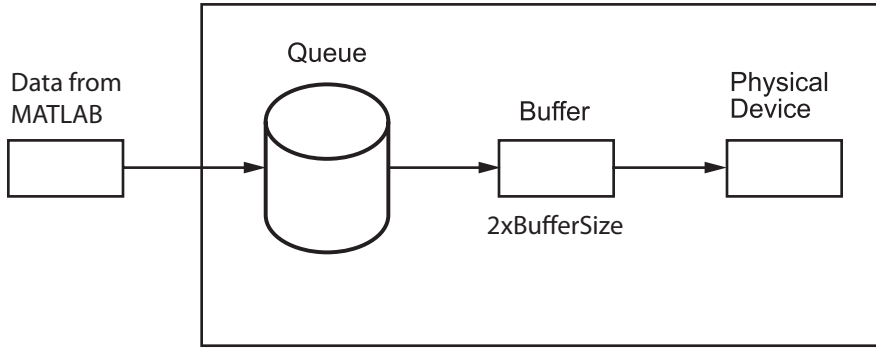
Description

The `AudioPlayer` object plays audio data using the computer's audio device.

To play audio data using the computer’s audio device:

1. Define and set up your audio player object. See “Construction” on page 4-141.
2. Call `step` to play audio data according to the properties of `dsp.AudioPlayer`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from the audio device using the process illustrated by the following figure.



Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.AudioPlayer` returns an audio player object, `H`, that plays audio samples using an audio output device in real-time.

`H = dsp.AudioPlayer('PropertyName',PropertyValue, ...)` returns an audio player object, `H`, with each property set to the specified value.

`H = dsp.AudioPlayer(SAMPLERATE,'PropertyName',PropertyValue, ...)` returns an audio player object, `H`, with the `SampleRate` property set to `SAMPLERATE` and other specified properties set to the specified values. This System object supports variable-size input. If you use variable-size signals with this System object, you may experience sound dropouts when the size of the input frame increases. To avoid this behavior, use a signal of maximum expected size when you first call `step` to start running through this System object.

Properties

`DeviceName`

Device to which to send audio data

Specify the device to which to send the audio data. The default is `Default`, which is the computer's standard output device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key.

`SampleRate`

Number of samples per second sent to audio device

Specify the number of samples per second in the signal as an integer. The default is `44100`. This property is tunable.

`DeviceDataType`

Data type used by device

Specify the data type used by the audio device to acquire audio data as `Determine from input data type` , `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from input data type`.

`BufferSizeSource`

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, an appropriate buffer size based on the `SampleRate` gets computed.

`BufferSize`

Buffer size

Specify the size of the buffer that the audio player object uses to communicate with the audio device as an integer. `BufferSize` is half the size of the sound card buffer. A frame of data cannot be passed to the queue until the device empties the buffer, which introduces latency. Latency is the time it takes the device to empty the queue and the buffer. `BufferSize` has to be smaller than the effective queue duration. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun).

This property applies when you set the `BufferSizeSource` property to `Property`. The default is `4096`. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to `'Property'`. You can select `BufferSize` in the list of properties.

`QueueDuration`

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is `1.0`. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:
$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}$.

To minimize latency, lower the `QueueDuration` or set it to `0`. However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device’s data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer underrun occurs. You can use `OutputNumUnderrunSamples` to monitor underrun. To correct the underrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer overrun occurs, causing the System object to wait before writing data to the queue. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the System object sends a buffer of samples from the top of the queue to the audio device. If the queue does not contain enough data to completely fill the buffer, the System object fills the remaining portion of the buffer with zeros.

`OutputNumUnderrunSamples`

Enable output of underrun count

Set to `true` to output the number of zero samples inserted due to queue underrun since the last call to the `step` method. The default is `false`.

`ChannelMappingSource`

Source of device channel mapping

Specify whether to determine the channel mapping as `'Auto'` or as `'Property'`. If you set the value of `ChannelMappingSource` to `'Auto'`, the `ChannelMapping` field is rendered inactive. If you set this property to `'Property'`, the vector specified in the `ChannelMapping` field is used to route the output.

`ChannelMapping`

Data-to-device channel mapping

Vector of valid channel indices to represent the mapping between data and device output channels. The term Channel Mapping refer to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio data to output a specific channel of audio data. By default, the `ChannelMapping` field is

[1:MAXOUTPUTCHANNELS], where MAXOUTPUTCHANNELS depends upon the selected device.

Methods

step	Write audio to audio output device

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Read and Play an Audio File

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Read in an AVI audio file, and play the file back using the standard audio output device.

```
AFR = dsp.AudioFileReader; % points to a default audio file
AP = audioDeviceWriter('SampleRate',AFR.SampleRate);
while ~isDone(AFR)
  audio = AFR();
  nUnderrun = AP(audio);
  if nUnderrun > 0
    fprintf('Audio player queue underrun by %d samples.\n'...
         ,nUnderrun);
  end
end
release(AFR);            % close the input file
release(AP);             % close the audio output device
```

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/ tcsh)`
	
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH = $MATLABROOT\bin \win64;%PATH%`

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Audio Device block reference page. The object properties correspond to the block parameters.

`dsp.AudioFileReader` | `dsp.AudioRecorder`

Topics

Set the Audio Hardware API on page 2-1784

Introduced in R2012a

step

System object: `dsp.AudioPlayer`
Package: `dsp`

Write audio to audio output device

Compatibility

Note The `dsp.AudioPlayer` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceWriter` object instead.

Syntax

```
step(H,AUDIO)
Underrun = step(H,AUDIO)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(H,AUDIO)` writes one frame of `AUDIO` samples to the audio output device.

`Underrun = step(H,AUDIO)` writes one frame of `AUDIO` samples to the audio output device. The output `Underrun` indicates the number of zero samples inserted due to queue underrun since the last call to the `step` method. This syntax applies when you set the `OutputNumUnderrunSamples` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AudioRecorder

Package: `dsp`

Record audio data using computer's audio device

Compatibility

Note The `dsp.AudioRecorder` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceReader` object from Audio Toolbox instead.

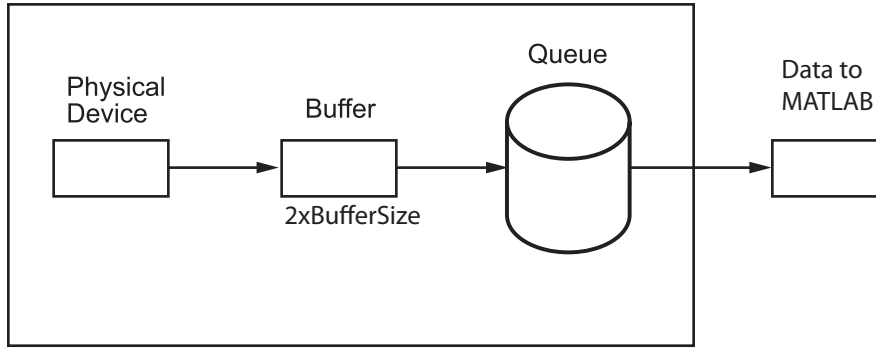
Description

The `AudioRecorder` object records audio data using the computer's audio device.

To record audio data using the computer's audio device:

1. Define and set up your audio recorder object. See "Construction" on page 4-150.
2. Call `step` to record audio data according to the properties of `dsp.AudioRecorder`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from a frame of data using the process illustrated by the following figure.



Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.AudioRecorder` returns an audio recorder object, `H`, that records audio samples using an audio input device in real-time.

`H = dsp.AudioRecorder('PropertyName',PropertyValue, ...)` returns an audio recorder object, `H`, with each property set to the specified value.

Properties

`DeviceName`

Device from which to acquire audio data

Specify the device from which to acquire audio data. The default is `Default`, which is the computer's standard input device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key. The tab completion functionality shows all valid audio device names for your computer.

`SampleRate`

Number of samples per second read from audio device

Specify the number of samples per second in the signal as an integer. The default is 44100. This property is tunable.

`NumChannels`

Number of audio channels

Specify the number of audio channels as an integer. The default is 2.

`DeviceDataType`

Data type used by device

Specify the data type used by the device to acquire audio data as `Determine from output data type` , `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from output data type`.

`BufferSizeSource`

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`.

`BufferSize`

Buffer size

Specify as an integer the size of the buffer that the audio recorder object uses to communicate with the audio device. This property applies when you set the `BufferSizeSource` property to `Property`. The default is `4096`. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun). The instant you receive the buffer from a device, you have samples that are relatively new and samples that are at least as old as the size of the buffer. Therefore, the buffer size introduces latency, which is the time required for the device to fill the queue and the buffer. `BufferSize` is half the size of the sound card buffer. The size of the buffer processed in each interrupt from the audio device affects the performance of the system. A frame of data cannot pass through the queue until the buffer is filled by the device, thus introducing latency. `BufferSize` has to be smaller than the effective queue duration. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to 'Property'. You can select `BufferSize` from the list of properties.

`QueueDuration`

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is `1.0`. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:
$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}$.

To minimize latency, lower the `QueueDuration` or set it to 0. However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device’s data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer overrun occurs. You can use `OutputNumOverrunSamples` to monitor overrun. To correct the overrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer underrun occurs, causing the System object to wait for new samples to become available. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the audio device sends a buffer of samples to the top of the queue.

`SamplesPerFrame`

Number of samples in the output signal

Specify the number of samples in the audio recorder's output as an integer. The default is 1024.

`OutputDataType`

Data type of the output

Select the output data type as `uint8`, `int16`, `int32` , `single` , or `double`. The default is `double`.

`OutputNumOverrunSamples`

Enable output of overrun count

Set to `true` to output the number of samples dropped due to queue overrun since the last call to the `step` method. The default is `false`.

`ChannelMappingSource`

Source of device channel mapping

Specify whether to determine the channel mapping as `'Auto'` or as `'Property'`. If you set the value of `ChannelMappingSource` to `'Auto'`, the `ChannelMapping` field is

rendered inactive. If you set this property to `'Property'`, the vector specified in the ChannelMapping field is used to route the input. Additionally, the `NumChannels` field is rendered inactive, because the channel map contains information about the number of data channels that the user is attempting to read.

`ChannelMapping`

Device-to-data channel mapping

Vector of valid channel indices to represent the mapping between device input channels and the data. The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. By default, the `ChannelMapping` field is [1:MAXNUMINPUTCHANNELS], where MAXNUMINPUTCHANNELS depends upon the selected device.

Methods

step Record audio from recording device

Common to All System Objects	
`release`	Allow System object property value changes

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/ tcsh)`
	
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH = $MATLABROOT\bin \win64;%PATH%`

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Audio Device block reference page. The object properties correspond to the block parameters.

`dsp.AudioFileReader` | `dsp.AudioPlayer`

Topics

Set the Audio Hardware API on page 2-868

Introduced in R2012a

step

System object: `dsp.AudioRecorder`
Package: `dsp`

Record audio from recording device

Compatibility

Note The `dsp.AudioRecorder` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceReader` object from Audio Toolbox instead.

Syntax

```
AUDIO = step(H)
[AUDIO,Overrun] = step(H)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`AUDIO = step(H)` reads one frame of audio samples from the selected audio input device.

`[AUDIO,Overrun] = step(H)` reads one frame of audio samples from the selected audio input device. The output `Overrun` indicates the number of samples dropped due to queue overrun since the last call to the `step` method. This syntax applies when you set the “OutputNumOverrunSamples” on page 4-0 property to `true`.

dsp.Autocorrelator

Package: `dsp`

Autocorrelation sequence

Description

The `Autocorrelator` object returns the autocorrelation sequence for a discrete-time, deterministic input, or the autocorrelation sequence estimate for a discrete-time, wide-sense stationary (WSS) random process at positive lags.

To obtain the autocorrelation sequence:

1. Create the `dsp.Autocorrelator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
ac = dsp.Autocorrelator
ac = dsp.Autocorrelator(Name,Value)
```

Description

`ac = dsp.Autocorrelator` returns an autocorrelator, `ac`, that computes the autocorrelation along the first dimension of an *N*-D array. By default, the autocorrelator computes the autocorrelation at lags from zero to *N* – 1, where *N* is the length of the input vector or the row dimension of the input matrix. Inputting a row vector results in a row of zero-lag autocorrelation sequence values, one for each column of the row vector. The default autocorrelator returns the unscaled autocorrelation and performs the computation in the time domain.

`ac = dsp.Autocorrelator(Name,Value)` returns an autocorrelator, `ac`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`MaximumLagSource` — Source of maximum lag

`Auto` (default) | `Property`

Specify how to determine the range of lags for the autocorrelation as `Auto` or `Property`. If the value of `MaximumLagSource` is `Auto`, the autocorrelator computes the autocorrelation over all nonnegative lags in the interval `[0, N-1]`, where *N* is the length of the first dimension of the input. Otherwise, the object computes the autocorrelation using lags in the range `[0,MaximumLag]`.

`MaximumLag` — Maximum positive lag

`1` (default) | `0` | positive integer

Specify the maximum lag as an integer greater than or equal to 0. The `MaximumLag` must be less than the length of the input data.

Dependencies

This property applies only when the `MaximumLagSource` property is `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Scaling` — Autocorrelation function scaling

`None` (default) | `Biased` | `Unbiased` | `Unity at zero-lag`

Specify the scaling to apply to the output as `None`, `Biased`, `Unbiased`, or `Unity at zero-lag`. Set this property to `None` to generate the autocorrelation function without

scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The `Biased` option scales the autocorrelation by 1/*N*, where *N* is the length of the input data. Scaling by 1/*N* yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by 1/*N* has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The `Unbiased` option scales the estimate of the autocorrelation by 1/*N* – 1. Scaling by *N* – 1 produces an unbiased estimate of the theoretical autocorrelation. However, using the unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the `Unity at zero-lag` option to normalize the autocorrelation estimate as identically one at lag zero. The default is `None`.

`Method` — Domain for computing autocorrelations
`Time Domain` (default) | `Frequency Domain`

Specify the domain for computing autocorrelations as `Time Domain` or `Frequency Domain`. You must set this property to `Time Domain` for fixed-point signals.

Fixed-Point Properties

`FullPrecisionOverride` — Full precision override for fixed-point arithmetic
`true` (default) | `false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

`RoundingMethod` — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the object is not in full precision mode.

`OverflowAction` — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the object is not in full precision mode.

`ProductDataType` — Product word and fraction lengths

`Full precision` (default) | `Same as input` | `Custom`

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain`.

`CustomProductDataType` — Product word and fraction lengths

`numerictype([],32,30)` (default) | numerictype

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `ProductDataType` property to `Custom`.

`AccumulatorDataType` — Accumulator word and fraction lengths

`Full precision` (default) | `Same as product` | `Same as input` | `Custom`

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`.

Dependencies

This property applies only when the `Method` property is `Time Domain`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype([],32,30)` (default) | numerictype

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `AccumulatorDataType` property to `Custom`.

`OutputDataType` — Output word and fraction lengths
`Same as accumulator` (default) | `Same as product` | `Same as input` | `Custom`

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`.

Dependencies

This property applies only when the `Method` property is `Time Domain`.

`CustomOutputDataType` — Output word and fraction lengths
`numerictype([],16,15)` (default) | numerictype

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `OutputDataType` property to `Custom`.

Usage

Syntax

```
y = ac(x)
```

Description

`y = ac(x)` computes the autocorrelation sequence `y` for the columns of the input `x`.

Input Arguments

x — Data input

vector | matrix | *N*-D array

Data input, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to `'Time Domain'`. When the input signal is complex, the output signal is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Autocorrelated output

vector | matrix | *N*-D array

Autocorrelated output of the two input signals. The size, data type, and complexity of the output matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Autocorrelation of Number Sequence

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
ac1 = dsp.Autocorrelator;
% x is a column vector
x = (1:100)';
y = ac1(x);
```

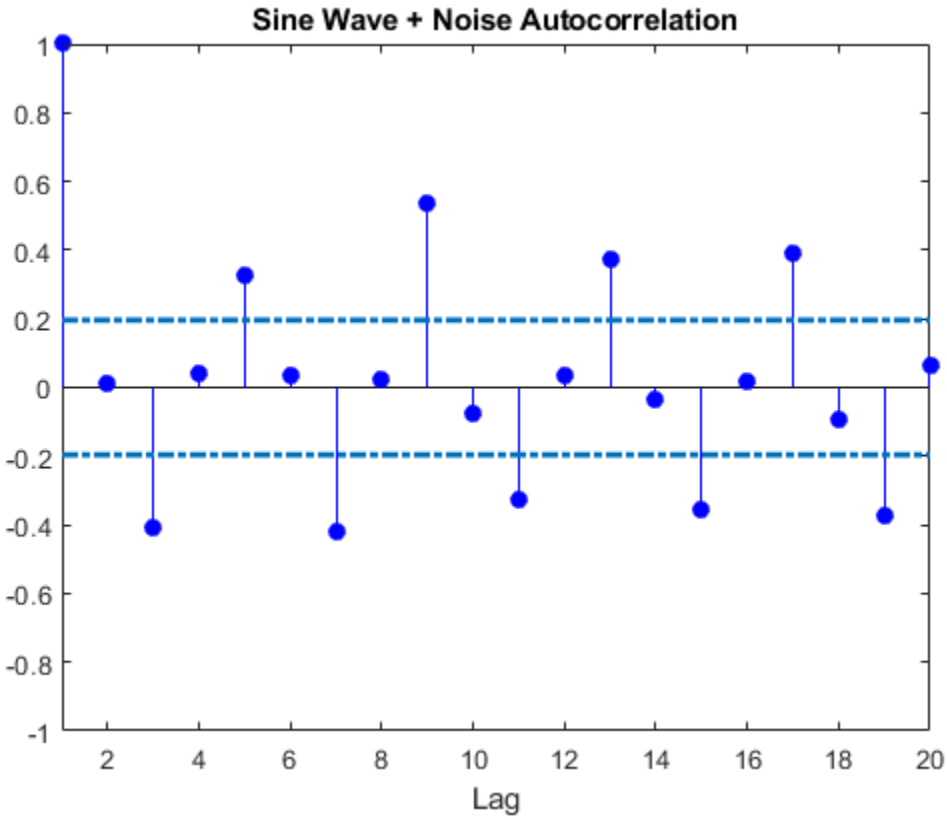
Autocorrelation of Noisy Sine Wave

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits.

```
S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))'+randn(100,1);
MaxLag = 20;
ac = dsp.Autocorrelator('MaximumLagSource',...
'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = ac(x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
```

```
     'linestyle','-.','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
     'linestyle','-.','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```



As this figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

More About

Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence, *x(n)*, the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0, 1, \ldots, N-1$$

where h is the lag and * denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where E{ } is the expectation operator. The `Unity at zero-lag` normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\widehat{\rho}_x(h) = \frac{1}{N}\sum_{k=0}^{N-h-1} x^*(n)x(n+h)$$

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence, y, is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u^*_{k,j} u_{(k+i),j} \qquad 0 \le i \le l$$

- $y_{0,j}$ is the zero-lag element in the jth column of the input.
- i is the index of the lag.
- j is the index of the input data column.
- * denotes the complex conjugate.
- M is the number of elements in each column.
- l is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags, $l=M–1$. Otherwise, l is the maximum nonnegative integer lag value specified.
- u is an M-by-N input matrix.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

dsp.BinaryFileReader

Package: `dsp`

Read data from binary file

Description

The `dsp.BinaryFileReader` System object reads multichannel signal data from a binary file. If the header is not empty, then the header precedes the signal data. The System object specifies the prototype of the header, and the type, size, and complexity of the data. The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the `dsp.BinaryFileWriter` System object.

The object accepts floating-point data or integer data. To read character data and fixed-point data, see the "Write and Read Character Data" on page 4-181 and "Write and Read Fixed-Point Data" on page 4-180 examples. The input data can be real or complex. When the data is complex, the object reads the data as interleaved real and imaginary components. For an example, see "Read Complex Data" on page 4-179. The reader assumes the default endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see "Change Endianness of Data" on page 4-182.

To read data from a binary file:

1. Create the `dsp.BinaryFileReader` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
reader = dsp.BinaryFileReader
reader = dsp.BinaryFileReader(fname)
reader = dsp.BinaryFileReader(fname,Name,Value)
```

Description

`reader = dsp.BinaryFileReader` creates a binary file reader object, `reader`, using the default properties.

`reader = dsp.BinaryFileReader(fname)` sets the `Filename` property to `fname`.

`reader = dsp.BinaryFileReader(fname,Name,Value)` with `Filename` set to `fname`, and each specified property set to the specified value. Unspecified properties have default values.

Example: `reader = dsp.BinaryFileReader('myFilename.bin','SamplesPerFrame',1000,'NumChannels',2);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Filename` — Name of file

`'Untitled.bin'` (default) | character vector | string scalar

Name of the file from which the object reads the data, specified as a character vector. If the file is not on the MATLAB path, then specify the full path for the file.

`HeaderStructure` — Size of header
`struct('Field1',[])` (default) | structure

The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this property to an empty structure, `struct([])`. To retrieve the file header, call the `readHeader` method on the reader object.

`SamplesPerFrame` — Number of samples per output frame
`1024` (default) | positive integer

Number of samples per output frame, specified as a positive integer. `SamplesPerFrame` specifies the number of rows of the output matrix that the object returns. The size of the data is `SamplesPerFrame`-by-`NumChannels`. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity.

`NumChannels` — Number of channels
`1` (default) | positive integer

Number of channels, specified as a positive integer. `NumChannels` specifies the number of columns of the output matrix that the object returns. This property defines the number of consecutive interleaved data samples stored in the file for each time instant. The size of the data is `SamplesPerFrame`-by-`NumChannels`. Once the end of file is reached, if the output matrix is not full, the object fills the matrix with zeros to make it a full-sized matrix.

`DataType` — Type of data in file
`'double'` (default) | `'single'` | `'int8'` | `'int16'` | `'int32'` | `'int64'` | `'uint8'` | `'uint16'` | `'uint32'` | `'uint64'`

Type of data in file, specified as a character vector. This property defines the data type of the matrix returned by the object algorithm.

`IsDataComplex` — Specify data complexity
`false` (default) | `true`

Option to specify data complexity, specified as `false` or `true`. When this property is set to `true`, the reader treats the data as complex. The object reads the data as interleaved

real and imaginary components. Consider a reader object configured to read the data as a 2-by-2 matrix. The object reads `[1 5 2 6 3 7 4 8]` as `[1 2; 3 4]+1j*[5 6; 7 8]`. If this property is set to `false`, the same object reads the data as `[1 5; 2 6]`.

Usage

Syntax

```
data = reader()
```

Description

`data = reader()` reads data from the binary file in a row-major format. The data type, size, and complexity of the data are determined by the properties of the reader object. Once the end of file is reached, the output contains zeros of the specified data type, size, and complexity.

Output Arguments

`data` — Data output
vector | matrix

Data read by the binary file reader, returned as a vector or a matrix. The size of the data is given by `SamplesPerFrame`-by-`NumChannels`, where `SamplesPerFrame` and `NumChannels` are the properties of the `dsp.BinaryFileReader` object.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.BinaryFileReader`

isDone End-of-data status

readHeader Read file header

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header as a structure with the following fields:

- DataType set to `double`.
- Complexity set to `false`.
- FrameSize (number of rows in the data matrix) set to 150.
- NumChannels (number of columns in the data matrix) set to 1.

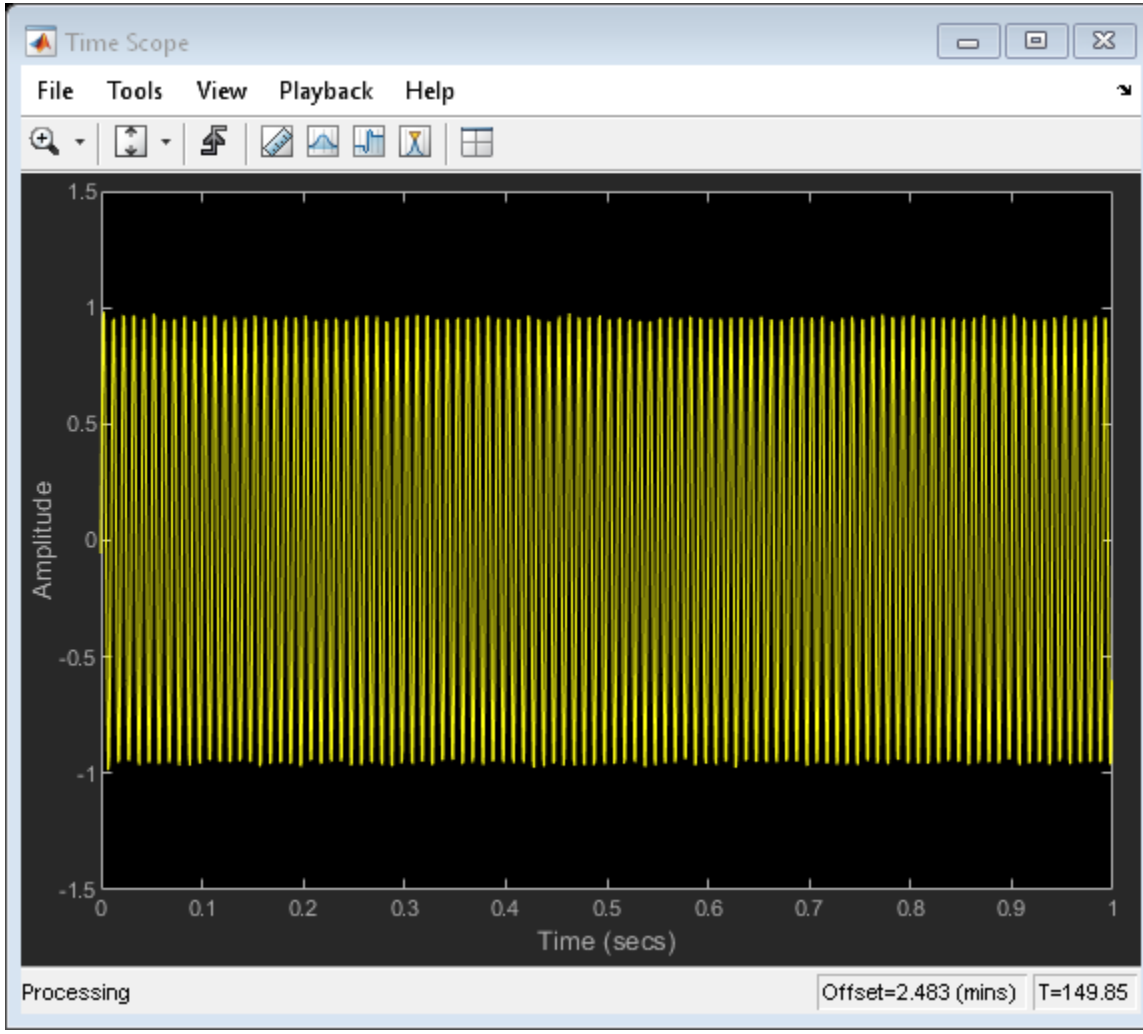
Create a `dsp.BinaryFileWriter` object using this header. The object writes the header first, followed by the data, to `ex_file.bin`. The data is a noisy sine wave signal. View the data in a time scope.

```
L = 150;
header = struct('DataType','double','Complexity',false,'FrameSize',L,'NumChannels',1);
writer = dsp.BinaryFileWriter('ex_file.bin','HeaderStructure',header);

sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    sine.SampleRate,'TimeSpan',1);

for i = 1:1000
    data = sine() + 0.01*randn(L,1);
```

```
        writer(data);
        scopewriter(data)
    end
```



Release the writer so that the reader can access the data from this file.

```
release(writer);
```

Read the Data

Read the data from the binary file, `ex_file.bin`, using the `dsp.BinaryFileReader` object. The file contains the header data followed by the actual data. The object reads the binary data until the end of file is reached. Specify the header to the reader using the `HeaderStructure` property of the reader object.

If the exact header is not known on the reader side, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. When the `readHeader` function reads the data from the binary file, the function extracts the header information based on how the fields are specified in the header prototype. For example, a header field set to `'double'` on the writer side can be specified as any string of 6 characters on the reader side. The `readHeader` function reads this field as a string of 6 characters from the binary file, which matches with `'double'`.

```
headerPrototype = struct('DataType','datype','Complexity',false,'FrameSize',1,'NumChann
reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype);
headerReader = readHeader(reader)
```

```
headerReader =

  struct with fields:

      DataType: 'double'
    Complexity: 0
     FrameSize: 150
   NumChannels: 1
```

The header data extracted by the `readHeader` function is assigned to the corresponding properties of the `reader` object.

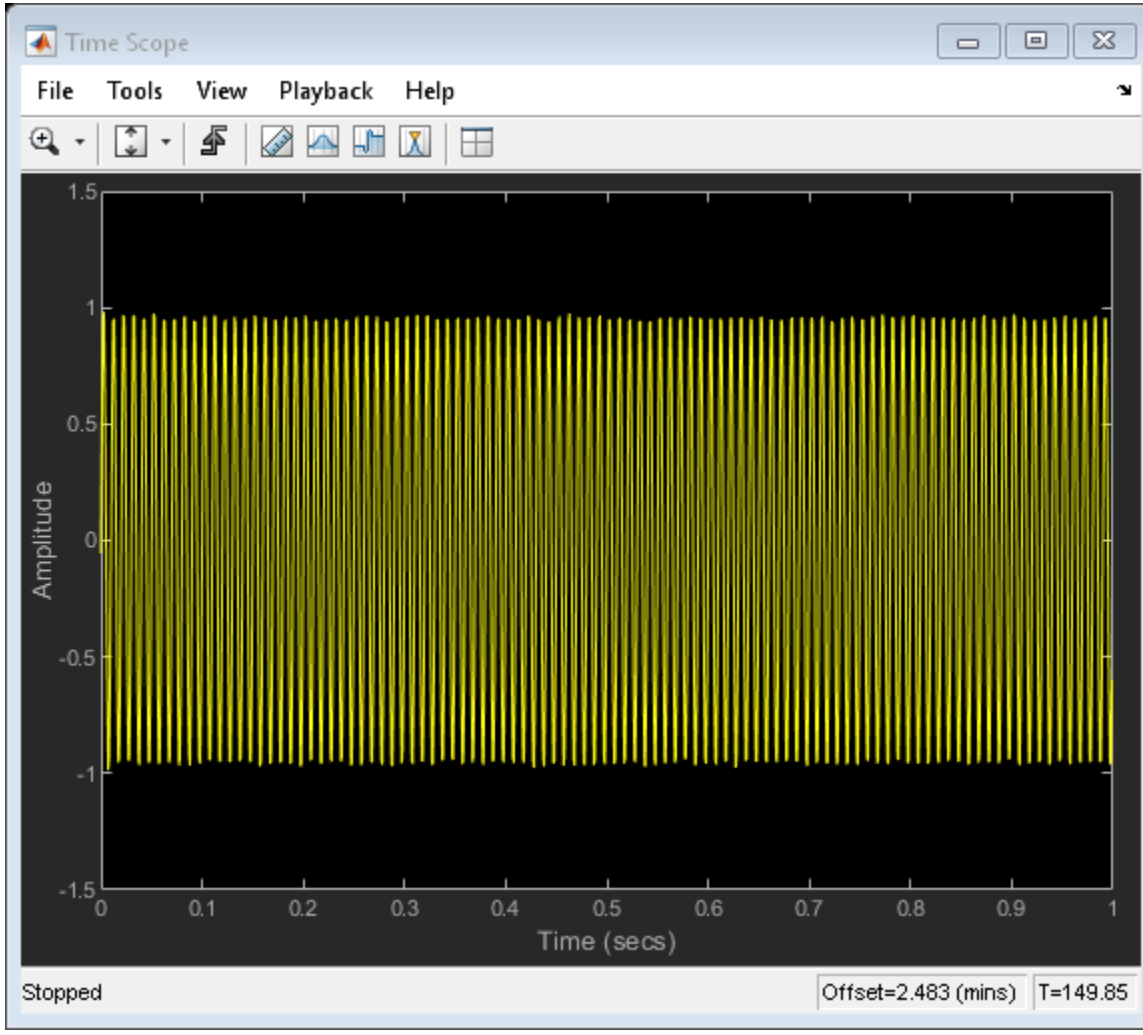
```
reader.IsDataComplex = headerReader.Complexity;
reader.DataType = headerReader.DataType;
reader.NumChannels = headerReader.NumChannels;
reader.SamplesPerFrame = headerReader.FrameSize;
```

Initialize a scope on the reader side to view the extracted binary file data.

```
scopereader = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    sine.SampleRate,'TimeSpan',1);
```

The data is read into a single channel (column) containing multiple frames, where each frame has 150 samples. View the data in a time scope.

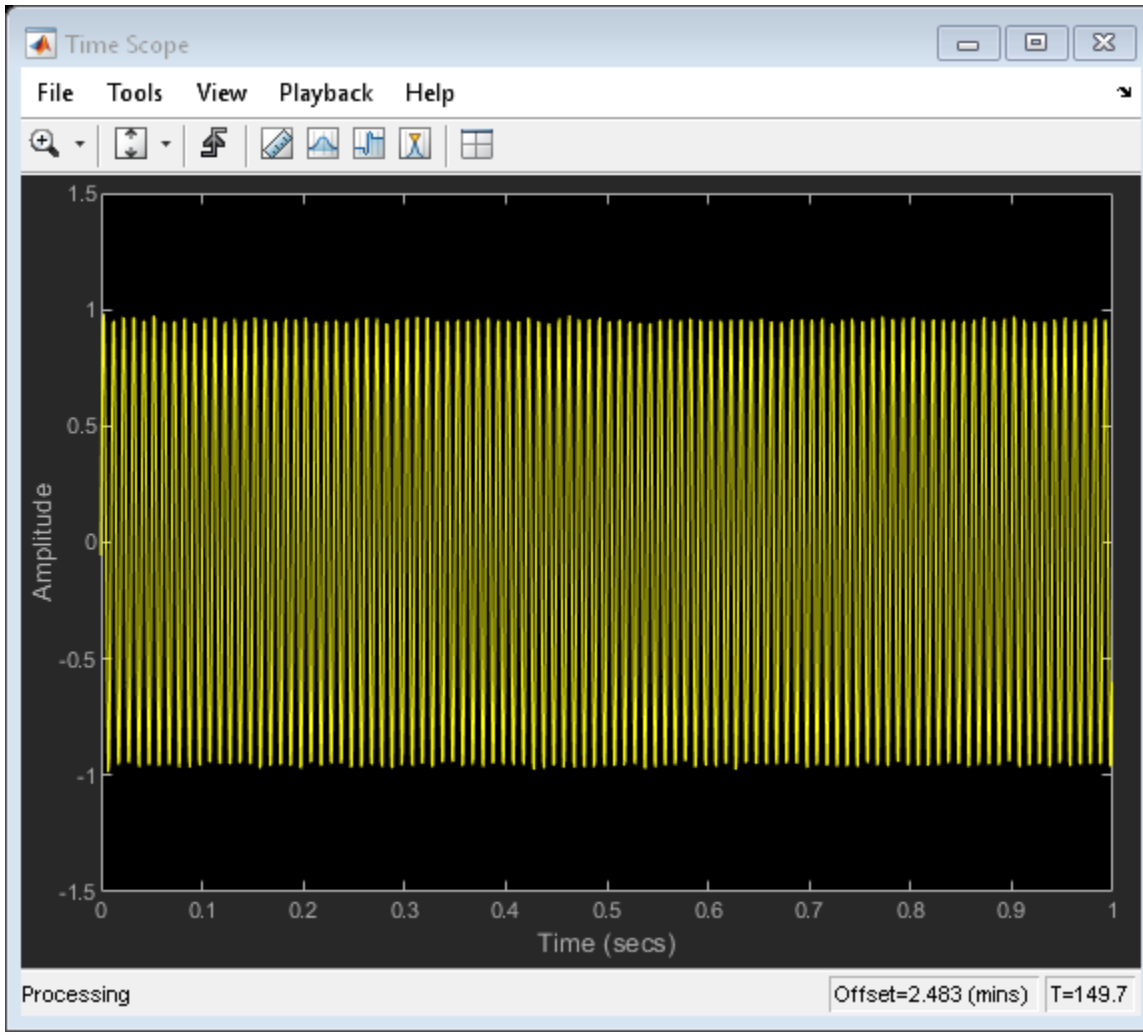
```
while ~isDone(reader)
    out = reader();
    scopereader(out)
end
release(reader);
release(scopereader);
```



Set the reader to read data in frames of size 300. Verify that the data read matches the data written to the file.

```
reader.SamplesPerFrame = 300;
while ~isDone(reader)
    out = reader();
    scopereader(out)
```

```
    end
    release(reader);
```



Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

The header has the following format:

- DataType set to `double`.
- Complexity set to `false`.
- FrameSize (number of rows in the data matrix) set to 3.
- NumChannels (number of columns in the data matrix) set to 4.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('DataType','double','Complexity',false,'FrameSize',3,'NumChannels',4);
writer = dsp.BinaryFileWriter('Matdata.bin','HeaderStructure',header);
writer(A);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Configure the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```
headerPrototype = struct('DataType','double','Complexity',false,'FrameSize',5,'NumChann
reader = dsp.BinaryFileReader('Matdata.bin','HeaderStructure',headerPrototype,'NumChann
    'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end
```

```
out = 5×4

     1     2     3     8
     4     5     6    10
     7     8     9    11
     0     0     0     0
     0     0     0     0
```

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is configured to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Read Header Data

Read the header data from a binary file using the `readHeader` function.

Write a header, followed by the data to a binary file named `myfile.dat`. The header is a 1-by-4 matrix of double precision values, followed by a 5-by-1 vector of single-precision values. The data is a sequence of 1000 double-precision values.

```
fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4],'double');
fwrite(fid,single((1:5).'),'single');
fwrite(fid,(1:1000).','double');
fclose(fid);
```

Read the header using a `dsp.BinaryFileReader` object. Specify the expected header structure. This structure specifies only the format of the expected binary file header and does not contain the exact values.

```
reader = dsp.BinaryFileReader('myfile.dat');
s = struct('A',zeros(1,4),'B',ones(5,1,'single'));
reader.HeaderStructure = s;
```

Read the header using the `readHeader` function.

```
H = readHeader(reader);
fprintf('H.A: ')
```

```
H.A:
```

```
fprintf('%d ',H.A);
```

```
1 2 3 4
```

```
fprintf('\nH.A datatype: %s\n',class(H.A))
```

```
H.A datatype: double
```

```
fprintf('H.B: ')
```

```
H.B:
```

```
fprintf('%d ',H.B);
```

```
1 2 3 4 5
```

```
fprintf('\nH.B datatype: %s\n',class(H.B))
```

```
H.B datatype: single
```

Read Complex Data

Read complex data from a binary file using the `dsp.BinaryFileReader` object.

Write a sequence of numbers to a binary file named `myfile.dat`. There is no header. The data is a 2-by-4 matrix of double-precision values. `fwrite` writes the data in a column-major format. That is, the 2-by-4 matrix `[1 2 3 4; 9 10 11 12]` is written as `[1 9 2 10 3 11 4 12]` in the binary file.

```
fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4; 9 10 11 12],'double');
fclose(fid);
```

Specify the data to be complex using the `IsDataComplex` property. The object reads the data as interleaved real and imaginary components. The `SamplesPerFrame` and `NumChannel` properties specify the number of rows and columns of the output data. The header structure is specified as empty.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',2,...
    'NumChannels',2,'IsDataComplex',true);
s = struct([]);
reader.HeaderStructure = s;
```

```
data = reader();
display(data);
```

```
data = 2×2 complex

   1.0000 + 9.0000i   2.0000 +10.0000i
   3.0000 +11.0000i   4.0000 +12.0000i
```

```
release(reader);
```

Alternatively, if you do not specify the data as complex, the reader reads the data as a `SamplesPerFrame`-by- `NumChannel` matrix of real values.

```
reader.IsDataComplex = false;
data = reader();
display(data);
```

```
data = 2×2

     1     9
     2    10
```

```
release(reader);
```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create an `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
```

```
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using $2^{(-fractionLength)}(storedInteger)$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using *fi*(*realValue*, *signedness*, *wordLength*, *fractionLength*). In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat','SamplesPerFrame',100,...
    'DataType','int16');
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);

fiDataReader = fi(realValue,1,wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)
```

```
ans = logical
   1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the `uint8` Data

Configure the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat','DataType','uint8','SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans = logical
   1
```

Change Endianness of Data

By default, the `dsp.BinaryFileReader` System object™ uses the endianness of the host machine. To change the endianness, such as when the host machine that writes the data does not have the same endianness as the host machine that reads the data, use the `swapbytes` function.

Write a numeric array into `myfile.dat` in big endian format. Read the data using the `dsp.BinaryFileReader` object. The reader object reads the data in little endian format.

```
fid = fopen('myfile.dat','w','b');
fwrite(fid,[1 2 3 4 5 6 7 8],'double');
```

```
fclose(fid);
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',8);
x = reader();
display(x);
```

```
x = 8×1
10^-318 ×

    0.3039
    0.0003
    0.0104
    0.0206
    0.0256
    0.0307
    0.0357
    0.0408
```

`x` does not match the original data. Change the endianness of `x` using the `swapbytes` function.

```
y = swapbytes(x);
display(y);
```

```
y = 8×1

     1
     2
     3
     4
     5
     6
     7
     8
```

`y` matches the original data.

dsp.BinaryFileWriter

Package: `dsp`

Write data to binary files

Description

The `dsp.BinaryFileWriter` System object writes multichannel signal data to a binary file. If the header is not empty, then the header precedes the signal data. The object specifies the file name and the structure of the header. The first time you write to the file, the object writes the header, followed by the data. On subsequent calls, the object writes the remaining data. If the header is empty, then no header is written.

The object can write floating-point data and integer data. To write character data and fixed-point data, see “Write and Read Character Data” on page 4-198 and “Write and Read Fixed-Point Data” on page 4-197. The input data can be real or complex. When the data is complex, the object writes the data as interleaved real and imaginary components. For an example, see “Write and Read Fixed-Point Data” on page 4-197. By default, the writer uses the endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change Endianness of Data Before Writing” on page 4-199 .

To write data to a binary file:

1. Create the `dsp.BinaryFileWriter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
writer = dsp.BinaryFileWriter
```

```
writer = dsp.BinaryFileWriter(fname)
writer = dsp.BinaryFileWriter(fname,Name,Value)
```

Description

`writer = dsp.BinaryFileWriter` creates a binary file writer object, `writer`, using the default properties.

`writer = dsp.BinaryFileWriter(fname)` sets the `Filename` property to `fname`.

`writer = dsp.BinaryFileWriter(fname,Name,Value)` with `Filename` set to `fname` and each property `Name` set to the specified `Value`. Unspecified properties have default values.

Example: `writer = dsp.BinaryFileWriter('myFilename.bin','HeaderStructure',struct('field1',1:10,'field2',single(1)));`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Filename` — Name of file

`'untitled.bin'` (default) | character vector | string scalar

Name of the file to which the object writes the data, specified as a character vector or a string scalar. You must specify the full path for the file.

`HeaderStructure` — Header to write at beginning of file

`struct([])` (default) | structure

Header to write at the beginning of the file, specified as a structure. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a

built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object writes a header formed by 10 double-precision values, `(1:10)`, followed by one single precision value, `single(1)`. If you do not specify a header, the object sets this property to an empty structure, `struct([])`.

Usage

Syntax

```
writer(data)
```

Description

`writer(data)` writes data to the binary file in a row-major format. Each call to the algorithm writes the elements of `data` at the end of the file. At the first call to the algorithm, the object writes the header first, followed by the data. If the header is empty, then no header is written.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if the data equals `[1 2; 3 4]+1j*[5 6; 7 8]`, then the object writes the elements as `1 5 2 6 3 7 4 8`.

Input Arguments

`data` — Data to be written to file

vector | matrix

Data to be written to the binary file in a row-major format, specified as a vector or a matrix. The object writes the data in row-major format. For example, if the input array is `[1 2 4 5; 8 7 9 2]`, the object writes the data as `[1 2 4 5 8 7 9 2]`.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if the data equals `[1 2; 3 4]+1j*[5 6; 7 8]`, then the object writes the elements as `[1 5 2 6 3 7 4 8]`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header as a structure with the following fields:

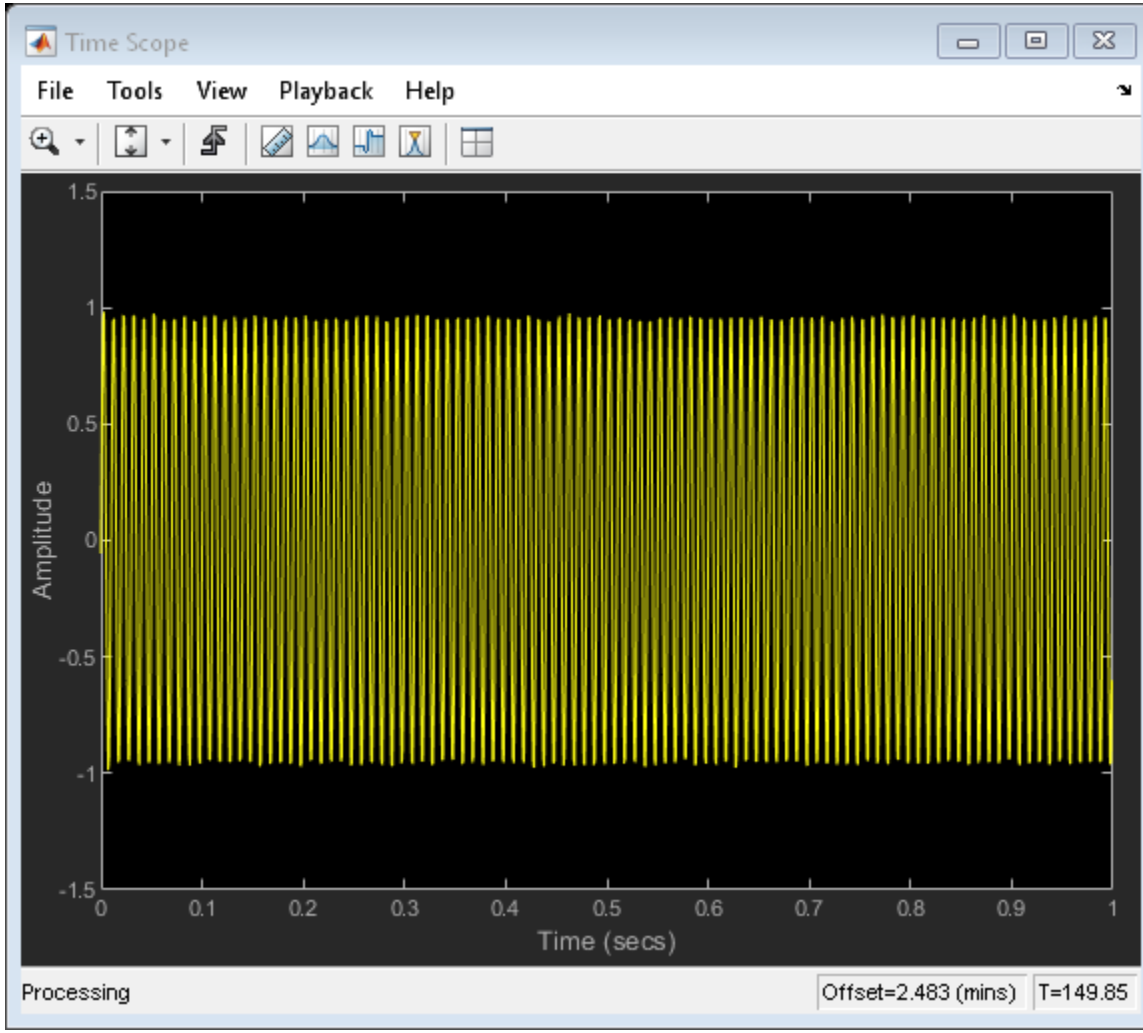
- DataType set to `double`.
- Complexity set to `false`.
- FrameSize (number of rows in the data matrix) set to 150.
- NumChannels (number of columns in the data matrix) set to 1.

Create a `dsp.BinaryFileWriter` object using this header. The object writes the header first, followed by the data, to `ex_file.bin`. The data is a noisy sine wave signal. View the data in a time scope.

```
L = 150;
header = struct('DataType','double','Complexity',false,'FrameSize',L,'NumChannels',1);
writer = dsp.BinaryFileWriter('ex_file.bin','HeaderStructure',header);
```

```
sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    sine.SampleRate,'TimeSpan',1);

for i = 1:1000
    data = sine() + 0.01*randn(L,1);
    writer(data);
    scopewriter(data)
end
```



Release the writer so that the reader can access the data from this file.

```
release(writer);
```

Read the Data

Read the data from the binary file, `ex_file.bin`, using the `dsp.BinaryFileReader` object. The file contains the header data followed by the actual data. The object reads the

binary data until the end of file is reached. Specify the header to the reader using the `HeaderStructure` property of the reader object.

If the exact header is not known on the reader side, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. When the `readHeader` function reads the data from the binary file, the function extracts the header information based on how the fields are specified in the header prototype. For example, a header field set to `'double'` on the writer side can be specified as any string of 6 characters on the reader side. The `readHeader` function reads this field as a string of 6 characters from the binary file, which matches with `'double'`.

```
headerPrototype = struct('DataType','datype','Complexity',false,'FrameSize',1,'NumChann
reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype);
headerReader = readHeader(reader)
```

```
headerReader =

  struct with fields:

       DataType: 'double'
     Complexity: 0
      FrameSize: 150
    NumChannels: 1
```

The header data extracted by the `readHeader` function is assigned to the corresponding properties of the `reader` object.

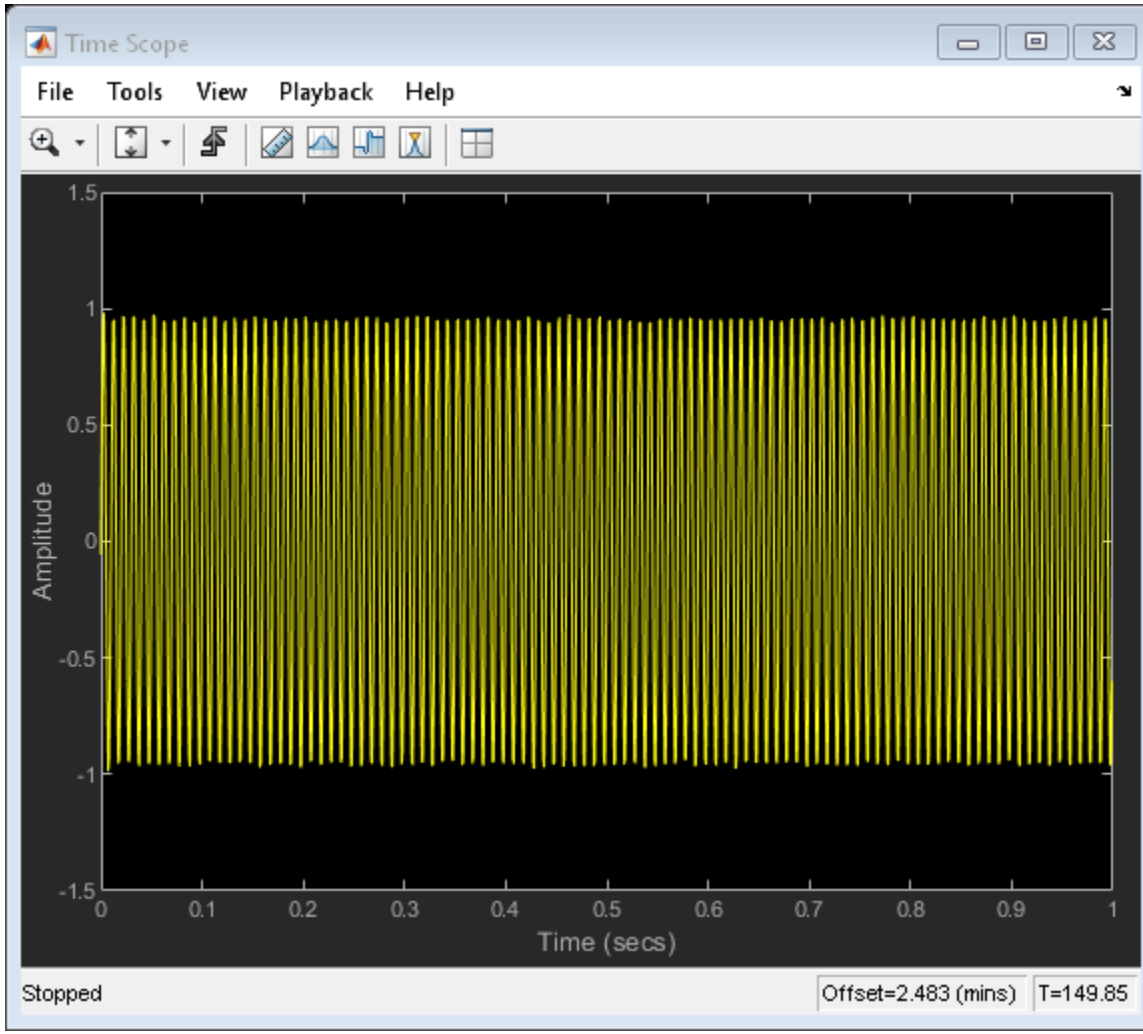
```
reader.IsDataComplex = headerReader.Complexity;
reader.DataType = headerReader.DataType;
reader.NumChannels = headerReader.NumChannels;
reader.SamplesPerFrame = headerReader.FrameSize;
```

Initialize a scope on the reader side to view the extracted binary file data.

```
scopereader = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    sine.SampleRate,'TimeSpan',1);
```

The data is read into a single channel (column) containing multiple frames, where each frame has 150 samples. View the data in a time scope.

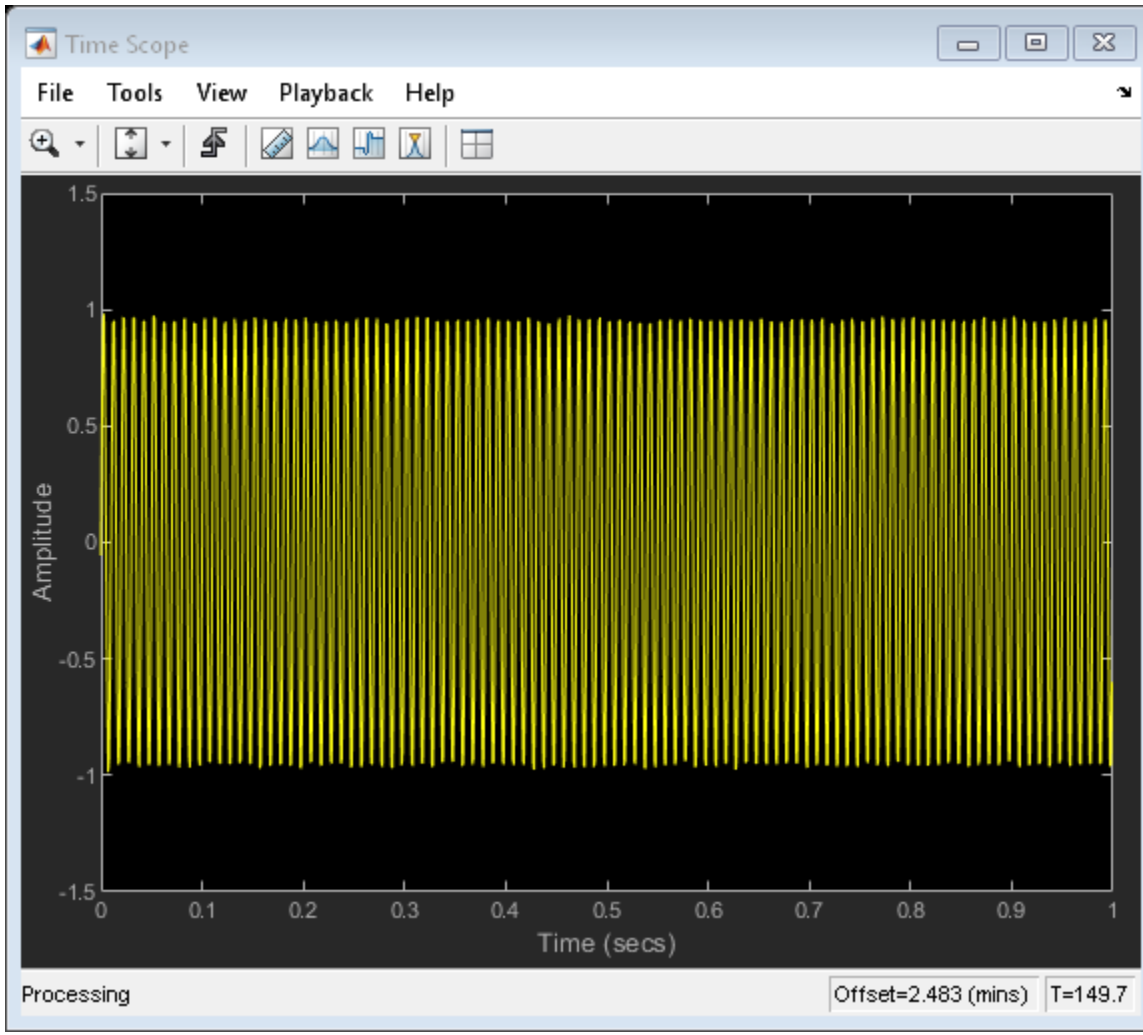
```
while ~isDone(reader)
    out = reader();
    scopereader(out)
end
release(reader);
release(scopereader);
```



Set the reader to read data in frames of size 300. Verify that the data read matches the data written to the file.

```
reader.SamplesPerFrame = 300;
while ~isDone(reader)
    out = reader();
    scopereader(out)
```

```
    end
    release(reader);
```



Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

The header has the following format:

- DataType set to `double`.
- Complexity set to `false`.
- FrameSize (number of rows in the data matrix) set to 3.
- NumChannels (number of columns in the data matrix) set to 4.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('DataType','double','Complexity',false,'FrameSize',3,'NumChannels',4);
writer = dsp.BinaryFileWriter('Matdata.bin','HeaderStructure',header);
writer(A);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Configure the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```
headerPrototype = struct('DataType','double','Complexity',false,'FrameSize',5,'NumChann
reader = dsp.BinaryFileReader('Matdata.bin','HeaderStructure',headerPrototype,'NumChann
    'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end
```

```
out = 5×4

     1     2     3     8
     4     5     6    10
     7     8     9    11
     0     0     0     0
     0     0     0     0
```

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is configured to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Write Complex Data

Create a `dsp.BinaryFileWriter` object which writes to a file named `myfile.dat`. There is no header. The data is complex.

```
writer = dsp.BinaryFileWriter('myfile.dat');
data = [1 2 3 4]+1i*[5 6 7 8];
writer(data);
release(writer);
```

Read the data using the `dsp.BinaryFileReader` System object™. To view data in the format it is written to the file, set the `IsDataComplex` property to `false`. The reader object reads the data as a sequence of numbers in a row major format. Set `SamplesPerFrame` to 1 and `NumChannels` to 8.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',1,...
    'NumChannels',8);
s = struct([]);
reader.HeaderStructure = s;
dataRead = reader();
```

You can see that the real and imaginary components of the original data are sample interleaved.

```
display(dataRead);
```

```
dataRead = 1×8
```

```
     1     5     2     6     3     7     4     8
```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create an `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using $2^{(-fractionLength)}(storedInteger)$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using *fi*(*realValue*, *signedness*, *wordLength*, *fractionLength*). In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat','SamplesPerFrame',100,...
    'DataType','int16');
data = reader();
fractionLength = 12;
```

```
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);

fiDataReader = fi(realValue,1,wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)

ans = logical
   1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the `uint8` Data

Configure the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat','DataType','uint8','SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans = logical
   1
```

Change Endianness of Data Before Writing

By default, the `dsp.BinaryFileWriter` System object™ uses the endianness of the host machine. To change the endianness, use the `swapbytes` function.

Write a numeric array into `myfile.dat` using the `dsp.BinaryFileWriter` object. Before writing the data, change the endianness of the data using the `swapbytes` function.

```
data = [1 2 3 4 2 2];
swapData = swapbytes(data);
writer = dsp.BinaryFileWriter('myfile.dat');
writer(swapData);
```

dsp.BiquadFilter

Package: `dsp`

IIR filter using biquadratic structures

Description

The `dsp.BiquadFilter` object implements an IIR filter structure using biquadratic or second–order sections (SOS).

To implement an IIR filter structure using biquadratic or SOS:

1. Create the `dsp.BiquadFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
biquad = dsp.BiquadFilter
biquad = dsp.BiquadFilter(sosmatrix,scalevalues)
biquad = dsp.BiquadFilter(Name,Value)
```

Description

`biquad = dsp.BiquadFilter` returns a biquadratic IIR (SOS) filter System object, `biquad`, which independently filters each channel (column) of the input over time using the SOS section `[1 0.3 0.4 1 0.1 0.2]` with a direct-form II transposed structure.

`biquad = dsp.BiquadFilter(sosmatrix,scalevalues)` returns a biquadratic filter object, with the `SOSMatrix` property set to `sosmatrix` and the `ScaleValues` property set to `scalevalues`.

`biquad = dsp.BiquadFilter(Name,Value)` returns a biquadratic filter object, `biquad`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Structure` — Filter structure

`'Direct form II transposed'` (default) | `'Direct form I'` | `'Direct form I transposed'` | `'Direct form II'`

Specify the filter structure as `'Direct form I'`, `'Direct form I transposed'`, `'Direct form II'`, `'Direct form II transposed'`.

`SOSMatrixSource` — SOS matrix source

`'Property'` (default) | `'Input port'`

Specify the source of the SOS matrix as `'Property'` or `'Input port'`.

`SOSMatrix` — SOS matrix

`[1 0.3 0.4 1 0.1 0.2]` (default) | *N*-by-6 matrix

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function, *H(z)*, of a biquad filter is:

$$H(z) = \frac{\sum_{k=0}^{2} b_k z^{-k}}{1 - \sum_{l=1}^{2} a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as (b_0, b_1, b_2, 1, $-a_1$, $-a_2$). You can use coefficients of real or complex values. This property applies only when you set the

`SOSMatrixSource` property to `Property`. The leading denominator coefficient of the biquad filter, a_0, equals 1 for each filter section, regardless of the specified value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

`ScaleValues` — Scale values for each biquad section

1 (default) | scalar | vector

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be either a scalar or a vector of length `N+1`, where `N` is the number of sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to `1`. If you set this property to a vector of `N+1`values, each value is used for a separate section of the filter.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialConditions` — Initial conditions for direct form II structures

`0` (default) | scalar | vector | matrix

Specify the initial conditions of the filter states when the `Structure` property is one of | `Direct form II` | `Direct form II transposed` |. The number of states or delay elements (zeros and poles) in a direct-form II biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all delay elements in the filter to that value. When you specify a vector of length equal to the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Dependencies

This property applies only when you set the `Structure` property to one of `Direct form II` or `Direct form II transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumeratorInitialConditions` — Initial conditions on zeros side

`0` (default) | scalar | vector | matrix

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. The number of states or delay elements in the numerator of a direct-form I biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the zeros side in the filter to that value. When you specify a vector of length equal to the number of delay elements on the zeros side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

Dependencies

This property applies only when you set the `Structure` property to one of `Direct form I` or `Direct form I transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DenominatorInitialConditions` — Initial conditions on poles side

`0` (default) | scalar | vector | matrix

Specify the initial conditions of the filter states on the side of the filter structure with the poles. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter

initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

Dependencies

This property only applies when you set the `Structure` property to one of `Direct form I` or `Direct form I transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OptimizeUnityScaleValues` — Optimize unity scale values

`true` (default) | `false`

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

`ScaleValuesInputPort` — How to specify scale values

`true` (default) | `false`

Select how to specify scale values. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

Dependencies

This property applies only when the `SOSMatrixSource` property is `Input port`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

`MultiplicandDataType` — Multiplicand word and fraction lengths
`Same as output` (default) | `Custom`

Specify the multiplicand fixed-point data type as one of `Same as output` or `Custom`.

Dependencies

This property applies only when you set the `Structure` property to `Direct form I transposed`.

`CustomMultiplicandDataType` — Custom multiplicand word and fraction lengths
`numerictype([],32,30)` (default) | numerictype

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `MultiplicandDataType` property to `Custom`.

`SectionInputDataType` — Section input word and fraction lengths
`Same as input` (default) | `Custom`

Specify the section input fixed-point data type as either `Same as input` or `Custom`.

`CustomSectionInputDataType` — Custom section input word and fraction lengths
`numerictype([],16,15)` (default) | numerictype

Specify the section input fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `SectionInputDataType` property to `Custom`.

`SectionOutputDataType` — Section output word and fraction lengths

`Same as section input` (default) | `Custom`

Specify the section output fixed-point data type as either `Same as section input` or `Custom`.

`CustomSectionOutputDataType` — Custom section output word and fraction lengths

`numerictype([],16,15)` (default) | numerictype

Specify the section output fixed-point type as a signed, scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `SectionOutputDataType` property to `Custom`.

`NumeratorCoefficientsDataType` — Numerator coefficients word and fraction lengths

`Same word length as input` (default) | `Custom`

Specify the numerator coefficients fixed-point data type as `Same word length as input` or `Custom`. Setting this property also sets the `DenominatorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

`CustomNumeratorCoefficientsDataType` — Custom numerator coefficients word and fraction lengths

`numerictype([],16,15)` (default) | numerictype

Specify the numerator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. The word length of the `CustomNumeratorCoefficientsDataType`,

`CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must be the same.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property` and the `NumeratorCoefficientsDataType` property to `Custom`.

`DenominatorCoefficientsDataType` — Denominator coefficients word and fraction lengths

`Same word length as input` (default) | `Custom`

Specify the denominator coefficients fixed-point data type as `Same word length as input` or `Custom`. Setting this property also sets the `NumeratorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

`CustomDenominatorCoefficientsDataType` — Custom denominator coefficients word and fraction lengths

`numerictype([],16,15)` (default) | `numerictype`

Specify the denominator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property` and the `DenominatorCoefficientsDataType` property to `Custom`.

`ScaleValuesDataType` — Scale values word and fraction lengths

`Same word length as input` (default) | `Custom`

Specify the scale values fixed-point data type as `Same word length as input` or `Custom`. Setting this property also sets the `NumeratorCoefficientsDataType` and `DenominatorCoefficientsDataType` properties to the same value.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

`CustomScaleValuesDataType` — Custom scale values word and fraction lengths

`numerictype([],16,15)` (default) | numerictype

Specify the scale values fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property` and the `ScaleValuesDataType` property to `Custom`.

`NumeratorProductDataType` — Numerator product word and fraction lengths

`Same as input` (default) | `Custom` | `Full precision`

Specify the mode to determine the numerator product fixed-point data type as:

- `Same as input` (default) — The numerator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomNumeratorProductDataType` property, which you can use to specify the custom numerator product data type. Specify the data type as a `numerictype` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `DenominatorProductDataType` property to the same value.

`CustomNumeratorProductDataType` — Custom numerator product word and fraction lengths

`numerictype([],32,30)` (default) | numerictype

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `NumeratorProductDataType` property to `Custom`.

`DenominatorProductDataType` — Denominator product word and fraction lengths

`Same as input` (default) | `Custom` | `Full precision`

Specify the mode to determine the denominator product fixed-point data type as:

- `Same as input` (default) — The denominator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomDenominatorProductDataType` property, which you can use to specify the custom denominator product data type. Specify the data type as a `numerictype` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `NumeratorProductDataType` property to the same value.

`CustomDenominatorProductDataType` — Custom denominator product word and fraction lengths

`numerictype([],32,30)` (default) | numerictype

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `DenominatorProductDataType` to `Custom`.

`NumeratorAccumulatorDataType` — Numerator accumulator word and fraction lengths

`Same as product` (default) | `Same as input` | `Custom`

Specify the numerator accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. Setting this property also sets the `DenominatorAccumulatorDataType` property to the same value.

`CustomNumeratorAccumulatorDataType` — Custom numerator accumulator word and fraction lengths

`numerictype([],32,30)` (default) | numerictype

Specify the numerator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `NumeratorAccumulatorDataType` property to `Custom`.

`DenominatorAccumulatorDataType` — Denominator accumulator word and fraction lengths

`Same as product` (default) | `Same as input` | `Custom`

Specify the denominator accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. Setting this property also sets the `NumeratorAccumulatorDataType` property to the same value.

`CustomDenominatorAccumulatorDataType` — Custom denominator accumulator word and fraction lengths

`numerictype([],32,30)` (default) | numerictype

Specify the denominator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `DenominatorAccumulatorDataType` property to `Custom`.

`StateDataType` — State word and fraction lengths

`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the state fixed-point data type as `Same as input`, `Same as accumulator`, or `Custom`.

Dependencies

This property applies when you set the "Structure" on page 4-0 property to `Direct form II` or `Direct form II transposed`.

`CustomStateDataType` — Custom state word and fraction lengths
`numerictype([],16,15)` (default) | numerictype

Specify the state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `StateDataType` property to `Custom`.

`NumeratorStateDataType` — Numerator state word and fraction lengths
`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the numerator state fixed-point data type as `Same as input`, `Same as accumulator`, or `Custom`. Setting this property also sets the `DenominatorStateDataType` property to the same value.

Dependencies

This property applies only when you set the "Structure" on page 4-0 property to `Direct form I transposed`.

`CustomNumeratorStateDataType` — Custom numerator state word and fraction lengths
`numerictype([],16,15)` (default) | numerictype

Specify the numerator state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `StateDataType` property to `Custom`.

`DenominatorStateDataType` — Denominator state word and fraction lengths
`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the denominator state fixed-point data type as `Same as input`, `Same as accumulator`, or `Custom`. Setting this property also sets the `NumeratorStateDataType` property to the same value.

Dependencies

This property applies only when you set the "Structure" on page 4-0 property to `Direct form I transposed`.

`CustomDenominatorStateDataType` — Custom denominator state word and fraction lengths

`numerictype([],16,15)` (default) | numerictype

Specify the denominator state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The `CustomNumeratorStateDataType` and `CustomDenominatorStateDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `StateDataType` property to `Custom`.

`OutputDataType` — Output word and fraction lengths

`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the output fixed-point data type as `Same as input`, `Same as accumulator`, or `Custom`.

`CustomOutputDataType` — Custom output word and fraction lengths

`numerictype([],16,15)` (default) | numerictype

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the "OutputDataType" on page 4-0 property to `Custom`.

Usage

Syntax

```
y = biquad(x)
y = biquad(x,num,den)
y = biquad(x,num,den,g)
```

Description

`y = biquad(x)` filters the input signal `x` , and outputs the filtered values, `y`. The biquad filter object filters each channel of the input signal over successive calls to the algorithm.

`y = biquad(x,num,den)` filters the input using `num` as the numerator coefficients, and `den` as the denominator coefficients of the biquad filter. This configuration applies when the `SOSMatrixSource` property is `Input port` and the `ScaleValuesInputPort` property is `false`.

`y = biquad(x,num,den,g)` specifies the scale values, `g`, of the biquad filter. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is `true`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

The data type of all the inputs must be the same. If the input is fixed-point, it must be signed fixed point with power-of-two slope and zero bias.

The complexity of `x`, `num`, and `den` must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

`num` — Numerator coefficients

3-by-*N* matrix

Numerator coefficients, specified as a 3-by-*N* numeric matrix, where *N* is the number of biquad filter sections. The complexity of `x`, `num`, and `den` must be the same.

The data type of all the inputs must be the same. If `num` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

Dependencies

This input applies only when you set `SOSMatrixSource` property is `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`
Complex Number Support: Yes

`den` — Denominator coefficients

2-by-*N* matrix

Denominator coefficients, specified as a 2-by-*N* numeric matrix, where *N* is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1.

The data type of all the inputs must be the same. If `den` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

The complexity of `x`, `num`, and `den` must be the same.

Dependencies

This input applies only when you set `SOSMatrixSource` property is `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`
Complex Number Support: Yes

`g` — Scale values

1-by-(*N* +1) vector

Scale values of the biquad filter, specified as a 1-by-(*N* +1) numeric vector, where `N` is the number of biquad filter sections.

The data type of all the inputs must be the same. If `g` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

Dependencies

This input applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.BiquadFilter`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Filter coefficients
cost	Estimate cost for implementing filter System objects
scale	Scale second-order sections of dsp.BiquadFilter System object
scaleopts	Create an options object for second-order section scaling
scalecheck	Check scaling of dsp.BiquadFilter System object
cumsec	Cumulative second-order section of BiquadFilter System object
sos	Convert quantized filter to second–order sections (SOS) form
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
tf	Convert discrete-time filter System object to transfer function

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Filter a Signal Using Biquadratic Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a power spectrum using the Spectrum Analyzer.

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t); % Input is 0.3 &amp;amp;
                                         % 3kHz sinusoids
src = dsp.SignalSource(xin, 100);
sink = dsp.SignalSink;

[z,p,k] = ellip(4,1,60,.4);    % Set up the filter
[s,g] = zp2sos(z,p,k);
biquad = dsp.BiquadFilter(s,g,'Structure','Direct form I');

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-160 -10]);

while ~isDone(src)
     input = src();
     filteredOutput = biquad(input);
     sink(filteredOutput);
     sa(filteredOutput)
end

filteredResult = sink.Buffer;
fvtool(biquad,'Fs',8000)
```

Design and apply a lowpass biquad filter System object using the `design` function.

```
lpSpec = fdesign.lowpass('Fp,Fst,Ap,Ast',500,550,0.5,60,10000);
lpfilter = design(lpSpec,'butter','systemobject',true)
fvtool(lpfilter);
```

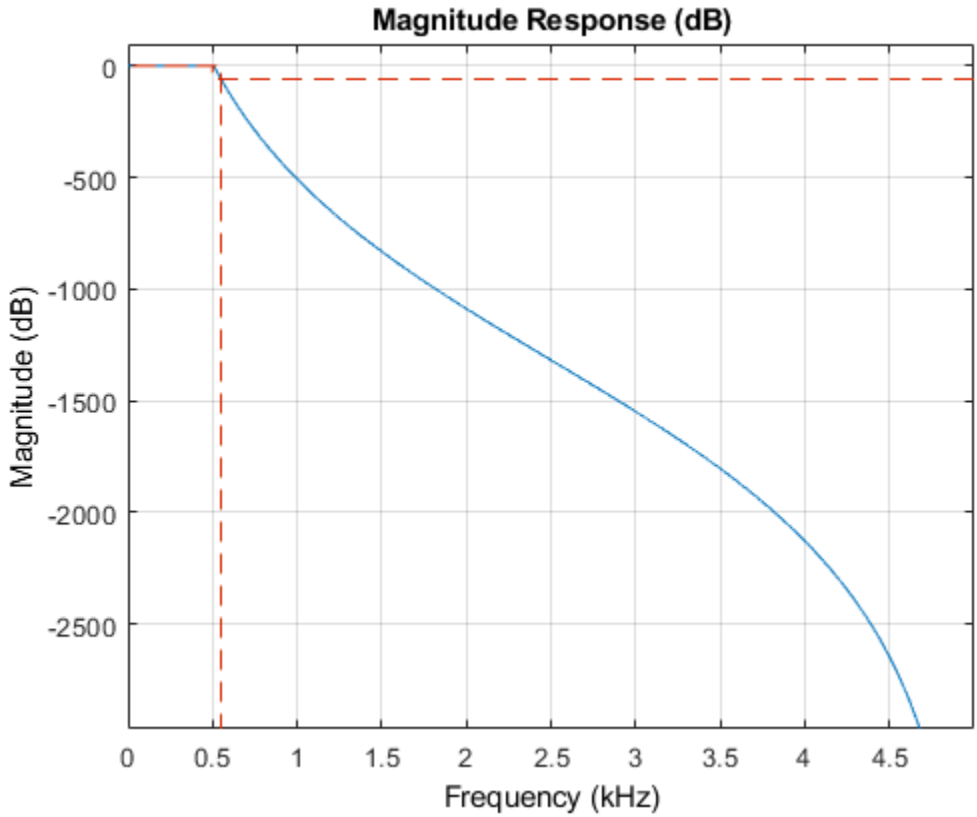
```
lpfilter =

  dsp.BiquadFilter with properties:

                Structure: 'Direct form II'
          SOSMatrixSource: 'Property'
                SOSMatrix: [42x6 double]
```

```
                ScaleValues: [43x1 double]
           InitialConditions: 0
  OptimizeUnityScaleValues: true

  Use get to show all properties
```



Linf-norm Scaling of a Biquad Filter

Demonstrate the Linf-norm scaling of a biquad filter using the `scale` function.

```
Fs = 8000; Fcutoff = 2000;
[z,p,k] = butter(10,Fcutoff/(Fs/2)); [s,g] = zp2sos(z,p,k);
```

```
biquad = dsp.BiquadFilter('Structure', 'Direct form I', ...
    'SOSMatrix', s,'ScaleValues', g);
scale(biquad,'linf','scalevalueconstraint','none','maxscalevalue',2)
```

Options for scaling SOS filter

Create an options scaling object that contains the scaling options settings you require.

```
EllipI = design(fdesign.lowpass('N,Fp,Ap,Ast',10,0.5,0.5,20), 'ellip', 'FilterStructure
```

```
EllipI =
  dsp.BiquadFilter with properties:

                      Structure: 'Direct form I'
                SOSMatrixSource: 'Property'
                      SOSMatrix: [5x6 double]
                   ScaleValues: [6x1 double]
      NumeratorInitialConditions: 0
    DenominatorInitialConditions: 0
        OptimizeUnityScaleValues: true

  Show all properties
```

```
opts = scaleopts(EllipI)
```

```
opts =

              sosReorder: 'auto'
           MaxNumerator: 2
     NumeratorConstraint: 'none'
            OverflowMode: 'wrap'
    ScaleValueConstraint: 'unit'
          MaxScaleValue: 'Not used'
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Biquad Filter block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source**
- **Action when the a0 values of the SOS matrix are not one** – the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the `Error` or `Warn` options found in the corresponding block.

Both this object and its corresponding block support variable-size input. When you call the object, it can handle an input argument which is changing in size.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

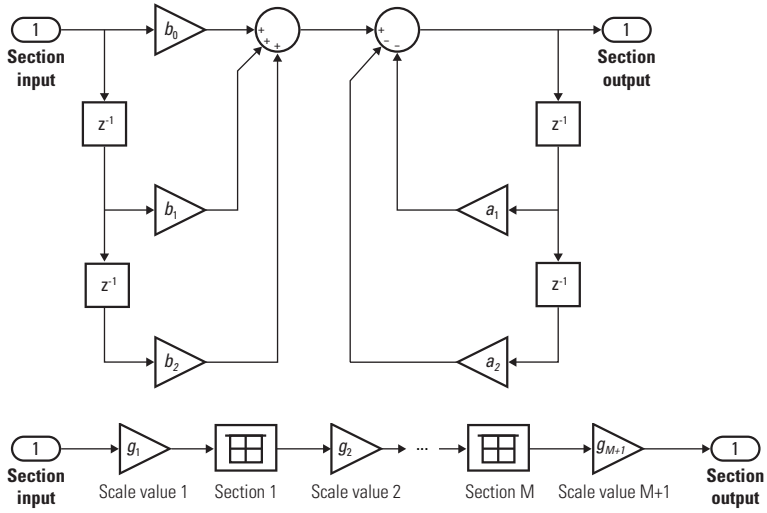
See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

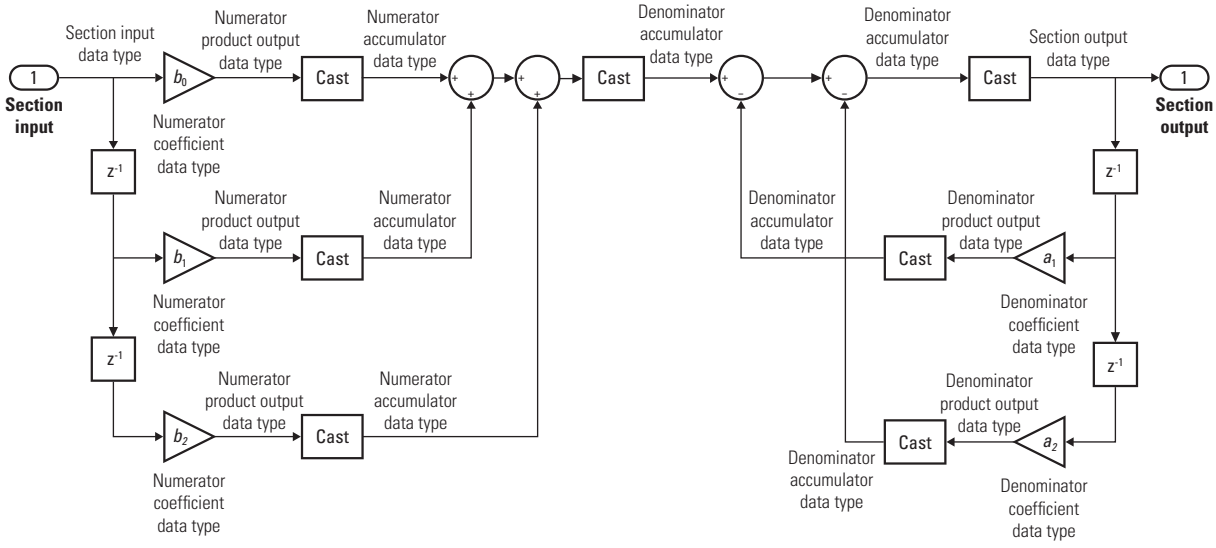
Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagrams show the data types used in the `dsp.BiquadFilter` object when the input is fixed-point. For each filter structure the object supports, the data types shown in the diagrams can be set through the respective fixed-point properties of the object.

Direct Form I

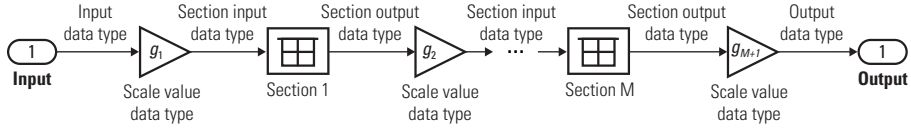


The following diagram shows the data types for one section of the filter for fixed-point signals.

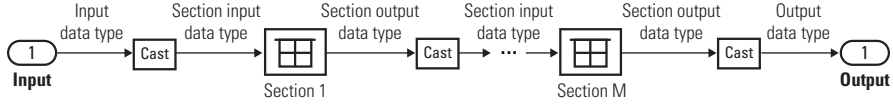


The following diagrams show the fixed-point data types between filter sections.

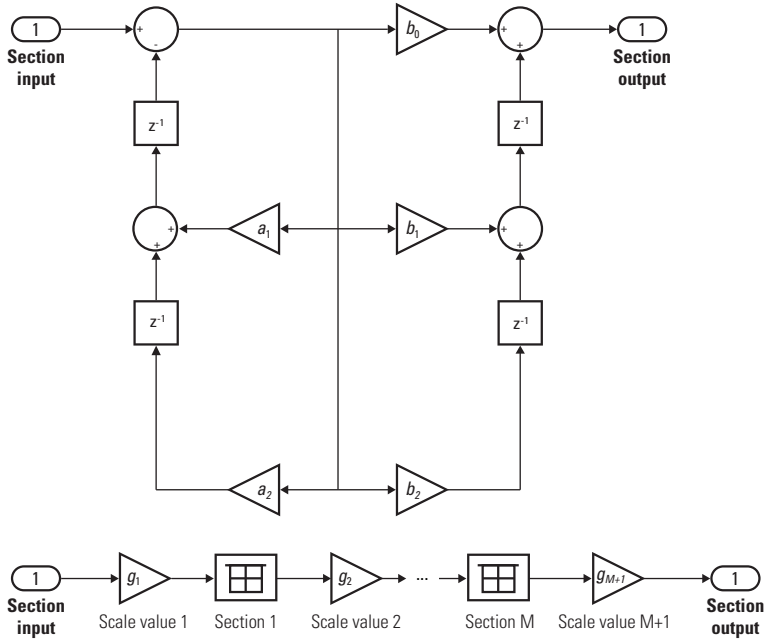
When the data is not optimized:



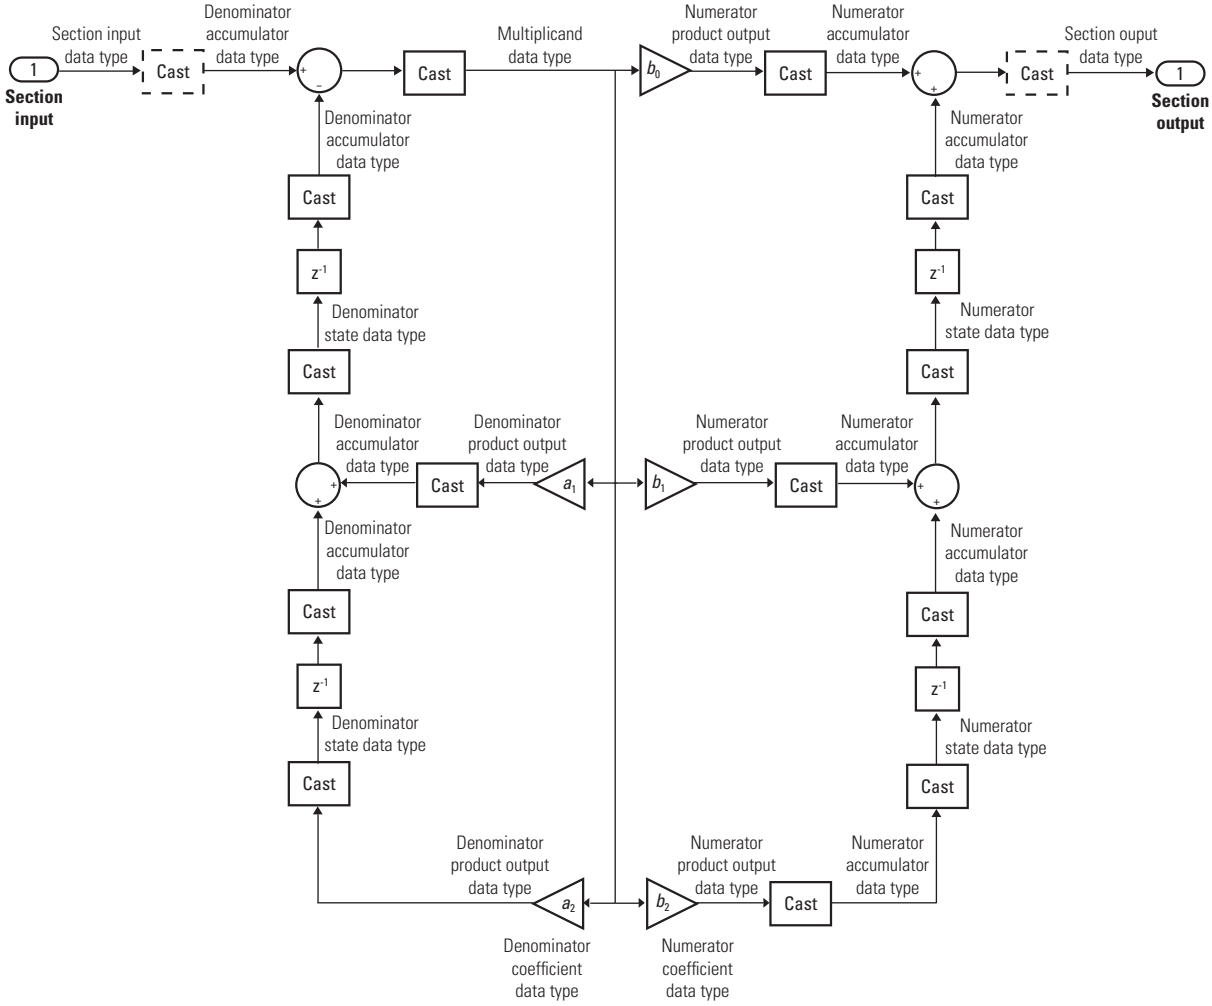
When you specify `OptimizeUnityScaleValues` to `true`, and scale values to 1:



Direct Form I Transposed



The following diagram shows the data types for one section of the filter for fixed-point signals.



The dashed casts are omitted when you specify `OptimizeUnityScaleValues` to `true`, and scale values to 1.

Introduced in R2012a

dsp.BlockLMSFilter

Package: `dsp`

Compute output, error, and weights using block LMS adaptive algorithm

Description

The `dsp.BlockLMSFilter` System object computes output, error, and weights using the block LMS adaptive algorithm.

To compute the output, error, and weights:

1. Create the `dsp.BlockLMSFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
blms = dsp.BlockLMSFilter
blms = dsp.BlockLMSFilter(length,blocksize)
blms = dsp.BlockLMSFilter(Name,Value)
```

Description

`blms = dsp.BlockLMSFilter` returns an adaptive FIR filter, `blms`, that filters the input signal and computes filter weights based on the block least mean squares (LMS) algorithm.

`blms = dsp.BlockLMSFilter(length,blocksize)` returns an adaptive FIR filter, `blms`, with the `Length` property set to `length` and the `BlockSize` property set to `blocksize`.

`blms = dsp.BlockLMSFilter(Name,Value)` returns an adaptive FIR filter, `blms`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Length` — Length of FIR filter weights vector

`32` (default) | positive integer

Specify the length of the FIR filter weights vector as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`BlockSize` — Number of samples acquired before weight adaptation

`32` (default) | positive integer

Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StepSizeSource` — Source of adaptation step size

`Property` (default) | `Input port`

Specify the source of the adaptation step size factor as `Property` or `Input port`.

`StepSize` — Adaptation step size

`0.1` (default) | nonnegative scalar

Specify the adaptation step size factor as a scalar, nonnegative numeric value.

Tunable: Yes

Dependencies

This property applies only when you set the "StepSizeSource" on page 4-0 property to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LeakageFactor` — Leakage factor used in leaky LMS algorithm

`1` (default) | scalar

Specify the leakage factor used in leaky LMS algorithm as a scalar numeric value between `0` and `1`, both inclusive. When the value is less than `1`, the System object implements a leaky LMS algorithm. The default is `1`, providing no leakage in the adapting algorithm.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialWeights` — Initial values of filter weights

`0` (default) | scalar | vector

Specify the initial values of the filter weights as a scalar or a vector of length equal to the "Length" on page 4-0 property value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`AdaptInputPort` — Additional input to enable adaptation of filter weights

`false` (default) | `true`

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the object. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

`WeightsResetInputPort` — Additional input to enable weights reset

`false` (default) | `true`

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, you must provide a reset control input to the object, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the object algorithm.

`WeightsResetCondition` — Condition that triggers the resetting of filter weights
`Non-zero` (default) | `Rising edge` | `Falling edge` | `Either edge`

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset signal input to the object algorithm.

Dependencies

This property applies only when you set the `WeightsResetInputPort` property to `true`.

`WeightsOutputPort` — Output filter weights
`true` (default) | `false`

Set this property to `true` to output the adapted filter weights. The default is `true`.

Usage

Syntax

```
[y,err,wts] = blms(x,d)
[y,err] = blms(x,d)
[ ___ ] = blms(x,d,mu)
[ ___ ] = blms(x,d,a)
[ ___ ] = blms(x,d,r)
[y,err,wts] = blms(x,d,mu,a,r)
```

Description

`[y,err,wts] = blms(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y`. The filter error is `err`, and the estimated filter weights is `wts`. The filter weights update once for every block of data that the object processes.

`[y,err] = blms(x,d)` returns only the filtered output `y` and the filter error `err` when the `WeightsOutputPort` property is `false`.

`[ ___ ] = blms(x,d,mu)` uses `mu` as the step size when you set the `StepSizeSource` property to `Input port`. These input arguments can be used with any of the previous sets of output arguments.

`[ ___ ] = blms(x,d,a)` uses `a` as the adaptation control when you set the `AdaptInputPort` property to `true`. When `a` is nonzero, the filter continuously updates the filter weights. When `a` is zero, the filter weights remain constant.

`[ ___ ] = blms(x,d,r)` uses `r` as a reset signal when you set the `WeightsResetInputPort` property to `true`. Use the `WeightsResetCondition` property to set the reset trigger condition. If a reset event occurs, the filter resets the filter weights to their initial values.

`[y,err,wts] = blms(x,d,mu,a,r)` filters input `x`, using `d` as the desired signal, `mu` as the step size, `a` as the adaptation control, and `r` as the reset signal. The object returns the filtered output `y`, the filter error `err`, and the adapted filter weights `wts`. Set the properties appropriately to provide all possible inputs.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the block LMS filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input length must be an integer multiple of the `BlockSize` property value.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The LMS filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

Data Types: `single` | `double`

`mu` — Step size

nonnegative scalar

Adaptation step size factor, specified as a scalar, nonnegative numeric value. The data type of the step size input must match the data type of `x` and `d`.

A small step size ensures a small steady state error between the output `y` and the desired signal `d`. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Dependencies

This property applies only when you set the “StepSizeSource” on page 4-0 property to `'Input port'`.

Data Types: `single` | `double`

`a` — Adaptation control

scalar

Adaptation control input that controls how the filter weights are updated. If the value of this input is nonzero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

Dependencies

This input is required when the `AdaptInputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`r` — Reset signal

scalar

Reset signal that resets the filter weights based on the values of the `WeightsResetInputPort` property.

Dependencies

This input is required when the `WeightsResetInputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

`y` — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

`err` — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights that produce an output signal that matches closely with the desired signal.

Data Types: `single` | `double`

`wts` — Adaptive filter weights

scalar | column vector

Adaptive filter weights, returned as a scalar or a column vector of length specified by the value in the `Length` property.

The data type of `wts` matches the data type of `y`.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.BlockLMSFilter`

msesim Estimated mean squared error for adaptive filters

maxstep Maximum step size for LMS adaptive filter convergence

Common to All System Objects

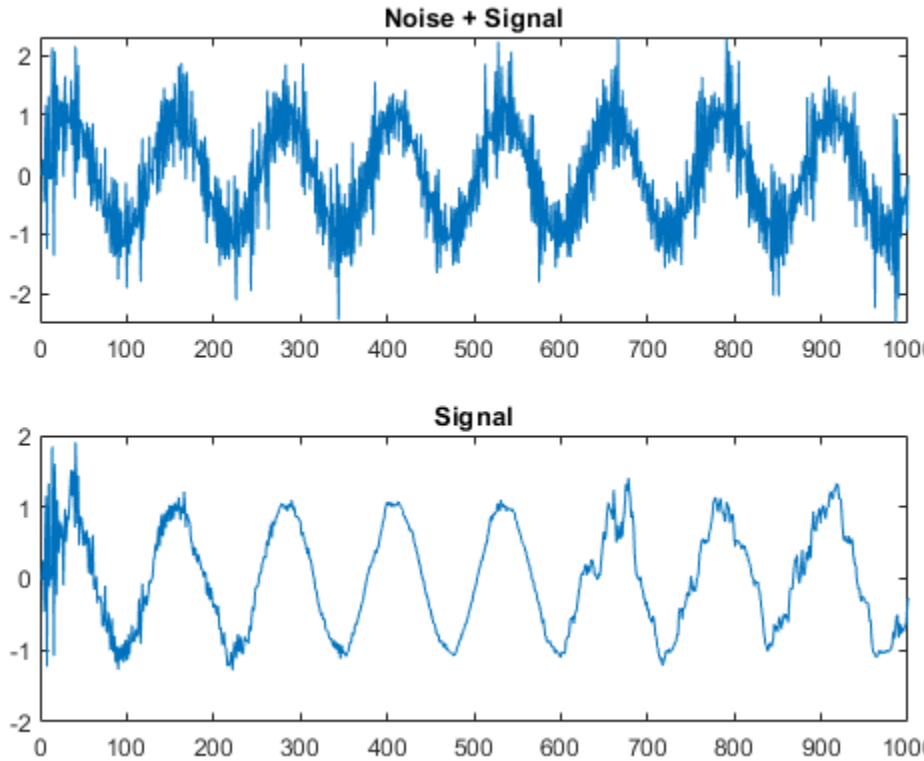
step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Remove Noise Using Block LMS Adaptive Algorithm

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
blms = dsp.BlockLMSFilter(10,5);
blms.StepSize = 0.01;
blms.WeightsOutputPort = false;
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,[.5, .75]);
x = randn(1000,1); % Noise
d = filt(x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = blms(x, d);
subplot(2,1,1);
plot(d);
title('Noise + Signal');
subplot(2,1,2);
plot(err);
title('Signal');
```

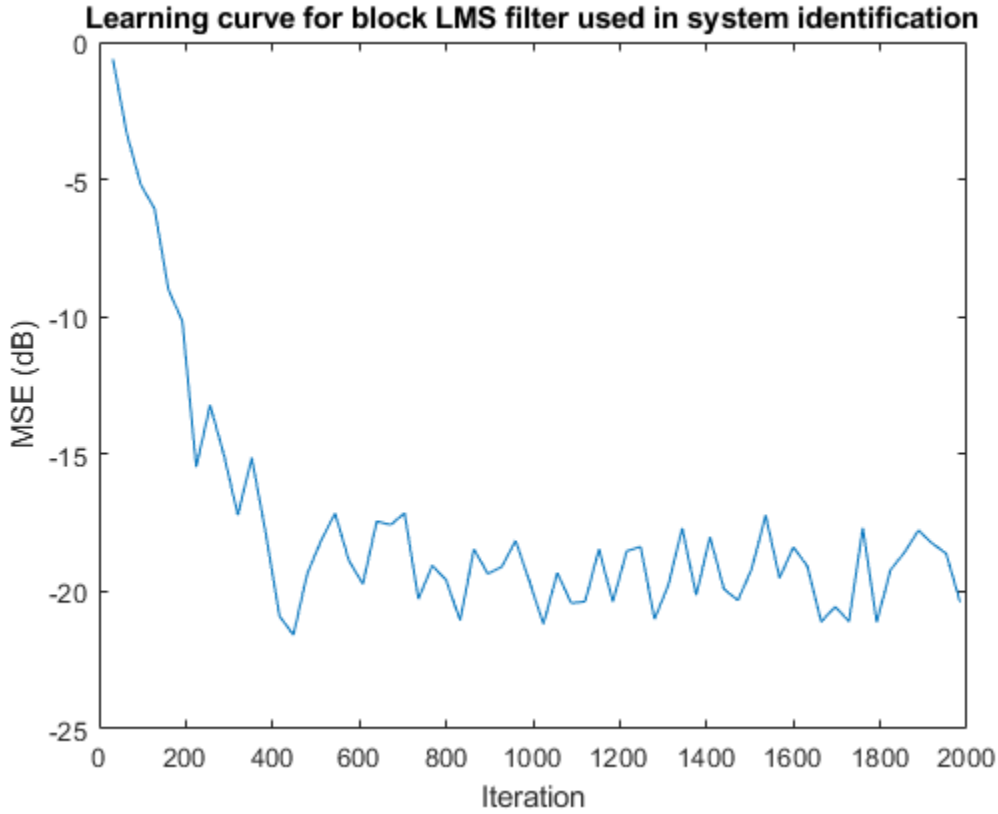


System Identification of FIR Filter Using Block LMS Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
fir = fir1(31,0.5);
firFilter = dsp.FIRFilter('Numerator',fir); % FIR system to be identified
iirFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iirFilter(sign(randn(2000,25)));
n = 0.1*randn(size(x));             % Observation noise signal
```

```
d = firFilter(x)+n;                     % Desired signal
l = 32;                                 % Filter length
mu = 0.008;                             % Block LMS Step size.
m  = 32;                                % Decimation factor for analysis
                                        % and simulation results
fir = dsp.BlockLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fir,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for block LMS filter used in system identification')
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Block LMS Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

System Objects
`dsp.FIRFilter` | `dsp.LMSFilter`

Introduced in R2012a

dsp.Buffer

Package: `dsp`

(To be removed) Buffer input signal

Description

The `Buffer` object buffers an input signal. The number of samples per channel in the input must equal the difference between the output buffer size and buffer overlap (i.e., `Length` - `OverlapLength`).

Note The `dsp.Buffer` System object will be removed in a future release. Use `dsp.AsyncBuffer` instead. For more details, see “Compatibility Considerations” on page 4-247.

To buffer an input signal:

1. Create the `dsp.Buffer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
buff = dsp.Buffer
buff = dsp.Buffer(len,ovrlap,ics)
```

Description

`buff = dsp.Buffer` returns a buffer System object, `buff`, used to buffer input signals with overlap.

`buff = dsp.Buffer(len,ovrlap,ics)` returns a buffer object, `buff`, with `Length` property set to `len`, `OverlapLength` property set to `ovrlap`, and `InitialConditions` property set to `ics`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Length` — Number of samples to buffer

`64` (default) | positive integer

Specify the number of consecutive samples from each input channel to buffer. You can set this property to any scalar integer greater than `0`.

Data Types: `double` | `int32`

`OverlapLength` — Amount of overlap between outputs

`0` (default) | positive integer

Specify the number of samples by which consecutive output frames overlap. You can set this property to any scalar integer in the range $0 \le L < M_o$, where M_o is the output frame size specified by the `Length` property.

The object takes L samples (rows) from the current output and repeats them in the next output. The object acquires $M_o - L$ *new* input samples before propagating the buffered data to the output.

Data Types: `double` | `int32`

`InitialConditions` — Initial output

`0` (default) | scalar | vector | matrix

Specify the value of the object's initial output for cases of nonzero latency as a scalar, vector, or matrix.

When there is nonzero latency, the buffer is initialized to the value(s) specified by the `InitialConditions` property. The object reads from the buffer to generate the first D output samples, where

$$D = \begin{cases} M_o + L & (L \geq 0) \\ M_o & (L < 0) \end{cases}$$

The dimensions of the `InitialConditions` property depend on the `OverlapLength`, L, and whether the input contains a single channel or multiple channels:

- When $L \neq 0$, the `InitialConditions` property must be a scalar.
- When $L = 0$, the `InitialConditions` property can be a scalar, or it can be a vector with the following constraints:
  - For single-channel inputs, the `InitialConditions` property can be a vector of length M_o if M_i is 1, or a vector of length M_i if M_o is 1.
  - For multichannel inputs, the `InitialConditions` property can be a vector of length $M_o * N$ if M_i is 1, or a vector of length $M_i * N$ if M_o is 1.

For general buffering between arbitrary frame sizes, the `InitialConditions` property must be a scalar value, which is then repeated across all elements of the initial output(s). However, in the special case where the input is a 1-by-N row vector, and the output of the block is an M_o-by-N matrix, `InitialConditions` can be:

- An M_o-by-N matrix.
- A length-M_o vector to be repeated across all columns of the initial output(s).
- A scalar to be repeated across all elements of the initial output(s).

In the special case where the output is a 1-by-N row vector, which is the result of unbuffering an M_i-by-N matrix, the `InitialConditions` can be:

- A vector containing M_i samples to output sequentially for each channel during the first M_i sample times.
- A scalar to be repeated across all elements of the initial output(s).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Usage

Syntax

```
y = buff(x)
```

Description

`y = buff(x)` creates output `y` based on current input and stored past values of `x` . Output length equals the `Length` property.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The number of input rows must be equal to `Length` – `OverlapLength`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Output Arguments

y — Buffer output

column vector | matrix

Buffer output, returned as a column vector or a matrix.

The following table shows the output dimensions of the `dsp.Buffer` System object when the input is a single-channel signal. M_i is the input frame size and M_o is the output frame size specified by the `Length` property.

Input Dimensions	Output Dimensions
1-by-1 (scalar)	M_o-by-1
M_i-by-1 (column vector)	M_o-by-1

The following table shows the output dimensions of the `dsp.Buffer` System object when the input is a multichannel signal. The output frame size, M_o can be greater or less than the input frame size, M_i. The object buffers each of the N input channels independently.

Input Dimensions	Output Dimensions
1-by-N (row vector)	M_o-by-N
M_i-by-N (matrix)	M_o-by-N

The data type and complexity of the output matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Create a Buffer

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a buffer of 256 samples with 128 sample overlap.

```
reader = dsp.SignalSource(randn(1024,1),128);
buff = dsp.Buffer(256,128);

for i = 1:8
    y = buff(reader());
end
```

y is of length 256 with 128 samples from previous input.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Buffer block reference page. The object properties correspond to the block properties, except as noted.

Compatibility Considerations

`dsp.Buffer` System object will be removed

Warns starting in R2019b

The `dsp.Buffer` System object will be removed in a future release. Use the `dsp.AsyncBuffer` object instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

dsp.BurgAREstimator

Package: `dsp`

(To be removed) Estimate of autoregressive (AR) model parameters using Burg method

---

Note The `dsp.BurgAREstimator` System object™ will be removed in a future release. Use `arburg` instead. For more information, see “Compatibility Considerations”.

Description

The `BurgAREstimator` object computes the estimate of the autoregressive (AR) model parameters using the Burg method.

To compute the estimate of the AR model parameters:

1. Define and set up your System object. See “Construction” on page 4-249.
2. Call `step` to compute the estimate according to the properties of `dsp.BurgAREstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`burgarest = dsp.BurgAREstimator` returns a Burg `BurgAREstimator` System object, `burgarest`, that performs parametric AR estimation using the Burg maximum entropy method.

`burgarest = dsp.BurgAREstimator('PropertyName',PropertyValue,...)` returns a Burg AR estimator object, `burgarest`, with each specified property set to the specified value.

Properties

`AOutputPort`

Enable output of polynomial coefficients

Set this property to `true` to output the polynomial coefficients, `A`, of the AR model the object computes. The default is `true`. Either the `AOutputPort` property, the `KOutputPort` property, or both must be `true`.

`KOutputPort`

Enable output of reflection coefficients

Set this property to `true` to output the reflection coefficients, `K`, for the AR model that the object computes. The default is `false`. Either the `AOutputPort` property, the `KOutputPort` property, or both must be `true`.

`EstimationOrderSource`

Source of estimation order

Specify how to determine estimator order as `Auto` or `Property`. When you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. When you set this property to `Property`, the value in `EstimationOrder` is used. The default is `Auto`.

`EstimationOrder`

Order of AR model

Set the AR model estimation order to a real positive integer. This property applies when you set the `EstimationOrderSource` to `Property`. The default is `4`.

Methods

step	Normalized estimate of AR model parameter

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Estimate the parameters of an AR model

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use the `dsp.BurgAREstimator` System object to estimate the parameters of an AR model.

```
rng default; % Use default random number generator and seed
noise = randn(100,1); % Normalized white Gaussian noise
x = filter(1,[1 1/2 1/3 1/4 1/5],noise);
burgarest = dsp.BurgAREstimator(...
    'EstimationOrderSource', 'Property', ...
    'EstimationOrder', 4);
[a, g] = burgarest(x);
x_est = filter(g, a, x);
plot(1:100,[x x_est]);
title('Original and estimated signals');
legend('Original', 'Estimated');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg AR Estimator block reference page. The object properties correspond to the block parameters, except:
Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

Compatibility Considerations

`dsp.BurgAREstimator` System object will be removed

Warns starting in R2019a

The `dsp.BurgAREstimator` System object will be removed in a future release. Use `arburg` instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

If your code has this form (R2016b or later):	If your code has this form (prior to R2016b):	Use this code instead:

`rng default; % Use default random number generator and default random seed`
`noise = randn(100,1); % Normalized white Gaussian noise`
`x = filter(1,[1 1/2 1/3 1/4 1/5],noise);`
`burgarest = dsp.BurgAREstimator(...`
`  'EstimationOrderSource', 'Property', ...`
`  'EstimationOrder', 4);`
`[a,g] = burgarest(x);`
 	
or
 	
`burgarest = dsp.BurgAREstimator(...`
`  'KOutputPort',true,...`
`  'EstimationOrderSource', 'Property', ...`
`  'EstimationOrder', 4);`
`[a,rc,g] = burgarest(x);`
 	
where,
 	
• *a* –– AR model parameters
• *rc* –– Reflection coefficients
• *g* –– Variance of white noise input
	`rng default; % Use default random number generator and default random seed`
	`noise = randn(100,1); % Normalized white Gaussian noise`
	`x = filter(1,[1 1/2 1/3 1/4 1/5],noise);`
	`burgarest = dsp.BurgAREstimator(...`
	`  'EstimationOrderSource', 'Property', ...`
	`  'EstimationOrder', 4);`
	`[a,g] = step(burgarest,x);`
	
	or
	
	`burgarest = dsp.BurgAREstimator(...`
	`  'KOutputPort',true,...`
	`  'EstimationOrderSource', 'Property', ...`
	`  'EstimationOrder', 4);`
	`[a,rc,g] = step(burgarest,x);`
		`rng default; % Use default random number generator and default random seed`
		`noise = randn(100,1); % Normalized white Gaussian noise`
		`x = filter(1,[1 1/2 1/3 1/4 1/5],noise);`
		`[arcoeffs,e] = arburg(x,4);`
		or
		`[arcoeffs,e,rccoeffs] = arburg(x,4);`
		
		The output *arcoeffs* is a row vector, while the output *a* is a column vector. To compare *arcoeffs* with *a*, transpose one of the vectors so that both have the same dimensions.
		
		where,
		
		• *arcoeffs* –– AR model parameters
		• *e* –– Variance of white noise input
		• *rccoeffs* –– Reflection coefficients

System Objects
`dsp.LevinsonSolver`

Functions
`arburg`

Introduced in R2012a

step

System object: `dsp.BurgAREstimator`
Package: `dsp`

Normalized estimate of AR model parameter

Syntax

```
[A,G] = step(burgarest,X)
[K,G] = step(burgarest,X)
[A,K,G] = step(burgarest,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[A,G] = step(burgarest,X)` computes the normalized estimate of the AR model parameters to fit the input, `X`, in the least square sense. The input `X` must be a column vector. Output `A` is a column vector that contains the normalized estimate of the AR model polynomial coefficients in descending powers of z. The scalar `G` is the AR model gain.

`[K,G] = step(burgarest,X)` returns `K`, a column vector containing the AR model reflection coefficients when you set the `KOutputPort` property to `true` and the `AOutputPort` property to `false`.

`[A,K,G] = step(burgarest,X)` returns the AR model polynomial coefficients `A`, reflection coefficients `K`, and the scalar gain `G` when the `AOutputPort` and `KOutputPort` properties are both `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.BurgSpectrumEstimator

Package: `dsp`

(To be removed) Parametric spectral estimate using Burg method

Note The `dsp.BurgSpectrumEstimator` System object™ will be removed in a future release. Use `pburg` instead. For more information, see “Compatibility Considerations”.

Description

The `BurgSpectrumEstimator` object computes a parametric spectral estimate of the input using the Burg method. The object fits an autoregressive (AR) model to the signal by minimizing the forward and backward prediction errors (via least-squares). The AR parameters are constrained to satisfy the Levinson-Durbin recursion.

To compute the parametric spectral estimate of the input:

1. Define and set up your System object. See “Construction” on page 4-257.
2. Call `step` to compute the estimate according to the properties of `dsp.BurgSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`burgspecest = dsp.BurgSpectrumEstimator` returns an object, `burgspecest`, that estimates the power spectral density (PSD) of the input frame using the Burg method.

`burgspecest = dsp.BurgSpectrumEstimator('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a

spectrum estimator, `burgspecest`, with each specified property set to the specified value.

Properties

`EstimationOrderSource`

Source of estimation order

Specify the source of the estimation order as `Auto` or `Property`. If you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. The default value is `Property`.

`EstimationOrder`

Order of AR model

Specify the order of AR model as a real positive integer. This property applies only when you set the `EstimationOrderSource` property to `Property`. The default value is `6`.

`FFTLengthSource`

Source of FFT length

Specify the source of the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the objects assumes the FFT length is one more than the estimation order. When you set this property to `Property`, the "FFTLength" on page 4-0 property value must be an integer power of two.

`FFTLength`

FFT length as power-of-two integer value

Specify the FFT length as a power-of-two numeric scalar. This property applies when you set the `FFTLengthSource` property to `Property`. The default value is `256`.

`SampleRate`

Sample rate of input time series

Specify the sampling rate of the original input time series as a positive numeric scalar in hertz. The default value is `1`.

Methods

step	Estimate of power spectral density

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Estimate PSD Using the Burg Method

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
x = randn(100,1);
burgspecest = dsp.BurgSpectrumEstimator('EstimationOrder', 4);
y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Fourth order AR filter
p = burgspecest(y); % Uses default FFT length of 256

plot((0:255)/256, p);
title('Burg Method Spectral Density Estimate');
xlabel('Normalized frequency'); ylabel('Power/frequency');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg Method block reference page. The object properties correspond to the block properties.

Compatibility Considerations

`dsp.BurgSpectrumEstimator` System object will be removed

Warns starting in R2019a

The `dsp.BurgSpectrumEstimator` System object will be removed in a future release. Use `pburg` instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

If your code has this form (R2016b or later):	If your code has this form (prior to R2016b):	Use this code instead:

`x = randn(100,1);`
`burgspecest = dsp.BurgSpectrumEstimator('PolynomialOrder',4);`
`y = filter(1,[1 1/2 1/3 1/4 1/5],x);`
`p = burgspecest(y); % Uses default FFT length of 256`
	`x = randn(100,1);`
	`burgspecest = dsp.BurgSpectrumEstimator('PolynomialOrder',4);`
	`y = filter(1,[1 1/2 1/3 1/4 1/5],x);`
	`p = step(burgspecest,y); % Uses default FFT length of 256`
		`x = randn(100,1);`
		`y = filter(1,[1 1/2 1/3 1/4 1/5],x);`
		`p = pburg(y,4,256,'onesided');`
		Uses default FFT length of 256
		The `pburg` function is in this format `Pxx = pburg(y,order,nfft,fs,'twosided')`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- When the FFT length is not a power of two, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Y = step(burgspecest,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(burgspecest,X)` outputs `Y`, a spectral estimate of input `X`, using the Burg method.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CepstralToLPC

Package: `dsp`

(To be removed) Convert cepstral coefficients to linear prediction coefficients

---

Note `dsp.CepstralToLPC` will be removed in a future release. For more information, see “Compatibility Considerations”.

Description

The `CepstralToLPC` object converts cepstral coefficients to linear prediction coefficients (LPC).

To convert cepstral coefficients to LPC:

1. Define and set up your System object. See “Construction” on page 4-263.
2. Call `step` to convert the coefficients according to the properties of `dsp.CepstralToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cc2lpc = dsp.CepstralToLPC` returns a System object, `cc2lpc`, that converts the cepstral coefficients(CCs) to linear prediction coefficients (LPCs).

`cc2lpc = dsp.CepstralToLPC('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `Cepstral to LPC` object, `cc2lpc`, with each specified property set to the specified value.

Properties

`PredictionErrorOutputPort`

Enable prediction error power output

Set this property to `true` to output the prediction error power. The prediction error power is the power of the error output of an FIR analysis filter represented by the LPCs for a given input signal. The default is `false`.

Methods

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

step

System object: `dsp.CepstralToLPC`
Package: `dsp`

LPC coefficients from column of cepstral coefficients

Syntax

```
A = step(cc2lpc,CC)
[A,P]=step(cc2lpc,CC)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`A = step(cc2lpc,CC)` computes the linear prediction coefficients (LPC) coefficients, `A` , from the columns of cepstral coefficients, `CC`.

`[A,P]=step(cc2lpc,CC)` converts the columns of the cepstral coefficients `CC` to the LPCs and returns the prediction error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Channelizer

Package: `dsp`

Polyphase FFT analysis filter bank

Description

The `dsp.Channelizer` System object separates a broadband input signal into multiple narrow subbands using a fast Fourier transform (FFT)-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To separate a broadband signal into multiple narrow subbands:

1. Create the `dsp.Channelizer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
channelizer = dsp.Channelizer
channelizer = dsp.Channelizer(M)
channelizer = dsp.Channelizer(Name,Value)
```

Description

`channelizer = dsp.Channelizer` creates a polyphase FFT analysis filter bank System object that separates a broadband input signal into multiple narrowband output signals. This object implements the inverse operation of the `dsp.ChannelSynthesizer` System object.

`channelizer = dsp.Channelizer(M)` creates an *M*-band polyphase FFT analysis filter bank, with the “NumFrequencyBands” on page 4-0 property set to *M*.

Example: channelizer = dsp.Channelize(16);

`channelizer = dsp.Channelizer(Name,Value)` creates a polyphase FFT analysis filter bank with each specified property set to the specified value. Enclose each property name in single quotes.

Example: channelizer = dsp.Channelizer('NumTapsPerBand',20,'StopbandAttenuation',140);

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`NumFrequencyBands` — Number of frequency bands

8 (default) | positive integer greater than 1

Number of frequency bands into which the object separates the input broadband signal, specified as a positive integer greater than 1. This property corresponds to the number of polyphase branches and the FFT length used in the filter bank.

Example: 16

Example: 64

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Specification` — Filter design parameters or coefficients

`'Number of taps per band and stopband attenuation'` (default) | `'Coefficients'`

Filter design parameters or filter coefficients, specified as one of these options:

- `'Number of taps per band and stopband attenuation'` — Specify the filter design parameters through the `NumTapsPerBand` and "Stopband attenuation (dB)" on page 2-0 properties.
- `'Coefficients'` — Specify the filter coefficients directly using the "LowpassCoefficients" on page 4-0 property.

`NumTapsPerBand` — Number of filter coefficients per frequency band

`12` (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by `NumFrequencyBands` × `NumTapsPerBand`. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 8

Example: 16

Dependencies

This property applies when you set `Specification` to `'Number of taps per band and stopband attenuation'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Stopband attenuation

`80` (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. When the stopband attenuation increases, the passband ripple decreases. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 80

Dependencies

This property applies when you set `Specification` to `'Number of taps per band and stopband attenuation'`.

Data Types: `single` | `double`

`LowpassCoefficients` — Coefficients of prototype lowpass filter
`[1×49 double]` (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

Tunable: Yes

Dependencies

This property applies when you set `Specification` to `'Coefficients'`.

Data Types: `single` | `double`

Usage

Syntax

```
channOut = channelizer(input)
```

Description

`channOut = channelizer(input)` separates the broadband input signal into a number of narrow band signals contained in the columns of the channelizer output.

Input Arguments

`input` — Data input
vector | matrix

Data input, specified as a vector or a matrix. The number of rows in the input signal must be a multiple of the number of frequency bands of the filter bank. Each column of the input corresponds to a separate channel. If *M* is the number of frequency bands, and the input is an *L*-by-1 matrix, then the output signal has dimensions *L*/*M*-by-*M*. Each narrowband signal forms a column in the output. If the input has more than one channel,

that is, it has dimensions *L*-by-*N* with *N* > 1, then the output has dimensions *L/M*-by-*M*-by-*N*.

This object supports variable-size input signals. You can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: randn(64,4)

Data Types: `single` | `double`

Output Arguments

`chanOut` — Channelizer output

matrix | 3-D array

Channelizer output, returned as a matrix or a 3-D array. If the input is an *L*-by-1 matrix, then the output signal has dimensions *L/M*-by-*M*, where *M* is the number of frequency bands. Each narrowband signal forms a column in the output. If the input has more than one channel, that is, it has dimensions *L*-by-*N* with *N* > 1, then the output has dimensions *L/M*-by-*M*-by-*N*.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.Channelizer

coeffs	Coefficients of prototype lowpass filter
tf	Return transfer function of overall prototype lowpass filter
polyphase	Return polyphase matrix
freqz	Frequency response of filters in channelizer
fvtool	Visualize the filters in the channelizer
bandedgeFrequencies	Compute the bandedge frequencies
centerFrequencies	Compute center frequencies
getFilters	Return matrix of channelizer FIR filters

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Quadrature Mirror Filter Bank

The quadrature mirror filter bank (QMF) contains an analysis filter bank section and a synthesis filter bank section. `dsp.Channelizer` implements the analysis filter bank. `dsp.ChannelSynthesizer` implements the synthesis filter bank using the efficient polyphase implementation based on a prototype lowpass filter.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40,-30,-20,10,15,25,35,-15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency',...
    offsets+(-375:125:500),'SamplesPerFrame',800);

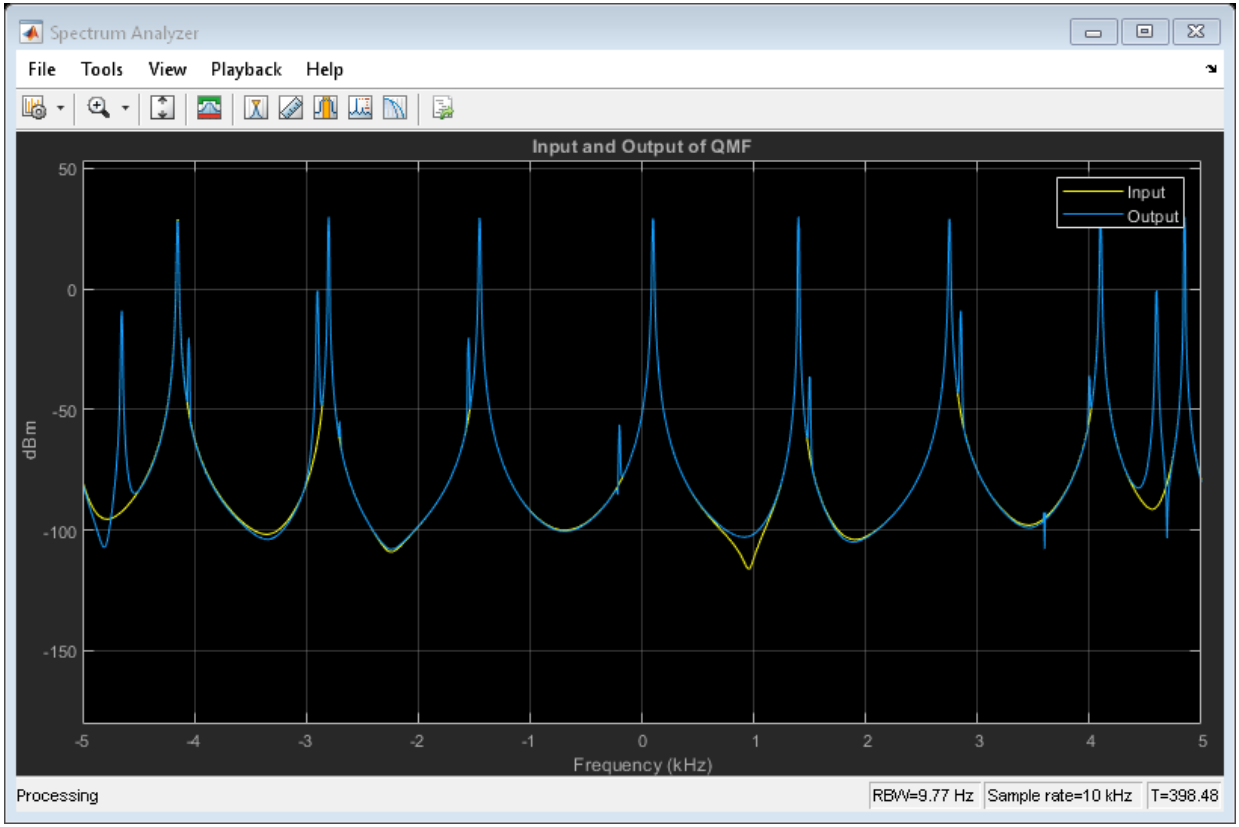
channelizer = dsp.Channelizer('StopbandAttenuation',140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation',140);
spectrumAnalyzer =  dsp.SpectrumAnalyzer('ShowLegend',true,'NumInputPorts',...
    2,'ChannelNames',{'Input','Output'},'Title','Input and Output of QMF');
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

```
for i = 1:5000
    x = sum(sinewave(),2);
```

```
    y = channelizer(x);
    v = synthesizer(y);
    spectrumAnalyzer(x,v)
end
```

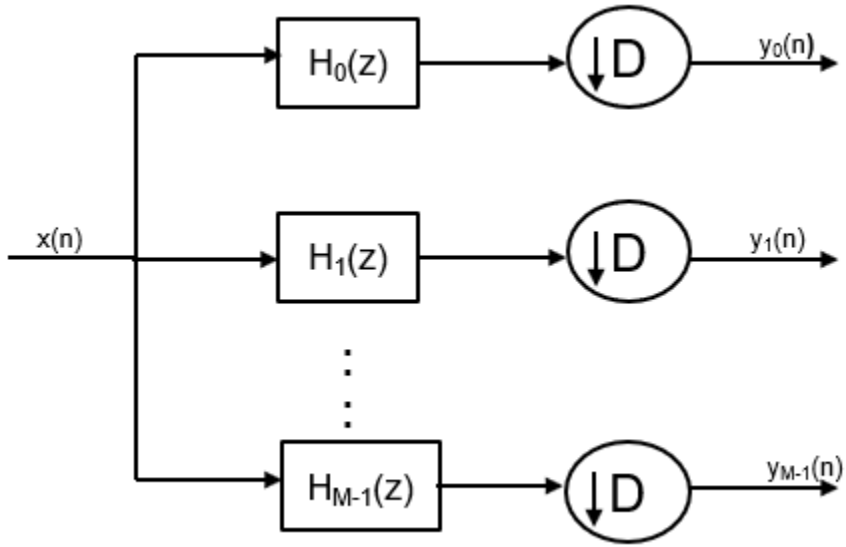


More About

Analysis Filter Bank

The analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal, *x(n)*, into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the

bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.



Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter. This filter has an impulse response of *h[n]*, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M. M is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high on the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other M – 1 branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by the following equation:

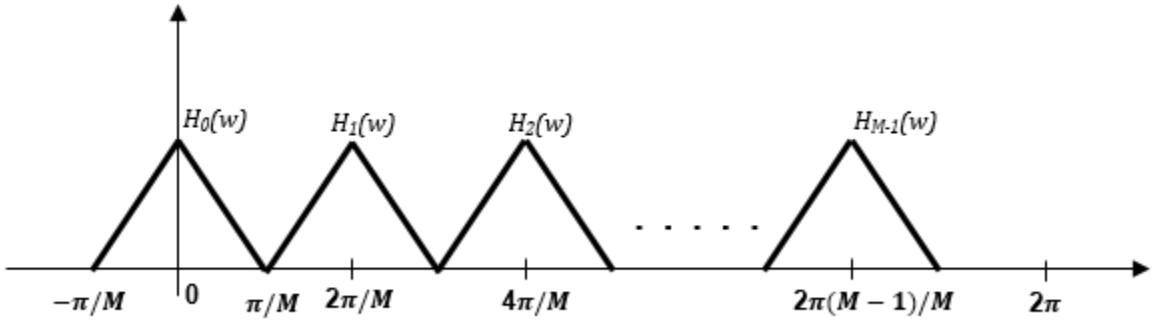
$$e^{-jw_k n}, \quad w_k = 2\pi k / M, \quad k = 0, 1, \ldots, M-1$$

Using the Prototype Lowpass Filter

The transfer function of the modulated kth bandpass filter is given by:

$$H_k(z) = H_0(ze^{-jw_k}), \quad w_k = 2\pi k/M, \quad k = 1, 2, \ldots, M-1$$

This figure shows the frequency response of M filters.

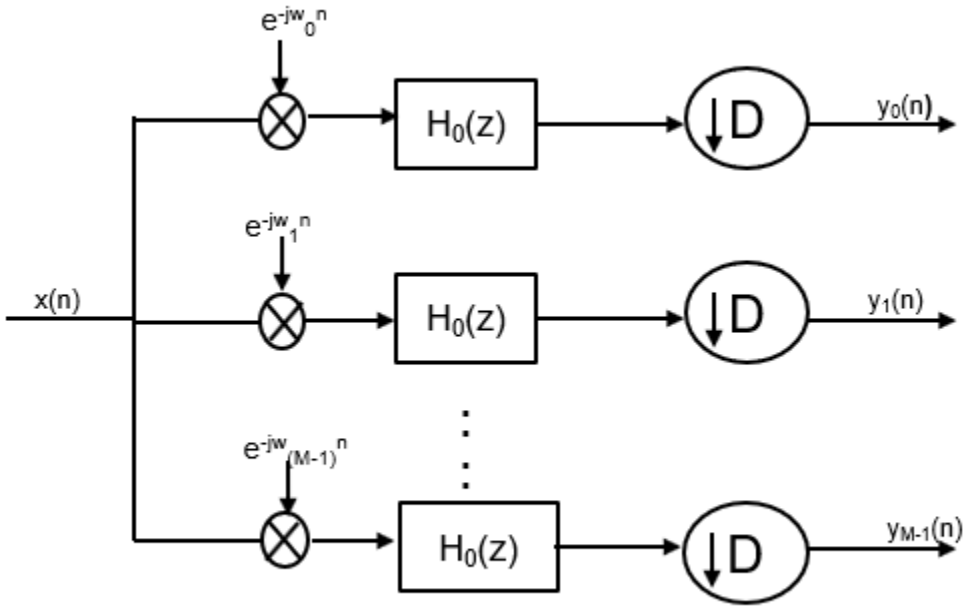


To obtain the frequency response characteristics of the filter $H_k(z)$, where k = 1,...,M-1, uniformly shift the frequency response of the prototype filter, $H_0(z)$, by multiples of 2π/M. Each subband filter, H_k(z), {k = 1,..., M – 1}, is derived from the prototype filter.

Shift Narrow Subbands to Baseband

The frequency components in the input signal, $x(n)$, are translated in frequency to baseband by multiplying $x(n)$ with the complex exponentials, $e^{-jw_k n}, w_k = 2\pi k / M, k = 1,2,..,M-1$, where $w_k = 2\pi k / M$, and $k = 1,2,\ldots,M-1$. The resulting product signals are passed through the lowpass filters, $H_0(z)$. The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor, $D \le M$, where M is the number of branches of the analysis filter bank.

The figure shows an analysis filter bank that uses the prototype lowpass filter.



$y_1(n)$, $y_2(n)$, ..., $y_{M-1}(n)$ are narrow subband signals translated into baseband.

Algorithms

Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure. To derive the polyphase structure, start with the transfer function of the prototype lowpass filter:

$$H_0(z) = b_0 + b_1 z^{-1} + ... + b_N z^{-N}$$

N+1 is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{matrix} \left(b_0 + b_M z^{-M} + b_{2M} z^{-2M} + .. + b_{N-M+1} z^{-(N-M+1)}\right) + \\ z^{-1}\left(b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + .. + b_{N-M+2} z^{-(N-M+1)}\right) + \\ \vdots \\ z^{-(M-1)}\left(b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + .. + b_N z^{-(N-M+1)}\right) \end{matrix}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1}E_1(z^M) + ... + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M)$, $E_1(z^M)$, ..., $E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, H_0(z).

The other filters in the filter bank, H_k(z), where k = 1, ..., M-1, are modulated versions of this prototype filter.

You can write the transfer function of the kth modulated bandpass filter as $H_k(z) = H_0(ze^{-jw_k})$.

Replacing z with ze^{-jw_k},

$$H_k(z) = h_0 + h_1 e^{-jwk} z^{-1} + h_2 e^{-j2wk} z^{-2} ... + h_N e^{-jNwk} z^{-N}$$

N+1 is the length of the kth filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & ... & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

.

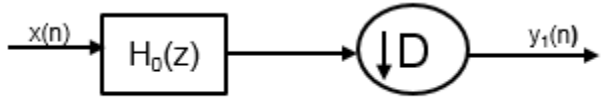
For all M channels in the filter bank, the MIMO transfer function, H(z), is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

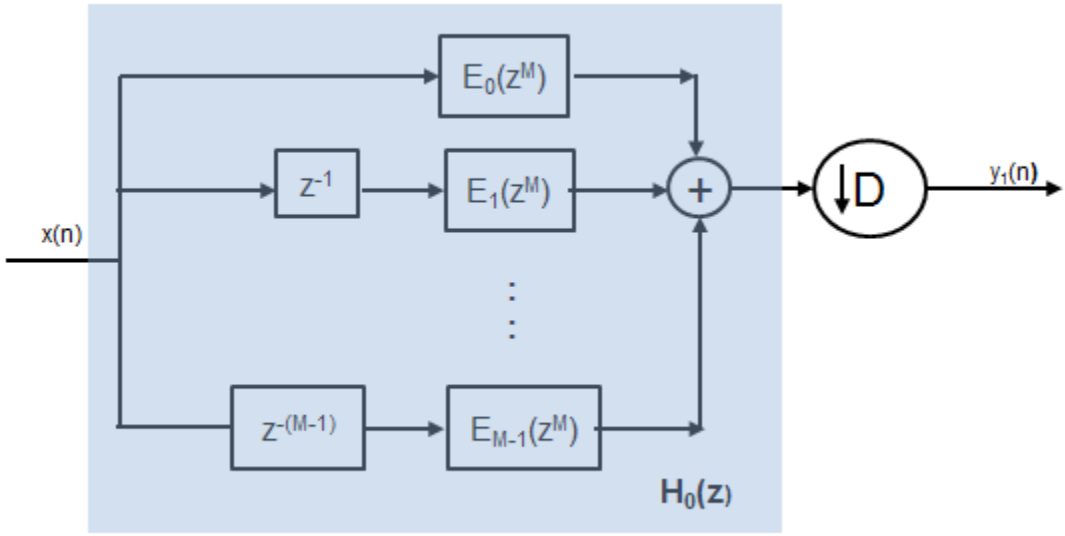
.

Here is the multirate noble identity for decimation, assuming that $D = M$.

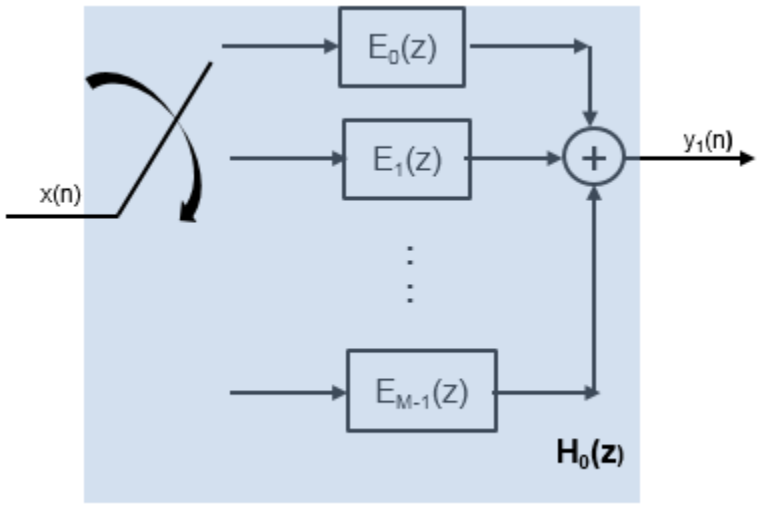
For illustration, consider the first branch of the filter bank that contains the lowpass filter.



Replace H_0(z) with its polyphase representation.



After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch.



For all M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a discrete Fourier transform (DFT) matrix. With the DFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

dsp.ChannelSynthesizer

Package: `dsp`

Polyphase FFT synthesis filter bank

Description

The `dsp.ChannelSynthesizer` System object merges multiple narrowband signals into a broadband signal by using an FFT based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To merge multiple narrowband signals into a broadband signal:

1. Create the `dsp.ChannelSynthesizer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
synthesizer = dsp.ChannelSynthesizer
synthesizer = dsp.ChannelSynthesizer(Name,Value)
```

Description

`synthesizer = dsp.ChannelSynthesizer` creates a synthesizer object, using the default properties.

`synthesizer = dsp.ChannelSynthesizer(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example: `synthesizer = dsp.ChannelSynthesizer('NumTapsPerBand',20,'StopbandAttenuation',140)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Specification` — Filter design parameters or coefficients

`'Number of taps per band and stopband attenuation'` (default) | `'Coefficients'`

Filter design parameters or filter coefficients, specified as one of these options:

- `'Number of taps per band and stopband attenuation'` — Specify the filter design parameters through the `NumTapsPerBand` and `StopbandAttenuation` properties.
- `'Coefficients'` — Specify the filter coefficients directly using `LowpassCoefficients`.

`NumTapsPerBand` — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by product of the number of frequency bands and `NumTapsPerBand`. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Dependencies

This property applies when you set `Specification` to `'Number of taps per band and stopband attenuation'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Stopband attenuation

`80` (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

Dependencies

This property applies when you set `Specification` to `'Number of taps per band and stopband attenuation'`.

Data Types: `single` | `double`

`LowpassCoefficients` — Coefficients of the prototype lowpass filter

`[1×49 double]` (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

Tunable: Yes

Dependencies

This property applies when you set `Specification` to `'Coefficients'`.

Data Types: `single` | `double`

Usage

Syntax

```
synthOut = synthesizer(input)
```

Description

`synthOut = synthesizer(input)` merges the narrowband input signals contained as columns in `input` into broadband signal, `synthOut`.

Input Arguments

`input` — Narrowband signals

matrix | 3-D array

Narrowband signals, specified as a matrix or a 3-D array. Each narrowband signal is stored as a column in the input signal. The number of columns in `input` corresponds to the number of frequency bands of the filter bank. If `input` is three-dimensional, each matrix corresponds to a separate channel. If M is the number of frequency bands, and `input` is an L-by-M matrix, then the output signal, `synthOut`, has dimensions $L \times M$-by-1. If `input` has more than one channel, that is, it has dimensions L-by-M-by-N, then `synthOut` has dimensions $L \times M$-by-N.

This object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel. The number of channels cannot change.

Data Types: `single` | `double`

Output Arguments

`synthOut` — Merged broadband signal

matrix | 3-D array

Merged broadband signal, returned as a matrix or a 3-D array. If M is the number of frequency bands, and `input` is an L-by-M matrix, then the output signal, `synthOut`, has dimensions $L \times M$-by-1. If `input` has more than one channel, that is, it has dimensions L-by-M-by-N, then `synthOut` has dimensions $L \times M$-by-N.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.ChannelSynthesizer

coeffs	Coefficients of prototype lowpass filter
tf	Return transfer function of overall prototype lowpass filter
polyphase	Return polyphase matrix

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Quadrature Mirror Filter Bank

The quadrature mirror filter bank (QMF) contains an analysis filter bank section and a synthesis filter bank section. `dsp.Channelizer` implements the analysis filter bank. `dsp.ChannelSynthesizer` implements the synthesis filter bank using the efficient polyphase implementation based on a prototype lowpass filter.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

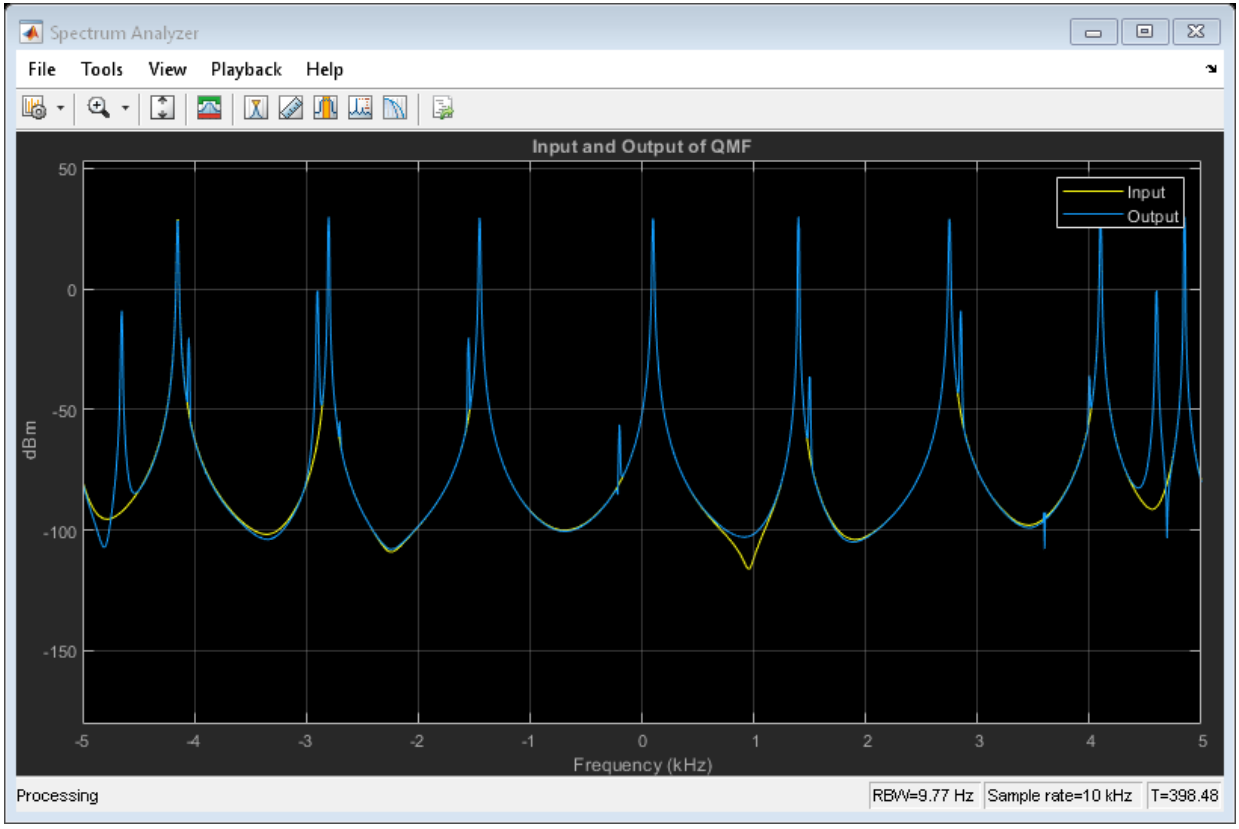
```
offsets = [-40,-30,-20,10,15,25,35,-15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency',...
    offsets+(-375:125:500),'SamplesPerFrame',800);

channelizer = dsp.Channelizer('StopbandAttenuation',140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation',140);
spectrumAnalyzer =  dsp.SpectrumAnalyzer('ShowLegend',true,'NumInputPorts',...
    2,'ChannelNames',{'Input','Output'},'Title','Input and Output of QMF');
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

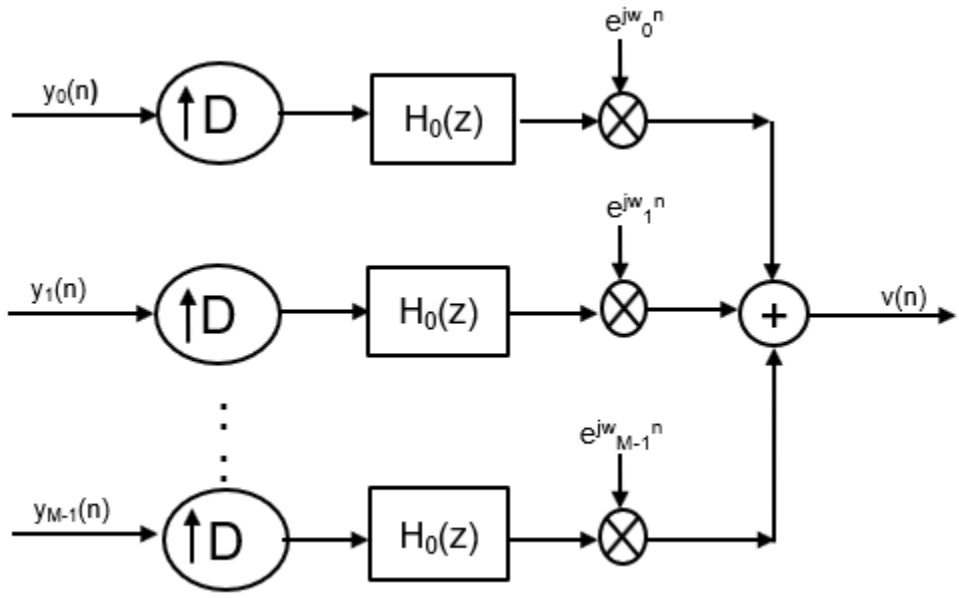
```
for i = 1:5000
    x = sum(sinewave(),2);
    y = channelizer(x);
    v = synthesizer(y);
    spectrumAnalyzer(x,v)
end
```



More About

Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals, $y_0(n)$, $y_1(n)$,..., $y_{M-1}(n)$ into a single broadband signal, $v(n)$. The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A complex exponential that follows the lowpass filter centers the baseband signal around w_k.



Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of *h*[n], a normalized two-sided bandwidth of 2π/*M*, and a cutoff frequency of π/*M*. *M* is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses. *M* can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other *M* – 1 branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{jw_k n}$, $w_k = 2\pi k / M$, $k = 0,1,\ldots,M-1$.

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal, *v(n)*.

Algorithms

Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1z^{-1} + ... + b_Nz^{-N}$$

N+1 is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{array}{c} \left(b_0 + b_Mz^{-M} + b_{2M}z^{-2M} + .. + b_{N-M+1}z^{-(N-M+1)}\right) + \\ z^{-1}\left(b_1 + b_{M+1}z^{-M} + b_{2M+1}z^{-2M} + .. + b_{N-M+2}z^{-(N-M+1)}\right) + \\ \vdots \\ z^{-(M-1)}\left(b_{M-1} + b_{2M-1}z^{-M} + b_{3M-1}z^{-2M} + .. + b_Nz^{-(N-M+1)}\right) \end{array}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1}E_1(z^M) + ... + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M)$, $E_1(z^M)$,..., $E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, H_0(z).

The other filters in the filter bank, H_k(z), where k = 1, ..., M-1, are modulated versions of this prototype filter.

You can write the transfer function of the kth modulated bandpass filter as $H_k(z) = H_0(ze^{jw_k})$. Replacing z with ze^{jw_k},

$$H_k(z) = h_0 + h_1e^{jwk}z^{-1} + h_2e^{j2wk}z^{-2}... + h_Ne^{jNwk}z^{-N}$$

N+1 is the length of the kth filter.

In polyphase form, the equation is as follows:

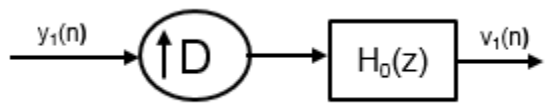
$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \dots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the MIMO transfer function, H(z), is given by:

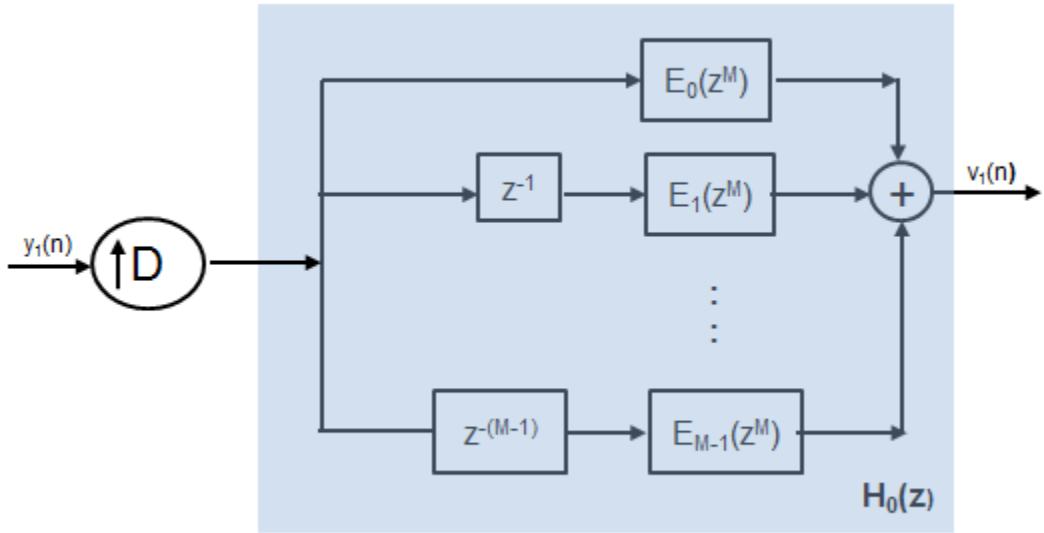
$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

Here is the multirate noble identity for interpolation, assuming that $D = M$:

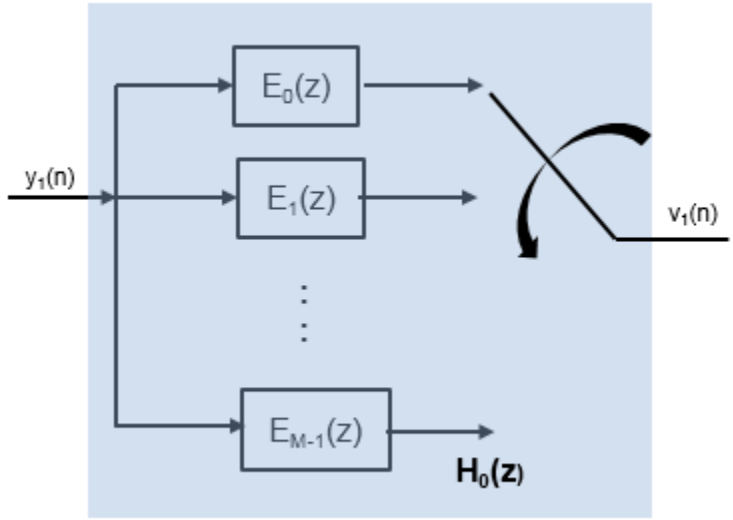
For illustration, consider the first branch of the filter bank that contains the lowpass filter.



Replace H_0(z) with its polyphase representation.



After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.



For all the M channels in the filter bank, the MIMO transfer function, H(z), is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

dsp.Chirp

Package: `dsp`

Generate swept-frequency cosine (chirp) signal

Description

The `Chirp` object generates a swept-frequency cosine (chirp) signal.

To generate the chirp signal:

1. Create the `dsp.Chirp` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
chirp = dsp.Chirp
chirp = dsp.Chirp(Name,Value)
```

Description

`chirp = dsp.Chirp` returns a chirp signal, `chirp`, with unity amplitude.

`chirp = dsp.Chirp(Name,Value)` returns a chirp signal, `chirp`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

Type — Frequency sweep type

`Linear` (default) | `Swept cosine` | `Logarithmic` | `Quadratic`

Specify the frequency sweep type as `Swept cosine`, `Linear`, `Logarithmic`, or `Quadratic`. This property specifies how the output instantaneous frequency sweep varies over time.

SweepDirection — Sweep direction

`Unidirectional` (default) | `Bidirectional`

Specify the sweep direction as either `Unidirectional` or `Bidirectional`.

InitialFrequency — Initial frequency (hertz)

`1000` (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the `Type` property to `Logarithmic`, the value of this property is one less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TargetFrequency — Target frequency (hertz)

`4000` (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time.

When you set the `Type` property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TargetTime` — Target time

1 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` property to `Swept cosine`, this property specifies the time at which the sweep reaches $2f_{tgt} - f_{init}$ Hz, where f_{tgt} is the `TargetFrequency` and f_{init} is the `InitialFrequency`. The target time should not be greater than the sweep time, specified by the `SweepTime` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SweepTime` — Sweep time

1 (default) | scalar greater than or equal to 0

When you set the `SweepDirection` property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` property to `Bidirectional`, the sweep time is half the period of the output frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime`. This property must be a positive numeric scalar.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialPhase` — Initial phase

`0` (default) | scalar greater than or equal to 0

Specify initial phase of the output in radians at time $t = 0$.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SampleRate` — Sample rate
`8000` (default) | positive scalar

Specify the sampling rate of the output in hertz as a positive numeric scalar.

Data Types: `single` | `double` | `logical`

`SamplesPerFrame` — Samples per output frame
`1` (default) | positive integer

Specify the number of samples to buffer into each output as a positive integer. The default value is `1`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OutputDataType` — Output data type
`double` (default) | `single`

Specify the output data type as `double` or `single`. The default value is `double`.

Usage

Syntax

```
y = chirp()
```

Description

`y = chirp()` returns a swept-frequency cosine output, `y`.

Output Arguments

`y` — Swept-frequency cosine output
scalar | column vector

Swept-frequency cosine output, returned as a scalar or a column vector. The length of the output vector equals the value you specify in the `SamplesPerFrame` property.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

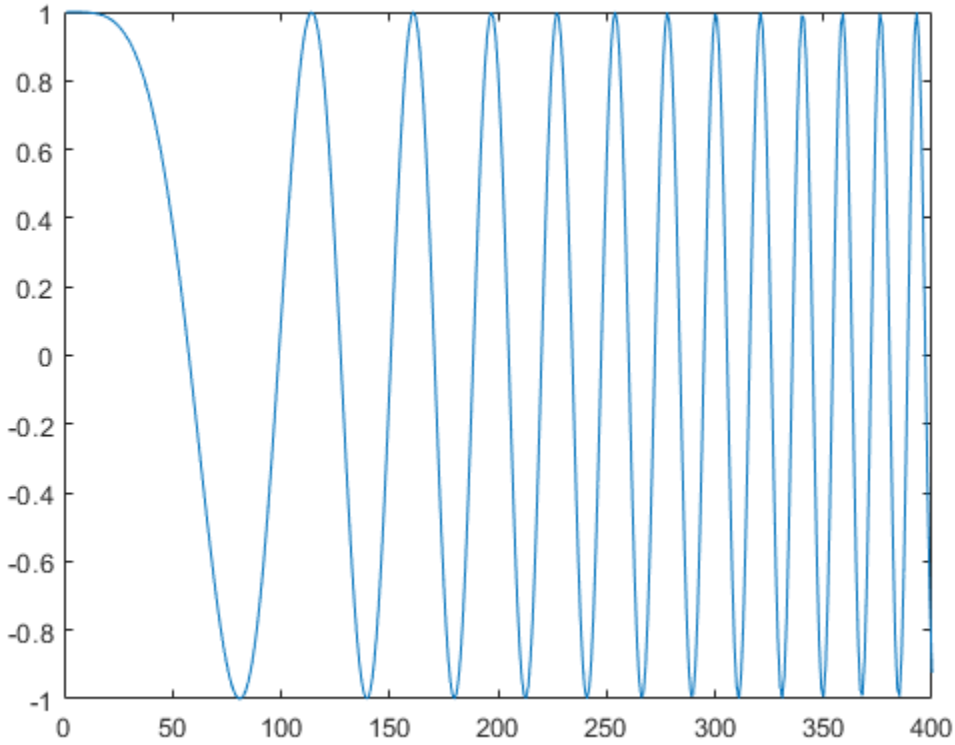
Examples

Generate a Bidirectional Swept Chirp Signal

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
chirp = dsp.Chirp(...
    'SweepDirection', 'Bidirectional', ...
    'TargetFrequency', 25, ...
    'InitialFrequency', 0,...
    'TargetTime', 1, ...
    'SweepTime', 1, ...
    'SamplesPerFrame', 400, ...
    'SampleRate', 400);

plot(chirp());
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Chirp block reference page. The object properties correspond to the block parameters.

dsp.CICCompensationDecimator

Package: `dsp`

Compensate for CIC decimation filter using FIR decimator

Description

You can compensate for the shortcomings of a CIC decimator, namely its passband droop and wide transition region, by following it with a compensation decimator. This System object lets you design and use such a filter.

To compensate for the shortcomings of a CIC filter using an FIR decimator:

1. Create the `dsp.CICCompensationDecimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
ciccompdec = dsp.CICCompensationDecimator
ciccompdec = dsp.CICCompensationDecimator(decim)
ciccompdec = dsp.CICCompensationDecimator(cic)
ciccompdec = dsp.CICCompensationDecimator(cic,decim)
ciccompdec = dsp.CICCompensationDecimator( ___ ,Name,Value)
```

Description

`ciccompdec = dsp.CICCompensationDecimator` returns a System object, `ciccompdec`, that applies an FIR decimator to each channel of an input signal. Using the properties of the object, the decimation filter can be designed to compensate for a preceding CIC filter.

`ciccompdec = dsp.CICCompensationDecimator(decim)` returns a CIC compensation decimator System object, with the `DecimationFactor` property set to `decim`.

`ciccompdec = dsp.CICCompensationDecimator(cic)` returns a CIC compensation decimator System object, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object, `cic`.

`ciccompdec = dsp.CICCompensationDecimator(cic,decim)` returns a CIC compensation decimator System object, `ciccompdec`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object `cic`, and the `DecimationFactor` property set to `decim`.

`ciccompdec = dsp.CICCompensationDecimator( ___ ,Name,Value)` returns a CIC compensation decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`CICDifferentialDelay` — Differential delay of the CIC filter being compensated
`1` (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CICNumSections` — Number of sections of the CIC filter being compensated
2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CICRateChangeFactor` — Rate-change factor of the CIC filter being compensated
2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DecimationFactor` — Decimation factor of compensator
2 (default) | positive integer scalar

Specify the decimation factor of the compensator System object as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DesignForMinimumOrder` — Design filter of minimum order or of specified order
`true` (default) | `false`

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

`FilterOrder` — Order of decimation compensator filter
12 (default) | positive integer scalar

Specify the order of the decimation compensator filter as a positive integer scalar.

Dependencies

This property applies only when you set the `DesignForMinimumOrder` property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandFrequency` — Passband edge frequency in hertz
`100000` (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. `PassbandFrequency` must be less than $F_s/2$, where F_s is the input sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandRipple` — Filter passband ripple in decibels
`0.1` (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SampleRate` — Input sample rate in hertz
`1200000` (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz.

Data Types: `single` | `double`

`StopbandAttenuation` — Filter stopband attenuation in decibels
`60` (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandFrequency` — Stopband edge frequency in hertz
`400000` (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. `StopbandFrequency` must be less than $F_s/2$, where F_s is the input sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

`CoefficientsDataType` — Word and fraction lengths of coefficients
`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see "Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters".

`RoundingMethod` — Rounding method for output fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

Usage

Syntax

```
y = ciccompdecim(x)
```

Description

`y = ciccompdecim(x)` returns the filtered and downsampled values, `y`, of the input signal, `x`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The System object treats a $K_i \times N$ input matrix as N independent channels, decimating each channel over the first dimension.

This object does not support complex unsigned fixed-point data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Filtered and downsampled signal

vector | matrix

Filtered and downsampled signal, returned as a vector or matrix. For a $K_i \times N$ input matrix, the result is a $K_o \times N$ output matrix, where $K_o = K_i / M$ and M is the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.CICCompensationDecimator`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost for implementing filter System objects
coeffs	Filter coefficients
polyphase	Polyphase decomposition of multirate filter

generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Impulse and Frequency Response of CIC Compensation Decimator

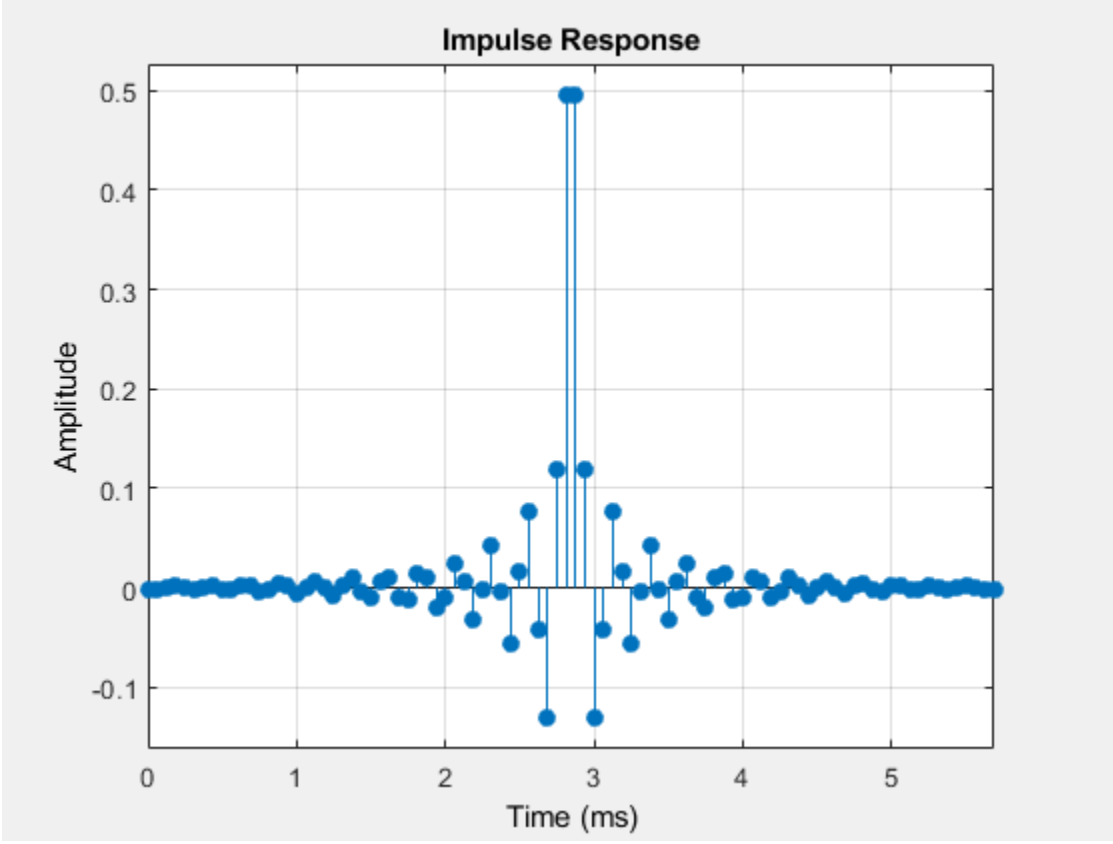
Design an CIC compensation decimator. Specify the decimation factor to be 2, passband frequency to be 4 kHz, stopband frequency to be 4.5 kHz, and the input sample rate to be 16 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;

CICCompDecim = dsp.CICCompensationDecimator('DecimationFactor',2,'PassbandFrequency',fP
    'StopbandFrequency',fStop,'SampleRate',fs);
```

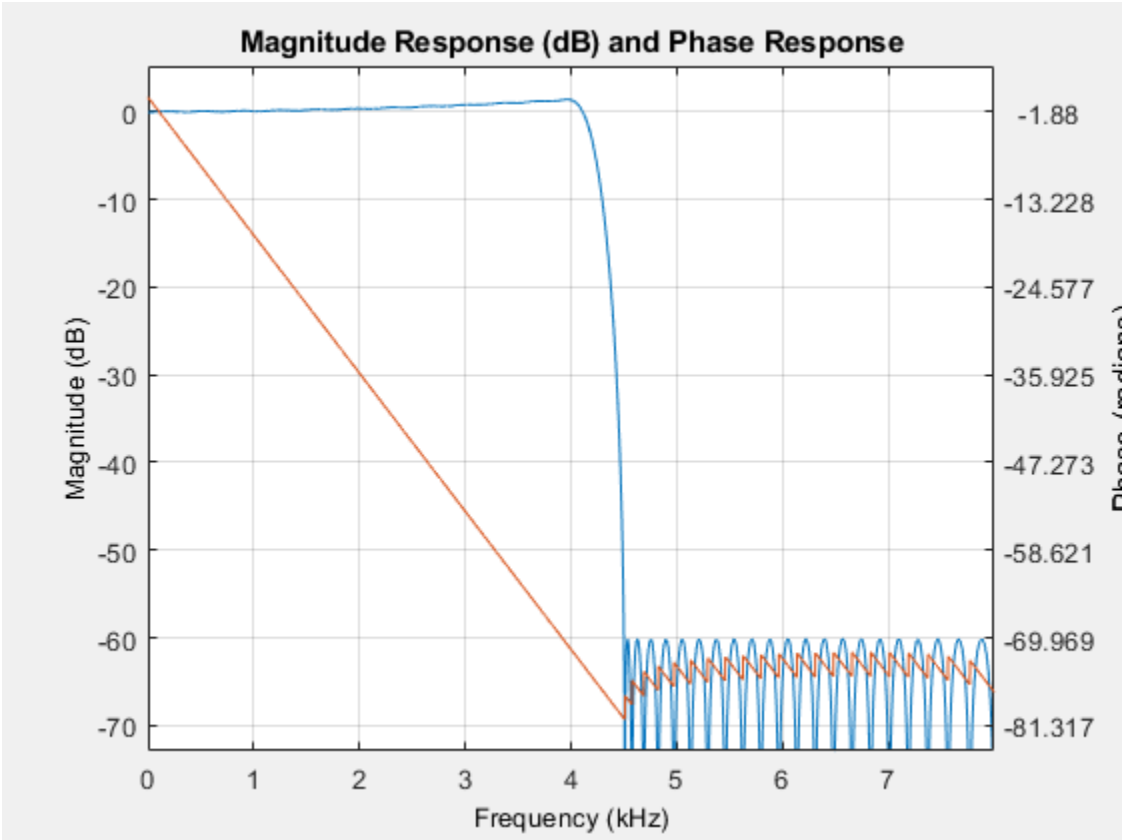
Plot the impulse response. The group delay of the filter is 45.5.

```
fvtool(CICCompDecim,'Analysis','impulse')
```



Plot the magnitude and Phase response.

```
fvtool(CICCompDecim,'Analysis','freq')
```



Compensation Decimator Design

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Design a compensation decimator for an existing CIC decimator having six sections and a decimation factor of 6.

```
CICDecim = dsp.CICDecimator('DecimationFactor',6, ...
    'NumSections',6);
```

Construct the compensation decimator. Specify a decimation factor of 2, an input sample rate of 16 kHz, a passband frequency of 4 kHz, and a stopband frequency of 4.5 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;

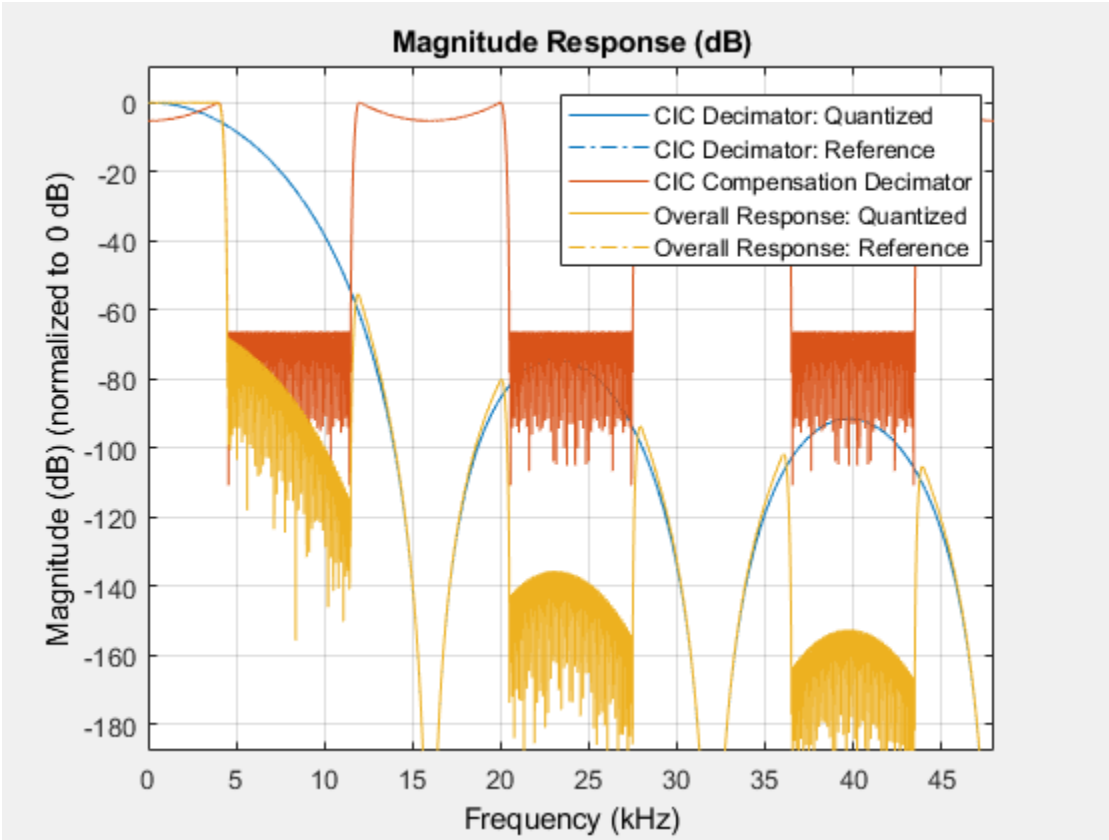
CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...
    'DecimationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
filtCasc = dsp.FilterCascade(CICDecim,CICCompDecim);

f = fvtool(CICDecim, CICCompDecim, filtCasc, ...
    'Fs', [fs*6 fs fs*6]);

f.NormalizeMagnitudeto1 = 'on';
legend(f,'CIC Decimator','CIC Compensation Decimator', ...
    'Overall Response');
```



Apply the design to a 1200-sample random input signal. Store the decimated output along the first dimension of the *y* array.

```
x = dsp.SignalSource(fi(rand(1200,1),1,16,15),'SamplesPerFrame',120);

y = fi(zeros(100,1),1,32,20);

for ind = 1:10
    x2 = CICDecim(x());
    y(((ind-1)*10)+1:ind*10,1) = CICCompDecim(x2);
end
```

Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)}\right]^N$$

R, D, and N are the rate change factor, the differential delay, and the number of sections of the CIC filter, respectively.

After decimation, the cic response has the form:okay

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)}\right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[RD\frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)}\right]^N \text{ for } \omega \le \omega_p < \pi$$

where ω_p is the passband frequency of the CIC compensation filter.

Notice that when $\omega/2R \ll \pi$, the previous equation for $Hciccomp(\omega)$ can be simplified using the fact that $\sin(x) \cong x$:

$$H_{ciccomp}(\omega) \approx \left[\frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)}\right]^N = \left[sinc\left(\frac{D\omega}{2}\right)\right]^{-N} \text{for } \omega \le \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This object does not support complex unsigned fixed-point data.

dsp.CICCompensationInterpolator

Package: `dsp`

Compensate for CIC interpolation filter using FIR interpolator

Description

You can compensate for the shortcomings of a CIC interpolator, namely its passband droop and wide transition region, by preceding it with a compensation interpolator. This System object lets you design and use such a filter.

To compensate for the shortcomings of a CIC filter using an FIR interpolator:

1. Create the `dsp.CICCompensationInterpolator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
ciccompint = dsp.CICCompensationInterpolator
ciccompint = dsp.CICCompensationInterpolator(interp)
ciccompint = dsp.CICCompensationInterpolator(cic)
ciccompint = dsp.CICCompensationInterpolator(cic,interp)
ciccompint = dsp.CICCompensationInterpolator( ___ ,Name,Value)
```

Description

`ciccompint = dsp.CICCompensationInterpolator` returns a System object, `ciccompint`, that applies an FIR interpolator to each channel of an input signal. Using the properties of the object, the interpolation filter can be designed to compensate for a subsequent CIC filter.

`ciccompint = dsp.CICCompensationInterpolator(interp)` returns a CIC compensation interpolator System object, `ciccompint`, with the `InterpolationFactor` property set to `interp`.

`ciccompint = dsp.CICCompensationInterpolator(cic)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`.

`ciccompint = dsp.CICCompensationInterpolator(cic,interp)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`, and the `InterpolationFactor` property set to `interp`.

`ciccompint = dsp.CICCompensationInterpolator( ___ ,Name,Value)` returns a CIC compensation interpolator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`CICDifferentialDelay` — Differential delay of the CIC filter being compensated
1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CICNumSections` — Number of sections of the CIC filter being compensated
2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CICRateChangeFactor` — Rate-change factor of the CIC filter being compensated
2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar. The default is 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DesignForMinimumOrder` — Design filter of minimum order or of specified order
`true` (default) | `false`

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

`FilterOrder` — Order of interpolation compensator filter
12 (default) | positive integer scalar

Specify the order of the interpolation compensator filter as a positive integer scalar.

Dependencies

This property applies only when you set the `DesignForMinimumOrder` property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InterpolationFactor` — Interpolation factor of compensator
2 (default) | positive integer scalar

Specify the interpolation factor of the compensator System object as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandFrequency` — Passband edge frequency in hertz
`100000` (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. `PassbandFrequency` must be less than $F_s/2$, where F_s is the output sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandRipple` — Filter passband ripple in decibels
`0.1` (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SampleRate` — Input sample rate in hertz
`600000` (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz.

Data Types: `single` | `double`

`StopbandAttenuation` — Filter stopband attenuation in decibels
`60` (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandFrequency` — Stopband edge frequency in hertz
`400000` (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. `StopbandFrequency` must be less than $F_s/2$, where F_s is the output sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

`CoefficientsDataType` — Word and fraction lengths of coefficients
`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see "Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters".

`RoundingMethod` — Rounding method for output fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

Usage

Syntax

```
y = ciccompint(x)
```

Description

`y = ciccompint(x)` outputs the upsampled and filtered values, `y`, of the input signal, `x`.

Input Arguments

`x` — Data input
vector | matrix

Data input, specified as a vector or a matrix. The System object treats a $K_i \times N$ input matrix as N independent channels, interpolating each channel over the first dimension.

This object does not support complex unsigned fixed-point data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Upsampled and filtered signal

vector | matrix

Upsampled and filtered signal, returned as a vector or matrix. For a $K_i \times N$ input matrix, the result is a $K_o \times N$ output matrix, where $K_o = K_i \times L$ and L is the interpolation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.CICCompensationInterpolator`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost for implementing filter System objects
coeffs	Filter coefficients
polyphase	Polyphase decomposition of multirate filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step	Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Impulse and Frequency Response of CIC Compensation Interpolator

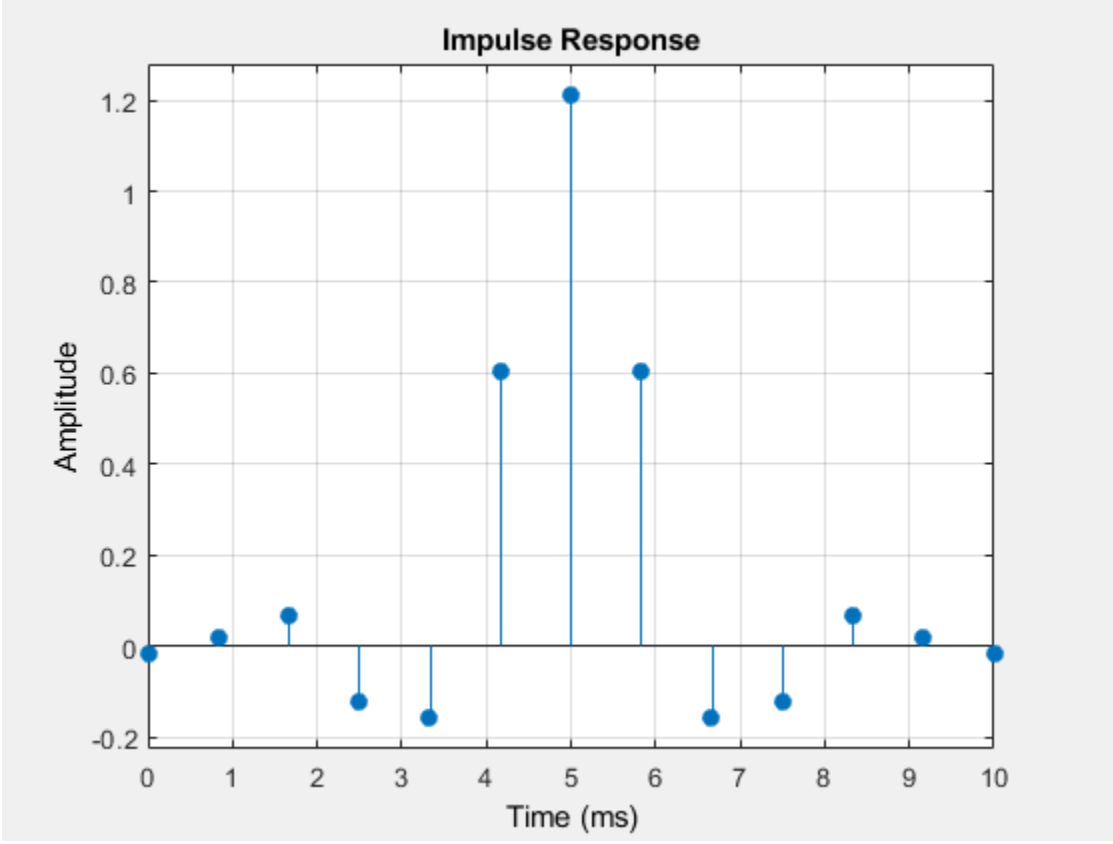
Design an CIC compensation interpolator. Specify the interpolation factor to be 2, passband frequency to be 200 Hz, stopband frequency to be 500 Hz, and the input sample rate to be 600 Hz.

```
fs = 600;
fPass = 200;
fStop = 500;

CICCompInterp = dsp.CICCompensationInterpolator('InterpolationFactor',2,'PassbandFreque
    'StopbandFrequency',fStop,'SampleRate',fs);
```

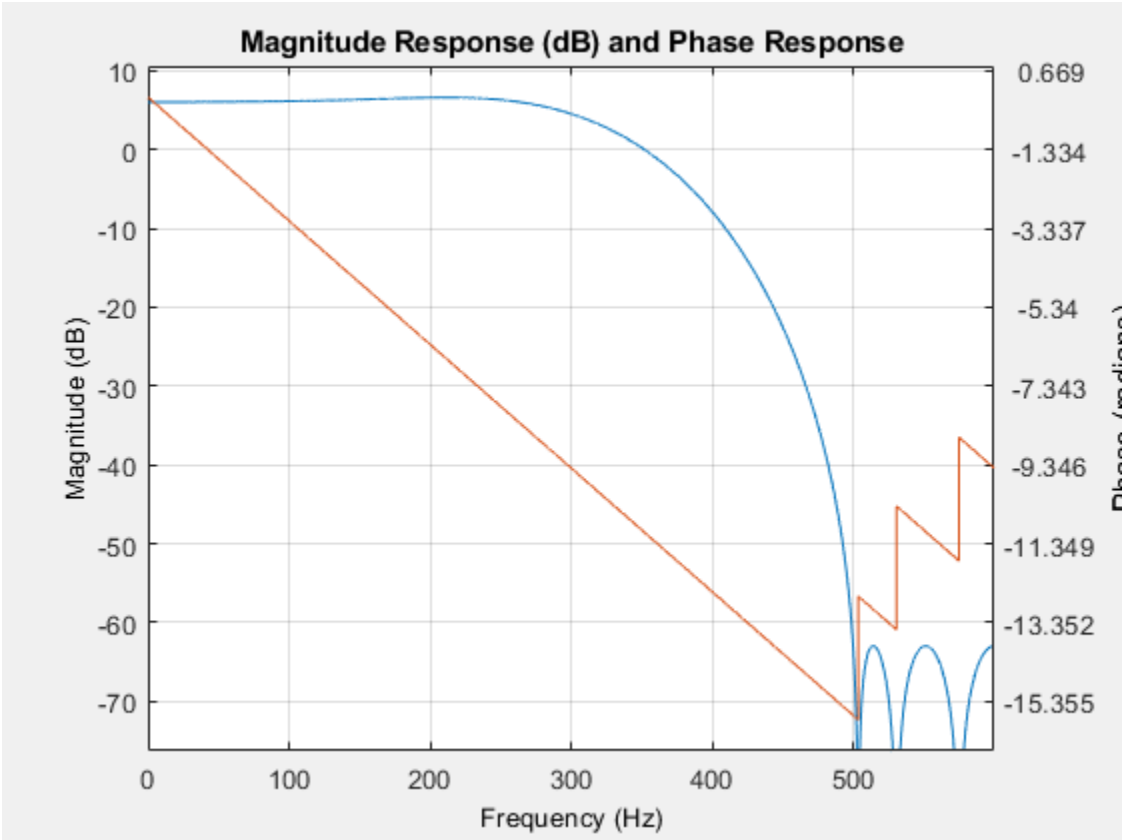
Plot the impulse response. The zeroth order coefficient is delayed 6 samples, which is equal to the group delay of the filter.

```
fvtool(CICCompInterp,'Analysis','impulse')
```



Plot the magnitude and Phase response.

```
fvtool(CICCompInterp,'Analysis','freq')
```



Compensation Interpolator Design

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Design a compensation interpolator for an existing CIC interpolator having six sections and an interpolation factor of 16.

```
CICInterp = dsp.CICInterpolator('InterpolationFactor',16, ...
    'NumSections',6);
```

Construct the compensation interpolator. Specify an interpolation factor of 2, an input sample rate of 600 Hz, a passband frequency of 100 Hz, and a stopband frequency of 250 Hz. Set the minimum attenuation of alias components in the stopband to be at least 80 dB.

```
fs = 600;
fPass = 100;
fStop = 250;
ast = 80;

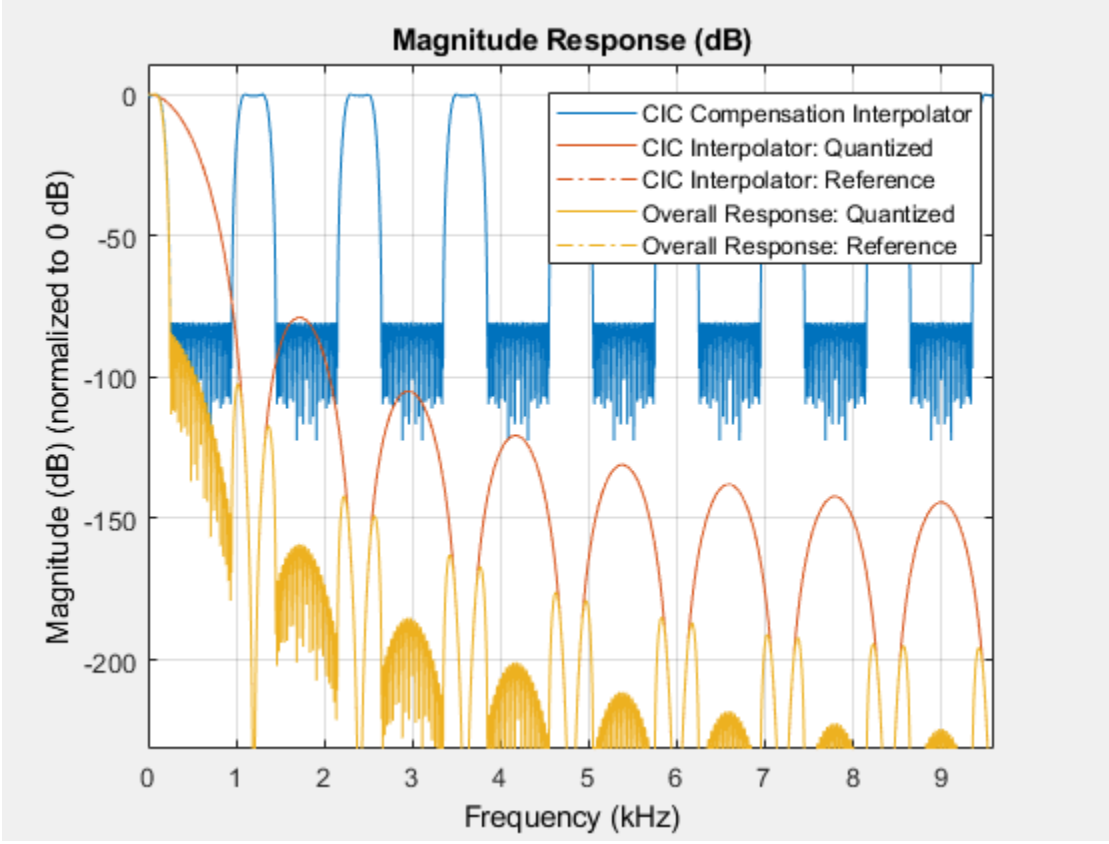
CICCompInterp = dsp.CICCompensationInterpolator(CICInterp, ...
    'InterpolationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'StopbandAttenuation',ast, ...
    'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
FC = dsp.FilterCascade(CICCompInterp, CICInterp);

f = fvtool(CICCompInterp,CICInterp,FC, ...
    'Fs', [fs*2 fs*16*2 fs*16*2]);

f.NormalizeMagnitudeto1 = 'on';
legend(f,'CIC Compensation Interpolator','CIC Interpolator', ...
    'Overall Response');
```



Apply the design to a 1000-sample random input signal.

```
x = dsp.SignalSource(fi(rand(1000,1),1,16,15),'SamplesPerFrame',100);

y = fi(zeros(32000,1),1,32,20);
for ind = 1:10
    x2 = CICCompInterp(x());
    y(((ind-1)*3200)+1:ind*3200) = CICInterp(x2);
end
```

Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)}\right]^N$$

R, D, and N are the rate change factor, the differential delay, and the number of sections of the CIC filter, respectively.

After decimation, the cic response has the form:okay

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)}\right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[RD\frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)}\right]^N \text{ for } \omega \le \omega_p < \pi$$

where ω_p is the passband frequency of the CIC compensation filter.

Notice that when $\omega/2R \ll \pi$, the previous equation for $Hciccomp(\omega)$ can be simplified using the fact that $\sin(x) \cong x$:

$$H_{ciccomp}(\omega) \approx \left[\frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)}\right]^N = \left[sinc\left(\frac{D\omega}{2}\right)\right]^{-N} \text{for } \omega \le \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This object does not support complex unsigned fixed-point data.

dsp.CICDecimator

Package: `dsp`

Decimate signal using cascaded integrator-comb (CIC) filter

Description

The `dsp.CICDecimator` System object decimates an input signal using a cascaded integrator-comb (CIC) decimation filter. The CIC decimation filter structure consists of *N* sections of cascaded integrators, followed by a rate change by a factor of *R*, followed by *N* sections of cascaded comb filters. For details, see “Algorithms” on page 4-345. The NumSections property specifies *N*, the number of sections in the CIC filter. The DecimationFactor property specifies *R*, the decimation factor. The `getFixedPointInfo` function returns the word lengths and fraction lengths of the fixed-point sections and the output for the `dsp.CICDecimator` System object. You can also generate HDL code for this System object using the `generatehdl` function.

Note This object requires a Fixed-Point Designer license.

To decimate a signal using a CIC filter:

1. Create the `dsp.CICDecimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
cicDecim = dsp.CICDecimator
cicDecim = dsp.CICDecimator(R,M,N)
```

```
cicDecim = dsp.CICDecimator(Name,Value)
```

Description

`cicDecim = dsp.CICDecimator` creates a CIC decimation System object that applies a CIC decimation filter to the input signal.

`cicDecim = dsp.CICDecimator(R,M,N)` creates a CIC decimation object with the `DecimationFactor` property set to `R`, the `DifferentialDelay` property set to `M`, and the `NumSections` property set to `N`.

`cicDecim = dsp.CICDecimator(Name,Value)` creates a CIC decimation object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combination.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`DecimationFactor` — Decimation factor

2 (default) | positive integer

Factor by which the input signal is decimated, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DifferentialDelay` — Differential delay of filter comb sections

1 (default) | positive integer

Differential delay value used in each of the comb sections of the filter, specified as a positive integer. For details, see “Algorithms” on page 4-345. If the differential delay is a built-in integer data type, the decimation factor must be the same integer data type or

`double`. For example, if the differential delay is an `int8`, then the decimation factor must be an `int8` or `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumSections` — Number of integrator and comb sections

2 (default) | positive integer

Number of integrator and comb sections of the CIC filter, specified as a positive integer. This number indicates the number of sections in either the comb part or the integrator part of the filter. The total number of sections in the CIC filter is twice the number of sections given by this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FixedPointDataType` — Fixed-point property designations

`Full precision` (default) | `Minimum section word lengths` | `Specify word lengths` | `Specify word and fraction lengths`

Fixed-point property designations, specified as one of the following:

- `Full precision` – The word length and fraction length of the CIC filter sections and the object output operate in full precision.
- `Minimum section word lengths` – Specify the output word length through the OutputWordLength property. The object determines the filter section data type and the output fraction length that give the best possible precision. For details, see `getFixedPointInfo` and `cicDecimOut` argument.
- `Specify word lengths` – Specify the word lengths of the CIC filter sections and the object output through the SectionWordLengths and OutputWordLength properties. The object determines the corresponding fraction lengths to give the best possible precision. For details, see `getFixedPointInfo` and the `cicDecimOut` argument.
- `Specify word and fraction lengths` – Specify the word length and fraction length of the CIC filter sections and the object output through the SectionWordLengths, SectionFractionLengths, OutputWordLength, and OutputFractionLength properties.

`SectionWordLengths` — Fixed-point word lengths for each filter section

`[16 16 16 16]` (default) | scalar | vector

Fixed-point word lengths to use for each filter section, specified as a scalar or a row vector of integers. The word length must be greater than or equal to 2. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length 2 × `NumSections`.

Example: `32`

Example: `[32 32 32 32]`

Dependencies

This property applies when you set the `FixedPointDataType` property to `'Specify word lengths'` or `'Specify word and fraction lengths'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SectionFractionLengths` — Fixed-point fraction lengths for each filter section

`0` (default) | scalar | vector

Fixed-point fraction lengths to use for each filter section, specified as a scalar or a row vector of integers. The fraction length can be negative, 0, or positive. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length 2 × `NumSections`.

Example: `-2`

Example: `[-2 0 5 8]`

Dependencies

This property applies when you set the `FixedPointDataType` property to `'Specify word and fraction lengths'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OutputWordLength` — Fixed-point word length for filter output

`32` (default) | scalar integer

Fixed-point word length to use for the filter output, specified as a scalar integer greater than or equal to 2.

Dependencies

This property applies when you set the `FixedPointDataType` property to `'Minimum section word lengths'`, `'Specify word lengths'`, or `'Specify word and fraction lengths'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OutputFractionLength` — Fixed-point fraction length for filter output
`0` (default) | scalar integer

Fixed-point fraction length to use for the filter output, specified as a scalar integer.

Dependencies

This property applies when you set `FixedPointDataType` property to `'Specify word and fraction lengths'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
cicDecimOut = cicDecim(input)
```

Description

`cicDecimOut = cicDecim(input)` decimates the input using a CIC decimator.

Input Arguments

`input` — Data input
vector | matrix

Data input, specified as a vector or matrix. The number of rows in the input must be a multiple of the “DecimationFactor” on page 4-0 . If the input is of `single` or `double` data type, property settings related to the fixed-point data types are ignored.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

`cicDecimOut` — CIC decimator output

vector | matrix

Decimated output, returned as a vector or a matrix. The output frame size equals (1 / `DecimationFactor`) × input frame size. The complexity of the output data matches that of the input data. If the input is `single` or `double`, the output data type matches the input data type.

If the input is of built-in integer data type or of fixed-point data type, the output word length and fraction length depend on the fixed-point data type setting you choose through the “FixedPointDataType” on page 4-0 property.

Full precision

When the `FixedPointDataType` is set to `'Full precision'`, the following relationship applies:

$$WL_{\text{output}} = WL_{\text{input}} + NumSect$$
$$FL_{\text{output}} = FL_{\text{input}}$$

where,

- WL_{output} –– Word length of the output data.
- FL_{output} –– Fraction length of the output data.
- WL_{input} –– Word length of the input data.
- FL_{input} –– Fraction length of the input data.
- *NumSect* –– Number of sections in the CIC filter specified through the “NumSections” on page 4-0 property.

The WL_{input} and FL_{input} are inherited from the data input you pass to the object algorithm. For built-in integer inputs, the fraction length is 0.

Minimum section word lengths

When the `FixedPointDataType` property is set to `'Minimum section word lengths'`, the output word length is the value you specify in the "OutputWordLength" on page 4-0 property. The output fraction length, FL_{output}, is given by:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

Specify word and fraction lengths

When the `FixedPointDataType` property is set to `'Specify word and fraction lengths'`, the output word length and fraction length are the values you specify in the "OutputWordLength" on page 4-0 and "OutputFractionLength" on page 4-0 properties.

Specify word lengths

When the `FixedPointDataType` property is set to `'Specify word lengths'`, the output word length is the value you specify in the `OutputWordLength` property. The output fraction length, FL_{output}, is given by:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CICDecimator

generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
impz	Impulse response of discrete-time filter System object
freqz	Frequency response of filter
phasez	Unwrapped phase response for filter
fvtool	Visualize frequency response of DSP filters
gain	CIC filter gain

getFixedPointInfo	Get fixed-point word and fraction lengths
info	Information about filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.CICDecimator.helpFilterAnalysis` in the MATLAB command prompt. For the corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Decimate a Signal Using a CICDecimator Object

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.CICDecimator` System object™ with `DecimationFactor` set to 4. Decimate a signal from 44.1 kHz to 11.025 kHz.

```
cicdec = dsp.CICDecimator(4);
cicdec.FixedPointDataType = 'Minimum section word lengths';
cicdec.OutputWordLength = 16;
```

Create a fixed-point sinusoidal input signal of 1024 samples, with a sampling frequency of 44.1e3 Hz.

```
Fs = 44.1e3;
n = (0:1023)';            % 0.0232 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create a `dsp.SignalSource` object.

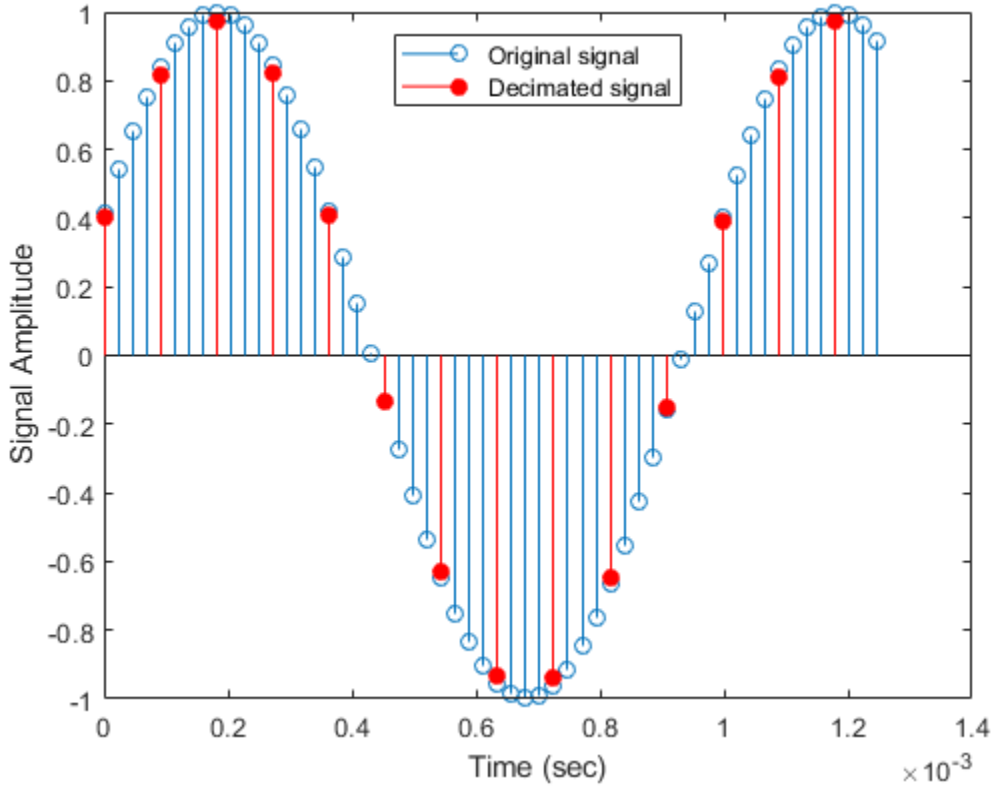
```
src = dsp.SignalSource(x,64);
```

Decimate the output with 16 samples per frame.

```
y = zeros(16,16);
for ii = 1:16
     y(ii,:) = cicdec(src());
end
```

Plot the first frame of the original and decimated signals. Output latency is 2 samples.

```
gainCIC = ...
   (cicdec.DecimationFactor*cicdec.DifferentialDelay)^cicdec.NumSections;
stem(n(1:56)/Fs,double(x(4:59)))
hold on;
stem(n(1:14)/(Fs/cicdec.DecimationFactor),double(y(1,3:end))/gainCIC,'r','filled')
xlabel('Time (sec)')
ylabel('Signal Amplitude')
legend('Original signal','Decimated signal','Location','north')
hold off;
```



Using the `info` method in `'long'` format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicdec,'long')
```

```
ans =
    'Discrete-Time FIR Multirate Filter (real)
     ----------------------------------------
     Filter Structure    : Cascaded Integrator-Comb Decimator
     Decimation Factor   : 4
     Differential Delay  : 1
     Number of Sections  : 2
     Stable              : Yes
     Linear Phase        : Yes (Type 1)
```

```
Implementation Cost

Fixed-Point Info
Section word lengths     : 20  19  19  18
Section fraction lengths : 15  14  14  13
Output  word length      : 16
Output  fraction length  : 11
'
```

Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLs and FLs vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator
```

```
cicD =
  dsp.CICDecimator with properties:

      DecimationFactor: 2
    DifferentialDelay: 1
          NumSections: 2
```

```
    FixedPointDataType: 'Full precision'
```

By default, the `FixedPointDataType` property of the object is set to `'Full precision'`. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```
nt = numerictype(1,16,15)

nt =

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 15

[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok

WLs = 1×5

    18    18    18    18    18

FLs = 1×5

    15    15    15    15    15
```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```
input = int64(randn(8,1))

input = 8x1 int64 column vector

    1
    2
   -2
    1
    0
   -1
```

```
    0
    0
```

```
output = cicD(input)
```

```
output=4×1 object
     0
     1
     3
     0

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 66
        FractionLength: 0
```

```
[WLs,FLs] = getFixedPointInfo(cicD) %#ok
```

```
WLs = 1×5

    66    66    66    66    66

FLs = 1×5

     0     0     0     0     0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

Minimum section word lengths

Release the object and change the `FixedPointDataType` property to `'Minimum section word lengths'`. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'
```

```
cicD =
  dsp.CICDecimator with properties:
```

```
      DecimationFactor: 2
     DifferentialDelay: 1
           NumSections: 2
    FixedPointDataType: 'Minimum section word lengths'
      OutputWordLength: 32
```

```
inputF = fi(randn(8,2),1,24,15)
```

```
inputF=8×2 object
    3.5784   -0.1241
    2.7694    1.4897
   -1.3499    1.4090
    3.0349    1.4172
    0.7254    0.6715
   -0.0630   -1.2075
    0.7148    0.7172
   -0.2050    1.6302

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 24
        FractionLength: 15
```

```
[WLs, FLs] = getFixedPointInfo(cicD,numerictype(inputF)) %#ok
```

```
WLs = 1×5

    26    26    26    26    32

FLs = 1×5

    15    15    15    15    21
```

Specify word and fraction lengths

Change the `FixedPointDataType` property to `'Specify word and fraction lengths'`. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'
```

```
cicD =
  dsp.CICDecimator with properties:

          DecimationFactor: 2
         DifferentialDelay: 1
               NumSections: 2
        FixedPointDataType: 'Specify word and fraction lengths'
        SectionWordLengths: [16 16 16 16]
    SectionFractionLengths: 0
          OutputWordLength: 32
      OutputFractionLength: 0
```

```
[WLs, FLs] = getFixedPointInfo(cicD,numerictype(inputF)) %#ok
```

```
WLs = 1×5

    16    16    16    16    32

FLs = 1×5

     0     0     0     0     0
```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numerictype` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```
WLs = 1×5

    16    16    16    16    32

FLs = 1×5

     0     0     0     0     0
```

Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to `'Specify word lengths'`.

```
cicD.FixedPointDataType = 'Specify word lengths'

cicD =
  dsp.CICDecimator with properties:

      DecimationFactor: 2
     DifferentialDelay: 1
           NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
      OutputWordLength: 32
```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD,numerictype(inputF))

WLs = 1×5

    16    16    16    16    32

FLs = 1×5

     5     5     5     5    21
```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

More About

CIC Filter

The CIC decimation filter decreases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

The CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The transfer function of the single rate CIC filter *H(z)* is given by the following equation:

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k}\right]^N = \frac{\left(1 - z^{-RM}\right)^N}{\left(1 - z^{-1}\right)^N} = \frac{1}{\left(1 - z^{-1}\right)^N} \cdot \frac{\left(1 - z^{-RM}\right)^N}{1} = H_I{}^N(z) \cdot H_C{}^N(z)$$

where,

- H_I is the transfer function of the integrator part of the filter.
- H_C is the transfer function of the comb part of the filter.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the decimation factor.
- M is the differential delay.

For the multirate implementation, the algorithm applies the noble identity for decimation and moves the rate change factor, R, to follow after the N sections of the cascaded integrators. The transfer function of the resulting filter is given by the following equation:

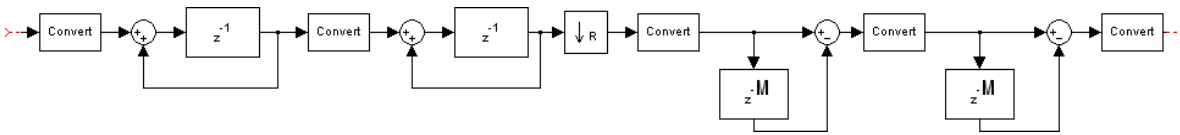
$$H(z) = \frac{\left(1 - z^{-M}\right)^N}{\left(1 - z^{-1}\right)^N}.$$

For a block diagram that shows the multirate implementation, see “Algorithms” on page 4-345.

Algorithms

CIC Decimation Filter

The filter *H(z)* in “More About” on page 4-344 is realized as a decimation filter when the N sections of the cascaded integrators are followed by a rate change factor of R, followed by N sections of comb filters.



This diagram shows two sections of cascaded integrators and two sections of cascaded comb filters. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feedforward path of the integrator because it is a preferred configuration for HDL implementation.

dsp.CICInterpolator

Package: `dsp`

Interpolate signal using cascaded integrator-comb filter

Description

The `dsp.CICInterpolator` System object interpolates an input signal using a cascaded integrator-comb (CIC) interpolation filter. The CIC interpolation filter structure consists of *N* sections of cascaded comb filters, followed by a rate change by a factor of *R*, followed by *N* sections of cascaded integrators. For details, see “Algorithms” on page 4-365. The NumSections property specifies *N*, the number of sections in the CIC filter. The InterpolationFactor property specifies *R*, the interpolation factor. The `getFixedPointInfo` function returns the word lengths and fraction lengths of the fixed-point sections and the output for the `dsp.CICInterpolator` System object. You can also generate HDL code for this System object using the `generatehdl` function.

Note This object requires a Fixed-Point Designer license.

To interpolate a signal using a CIC filter:

1. Create the `dsp.CICInterpolator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
cicInterp = dsp.CICInterpolator
cicInterp = dsp.CICInterpolator(R,M,N)
```

```
cicInterp = dsp.CICInterpolator(Name,Value)
```

Description

`cicInterp = dsp.CICInterpolator` creates a CIC interpolation System object that applies a CIC interpolation filter to the input signal.

`cicInterp = dsp.CICInterpolator(R,M,N)` creates a CIC interpolation object with the `InterpolationFactor` property set to `R`, the `DifferentialDelay` property set to `M`, and the `NumSections` property set to `N`.

`cicInterp = dsp.CICInterpolator(Name,Value)` creates a CIC interpolation object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`InterpolationFactor` — Interpolation factor

2 (default) | positive integer

Factor by which the input signal is interpolated, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DifferentialDelay` — Differential delay of filter comb sections

1 (default) | positive integer

Differential delay value used in each of the comb sections of the filter, specified as a positive integer. For details, see “Algorithms” on page 4-365. If the differential delay is of built-in integer class data type, the interpolation factor must be the same integer data

type or `double`. For example, if the differential delay is an `int8`, then the interpolation factor must be an `int8` or `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumSections` — Number of integrator and comb sections

2 (default) | positive integer

Number of integrator and comb sections of the CIC filter, specified as a positive integer. This number indicates the number of sections in either the comb part or the integrator part of the filter. The total number of sections in the CIC filter is twice the number of sections given by this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FixedPointDataType` — Fixed-point property designations

`Full precision` (default) | `Minimum section word lengths` | `Specify word lengths` | `Specify word and fraction lengths`

Fixed-point property designations, specified as one of the following:

- `Full precision` – The word length and fraction length of the CIC filter sections and the object output operate in full precision.
- `Minimum section word lengths` – Specify the output word length through the OutputWordLength property. The object determines the filter section data type and the output fraction length that give the best possible precision. For details, see `getFixedPointInfo` and `cicInterpOut` argument.
- `Specify word lengths` – Specify the word lengths of the CIC filter sections and the object output through the SectionWordLengths and OutputWordLength properties. The object determines the corresponding fraction lengths to give the best possible precision. For details, see `getFixedPointInfo` and the `cicInterpOut` argument.
- `Specify word and fraction lengths` – Specify the word length and fraction length of the CIC filter sections and the object output through the SectionWordLengths, SectionFractionLengths, OutputWordLength, and OutputFractionLength properties.

`SectionWordLengths` — Fixed-point word lengths for each filter section

`[16 16 16 16]` (default) | scalar | vector

Fixed-point word lengths to use for each filter section, specified as a scalar or a row vector of integers. The word length must be greater than or equal to 2. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length 2 × `NumSections`.

Example: `32`

Example: `[32 32 32 32]`

Dependencies

This property applies when you set the `FixedPointDataType` property to `'Specify word lengths'` or `'Specify word and fraction lengths'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SectionFractionLengths` — Fixed-point fraction lengths for each filter section

`0` (default) | scalar | vector

Fixed-point fraction lengths to use for each filter section, specified as a scalar or a row vector of integers. The fraction length can be negative, 0, or positive. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length 2 × `NumSections`.

Example: `-2`

Example: `[-2 0 5 8]`

Dependencies

This property applies when you set the `FixedPointDataType` property to `'Specify word and fraction lengths'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OutputWordLength` — Fixed-point word length for filter output

`32` (default) | scalar integer

Fixed-point word length to use for the filter output, specified as a scalar integer greater than or equal to 2.

Dependencies

This property applies when you set the `FixedPointDataType` property to one of `'Minimum section word lengths'`, `'Specify word lengths'`, or `'Specify word and fraction lengths'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OutputFractionLength` — Fixed-point fraction length for filter output
`0` (default) | scalar integer

Fixed-point fraction length to use for the filter output, specified as a scalar integer.

Dependencies

This property applies when you set the `FixedPointDataType` property to `'Specify word and fraction lengths'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
cicInterpOut = cicInterp(input)
```

Description

`cicInterpOut = cicInterp(input)` interpolates the input using a CIC interpolator.

Input Arguments

`input` — Data input
vector | matrix

Data input, specified as a vector or matrix. If the input is of single or double data type, property settings related to the fixed-point data types are ignored.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

`cicInterpOut` — CIC interpolator output

vector | matrix

Interpolated output, returned as a vector or a matrix. The output frame size equals ("InterpolationFactor" on page 4-0) × input frame size. The complexity of the output data matches that of the input data. If the input is `single` or `double`, the output data type matches the input data type.

If the input is of built-in integer data type or of fixed-point data type, the output word length and fraction length depend on the fixed-point data type setting you choose through the "FixedPointDataType" on page 4-0 property.

Full precision

When the `FixedPointDataType` property is set to `'Full precision'`, the following relationship applies:

$$WL_{\text{output}} = WL_{\text{input}} + NumSect$$
$$FL_{\text{output}} = FL_{\text{input}}$$

where,

- WL_{output} –– Word length of the output data.
- FL_{output} –– Fraction length of the output data.
- WL_{input} –– Word length of the input data.
- FL_{input} –– Fraction length of the input data.
- *NumSect* –– Number of sections in the CIC filter specified through the "NumSections" on page 4-0 property.

WL_{input} and FL_{input} are inherited from the data input you pass to the object algorithm. For built-in integer inputs, the fraction length is 0.

Minimum section word lengths

When the `FixedPointDataType` property is set to `'Minimum section word lengths'`, the output word length is the value you specify in "OutputWordLength" on

page 4-0 property. The output fraction length, FL_{output} is given by the following equation:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

Specify word and fraction lengths

When the `FixedPointDataType` is set to `'Specify word and fraction lengths'`, the output word length and fraction length are the values you specify in the "OutputWordLength" on page 4-0 and "OutputFractionLength" on page 4-0 properties.

Specify word lengths

When the `FixedPointDataType` is set to `'Specify word lengths'`, the output word length is the value you specify in the `OutputWordLength` property. The output fraction length, FL_{output} is given by the following equation:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CICInterpolator

generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
impz	Impulse response of discrete-time filter System object
freqz	Frequency response of filter
phasez	Unwrapped phase response for filter
fvtool	Visualize frequency response of DSP filters
gain	CIC filter gain
getFixedPointInfo	Get fixed-point word and fraction lengths

info	Information about filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.CICInterpolator.helpFilterAnalysis` in the MATLAB command prompt. For the corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Interpolate a Signal Using CICInterpolator Object

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.CICInterpolator` System object™ with `InterpolationFactor` set to 2. Interpolate signal by a factor of 2 from 22.05 kHz to 44.1 kHz.

```
cicint = dsp.CICInterpolator(2);
```

Create fixed-point sinusoidal input signal of 512 samples, with a sampling frequency 22.05 kHz.

```
Fs = 22.05e3;
n = (0:511)';      % 0.0113 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create `dsp.SignalSource` System object.

```
src = dsp.SignalSource(x,32);
```

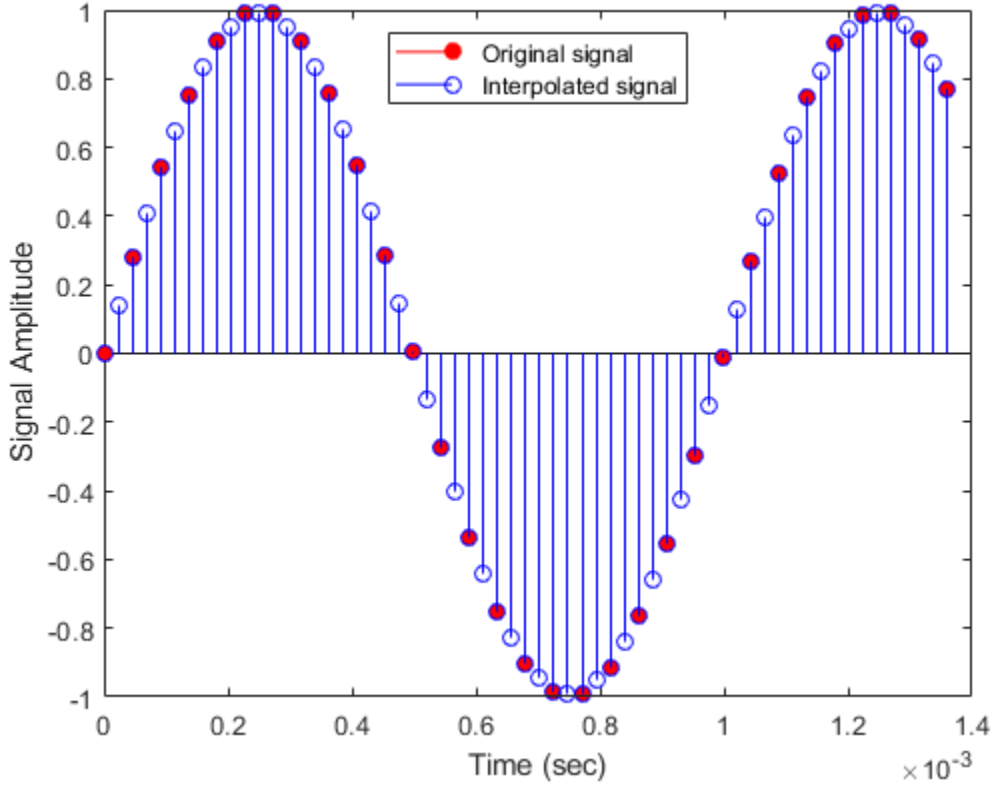
Interpolate the output with 64 samples per frame.

```
y = zeros(16,64);
for ii = 1:16
```

```
    y(ii,:) = cicint(src());
end
```

Plot the first frame of the original and interpolated signals. Output latency is 2 samples.

```
gainCIC = ...
   (cicint.InterpolationFactor*cicint.DifferentialDelay)...
   ^cicint.NumSections/cicint.InterpolationFactor;
stem(n(1:31)/Fs, double(x(1:31)),'r','filled')
hold on;
stem(n(1:61)/(Fs*cicint.InterpolationFactor), ...
   double(y(1,4:end))/gainCIC,'b')
xlabel('Time (sec)')
ylabel('Signal Amplitude')
legend('Original signal','Interpolated signal',...
   'location','north')
hold off;
```



Using the `info` method in `'long'` format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicint,'long')
```

```
ans =
    'Discrete-Time FIR Multirate Filter (real)

```

Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLs and FLs vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator
```

```
cicD =
  dsp.CICDecimator with properties:

      DecimationFactor: 2
    DifferentialDelay: 1
          NumSections: 2
```

```
    FixedPointDataType: 'Full precision'
```

By default, the `FixedPointDataType` property of the object is set to `'Full precision'`. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```
nt = numerictype(1,16,15)

nt =

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 15

[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok

WLs = 1×5

    18    18    18    18    18

FLs = 1×5

    15    15    15    15    15
```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```
input = int64(randn(8,1))

input = 8x1 int64 column vector

    1
    2
   -2
    1
    0
   -1
```

```
    0
    0
```

```
output = cicD(input)
```

```
output=4×1 object
     0
     1
     3
     0

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 66
        FractionLength: 0
```

```
[WLs,FLs] = getFixedPointInfo(cicD) %#ok
```

```
WLs = 1×5

    66    66    66    66    66

FLs = 1×5

     0     0     0     0     0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

Minimum section word lengths

Release the object and change the `FixedPointDataType` property to `'Minimum section word lengths'`. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'
```

```
cicD =
  dsp.CICDecimator with properties:
```

```
      DecimationFactor: 2
     DifferentialDelay: 1
           NumSections: 2
    FixedPointDataType: 'Minimum section word lengths'
      OutputWordLength: 32
```

```
inputF = fi(randn(8,2),1,24,15)
```

```
inputF=8×2 object
    3.5784   -0.1241
    2.7694    1.4897
   -1.3499    1.4090
    3.0349    1.4172
    0.7254    0.6715
   -0.0630   -1.2075
    0.7148    0.7172
   -0.2050    1.6302

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 24
        FractionLength: 15
```

```
[WLs, FLs] = getFixedPointInfo(cicD,numerictype(inputF)) %#ok
```

```
WLs = 1×5

    26    26    26    26    32

FLs = 1×5

    15    15    15    15    21
```

Specify word and fraction lengths

Change the `FixedPointDataType` property to `'Specify word and fraction lengths'`. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'
```

```
cicD =
  dsp.CICDecimator with properties:

         DecimationFactor: 2
        DifferentialDelay: 1
              NumSections: 2
       FixedPointDataType: 'Specify word and fraction lengths'
       SectionWordLengths: [16 16 16 16]
    SectionFractionLengths: 0
          OutputWordLength: 32
      OutputFractionLength: 0
```

```
[WLs, FLs] = getFixedPointInfo(cicD,numerictype(inputF)) %#ok
```

```
WLs = 1×5

    16    16    16    16    32

FLs = 1×5

     0     0     0     0     0
```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numerictype` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```
WLs = 1×5

    16    16    16    16    32

FLs = 1×5

     0     0     0     0     0
```

Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to `'Specify word lengths'`.

```
cicD.FixedPointDataType = 'Specify word lengths'

cicD =
  dsp.CICDecimator with properties:

      DecimationFactor: 2
     DifferentialDelay: 1
           NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
      OutputWordLength: 32
```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD,numerictype(inputF))

WLs = 1×5

    16    16    16    16    32

FLs = 1×5

     5     5     5     5    21
```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

More About

CIC Filter

The CIC interpolation filter increases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

The CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The transfer function of the single rate CIC filter *H(z)* is given by the following equation:

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k}\right]^N = \frac{(1-z^{-RM})^N}{(1-z^{-1})^N} = \frac{(1-z^{-RM})^N}{1} \cdot \frac{1}{(1-z^{-1})^N} = H_C{}^N(z) \cdot H_I{}^N(z)$$

where,

- H_C is the transfer function of the comb part of the filter.
- H_I is the transfer function of the integrator part of the filter.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the interpolation factor.
- M is the differential delay.

For the multirate implementation, the algorithm applies the noble identity for interpolation and moves the rate change factor, R, to follow after the N sections of the cascaded comb filters. The transfer function of the resulting filter is given by the following equation:

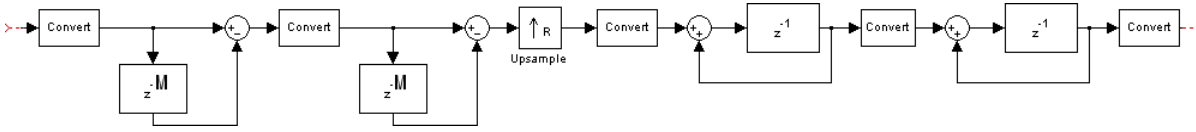
$$H(z) = \frac{\left(1-z^{-M}\right)^N}{\left(1-z^{-1}\right)^N}.$$

For a block diagram that shows the multirate implementation, see “Algorithms” on page 4-365.

Algorithms

CIC Interpolation Filter

The filter *H(z)* in “More About” on page 4-364 is realized as an interpolation filter when N sections of cascaded comb filters are followed by a rate change by a factor R, followed by N sections of cascaded integrators.



This diagram shows two sections of cascaded comb filters and two sections of cascaded integrators. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feedforward path of the integrator since it is a preferred configuration for HDL implementation.

dsp.HDLCICDecimation

Package: `dsp`

Decimate signal using cascaded integrator-comb filter — optimized for HDL code generation

Description

The `dsp.HDLCICDecimation` System object decimates an input signal by using a cascaded integrator-comb (CIC) decimation filter. CIC filters are a class of linear phase FIR filters comprised of a comb part and an integrator part. The CIC decimation filter structure consists of *N* sections of cascaded integrators, a rate change factor of *R*, and then *N* sections of cascaded comb filters. For more information about CIC decimation filter, see “Algorithms” on page 4-377.

The System object supports fixed decimation rate. It provides an architecture suitable for HDL code generation and hardware deployment.

The System object supports real and complex fixed-point inputs.

To filter input data with an HDL-optimized CIC decimation filter:

1. Create the `dsp.HDLCICDecimation` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
cicDecFilt = dsp.HDLCICDecimation
cicDecFilt = dsp.HDLCICDecimation(Name,Value)
```

Description

`cicDecFilt = dsp.HDLCICDecimation` creates an HDL-optimized CIC decimation filter System object, `cicDecFilt`, with default properties.

`cicDecFilt = dsp.HDLCICDecimation(Name,Value)` creates the filter with properties set using one or more name-value pairs. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`DecimationFactor` — Decimation factor
2 (default) | integer from 2 to 2048

Specify the decimation factor as an integer from 2 to 2048. This value represents the rate with which you want to decimate the block input.

`DifferentialDelay` — Differential delay
1 (default) | 2

Specify the differential delay used in the comb part of the filter as either 1 or 2 cycles.

`NumSections` — Number of integrator and comb sections
2 (default) | integer from 1 to 6

Specify the number of sections in the comb part or integrator part of the filter as an integer from 1 to 6.

`OutputDataType` — Data type of output when using fixed decimation factor
`'Full precision'` (default) | `'Same word length as input'` | `'Minimum section word lengths'`

Choose the data type of the filtered output data.

- `'Full precision'` — The output data type has a word length equal to the input word length plus gain bits.
- `'Same word length as input'` — The output data type has a word length equal to the input word length.
- `'Minimum section word lengths'` — The output data type uses the word length you specify in the OutputWordLength property. When you choose this option, the System object applies a pruning algorithm internally. For more information about pruning, see “Output Data Type” on page 4-378.

`OutputWordLength` — Word length of output
16 (default) | integer from 2 to 104

Word length of the output, specified as an integer from 2 to 104.

Dependencies

To enable this property, set the `OutputDataType` property to `'Minimum section word lengths'`.

Note When the **Output word length** value entered is in the range 2 to 6, there are chances of output data getting overflowed.

`ResetIn` — Enable reset argument
`false` (default) | `true`

When you set this property to `true`, the System object expects a `reset` input argument.

Usage

Syntax

```
[dataOut,validOut] = cicDecFilt(dataIn,validIn)
[dataOut,validOut] = cicDecFilt(dataIn,validIn,reset)
```

Description

`[dataOut,validOut] = cicDecFilt(dataIn,validIn)` filters and decimates the input data using a fixed decimation factor only when `validIn` is `true`.

`[dataOut,validOut] = cicDecFilt(dataIn,validIn,reset)` filters the input data when `reset` is `false` and clears filter internal states when `reset` is `true`. The System object expects the `reset` argument only when you set the ResetIn property to `true`.

Input Arguments

`dataIn` — Input data

scalar

Input data, specified as a signed integer or signed fixed-point value with a word length less than or equal to 32.

Data Types: `int8` | `int16` | `int32` | `fi`

`validIn` — Indication of valid input data

logical scalar

Control signal that indicate if the input data is valid.

When `validIn` is `1` (`true`), the System object captures the value from the `dataIn` input argument. When `validIn` is `0` (`false`), the System object ignores the `dataIn` input value.

Data Types: `logical`

`reset` — Clears internal states

logical scalar

Clears internal states, specified as a logical scalar.

When this value is `1` (`true`), the System object stops the current calculation and clears all internal states. When this value is `0` (`false`) and `validIn` is `1` (`true`), the System object starts a new filtering operation.

Dependencies

To enable this argument, set the ResetIn property to `true`.

Data Types: `logical`

Output Arguments

`dataOut` — Output data

scalar

CIC decimated output data, returned as a scalar.

The OutputDataType property sets the output data type. See “OutputDataType” on page 4-0 .

Data Types: `int8` | `int16` | `int32` | `fi`
Complex Number Support: Yes

`validOut` — Indication of valid output data

logical scalar

Control signal that indicates if the data from the `dataOut` output argument is valid. When this value is `1` (`true`), the System object returns valid data from the `dataOut` output argument. When this value is `0` (`false`), the values of the `dataOut` output argument are not valid.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLCICDecimation

getLatency	Latency of CIC decimation filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Create CIC Decimation Filter for HDL Code Generation

This example shows how to use the `dsp.HDLCICDecimation` System object™ to filter and downsample data. The example performs these steps:

1. Generate a frame of random input samples.
2. Generate reference output data from the `dsp.CICDecimation` System object™.
3. Run a function that contains the `dsp.HDLCICDecimation` System object™. This function operates on a stream of data samples rather than a frame.
4. Compare the output of the function with the reference data.

You can generate HDL code from the function.

Set up input data parameters.

```
R = 8; % Decimation factor
M = 1; % Differential delay
N = 3; % Number of sections

numFrames = 2;
dataSamples = cell(1,numFrames);
refOutput = [];
```

Generate a frame of random input samples. To generate reference output data for comparison, apply the samples to the `dsp.CICDecimation` System object.

```
totalsamples = 0;
for i = 1:numFrames
    framesize(i) = R*randi([5 20],1,1);
    dataSamples{i} = fi(randn(framesize(i),1),1,16,8);
    ref_cic = dsp.CICDecimator('DifferentialDelay',M,...
                               'NumSections',N,...
                               'DecimationFactor',R);
    refOutput = [refOutput,ref_cic(dataSamples{i}).'];
    release(ref_cic);
end
```

Write a function that creates and calls the `dsp.HDLCICDecimation` System object™. You can generate HDL from this function. Set the properties of the object to match the input data parameters.

```
function [dataOut,validOut] = HDLCIC_R8(dataIn,validIn,resetIn)
%HDLCIC_R8
% Performs CIC decimation with a decimation factor of 8.
% dataIn is a scalar fixed-point value.
% validIn is a logical scalar value.
% resetIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent cic8;
  if isempty(cic8)
    cic8 = dsp.HDLCICDecimation('DecimationFactor',8,...
                                'DifferentialDelay',1,...
                                'NumSections',3,...
                                'ResetIn',true);
  end
  [dataOut,validOut] = step(cic8,dataIn,validIn,resetIn);
end
```

Initialize the output vectors to a size large enough to accommodate the output data. The final size will be smaller than `totalsamples` due to decimation. The object has a latency of 3+N cycles. To clear previous output of function, reset is used.

```
latency = 3+N;
dataOut = zeros(1,totalsamples+numFrames*latency);
validOut = zeros(1,totalsamples+numFrames*latency);
idx = 0;
for ij = 1:numFrames
    for ii = 1:length(dataSamples{ij})
        idx = idx+1;
        [dataOut(idx),validOut(idx)] = HDLCIC_R8(...
            dataSamples{ij}(ii),...
            true,false);
    end
    for ii = 1:latency
        idx = idx+1;
        [dataOut(idx),validOut(idx)] = HDLCIC_R8(...
            fi(0,1,16,8),...
           false,true);
```

```
    end
end
```

Compare the results against the output from the `dsp.CICDecimation` object.

```
cicOutput = dataOut(validOut==1);

fprintf('\nHDL CIC Decimation\n');
difference = (abs(cicOutput-refOutput(1:length(cicOutput)))>0);
fprintf('\nTotal number of samples differed between Behavioral and HDL simulation: %d \
```

```
HDL CIC Decimation

Total number of samples differed between Behavioral and HDL simulation: 0
```

Explore Latency of HDL CIC Decimation Object

The latency of the `dsp.HDLCICDecimation` System object™ varies depending on how many integrator and comb sections your filter has. Use the `getLatency` function to find the latency of a particular filter configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is continuously valid.

Create a `dsp.HDLCICDecimation` System object™ and request the latency. The default filter has two sections.

```
hdlcic = dsp.HDLCICDecimation
```

```
hdlcic =
  dsp.HDLCICDecimation with properties:

     DecimationFactor: 2
    DifferentialDelay: 1
           NumSections: 2
       OutputDataType: 'Full precision'
              ResetIn: false
```

```
L_def = getLatency(hdlcic)
```

```
L_def = 5
```

Modify the filter object to have three integrator and comb sections. Check the resulting change in latency.

```
hdlcic.NumSections = 3;
L_3sec = getLatency(hdlcic)
```

```
L_3sec = 6
```

Algorithms

CIC Decimation Filter

The transfer function of a CIC decimation filter is

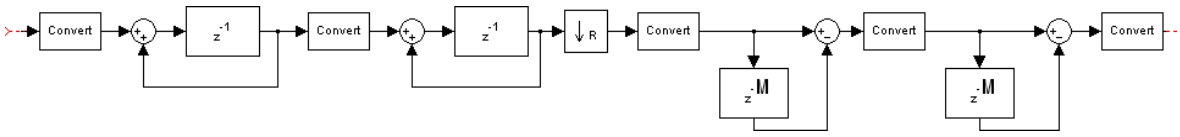
$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k}\right]^N = \frac{\left(1 - z^{-RM}\right)^N}{\left(1 - z^{-1}\right)^N} = \frac{1}{\left(1 - z^{-1}\right)^N} \cdot \frac{\left(1 - z^{-RM}\right)^N}{1} = {H_I}^N(z) \cdot {H_C}^N(z),$$

where

- H_I is the transfer function of the integrator part of the filter.
- H_C is the transfer function of the comb part of the filter.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the decimation factor.
- M is the differential delay.

CIC Filter Structure

The `dsp.HDLCICDecimation` System object has the following CIC filter structure. The structure consists of N sections of cascaded integrators, a rate change factor of R, followed by N sections of cascaded comb filters [1].



The unit delay in the integrator part of the CIC filter can be located in either the feed-forward or feedback path. These two configurations yield an identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This System object puts the unit delay in the feed-forward path of the integrator, because the configuration is preferred for HDL implementation.

Fixed Decimation

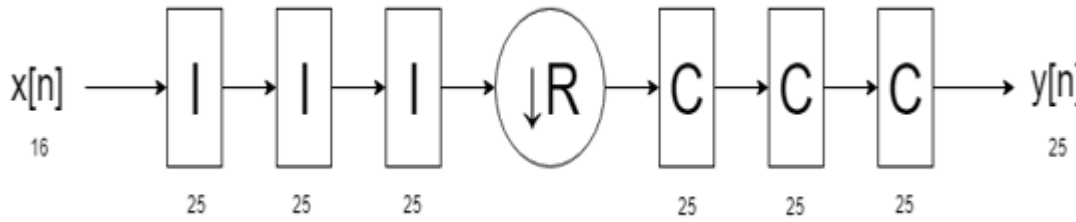
The System object down samples the integrator stage output using *R*, a fixed decimation rate by using the DecimationFactor property. At the down sampler stage, the System object uses a counter to count the valid input samples, which depend on the decimation rate. The System object provides decimated output to the comb part.

Output Data Type

This section explains how the System object determines the output data type. For example, consider a filter with `DecimationFactor`, `DifferentialDelay`, and `NumSections` values 8, 1, and 3, respectively, with an input width of 16 bits.

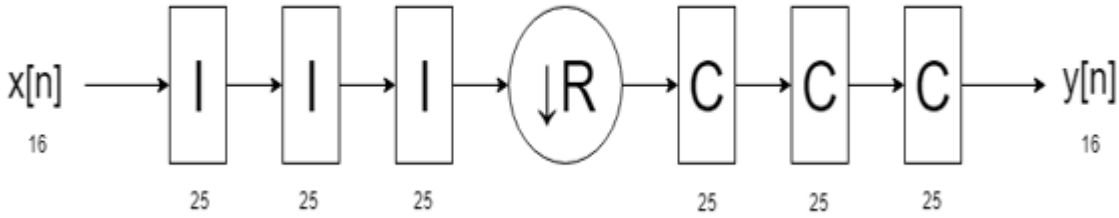
The output word length is calculated as: $B_{OUT} = B_{IN} + [\log_2(Gain)]$, where $Gain = (R * M)^N$, B_{IN} is the input word length, and B_{OUT} is the output word length.

When you set the `OutputDataType` property to `'Full precision'`, the System object returns data with a word length of 25 bits, by adding nine gain bits to the input word length.



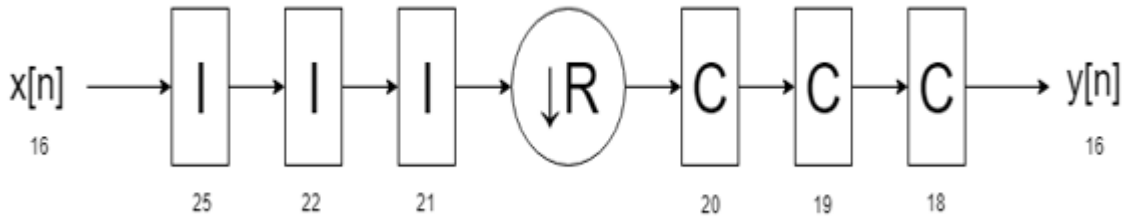
When you set the `OutputDataType` property to `'Same word length as input'`, the System object returns data with a word length of 16 bits, which is same as the input word

length. The internal integrator and comb stages still use the full-precision data type with 25 bits.



When you set the `OutputDataType` property to `'Minimum section word lengths'` and the `OutputWordLength` property to `16`, the System object returns data with a word length of 16 bits by changing the bit width at each stage, based on the pruning algorithm.

If the output data type is less than the number of bits requested at the output, the least significant bits (LSBs) at the earlier stages are pruned. The number of LSBs to discard at each stage is provided in the Hogenauer algorithm. This algorithm minimizes the loss of information in the output data [1].

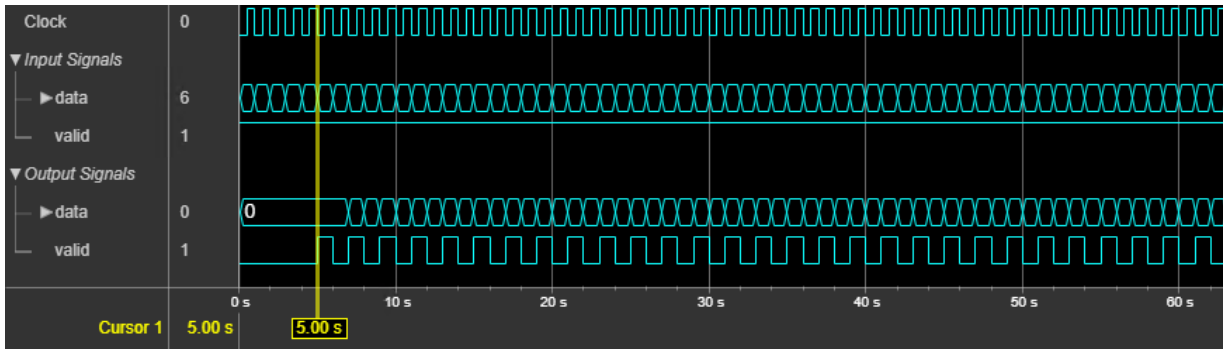


Latency

This section shows the latency of the System object when operated with fixed decimation rate.

This figure shows the output of the System object for the default configuration, that is, fixed decimation rate with `DecimationFactor`, `DifferentialDelay`, and

`NumSections` values 2, 1, and 2, respectively. The System object returns valid output data at every second cycle based on the fixed DecimationFactor value of 2. The latency of the System object is 5 clock cycles, calculated as 3 + *N*.



Performance

The performance of the synthesized HDL code varies with your target and synthesis options. This table shows the resource and performance data synthesis results of the filter with the default configuration at fixed decimation rate. In the default configuration, `DecimationFactor`, `DifferentialDelay`, and `NumSections` values are 2, 1, and 2, respectively. The generated HDL is targeted to Xilinx Zynq XC7Z045-FFG900-2 FPGA. The design achieves a clock frequency of 700.77 MHz.

Resource	Number Used
LUTs	96
Registers	166

The resources and frequencies vary based on the *R*, *M*, and *N* values and other parameter values selected in the block mask.

dsp.ColoredNoise

Package: `dsp`

Generate colored noise signal

Description

The `dsp.ColoredNoise` System object generates a colored noise signal with a power spectral density (PSD) of $1/|f|^{\alpha}$ over its entire frequency range. The inverse frequency power, α, can be any value in the interval `[-2 2]`. The type of colored noise the object generates depends on the "Color" on page 4-0 you choose. When you set `Color` to `'custom'`, you can specify the power density of the noise through the "InverseFrequencyPower" on page 4-0 property.

The size and data type properties of the generated signal depend on "SamplesPerFrame" on page 4-0 , "NumChannels" on page 4-0 , and the "OutputDataType" on page 4-0 properties.

This object uses the default MATLAB random stream, `RandStream`. Reset the default stream for repeatable simulations.

To generate colored noise signal:

1. Create the `dsp.ColoredNoise` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
cn = dsp.ColoredNoise
cn = dsp.ColoredNoise(Name,Value)
```

```
cn = dsp.ColoredNoise(pow,samp,numChan,Name,Value)
cn = dsp.ColoredNoise(color,samp,numChan,Name,Value)
```

Description

`cn = dsp.ColoredNoise` creates a colored noise object, `cn`, that outputs a noise signal one sample or frame at a time, with a $1/|f|^{\alpha}$ spectral characteristic over its entire frequency range. Typical values for α are $\alpha = 1$ (pink noise) and $\alpha = 2$ (brownian noise).

`cn = dsp.ColoredNoise(Name,Value)` creates a colored noise object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dsp.ColoredNoise('Color','pink');`

`cn = dsp.ColoredNoise(pow,samp,numChan,Name,Value)` creates a colored noise object with the `InverseFrequencyPower` property set to *pow*, the `SamplesPerFrame` property set to *samp*, and the `NumChannels` property set to *numChan*.

Example: `dsp.ColoredNoise(1,44.1e3,1,'OutputDataType','single');`

`cn = dsp.ColoredNoise(color,samp,numChan,Name,Value)` creates a colored noise object with the `Color` property set to *color*, the `SamplesPerFrame` property set to *samp*, and the `NumChannels` property set to *numChan*.

Example: `dsp.ColoredNoise('pink',1024,2,'OutputDataType','single');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Color` — Noise color

`'custom'` (default) | `'pink'` | `'white'` | `'brown'` | `'blue'` | `'purple'`

Noise color, specified as one of the following. Each color is associated with a specific inverse frequency power of the generated noise sequence.

- `'pink'` –– The inverse frequency power, α equals 1.
- `'white'` –– α = 0.
- `'brown'` –– α = 2. Also known as red or Brownian noise.
- `'blue'` –– α = -1. Also known as azure noise.
- `'purple'` –– α = -2. Also known as violet noise.
- `'custom'` –– For noise with a custom inverse frequency power, α equals the value of the "InverseFrequencyPower" on page 4-0 property.

  `InverseFrequencyPower`, α can be any value in the interval `[-2,2]`.

`InverseFrequencyPower` — Inverse frequency power
1 (default) | real scalar in [-2 2]

Inverse frequency power, α, specified as a real scalar in the interval `[-2 2]`. The inverse exponent defines the PSD of the random process as $1/|f|^{\alpha}$. Values of "InverseFrequencyPower" on page 4-0 greater than 0 generate lowpass noise with a singularity (pole) at $f = 0$. These processes exhibit long memory. Values of `InverseFrequencyPower` less than 0 generate highpass noise with increments that are negatively correlated. These processes are referred to as anti-persistent. Special cases include:

- `1` –– Pink noise
- `2` –– Brown, red, or Brownian noise
- `0` –– White noise process with a flat PSD
- `-1` –– Blue or azure noise
- `-2` –– Purple of violet noise

In a log-log plot of power as a function of frequency, processes generated by this object exhibit an approximate linear relationship with slope equal to $-\alpha$.

Example: `1.2`

Example: `-1.4`

Dependencies

This property applies only when you set "Color" on page 4-0 to `'custom'`.

`SamplesPerFrame` — Number of samples per output channel
`1024` (default) | positive integer

Number of samples per output channel, specified as a positive integer. This property determines the number of rows of the signal.

Example: 512

NumChannels — Number of output channels

1 (default) | positive integer

Number of output channels, specified as an integer. This property determines the number of columns of the signal.

Example: 5

Example: 25

RandomStream — Source of random number stream

'Global stream' (default) | 'mt19937ar with seed'

Source of the random number stream, specified as one of the following:

- 'Global stream' –– The current global random number stream is used for normally distributed random number generation.
- 'mt19937ar with seed' –– The mt19937ar algorithm is used for normally distributed random number generation. The reset function reinitializes the random number stream to the value of the Seed property.

Seed — Initial seed

67 (default) | nonnegative integer

Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. The reset function reinitializes the random number stream to the value of the Seed property.

Example: 3

Example: 34

Dependencies

This property applies only when you set the RandomStream property to 'mt19937ar with seed'.

Data Types: double

`BoundedOutput` — Set output bounds to +1 and −1
`false` (default) | `true`

Specify the output to be bounded between +1 and −1, specified as:

- `true` –– The internal random source that generates the noise is uniform. If `Color` is set to `'white'`, there is no color filter applied to the output of the random source. The output is uniform noise of amplitude between +1 and −1. If `Color` is set to any other option, then a coloring filter is applied to the output of the random source, followed by a gain ensures that the absolute maximum output never exceeds `1`.
- `false` –– The internal random source is Gaussian. The output is not bounded.

Data Types: `logical`

`OutputDataType` — Output data type
`'double'` (default) | `'single'`

Output data type, specified as either `'double'` or `'single'`.

Usage

Syntax

```
noiseOut = cn()
```

Description

`noiseOut = cn()` outputs one sample or one frame of colored noise data.

Output Arguments

`noiseOut` — Colored noise output
vector | matrix

Colored noise output, returned as a vector or matrix. The “SamplesPerFrame” on page 4-0 , “NumChannels” on page 4-0 , and the “OutputDataType” on page 4-0 properties specify the size and data type of the output.

Example:
`[0.5377;2.1027;-1.1403;0.5885;0.6229;-0.8971;-0.7435;-0.0588;3.458;4.4537]`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Measure Pink Noise Power in Octave Bands

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

The output from this example shows that pink noise has approximately equal power in octave bands.

Generate a single-channel signal of pink noise that is 44,100 samples in length. Set the random number generator to the default settings for reproducible results.

```
pinkNoise = dsp.ColoredNoise(1,44.1e3,1);
rng default;
x = pinkNoise();
```

Set the sampling frequency to 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
```

```
count = 1;
freqinterval = zeros(7,2);
Pwr = zeros(7,1);
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)
```

```
ans=7×2 table
    freqinterval       Pwr
    ____________    _______

     100      200    0.17549
     200      400    0.20313
     400      800     0.2438
     800     1600     0.2503
    1600     3200    0.25233
    3200     6400    0.26828
    6400    12800    0.25211
```

The pink noise has roughly equal power in octave bands.

Rerun the preceding code with `'InverseFrequencyPower'` equal to 0, which generates a white noise signal. A white noise signal has a flat power spectral density, or equal power per unit frequency. Set the random number generator to the default settings for reproducible results.

```
whiteNoise = dsp.ColoredNoise(0,44.1e3,1);
rng default;
x = whiteNoise();
```

Set the sampling frequency is 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
```

```
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)
```

```
ans=7×2 table
    freqinterval        Pwr
    ____________    _________

     100      200    0.0031417
     200      400    0.0073833
     400      800     0.017421
     800     1600     0.035926
    1600     3200     0.071139
    3200     6400      0.15183
    6400    12800      0.28611
```

White noise has approximately equal power per unit frequency, so octave bands have an unequal distribution of power. Because the width of an octave band increases with increasing frequency, the power per octave band increases for white noise.

PSD of Pink Noise Realization

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate a pink noise signal 2048 samples in length. The sampling frequency is 1 Hz. Obtain an estimate of the power spectral density using Welch's overlapped segment averaging.

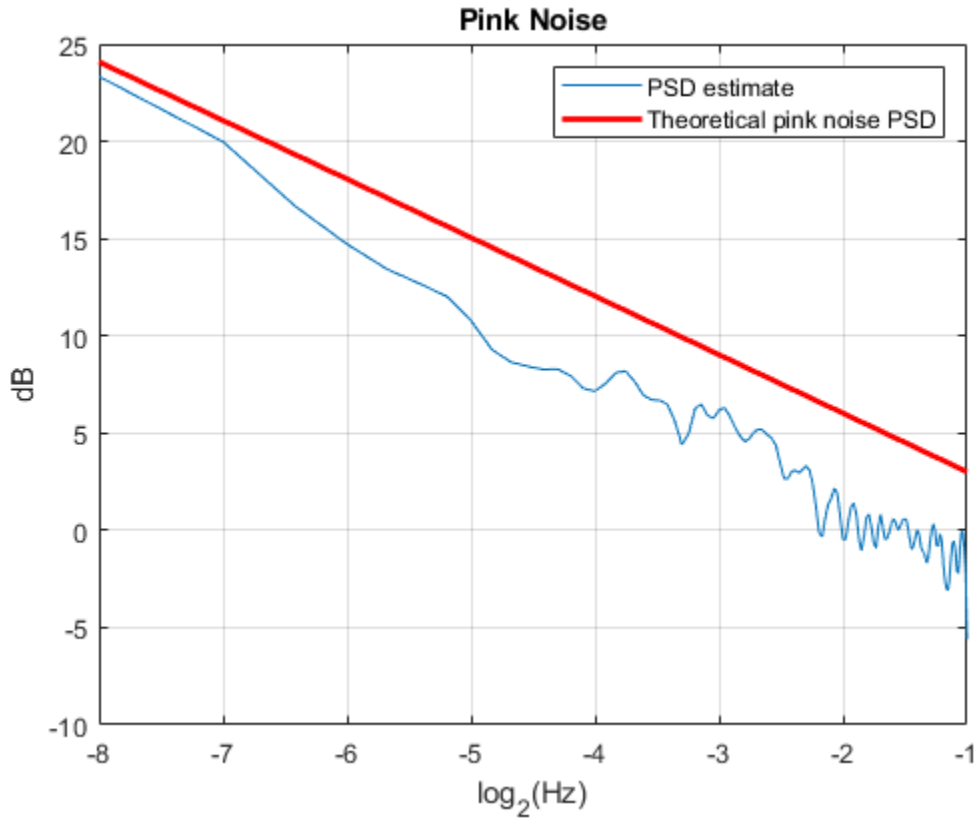
```
cn = dsp.ColoredNoise('pink','SamplesPerFrame',2048);
x = cn();
Fs = 1;
[Pxx,F] = pwelch(x,hamming(128),[],[],Fs,'psd');
```

Construct the theoretical PSD of the pink noise process.

```
PSDPink = 1./F(2:end);
```

Display the Welch PSD estimate of the noise along with the theoretical PSD on a log-log plot. Plot the frequency axis with a base-2 logarithmic scale to clearly show the octaves. Plot the PSD estimate in dB, $10\log_{10}$.

```
plot(log2(F(2:end)),10*log10(Pxx(2:end)))
hold on
plot(log2(F(2:end)),10*log10(PSDPink),'r','linewidth',2)
xlabel('log_2(Hz)')
ylabel('dB')
title('Pink Noise')
grid on
legend('PSD estimate','Theoretical pink noise PSD')
hold off
```

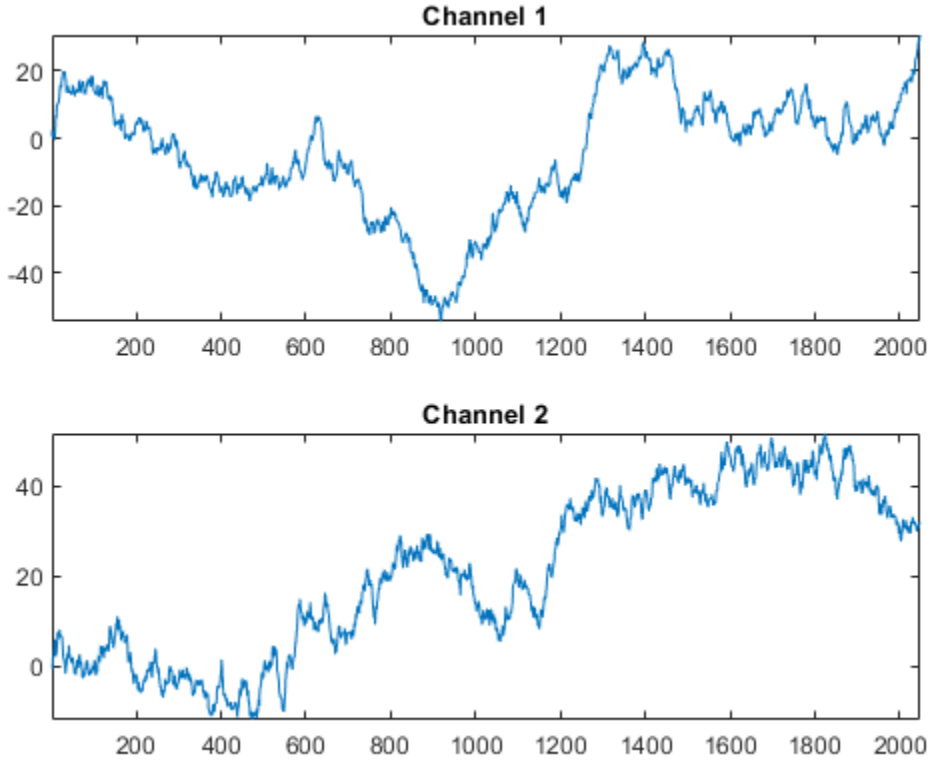


Two-Channel Brownian Noise

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two channels of Brownian noise by setting `Color` to `'brown'` and `NumChannels` to 2.

```
cn = dsp.ColoredNoise('brown','SamplesPerFrame',2048,...
    'NumChannels',2);
x = cn();
subplot(2,1,1)
plot(x(:,1)); title('Channel 1'); axis tight;
subplot(2,1,2)
plot(x(:,2)); title('Channel 2'); axis tight;
```

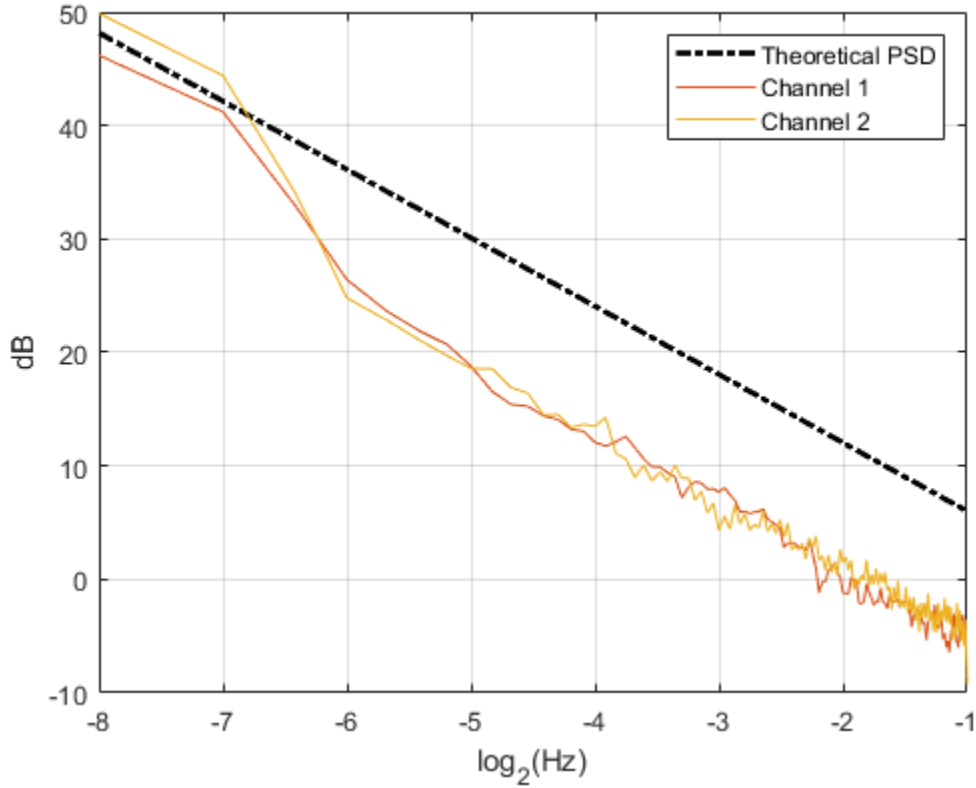


The sampling frequency is 1 Hz. Obtain Welch PSD estimates for both channels. The fourth argument of `pwelch`, `NFFT`, which is the number of FFT points, is empty. Hence, `NFFT` is set to 256. For even NFFT, The number of FFT points used to calculate the PSD estimate is (NFFT/2+1), which equals 129.

```
Fs = 1;
Pxx = zeros(129,size(x,2));
for nn = 1:size(x,2)
[Pxx(:,nn),F] = pwelch(x(:,nn),hamming(128),[],[],Fs,'psd');
end
```

Construct the theoretical PSD of a Brownian process. Plot the theoretical PSD along with both realizations on a log-log plot. Use a base-2 logarithmic scale for the frequency axis and plot the power spectral densities in dB.

```
PSDBrownian = 1./F(2:end).^2;
figure;
plot(log2(F(2:end)),10*log10(PSDBrownian),'k-.','linewidth',2);
hold on;
plot(log2(F(2:end)),10*log10(Pxx(2:end,:)));
xlabel('log_2(Hz)'); ylabel('dB');
grid on;
legend('Theoretical PSD','Channel 1', 'Channel 2');
```



Add Pink Noise at 0 dB SNR

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

This example shows how to stream in an audio file and add pink noise at a 0 dB signal-to-noise ratio (SNR). The example reads in frames of an audio file 1024 samples in length, measures the root mean square (RMS) value of the audio frame, and adds pink noise with the same RMS value as the audio frame.

Set up the System objects. Set `'SamplesPerFrame'` for both the file reader and the colored noise generator to 1024 samples. Set `Color` to `'pink'` to generate pink noise with a $1/|f|$ power spectral density.

```
N = 1024;
afr = dsp.AudioFileReader('Filename','speech_dft.mp3','SamplesPerFrame',N);
adw = audioDeviceWriter('SampleRate',afr.SampleRate);
cn = dsp.ColoredNoise('pink','SamplesPerFrame',N);
```

Stream the audio file in 1024 samples at a time. Measure the signal RMS value for each frame, generate a frame of pink noise equal in length, and scale the RMS value of the pink noise to match the signal. Add the scaled noise to the signal and play the output.

```
while ~isDone(afr)
    audio = afr();
    speechRMS = rms(audio);
    noise = cn();
    noiseRMS = rms(noise);
    noise = noise*(speechRMS/noiseRMS);
    sigPlusNoise = audio+noise;
    adw(sigPlusNoise);
end
release(afr);
release(adw);
```

Averaged Power Spectrum of Pink Noise

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

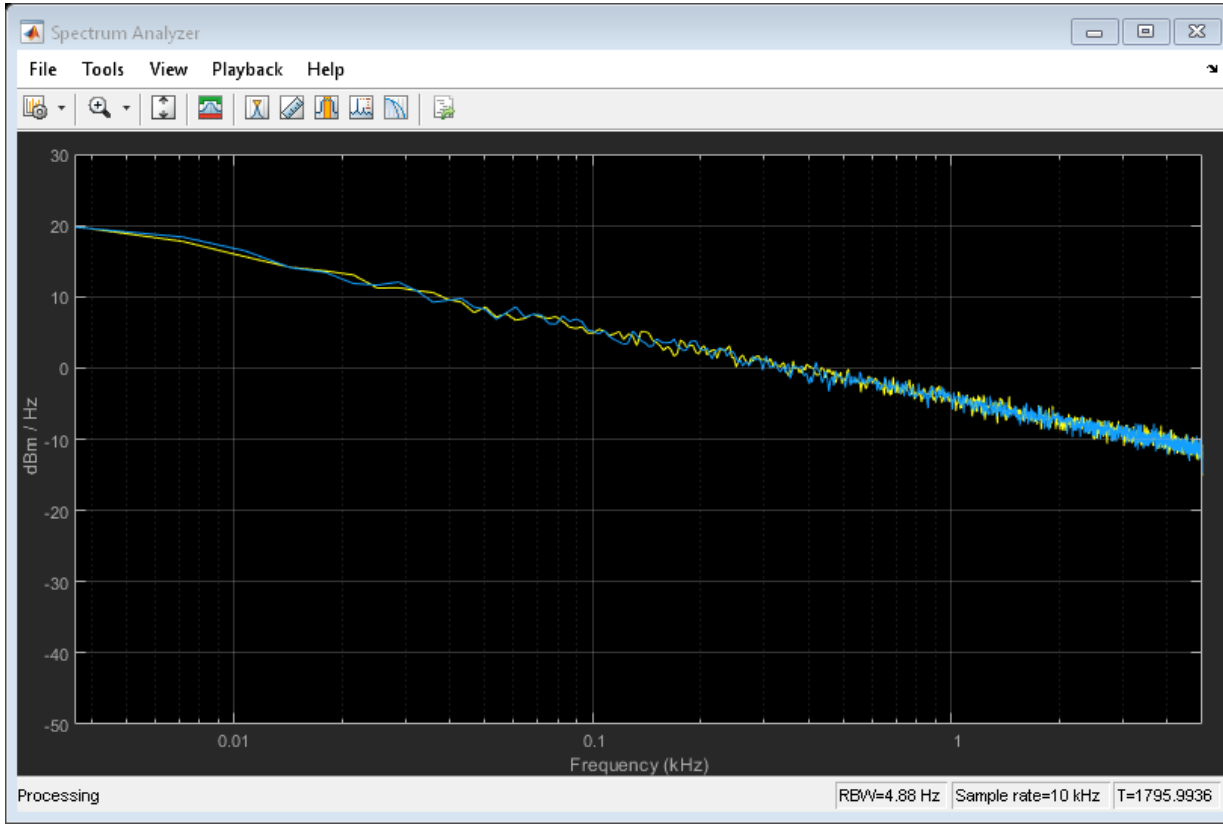
Generate two-channels of pink noise and compute the power spectrum based on a running average of 50 PSD estimates.

Set up the colored noise generator to generate two channels of pink noise with 1024 samples. Set up the spectrum analyzer to compute modified periodograms using a Hamming window and 50% overlap. Obtain a running average of the PSD using 50 spectral averages.

```
pinkNoise = dsp.ColoredNoise('pink',1024,2);
sa = dsp.SpectrumAnalyzer('SpectrumType','Power density', ...
    'OverlapPercent',50,'Window','Hamming', ...
    'SpectralAverages',50,'PlotAsTwoSidedSpectrum',false, ...
    'FrequencyScale','log','YLimits',[-50 30]);
```

Run the simulation for 30 seconds.

```
tic
while toc < 30
    pink = pinkNoise();
    sa(pink);
end
```



More About

Colored Noise Processes

Many phenomena in diverse fields, such as hydrology and finance, produce time series with PSD functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^{\alpha}}$$

where α is a real number in the interval [-2,2] and $L(f)$ is a positive, slowly-varying or constant function. Plotting the PSD of such processes on a log-log plot displays an

approximate linear relationship between the log frequency and log PSD with slope equal to -α

$$\ln S(f) = -\alpha \ln|f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as a function of the frequency on a base-2 logarithmic scale. The slope of the plot is then dB/octave. Rewriting the preceding equation, you obtain

$$10\log S(f) = -10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)} + 10\frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)}$$

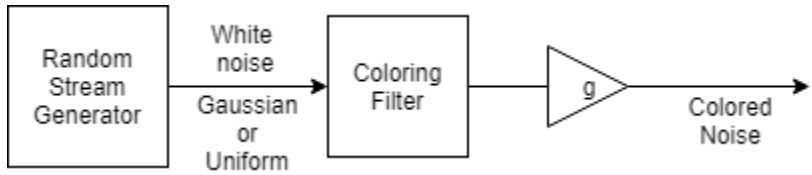
If $\alpha > 0$, S(f) goes to infinity as the frequency, f, approaches 0. Stochastic processes with PSDs of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If $\alpha<0$, the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of $\frac{1}{|f|^{\alpha}}$ processes include:

- $\alpha = 0$ — White noise, where L(f) is a constant proportional to the process variance.
- $\alpha = 1$ — Pink, or flicker noise. Pink noise has equal energy per octave. See “Measure Pink Noise Power in Octave Bands” on page 4-387 for a demonstration. The power spectral density of pink noise decreases 3 dB per octave.
- $\alpha = 2$ — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still define a generalized power spectrum, which behaves like $\frac{1}{|f|^2}$. Accordingly, power in a brown noise decreases 6 dB per octave.
- $\alpha = -1$ — blue noise. The power spectral density of blue noise increases 3 dB per octave.
- $\alpha = -2$ — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

Algorithms

The figure shows the overall process of generating the colored noise.



The random stream generator produces a stream of white noise that is either Gaussian or uniform in distribution. A coloring filter applied to the white noise generates colored noise with a power spectral density (PSD) function given by:

$$S(f) = \frac{L(f)}{|f|^{\alpha}}$$

When α, the inverse frequency power, equals 0, no coloring filter is applied to the output of the random stream generator. If the bounded option is enabled, the output is uniform white noise with amplitude between +1 and −1. If the bounded output is not enabled, the output is a Gaussian white noise and the values are not bounded between +1 and −1. If α is set to any other value, then a coloring filter is applied to the output of the random stream generator. If the bounded output option is enabled, a gain g is applied to the output of the coloring filter to ensure that the absolute maximum output never exceeds 1.

For details on colored noise processes and how the value of α affects the PSD of the colored noise, see “Colored Noise Processes” on page 4-396.

When the inverse frequency power α is positive, the colored noise is generated using an auto regressive (AR) model of order 63. The AR coefficients are:

$$a_0 = 1,$$

$$a_k = (k - 1 - \frac{\alpha}{2})\frac{a_k - 1}{k}, \quad k = 1, 2, \ldots, 63$$

Pink and brown noises are special cases, which are generated from specially tuned SOS filters of orders 12 and 10, respectively. These filters are optimized for better performance.

When the inverse frequency power α is negative, the colored noise is generated using a moving average (MA) model of order 255. The MA coefficients are:

$$b_0 = 1,$$

$$b_k = \left(k - 1 + \frac{\alpha}{2}\right)\frac{b_{k-1}}{k},\ \ k = 1, 2, \cdots, 255$$

Purple noise is generated from a first order filter, $B = [1\ -1]$.

The coloring filters applied (except pink, brown, and purple) are detailed on pp. 820–822 in [2].

dsp.ComplexBandpassDecimator

Package: `dsp`

Extract a frequency subband using a one-sided (complex) bandpass decimator

Description

The `dsp.ComplexBandpassDecimator` System object extracts a specific sub-band of frequencies using a one-sided, multistage, complex bandpass decimator. The object determines the bandwidth of interest using the specified `CenterFrequency`, `DecimationFactor` and `Bandwidth` values.

To extract a frequency subband using a complex bandpass decimator:

1. Create the `dsp.ComplexBandpassDecimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
bpdecim = dsp.ComplexBandpassDecimator
bpdecim = dsp.ComplexBandpassDecimator(d)
bpdecim = dsp.ComplexBandpassDecimator(d,Fc)
bpdecim = dsp.ComplexBandpassDecimator(d,Fc,Fs)
bpdecim = dsp.ComplexBandpassDecimator(Name,Value)
```

Description

`bpdecim = dsp.ComplexBandpassDecimator` creates a System object that filters each channel of the input over time using a one-sided, multistage, complex bandpass

decimation filter. The object determines the bandwidth of interest using the default center frequency, decimation factor, and bandwidth values.

`bpdecim = dsp.ComplexBandpassDecimator(d)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`.

`bpdecim = dsp.ComplexBandpassDecimator(d,Fc)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`, and the `CenterFrequency` property set to `Fc`.

`bpdecim = dsp.ComplexBandpassDecimator(d,Fc,Fs)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`, the `CenterFrequency` property set to `Fc`, and the `SampleRate` property set to `Fs`.

Example: `dsp.ComplexBandpassDecimator(48e3/1e3,2e3,48e3);`

`bpdecim = dsp.ComplexBandpassDecimator(Name,Value)` creates a complex bandpass decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example:
```
dsp.ComplexBandpassDecimator(48e3/1e3,2e3,48e3,'CenterFrequency',1e3
);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`CenterFrequency` — Center frequency in Hz

`0` (default) | real scalar

Center frequency of the desired band in Hz, specified as a real, finite numeric scalar in the range [-`SampleRate`/2, `SampleRate`/2].

Tunable: Yes

Data Types: `single` | `double`

`Specification` — Filter design parameters

`'Decimation factor'` (default) | `'Bandwidth'` | `'Decimation factor and bandwidth'`

Filter design parameters, specified as:

- `'Decimation factor'` –– The object specifies the decimation factor through the `Decimation Factor` property. The bandwidth of interest (*BW*) is computed using the following equation:

  $$BW = Fs/D$$

  where

  - *Fs* –– Sample rate specified through `SampleRate` property.
  - *D* –– Decimation factor.
- `'Bandwidth'` –– The object specifies the bandwidth through the `Bandwidth` property. The decimation factor (*D*) is computed using the following equation:

  $$D = \text{floor}\left(\frac{Fs}{BW + TW}\right)$$

  where

  - *Fs* –– Sample rate specified through `SampleRate` property.
  - *BW* –– Bandwidth of interest.
  - *TW* –– Transition width specified through the `TransitionWidth` property.
- `'Decimation factor and bandwidth'` –– The decimation factor and the bandwidth of interest are specified through the `DecimationFactor` and `Bandwidth` properties.

`DecimationFactor` — Decimation factor

2 (default) | positive integer

Factor by which to reduce the bandwidth of the input signal, specified as a positive integer. The frame size (number of rows) of the input signal must be a multiple of the decimation factor.

Dependencies

This property applies when you set `Specification` to either `'Decimation factor'` or `'Decimation factor and bandwidth'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Stopband attenuation in dB

`80` (default) | positive scalar

Stopband attenuation of the filter in dB, specified as finite positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TransitionWidth` — Transition width in Hz

`100` (default) | positive scalar

Transition width of the filter in Hz, specified as a positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Bandwidth` — Bandwidth (Hz)

`5000` (default) | real positive scalar

Width of the frequency band of interest, specified as a real positive scalar in Hz.

Dependencies

This property applies when you set `Specification` to either `'Bandwidth'` or `'Decimation factor and bandwidth'`.

Data Types: `single` | `double`

`PassbandRipple` — Passband ripple (dB)

`1` (default) | positive scalar

Passband ripple of the filter, specified as a positive scalar in dB.

Dependencies

This property applies when you set `Specification` to either `'Bandwidth'` or `'Decimation factor and bandwidth'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MinimizeComplexCoefficients` — Flag to minimize number of complex coefficients

`true` (default) | `false`

Flag to minimize the number of complex filter coefficients, specified as:

- `true` –– The first stage of the multistage filter is bandpass (complex coefficients) centered at the specified center frequency. The first stage is followed by a mixing stage that heterodynes the signal to DC. The remaining filter stages, all with real coefficients, follow.
- `false` –– The input signal is first passed through the different stages of the multistage filter. All stages are bandpass (complex coefficients). The signal is then heterodyned to DC if `MixToBaseband` is `true`, and the frequency offset resulting from the decimation is nonzero.

`MixToBaseband` — Flag to mix signal to baseband

`true` (default) | `false`

Flag to mix the signal to baseband, specified as:

- `true` –– The object heterodynes the filtered, decimated signal to DC. This mixing stage runs at the output sample rate of the filter.
- `false` –– The object skips the mixing stage.

Dependencies

This property applies when you set `MinimizeComplexCoefficients` to `false`.

`SampleRate` — Input sample rate in Hz

`44100` (default) | real positive scalar

Sampling rate of the input signal in Hz, specified as a real positive scalar.

Data Types: `single` | `double`

Usage

Syntax

```
y = bpdecim(x)
```

Description

`y = bpdecim(x)` filters the real or complex input signal, `x`, to produce the output, `y`. The output contains the subband of frequencies specified by the System object properties. The System object filters each channel of the input signal independently over time. The frame size (first dimension) of `x` must be a multiple of the decimation factor.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The number of rows in the input must be a multiple of the decimation factor.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

vector | matrix

Output of the complex bandpass decimator, returned as a vector or a matrix. The output contains the subband of frequencies specified by the System object properties. The number of rows (frame size) in the output signal is 1/*D* times the number of rows in the input signal, where *D* is the decimation factor. The number of channels (columns) does not change.

The data type of the output is same as the data type of the input. The output signal is always complex.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.ComplexBandpassDecimator

cost	Implementation cost of the complex bandpass decimator
freqz	Frequency response of the multirate multistage filter
info	Information about filter System object
visualizeFilterStages	Visualize filter stages

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Compute Cost of Complex Bandpass Decimator

Compute the implementation cost of a complex bandpass decimator using the `cost` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44,100 Hz.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100)
```

```
cbp =
  dsp.ComplexBandpassDecimator with properties:

               CenterFrequency: 5000
                 Specification: 'Decimation factor'
              DecimationFactor: 12
           StopbandAttenuation: 80
```

```
              TransitionWidth: 100
    MinimizeComplexCoefficients: true
                     SampleRate: 44100
```

Compute the implementation cost of `cbp` using the `cost` function.

```
c = cost(cbp)
```

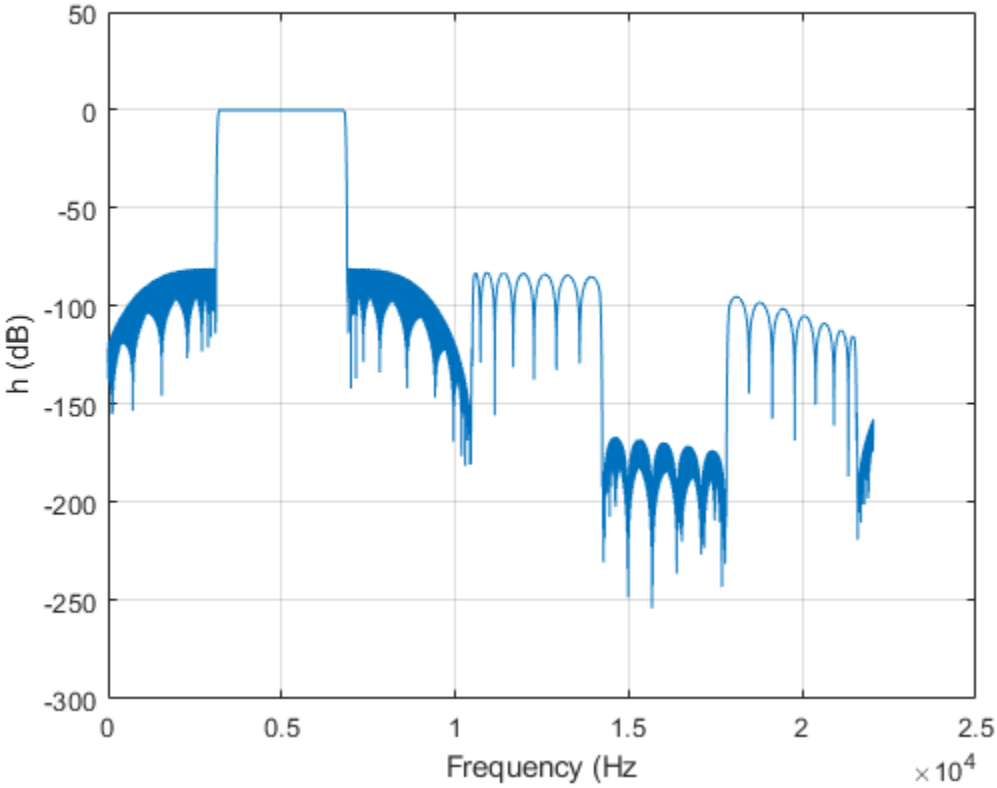
```
c = struct with fields:
                       NumCoefficients: 201
                            NumStates: 379
    RealMultiplicationsPerInputSample: 44.3333
          RealAdditionsPerInputSample: 43.8333
```

Compute Frequency Response of Complex Bandpass Decimator

Compute the complex frequency response of a complex bandpass decimator using the `freqz` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44100 Hz. Compute and display the frequency response.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100);
[h,f] = freqz(cbp);
plot(f,20*log10(abs(h)))
grid on
xlabel('Frequency (Hz')
ylabel('h (dB)')
```



Filter Signal Through Complex Bandpass Decimator

Filter an input signal through a complex bandpass decimator and visualize the filtered spectrum in a spectrum analyzer.

Initialization

Create a `dsp.ComplexBandpassDecimator` System object™ with center frequency set to 2000 Hz, bandwidth of interest set to 1000 Hz, and sample rate set to 48 kHz. The decimation factor is computed as the ratio of the sample rate to the bandwidth of interest. The input to the decimator is a sine wave with a frame length of 1200 samples with tones

at 1625 Hz, 2000 Hz, and 2125 Hz. Create a `dsp.SpectrumAnalyzer` scope to visualize the signal spectrum.

```
Fs = 48e3;
CF = 2000;
BW = 1000;
D  =  Fs/BW;
FrameLength = 1200;
bpdecim = dsp.ComplexBandpassDecimator(D,CF,Fs);

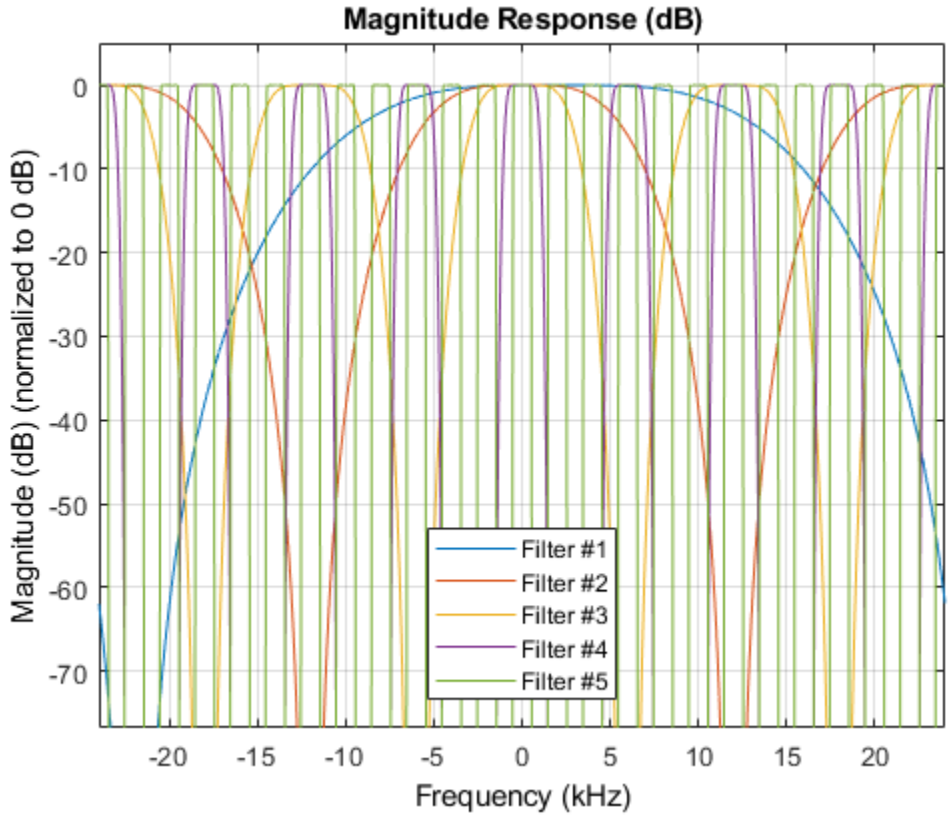
sa = dsp.SpectrumAnalyzer('SampleRate',Fs/D,...
    'YLimits',[-120 40],...
    'FrequencyOffset',CF);

tones = [1625 2000 2125];
sin = dsp.SineWave('SampleRate',Fs,'Frequency',tones,...
    'SamplesPerFrame',FrameLength);
```

Visualize Filter Stages

Using the `visualizeFilterStages` function, you can visualize the response of each individual filter stage using FVTool.

```
visualizeFilterStages(bpdecim)
```



Display Filter `info`

The `info` function displays information about the bandpass decimator.

```
fprintf('%s',info(bpdecim))
```

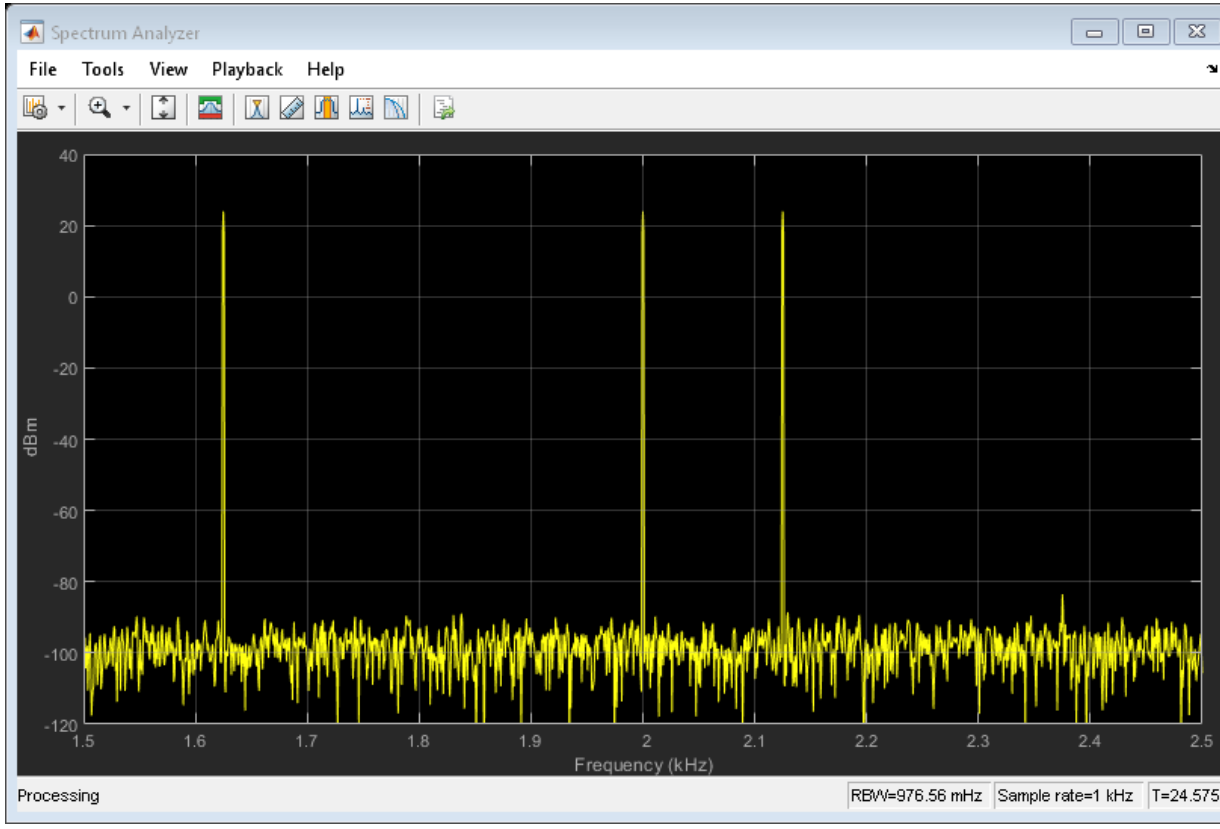
```
Overall Decimation Factor       : 48
Bandwidth                       : 1000 Hz
Number of Filters               : 5
Real multiplications per Input Sample: 14.708333
Real additions per Input Sample      : 13.833333
Number of Coefficients               : 89
Filters:
   Filter 1:
```

```
   dsp.FIRDecimator     - Decimation Factor   : 2
   Filter 2:
   dsp.FIRDecimator     - Decimation Factor   : 2
   Filter 3:
   dsp.FIRDecimator     - Decimation Factor   : 2
   Filter 4:
   dsp.FIRDecimator     - Decimation Factor   : 3
   Filter 5:
   dsp.FIRDecimator     - Decimation Factor   : 2
```

Stream In and Filter Signal

Construct a for-loop to run for 1000 iterations. In each iteration, stream in 1200 samples (one frame) of the noisy sine wave and apply the complex bandpass decimator on each frame of the input signal. Visualize the input and output spectrum in the spectrum analyzer, `sa`.

```
for index = 1:1000
    x = sum(sin(),2) +  1e-4*randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end
```



The bandpass decimator with center frequency at 2000 Hz and a bandwidth of 1000 Hz passes the three sine wave tones at 1625 Hz, 2000 Hz, and 2125 Hz.

Change the center frequency of the decimator to 2400 Hz and filter the signal.

```
release(bpdecim);
bpdecim.CenterFrequency = 2400
```

```
bpdecim =

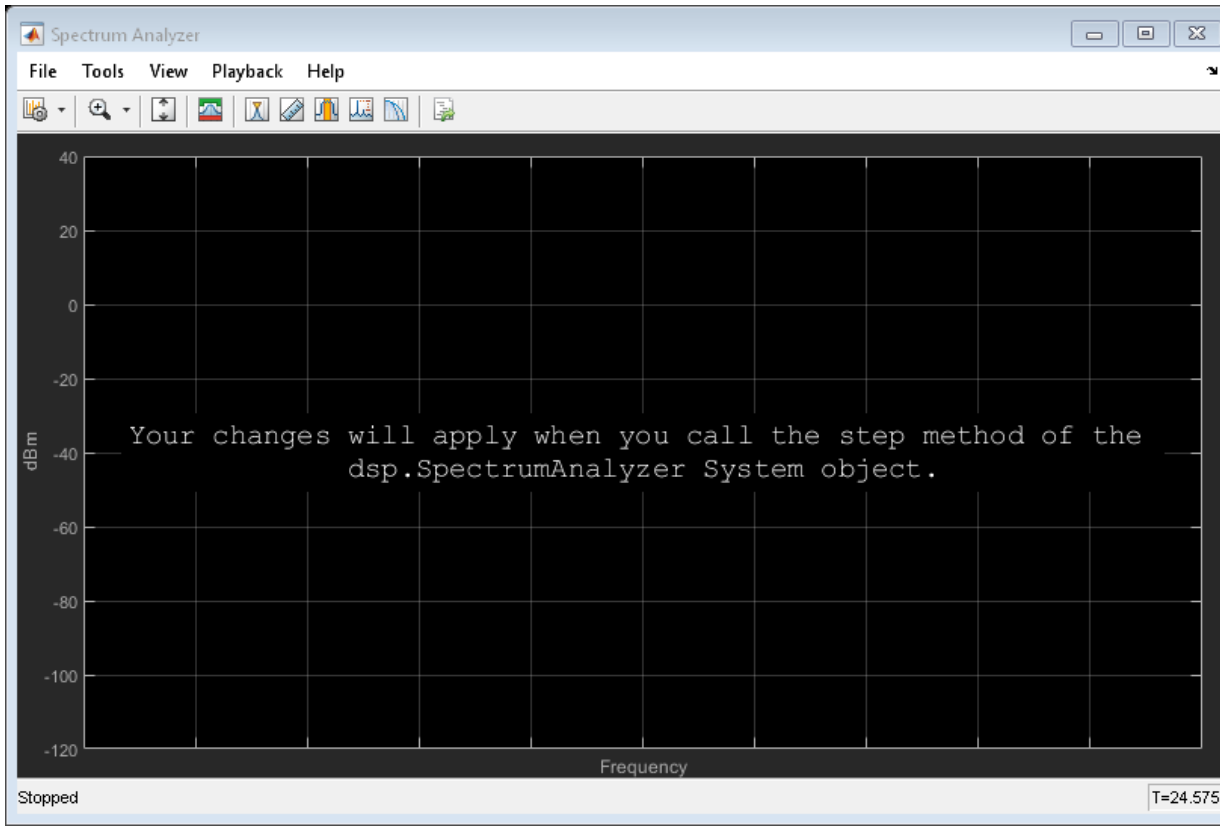
  dsp.ComplexBandpassDecimator with properties:

              CenterFrequency: 2400
                Specification: 'Decimation factor'
```

```
              DecimationFactor: 48
          StopbandAttenuation: 80
             TransitionWidth: 100
MinimizeComplexCoefficients: true
                  SampleRate: 48000
```

Configure the spectrum analyzer to show the bandwidth of interest, [-1900, 2900] Hz.

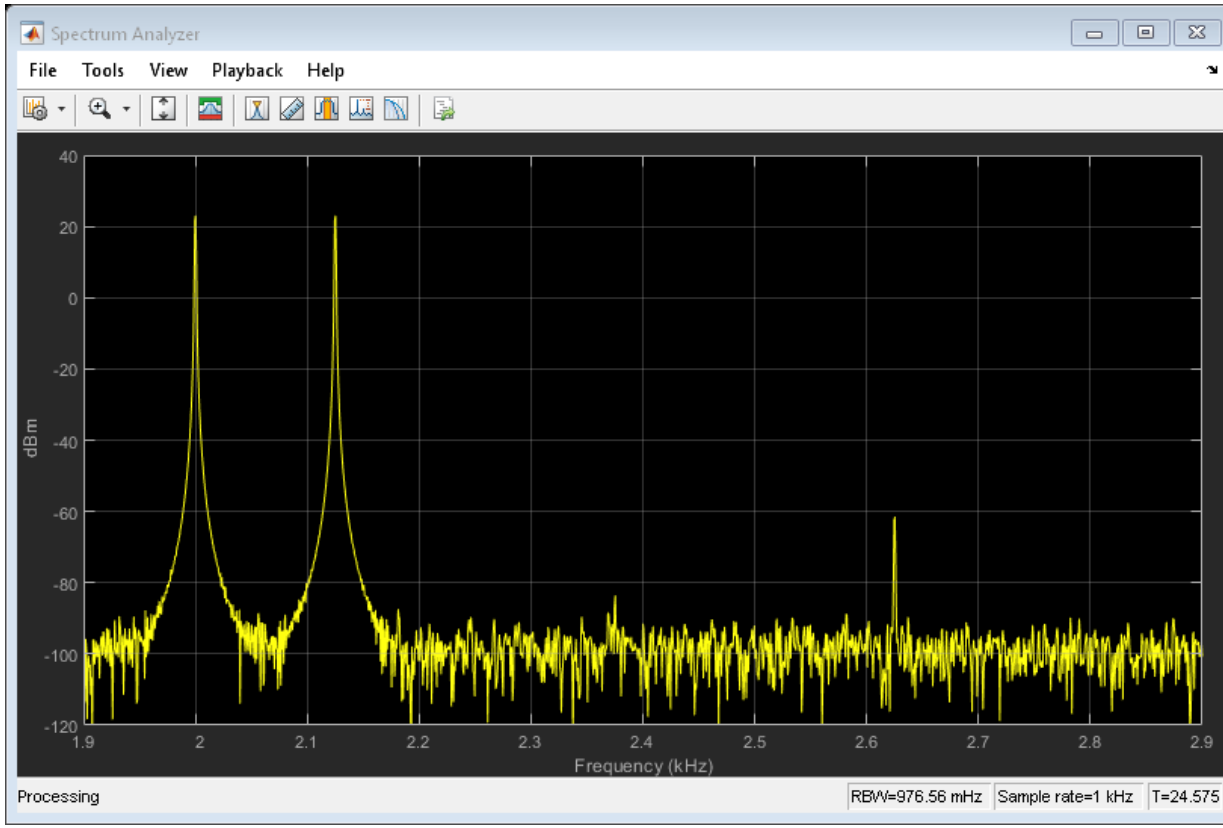
```
release(sa)
sa.FrequencyOffset = 2400;
```



Stream in the data and filter the signal.

```
for index = 1:1000
    x = sum(sin(),2) +  1e-4 * randn(FrameLength,1);
```

```
    z = bpdecim(x);
    sa(z);
end
```



The tones at 2000 Hz and 2125 Hz are passed through the decimator, while the tone at 1625 Hz is filtered out.

Algorithms

The complex bandpass decimator is designed by applying a complex frequency shift transformation on a lowpass prototype filter. The lowpass prototype in this case is a multirate, multistage finite impulse response (FIR) filter. The desired frequency shift applies only to the first stage. Subsequent stages scale the desired frequency shift by

their respective cumulative decimation factors. For details, see “Complex Bandpass Filter Design” and “Zoom FFT”.

dsp.Convolver

Package: `dsp`

Convolution of two signals

Description

The `dsp.Convolver` System object convolves the first dimension of an *N*-D input array, *u*, with the first dimension of an *N*-D input array, *v*. You can convolve the inputs in the time domain or frequency domain. In the time domain, the object convolves the first input with the second input. In the frequency domain, the object multiplies the Fourier transforms of both the inputs, and computes the inverse Fourier transform of the product. In this domain, depending on the input length, the object can require fewer computations. For more information on the two computation methods, see “Algorithms” on page 4-426.

To convolve two inputs:

1. Create the `dsp.Convolver` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
cnv = dsp.Convolver
cnv = dsp.Convolver(Name,Value)
```

Description

`cnv = dsp.Convolver` creates a convolution System object, `cnv`, to convolve two inputs in the time domain or frequency domain.

`cnv = dsp.Convolver(Name,Value)` creates a convolution System object, `cnv`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `cnv = dsp.Convolver('Method','Frequency Domain')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Method` — Domain for computing convolutions

`'Time Domain'` (default) | `'Frequency Domain'` | `'Fastest'`

Domain in which the System object computes convolutions, specified as one of the following:

- `'Time Domain'` –– Computes the convolutions in the time domain, which minimizes memory usage. For more information, see “Time-Domain Computation” on page 4-426.
- `'Frequency Domain'` –– Computes the convolutions in the frequency domain, which can require fewer computations depending on the input length. For more information, see “Frequency-Domain Computation” on page 4-426.
- `'Fastest'` –– Computes the convolutions in the domain that minimizes the number of computations.

Note Fixed-point signals are supported for the time domain only. To use the following fixed-point properties, set `Method` to `'Time Domain'`.

Fixed-Point Properties

`FullPrecisionOverride` — Full-precision override for fixed-point arithmetic

`true` (default) | `false`

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` –– The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` –– Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

`RoundingMethod` — Rounding method

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Select the rounding mode for fixed-point operations.

Dependencies

This property applies when you set the `FullprecisionOverride` property to `false` and at least one of the `ProductDataType`, `AccumulatorDataType`, and `OutputDataType` properties to any option other than `'Full precision'`.

`OverflowAction` — Overflow action

`'Wrap'` (default) | `'Saturate'`

The overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` –– The object wraps the result of its fixed-point operations.
- `'Saturate'` –– The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property applies when you set the `FullprecisionOverride` property to `false` and at least one of the `ProductDataType`, `AccumulatorDataType`, and `OutputDataType` properties to any option other than `'Full precision'`.

`ProductDataType` — Product output data type

`'Full precision'` (default) | `'Custom'` | `'Same as first input'`

Data type of the output of a product operation in the `dsp.Convolver` object, specified as one of the following:

- `'Full precision'` –– The object computes the product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Custom'` –– The product output data type is specified as a custom numeric type through the `CustomProductDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and `OverflowAction` properties.
- `'Same as first input'` –– The object specifies the product output data type to be the same as the first input data type.

For more information on the product output data type, see the “Fixed Point” on page 4-427 section.

`CustomProductDataType` — Product word and fraction lengths
`numerictype([],32,30)` (default)

The product output data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `ProductDataType` to `'Custom'`.

`AccumulatorDataType` — Accumulator data type
`'Full precision'` (default) | `'Custom'` | `'Same as first input'` | `'Same as product'`

Data type of the output of an accumulation operation in the `dsp.Convolver` object, specified as one of the following:

- `'Full precision'` –– The object computes the accumulator data type using the full precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Custom'` –– The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.

- `'Same as first input'` –– The object specifies the accumulator data type to be the same as the first input data type.
- `'Same as product'` –– The object specifies the accumulator data type to be the same as the product data type.

For more information on the accumulator data type, see the “Fixed Point” on page 4-427 section.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype([],32,30)` (default)

The accumulator data type, specified as an auto signed numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `AccumulatorDataType` to `'Custom'`.

`OutputDataType` — Output data type
`'Same as accumulator'` (default) | `'Custom'` | `'Same as first input'` | `'Same as product'`

Data type of the output of the `dsp.Convolver` object, specified as one of the following:

- `'Same as accumulator'` –– The object specifies the output data type to be the same as the accumulator data type. For more details on the accumulator data type, see the “AccumulatorDataType” on page 4-0 property.
- `'Custom'` –– The output data type is specified as a custom numeric type through the `CustomOutputDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- `'Same as first input'` –– The object specifies the output data type to be the same as the first input data type.
- `'Same as product'` –– The object specifies the output data type to be the same as the product data type.

For more information on the output data type, see the “Fixed Point” on page 4-427 section.

`CustomOutputDataType` — Output word and fraction lengths
`numerictype([],16,15)` (default)

The output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `OutputDataType` to `'Custom'`.

Usage

Syntax

```
cnvOut = cnv(input1, input2)
```

Description

`cnvOut = cnv(input1, input2)` convolves the two inputs, `input1` and `input2`, along their first dimensions, and returns the convolved output, `cnvOut`.

Input Arguments

`input1` — First data input

vector | matrix | *N*-D array

First data input, specified as a vector, matrix, or *N*-D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: ones(10,3,2)

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

`input2` — Second data input

vector | matrix | *N*-D array

Second data input, specified as a vector, matrix, or *N*-D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: randn(4,3,2)

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Output Arguments

`cnvOut` — Convolved output

vector | matrix | *N*-D array

The convolved output of the two inputs, returned as a vector, matrix, or *N*-D array.

- When both inputs are *N*-D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when *u* is an M_u-by-*N*-by-*P* array, and *v* is an M_v-by-*N*-by-*P* array, the output is an (M_u+M_v–1)-by-*N*-by-*P* array.
- When one input is a column vector and the other is an *N*-D array, the object independently convolves the vector with the first dimension of the *N*-D input array. For example, when *u* is an M_u-by-1 column vector and *v* is an M_v-by-*N* matrix, the output is an (M_u+M_v–1)-by-*N* matrix.
- When *u* and *v* are column vectors with lengths M_u and M_v, the object performs the vector convolution. The output is an (M_u+M_v–1)-by-1 column vector.

When both the inputs are real, the output is real. When one or both inputs are complex, the output is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Convolve Two Rectangular Sequences

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.Convolver` object.

```
conv = dsp.Convolver
```

```
conv =
  dsp.Convolver with properties:

    Method: 'Time Domain'

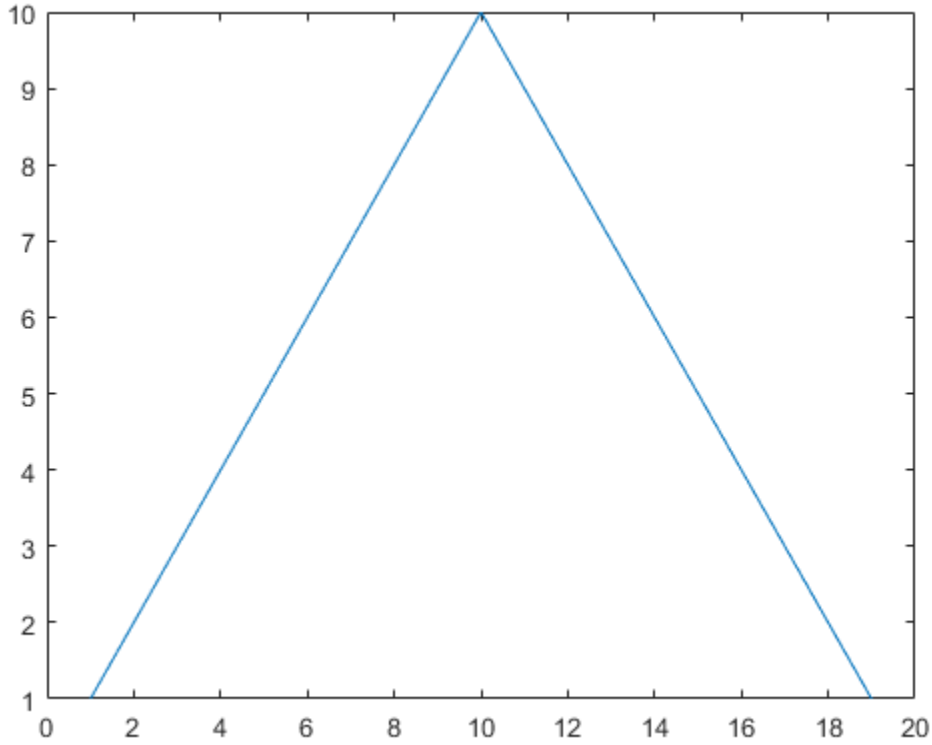
  Show all properties
```

Convolve two rectangular sequences.

```
x = ones(10,1);
y = conv(x,x);
```

Plot the resulting convolved sequence, which is a triangular sequence.

```
plot(y)
```



More About

Convolution

The convolution of two signals is the integral that measures the amount of overlap of one signal as it is shifted over another signal.

The convolution of two discrete time sequences, $u[n]$ and $v[n]$, is given by the following equation:

$$y(k) = \sum_{n} u(n-k)v(k)$$

Algorithms

Time-Domain Computation

When you set the computation domain to *time*, the algorithm computes the convolution of the two inputs in the time domain.

When the two inputs, u and v, are of size M_u-by-N and M_v-by-N respectively, the jth column of the convolution output is given by the following equation:

$$y_{i,\,j} = \sum_{k\,=\,0}^{\max(M_u, M_v) - 1} u_{k,\,j} v_{(i\,-\,k),\,j} \quad 0 \le i \le (M_u + M_v - 2)$$

Inputs u and v are zero when they are indexed outside their valid ranges.

When u is an M_u-by-1 column and v an M_v-by-N matrix, the output is an (M_u+M_v–1)-by-N matrix whose jth column is computed using the following equation:

$$y_{i,\,j} = \sum_{k\,=\,0}^{\max(M_u, M_v) - 1} u_k v_{(i\,-\,k),\,j} \quad 0 \le i \le (M_u + M_v - 2)$$

When both the inputs are column vectors with lengths M_u and M_v, the object performs the vector convolution given by the following equation:

$$y_i = \sum_{k\,=\,0}^{\max(M_u, M_v) - 1} u_k v_{(i\,-\,k)} \quad 0 \le i \le (M_u + M_v - 2)$$

The output is an (M_u+M_v–1)-by-1 column vector.

Frequency-Domain Computation

When you set the computation domain to *frequency*, the algorithm computes the convolution in the frequency domain.

In this domain, the algorithm computes the convolution sequence by taking the Fourier transform of both the input signals, multiplying the Fourier transforms, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

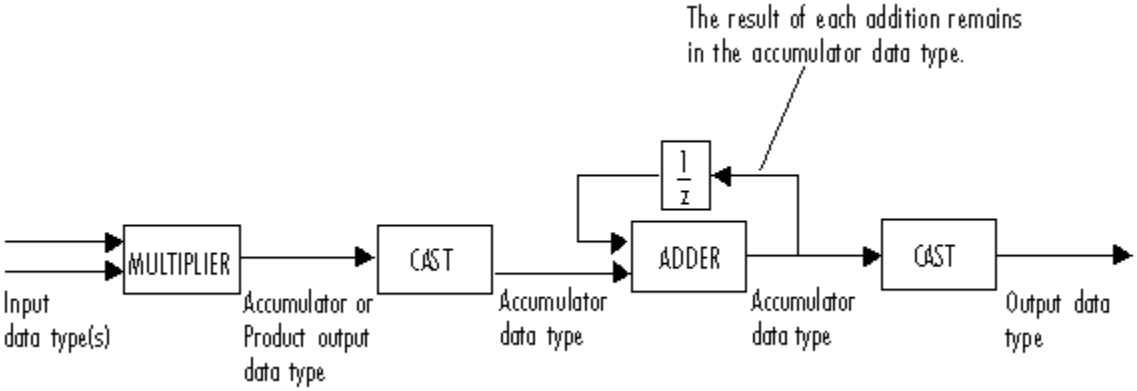
See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types used within the `dsp.Convolver` System objectfor fixed-point signals.

Fixed-point signals are supported for the time domain only.



The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data

type. For details on the complex multiplication performed, see “Multiplication Data Types”.

When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

Blocks
Convolution

Introduced in R2012a

dsp.Counter

Package: `dsp`

Count up or down through specified range of numbers

Description

The `Counter` object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

1. Create the `dsp.Counter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
count = dsp.Counter
count = dsp.Counter(Name,Value)
```

Description

`count = dsp.Counter` returns a counter System object, `count`, that counts up when the input is nonzero.

`count = dsp.Counter(Name,Value)` returns a counter System object, `count`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Direction` — Count up or down
`Up` (default) | `Down`

Specify the counter direction as `Up` or `Down`.

Tunable: Yes

`CountEventInputPort` — Add input to specify a count event
`true` (default) | `false`

Set this property to `true` to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the `CountEventCondition` property. When you set this property to `false`, the internal counter is free running, that is, the counter increments or decrements on every call to the object algorithm.

`CountEventCondition` — Condition that increments, decrements, or resets internal counter
`Non-zero` (default) | `Rising edge` | `Falling edge` | `Either edge`

Specify the event at the count event input that increments or decrements the counter as `Rising edge`, `Falling edge`, `Either edge` or `Non-zero`.

If you set the `ResetInputPort` and `CountEventInputPort` properties to `true`, the counter is reset when the event you specify for the `CountEventCondition` occurs.

Dependencies

This property applies only when you set the `CountEventInputPort` property to `true`.

`CounterSizeSource` — Source of counter size data type
`Property` (default) | `Input port`

Specify the source of the counter size data type as `Property` or `Input port`.

`CounterSize` — Range of integer values to count through

`Maximum` (default) | `8 bits` | `16 bits` | `32 bits`

Specify the range of integer values to count through before recycling to zero as `8 bits`, `16 bits`, `32 bits` or `Maximum`.

`MaximumCount` — Counter's maximum value

`255` (default) | `0` | positive integer

Specify the counter's maximum value as a numeric scalar value.

Tunable: Yes

Dependencies

This property applies only when you set the `CounterSizeSource` property to `Property` and the `CounterSize` property to `Maximum`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialCount` — Counter initial value

`0` (default) | `0` | positive integer

Specify the initial value for the counter.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CountOutputPort` — Output count

`true` (default) | `false`

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

`HitOutputPort` — Output hit events

`true` (default) | `false`

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

`HitValues` — Values whose occurrence in count produce a true hit output

32 (default) | scalar integer | vector of integers

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit.

Dependencies

This property applies only when you set the `HitOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ResetInputPort` — Add input to enable internal counter reset

`true` (default) | `false`

When you set this property to `true`, specify a reset input to the object algorithm. When the reset input receives the event you specify for the `CountEventCondition` property, the counter resets. If you set the `CountEventInputPort` property to `false`, the counter resets whenever the reset input is not zero.

`SamplesPerFrame` — Number of samples in each output frame

1 (default) | positive integer

Specify the number of samples in each output frame.

Dependencies

This property applies only when you set the `CountEventInputPort` property to `false`, indicating a free-running counter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CountOutputDataType` — Data type of count output

`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`

Specify the data type of the count output, `cnt`, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`.

Dependencies

This property applies when you set the `CountOutputPort` property to `true`.

Usage

Syntax

```
[cnt,hit] = count(event,reset)
cnt = count(event,reset)
hit = count(event,reset)
[ ___ ] = count()
[ ___ ] = count(event)
```

Description

`[cnt,hit] = count(event,reset)` increments, decrements, or resets the internal counter as specified by the values of the `event` and `reset` inputs. The output argument `cnt` denotes the present value of the counter. A trigger event at the `event` input causes the counter to increment or decrement. A trigger event at the `reset` input resets the counter to its initial state.

`cnt = count(event,reset)` returns the current value of the count when you set the `CountOutputPort` property to `true` and the `HitOutputPort` property to `false`.

`hit = count(event,reset)` returns a Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. This condition applies when you set the `HitOutputPort` property to `true` and the `CountOutputPort` property to `false`.

`[ ___ ] = count()` increments or decrements the free-running internal counter when you set the `CountEventInputPort` property to `false` and the `ResetInputPort` property to `false`.

`[ ___ ] = count(event)` increments or decrements the internal counter when the `event` input matches the event you specify for the `CountEventCondition` property and you set the `ResetInputPort` property to `false`.

Input Arguments

`event` — Event that causes counter to increment or decrement
scalar

Event that causes the counter to increment or decrement, specified as a scalar. The `CountEventCondition` property specifies the event under which the counter value changes.

Dependencies

This input is valid only when `CountEventInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`reset` — Reset of internal counter

scalar

A trigger event at the reset input resets the counter to the initial state.

Dependencies

This input is valid only when `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

`cnt` — Present value of counter

scalar | column vector

Current value of the count, returned as a scalar. The data type of this output is set by the `CountOutputDataType` property. If `CountEventInputPort` is `false`, the number of elements in this output vector is determined by the value you specify in the `SamplesPerFrame` property.

Dependencies

This output is enabled only when you set the `CountOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`hit` — Indicates if counter matches hit values

scalar | column vector

Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. If `CountEventInputPort` is `false`, the number of elements in

this output vector is determined by the value you specify in the `SamplesPerFrame` property.

Dependencies

This output is enabled when you set the `HitOutputPort` property to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Count the Rising Edges

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use `dsp.Counter` System object™ to count at every rising edge of the input signal.

```
count = dsp.Counter('MaximumCount', 5, ...
    'CountOutputPort', true, ...
    'HitOutputPort', false, ...
    'ResetInputPort', false);
sgnl = [0 1 0 1 0 1 0 1 0 1 ];
cnt = zeros(1,12);
for ii = 1:length(sgnl)
```

```
    cnt(ii) = count(sgnl(ii));
end
disp(cnt);
```

```
     0     1     1     2     2     3     3     4     4     5     5     0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Counter block reference page. The object properties correspond to the block parameters.

- The `CountEventCondition` object property does not have a free-running option. Set the `CountEventInputPort` property to `false` to obtain the free-running option.
- The `CounterSizeSource` and `CounterSize` object properties correspond to the **Counter size** block parameter.
- The `CountOutputPort` and `HitOutputPort` correspond to the **Output** block parameter.
- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

System Objects

`dsp.AsyncBuffer` | `dsp.Delay` | `dsp.DelayLine`

Introduced in R2012a

dsp.CoupledAllpassFilter

Package: `dsp`

Coupled allpass IIR filter

Description

The `dsp.CoupledAllpassFilter` object implements a coupled allpass filter structure composed of two allpass filters connected in parallel. Each allpass branch can contain multiple sections. The overall filter output is computed by adding the output of the two respective branches. An optional second output can also be returned, which is power complementary to the first. For example, from the frequency domain perspective, if the first output implements a lowpass filter, the second output implements the power complementary highpass filter. For real signals, the power complementary output is computed by subtracting the output of the second branch from the first. `dsp.CoupledAllpassFilter` supports double- and single-precision floating point and allows you to choose between different realization structures. This System object also supports complex coefficients, multichannel variable length input, and tunable filter coefficient values.

To filter each channel of the input:

1. Create the `dsp.CoupledAllpassFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
caf = dsp.CoupledAllpassFilter
caf = dsp.CoupledAllpassFilter(AllpassCoeffs1,AllpassCoeffs2)
caf = dsp.CoupledAllpassFilter(struc,AllpassCoeffs1,AllpassCoeffs2)
```

```
caf = dsp.CoupledAllpassFilter(Name,Value)
```

Description

`caf = dsp.CoupledAllpassFilter` returns a coupled allpass filter System object, `caf`, that filters each channel of the input signal independently. The coupled allpass filter uses the default inner structures and coefficients.

`caf = dsp.CoupledAllpassFilter(AllpassCoeffs1,AllpassCoeffs2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to `'Minimum multiplier'`, `AllpassCoefficients1` set to `AllpassCoeffs1`, and `AllpassCoefficients2` set to `AllpassCoeffs2`.

`caf = dsp.CoupledAllpassFilter(struc,AllpassCoeffs1,AllpassCoeffs2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to `struc` and the relevant coefficients set to `AllpassCoeffs1` and `AllpassCoeffs2`. `struc` can be `'Minimum multiplier'` | `'Wave Digital Filter'` | `'Lattice'`.

`caf = dsp.CoupledAllpassFilter(Name,Value)` returns a Coupled allpass filter System object, `caf`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Structure` — Internal structure of allpass branches

`'Minimum multiplier'` (default) | `'Wave Digital Filter'` | `'Lattice'`

Specify the internal structure of allpass branches as one of `'Minimum multiplier'`, `'Wave Digital Filter'`, or `'Lattice'`. Each structure uses a different pair of coefficient values, independently stored in the relevant object property.

`AllpassCoefficients1` — Allpass polynomial coefficients of branch 1

`[0 0.5]` (default) | row vector | cell array

Specify the polynomial filter coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the `Structure` property to `'Minimum multiplier'`.

Data Types: `single` | `double`

`WDFCoefficients1` — Wave Digital Filter coefficients of branch 1

`[0.5 0]` (default) | row vector | cell array

Specify the Wave Digital Filter coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the `Structure` property to `'Wave Digital Filter'`.

Data Types: `single` | `double`

`LatticeCoefficients1` — Lattice coefficients of branch 1

`[0.5 0]` (default) | row vector | cell array

Specify the allpass lattice coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the `Structure` property to `'Lattice'`.

Data Types: `single` | `double`

`Delay` — Length in samples for branch 1

`0` (default) | positive integer scalar

Integer number of the delay taps in the top branch, specified as a positive integer scalar.

Tunable: Yes

Dependencies

This property is applicable only if you set the `PureDelayBranch` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Gain1` — Independent Branch 1 Phase Gain

`1` (default) | `'–1'` | `'0+i'` | `'0–i'`

`Gain1` is the individual branch phase gain. This property can accept only values equal to `'1'`, `'–1'`, `'0+i'`, or `'0–i'`. This property is nontunable.

Data Types: `char`

`AllpassCoefficients2` — Allpass polynomial coefficients of branch 2

`{[ ]}` (default) | row vector | cell array

Specify the polynomial filter coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the `Structure` property to `'Minimum multiplier'`.

Data Types: `single` | `double`

`WDFCoefficients2` — Wave Digital Filter coefficients of branch 2

`{[ ]}` (default) | row vector | cell array

Specify the Wave Digital Filter coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the `Structure` property to `'Wave Digital Filter'`.

Data Types: `single` | `double`

`LatticeCoefficients2` — Lattice coefficients of branch 2

`{[ ]}` (default) | row vector | cell array

Specify the allpass lattice coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the `Structure` property to `'Lattice'`.

Data Types: `single` | `double`

`Gain2` — Independent Branch 2 Phase Gain

`'1'` (default) | `'–1'` | `'0+1i'` | `'0–1i'`

Specify the value of the independent phase gain applied to branch 2. This property can accept only values equal to `'1'`, `'–1'`, `'0+i'`, or `'0–i'`. This property is nontunable.

Data Types: `char`

`Beta` — Coupled phase gain

1 (default) | complex value with magnitude equal to 1

Specify the value of the phasor gain in complex conjugate form, in each of the two branches, and in complex coefficient configuration. The absolute value of this property should be 1 and its default value is 1.

Tunable: Yes

Dependencies

This property is applicable only when the selected `Structure` property supports complex coefficients.

Data Types: `single` | `double`

`PureDelayBranch` — Replace allpass filter in first branch with pure delay

`false` (default) | `true`

If you set `PureDelayBranch` to `true`, the property holding the coefficients for the first allpass branch is disabled and Delay becomes enabled. You can use this property to improve performance, when one of the two allpass branches is known to be a pure delay (e.g. for halfband filter designs)

Data Types: `logical`

`ComplexConjugateCoefficients` — Allow inferring coefficients of second allpass branch as complex conjugate of first

`false` (default) | `true`

When the input signal is real, this property triggers the use of an optimized structural realization. This property enables providing complex coefficients for only the first branch. The coefficients for the second branch are automatically inferred as complex conjugate values of the first branch coefficients

Dependencies

This property is only enabled if the currently selected structure supports complex coefficients. Use it only if the filter coefficients are actually complex.

Data Types: `logical`

Usage

Syntax

```
y = caf(x)
[y,ypc] = caf(x)
```

Description

`y = caf(x)` filters the input signal `x` to produce the output `y`. When `x` is a matrix, each column is filtered independently as a separate channel over time.

`[y,ypc] = caf(x)` also returns `ypc`, the power complementary signal to the primary output `y`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Lowpass filtered output

vector | matrix

Lowpass filtered output, returned as a vector or a matrix. The size and data type of the output signal matches that of the input signal.

Data Types: `double` | `single`

ypc — Highpass filtered output

vector | matrix

Power complimentary highpass filtered output, returned as a vector or a matrix. The size and data type of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.CoupledAllpassFilter`

fvtool	Visualize frequency response of coupled allpass filter
getBranches	Return internal allpass branches
freqz	Frequency response of filter
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Filter coefficients
cost	Estimate cost for implementing filter System objects
grpdelay	Group delay response of discrete-time filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

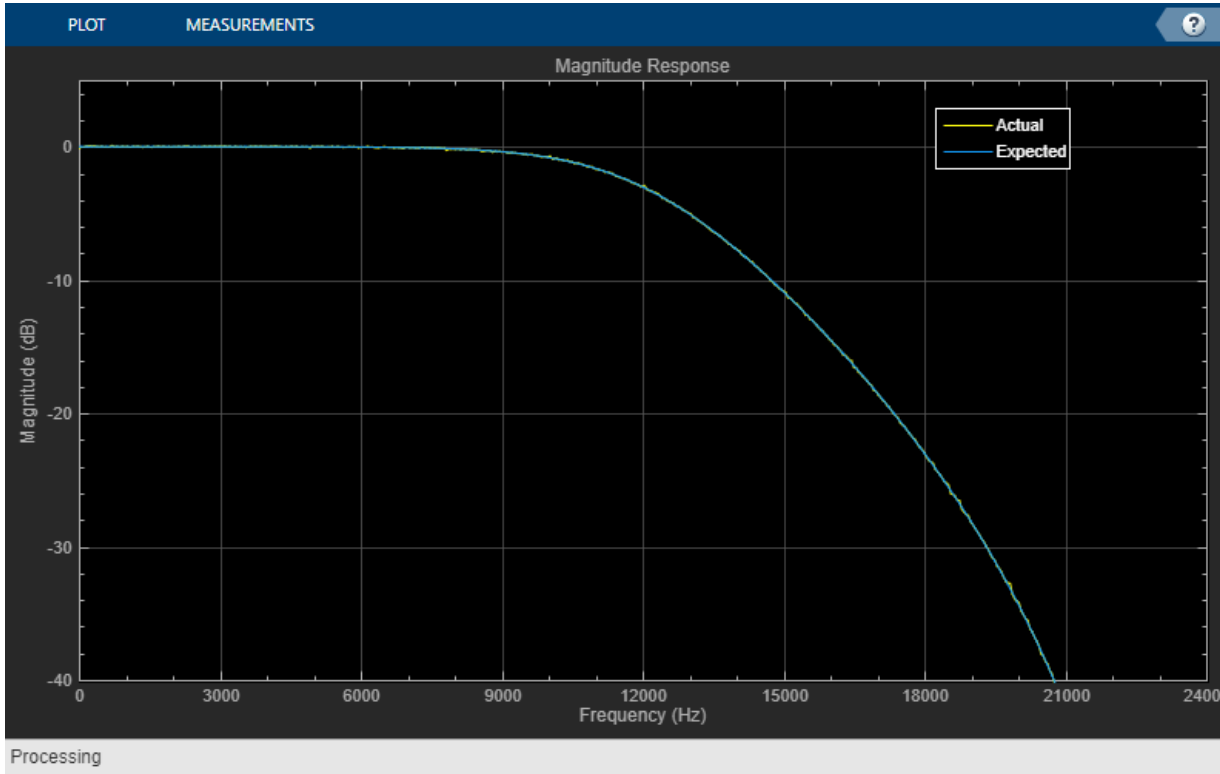
Allpass Realization of a Butterworth Lowpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Realize a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```
Fs = 48000;    % in Hz
Fc = 12000;    % in Hz
frameLength = 1024;
[b, a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1, c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
tfe = dsp.TransferFunctionEstimator('FrequencyRange', 'onesided',...
    'SpectralAverages', 2);
```

```
aplot = dsp.ArrayPlot('PlotType', 'Line',...
    'YLimits', [-40 5],...
    'YLabel', 'Magnitude (dB)',...
    'SampleIncrement', Fs/frameLength,...
    'XLabel', 'Frequency (Hz)',...
    'Title', 'Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Actual','Expected'});
Niter = 200;
for k = 1:Niter
    in = randn(frameLength,1);
    out = caf(in);
    A = tfe(in,out);
    aplot(db([A,AExp]));
end
```



Allpass Realization of an Elliptic Highpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

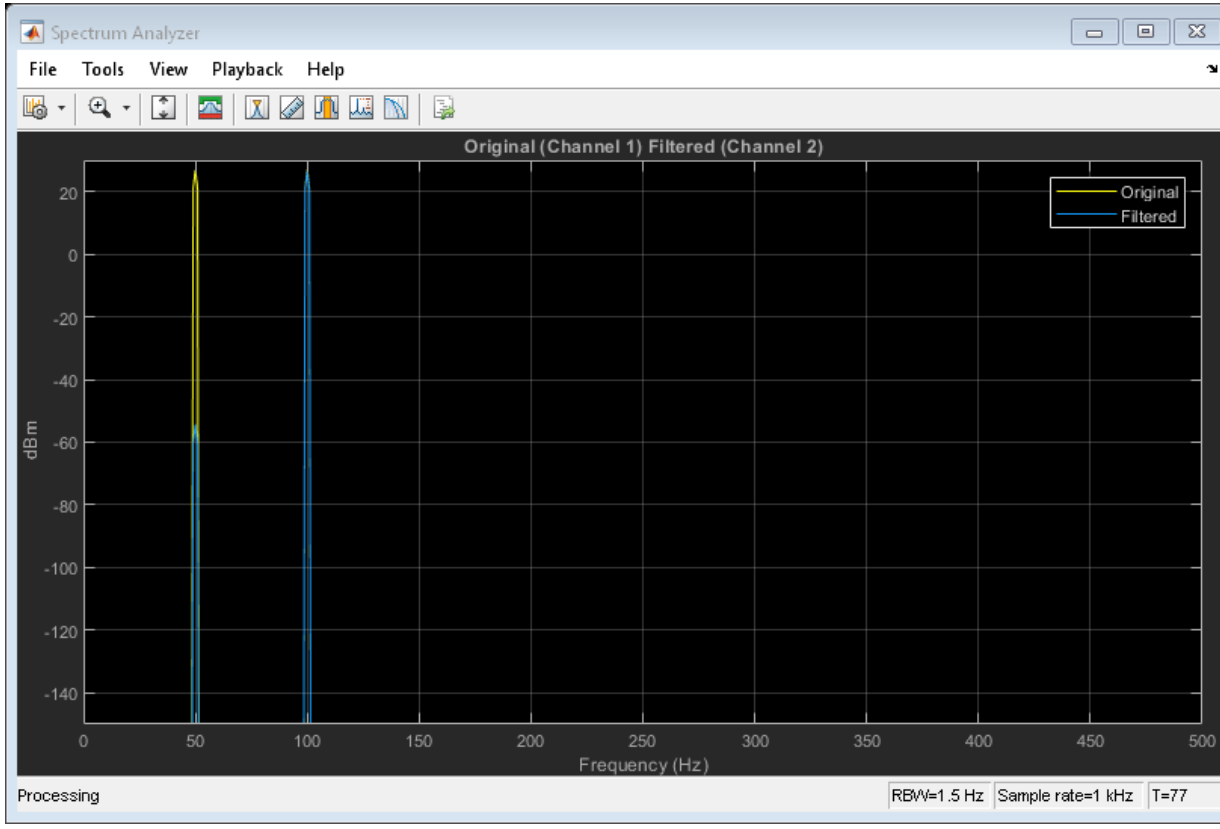
Remove a low-frequency sinusoid using an elliptic highpass filter design implemented through a coupled allpass structure.

Initialize

```
Fs = 1000;
f1 = 50; f2 = 100;
Fpass = 70; Apass = 1;
Fstop = 60; Astop = 80;
filtSpecs = fdesign.highpass(Fstop,Fpass,Astop,Apass,Fs);
hpSpec = design(filtSpecs,'ellip','FilterStructure','cascadeallpass',...
    'SystemObject',true);
frameLength = 1000;
nFrames = 100;
sine   = dsp.SineWave('Frequency',[f1,f2],'SampleRate',Fs,...
  'SamplesPerFrame',frameLength); % Input composed of two sinusoids.
sa = dsp.SpectrumAnalyzer('SampleRate',Fs,'YLimits',[-150 30],...
  'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,...
  'FrequencyResolutionMethod', 'WindowLength','WindowLength',1000,...
  'FFTLengthSource', 'Property','FFTLength', 1000,...
  'Title','Original (Channel 1) Filtered (Channel 2)',...
  'ChannelNames',{'Original','Filtered'});
```

Simulate

```
for k = 1:nFrames
  original = sum(sine(),2); % Add the two sinusoids together
  filtered = hpSpec(original);
  sa([original,filtered]);
end
```



View Power Complementary Output of Coupled Allpass Filter

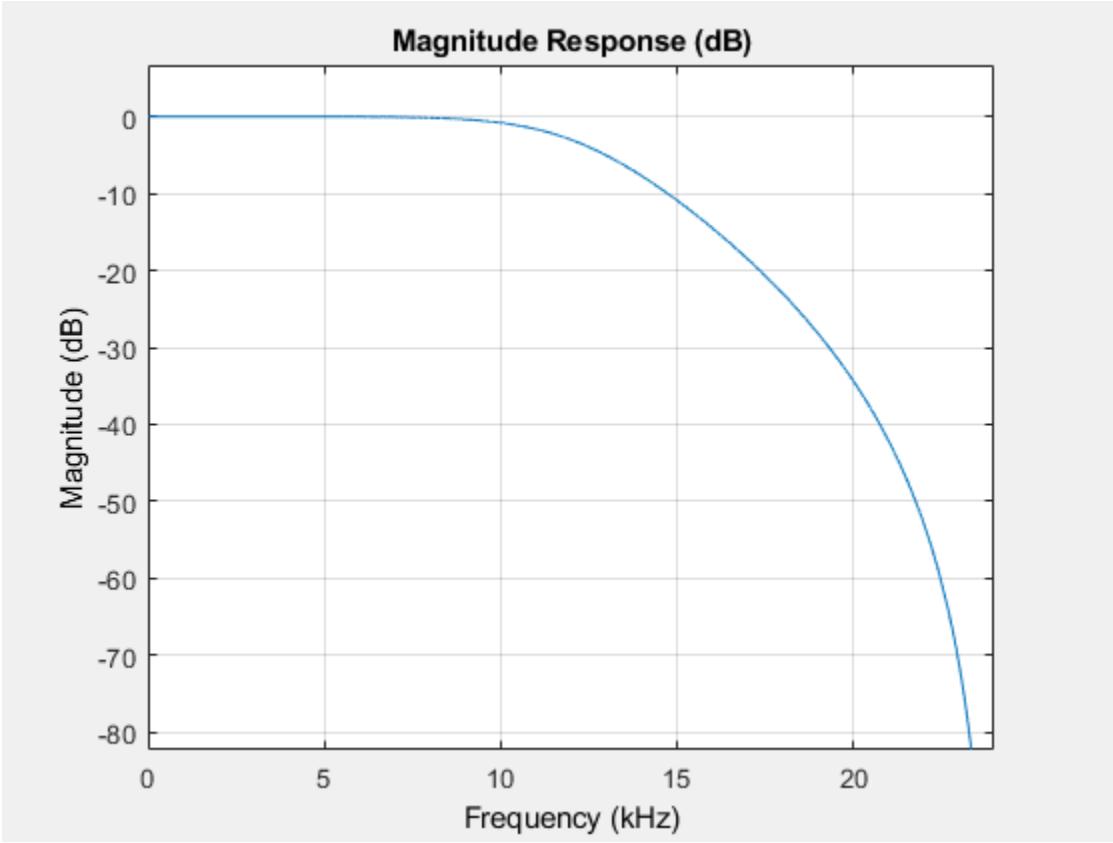
Design a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```
Fs = 48000;    % in Hz
Fc = 12000;    % in Hz
frameLength = 1024;
[b,a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1,c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
```

Using the `'SubbandView'` option of the `dsp.CoupledAllpassFilter`, you can visualize the lowpass filter output, the power complementary highpass filter output, or both using the `fvtool`.

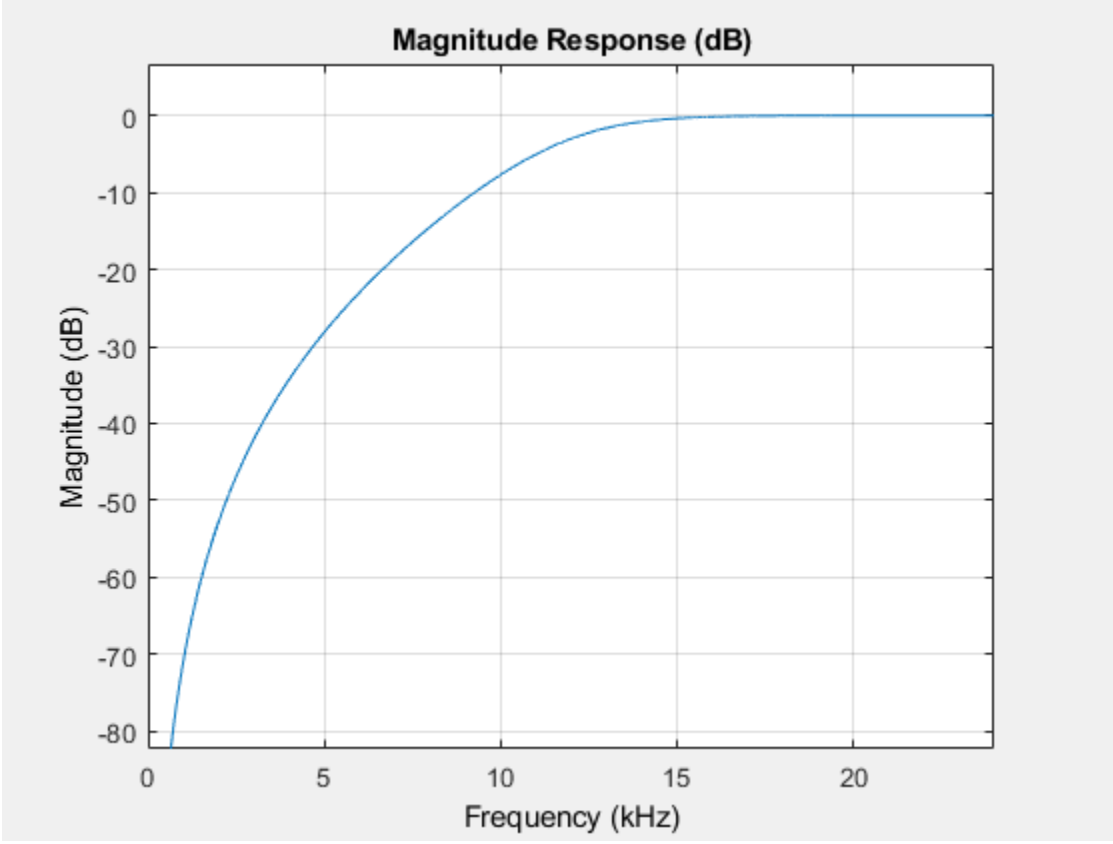
To view the lowpass filter output, set `'SubbandView'` to `1`.

```
fvtool(caf,'SubbandView',1,'Fs',Fs)
```



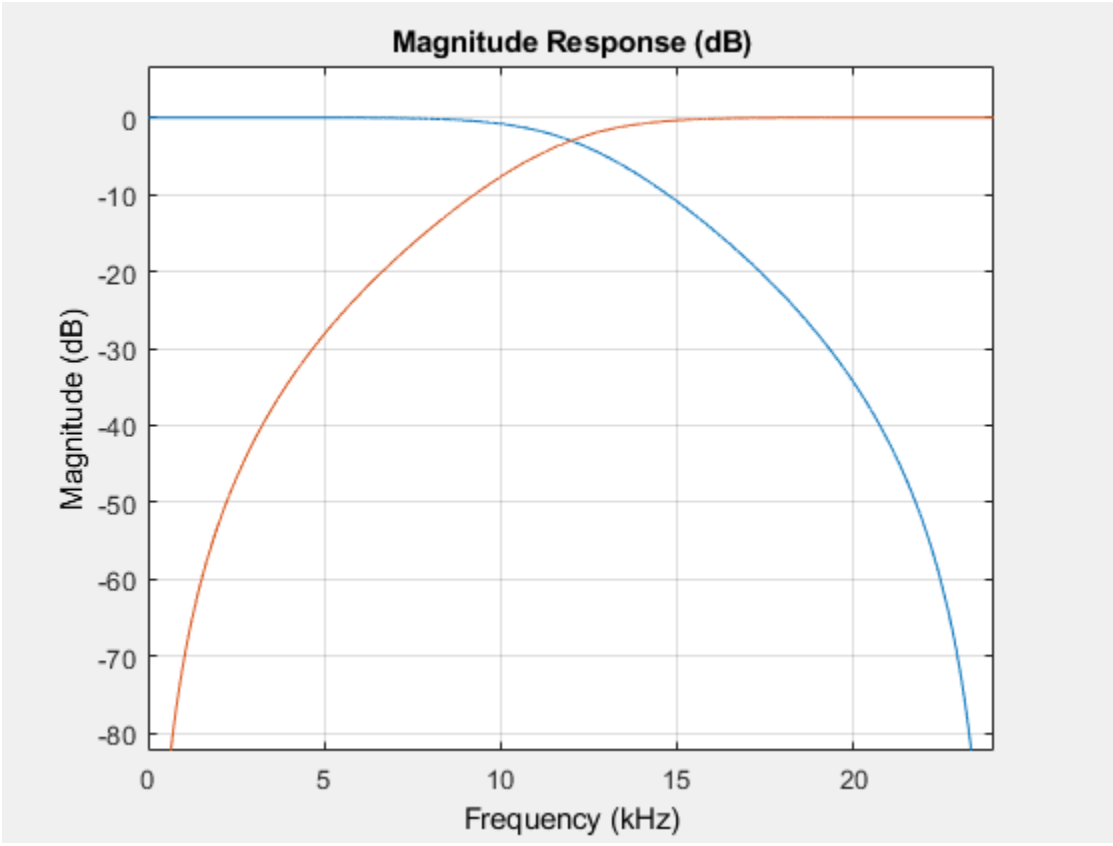
To view the highpass filter output, set `'SubbandView'` to `2`.

```
fvtool(caf,'SubbandView',2,'Fs',Fs)
```



To view both the outputs, set `'SubbandView'` to `'all'`, [1 2] or [1;2].

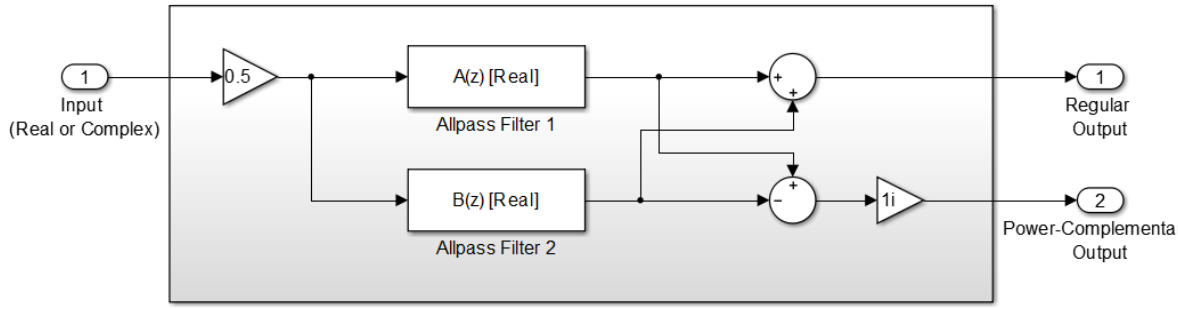
```
fvtool(caf,'SubbandView','all','Fs',Fs);
```



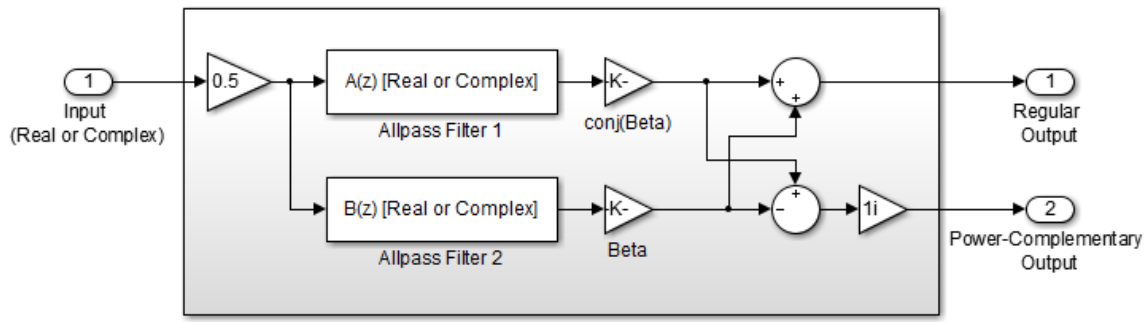
Algorithms

The following three figures summarize the main structures supported by `dsp.CoupledAllpassFilter`.

- Minimum Multiplier and WDF



- Lattice



- Lattice with Complex Conjugate Coefficients

dsp.CrossSpectrumEstimator

Package: `dsp`

Estimate cross-spectral density

Description

The `dsp.CrossSpectrumEstimator` System object computes the cross-spectrum density of a signal, using the Welch's averaged periodogram method.

To implement the cross-spectrum estimation object:

1. Create the `dsp.CrossSpectrumEstimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
cse = dsp.CrossSpectrumEstimator
cse = dsp.CrossSpectrumEstimator(Name,Value)
```

Description

`cse = dsp.CrossSpectrumEstimator` returns a System object, `cse`, that computes the cross-power spectrum of real or complex signals using the periodogram method and Welch’s averaged, modified periodogram method.

`cse = dsp.CrossSpectrumEstimator(Name,Value)` returns a `dsp.CrossSpectrumEstimator` System object, `cse`, with each specified property name set to the specified value. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`FFTLengthSource` — Source of FFT length value

`'Auto'` (default) | `'Property'`

Specify the source of the FFT length value as either `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the cross-spectrum estimator sets the FFT length to the input frame size. If you set this property to `'Property'`, then specify the number of FFT points using the `FFTLength` property.

`FFTLength` — FFT Length

128 (default) | positive integer

Specify the length of the FFT that the cross-spectrum estimator uses to compute cross-spectral estimates as a positive, integer scalar.

Dependencies

This property applies when you set the `FFTLengthSource` property to `'Property'`.

Data Types: `double`

`Window` — Window function

`'Hann'` (default) | `'Rectangular'` | `'Chebyshev'` | `'Flat Top'` | `'Hamming'` | `'Kaiser'`

Specify a window function for the cross-spectrum estimator as one of `'Rectangular'`, `'Chebyshev'`, `'Flat Top'`, `'Hamming'`, `'Hann'`, or `'Kaiser'`.

`SidelobeAttenuation` — Side lobe attenuation of window

`60` (default) | positive scalar

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB).

Dependencies

This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`.

Data Types: `double`

`FrequencyRange` — Frequency range of the cross-spectrum estimate

`'Twosided'` (default) | `'onesided'` | `'centered'`

Specify the frequency range of the cross-spectrum estimator as one of `'twosided'`, `'onesided'`, or `'centered'`.

If you set the `FrequencyRange` to `'onesided'`, the cross-spectrum estimator computes the one-sided spectrum of real input signals, `x` and `y`. If the FFT length, NFFT, is even, the length of the cross-spectral estimate is `NFFT/2+1` and is computed over the interval `[0, SampleRate/2]`. If NFFT is odd, the length of the cross-spectrum estimate is equal to `(NFFT+1)/2`, and the interval is `[0, SampleRate/2]`.

If you set the `FrequencyRange` to `'twosided'`, the cross-spectrum estimator computes the two-sided spectrum of complex or real input signals, `x` and `y`. The length of the cross-spectrum estimate is equal to NFFT. This value is computed over `[0, SampleRate]`.

If you set the `FrequencyRange` to `'centered'`, the cross-spectrum estimator computes the centered two-sided spectrum of complex or real input signals, `x` and `y`. The length of the cross-spectrum estimate is equal to NFFT, and the estimate is computed between `[-SampleRate/2, SampleRate/2]` and `(-SampleRate/2, SampleRate/2)` for even and odd lengths, respectively.

`AveragingMethod` — Averaging method

`'Running'` (default) | `'Exponential'`

Specify the averaging method as `'Running'` or `'Exponential'`. In the running averaging method, the object computes an equally weighted average of a specified number of spectrum estimates defined by the `SpectralAverages` property. In the exponential method, the object computes the average over samples weighted by an exponentially decaying forgetting factor.

`SpectralAverages` — Number of spectral averages

8 (default) | positive integer

Specify the number of spectral averages as a positive, integer scalar. The object computes the current cross-spectral estimate by averaging the last `N` estimates. `N` is the number of spectral averages defined in the `SpectralAverages` property.

Dependencies

This property applies when you set `AveragingMethod` to `'Running'`.

Data Types: `double`

`ForgettingFactor` — Forgetting factor

`0.9` (default) | scalar in the range (`0`,`1`]

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one.

Tunable: Yes

Dependencies

This property applies when you set `AveragingMethod` to `'Exponential'`.

Data Types: `single` | `double`

`SampleRate` — Sample rate of input

`1` (default) | positive scalar

Specify the sample rate of the input, in hertz, as a finite numeric scalar. The sample rate is the rate at which the signal is sampled in time.

Data Types: `single` | `double`

Usage

Syntax

```
pxy = cse(x,y)
```

Description

`pxy = cse(x,y)` computes the cross power spectrum density, `pxy`, of the input signals, `x` and `y`.

Input Arguments

x — First data input

vector | matrix

First data input, specified as a vector or a matrix. The inputs, `x` and `y` must have the same size and data type.

Data Types: `single` | `double`

y — Second data input

vector | matrix

Second data input, specified as a vector or a matrix. The inputs, `x` and `y` must have the same size and data type.

Data Types: `single` | `double`

Output Arguments

pxy — Cross-power spectrum density output

vector | matrix

Cross-power spectrum density output, returned as a vector or a matrix. The output has the same size and data type as the input signals.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.CrossSpectrumEstimator`

getFrequencyVector	Vector of frequencies at which estimation is done
getRBW	Resolution bandwidth of spectrum

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Compute Cross-Power Spectrum of Two Noisy Sine Waves

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two sine waves.

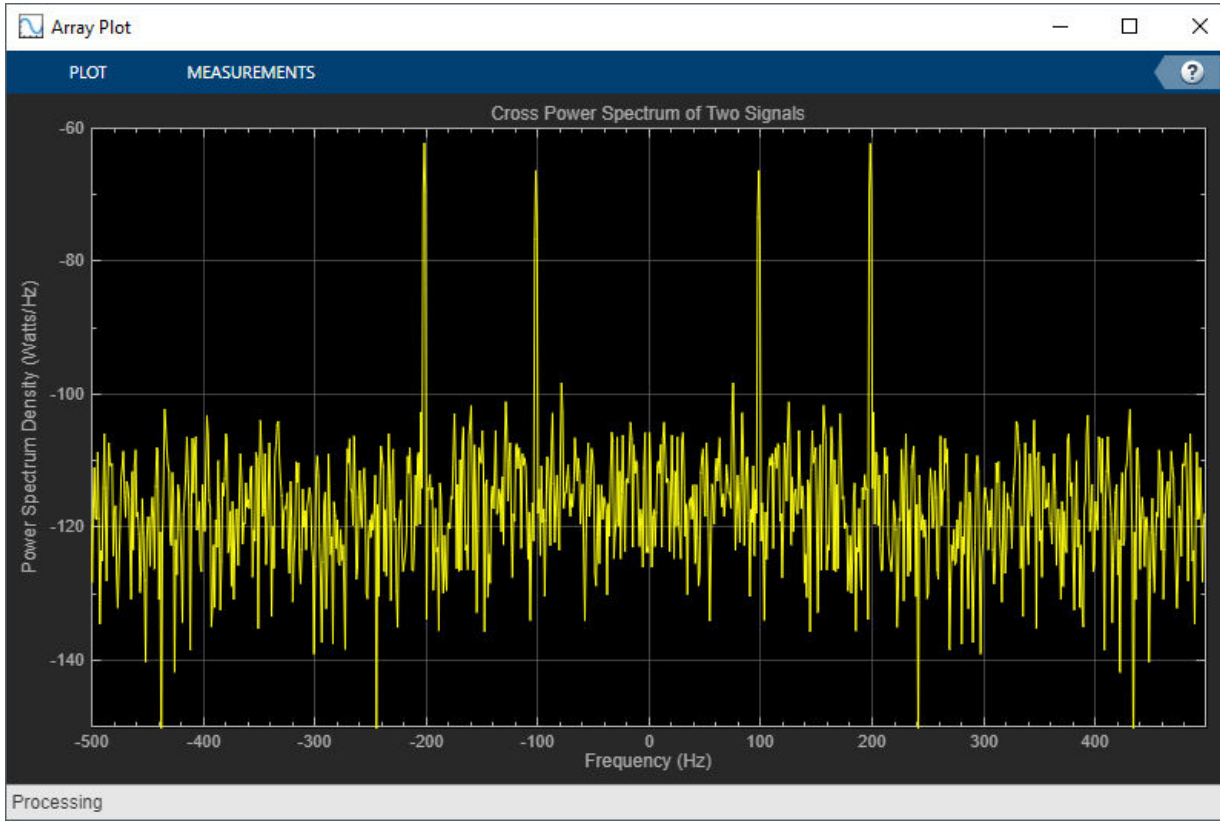
```
sin1 = dsp.SineWave('Frequency',200, 'SampleRate', 1000);
sin1.SamplesPerFrame = 1000;
sin2 = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
sin2.SamplesPerFrame =  1000;
```

Use the `dsp.CrossSpectrumEstimator` System object™ to compute the cross-spectrum of the signals. Also, use the `dsp.ArrayPlot` object to display the spectra.

```
cse = dsp.CrossSpectrumEstimator('SampleRate', sin1.SampleRate,...
    'FrequencyRange','centered');
aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
    [-150 -60],'YLabel','Power Spectrum Density (Watts/Hz)',...
    'XLabel','Frequency (Hz)',...
    'Title','Cross Power Spectrum of Two Signals');
```

Add random noise to the sine waves. Stream in the data, and plot the cross-power spectrum of the two signals.

```
for ii = 1:10
x = sin1() + 0.05*randn(1000,1);
y = sin2() + 0.05*randn(1000,1);
Pxy = cse(x, y);
aplot(20*log10(abs(Pxy)));
end
```



Algorithms

Welch's Method of Averaged Modified Periodograms

Give two signal inputs, x and y:

1. Multiply the inputs by the window and scale the result by the window power.
2. Compute FFT of the signals, X and Y, and multiply X with conj(Y) using `Z = X.*conj(Y)`.

3 Compute the current cross power spectrum estimate by taking the moving average of the last *N* number of *Z*'s and scaling the answer by the sample rate. For details on the moving average methods, see “Averaging Method” on page 4-1675.

For further information on the algorithms, refer to the “Algorithms” on page 2-1693 section in Spectrum Analyzer.

dsp.Crosscorrelator

Package: `dsp`

Cross-correlation of two inputs

Description

The `dsp.Crosscorrelator` System object computes the cross-correlation of two *N*-D input arrays along the first dimension. The computation can be done in the time domain or frequency domain. You can specify the domain through the “Method” on page 4-0 property. In the time domain, the object convolves the first input signal, *u*, with the time-reversed complex conjugate of the second input signal, *v*. To compute the cross-correlation in the frequency domain, the object:

1. Takes the Fourier transform of both input signals, resulting in *U* and *V*.
2. Multiplies *U* and V^*, where * denotes the complex conjugate.
3. Computes the inverse Fourier transform of the product.

If you set `Method` to `'Fastest'`, the object chooses the domain that minimizes the number of computations. For information on these computation methods, see “Algorithms” on page 4-475.

To obtain the cross-correlation for two discrete-time deterministic inputs:

1. Create the `dsp.Crosscorrelator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
xcorr = dsp.Crosscorrelator
```

```
xcorr = dsp.Crosscorrelator(Name,Value)
```

Description

`xcorr = dsp.Crosscorrelator` returns a cross-correlator object, `xcorr`, that computes the cross-correlation of two inputs in the time domain or frequency domain.

`xcorr = dsp.Crosscorrelator(Name,Value)` returns a cross-correlator object with each specified property set to the specified value. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Method` — Domain for computing correlations

`'Time Domain'` (default) | `'Frequency Domain'` | `'Fastest'`

Domain in which the System object computes the correlation, specified as one of the following:

- `'Time Domain'` –– Computes the cross-correlation in the time domain, which minimizes the memory usage.
- `'Frequency Domain'` –– Computes the cross-correlation in the frequency domain. For more information, see “Algorithms” on page 4-475.
- `'Fastest'` –– Computes the cross-correlation in the domain that minimizes the number of computations.

To cross-correlate fixed-point signals, set this property to `'Time Domain'`.

Fixed-Point Properties

Note Fixed-point signals are supported for the time domain only. To use these properties, set `Method` to `'Time Domain'`.

`FullPrecisionOverride` — Full-precision override for fixed-point arithmetic

`true` (default) | `false`

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` –– The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` –– Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

`RoundingMethod` — Rounding method for fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `OutputDataType` set to `'Same as accumulator'`, `ProductDataType` set to `'Full precision'`, and `AccumulatorDataType` set to `'Full precision'`

Under these conditions, the object operates in full precision mode.

In addition, if `Method` is set to either `'Frequency Domain'` or `'Fastest'`, the `RoundingMethod` property does not apply.

`OverflowAction` — Overflow action for fixed-point operations

`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` –– The object wraps the result of its fixed-point operations.
- `'Saturate'` –– The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `OutputDataType` set to `'Same as accumulator'`, `ProductDataType` set to `'Full precision'`, and `AccumulatorDataType` set to `'Full precision'`

Under these conditions, the object operates in full precision mode.

In addition, if `Method` is set to either `'Frequency Domain'` or `'Fastest'`, the `OverflowAction` property does not apply.

`ProductDataType` — Data type of product output

`'Full precision'` (default) | `'Custom'` | `'Same as first input'`

Data type of the product output in this object, specified as one of the following:

- `'Full precision'` –– The product output data type has full precision.
- `'Same as first input'` –– The object specifies the product output data type to be the same as that of the first input data type.
- `'Custom'` –– The product output data type is specified as a custom numeric type through the “CustomProductDataType” on page 4-0 property.

For more information on the product output data type, see “Multiplication Data Types” and the “Fixed Point” on page 4-477 section.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomProductDataType` — Word and fraction lengths of product data type

`numerictype([],32,30)` (default)

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and "ProductDataType" on page 4-0 to `'Custom'`.

`AccumulatorDataType` — Data type of accumulation operation

`'Full precision'` (default) | `'Same as first input'` | `'Same as product'` | `'Custom'`

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` –– The accumulation operation has full precision.
- `'Same as product'` –– The object specifies the accumulator data type to be the same as that of the product output data type.
- `'Same as first input'` –– The object specifies the accumulator data type to be the same as that of the first input data type.
- `'Custom'` –– The accumulator data type is specified as a custom numeric type through the "CustomAccumulatorDataType" on page 4-0 property.

For more information on the accumulator data type this object uses, see the "Fixed Point" on page 4-477 section.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomAccumulatorDataType` — Word and fraction lengths of accumulator data type

`numerictype([],32,30)` (default)

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and "AccumulatorDataType" on page 4-0 to `'Custom'`.

`OutputDataType` — Data type of object output
`'Same as accumulator'` (default) | `'Same as first input'` | `'Same as product'` | `'Custom'`

Data type of the object output, specified as one of the following:

- `'Same as accumulator'` –– The output data type is the same as that of the accumulator output data type.
- `'Same as first input'` –– The output data type is the same as that of the first input data type.
- `'Same as product'` –– The output data type is the same as that of the product output data type.
- `'Custom'` –– The output data type is specified as a custom numeric type through the "CustomOutputDataType" on page 4-0 property.

For more information on the output data type this object uses, see the "Fixed Point" on page 4-477 section.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomOutputDataType` — Word and fraction lengths of output data type
`numerictype([],16,15)` (default)

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and "OutputDataType" on page 4-0 to `'Custom'`.

Usage

Syntax

```
y = xcorr(u,v)
```

Description

`y = xcorr(u,v)` computes the cross-correlation of the two input signals, `u` and `v`.

Input Arguments

u — First data input signal

vector | matrix | *N*-D array

First data input signal, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to `'Time Domain'`. When one or both of the input signals are complex, the output signal is also complex. Both data inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

v — Second data input signal

scalar | column vector | matrix

Second data input signal, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to `'Time Domain'`. When one or both of the input signals are complex, the output signal is also complex. Both data inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Cross-correlated output

vector | matrix | *N*-D array

Cross-correlated output of the two input signals.

When the inputs are *N*-D arrays, the object outputs an *N*-D array. All the dimensions of the output array, except for the first dimension, match the input array. For example:

- When the inputs *u* and *v* have dimensions M_u-by-*N*-by-*P* and M_v-by-*N*-by-*P*, respectively, the object outputs an (M_u + M_v – 1)-by-*N*-by-*P* array.

- When the inputs *u* and *v* have the dimensions M_u-by-*N* and M_v-by-*N*, the object outputs an (M_u + M_v – 1)-by-*N* matrix.

If one input is a column vector and the other input is an *N*-D array, the object computes the cross-correlation of the vector with each column in the *N*-D array. For example:

- When the input *u* is an M_u-by-1 column vector and *v* is an M_v-by-*N* matrix, the object outputs an (M_u + M_v – 1)-by-*N* matrix.
- Similarly, when *u* and *v* are column vectors with lengths M_u and M_v, respectively, the object performs the vector cross-correlation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

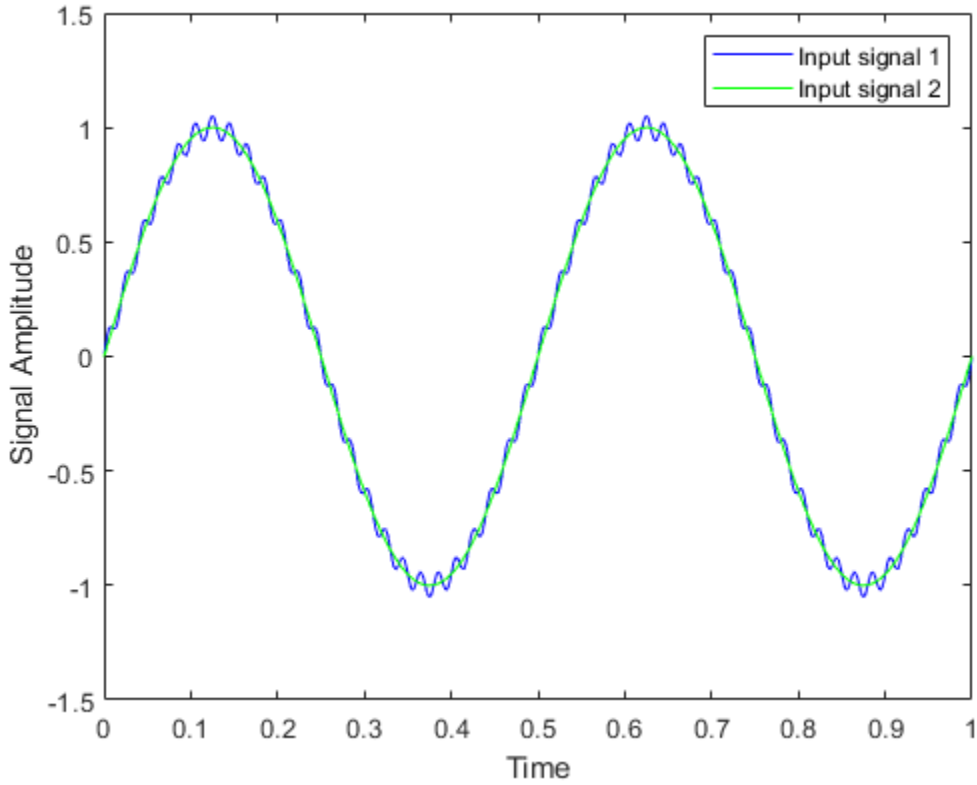
Examples

Compute Correlation Between Two Signals

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

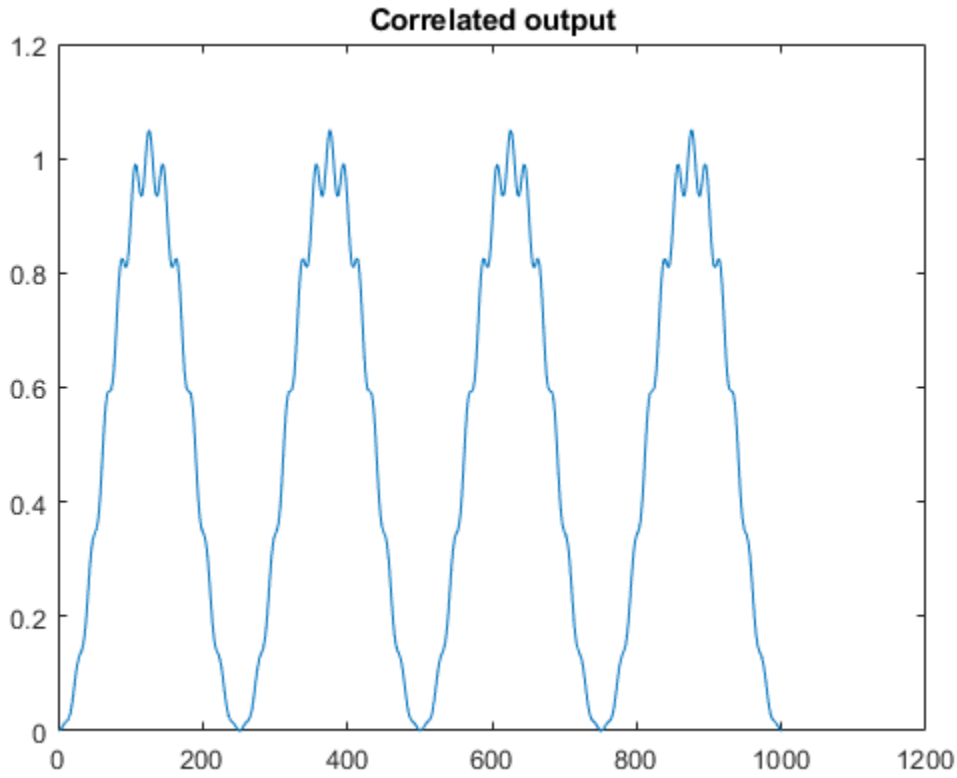
Compute the cross-correlation between two sinusoidal signals using the `dsp.Crosscorrelator` object. Perform the computation in the time domain, which is the object's default setting.

```
xcorr = dsp.Crosscorrelator;
t = 0:0.001:1;
x1 = sin(2*pi*2*t)+0.05*sin(2*pi*50*t);
x2 = sin(2*pi*2*t);
y = xcorr(x1,x2);
figure
plot(t,x1,'b',t,x2,'g')
xlabel('Time')
ylabel('Signal Amplitude')
legend('Input signal 1','Input signal 2')
```



Plot the correlated output.

```
figure,
plot(y)
title('Correlated output')
```



Cross-Correlation of Input Noise and Delayed Version

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

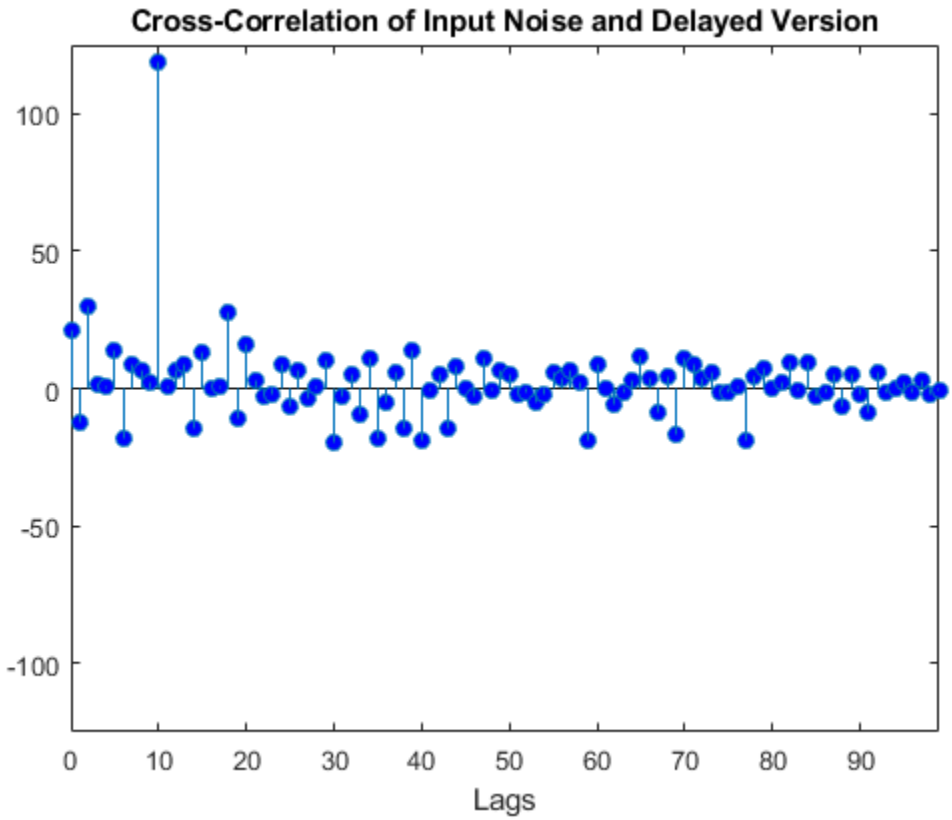
Compute the cross-correlation of a noisy input signal with its delayed version. The peak of the correlation output occurs at the lag, which corresponds to the delay between the signals.

Use `randn` to create the white Gaussian noisy input, `x`. Create a delayed version of this input, `x1`, using the `dsp.Delay` object.

```
S = rng('default');
x = randn(100,1);
delay = dsp.Delay(10);
x1 = delay(x);
```

Compute the cross-correlation between the two inputs. Plot the correlation output with respect to the lag between the inputs.

```
xcorr = dsp.Crosscorrelator;
y = xcorr(x1,x);
lags = 0:99;
stem(lags,y(100:end),'markerfacecolor',[0 0 1])
axis([0 99 -125 125])
xlabel('Lags')
title('Cross-Correlation of Input Noise and Delayed Version')
```



The correlation sequence peaks when the lag is 10, indicating that the correct delay between the two signals is 10 samples.

More About

Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length-N deterministic inputs or realizations of jointly wide-sense stationary (WSS) random processes, x and y, the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \le h \le N-1 \\ r_{yx}^*(h) & -(N-1) \le h \le 0 \end{cases}$$

where h is the lag and * denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where E{ } is the expectation operator.

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the jth column of the output, y_{uv}, has these elements:

$$y_{uv(i,\,j)} = \sum_{k=0}^{\max(M_u, M_v)-1} u_{k,\,j}^* v_{(k+i),\,j} \qquad 0 \le i < M_v$$

$$y_{uv(i,\,j)} = y_{vu(-i,\,j)}^* \qquad -M_u < i < 0$$

where:

- * denotes the complex conjugate.
- u is an M_u-by-N input matrix.

- v is an M_v-by-N input matrix.
- $y_{u,v}$ is an (M_u + M_v – 1)-by-N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The jth column of the output, $y_{u,v}$, has these elements:

$$y_{uv(i,\,j)} = \sum_{k\,=\,0}^{\max(M_u,\,M_v)\,-\,1} u_k^* v_{(k\,+\,i),\,j} \qquad 0 \le i < M_v$$

$$y_{uv(i,\,j)} = y^*_{vu(\,-\,i,\,j)} \qquad -M_u < i < 0$$

where:

- * denotes the complex conjugate.
- u is an M_u-by-1 column vector.
- v is an M_v-by-N matrix.
- y_{uv} is an (M_u + M_v – 1)-by-N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate Two Column Vectors

When the inputs are two column vectors, the jth column of the output, y_{uv}, has these elements:

$$y_{uv(i)} = \sum_{k\,=\,0}^{\max(M_u,\,M_v)\,-\,1} u_k^* v_{(k\,+\,i)} \qquad 0 \le i < M_v$$

$$y_{uv(i)} = y^*_{vu(\,-\,i)} \qquad -M_u < i < 0$$

where:

- * denotes the complex conjugate.
- u is an M_u-by-1 column vector.

- v is an M_v-by-1 column vector.
- y_{uv} is an $(M_u + M_v - 1)$-by-1 column vector.

Inputs u and v are zero when indexed outside their valid ranges.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

1. Takes the Fourier transform of both input signals, U and V.
2. Multiplies U and V^*, where * denotes the complex conjugate.
3. Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

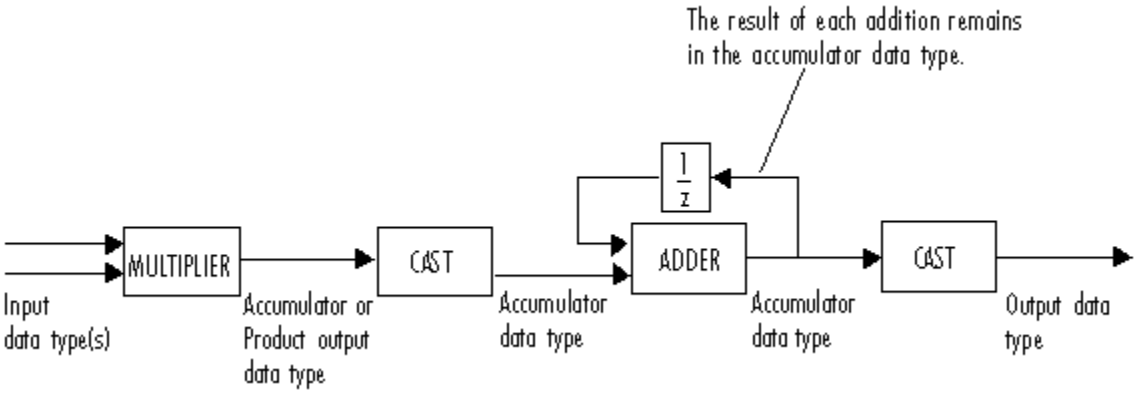
Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The diagram shows the data types the `dsp.Crosscorrelator` object uses for fixed-point signals (time domain only).



You can set the product output, accumulator, and output data types using the corresponding fixed-point properties of the object.

When the input is real, the output of the multiplier is in the product output data type. When the input is complex, the output of the multiplier is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal object data types are unsigned fixed point only when both inputs are unsigned fixed-point signals.

Introduced in R2012a

dsp.CumulativeProduct

Package: `dsp`

Cumulative product of channel, column, or row elements

Description

The `dsp.CumulativeProduct` System object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

1. Create the `dsp.CumulativeProduct` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
cprod = dsp.CumulativeProduct
cprod = dsp.CumulativeProduct(Name,Value)
```

Description

`cprod = dsp.CumulativeProduct` returns a cumulative product object, `cprod`, that computes the cumulative product of input matrix or input vector elements along the default dimension.

`cprod = dsp.CumulativeProduct(Name,Value)` returns a cumulative product object with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Dimension` — Computation dimension for cumulative product
`Channels (running product)` (default) | `Rows` | `Columns`

Specify the computation dimension as `Channels (running product)`, `Rows`, or `Columns`.

`ResetInputPort` — Enable resetting cumulative product through input port
`false` (default) | `true`

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the object algorithm to reset the cumulative product.

Dependencies

You can access this property when the "Dimension" on page 4-0 property is set to `Channels (running product)`.

`ResetCondition` — Reset condition for cumulative product
`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero`

Specify the event on the reset input port that causes resetting the cumulative product to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

Dependencies

This property applies when you set the "ResetInputPort" on page 4-0 property to `true` and the "Dimension" on page 4-0 property to `Channels (running product)`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

`IntermediateProductDataType` — Intermediate product word and fraction lengths
`Same as input` (default) | `Custom`

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`.

`CustomIntermediateProductDataType` — Intermediate product word and fraction lengths
`numerictype([], 16, 15)` (default) | numerictype

Specify the intermediate product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `IntermediateProductDataType` property to `Custom`.

`ProductDataType` — Product output word and fraction lengths
`Same as input` (default) | `Custom`

Specify the product output fixed-point data type as one of | `Same as input` | `Custom` |.

`CustomProductDataType` — Custom product output word and fraction lengths
`numerictype([], 32, 30)` (default) | numerictype

Specify the product output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

`AccumulatorDataType` — Accumulator word and fraction lengths
`Same as input` (default) | `Same as product output` | `Custom`

Specify the accumulator fixed-point data type as `Same as product output`, `Same as input`, or `Custom`.

`CustomAccumulatorDataType` — Custom accumulator word and fraction lengths
`numerictype([], 32, 30)` (default) | numerictype

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

`OutputDataType` — Output word and fraction lengths
`Same as input` (default) | `Same as product output` | `Custom`

Specify the output fixed-point data type as one of | `Same as product output` | `Same as input` | `Custom` |.

`CustomOutputDataType` — Custom output word and fraction lengths
`numerictype([], 16, 15)` (default) | numerictype

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the “OutputDataType” on page 4-0 property to `Custom`.

Usage

Syntax

```
y = cprod(x)
y = cprod(x,r)
```

Description

`y = cprod(x)` computes the cumulative product along the specified dimension for the input `x`.

`y = cprod(x,r)` resets the cumulative product object's state based on the `ResetCondition` property value and the value of the reset signal, `r`, when the `ResetInputPort` property is `true`.

Input Arguments

`x` — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

`r` — Reset signal

scalar

Reset signal used to reset the running cumulative product, specified as a scalar. The object resets the running cumulative product if the reset signal satisfies the `ResetCondition`.

Dependencies

This input is applicable only when `Dimension` is set to `'Channels (running product)'` and `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical` | `fi`

Output Arguments

y — Cumulative product

vector | matrix

Cumulative product of the input signal, returned as a vector or a matrix.

The size, data type, and complexity characteristics of the output signal match that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Cumulative Product of Matrix

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use the `dsp.CumulativeProduct` object to compute the cumulative product of a matrix.

```
cprod = dsp.CumulativeProduct;
x = magic(2)
```

```
x = 2×2

     1     3
     4     2

 y = cprod(x)

y = 2×2

     1     3
     4     6
```

The cumulative product is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except the **Reset port** block parameter corresponds to both the `ResetCondition` and `ResetInputPort` object properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

System Objects
`dsp.CumulativeSum`

Introduced in R2012a

dsp.CumulativeSum

Package: `dsp`

Cumulative sum of channel, column, or row elements

Description

The `dsp.CumulativeSum` System object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

1. Create the `dsp.CumulativeSum` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
csum = dsp.CumulativeSum
csum = dsp.CumulativeSum(Name,Value)
```

Description

`csum = dsp.CumulativeSum` returns a cumulative sum System object, `csum`, which computes the running cumulative sum for each channel in the input.

`csum = dsp.CumulativeSum(Name,Value)` returns a cumulative sum object, `csum`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Dimension` — Computation dimension for cumulative sum
`Channels (running sum)` (default) | `Rows` | `Columns`

Specify the computation dimension as `Channels (running sum)`, `Rows`, or `Columns`.

`ResetInputPort` — Enable resetting cumulative sum through input port
`false` (default) | `true`

Set this property to `true` to enable resetting the cumulative sum. When you set this property to `true`, you also specify a reset input to the object algorithm to reset the cumulative sum.

`ResetCondition` — Reset condition for cumulative sum
`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero`

Specify the event on the reset input port that resets the cumulative sum as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

Dependencies

This property applies when you set the “ResetInputPort” on page 4-0 property to `true`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

`AccumulatorDataType` — Accumulator word and fraction lengths
`Same as input` (default) | `Custom`

Specify the accumulator fixed-point data type as `Same as input` or `Custom`.

`CustomAccumulatorDataType` — Custom accumulator word and fraction lengths
`numerictype([], 32, 30)` (default) | numerictype

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

`OutputDataType` — Output word and fraction lengths
`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the output fixed-point data type as `Same as accumulator`, `Same as input`, or `Custom`.

`CustomOutputDataType` — Custom output word and fraction lengths
`numerictype([], 16, 15)` (default) | numerictype

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the "OutputDataType" on page 4-0 property to `Custom`.

Usage

Syntax

```
y = csum(x)
y = csum(x,r)
```

Description

`y = csum(x)` computes the cumulative sum along the specified dimension for the input `x`.

`y = csum(x,r)` resets the System object state based on the `ResetCondition` property value and the value of the reset signal, `r`. You can only reset the state if the `ResetInputPort` property is `true`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

r — Reset signal

scalar

Reset signal used to reset the running cumulative sum, specified as a scalar. The object resets the running cumulative sum if the reset signal satisfies the `ResetCondition`.

Dependencies

This input is applicable only when `Dimension` is set to `'Channels (running sum)'` and `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical` | `fi`

Output Arguments

y — Cumulative sum

vector | matrix

Cumulative sum of the input signal, returned as a vector or a matrix.

The size, data type, and complexity characteristics of the output signal match that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Cumulative Sum of Matrix

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use the `dsp.CumulativeSum` object to compute the cumulative sum of a matrix.

```
csum = dsp.CumulativeSum;
x = magic(2)
```

```
x = 2×2

     1     3
     4     2

 y = csum(x)

y = 2×2

     1     3
     5     5
```

The cumulative sum is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Sum block reference page. The object properties correspond to the block properties, except the **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

Extended Capabilities

System Objects
`dsp.CumulativeProduct`

Introduced in R2012a

dsp.DCBlocker

Package: `dsp`

Block DC component (offset) from input signal

Description

The `dsp.DCBlocker` System object removes the DC offset from each channel (column) of the input signal. The operation runs over time to continually estimate and remove the DC offset.

To block the DC component of the input signal:

1. Create the `dsp.DCBlocker` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
dcblker = dsp.DCBlocker
dcblker = dsp.DCBlocker(Name,Value)
```

Description

`dcblker = dsp.DCBlocker` creates a DC blocker System object, `dcblker`, to block the DC component from each channel (column) of the input signal.

`dcblker = dsp.DCBlocker(Name,Value)` creates a DC blocker System object, `dcblker`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: dcblker = dsp.DCBlocker('Algorithm','FIR')

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Algorithm` — Algorithm for estimating DC offset

`'IIR'` (default) | `'FIR'` | `'CIC'` | `'Subtract mean'`

Algorithm for estimating DC offset, specified as one of the following:

- `'IIR'` –– The object uses a recursive estimate based on a narrow, lowpass elliptic filter. The "Order" on page 4-0 property sets the order of the filter, and the "NormalizedBandwidth" on page 4-0 property sets its bandwidth. This algorithm typically uses less memory than the FIR algorithm and is more efficient.
- `'FIR'` –– The object uses a nonrecursive, moving average estimate based on a finite number of past input samples. The "Length" on page 4-0 property sets the number of samples. The FIR filter has a linear phase response and does not cause any phase distortion to the signal. The IIR filter requires less memory and is more efficient to implement.
- `'CIC'` –– The object uses a CIC decimator, with a decimation factor of 1, whose differential delay is calculated using the NormalizedBandwidth property. It uses two sections to ensure that the first sidelobe attenuation is at least 25 dB below the main lobe of the filter. This algorithm requires fixed-point inputs and can be used for HDL code generation.
- `'Subtract mean'` –– The object computes the means of the columns of the input matrix, and subtracts the means from the input. This method does not retain state between inputs.

You can visualize the IIR, FIR, and CIC responses by using the `fvtool` function.

`NormalizedBandwidth` — Normalized bandwidth of lowpass IIR or CIC filter

`0.001` (default) | real scalar greater than 0 and less than 1

Normalized bandwidth of the IIR or CIC filter, specified as a real scalar greater than 0 or less than 1. The normalized bandwidth is used to estimate the DC component of the input signal.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to `'IIR'` or `'CIC'`.

`Order` — Order of lowpass IIR elliptic filter

`6` (default) | integer greater than 3

Order of the lowpass IIR elliptic filter that is used to estimate the DC level, specified as an integer greater than 3.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to `'IIR'`.

`Length` — Number of past input samples used in FIR algorithm

`50` (default) | positive integer

Number of past input samples used in the FIR algorithm to estimate the running mean, specified as a positive integer.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to `'FIR'`.

Usage

Syntax

```
dcblkerOut = dcblker(input)
```

Description

`dcblkerOut = dcblker(input)` removes the DC component from each channel (column) of the input and returns the output.

Input Arguments

`input` — Input signal

vector | matrix | *N*-D array

Data input to the DC blocker object, specified as a vector, matrix, or *N*-D array.

Example: t = (0:0.001:100)'; x = sin(30*pi*t) + 1;

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

Output Arguments

`dcblkerOut` — Signal with DC component removed

vector | matrix | *N*-D array

Signal with DC component removed, returned as a vector, matrix, or *N*-D array.The output dimensions match the input dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Remove DC Component and Display Results

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Remove the DC component of an input signal using the IIR, FIR, and subtract mean estimation algorithms.

Create a signal composed of a 15 Hz tone, a 25 Hz tone, and a DC offset.

```
t = (0:0.001:100)';
x = sin(30*pi*t) + 0.33*cos(50*pi*t) + 1;
```

Create three DC blocker objects for the three estimation algorithms.

```
dc1 = dsp.DCBlocker('Algorithm','IIR','Order', 6);
dc2 = dsp.DCBlocker('Algorithm','FIR','Length', 100);
dc3 = dsp.DCBlocker('Algorithm','Subtract mean');
```

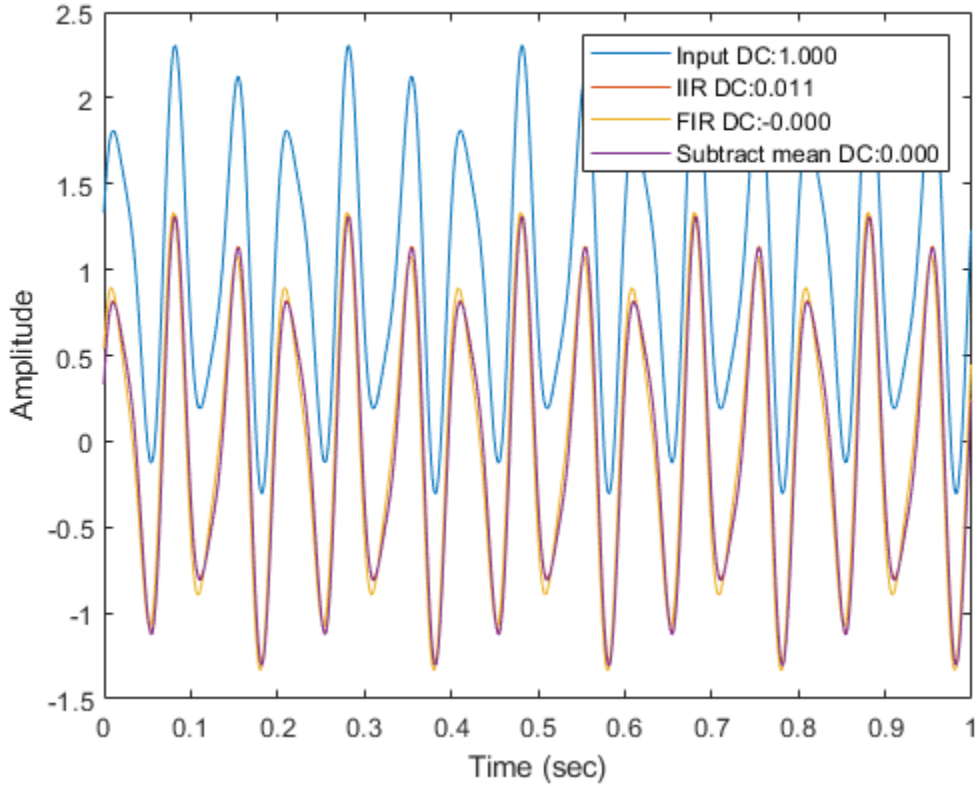
For each second of time, pass the input signal through the DC blockers. By implementing the DC blockers in 1-second increments, you can observe differences in the convergence times.

```
for idx = 1 : 100
    range = (1:1000) + 1000*(idx-1);
    y1 = dc1(x(range));          % IIR estimate
    y2 = dc2(x(range));          % FIR estimate
    y3 = dc3(x(range));          % Subtract mean
end
```

Plot the input and output data for the three DC blockers for the first second of time, and show the mean value for each signal. The mean values for the three algorithm types show that the `FIR` and `Subtract mean` algorithms converge more quickly.

```
plot(t(1:1000),x(1:1000), ...
    t(1:1000),y1, ...
```

```
    t(1:1000),y2, ...
    t(1:1000),y3);
xlabel('Time (sec)')
ylabel('Amplitude')
legend(sprintf('Input DC:%.3f',mean(x)), ...
    sprintf('IIR DC:%.3f',mean(y1)), ...
    sprintf('FIR DC:%.3f',mean(y2)), ...
    sprintf('Subtract mean DC:%.3f',mean(y3)));
```



Frequency Response Before and After DC Blocker

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Compare the spectrum of an input signal with a DC offset to the spectrum of the same signal after applying a DC blocker. Enable the DC blocker to use the `FIR` estimation algorithm.

Create an input signal composed of three tones and that has a DC offset of 1. Set the sampling frequency to 1 kHz and set the signal duration to 100 seconds.

```
fs = 1000;
t = (0:1/fs:100)';
x = sin(30*pi*t) + 0.67*sin(40*pi*t) + 0.33*sin(50*pi*t) + 1;
```

Create a DC blocker object that uses the FIR algorithm to estimate the DC offset.

```
dcblker = dsp.DCBlocker('Algorithm','FIR','Length',100);
```

Create a spectrum analyzer with power units set to `dBW` and a frequency range of `[-30 30]` to display the frequency response of the input signal. Using the `clone` function, create a second spectrum analyzer to display the response of the output. Then, use the `Title` property of the spectrum analyzers to label them.

```
hsa = dsp.SpectrumAnalyzer('SampleRate',fs, ...
    'PowerUnits','dBW','FrequencySpan','Start and stop frequencies',...
    'StartFrequency',-30,'StopFrequency',30,'YLimits',[-200 20],...
    'Title','Signal Spectrum');

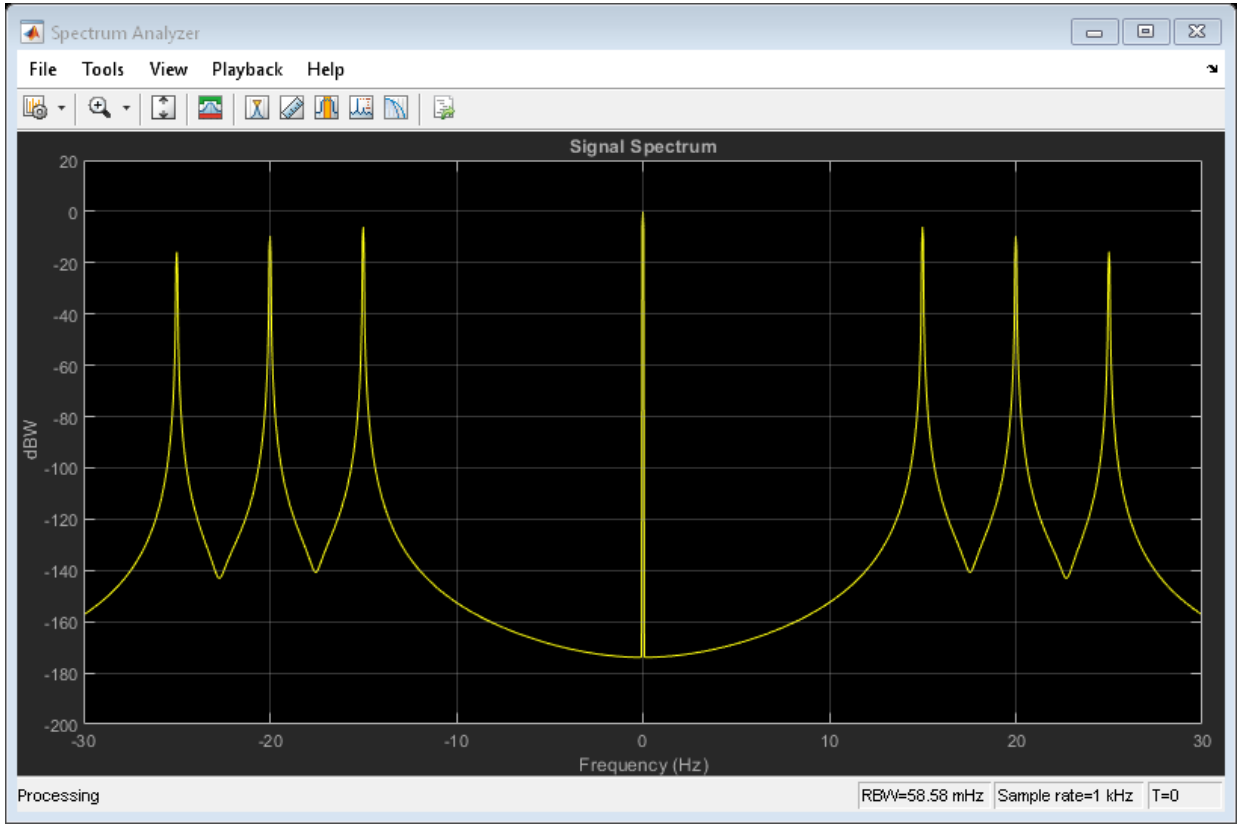
hsb = clone(hsa);
hsb.Title = 'Signal Spectrum After DC Blocker';
```

Pass the input signal, `x`, through the DC blocker to generate the output signal, `y`.

```
y = dcblker(x);
```

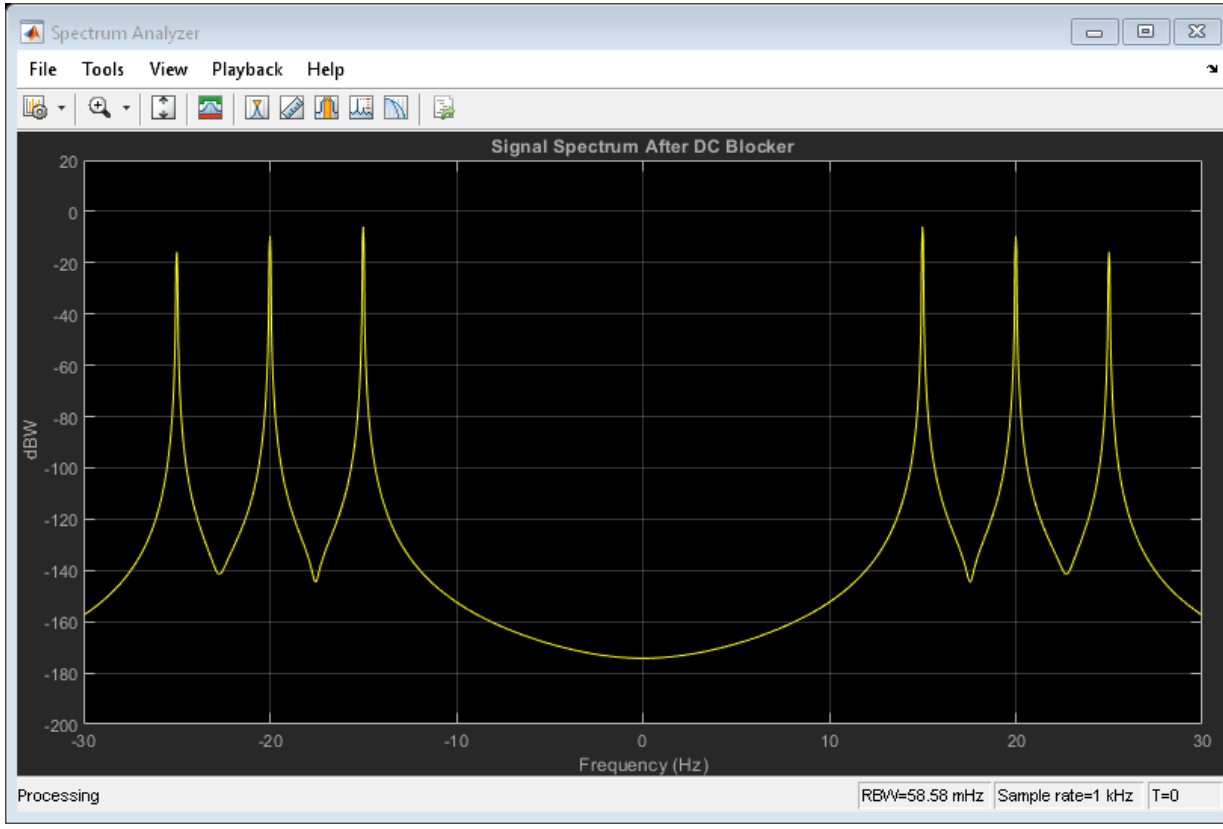
Use the first spectrum analyzer to display the frequency characteristics of the input signal. The tones at 15, 20, and 25 Hz, and the DC component, are clearly visible.

```
hsa(x)
```



Use the second spectrum analyzer to display the frequency characteristics of the output signal. The DC component has been removed.

```
hsb(y)
```



Remove DC Offset from Fixed-Point Data

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Remove a DC offset from a fixed-point signal by using a DC blocker. The DC blocker uses the CIC lowpass filtering method to estimate the DC offset.

Generate random binary data.

```
data = randi([0 1],1.2e5,1);
```

Create a 64-QAM modulator System object and modulate the data by running its algorithm.

```
mod = comm.RectangularQAMModulator('ModulationOrder',64, ...
                                   'BitInput',true);
modOut = mod(data);
```

Determine the constellation reference points for the modulator.

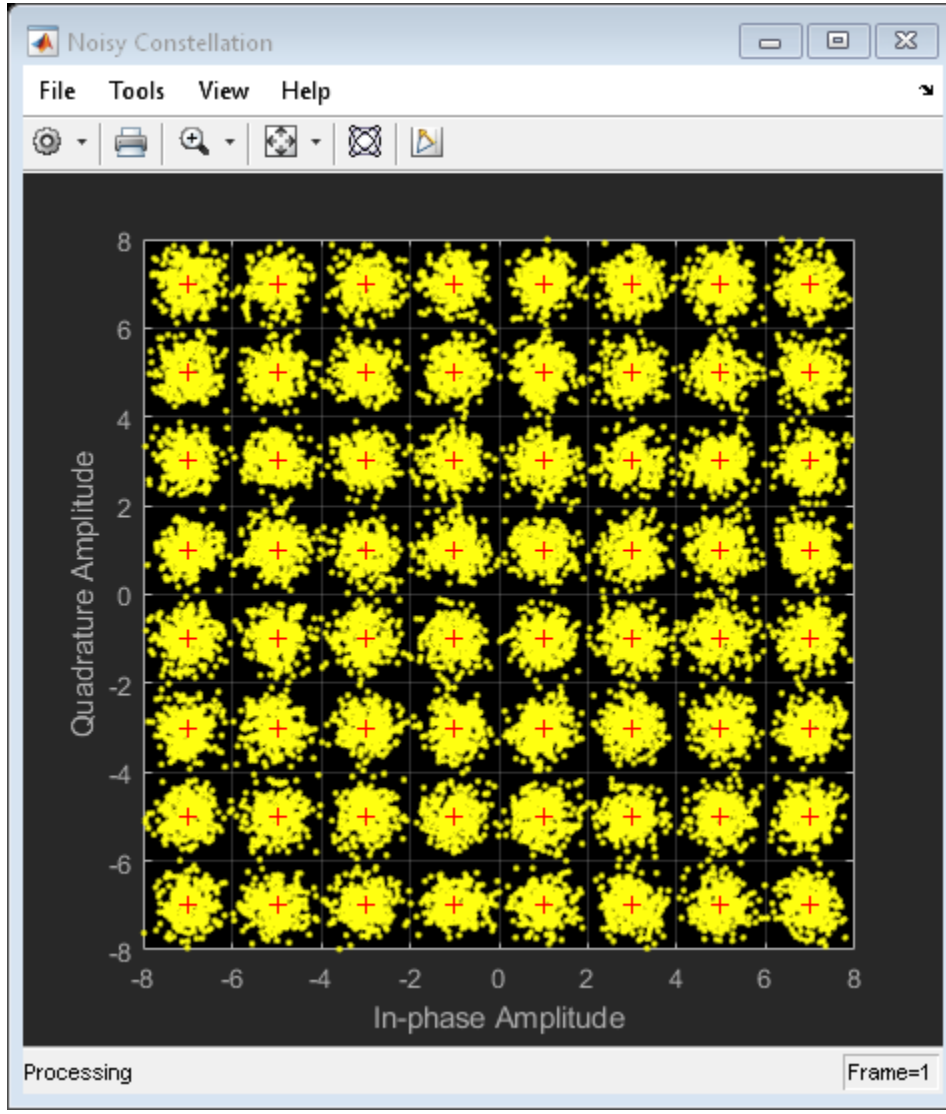
```
cRefPts = constellation(mod);
```

Add AWGN to the modulated signal by using the appropriate System object and running its algorithm.

```
noise = comm.AWGNChannel('EbNo', 14.75, ...
                         'BitsPerSymbol', 6, ...
                         'SignalPower', 42, ...
                         'SamplesPerSymbol', 1);
noisyOut = noise(modOut);
```

Display the scatter plot of the noisy signal by using a constellation diagram object. The red plus markers show the ideal symbol locations.

```
constDiag = comm.ConstellationDiagram('Name','Noisy Constellation',...
    'ReferenceConstellation',cRefPts, ...
    'XLimits',[-8 8],'YLimits',[-8 8]);
constDiag(noisyOut)
```

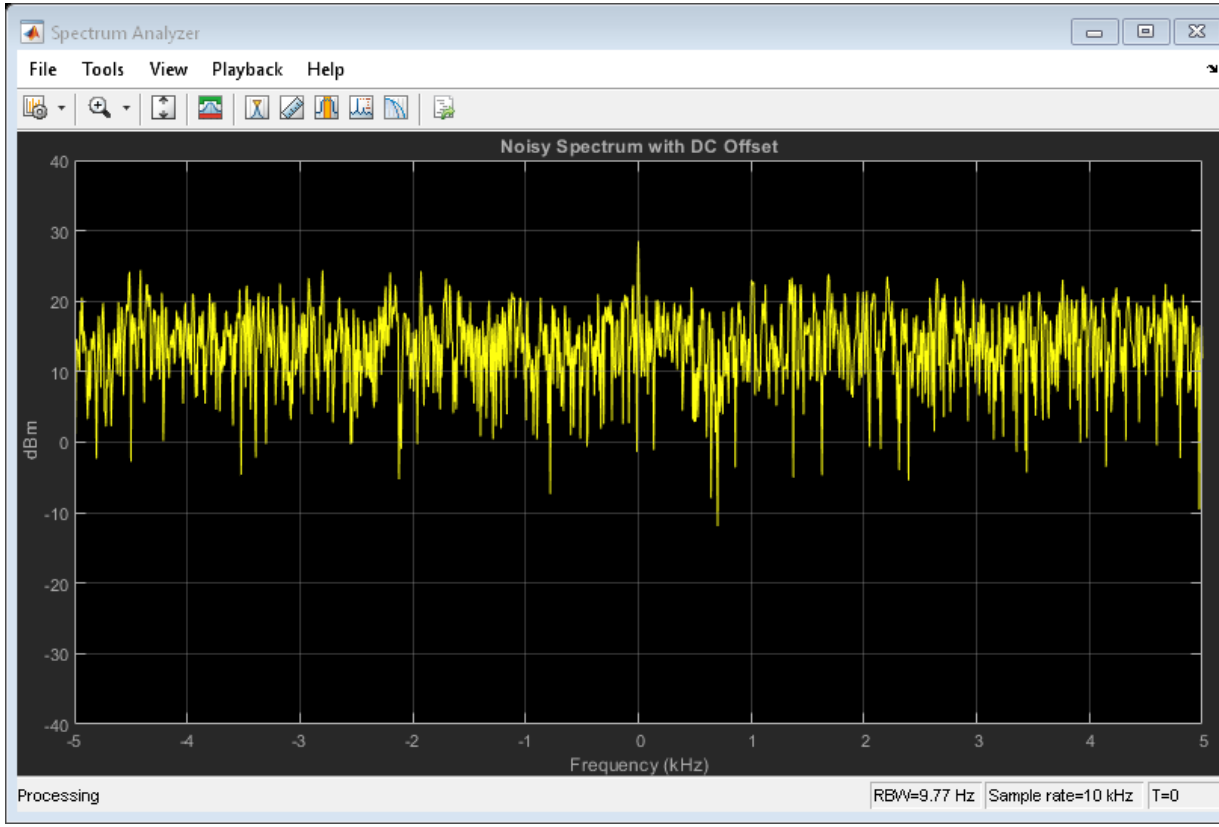


Add a DC offset of 1 to the modulated signal.

```
noisyOut = noisyOut + 1;
```

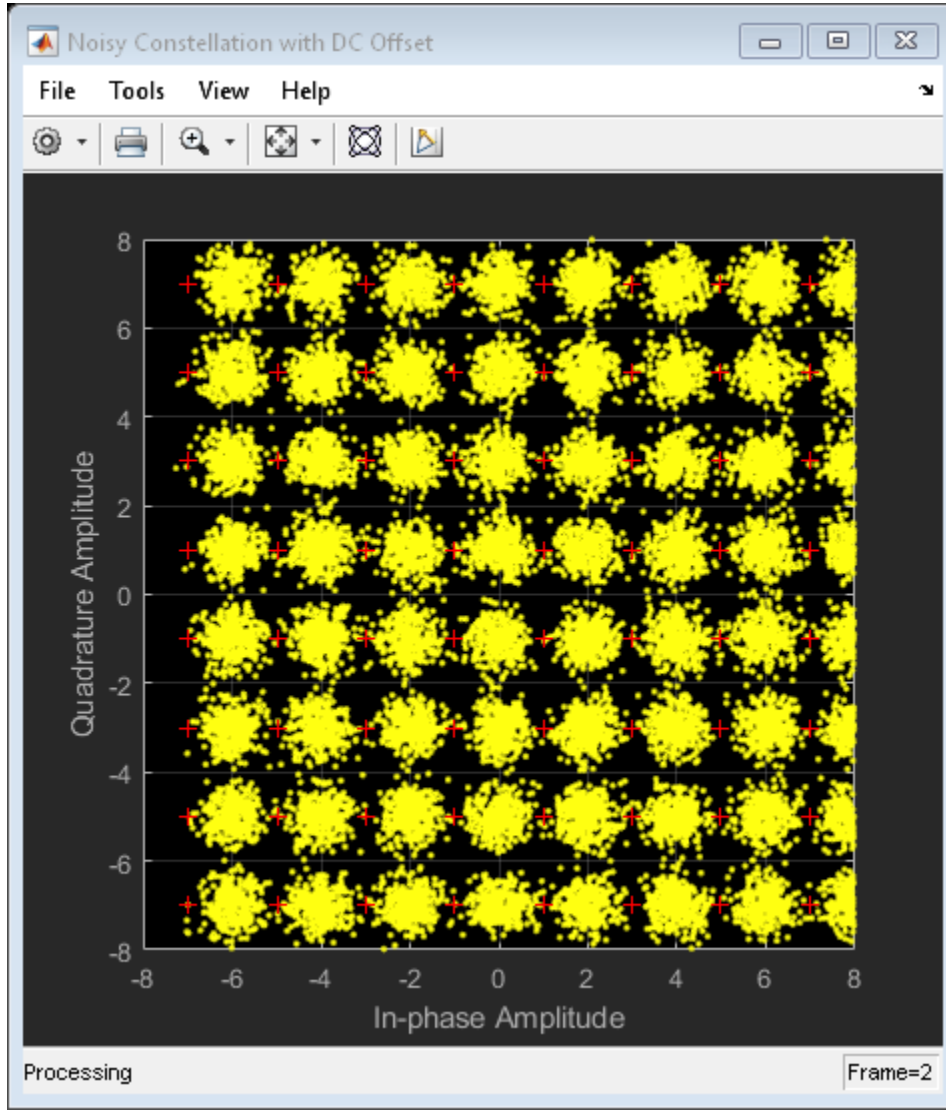
Display the spectrum of the signal. The spike at 0 kHz is due to the introduced offset.

```
specAna = dsp.SpectrumAnalyzer(...
  'YLimits',[-40,40], ...
  'Title','Noisy Spectrum with DC Offset');
specAna(noisyOut);
```



View the effect of the DC offset on the constellation. The constellation has shifted one unit to the right.

```
constDiag(noisyOut)
constDiag.Name = 'Noisy Constellation with DC Offset';
```



Convert the noisy signal to a signed, fixed-point object that has a 16-bit word length and an 11-bit fraction length.

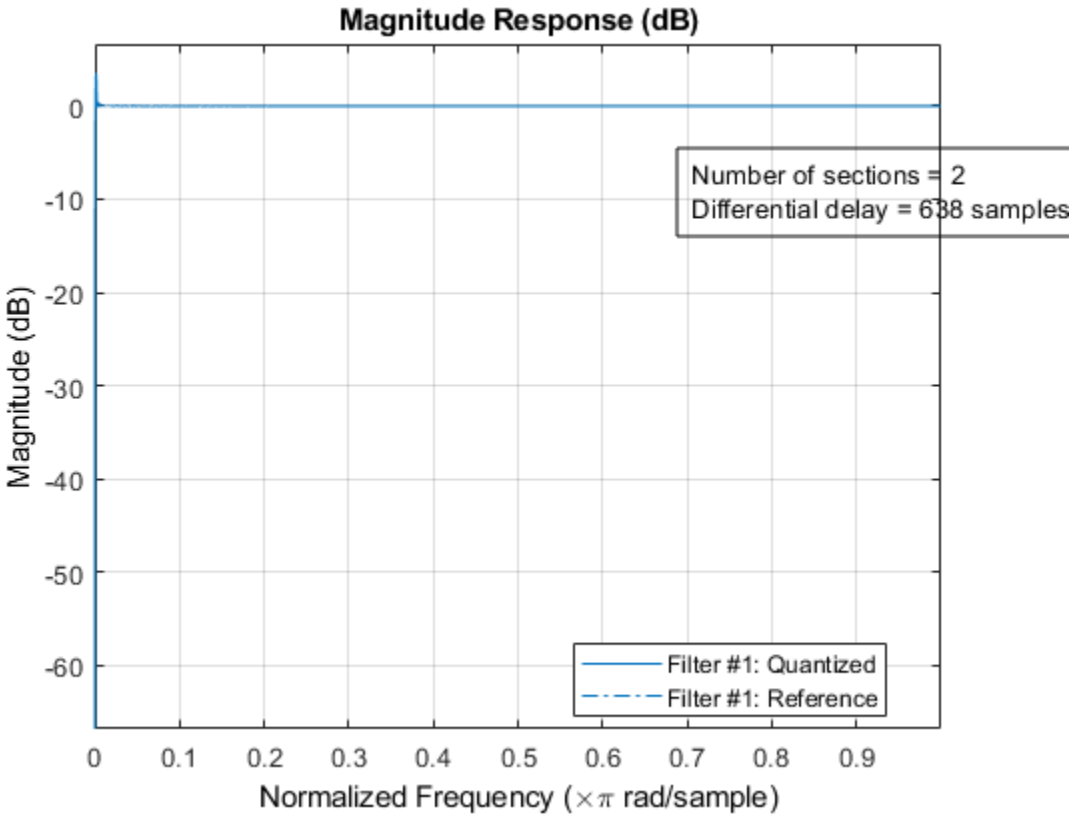
```
noisyOut = fi(noisyOut,1,16,11);
```

Remove the offset by creating a DC blocker object. The object uses the CIC algorithm to estimate the DC offset.

```
dcblker = dsp.DCBlocker('Algorithm','CIC');
```

Visualize the frequency response of the CIC estimating filter.

```
fvtool(dcblker)
```

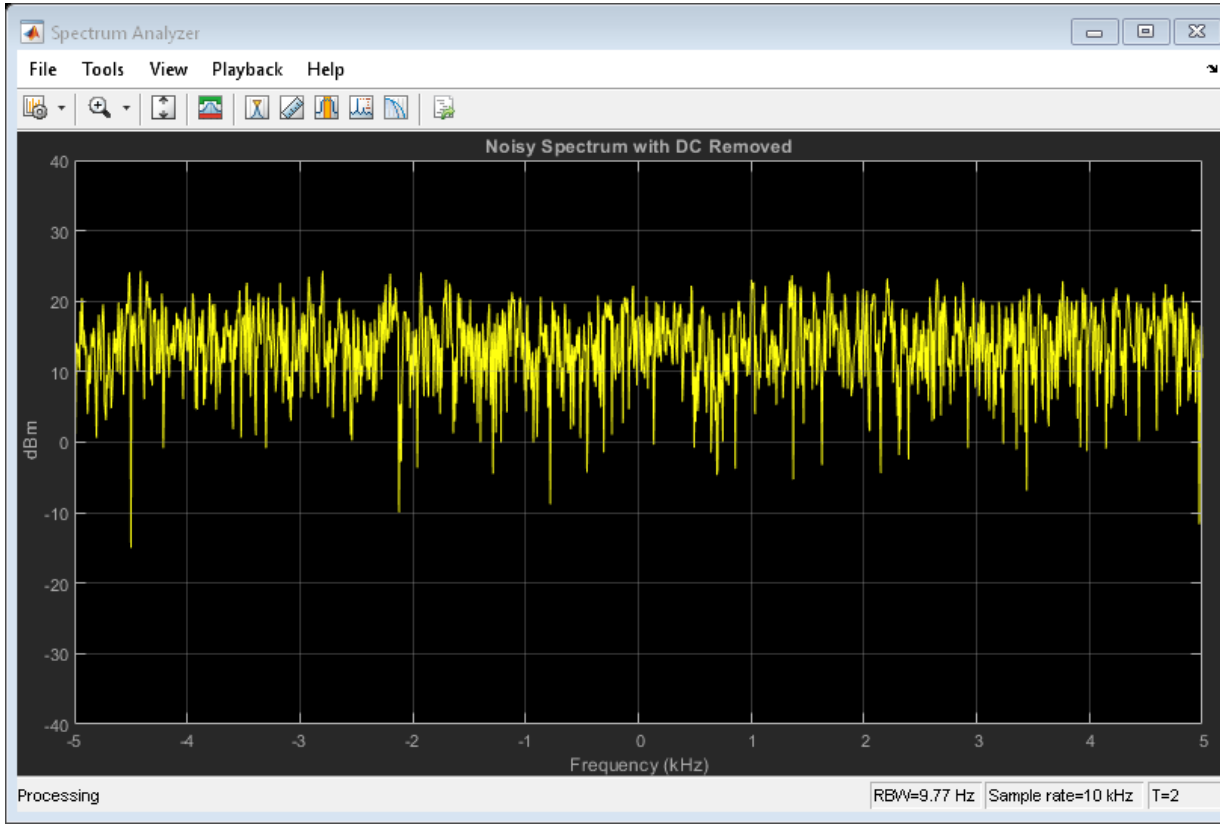


Pass the offset, noisy signal through the DC blocker and convert its output to a double.

```
dcBlockerOutFxP = dcblker(noisyOut);
dcBlockerOut = double(dcBlockerOutFxP);
```

Plot the signal spectrum to show the effect of removing the DC offset. The spike at 0 kHz has been removed.

```
specAna(dcBlockerOut);
specAna.Title = 'Noisy Spectrum with DC Removed';
```



Plot the constellation and verify that the signal shifted back to the left.

```
constDiag(dcBlockerOut)
constDiag.Name = 'Noisy Constellation with DC Removed';
```

To see the effects of removing a DC offset, vary the value of the `NormalizedBandwidth` property in the DC blocker object.

Algorithms

The DC blocker subtracts the DC component from the input signal. You can estimate the DC component by using the IIR, FIR, CIC, or subtract mean algorithm.

IIR

Pass the input signal through an IIR lowpass elliptical filter.

The elliptical IIR filter has a passband ripple of 0.1 dB and a stopband attenuation of 60 dB. You specify the normalized bandwidth and the filter order.

FIR

Pass the input signal through an FIR filter that uses a nonrecursive moving average from a finite number of past input samples.

The FIR filter coefficients are given as `ones(1,Length)/Length`, where you specify the `Length`. The FIR filter structure is a direct form I transposed structure.

CIC

Pass the input signal through a CIC filter. Because the CIC filter amplifies the signal, the filter gain is estimated and subtracted from the DC estimate.

The Cascaded Integrator-Comb (CIC) filter consists of two integrator-comb pairs. These pairs help to ensure that the peak of the first sidelobe of the filter response is attenuated by at least 25 dB relative to the peak of the main lobe. The normalized 3-dB bandwidth is used to calculate the differential delay. The delay is used to determine the gain of the CIC filter. The inverse of the filter gain is used as a multiplier, which is applied to the output of the CIC filter. This ensures that the aggregate gain of the DC estimate is 0 dB.

The following equation characterizes the aggregate magnitude response of the filter and the multiplier:

$$\left|H(e^{j\omega})\right| = \left|\frac{\sin(M\frac{\pi}{2}B_{norm})}{M\sin(\frac{\pi}{2}B_{norm})}\right|^N$$

- B_{norm} is the normalized bandwidth such that $0 < B_{norm} < 1$.
- M is the differential delay in samples.
- N is the number of sections, equal to 2.

Set the differential delay, M, to the smallest integer such that $|H(e^{j\omega})| < 1/\sqrt{2}$. Once M is known, the gain of the CIC filter is calculated as M^N. Therefore, to precisely compensate for the filter gain, the multiplier is set to $(1/M)^N$.

Subtract Mean

Compute the mean value of each column of the input signal and subtract the mean from the input. For example, if the input is [1 2 3 4; 3 4 5 6], then a DC Blocker set to this mode outputs [-1 -1 -1 -1; 1 1 1 1].

Introduced in R2014a

dsp.DCT

Package: `dsp`

(To be removed) Discrete cosine transform (DCT)

Note The `dsp.DCT` System object™ will be removed in a future release. Use `dct` instead. For more information, see “Compatibility Considerations”.

Description

The `DCT` object computes the discrete cosine transform (DCT) of input.

To compute the DCT of input:

1. Define and set up your DCT object. See “Construction” on page 4-513.
2. Call `step` to compute the DCT according to the properties of `dsp.DCT`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dct = dsp.DCT` returns a discrete cosine transform (DCT) object, `dct`, used to compute the DCT of a real or complex input signal.

`dct = dsp.DCT('PropertyName',PropertyValue, ...)` returns a DCT object, `dct`, with each property set to the specified value.

Properties

SineComputation

Method to compute sines and cosines

Specify how the DCT object computes the trigonometric values as `Trigonometric function` or `Table lookup`. This property must be set to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` property to `Table lookup`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

`ProductDataType`

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision` , `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision` , `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the “OutputDataType” on page 4-0 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step Discrete cosine transform (DCT) of input

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Analyze the Energy Content in a Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
dct = dsp.DCT;
X = dct(x);
```

Set the DCT coefficients which represent less than 0.1% of the total energy to 0 and reconstruct the sequence using IDCT.

```
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end
```

```
disp(['Number of DCT coefficients that represent 99.9%',...
    'of the total energy in the sequence: ',num2str(ii)]);
```

```
Number of DCT coefficients that represent 99.9%of the total energy in the sequence: 10
```

```
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
idct = dsp.IDCT;
xt = idct(XXt);
plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
    'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DCT block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`dsp.DCT` System object will be removed

Warns starting in R2019a

The `dsp.DCT` System object will be removed in a future release. Use `dct` instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

If your code has this form (R2016b or later):	If your code has this form (prior to R2016b):	Use this code instead:

`x = (1:128).' + 50*cos((1:128)*pi/40) + 50*cos((1:128).'*2*p`
`dctObj = dsp.DCT;`
`X = dctObj(x);`
	`x = (1:128).' + 50*cos((1:128)*pi/40) + 50*cos((1:128).'*2*p`
	`dctObj = dsp.DCT;`
	`X = step(dctObj,x);`
		`x = (1:128).' + 50*cos((1:128)*pi/40) + 50*cos((1:128).'*2*p`
		`X = dct(x);`

Extended Capabilities

Functions
`dct`

System Objects
`dsp.FFT` | `dsp.IFFT`

Introduced in R2012a

step

System object: `dsp.DCT`
Package: `dsp`

Discrete cosine transform (DCT) of input

Syntax

```
Y = step(dct,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dct,X)` computes the `DCT` of the input `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Delay

Package: dsp

Delay input signal by fixed samples

Description

Note The Units property no longer supports the 'Frames' option. Use 'Samples' instead. The InitialConditions property no longer supports a cell array format. Use a Length-by-numChans matrix instead, where numChans is the number of input channels. For more details, see "Compatibility Considerations" on page 4-529.

The dsp.Delay System object delays the input by a specified number of samples along each channel (column) of the input. You can specify the initial output of the object through the "InitialConditions" on page 4-0 property. To reset the delay, enable the "ResetCondition" on page 4-0 through the "ResetInputPort" on page 4-0 .

To delay the input:

1. Create the dsp.Delay object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
delay = dsp.Delay
delay = dsp.Delay(Name,Value)
delay = dsp.Delay(len,Name,Value)
```

Description

`delay = dsp.Delay` creates a System object that delays the input by 1 sample.

`delay = dsp.Delay(Name,Value)` creates a delay System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `delay = dsp.Delay('InitialConditionsPerChannel',true);`

`delay = dsp.Delay(len,Name,Value)` creates a delay System object, `delay`, with the `Length` property set to `len`, and other specified properties set to the specified values. Enclose each property name in single quotes.

Example: `delay = dsp.Delay(10,'ResetInputPort',true,'ResetCondition','Rising edge');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Units` — Units of delay

`'Samples'`

Units of delay, specified as `'Samples'`.

`Length` — Amount of delay to apply to input signal

1 (default) | scalar positive integer | vector of positive integers

Amount of delay in samples to apply to the input signal, specified as one of the following:

- Scalar positive integer –– The object applies equal delay to all the channels.
- Vector of positive integers –– The length of the vector must equal the number of input channels (columns). The object delays each channel by the amount specified by the respective element in the delay vector.

`InitialConditionsPerChannel` — Enable different initial conditions per channel
`false` (default) | `true`

Enable different initial conditions per channel, specified as either:

- `false` -– The object applies the same initial conditions for all channels.
- `true` -– The object applies different initial conditions for each channel.

The value of this property must be the same as the value you choose for the `InitialConditionsPerSample` property. This value determines the size of the initial conditions array. For more details, see the "InitialConditions" on page 4-0 property.

`InitialConditionsPerSample` — Enables different initial conditions per sample
`false` (default) | `true`

Different initial conditions per sample, specified as either:

- `false` -– The object applies the same initial conditions for all samples.
- `true` -– The object applies different initial conditions for each sample.

The value of this property must be the same as the value you choose for the `InitialConditionsPerChannel` property. This value determines the size of the initial conditions array. For more details, see the "InitialConditions" on page 4-0 property.

`InitialConditions` — Initial output of the object
`0` (default) | `scalar` | `vector` | `matrix`

Initial output of System object, specified as a scalar, vector, or a matrix. The dimensions of the initial condition matrix must be (`Length` property value)-by-(number of input channels).

If the input is an *M*-by-*N* matrix, the dimensions of the `InitialConditions` property value must be as follows:

`InputConditionsPerChannel`	`InputConditionsPerSample`	`InitialConditions`
`false`	`false`	scalar
`true`	`true`	`Length`-by-*N* matrix

`ResetInputPort` — Enable reset condition
`false` (default) | `true`

Enable the reset condition so that you can pass the reset control input to the object, specified as either:

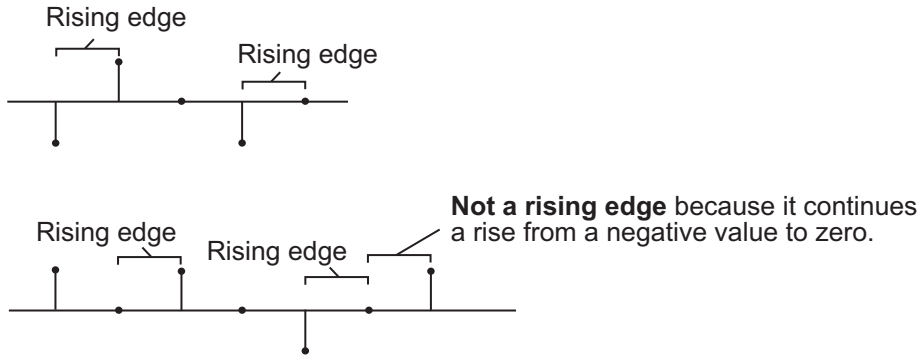
- `false` -- The object does not reset the delay states.
- `true` -- You must pass a reset control input to the object by using the "ResetCondition" on page 4-0 property. The object resets the delay states based on the values of the `ResetCondition` property and the reset control that is input to the object.

`ResetCondition` — Event that triggers reset of delay

`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

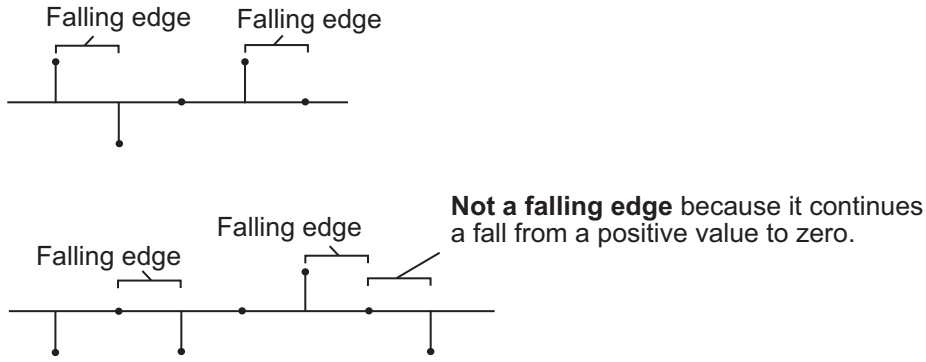
Event that triggers the reset of the delay, specified as one of the following. The object resets the delay whenever a reset event is detected in its reset input.

- `'Non-zero'` -- Triggers a reset operation at each sample, when the reset input is not zero.
- `'Rising edge'` -- Triggers a reset operation when the reset input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `'Falling edge'` -- Triggers a reset operation when the reset input does one of the following:
  - Falls from a positive value to a negative value or zero.

- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.



- `'Either edge'` –– Triggers a reset operation when the reset input is a rising edge or a falling edge.

Dependencies

This property applies only when you set the `ResetInputPort` property to `true`.

Usage

Syntax

```
delayOut = delay(dataInput)
delayOut = delay(dataInput,resetInput)
```

Description

`delayOut = delay(dataInput)` adds delay to the data input and returns the delayed output. Each column of the input is treated as an independent channel.

`delayOut = delay(dataInput,resetInput)` adds delay to the data input and selectively resets the state of the System object based on the value of the reset input and the value of the “ResetCondition” on page 4-0 property.

To pass the reset input, set “ResetInputPort” on page 4-0 property to `true`.

```
delay = dsp.Delay('ResetInputPort',true);
...
delayOut = delay(dataInput,resetInput);
```

Input Arguments

`dataInput` — Data input

vector | matrix

Data input that is delayed by the object, specified as a vector or a matrix.

Example: [1;2;3;4;5]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

`resetInput` — Reset input

scalar

Reset input, specified as a scalar.

Example: 2

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

`delayOut` — Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The size and data type of the output match the size and data type of the data input.

Example: [0;0;1;2;3]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Delay Input

Delay input by five samples by using the `dsp.Delay` System object™. By default, the initial conditions are 0.

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Delay input by 4 samples.

```
delay = dsp.Delay(4);
input = [(1:10)' (11:20)'];
delayOut = delay(input) %#ok
```

```
delayOut = 10×2

     0     0
     0     0
     0     0
     0     0
     1    11
     2    12
     3    13
     4    14
     5    15
     6    16
```

```
release(delay);
```

Specify initial conditions for each channel and for each sample. The `InitialConditions` property must be a (*Length*)-by-(*NumChannels*) matrix.

```
delay.InitialConditionsPerChannel = true;
delay.InitialConditionsPerSample = true;
delay.InitialConditions = [(0.1:0.1:0.4)' (0.5:0.1:0.8)'];
delayOut = delay(input) %#ok
```

```
delayOut = 10×2

    0.1000    0.5000
    0.2000    0.6000
    0.3000    0.7000
    0.4000    0.8000
    1.0000   11.0000
    2.0000   12.0000
    3.0000   13.0000
    4.0000   14.0000
    5.0000   15.0000
    6.0000   16.0000
```

```
release(delay);
```

Reset the delay by setting the reset event to `'Rising edge'`. In this mode, a reset event occurs when the reset input:

- Rises from a negative value to 0.
- Rises from a negative value to a positive value.
- Rises form 0 to a positive value, where the rise is not a continuation from a negative value to 0.

Pass an initial reset input of 0.

```
delay.ResetInputPort = true;
delay.ResetCondition = 'Rising edge';
delayOut = delay(input,0) %#ok
```

```
delayOut = 10×2

    0.1000    0.5000
    0.2000    0.6000
    0.3000    0.7000
    0.4000    0.8000
```

```
    1.0000   11.0000
    2.0000   12.0000
    3.0000   13.0000
    4.0000   14.0000
    5.0000   15.0000
    6.0000   16.0000
```

Continue to run the delay. The delay samples now contain the rest of the input vector.

```
delayOut = delay(input,0) %#ok
```

```
delayOut = 10×2

     7    17
     8    18
     9    19
    10    20
     1    11
     2    12
     3    13
     4    14
     5    15
     6    16
```

Change the reset input to 2, indicating a rising edge.

```
delayOut = delay(input,2)
```

```
delayOut = 10×2

    0.1000    0.5000
    0.2000    0.6000
    0.3000    0.7000
    0.4000    0.8000
    1.0000   11.0000
    2.0000   12.0000
    3.0000   13.0000
    4.0000   14.0000
    5.0000   15.0000
    6.0000   16.0000
```

The delay values are reset to the initial conditions.

Compatibility Considerations

Setting delay `Units` to `'Frames'` is no longer supported

Errors starting in R2018a

Starting in R2018a, setting the delay `Units` to `'Frames'` errors. To resolve the error, set `Units` to `'Samples'` and specify `Length` in samples instead of frames. Calculate the number of samples by multiplying the frame delay value by the frame size.

Initial conditions are not supported in a cell array format

Errors starting in R2018a

The `InitialConditions` vector no longer supports cell array format. Specify the initial conditions as a `Length`-by-`numChans` matrix instead, where `numChans` is the number of input channels.

dsp.DelayLine

Package: `dsp`

Rebuffer sequence of inputs with one-sample shift

Description

The `dsp.DelayLine` System object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

1. Create the `dsp.DelayLine` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
dline = dsp.DelayLine
dline = dsp.DelayLine(delaysize,initial)
dline = dsp.DelayLine(Name,Value)
```

Description

`dline = dsp.DelayLine` returns a delay line System object, `dline`, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

`dline = dsp.DelayLine(delaysize,initial)` returns a delay line System object, `dline`, with the `Length` property set to `delaysize` and the `InitialConditions` property set to `initial`.

`dline = dsp.DelayLine(Name,Value)` returns a delay line object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Length` — Number of rows in output matrix
`64` (default) | positive integer

Specify the number of rows in the output matrix as a scalar positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialConditions` — Initial delay line output
`0` (default) | scalar | vector | matrix

Set the value of the object's initial output as one of `scalar`, `vector`, or `matrix`.

For vector outputs, you can use these options for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, you can use these options for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DirectFeedthrough` — Enable passing input data to output without extra frame delay
`false` (default) | `true`

When you set this property to `true`, the input data is available immediately at the output. When you set this property to `false`, the output has a delay of one frame.

`EnableOutputInputPort` — Enable selective output linearization
`false` (default) | `true`

The object uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If the input value is `true`, the object's output is linearized and thus valid. If the input value is `false`, the output is not linearized and is invalid. This allows the object to be more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid.

`HoldPreviousValue` — Hold previous valid value for invalid output
`false` (default) | `true`

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data.

Dependencies

This property applies only when you set the `EnableOutputInputPort` property to `true`.

Usage

Syntax

```
y = dline(x)
y = dline(x,en)
```

Description

`y = dline(x)` returns the delayed version of input `x`. `y` is an output matrix with the same number of rows as the delay line size. Each column of `x` is treated as a separate channel.

`y = dline(x,en)` selectively outputs the delayed version of input `x` depending on the Boolean input `en`. This occurs only when you set the `EnableOutputInputPort` property to `true`. If `en` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

en — Enable output input port

`true` | `false`

Enable output input port signal, specified as a logical value.

If `en` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Dependencies

This input is valid only when you set the `EnableOutputInputPort` property to `true`.

Data Types: `logical`

Output Arguments

y — Delay line output

vector | matrix

Delay line output, returned as a vector or a matrix.

When the input is an *Mi*-by-*N* matrix, the System object rebuffers the input into a sequence of *Mo*-by-*N* matrix outputs, where *Mo* is the output frame size specified by the `Length` property. Depending on whether *Mo* is greater than, less than, or equal to the input frame size, *Mi*, the output frames can be underlapped or overlapped. Each of the *N* input channels is rebuffered independently:

- When *Mo* > *Mi*, the output frame overlap is the difference between the output and input frame size, *Mo*–*Mi*.
- When *Mo* < *Mi*, the output is underlapped; the object discards the first *Mi*–*Mo* samples of each input frame so that only the last *Mo* samples are buffered into the corresponding output frame.
- When *Mo* = *Mi*, the output data is identical to the input data, but is delayed by the latency of the object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Delay Line

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use a delay line object with a delay line size of 4 samples.

```
delayline = dsp.DelayLine( ...
    'Length', 4, ...
    'DirectFeedthrough', true, ...
    'InitialConditions', -2, ...
    'EnableOutputInputPort', true, ...
    'HoldPreviousValue', true);
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
    y(:,ii) = delayline(ii, en(ii));
end
disp(y);
```

```
    -2    -2    -2     1     1
    -2    -2    -2     2     2
    -2     1     1     3     3
     1     2     2     4     4
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay Line block reference page. The object properties correspond to the block properties.

dsp.Differentiator

Package: `dsp`

Direct form FIR fullband differentiator filter

Description

The `dsp.Differentiator` System object applies a fullband differentiator filter on the input signal to differentiate all its frequency components. This object uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the differentiator is $D(\omega) = j\omega$ for $-\pi \le \omega \le \pi$. You can design the filter with minimum order with a specified order. This object supports fixed-point operations.

To filter each channel of your input:

1. Create the `dsp.Differentiator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
DF = dsp.Differentiator
DF = dsp.Differentiator(Name,Value)
```

Description

`DF = dsp.Differentiator` returns a differentiator, `DF`, which independently filters each channel of the input over time using the given design specifications.

`DF = dsp.Differentiator(Name,Value)` sets each property name to the specified value. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`DesignForMinimumOrder` — Design minimum order filter

`true` (default) | `false`

Option to design a minimum-order filter, specified as a logical scalar. The filter has 2 degrees of freedom. When you set this property to

- `true` — The object designs the filter with the minimum order that meets the `PassbandRipple` value.
- `false` — The object designs the filter with order that you specify in the `FilterOrder` property.

This property is not tunable.

`FilterOrder` — Order of the filter

31 (default) | odd positive integer

Order of the filter, specified as an odd positive integer.

This property is not tunable.

Dependencies

You can specify the filter order only when `'DesignForMinimumOrder'` is set to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandRipple` — Maximum passband ripple

0.1 (default) | positive real scalar

Maximum passband ripple in dB, specified as a positive real scalar.

This property is not tunable.

Dependencies

You can specify the passband ripple only when `'DesignForMinimumOrder'` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ScaleCoefficients` — Scale filter coefficients

`false` (default) | `true`

Option to scale the filter coefficients, specified as a logical scalar. When you set this property to `true`, the object scales the filter coefficients to preserve the input dynamic range.

This property is not tunable.

Fixed-Point Properties

`CoefficientsDataType` — Word and fraction lengths of coefficients

`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)`, corresponds to a signed numeric type object with 16-bit coefficients. To give the best possible precision, the fraction length is computed based on the coefficient values.

This property is not tunable.

The word length of the output is the same as the word length of the input. The object computes the fraction length of the output such that the entire dynamic range of the output can be represented without overflow. For details on how the object computes the fraction length of the output, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

`RoundingMethod` — Rounding method for output fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

This property is not tunable.

Usage

Syntax

```
y = DF(x)
```

Description

`y = DF(x)` applies a fullband differentiator filter to the input signal, `x`. `y` is a differentiated version of `x`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length. The data type characteristics (double, single, or fixed-point) and the real-complex characteristics (real or complex valued) must be the same for the input data and output data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Differentiated signal

vector | matrix

Differentiated signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, `x`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.Differentiator`

getFilter Get underlying FIR filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Group Delay Estimation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Estimate the group delay of a linear phase FIR filter using a `dsp.TransferFunctionEstimator` object followed by `dsp.PhaseExtractor` and `dsp.Differentiator` objects. The group delay of a linear phase FIR filter is given by $GD = -(d\theta(\omega)/d\omega) = -\frac{N}{2}$, where $\theta(\omega)$ is the phase information of the filter, ω is the frequency vector, and *N* is the order of the filter.

Set Up the Objects

Create a linear phase FIR lowpass filter. Set the order to 200, the passband frequency to 255 Hz, the passband ripple to 0.1 dB, and the stopband attenuation to 80 dB. Specify a sample rate of 512 Hz.

```
Fs = 512;
LPF = dsp.LowpassFilter('SampleRate',Fs,'PassbandFrequency',255,...
    'DesignForMinimumOrder',false,'FilterOrder',200);
```

To estimate the transfer function of the lowpass filter, create a transfer function estimator. Specify the window to be `Hann`. Set the FFT length to 1024 and the number of spectral averages to 200.

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange','twosided',...
    'SpectralAverages',200,'FFTLengthSource','Property',...
    'FFTLength',1024);
```

To extract the unwrapped phase from the frequency response of the filter, create a phase extractor.

```
PE = dsp.PhaseExtractor;
```

To differentiate the phase θ, create a differentiator filter. This value is used in computing the group delay.

```
DF = dsp.Differentiator;
```

To smoothen the input, create a variable bandwidth FIR filter.

```
Gain1 = 512/pi;
Gain2 = -1;
VBFilter = dsp.VariableBandwidthFIRFilter('CutoffFrequency',10,...
    'SampleRate',Fs);
```

To view the group delay of the filter, create an array plot object.

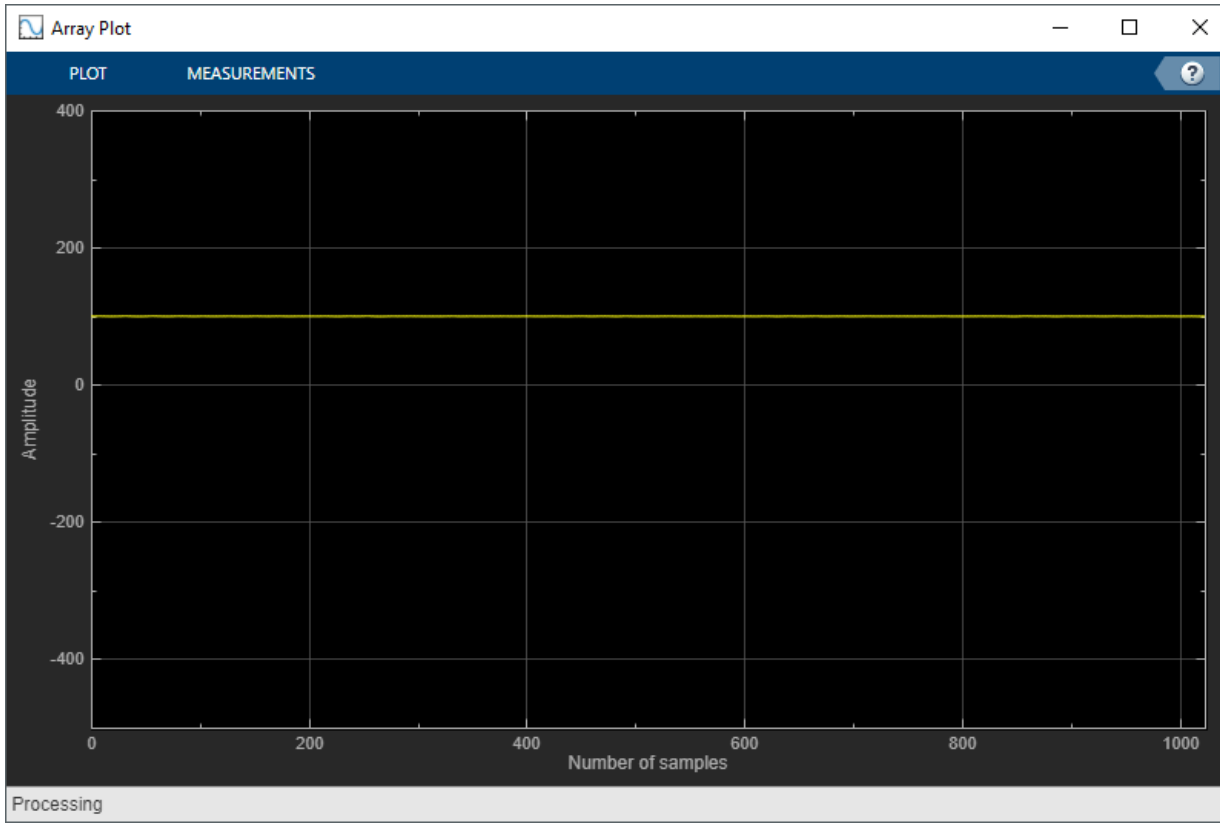
```
AP = dsp.ArrayPlot('PlotType','Line','YLimits',[-500 400],...
    'YLabel','Amplitude','XLabel','Number of samples');
```

Run the Algorithm

The `for`-loop is the streaming loop that estimates the group delay of the filter. In the loop, the algorithm filters the input signal, estimates the transfer function of the filter, and differentiates the phase of the filter to compute the group delay.

```
Niter = 1000; % Number of iterations
for k = 1:Niter
        x = randn(512,1);  % Input signal = white Gaussian noise
        y = LPF(x);   % Filter noise with Lowpass FIR filter
        H = TFE(x,y); % Compute transfer function estimate
```

```
        Phase = PE(H); % Extract the Unwrapped phase
        phaseaftergain1 = Gain1*Phase;
        DiffOut = DF(phaseaftergain1); % Differentiate the phase
        phaseaftergain2 = Gain2 * DiffOut;
        VBFOut = VBFilter(phaseaftergain2); % Smooth the group delay
        AP(VBFOut); % Display the group delay
end
```



As you can see, the group delay of the lowpass filter is 100.

Convert FM Signal to AM Signal

Create an FM wave on a 100 Hz carrier signal sampled at 1.5 kHz.

```
Fc = 1e2;   % Carrier
Fs = 1.5e3; % Sample rate
sinewave = dsp.SineWave('Frequency',10,...
                            'SamplesPerFrame',1e3,...
                            'SampleRate',Fs);
```

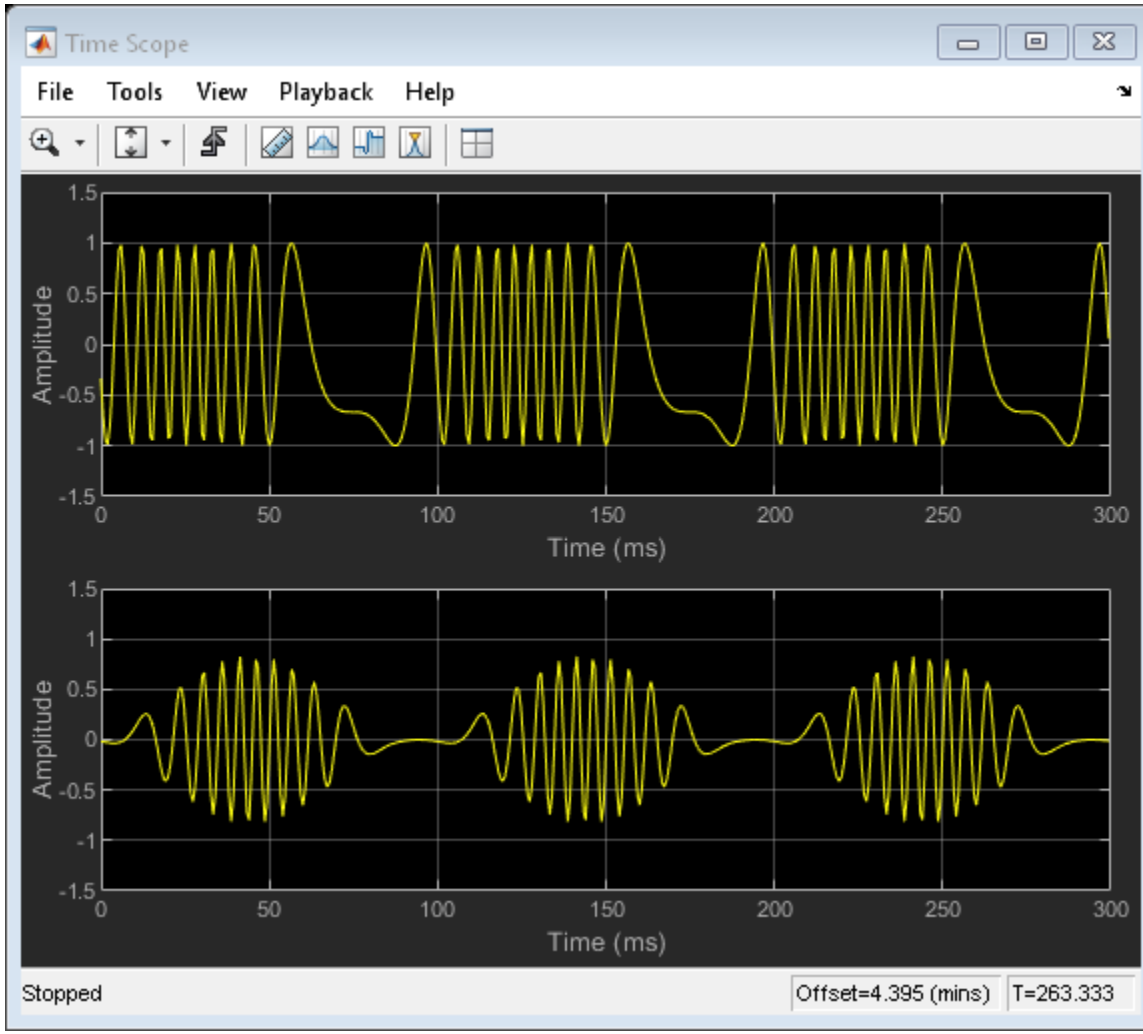
Convert the FM signal to an AM signal.

```
ts = dsp.TimeScope(2,...
                       'TimeSpan',0.3,...
                       'BufferLength',10*Fs,...
                       'SampleRate',Fs,...
                       'ShowGrid',true,...
                       'YLimits',[-1.5 1.5],...
                       'LayoutDimensions',[2 1]);

df = dsp.Differentiator;

tic
while toc<2.2
    x = step(sinewave);
    fm_y = modulate(x,Fc,Fs,'fm');
    am_y = step(df,fm_y);
    step(ts,fm_y,am_y);
end

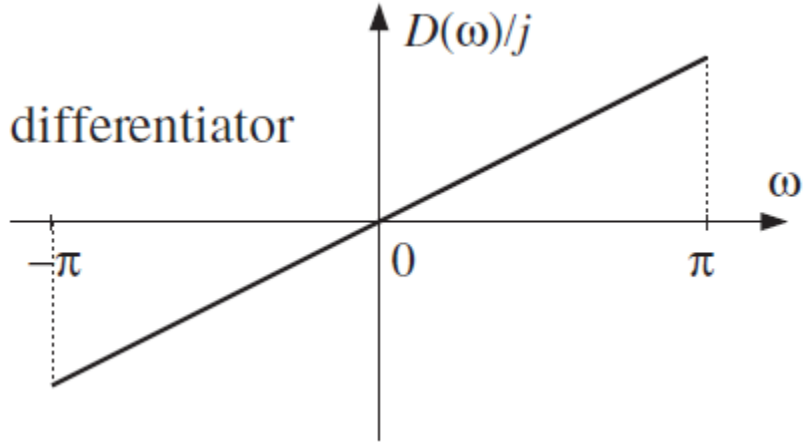
release(df);
release(ts);
```



Algorithms

Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by $D(\omega) = j\omega$, defined over the Nyquist interval $-\pi \le \omega \le \pi$.



The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by $d(n) = -d(-n)$. Hence $d(0) = 0$. The differentiator must have zero response at zero frequency.

Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by $h(n) = -h(M-1-n)$, where M is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If M is odd, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) = 0$. This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because $H_r(\pi) = 0$. This differentiator has a linear response over the limited frequency range $[0\ 2\pi f_p]$, where f_p is

the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as ω increases from 0 to $2\pi f_p$.

If M is even, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) \neq 0$. This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

dsp.DigitalDownConverter

Package: `dsp`

Translate digital signal from intermediate frequency (IF) band to baseband and decimate it

Description

The `dsp.DigitalDownConverter` object translates digital signal from intermediate frequency (IF) band to baseband and decimates it.

To digitally downconvert the input signal:

1. Create the `dsp.DigitalDownConverter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
dwnConv = dsp.DigitalDownConverter
dwnConv = dsp.DigitalDownConverter(Name,Value)
```

Description

`dwnConv = dsp.DigitalDownConverter` returns a digital downconverter (DDC) System object, `dwnConv`.

`dwnConv = dsp.DigitalDownConverter(Name,Value)` returns a DDC object, `dwnConv`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`SampleRate` — Sample rate of input signal

`30000000` (default) | positive scalar

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property.

Data Types: `single` | `double`

`DecimationFactor` — Decimation factor

`100` (default) | positive integer scalar | vector of positive integers

Set this property to a positive integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar, the object automatically chooses the decimation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. Both elements of the `DecimationFactor` vector must be greater than one.

When you set this property to a 1-by-3 vector, the *i* th element of the vector specifies the decimation factor for the *i*th filtering stage. The first and second elements of the `DecimationFactor` vector must be greater than one, and the third element must be 1 or 2.

Data Types: `double`

`MinimumOrderDesign` — Minimum order filter design

`true` (default) | `false`

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

Data Types: `logical`

`NumCICSections` — Number of sections of CIC decimator

3 (default) | positive integer scalar

Number of sections of CIC decimator, specified as a positive integer scalar.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

`SecondFilterOrder` — Order of CIC compensation filter stage

12 (default) | positive integer scalar

Order of CIC compensation filter stage, specified as a positive integer scalar.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

`ThirdFilterOrder` — Order of third filter stage

10 (default) | even positive integer

Order of third filter stage, specified as an even positive integer scalar. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the `ThirdFilterOrder` property because the third filter stage is bypassed.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

`Bandwidth` — Two-sided bandwidth of input signal in Hz

`200000` (default) | positive integer scalar

Two-sided bandwidth of input signal in Hz, specified as a positive integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. Set the value of this property to less than `SampleRate/DecimationFactor`.

Data Types: `double`

`StopbandFrequencySource` — Source of stopband frequency

`Auto` (default) | `Property`

Specify the source of the stopband frequency as one of `Auto` | `Property`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately F_c = `SampleRate/`M`/2` Hz, where M is the total decimation factor that you specify in the `DecimationFactor` property. The object computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response computed as $2\times(F_c - F_p)$, and the passband frequency, F_p, equals `Bandwidth/2`.

`StopbandFrequency` — Stopband frequency in Hz

`150000` (default) | positive scalar

Stopband frequency in Hz, specified as a positive scalar.

Dependencies

This property applies when you set the `StopbandFrequencySource` property to `Property`.

Data Types: `double`

`PassbandRipple` — Passband ripple of cascade response in dB

`0.1` (default) | positive scalar

Passband ripple of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the

cascade response meets the passband ripple that you specify in the `PassbandRipple` property.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

`StopbandAttenuation` — Stopband attenuation of cascade response in dB

`60` (default) | positive scalar

Stopband attenuation of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

`Oscillator` — Type of oscillator

`Sine wave` (default) | `NCO` | `Input port` | `None`

Specify the oscillator as one of `Sine wave` | `NCO` | `Input port` | `None`. When you set this property to `Sine wave`, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to `Input port`, the object performs frequency down conversion using the complex oscillator signal, `z`, that you pass as an input to the object. When you set this property to `None`, the mixer stage in the object is not present and the object acts as three stage cascaded decimator.

`CenterFrequency` — Center frequency of input signal in Hz

`14000000` (default) | positive scalar

Center frequency of input signal in Hz, specified as a positive scalar that is less than or equal to half the value of the `SampleRate` property. The object down converts the input signal from the passband center frequency you specify in the `CenterFrequency` property, to `0` Hz.

Dependencies

This property applies when you set the `Oscillator` property to `Sine wave` or `NCO`.

Data Types: `double`

`NumAccumulatorBits` — Number of NCO accumulator bits

16 (default) | positive integer

Number of NCO accumulator bits, specified as a positive integer in the range `[1 128]`.

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

Data Types: `double`

`NumQuantizedAccumulatorBits` — Number of NCO quantized accumulator bits

12 (default) | positive integer

Number of NCO quantized accumulator bits, specified as an integer scalar in the range `[1 128]`. The value you specify in this property must be less than the value you specify in the `NumAccumulatorBits` property.

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

Data Types: `double`

`Dither` — Dither control for NCO

`true` (default) | `false`

When you set this property to `true`, a number of dither bits specified in the `NumDitherBits` property will be used to apply dither to the NCO signal.

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

`NumDitherBits` — Number of NCO dither bits

4 (default) | positive integer

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property.

Dependencies

This property applies when you set the `Oscillator` property to `NCO` and the Dither property to `true`.

Data Types: `double`

Fixed-Point Properties

`FiltersInputDataType` — Data type of input of each filter stage

`Same as input` (default) | `Custom`

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of `Same as input` | `Custom`. The object casts the data at the input of each filter stage according to the value you set in this property.

`CustomFiltersInputDataType` — Fixed-point data type of input of each filter stage

`numerictype([],16,15)` (default) | numeric type

Specify the filters input fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies when you set the `FiltersInputDataType` property to `Custom`.

`OutputDataType` — Data type of output

`Same as input` (default) | `Custom`

Specify the data type of output as `Same as input` | `Custom`.

`CustomOutputDataType` — Fixed-point data type of output

`numerictype([],16,15)` (default) | numeric type

Specify the output fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage

Syntax

```
y = dwnConv(x)
y = dwnConv(x,z)
```

Description

`y = dwnConv(x)` takes an input `x` and outputs a signal, `y` that is frequency downconverted and downsampled.

`y = dwnConv(x,z)` uses the complex input, `z`, as the oscillator signal used to frequency down convert input `x` when you set the `Oscillator` property to `Input port`.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The length of input `x` must be a multiple of the decimation factor. When the data type of `x` is `double` or `single` precision, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed-point type, the data type of `y` is defined by the `OutputDataType` property.

The input can have multiple channels only if its data type is `double` or `single`. The input can be of data type `double`, `single`, signed integer, or signed fixed-point (`fi` objects).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

z — Oscillator signal

column vector | matrix

Oscillator signal used to frequency down convert the input signal, specified as a column vector or a matrix. This input must be complex. The length of `z` must be equal to the length of `x`. `z` can be `double`, `single`, signed integer, or signed fixed-point (`fi` objects).

Dependencies

This input applies when you set the `Oscillator` property to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

y — Down converted and down sampled signal

column vector | matrix

Down converted and down sampled signal, returned as a column vector or a matrix. The length of `y` is equal to the length of `x` divided by the `DecimationFactor`. When the data type of `x` is `double` or `single` precision, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed point type, the data type of `y` is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.DigitalDownConverter`

getDecimationFactors	Get decimation factors of each filter stage of a digital down converter
getFilterOrders	Get orders of digital down converter or digital up converter filter cascade
getFilters	Get handles to digital down converter or digital up converter filter cascade objects
fvtool	Visualize frequency response of digital down converter or digital up converter filter cascade
groupDelay	Group delay of digital down converter or digital up converter filter cascade
visualizeFilterStages	Display response of digital down converter or digital up converter filter cascade
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Upconvert and Downconvert a Sine Wave Signal

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a sine wave generator to obtain the 1 KHz sinusoidal signal with a sample rate of 6 KHz.

```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate',...
Fs,'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a `DigitalUpConverter` object. Use minimum order filter designs and set passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set the double sided signal bandwidth to 2 KHz.

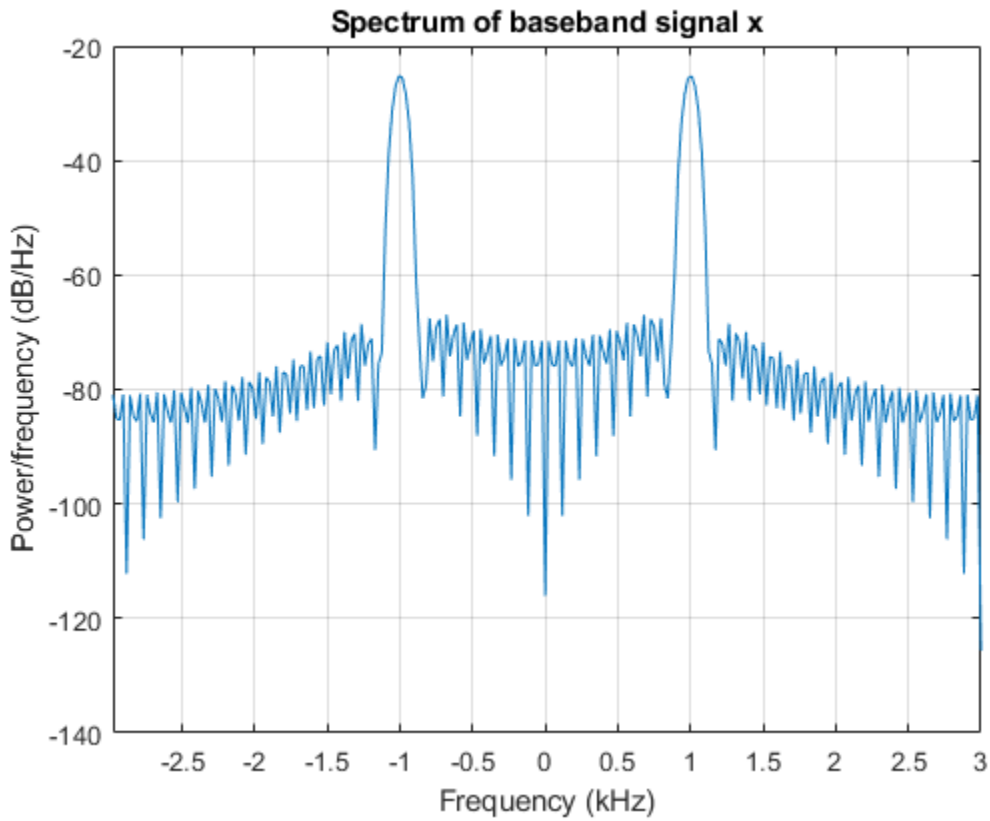
```
upConv = dsp.DigitalUpConverter(...
 'InterpolationFactor', 20,...
 'SampleRate', Fs,...
 'Bandwidth', 2e3,...
 'StopbandAttenuation', 55,...
 'PassbandRipple',0.2,...
 'CenterFrequency',50e3);
```

Create a `DigitalDownConverter` object. Use minimum order filter designs and set the passband ripple to 0.2 dB and the stopband attenuation to 55 dB.

```
dwnConv = dsp.DigitalDownConverter(...
  'DecimationFactor',20,...
  'SampleRate', Fs*20,...
  'Bandwidth', 3e3,...
  'StopbandAttenuation', 55,...
  'PassbandRipple',0.2,...
  'CenterFrequency',50e3);
```

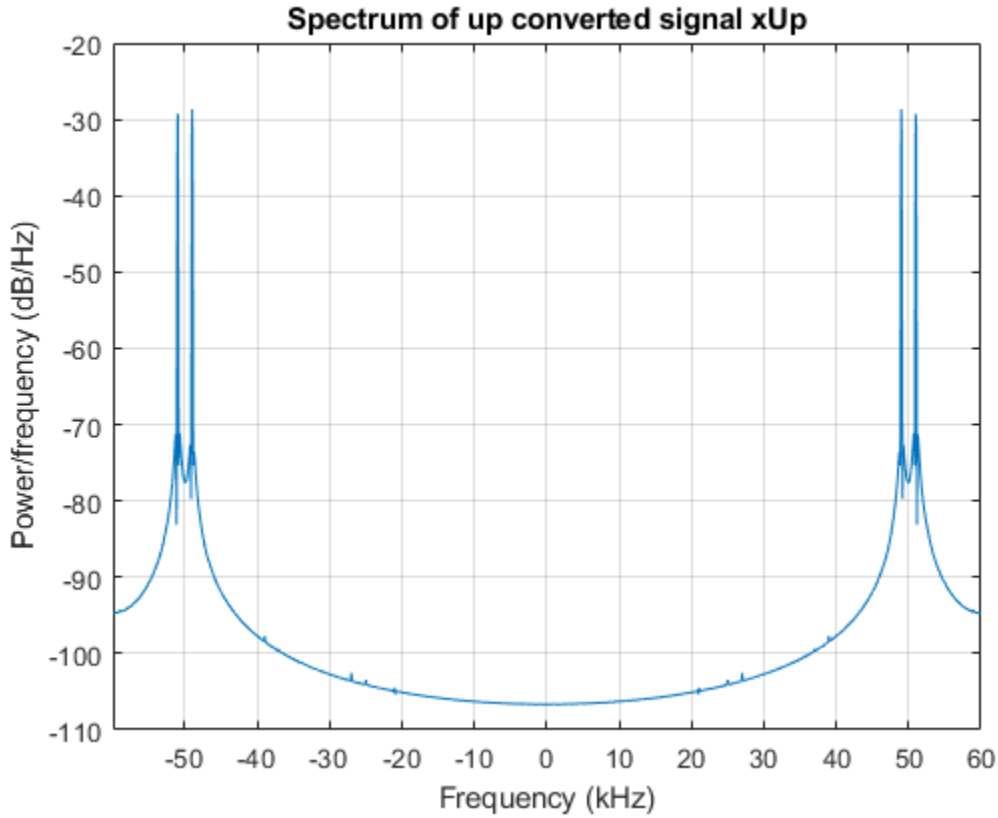
Create a spectrum estimator to visualize the signal spectrum before up converting, after up converting, and after down converting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x,window,[],[],Fs,'centered')
title('Spectrum of baseband signal x')
```



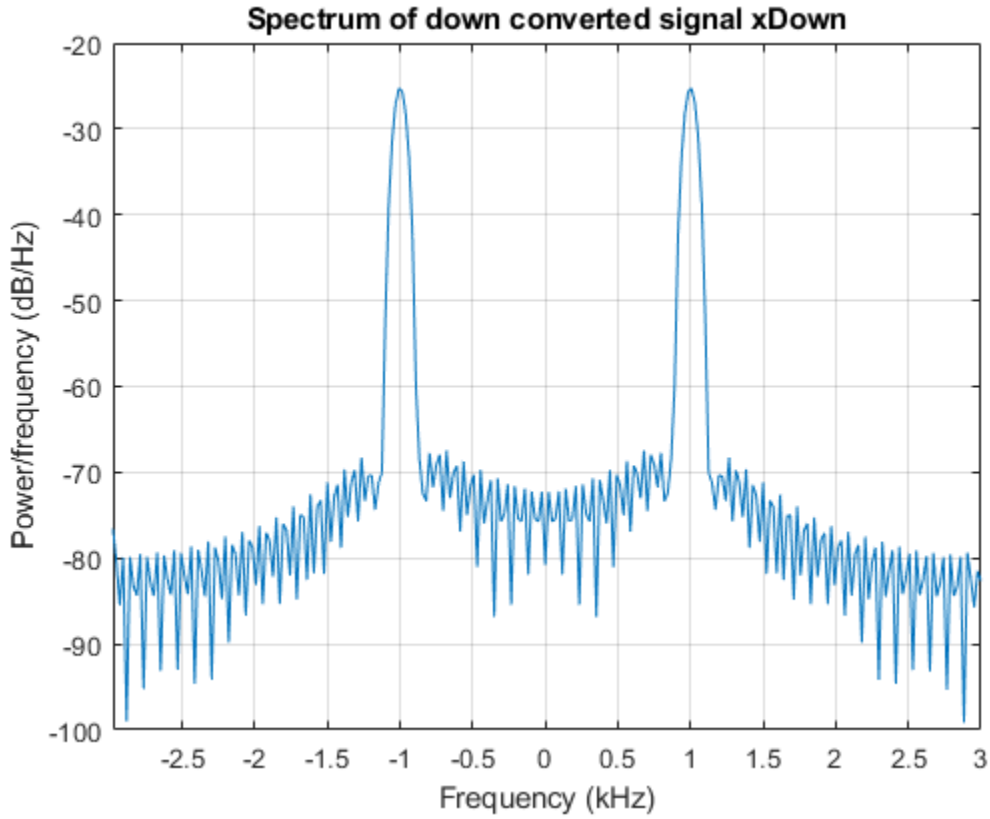
Up convert the signal and visualize the spectrum

```
xUp = upConv(x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered');
title('Spectrum of up converted signal xUp')
```



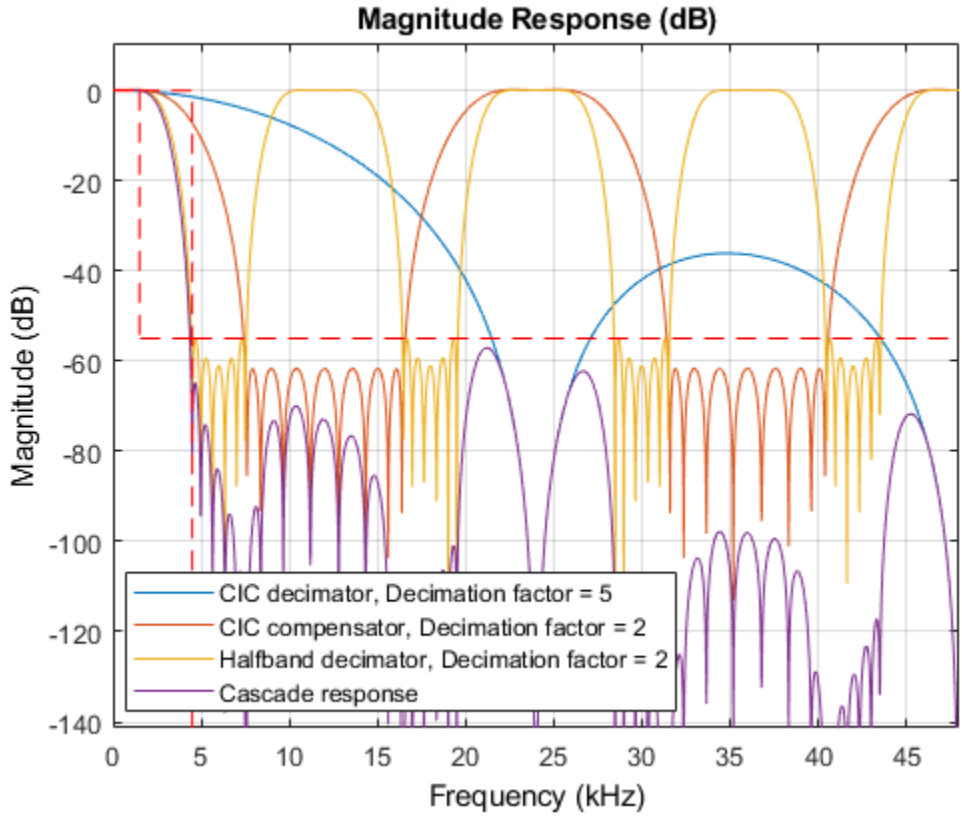
Down convert the signal and visualize the spectrum

```
xDown = dwnConv(xUp); % down convert
window = hamming(floor(length(xDown)/10));
figure; pwelch(xDown,window,[],[],Fs,'centered')
title('Spectrum of down converted signal xDown')
```



Visualize the response of the decimation filters

```
visualizeFilterStages(dwnConv)
```



Get Decimation Factors

Get decimation factors of each filter stage of the `dsp.DigitalDownConverter` System object™.

Create a `dsp.DigitalDownConverter` System object with the default settings. Using the `getDecimationFactors` function, obtain the decimation factors of each stage of the object.

```
dwnConv = dsp.DigitalDownConverter
```

```
dwnConv =
  dsp.DigitalDownConverter with properties:

          DecimationFactor: 100
         MinimumOrderDesign: true
                  Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
             PassbandRipple: 0.1000
        StopbandAttenuation: 60
                 Oscillator: 'Sine wave'
            CenterFrequency: 14000000
                 SampleRate: 30000000

  Show all properties
```

```
M = getDecimationFactors(dwnConv) %#ok
```

```
M = 1×3

    25     2     2
```

The `DecimationFactor` property of the object is set to 100. The output `M` is by default a 1-by-3 vector, where each element in the vector is a factor of the overall decimation factor.

When you set the `DecimationFactor` to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively.

```
dwnConv.DecimationFactor = [10 10]
```

```
dwnConv =
  dsp.DigitalDownConverter with properties:

          DecimationFactor: [10 10]
         MinimumOrderDesign: true
                  Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
             PassbandRipple: 0.1000
        StopbandAttenuation: 60
                 Oscillator: 'Sine wave'
            CenterFrequency: 14000000
                 SampleRate: 30000000
```

```
  Show all properties

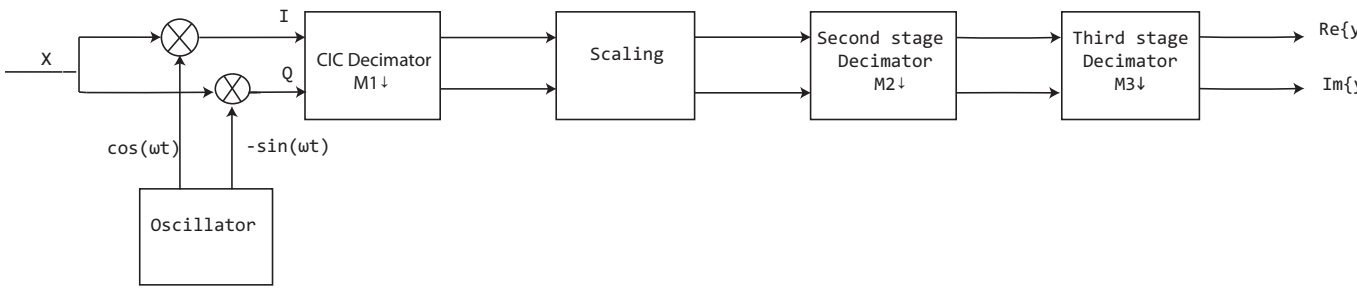
M = getDecimationFactors(dwnConv)
M = 1×2

    10    10
```

The output of the `getDecimationFactors` function is now a 1-by-2 vector.

Algorithms

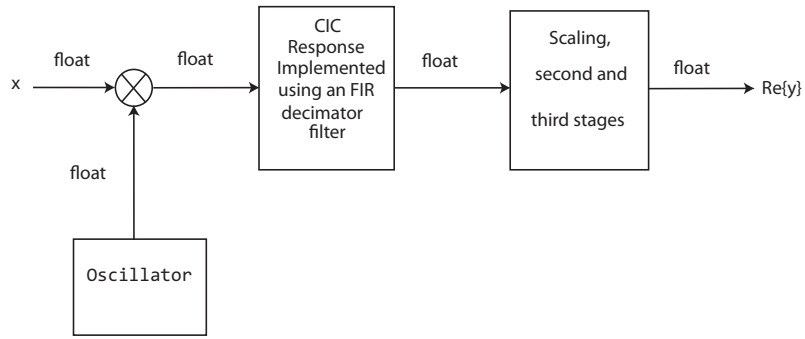
The object downconverts the input signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. The object downsamples the frequency downconverted signal using a cascade of three decimation filters. In this case, the filter cascade consists of a CIC decimator, a CIC compensator, and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.



The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. When you set the **Oscillator** property to `InputPort`, the normalization factor does not include the oscillator power factor. Depending on the setting of the **DecimationFactor** property, you may be able to bypass the third filter stage. When the input data type is double or single,

the object implements an *N*-section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed-point type. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.



For details of fixed-point operation, see “Fixed Point” on page 4-567.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

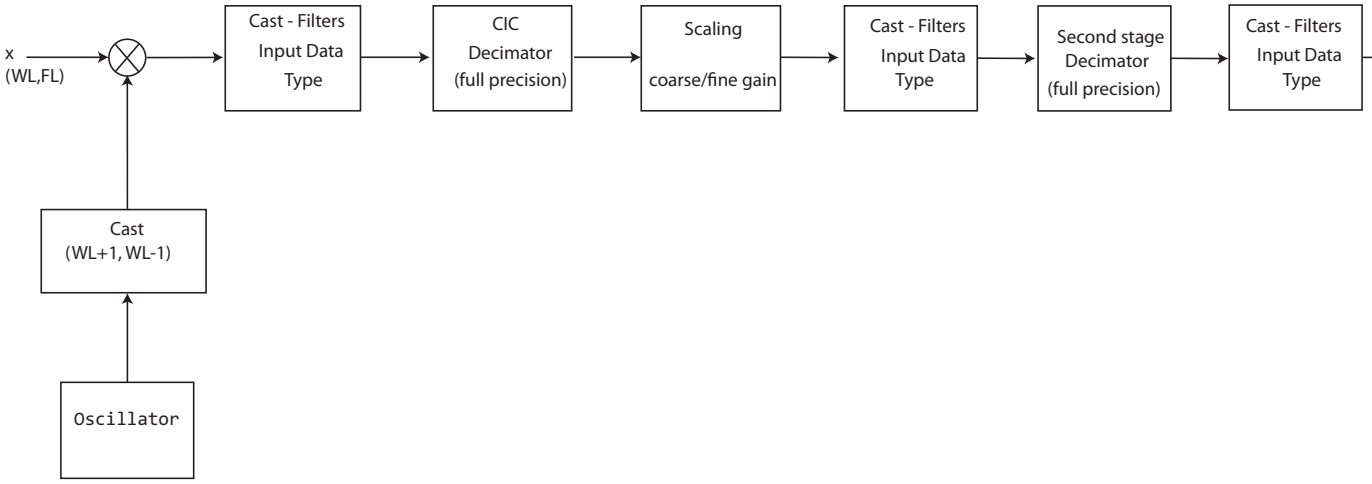
Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

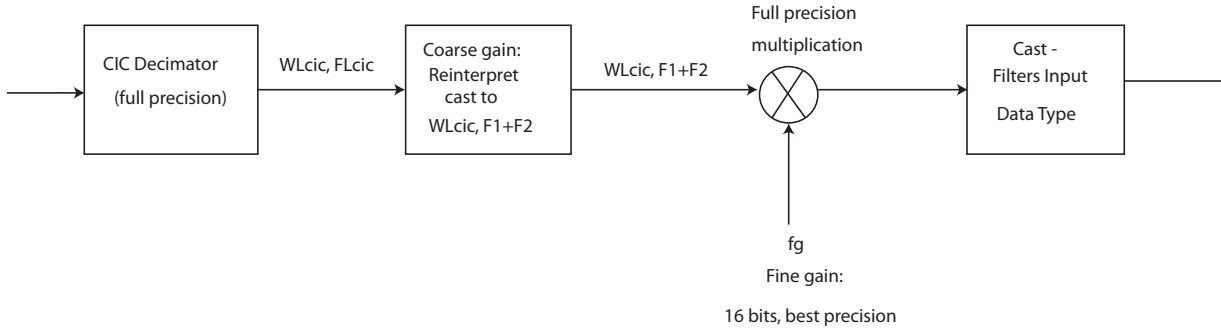
Design and simulate fixed-point systems using Fixed-Point Designer™.

The following block diagram represents the DDC arithmetic with signed fixed-point inputs.



- `WL` is the word length of the input, and `FL` is the fraction length of the input.
- The input of each filter is cast to the data type specified in the **FiltersInputDataType** and **CustomFiltersInputDataType** properties.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.



If the normalization gain is G (where $0<G\leqq1$), then:

- `WLcic` is the word length of the CIC decimator output and `FLcic` is the fraction length of the CIC decimator output
- `F1 = abs(nextpow2(G))`, indicating the part of G achieved using bit shifts (coarse gain)
- `F2` = fraction length specified by the **FiltersInputDataType** and **CustomFiltersInputDataType** properties
- `fg = fi((2^F1)*G, true, 16)`, indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

dsp.DigitalUpConverter

Package: dsp

Interpolate digital signal and translate it from baseband to IF band

Description

The dsp.DigitalUpConverter System object interpolates a digital signal, and translates it from baseband to intermediate frequency (IF) band.

To digitally upconvert the input signal:

1. Create the dsp.DigitalUpConverter object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
upConv = dsp.DigitalUpConverter
upConv = dsp.DigitalUpConverter(Name,Value)
```

Description

upConv = dsp.DigitalUpConverter returns a digital up-converter (DUC) System object, upConv.

upConv = dsp.DigitalUpConverter(Name,Value) returns a DUC System object with the specified property Name set to the specified value Value. You can specify one or more name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN). Enclose each property name in single quotes. For example, create an object that upsamples the input signal by a factor of 20, using a filter with the specified qualities.

```
upConv = dsp.DigitalUpConverter('InterpolationFactor',20,...
'SampleRate',Fs,...
'Bandwidth',2e3,...
'StopbandAttenuation',55,...
'PassbandRipple',0.2,...
'CenterFrequency',50e3);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`SampleRate` — Sample rate of input signal

`30000000` (default) | positive scalar

Set this property to a positive scalar value. The value of this property multiplied by the total interpolation factor must be greater than or equal to twice the value of the `CenterFrequency` property.

Data Types: `single` | `double`

`InterpolationFactor` — Interpolation factor

`100` (default) | positive integer | vector of positive integers

Interpolation factor, specified as a positive integer, or a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. Both elements of this `InterpolationFactor` vector must be greater than 1.

When you set this property to a 1-by-3 vector, the *i*th element of the vector specifies the interpolation factor for the *i*th filtering stage. The second and third elements of this `InterpolationFactor` vector must be greater than 1 and the first element must equal `1` or `2`.

Data Types: `double`

`MinimumOrderDesign` — Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as `true` or `false`.

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

Data Types: `logical`

`SecondFilterOrder` — Order of CIC compensation filter stage

`12` (default) | positive integer

Order of CIC compensation filter stage, specified as a positive integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

`FirstFilterOrder` — Order of first filter stage

`10` (default) | positive even integer

Order of first filter stage, specified as a positive even integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property, because the first filter stage is bypassed.

Data Types: `double`

`NumCICSections` — Number of sections of CIC interpolator

`3` (default) | positive integer

Number of sections of CIC interpolator, specified as a positive integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

`Bandwidth` — Two-sided bandwidth of input signal in Hz

`200000` (default) | positive integer

Two-sided bandwidth of input signal in Hz, specified as a positive integer. The object sets the passband frequency of the cascade of filters to half of the value that you specify in this `Bandwidth` property.

Data Types: `double`

`StopbandFrequencySource` — Source of stopband frequency

`Auto` (default) | `Property`

Source of stopband frequency, specified as `Auto` or `Property`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately F_c = `SampleRate`/2 Hz and computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response, computed as $2\times(F_c–F_p)$. F_p is the passband frequency computed by `Bandwidth`/2.

`StopbandFrequency` — Stopband frequency in Hz

`150000` (default) | positive scalar

Stopband frequency in Hz, specified as a positive scalar.

Dependencies

To enable this property, set the `StopbandFrequencySource` property to `Property`.

Data Types: `double`

`PassbandRipple` — Passband ripple of cascade response in dB

`0.1` (default) | positive scalar

Passband ripple of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in this `PassbandRipple` property.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

`StopbandAttenuation` — Stopband attenuation of cascade response in dB

`60` (default) | positive scalar

Stopband attenuation of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in this `StopbandAttenuation` property.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

`Oscillator` — Type of oscillator

`Sine wave` (default) | `NCO`

Type of oscillator, specified as `Sine wave` or `NCO`. When you set this property to `Sine wave`, the object frequency-upconverts the output of the interpolation filter cascade by using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object frequency-upconverts the output by using a complex exponential obtained from a numerically controlled oscillator (NCO).

`CenterFrequency` — Center frequency of output signal in Hz

`14000000` (default) | positive scalar

Center frequency of output signal in Hz, specified as a positive scalar. The value of this property must be less than or equal to half the product of the `SampleRate` property and

the total interpolation factor. The object up converts the input signal so that the output spectrum centers at this frequency you specify in the `CenterFrequency` property.

Data Types: `double`

NCO Properties

`NumAccumulatorBits` — Number of NCO accumulator bits

16 (default) | integer in the range [1, 128]

Number of NCO accumulator bits, specified as an integer in the range [1, 128]. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `double`

`NumQuantizedAccumulatorBits` — Number of NCO accumulator bits

12 (default) | integer in the range [1, 128]

Number of NCO accumulator bits, specified as an integer in the range [1, 128]. The value you specify for this property must be less than the value you specify in the `NumAccumulatorBits` property. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `double`

`Dither` — Dither control for NCO

`true` (default) | `false`

Dither control for NCO, specified as `true` or `false`. When you set this property to `true`, the object uses the number of dither bits specified in the `NumDitherBits` property when applying dither to the NCO signal. When this property is `false`, the NCO does not apply dither to the signal. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `logical`

`NumDitherBits` — Number of NCO dither bits

4 (default) | positive integer

Number of NCO dither bits, specified as a positive integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO` and the `Dither` property to `true`.

Data Types: `double`

Fixed-Point Properties

`FiltersOutputDataType` — Data type at output of each filter stage

`Same as input` (default) | `Custom`

Data type at the output of the first (if it has not been bypassed), second, and third filter stages, specified as `Same as input` or `Custom`. The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal is scaled by the normalization factor.

`CustomFiltersOutputDataType` — Fixed-point data type at output of each filter stage

`numerictype([],16,15)` (default) | `numerictype` object

Fixed-point data type at output of each filter stage, specified as a scaled `numerictype` object with the `Signedness` property set to `Auto`.

Dependencies

To enable this property, set the `FiltersOutputDataType` property to `Custom`.

`OutputDataType` — Data type of output

`Same as input` (default) | `Custom`

Data type of output, specified as `Same as input` or `Custom`.

`CustomOutputDataType` — Fixed-point data type of output

`numerictype([],16,15)` (default) | `numerictype` object

Fixed-point data type of output, specified as a scaled `numerictype` object the `Signedness` property set to `Auto`.

Dependencies

To enable this property, set the `OutputDataType` property to `Custom`.

Usage

Syntax

```
y = upConv(x)
```

Description

`y = upConv(x)` returns an upsampled and frequency-upconverted signal `y`, for a real or complex input column vector `x`.

Input Arguments

x — Input signal

real or complex column vector

Input signal, specified as a column vector of real or complex values. The length of input `x` must be a multiple of the decimation factor. When the data type of `x` is `double` or `single`, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed-point type, the data type of `y` is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

y — Upconverted and upsampled signal

column vector

Upconverted and upsampled signal, returned as a column vector. The length of `y` is equal to the length of `x` divided by the `InterpolationFactor`. When the data type of `x` is

`double` or `single`, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed-point type, the data type of `y` is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.DigitalUpConverter`

getInterpolationFactors	Get interpolation factors of each filter stage of digital upconverter
getFilterOrders	Get orders of digital down converter or digital up converter filter cascade
getFilters	Get handles to digital down converter or digital up converter filter cascade objects
fvtool	Visualize frequency response of digital down converter or digital up converter filter cascade
groupDelay	Group delay of digital down converter or digital up converter filter cascade
visualizeFilterStages	Display response of digital down converter or digital up converter filter cascade
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Upconvert Sine Wave Signal

Create a DUC System object™ that upsamples a 1-kHz sinusoidal signal by a factor of 20 and upconverts it to 50 kHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a sine wave generator to obtain the 1-kHz sinusoidal signal with a sample rate of 6 kHz.

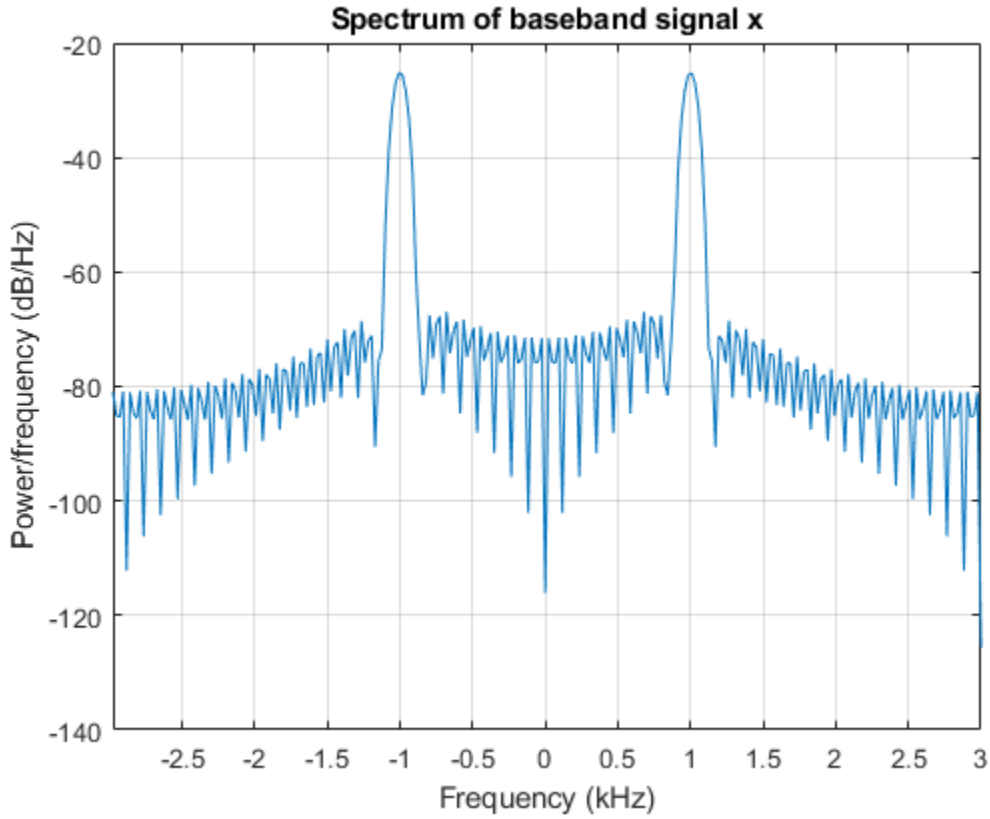
```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate',Fs,'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a DUC System object. Use minimum order filter designs and set the passband ripple to 0.2 dB and stopband attenuation to 55 dB. Set the double-sided signal bandwidth to 2 kHz.

```
upConv = dsp.DigitalUpConverter(...
     'InterpolationFactor',20,...
     'SampleRate',Fs,...
     'Bandwidth',2e3,...
     'StopbandAttenuation',55,...
     'PassbandRipple',0.2,...
     'CenterFrequency',50e3);
```

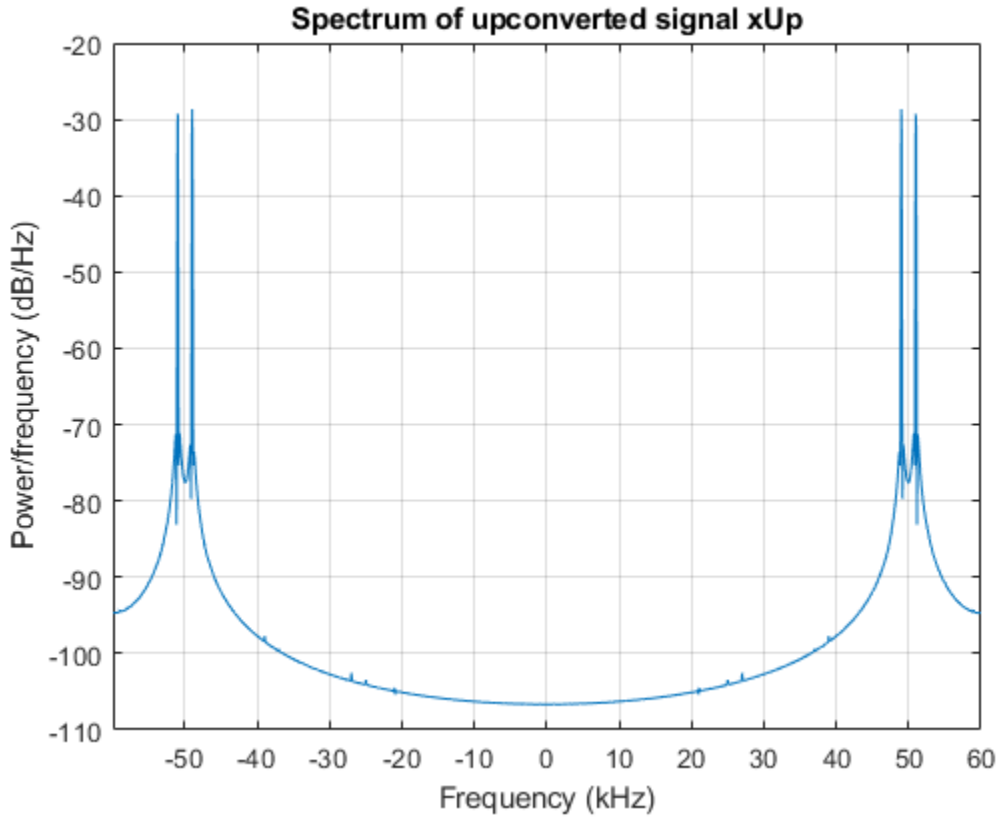
Create a spectrum estimator to visualize the signal spectrum before and after upconverting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x,window,[],[],Fs,'centered')
title('Spectrum of baseband signal x')
```



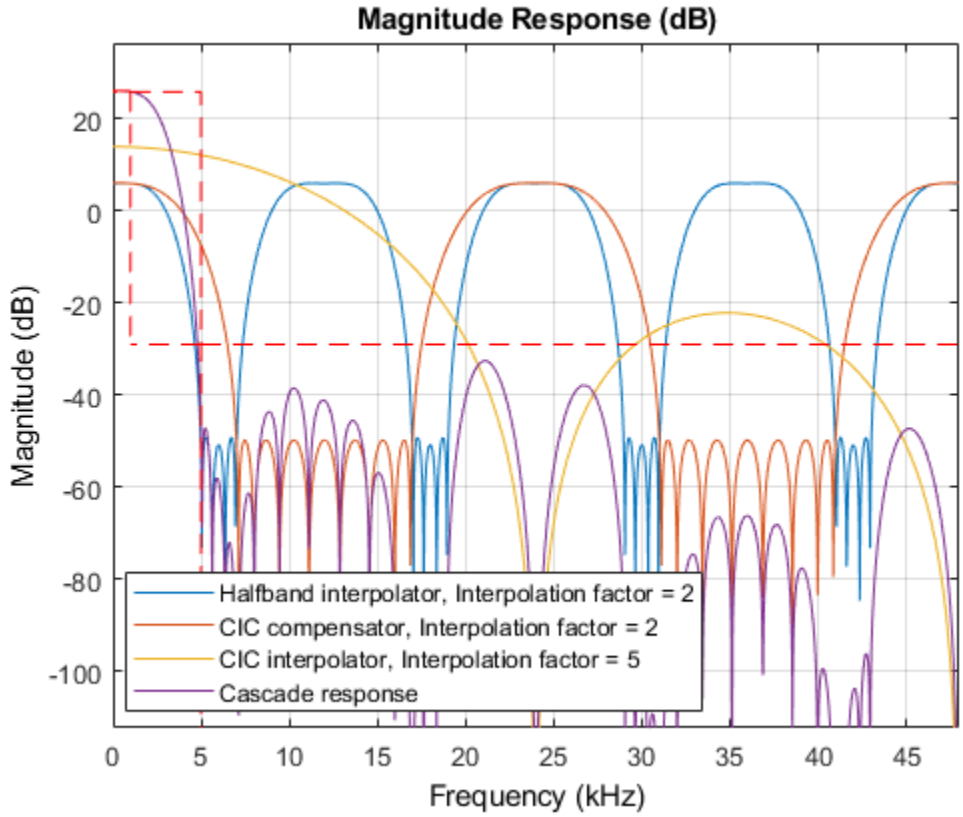
Upconvert the signal and visualize the spectrum.

```
xUp = upConv(x);
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered')
title('Spectrum of upconverted signal xUp')
```



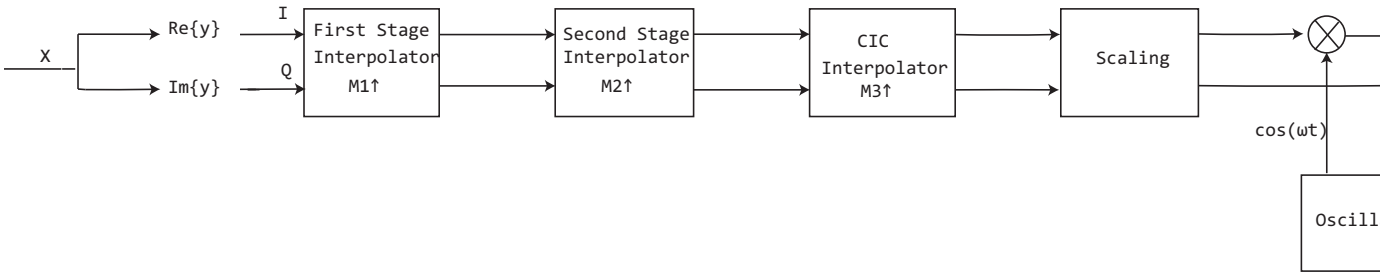
Visualize the response of the interpolation filters.

```
visualizeFilterStages(upConv)
```



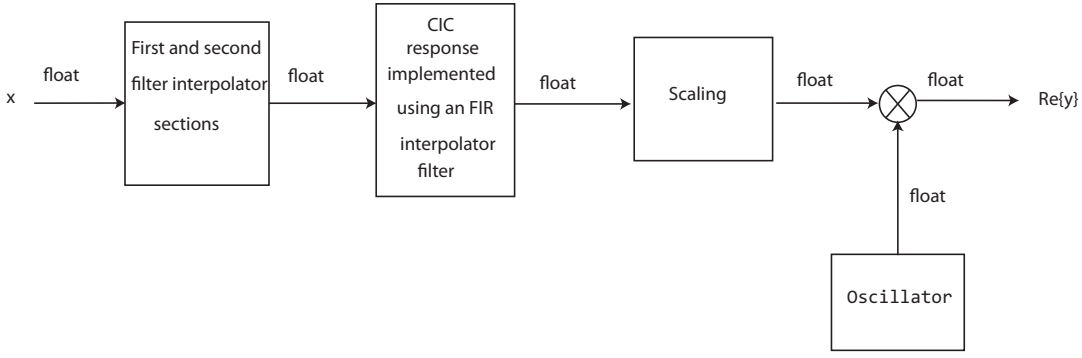
Algorithms

The object up samples the input signal using a cascade of three interpolation filters. This object frequency-upconverts the upsampled signal by multiplying it by a complex exponential with center frequency equal to the value in the `CenterFrequency` property. In this case, the filter cascade consists of a FIR interpolation stage, a second stage for CIC compensation, and a CIC interpolator. The block diagram shows the architecture of the digital up converter.



The scaling section normalizes the CIC gain and the oscillator power. It can also contain a correction factor to achieve the desired ripple specification. Depending on the setting of the `InterpolationFactor` property, you might be able to bypass the first filter stage. When the input data type is floating point, the object implements an *N*-section CIC interpolation filter as a FIR filter with a response that corresponds to a cascade of *N* boxcar filters. The CIC filter is emulated with a FIR filter so that you can run simulations with floating-point data. When the input data is fixed-point type, the object implements a true CIC filter with actual comb and integrator sections.

The diagram represents the DUC arithmetic with floating-point inputs.



For details of fixed-point operation, see “Fixed Point” on page 4-584.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

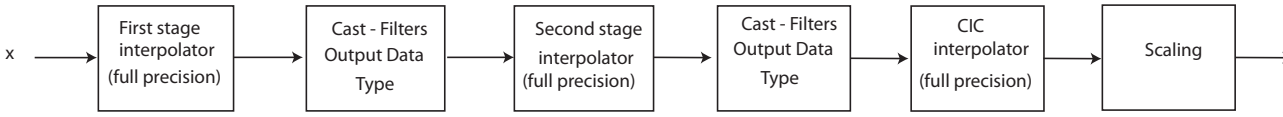
Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

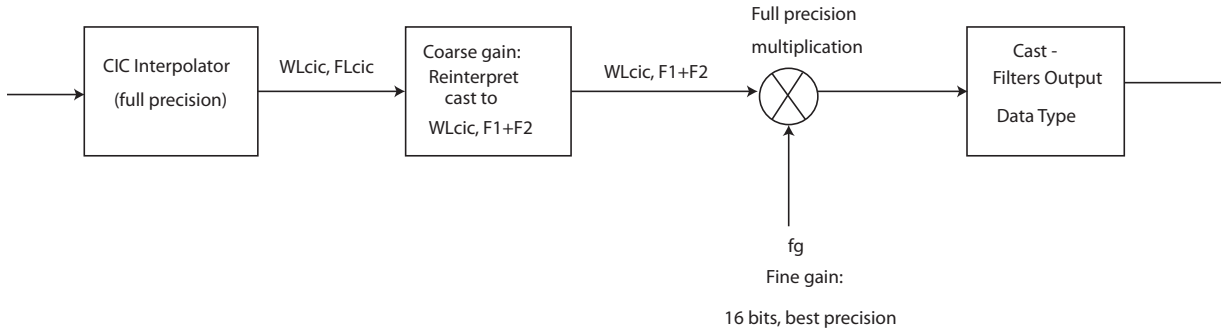
The block diagram represents the DUC arithmetic with signed fixed-point inputs.



- *WL* is the word length of the input, and *FL* is the fraction length of the input.
- The output of each filter is cast to the data type specified in the `FiltersOutputDataType` and `CustomFiltersOutputDataType` properties. The casting of the CIC output occurs after the scaling factor is applied.

- The oscillator output is cast to a word length equal to the `FiltersOutputDataType` word length plus one. The fraction length is equal to the `FiltersOutputDataType` word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse-gain and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The figure shows the coarse-gain and fine-gain operations.



If the normalization gain is G (where $0<G\leqq 1$), then:

- WL_{cic} is the word length of the CIC interpolator output, and FL_{cic} is the fraction length of the CIC interpolator output.
- `F1 = abs(nextpow2(G))`, indicating the part of G achieved by using bit shifts (coarse gain).
- *F2* is the fraction length specified by the `FiltersOutputDataType` and `CustomFiltersOutputDataType` properties.
- `fg = fi((2^F1)*G,true,16)`, indicating that the remaining gain cannot be achieved with a bit shift (fine gain).

getInterpolationFactors

Package: `dsp`

Get interpolation factors of each filter stage of digital upconverter

Syntax

```
M = getInterpolationFactors(upConv)
```

Description

`M = getInterpolationFactors(upConv)` returns a vector, `M`, with the interpolation factors of each filter stage of digital up converter `upConv`. If the first filter stage is bypassed, then `M` is a 1-by-2 vector that contains the interpolation factors of the second and third stages. If the first filter stage is not bypassed, then `M` is a 1-by-3 vector containing the interpolation factors of the first, second, and third filter stages.

Examples

Get Interpolation Factors

Get interpolation factors of each filter stage of a `dsp.DigitalUpConverter` System object™.

Create a `dsp.DigitalUpConverter` System object with the default settings. Using the `getInterpolationFactors` function, obtain the interpolation factors of each stage of the object.

```
upConv = dsp.DigitalUpConverter
```

```
upConv =
  dsp.DigitalUpConverter with properties:

        InterpolationFactor: 100
```

```
         MinimumOrderDesign: true
                  Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
             PassbandRipple: 0.1000
        StopbandAttenuation: 60
                 Oscillator: 'Sine wave'
            CenterFrequency: 14000000
                 SampleRate: 300000

  Show all properties
```

```
M = getInterpolationFactors(upConv) %#ok
```

```
M = 1×3

     2     2    25
```

The `InterpolationFactor` property of the object is set to `100`. By default, the output `M` is a 1-by-3 vector, where each element in the vector is a factor of the overall interpolation factor.

When you set the `InterpolationFactor` property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. The output of the `getInterpolationFactors` function is now a 1-by-2 vector.

```
upConv.InterpolationFactor = [10 10]
```

```
upConv =
  dsp.DigitalUpConverter with properties:

        InterpolationFactor: [10 10]
         MinimumOrderDesign: true
                  Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
             PassbandRipple: 0.1000
        StopbandAttenuation: 60
                 Oscillator: 'Sine wave'
            CenterFrequency: 14000000
                 SampleRate: 300000

  Show all properties
```

```
M = getInterpolationFactors(upConv)

M = 1×2

    10    10
```

Input Arguments

upConv — Digital up converter

`dsp.DigitalUpConverter` System object

Digital up converter, specified as a `dsp.DigitalUpConverter` System object.

Output Arguments

M — Interpolation factors

vector

Interpolation factors of each filter stage, returned as a 1-by-2 or 1-by-3 vector. If the first filter stage is bypassed, then `M` is a 1-by-2 vector containing the interpolation factors of the second and third stages. If the first filter stage is not bypassed, then `M` is a 1-by-3 vector containing the interpolation factors of the first, second, and third filter stages.

Data Types: `double`

dsp.DyadicAnalysisFilterBank

Package: `dsp`

Dyadic analysis filter bank

Description

The `dsp.DyadicAnalysisFilterBank` System object decomposes a broadband signal into a collection of subbands with smaller bandwidths and slower sample rates. The System object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

1. Create the `dsp.DyadicAnalysisFilterBank` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
dydan = dsp.DyadicAnalysisFilterBank
dydan = dsp.DyadicAnalysisFilterBank(Name,Value)
```

Description

`dydan = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `dydan`, that computes the level-two discrete wavelet transform (DWT) of a column

vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

`dydan = dsp.DyadicAnalysisFilterBank(Name,Value)` returns a dyadic analysis filter bank object, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Filter` — Type of filter used in subband decomposition

`Custom` (default) | `Biorthogonal` | `Coiflets` | `Daubechies` | `Discrete Meyer` | `Haar` | `Reverse Biorthogonal` | `Symlets`

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as `Custom` , `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. All property values except `Custom` require Wavelet Toolbox software. If the value of this property is `Custom`, the filter coefficients are specified by the values of the `CustomLowpassFilter` and `CustomHighpassFilter` properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function `wfilters` to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

Filter	Example Setting	Syntax for Analysis Filters
Haar	N/A	`[Lo_D,Hi_D]=wfilters('haar');`
Daubechies extremal phase	`WaveletOrder=3;`	`[Lo_D,Hi_D]=wfilters('db3');`
Symlets (Daubechies least-asymmetric)	`WaveletOrder=4;`	`[Lo_D,Hi_D]=wfilters('sym4');`

Filter	Example Setting	Syntax for Analysis Filters
Coiflets	`WaveletOrder=1;`	`[Lo_D,Hi_D]=wfilters('coif1');`
Biorthogonal	`FilterOrder='[3/1]';`	`[Lo_D,Hi_D,Lo_R,Hi_R]=...` `wfilters('bior3.1');`
Reverse biorthogonal	`FilterOrder='[3/1]';`	`[Lo_D,Hi_D,Lo_R,Hi_R]=...` `wfilters('rbior3.1');`
Discrete Meyer	N/A	`[Lo_D,Hi_D]=wfilters('dmey');`

`CustomLowpassFilter` — Lowpass FIR filter coefficients

`[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in powers of z^{-1}. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomHighpassFilter` property. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

Dependencies

This property applies when you set the `Filter` property to `Custom`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CustomHighpassFilter` — Highpass FIR filter coefficients

`[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]` (default) | row vector

Specify a vector of highpass FIR filter coefficients, in powers of z^{-1}. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

Dependencies

This property applies when you set the `Filter` property to `Custom`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WaveletOrder` — Order for orthogonal wavelets

2 (default) | positive integer

Specify the order of the wavelet selected in the `Filter` property.

Dependencies

This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

`FilterOrder` — Analysis and synthesis filter orders for biorthogonal filters

`1 / 1` (default) | `1 / 3` | `1 / 5` | `2 / 2` | `2 / 4` | `2 / 6` | `2 / 8` | `3 / 1` | `3 / 3` | `3 / 5` | `3 / 7` | `3 / 9` | `4 / 4` | `5 / 5` | `6 / 8`

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as `1 / 1`, `1 / 3`, `1 / 5`, `2 / 2`, `2 / 4`, `2 / 6`, `2 / 8`, `3 / 1`, `3 / 3`, `3 / 5`, `3 / 7`, `3 / 9`, `4 / 4`, `5 / 5`, or `6 / 8`. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter.

Dependencies

This property applies when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`.

Data Types: `char`

`NumLevels` — Number of filter bank levels used in analysis (decomposition)

2 (default) | integer greater than or equal to 1

Specify the number of filter bank analysis levels a positive integer greater than or equal to 1. A level-N asymmetric structure produces $N+1$ output subbands. A level-N symmetric structure produces 2^N output subbands. The size of the input along the first dimension must be a multiple of 2^N, where N is the number of levels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TreeStructure` — Structure of filter bank

`Asymmetric` (default) | `Symmetric`

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the

analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension and N is the value of the `NumLevels` property. When this property is `Asymmetric`, the output has $N+1$ subbands. The following equation gives the length of the output in the kth subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \le k \le N \\ \frac{M}{2^N} & k = N+1 \end{cases}$$

Usage

Syntax

```
y = dydan(x)
```

Description

`y = dydan(x)` computes the subband decomposition of the input `x` and outputs the dyadic subband decomposition in `y` as a single concatenated column vector or matrix of coefficients.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. Each column of `x` is treated as an independent input, and the number of rows of `x` must be a multiple of 2^N, where N is the number of levels specified by the `NumLevels` property.

Data Types: `single` | `double`

Output Arguments

y — Dyadic subband decomposition output

column vector | matrix

Dyadic subband decomposition output, returned as a column vector or a matrix. The elements of `y` are ordered with the highest-frequency subband first followed by subbands in decreasing frequency.

When `TreeStructure` is set to `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension, and N is the value of the `NumLevels` property. When `TreeStructure` is set to `Asymmetric`, the output has $N+1$ subbands. The following equation gives the length of the output in the kth subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \le k \le N \\ \frac{M}{2^N} & k = N+1 \end{cases}$$

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a `haar` wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);
```

Subband outputs.

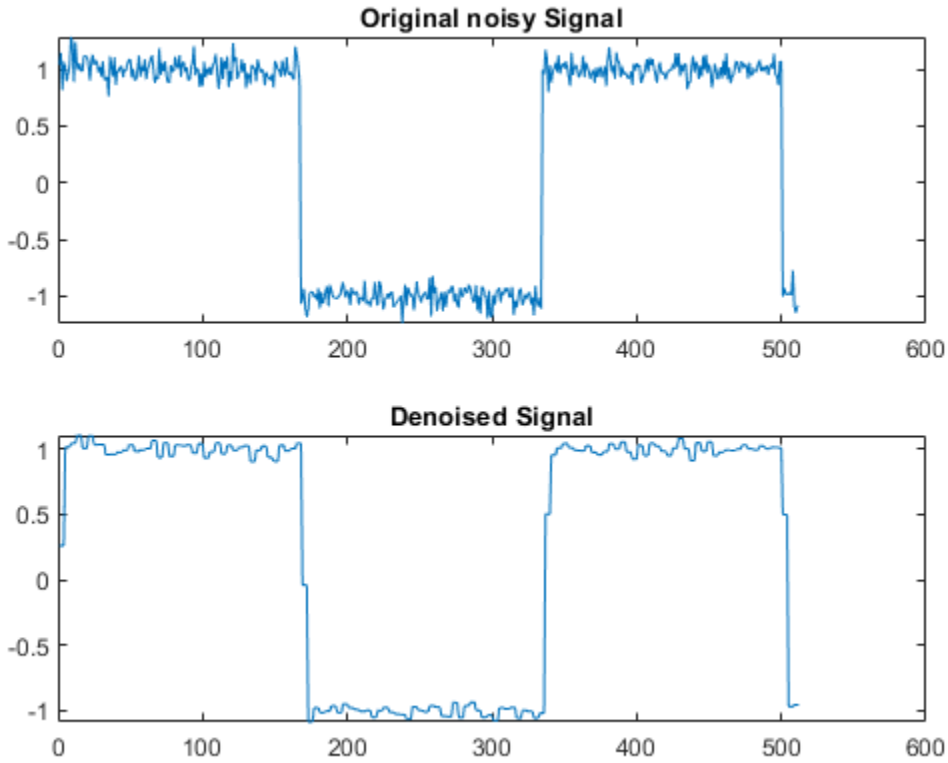
```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
    zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```



Subband Ordering For Asymmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Sampling frequency 1 kHz input length 1024

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

Default asymmetric structure with order 3 extremal phase wavelet

```
dydan = dsp.DyadicAnalysisFilterBank;
Y = dydan(xn);
```

Level 2 yields 3 subbands (two detail-one approximation) Nyquist frequency is 500 Hz

```
D1 = Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

Subband Ordering For Symmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Sampling frequency 1 kHz input length 1024.

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

```
dydan = dsp.DyadicAnalysisFilterBank('TreeStructure',...
'Symmetric');
Y = dydan(xn);
D1 = Y(1:256); % subband approx. [375,500] Hz
D2 = Y(257:512); % subband approx. [250,375] Hz
D3 = Y(513:768); % subband approx. [125,250] Hz
Approx = Y(769:1024); % subband approx. [0, 125] Hz
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Analysis Filter Bank block reference page. The object properties correspond to the block parameters, except:
The dyadic analysis filter bank object always concatenates the subbands into a single column vector for a column vector input, or into the columns of a matrix for a matrix input. This behavior corresponds to the block's behavior when you set the **Output** parameter to `Single port`.

System Objects
`dsp.DyadicSynthesisFilterBank` | `dsp.SubbandAnalysisFilter`

Introduced in R2012a

dsp.DyadicSynthesisFilterBank

Package: `dsp`

Reconstruct signals from subbands

Description

The `dsp.DyadicSynthesisFilterBank` System object reconstructs signals from subbands with smaller bandwidths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

1. Create the `dsp.DyadicSynthesisFilterBank` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
dydsyn = dsp.DyadicSynthesisFilterBank
dydsyn = dsp.DyadicSynthesisFilterBank(Name,Value)
```

Description

`dydsyn = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `dydsyn`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`dydsyn = dsp.DyadicSynthesisFilterBank(Name,Value)` returns a dyadic synthesis filter bank object, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Filter` — Type of filter used in filter bank

`Custom` (default) | `Biorthogonal` | `Coiflets` | `Daubechies` | `Discrete Meyer` | `Haar` | `Reverse Biorthogonal` | `Symlets`

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. If you set this property to `Custom`, the `CustomLowpassFilter` and `CustomHighpassFilter` properties specify the filter coefficients. Otherwise, the object uses the `wfilters` function to construct the filters. Depending on the filter, the `WaveletOrder` or "FilterOrder" on page 4-0 property might apply. For a list of the supported wavelets, see the following table.

Filter	Sample Setting for Related Filter Specification Properties	Corresponding Wavelet Toolbox Function Syntax
`Haar`	None	`wfilters('haar')`
`Daubechies`	`H.WaveletOrder = 4`	`wfilters('db4')`
`Symlets`	`H.WaveletOrder = 3`	`wfilters('sym3')`
`Coiflets`	`H.WaveletOrder = 1`	`wfilters('coif1')`
`Biorthogonal`	`H.FilterOrder = '[3/1]'`	`wfilters('bior3.1')`
`Reverse Biorthogonal`	`H.FilterOrder = '[3/1]'`	`wfilters('rbior3.1')`
`Discrete Meyer`	None	`wfilters('dmey')`

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the `CustomLowpassFilter` and `CustomHighpassFilter` properties to specify lowpass and highpass FIR filters.

`CustomLowpassFilter` — Lowpass FIR filter coefficients

`[0.3327 0.8069 0.4599 -0.1350 -0.0854 0.0352]` (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomHighpassFilter` property. To perfectly reconstruct a signal decomposed by the `dsp.DyadicAnalysisFilterBank` object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

Dependencies

This property applies when you set the `Filter` property to `Custom`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CustomHighpassFilter` — Highpass FIR filter coefficients

`[0.0352 0.0854 -0.1350 -0.4599 0.8069 -0.3327]` (default) | row vector

Specify a vector of highpass FIR filter coefficients, in descending powers of z. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. To perfectly reconstruct a signal decomposed by the `dsp.DyadicAnalysisFilterBank` object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

Dependencies

This property applies when you set the `Filter` property to `Custom`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WaveletOrder` — Wavelet order

2 (default) | positive integer

Specify the order of the wavelet selected in the `Filter` property.

Dependencies

This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

`FilterOrder` — Wavelet order for synthesis filter stage

`1 / 1` (default) | `1 / 3` | `1 / 5` | `2 / 2` | `2 / 4` | `2 / 6` | `2 / 8` | `3 / 1` | `3 / 3` | `3 / 5` | `3 / 7` | `3 / 9` | `4 / 4` | `5 / 5` | `6 / 8`

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.
- Fifth order: `'[5/5]'`.
- Sixth order: `'[6/8]'`.

Dependencies

This property applies when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`.

Data Types: `char`

`NumLevels` — Number of filter bank levels

2 (default) | integer greater than or equal to 1

Specify the number of filter bank levels as a scalar integer. An N-level asymmetric structure has $N + 1$ input subbands, and an N-level symmetric structure has 2^N input subbands.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TreeStructure` — Structure of filter bank

`Asymmetric` (default) | `Symmetric`

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level.

Usage

Syntax

```
y = dydsyn(x)
```

Description

`y = dydsyn(x)` reconstructs the concatenated subband input `x` to output `y`. Each column of input `x` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. Each column of input `x` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of `x` must be a multiple of 2^N, where N is the value of the `NumLevels` property.

Data Types: `single` | `double`

Output Arguments

y — Reconstructed signal

column vector | matrix

Reconstructed signal, returned as a column vector or a matrix.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a `haar` wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);
```

Subband outputs.

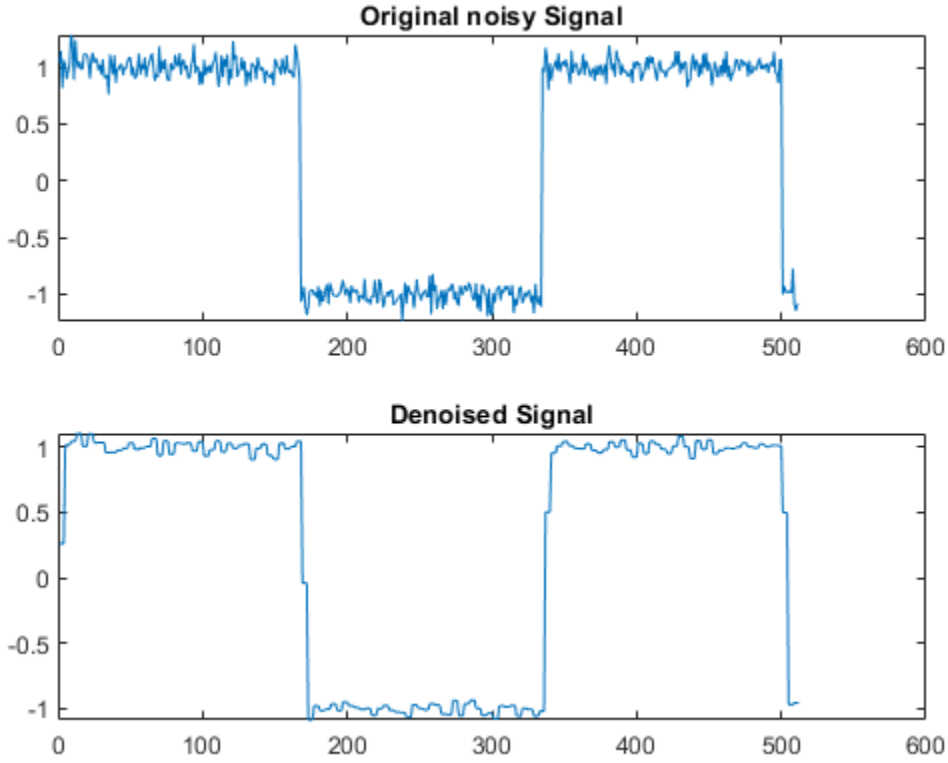
```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
    zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Synthesis Filter Bank block reference page. The object properties correspond to the block parameters, except:
The object only receives data as a vector or matrix of concatenated subbands.

Introduced in R2012a

dsp.FarrowRateConverter

Package: `dsp`

Polynomial sample rate converter with arbitrary conversion factor

Description

The `dsp.FarrowRateConverter` System object implements a polynomial-fit sample rate conversion filter using a Farrow structure. You can use this object to convert the sample rate of a signal up or down by an arbitrary factor. This object supports fixed-point operations.

To convert the sample rate of a signal:

1. Create the `dsp.FarrowRateConverter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
frc = dsp.FarrowRateConverter
frc = dsp.FarrowRateConverter(Name,Value)
frc = dsp.FarrowRateConverter(fsIn,fsOut,tol,np)
```

Description

`frc = dsp.FarrowRateConverter` creates a polynomial filter-based sample rate converter System object, `frc`. For each channel of an input signal, `frc` converts the input sample rate to the output sample rate.

`frc = dsp.FarrowRateConverter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `frc = dsp.FarrowRateConverter('Specification','Coefficients','Coefficients',[1 2; 3 4])` returns a filter that converts from 44.1 kHz to 48 kHz using custom coefficients that implement a 2nd-order polynomial filter.

`frc = dsp.FarrowRateConverter(fsIn,fsOut,tol,np)` returns a sample rate converter System object, `frc`, with InputSampleRate property set to `fsIn`, OutputSampleRate property set to `fsOut`, OutputRateTolerance property set to `tol`, and PolynomialOrder property set to `np`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

Filter Properties

`InputSampleRate` — Sample rate of input signal

`44100` (default) | positive scalar in Hz

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OutputSampleRate` — Sample rate of output signal

`48000` (default) | positive scalar in Hz

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate can represent an upsample or downsample of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`OutputRateTolerance` — Maximum tolerance for output sample rate

`0` (default) | positive scalar

Maximum tolerance for the output sample rate, specified as a positive scalar from 0 through 0.5, inclusive.

The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as `0.01`, then the actual output sample rate is in the range `OutputSampleRate` ± 1%. This flexibility often enables a simpler filter design.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Specification` — Method for specifying filter coefficients

`'Polynomial order'` (default) | `'Coefficients'`

Method for specifying filter coefficients for the interpolator filter, specified as one of the following:

- `'Polynomial order'` — Use the `PolynomialOrder` property to specify the order of the Lagrange-interpolation-filter polynomial. The object calculates coefficients that meet the rate and tolerance properties.
- `'Coefficients'` — Use the `Coefficients` property to specify the polynomial coefficients directly.

`PolynomialOrder` — Order of Lagrange-interpolation-filter polynomial

3 (default) | positive integer less than or equal to 4

Order of the Lagrange-interpolation-filter polynomial, specified as a positive integer less than or equal to 4. The object calculates coefficients that meet the rate and tolerance properties.

Dependencies

This property applies only when you set `Specification` to `'Polynomial order'`.

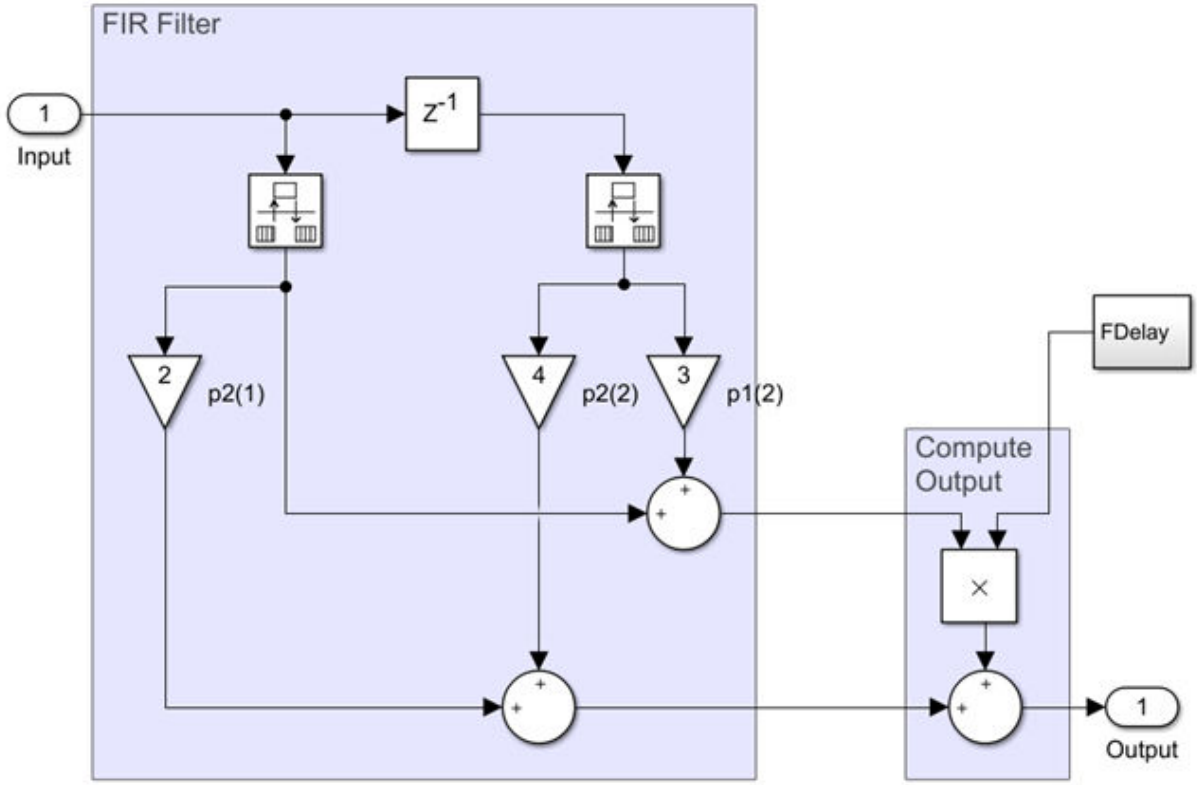
Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Coefficients` — Filter polynomial coefficients

`[-1 1; 1 0]` (default) | real-valued square matrix

Filter polynomial coefficients, specified as a real-valued *M*-by-*M* matrix, where *M* is the polynomial order.

The diagram shows the signal flow graph for a `dsp.FarrowRateConverter` object with coefficients set to `[1 2; 3 4]`.



Each branch of the FIR filter corresponds to a row of the coefficient matrix.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding method for fixed-point operations, specified as a character vector. For more information on the rounding methods see “Rounding Modes”.

`OverflowAction` — Overflow action for fixed-point operations
`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as either `'Wrap'` or `'Saturate'`. For more details on the overflow actions, see “Overflow Handling”.

`CoefficientsDataType` — Data type of filter coefficients
`numerictype(1,16)` (default) | `numerictype` object

Data type of the filter coefficients, specified as a signed `numerictype` object. The default data type is a signed, 16-bit `numerictype` object. You must specify a `numerictype` object without specific binary-point scaling. To maximize precision, the object determines the fraction length of this data type based on the coefficient values.

`FractionalDelayDataType` — Data type of fractional delay
`numerictype(0,8)` (default) | `numerictype` object

Data type of the fractional delay, specified as an unsigned `numerictype` object. The default data type is an unsigned, 8-bit `numerictype` object. You must specify a `numerictype` object without specific binary-point scaling. To maximize precision, the object determines the fraction length of this data type based on the fractional delay values.

`MultiplicandDataType` — Data type of multiplicand
`numerictype(1,16,13)` (default) | `numerictype` object

Data type of the multiplicand, specified as a signed `numerictype` object. The default data type is a signed 16-bit `numerictype` object with 13-bit fraction length. You must specify a `numerictype` object that has a specific binary point scaling.

`OutputDataType` — Data type of output
`'Same word length as input'` (default) | `'Same as accumulator'` | `numerictype` object

Data type of the output, specified as one of the following:

- `'Same word length as input'` — Output word length and fraction length are the same as the input.
- `'Same as accumulator'` — Output word length and fraction length are the same as the accumulator.
- `numerictype` object — Signed fixed-point output data type. If you do not specify a fraction length, the object computes the fraction length based on the input range. The object preserves the dynamic range of the input.

Usage

Syntax

```
y = frc(x)
```

Description

`y = frc(x)` resamples input `x` to create output `y` according to the rate conversion defined by `frc`.

Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix. The row length of `x` must be a multiple of the overall decimation factor. Each column of `x` is treated as a separate channel.

Output Arguments

y — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FarrowRateConverter

getPolynomialCoefficients	Get polynomial coefficients of farrow rate conversion filter
getActualOutputRate	Get actual output rate
getRateChangeFactors	Get overall interpolation and decimation factors
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Filter Analysis

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost for implementing filter System objects

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Upsample an Audio Signal Using dsp.FarrowRateConverter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `dsp.AudioFileWriter` System objects are not supported in MATLAB Online.

Create a `dsp.FarrowRateConverter` System object™ to convert an audio signal from 44.1 kHz to 96 kHz. Set the polynomial order for the filter.

```
fs1 = 44.1e3;
fs2 = 96e3;
LagrangeOrder = 2; % 1 = linear interpolation
frc = dsp.FarrowRateConverter('InputSampleRate',fs1,...
                              'OutputSampleRate',fs2,...
                              'PolynomialOrder',LagrangeOrder);
ar = dsp.AudioFileReader('guitar10min.ogg','SamplesPerFrame',14700);
aw = dsp.AudioFileWriter('guitar10min_96kHz.wav','SampleRate',fs2);
```

Check the resulting interpolation and decimation factors.

```
[interp,decim] = getRateChangeFactors(frc)
```

```
interp = 320
```

```
decim = 147
```

Display the polynomial that the object uses to fit the input samples.

```
coeffs = getPolynomialCoefficients(frc)
```

```
coeffs = 3×3

    0.5000   -0.5000         0
   -1.0000         0    1.0000
    0.5000    0.5000         0
```

Convert 100 frames of the audio signal. Write the result to a file.

```
for n = 1:1:100
   x = ar();
   y = frc(x);
   aw(y);
end
```

Release the `AudioFileWriter` System object™ to complete creation of the output file.

```
release(aw)
release(ar)
```

Plot the input and output signals of the 100th frame of data. Delay the input to compensate for the latency of the filter.

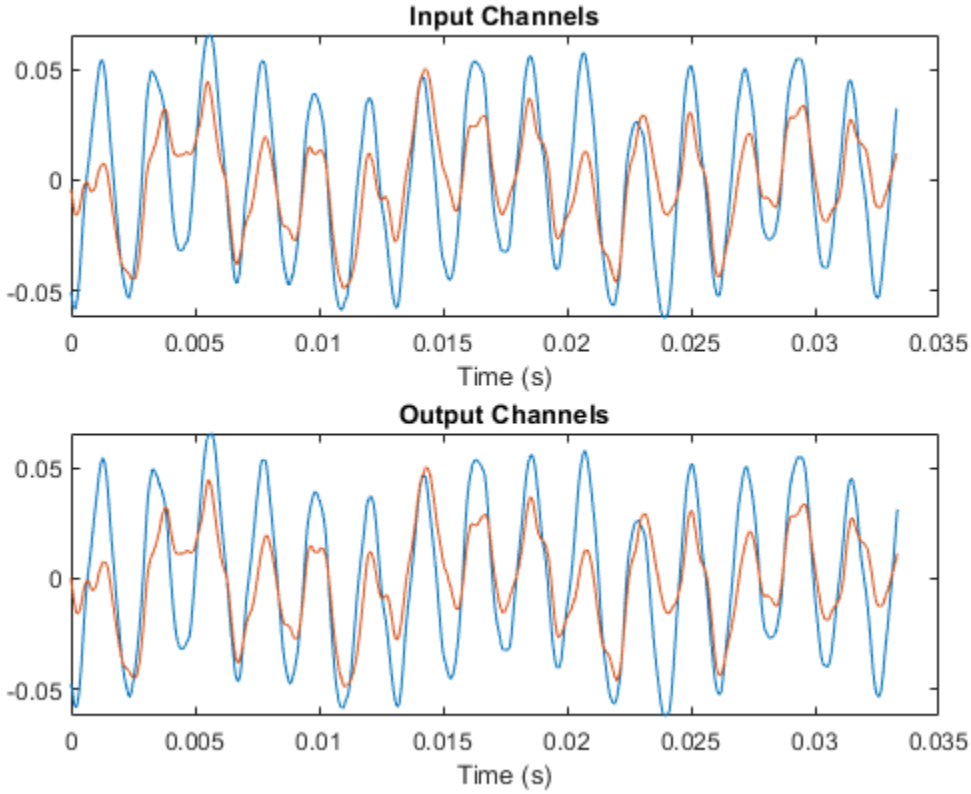
```
t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

delay = ceil((LagrangeOrder+1)/2)/fs1;
el1 = 1:length(t1)-delay;
el2 = 1:length(t2);
el2(1:delay) = [];

figure

subplot(2,1,1)
plot(t1(1:length(el1)),x(el1,1))
hold on
plot(t1(1:length(el1)),x(el1,2))
xlabel('Time (s)')
title('Input Channels')

subplot(2,1,2)
plot(t2(1:length(el2)),y(el2,1))
hold on
plot(t2(1:length(el2)),y(el2,2))
xlabel('Time (s)')
title('Output Channels')
```



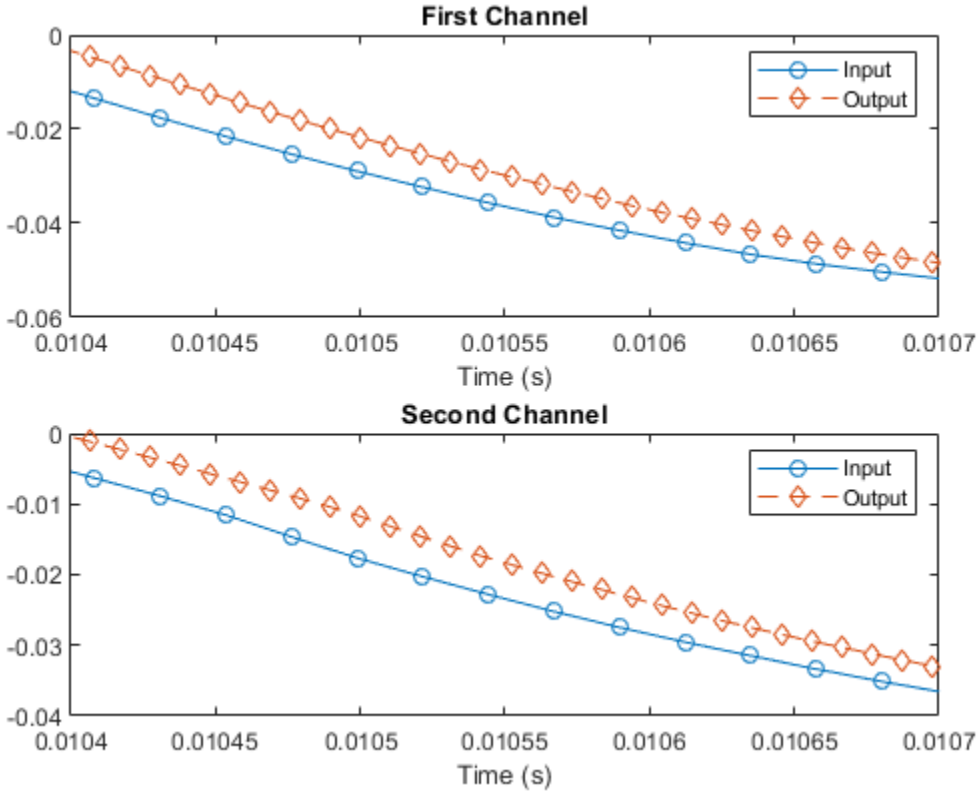
Zoom in to see the difference in sample rates.

```
figure

subplot(2,1,1)
plot(t1(1:length(el1)),x(el1,1),'o-')
hold on
plot(t2(1:length(el2)),y(el2,1),'d--')
xlim([0.0104 0.0107])
title('First Channel')
xlabel('Time (s)')
legend('Input','Output')

subplot(2,1,2)
```

```
plot(t1(1:length(el1)),x(el1,2),'o-')
hold on
plot(t2(1:length(el2)),y(el2,2),'d--')
xlim([0.0104 0.0107])
xlabel('Time (s)')
title('Second Channel')
legend('Input','Output')
```



Reduce Input Size Restriction by Adjusting Tolerance

Create a `dsp.FarrowRateConverter` System object™ with 0% tolerance. The output rate is equal to the `OutputSampleRate property`. The input size must be a multiple of the decimation factor, `M`. In this case M is 320.

```
frc = dsp.FarrowRateConverter('InputSampleRate',96e3,'OutputSampleRate',44.1e3);
FsOut = getActualOutputRate(frc)
```

```
FsOut = 44100
```

```
[L,M] = getRateChangeFactors(frc)
```

```
L = 147
```

```
M = 320
```

Allow a 1% tolerance on the output rate and observe the difference in decimation factor.

```
frc.OutputRateTolerance = 0.01;
FsOut2 = getActualOutputRate(frc)
```

```
FsOut2 = 4.4308e+04
```

```
[L2,M2] = getRateChangeFactors(frc)
```

```
L2 = 6
```

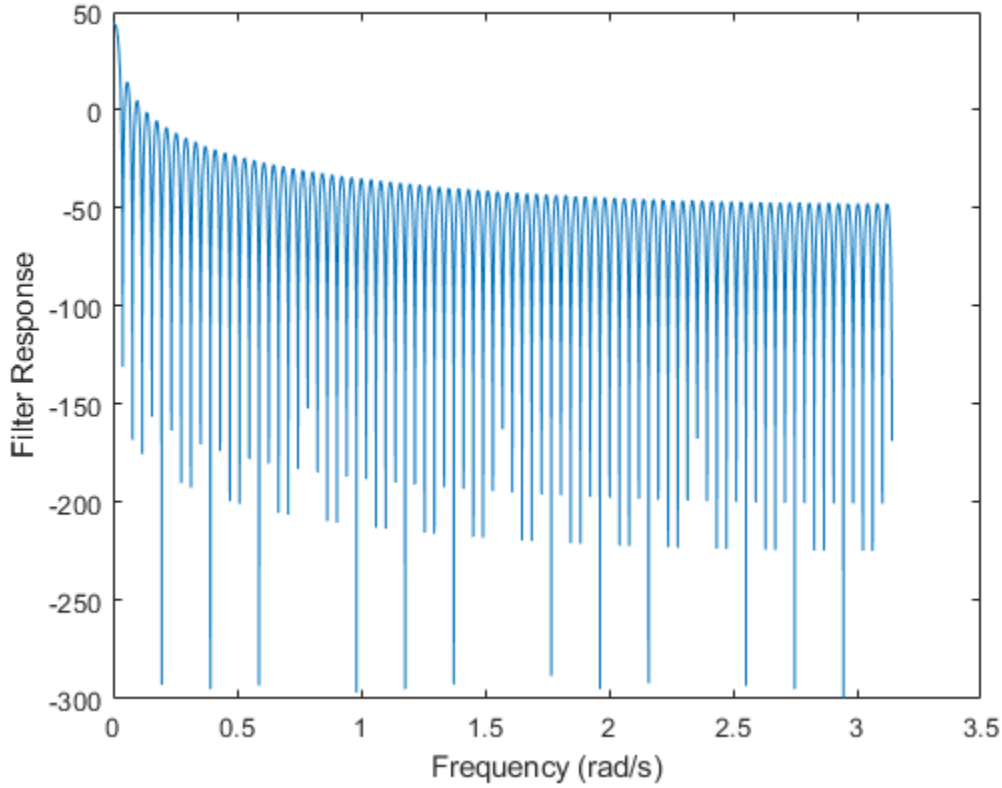
```
M2 = 13
```

The decimation factor is now only 13. The lower the decimation factor, the more flexibility in input size. The output rate is within the range `OutputSampleRate` ± 1%.

Frequency Response of dsp.FarrowRateConverter

Create a `dsp.FarrowRateConverter` System object™ with default properties. Compute and display the frequency response.

```
frc = dsp.FarrowRateConverter;
[h,f] = freqz(frc);
plot(f,20*log10(abs(h)))
ylabel('Filter Response')
xlabel('Frequency (rad/s)')
```



Determine Computational Cost of dsp.FarrowRateConverter

Create a dsp.FarrowRateConverter System object™ with default values. Determine its computational cost: the number of coefficients, number of states, multiplications per input sample, and additions per input sample.

```
frc = dsp.FarrowRateConverter;
cst = cost(frc)
```

```
cst = struct with fields:
                  NumCoefficients: 16
                       NumStates: 3
    MultiplicationsPerInputSample: 13.0612
```

```
          AdditionsPerInputSample: 11.9728
```

Repeat the computation, allowing for a 10% tolerance in the output sample rate.

```
frc.OutputRateTolerance = 0.1;
ctl = cost(frc)
```

```
ctl = struct with fields:
                  NumCoefficients: 16
                        NumStates: 3
    MultiplicationsPerInputSample: 12
          AdditionsPerInputSample: 11
```

Algorithms

Farrow filters implement piecewise polynomial interpolation using Horner's rule to compute samples from the polynomial. The polynomial coefficients used to fit the input samples correspond to the Lagrange interpolation coefficients.

Once a polynomial is fitted to the input data, the value of the polynomial can be calculated at any point. Therefore, a polynomial filter enables interpolation at arbitrary locations between input samples.

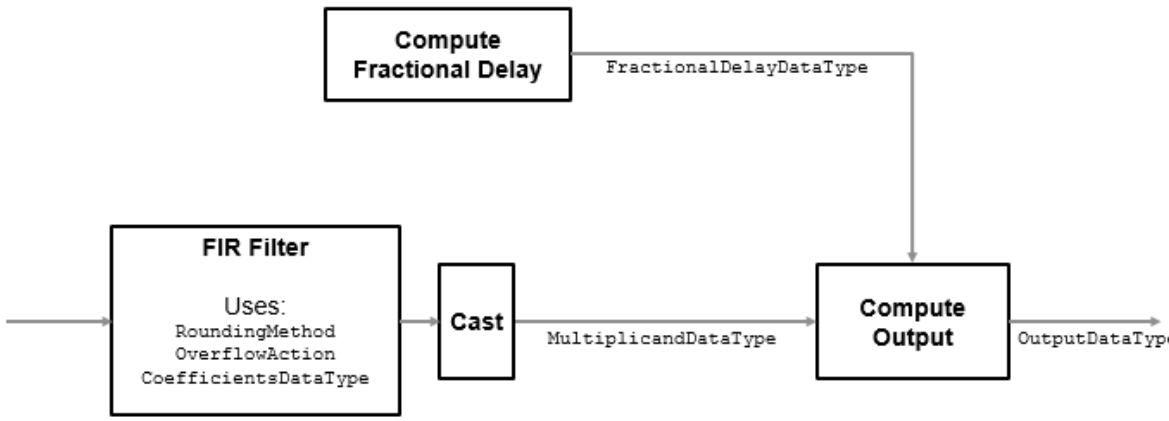
You can use a polynomial of any order to fit to the existing samples. However, since large-order polynomials frequently oscillate, polynomials of order 1, 2, 3, or 4 are used in practice.

The block computes interpolated values at the desired locations by varying only the fractional delay, μ. This value is the interval between the previous input sample and the current output sample. All filter coefficients remain constant.

- The input samples are filtered using $M + 1$ FIR filters, where M is the polynomial order.
- The outputs of these filters are multiplied by the fractional delay, μ.
- The output is the sum of the multiplication results.

The diagram shows the data types that the `dsp.FarrowRateConverter` object uses for fixed-point signals and floating-point signals. You can specify these data types using the

properties of the object, see “Fixed-Point Properties” on page 4-0 . If the input is floating point, all data types in filter are the same as the input data type, `single` or `double`.



If the input is fixed point, the FIR filter defines internal data types using the `RoundingMode`, `OverflowMode`, and `CoefficientsDataType` properties. The accumulators and products within the FIR filter use full precision data types. The object casts the output of the FIR filter to `MultiplicandDataType`.

dsp.FastTransversalFilter

Package: dsp

Fast transversal least-squares FIR adaptive filter

Description

The dsp.FastTransversalFilter computes output, error and coefficients using a fast transversal least-squares FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Create the dsp.FastTransversalFilter object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
ftf = dsp.FastTransversalFilter
ftf = dsp.FastTransversalFilter(len)
ftf = dsp.FastTransversalFilter(Name,Value)
```

Description

ftf = dsp.FastTransversalFilter returns a System object, ftf, which is a fast transversal, least-squares FIR adaptive filter. This System object computes the filtered output and the filter error for a given input and desired signal.

ftf = dsp.FastTransversalFilter(len) returns a dsp.FastTrasversalFilter System object with the Length property set to len.

`ftf = dsp.FastTransversalFilter(Name,Value)` returns a `dsp.FastTransversalFilter` System object with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Method` — Method to calculate filter coefficients

`'Fast transversal least-squares'` (default) | `'Sliding-window fast transversal least-squares'`

Specify the method used to calculate filter coefficients as either `'Fast transversal least-squares'` or `'Sliding-window fast transversal least-squares'`. For algorithms used to implement these two different methods, refer to [1]. This property is nontunable.

`Length` — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value.

Data Types: `double`

`SlidingWindowBlockLength` — Width of sliding window

32 (default) | positive integer

Specify the width of the sliding window as a positive integer value greater than or equal to the `Length` property value. The default vale is the value of the `Length` property.

Dependencies

This property applies only if the `Method` property is set to `'Sliding-window fast transversal least-squares'`.

Data Types: `double`

`ForgettingFactor` — Fast transversal filter forgetting factor

`1` (default) | positive scalar

Specify the fast transversal filter forgetting factor as a positive scalar in the range (0,1]. Setting this value to 1 denotes infinite memory while filter adaptation. Setting this property value to 1 denotes infinite memory while adapting to find the new filter. For best results, set this property to a value that lies in the range `[1-0.5/L,1]`, where `L` is the Length property value.

Tunable: Yes

Dependencies

This property applies only if the `Method` property is set to `'Fast transversal least-squares'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`InitialPredictionErrorPower` — Initial prediction error power

`10` (default) | positive scalar

Specify the initial value of the forward and backward prediction error vectors as a positive numeric scalar. This scalar should be sufficiently large to maintain stability and prevent an excessive number of Kalman gain rescues.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialConversionFactor` — Initial conversion factor (gamma)

`1` (default) | scalar | 2-element row vector

Specify the initial value of the conversion factor of the fast transversal filter.

The value of this property depends on the `Method` property. If `Method` is set to:

- `'Fast transversal least-squares'` –– This property must be a positive numeric value less than or equal to `1`
- `'Sliding-window fast transversal least-squares'` –– This property must be a two-element numeric vector. The first element of this vector must lie within the

range `[0,1]`, and the second element must be less than or equal to `-1`. In this case, the default value is `[1,-1]`.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`InitialCoefficients` — Initial coefficients of filter
`0` (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LockCoefficients` — Locked status of coefficient updates
`false` (default) | `true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Tunable: Yes

Usage

Syntax

```
[y,err] = ftf(x,d)
```

Description

`[y,err] = ftf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the fast transversal filter. The input, `x`, and the desired signal, `d` must have the same size and data type.

The data input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The fast transversal filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible. You can access the current filter weights by calling `ftf.Coefficients`, where `ftf` is the fast transversal filter object.

The input and the desired signal must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge toward optimal filter weights that produce an output signal that matches closely with the desired signal.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FastTransversalFilter`

msesim	Estimated mean squared error for adaptive filters

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

System Identification Using Fast Transversal Filter

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
ftf1 = dsp.FastTransversalFilter(11,'ForgettingFactor',0.99);
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,.25);
x = randn(1000,1);
d = filt(x) + 0.01*randn(1000,1);
[y,e] = ftf1(x,d);
w = ftf1.Coefficients;
```

```
subplot(2,1,1);
plot(1:1000,[d,y,e])
title('System Identification of an FIR filter');
legend('Desired','Output','Error');
xlabel('time index');
ylabel('signal value');
subplot(2,1,2);
stem([filt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #');
ylabel('coefficient value');
```

Introduced in R2013b

dsp.FFT

Package: `dsp`

Discrete Fourier transform

Description

The `dsp.FFT` System object computes the discrete Fourier transform (DFT) of an input using fast Fourier transform (FFT). The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen from FFTW [1] , [2]

To compute the DFT of an input:

1. Create the `dsp.FFT` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
ft = dsp.FFT
ft = dsp.FFT(Name,Value)
```

Description

`ft = dsp.FFT` returns a `FFT` object, `ft`, that computes the DFT of an *N*-D array. For column vectors or multidimensional arrays, the `FFT` object computes the DFT along the first dimension. If the input is a row vector, the `FFT` object computes a row of single-sample DFTs and issues a warning.

`ft = dsp.FFT(Name,Value)` returns a `FFT` object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`FFTImplementation` — FFT implementation
`Auto` (default) | `Radix-2` | `FFTW`

Specify the implementation used for the FFT as one of `Auto`, `Radix-2`, or `FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

`BitReversedOutput` — Order of output elements relative to input elements
`false` (default) | `true`

Designate order of output channel elements relative to order of input elements. Set this property to `true` to output the frequency indices in bit-reversed order. The default is `false`, which corresponds to a linear ordering of frequency indices.

`Normalize` — Divide butterfly outputs by two
`false` (default) | `true`

Set this property to `true` if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is `false` with no scaling.

`FFTLengthSource` — Source of FFT length
`Auto` (default) | `Property`

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal.

`FFTLength` — FFT length
`64` (default) | integer

FFT length, specified as an integer greater than or equal to 2.

This property must be a power of two if any of these conditions apply:

- The input is a fixed-point data type.
- The BitReversedOutput property is `true`.
- The FFTImplementation property is `Radix-2`.

Dependencies

This property applies when you set the `FFTLengthSource` property to `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WrapInput` — Boolean value of wrapping or truncating input
`true` (default) | `false`

Wrap input data when FFT length is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is set to false, truncation of the input data to the FFT length occurs before the FFT operation.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

`SineTableDataType` — Sine table word and fraction lengths
`Same word length as input` (default) | `Custom`

Specify the sine table data type as `Same word length as input` or `Custom`.

`CustomSineTableDataType` — Sine table word and fraction lengths
`numerictype([],16)` (default) | numerictype

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `SineTableDataType` property to `Custom`.

`ProductDataType` — Product word and fraction lengths
`Full precision` (default) | `Same as input` | `Custom`

Specify the product data type as `Full precision`, `Same as input`, or `Custom`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype([],32,30)` (default) | numerictype

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

`AccumulatorDataType` — Accumulator word and fraction lengths
`Full precision` (default) | `Same as input` | `Same as product` | `Custom`

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype([],32,30)` (default) | numerictype

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

`OutputDataType` — Output word and fraction lengths
`Full precision` (default) | `Same as input` | `Custom`

Specify the output data type as one of `Full precision`, `Same as input`, `Custom`.

`CustomOutputDataType` — Output word and fraction lengths
`numerictype([],16,15)` (default) | numerictype

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the "OutputDataType" on page 4-0 property to `Custom`.

Usage

Syntax

```
y = ft(x)
```

Description

`y = ft(x)` computes the DFT, `y`, of the input `x` along the first dimension of `x`.

Input Arguments

`x` — Time-domain input signal
vector | matrix | *N*-D array

Time-domain input signal, specified as a vector, matrix, or *N*-D array.

When the `FFTLengthSource` property is set to `'Auto'`, the length of `x` along the first dimension must be a positive integer power of two. This length is also the FFT length. When the `FFTLengthSource` property is `'Property'`, the value you specify in `FFTLength` property must be a positive integer power of two.

Variable-size input signals are only supported when the `FFTLengthSource` property is set to `'Auto'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Discrete Fourier transform of input signal

vector | matrix | *N*-D array

Discrete Fourier transform of input signal, returned as a vector, matrix, or an *N*-D array. When `FFTLengthSource` property is set to `'Auto'`, the FFT length is same as the number of rows in the input signal. When `FFTLengthSource` property is set to `'Property'`, the FFT length is specified through the `FFTLength` property.

To support non-power-of-two transform lengths with variable-size data, set the `FFTImplementation` property to `'FFTW'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Single-Sided Amplitude Spectrum of Signal

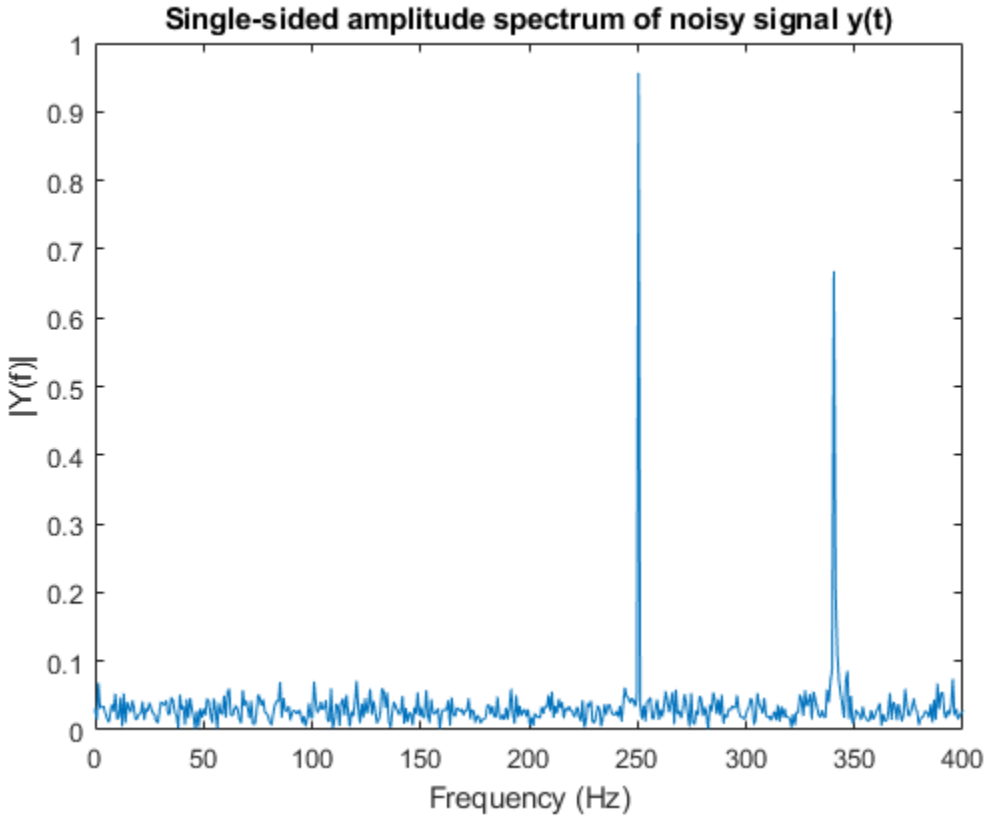
Find frequency components of a signal in additive noise.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
Fs = 800; L = 1000;
t = (0:L-1)'/Fs;
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);
y = x + .5*randn(size(x)); % noisy signal
ft = dsp.FFT('FFTLengthSource','Property', ...
    'FFTLength',1024);
Y = ft(y);
```

Plot the single-sided amplitude spectrum

```
plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512)/1024))
title('Single-sided amplitude spectrum of noisy signal y(t)')
xlabel('Frequency (Hz)'); ylabel('|Y(f)|')
```



Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

`Note:` If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj(x))`.

Consider a time-domain signal $x[n]$, which is defined over the finite time interval $0 \le n \le N-1$. The energy of the signal $x[n]$ is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT coefficients, $X[k]$, are considered signal values in the frequency domain. The energy of the signal $x[n]$ in the frequency-domain is therefore the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N}\sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N}\sum_{k=0}^{N-1} |X[k]|^2$$

Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLengthSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2, so select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,'PhaseOffset',10,...
    'SampleRate',44100,'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW','ConjugateSymmetricInput',true);
rng(1);
```

Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients that constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
```

```
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort(((1/L)*FFTCoeffMagSq),1,'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReconstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
```

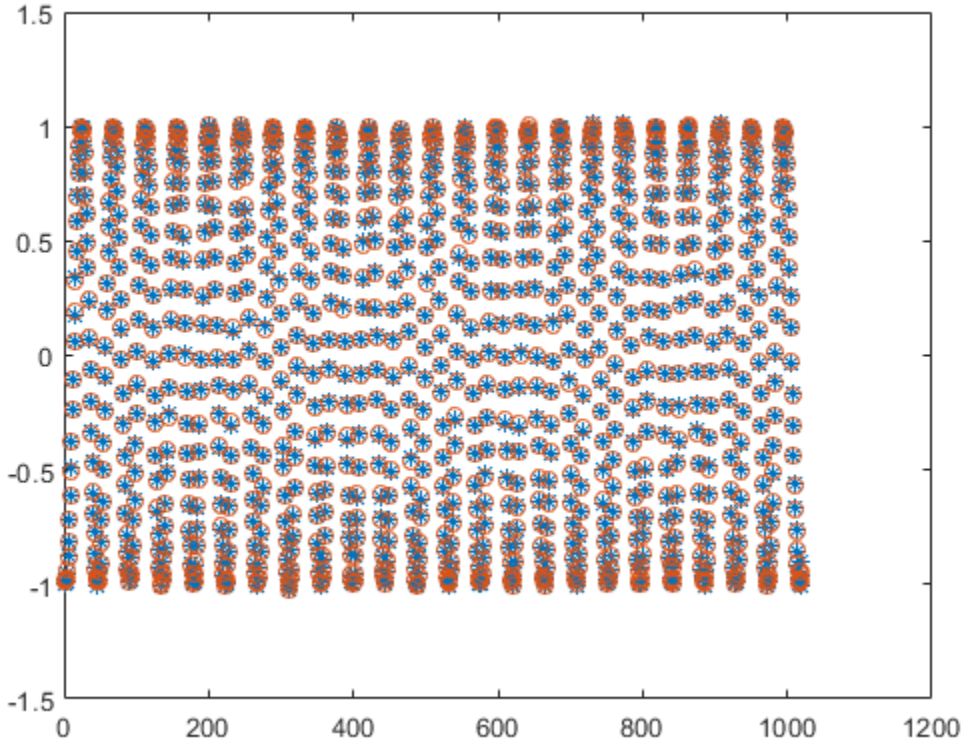
```
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input,'*');
hold on;
plot(ReconstrSignal,'o');
hold off;
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:

  - `FFTImplementation` is set to `'FFTW'`.
  - `FFTImplementation` is set to `'Auto'`, `FFTLengthSource` is set to `'Property'`, and `FFTLength` is not a power of two.

  Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

System Objects
`dsp.IFFT`

Introduced in R2012a

dsp.FilterCascade

Package: `dsp`

Create cascade of filter System objects

Description

The `dsp.FilterCascade` object creates a multistage System object that enables cascading of filter System objects, delays, and scalar gains. This object operates similar to the `cascade` function. However, the `cascade` function does not support delay as a filter stage.

You can pass the `dsp.FilterCascade` System object as a stage to another `dsp.FilterCascade` System object. You can also pass `dsp.FilterCascade` System object as an input to the `cascade` function.

When you call the object, the size, data type, and complexity of the input signal must be supported by all of the stages in the filter cascade. This object supports variable-size signals if the filter stages within the object support variable-size signals.

To filter a signal with a cascade of filters:

1. Create the `dsp.FilterCascade` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Alternatively, you can generate a MATLAB function from the filter cascade object, and call that function to filter a signal. The generated function supports C/C++ code generation. For more details, see the `generateFilteringCode` function.

Creation

Syntax

```
FC = dsp.FilterCascade
FC = dsp.FilterCascade(filt1,filt2,...,filtn)
```

Description

`FC = dsp.FilterCascade` returns a System object, `FC` that has a single stage, a `dsp.FIRFilter` System object with default properties.

`FC = dsp.FilterCascade(filt1,filt2,...,filtn)` returns a multistage System object, `FC`, with the first stage set to `filt1`, the second stage set to `filt2`, and so on. Each stage can be a filter System object, a `dsp.FilterCascade` System object, a `dsp.Delay` System object, or a scalar gain value.

For example, create a filter cascade that includes a lowpass filter, a highpass filter, and a gain stage.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...
                           'PassbandFrequency',12000);
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...
                            'PassbandFrequency',8000);
gain = 2;
bpFilt = dsp.FilterCascade(lpFilt,hpFilt,2);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

Stage*i* — Filter stage
`dsp.FIRFilter` System object with default properties (default) | filter System object | delay System object | scalar gain value

Filter stage, specified as a filter System object, delay System object, or a scalar gain value. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

You can modify an existing stage by modifying the associated property. For example:

```
FC = dsp.FilterCascade(dsp.FIRFilter,5)

FC =

  dsp.FilterCascade with properties:

    Stage1: [1×1 dsp.FIRFilter]
    Stage2: 5

K>> FC.Stage2 = dsp.FIRDecimator

FC =

  dsp.FilterCascade with properties:

    Stage1: [1×1 dsp.FIRFilter]
    Stage2: [1×1 dsp.FIRDecimator]
```

To change the number of stages in a cascade, use the `addStage` and `removeStage` functions.

Usage

Syntax

```
y = FC(x)
```

Description

`y = FC(x)` filters input signal `x` by using the filter cascade defined in `FC` and returns filtered output `y`. The size, data type, and complexity of the input signal must be supported by all of the stages in the filter cascade. This object supports variable-size signals if the filter stages within the object support variable-size signals.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. When the input is a matrix, each column of the matrix represents an independent data channel.

Data Types: `single` | `double`

Output Arguments

y — Filtered output data

vector | matrix

Filtered output data, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FilterCascade`

addStage	Add filter stage to cascade
generateFilteringCode	Generate MATLAB code for a filter cascade
getNumStages	Get number of stages in filter cascade

releaseStages	Release locked state of all stages in cascade
removeStage	Remove stage from filter cascade

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Filter Signal Using Cascaded Lowpass and Highpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Design a bandpass filter by cascading:

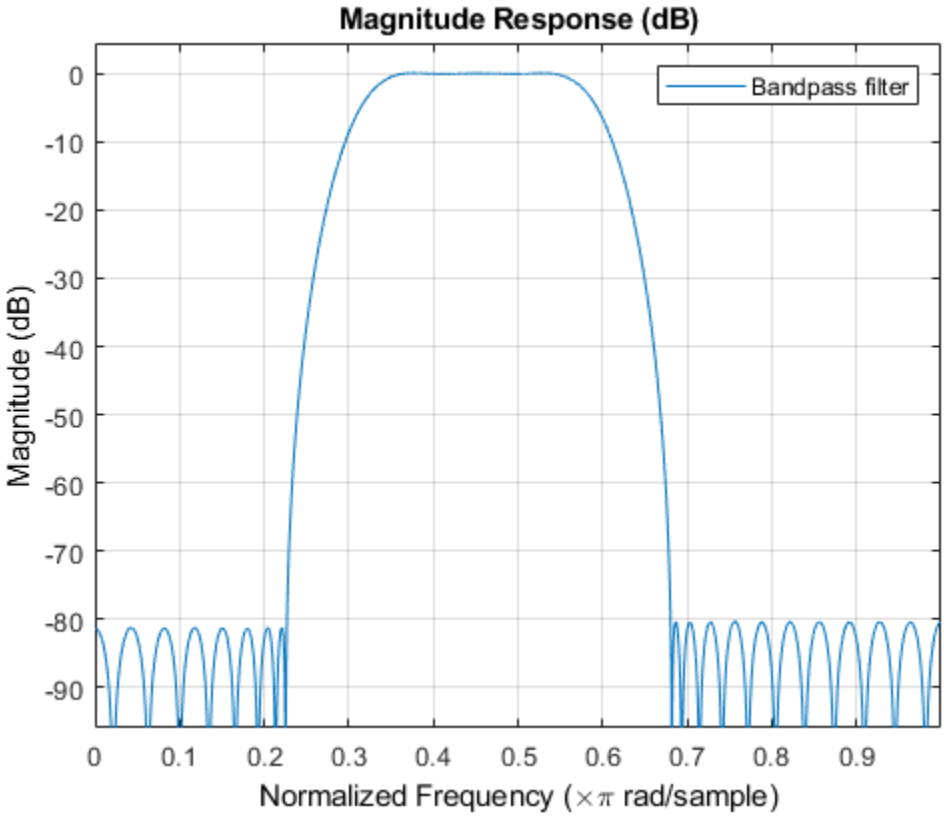
- A highpass filter with a stopband frequency of 5000 Hz and a passband frequency of 8000 Hz
- A lowpass filter with a passband frequency of 12,000 Hz and a stopband frequency of 15,000 Hz

Visualize the frequency response using `fvtool`.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...
    'PassbandFrequency',12000);
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...
    'PassbandFrequency',8000);

bpFilt = dsp.FilterCascade(lpFilt,hpFilt);

fvtool(bpFilt);
legend('Bandpass filter');
```



Pass a noisy sine wave as the input to the bandpass filter. The input is a sum of three sine waves with frequencies at 3 kHz, 10 kHz, and 15 kHz. The sampling frequency is 48 kHz. View the input and the filtered output on a spectrum analyzer.

The tones at 3 kHz and 15 kHz are attenuated, and the tone at 10 kHz is preserved by the bandpass filter.

```
Sine1 = dsp.SineWave('Frequency',3e3,'SampleRate',48e3,'SamplesPerFrame',6000);
Sine2 = dsp.SineWave('Frequency',10e3,'SampleRate',48e3,'SamplesPerFrame',6000);
Sine3 = dsp.SineWave('Frequency',15e3,'SampleRate',48e3,'SamplesPerFrame',6000);

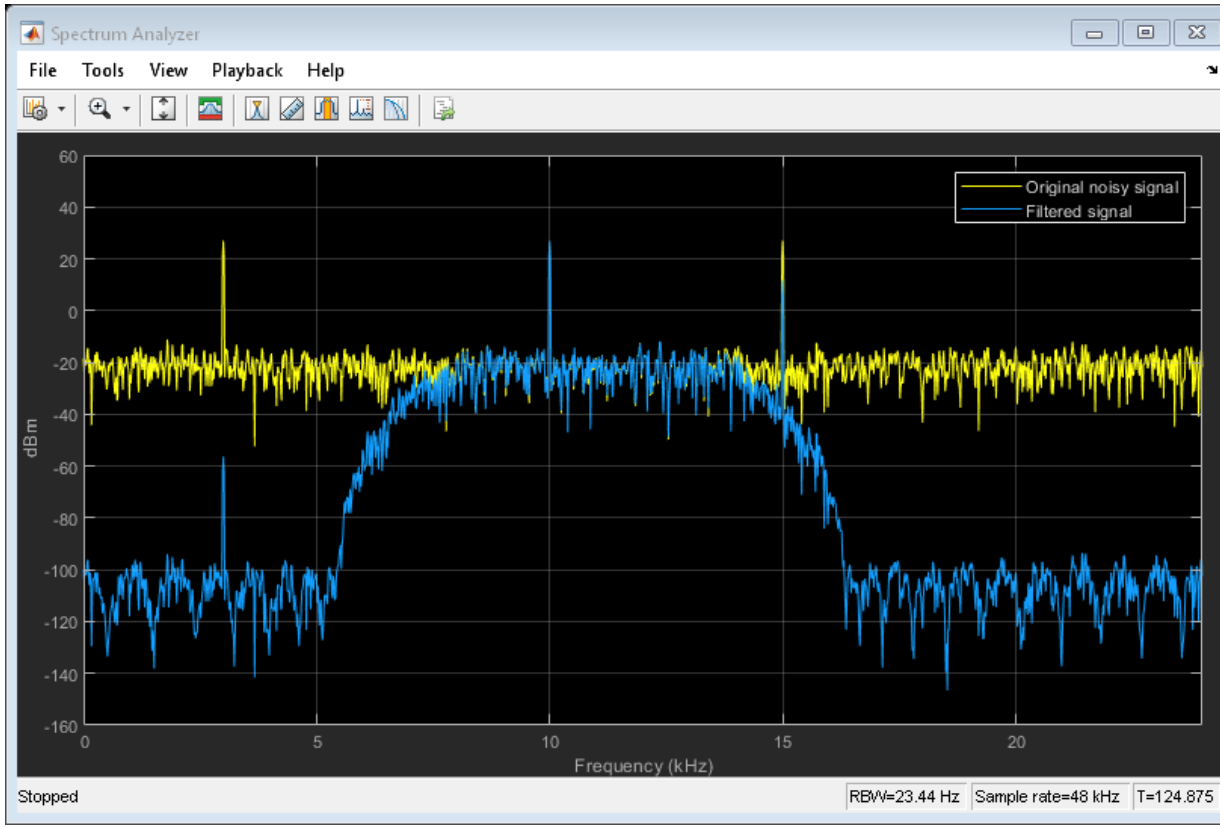
SpecAna = dsp.SpectrumAnalyzer('PlotAsTwoSidedSpectrum',false, ...
    'SampleRate',Sine1.SampleRate, ...
    'NumInputPorts',2,...
```

```
    'ShowLegend',true, ...
    'YLimits',[-160,60]);

SpecAna.ChannelNames = {'Original noisy signal','Filtered signal'};

for i = 1:1000
    x = Sine1() + Sine2() + Sine3() + 0.1.*randn(Sine1.SamplesPerFrame,1);
    y = bpFilt(x);
    SpecAna(x,y);

end
release(SpecAna)
```



Design Compensation Decimator for CIC Decimator

Create a CIC decimator. Cascade the decimator with a gain.

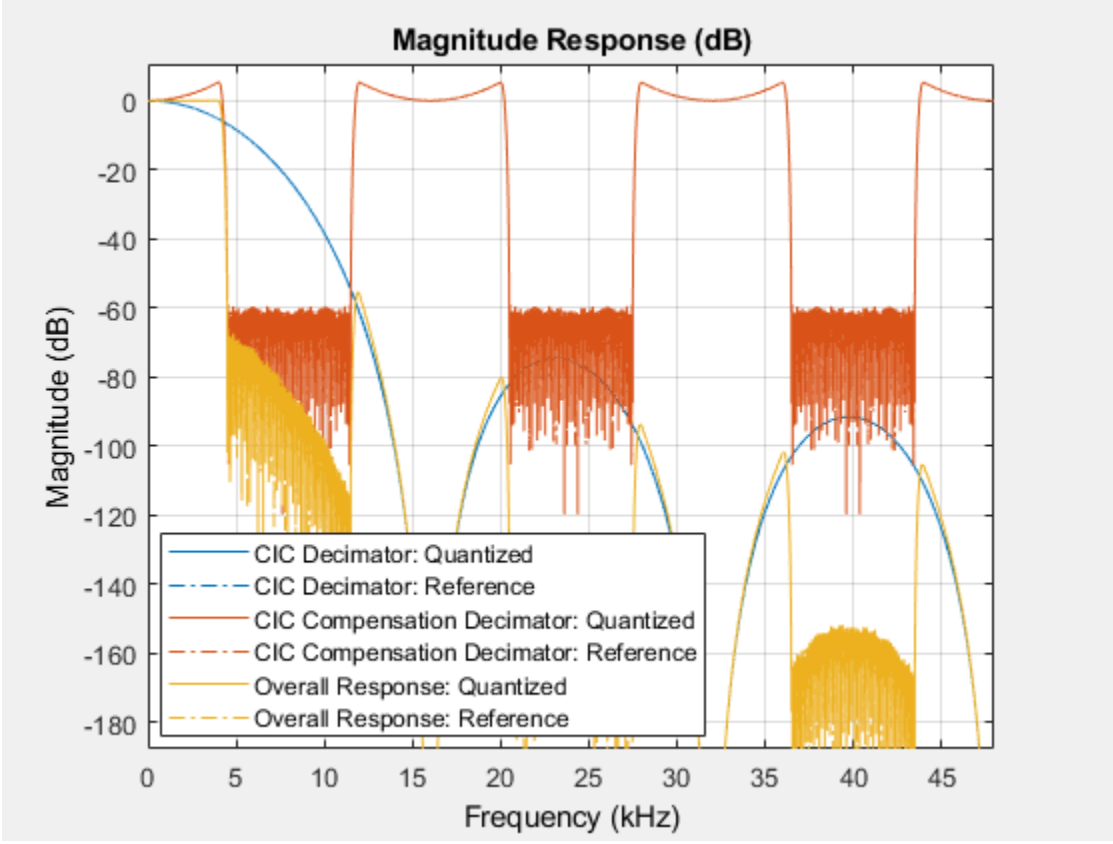
```
cicdecim = dsp.CICDecimator('DecimationFactor',6,...
    'NumSections',6);
decimcasc = dsp.FilterCascade(cicdecim,1/gain(cicdecim));
```

Design a compensation decimator and cascade it with the filter cascade, `decimcasc`. This operation nests a `dsp.FilterCascade` object as a stage in another filter cascade. The CIC compensation decimator has an inherent gain, `gain(cicdecim)`. The factor of `1/gain(cicdecim)` from the decimation filter cascade, `decimcasc`, compensates for the compensation filter gain.

```
fs = 16e3;     % Sampling frequency of input of compensation decimator
fPass = 4e3;   % Passband frequency
fStop = 4.5e3; % Stopband frequency
ciccomp = dsp.CICCompensationDecimator(cicdecim,...
    'DecimationFactor',2, ...
    'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop, ...
    'SampleRate',fs);
filtchain = dsp.FilterCascade(decimcasc,ciccomp);
```

Visualize the frequency response of the cascade of cascades.

```
f = fvtool(decimcasc,ciccomp,filtchain,'Fs',[fs*6,fs,fs*6],...
    'Arithmetic','fixed');
legend(f,'CIC Decimator','CIC Compensation Decimator',...
    'Overall Response');
```



Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100-Hz transition width, a 2-kHz sampling frequency, and 60-dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```
decimSpec = fdesign.decimator(4,'Nyquist',4,'Tw,Ast',100,60,2000);
filtCasc = design(decimSpec,'multistage','SystemObject',true);
```

Verify your design by using `fvtool`.

```
info(filtCasc)
```

```
ans =
    'Discrete-Time Filter Cascade

     Arithmetic         : double

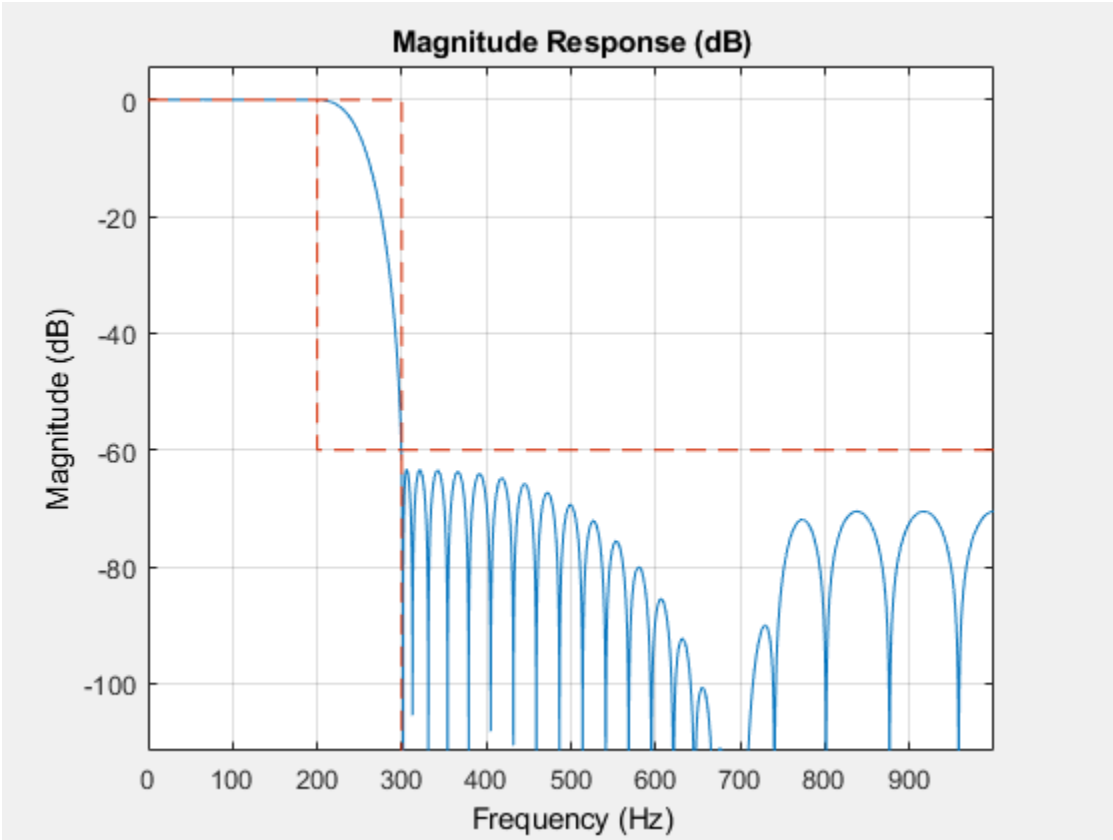
     '
```

```
fvtool(filtCasc)
```



Generate code to filter data using this design. You cannot generate C/C++ code from the `dsp.FilterCascade` object directly, but you can generate C/C++ code from the generated function. The function defines the filter stages and calls them in sequence. The function is saved in a file called my`Decimator.m` in the current directory.

```
generateFilteringCode(filtCasc,'myDecimator');
```

The my`Decimator` function creates a filter cascade and calls each stage object in turn.

```
type myDecimator
```

```
function y = myDecimator(x)
%MYDECIMATOR Construct filter cascade and process each stage
```

```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You cannot generate code directly from `dsp.FilterCascade`. If the filters in each stage support code generation, you can generate C/C++ code from the function returned by `generateFilteringCode`.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

System Objects

`dsp.Delay` | `dsp.FIRFilter`

Functions
`cascade`

Introduced in R2014b

addStage

Package: `dsp`

Add filter stage to cascade

Syntax

```
addStage(FC,newFilt)
addStage(FC,newFilt,stageId)
```

Description

`addStage(FC,newFilt)` adds a filter stage represented by the `newFilt` System object as the final stage of the `dsp.FilterCascade` System object, `FC`. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

`addStage(FC,newFilt,stageId)` adds `newFilt` at stage position `stageId` of the filter cascade `FC`. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when `newFilt` is added.

Examples

Add Filter Stage to Filter Cascade

Call `addStage` with only the System object™ arguments,. The function adds the new filter stage as the final stage in the filter cascade.

```
FC = dsp.FilterCascade
```

```
FC =
  dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
```

```
addStage(FC,dsp.IIRFilter)
FC
```

```
FC =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
```

Call `addStage` with an index argument. The function adds the new filter stage at the specified index. This example creates a filter cascade with three stages, and then adds a filter as the second stage of the cascade.

```
FC = dsp.FilterCascade(dsp.CICDecimator,dsp.FIRDecimator,dsp.FIRFilter)
```

```
FC =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.CICDecimator]
    Stage2: [1x1 dsp.FIRDecimator]
    Stage3: [1x1 dsp.FIRFilter]
```

```
addStage(FC,dsp.IIRFilter,2)
FC
```

```
FC =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.CICDecimator]
    Stage2: [1x1 dsp.IIRFilter]
    Stage3: [1x1 dsp.FIRDecimator]
    Stage4: [1x1 dsp.FIRFilter]
```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

`newFilt` — Filter stage to add
filter System object | delay System object | scalar gain value

Filter stage to add, specified as one of the supported System objects or a scalar gain value. Each stage can be a filter or delay object, or a scalar gain value. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

`stageId` — Index of filter stage to be added
positive integer

Index of filter stage to be added, specified as a positive integer. The object adds this stage to the filter cascade. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when the new filter is added.

generateFilteringCode

Package: `dsp`

Generate MATLAB code for a filter cascade

Syntax

```
generateFilteringCode(FC)
generateFilteringCode(FC,fileName)
```

Description

`generateFilteringCode(FC)` creates a MATLAB function that contains code to create the stages of a filter cascade, `FC`, and calls each stage in sequence. If the filters in each stage support code generation, you can generate C/C++ code from the function returned by `generateFilteringCode`.

`generateFilteringCode(FC,fileName)` generates code and saves the resulting function to the file specified in `fileName`.

Examples

Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100-Hz transition width, a 2-kHz sampling frequency, and 60-dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```
decimSpec = fdesign.decimator(4,'Nyquist',4,'Tw,Ast',100,60,2000);
filtCasc = design(decimSpec,'multistage','SystemObject',true);
```

Verify your design by using `fvtool`.

```
 info(filtCasc)
```

```
ans =
    'Discrete-Time Filter Cascade

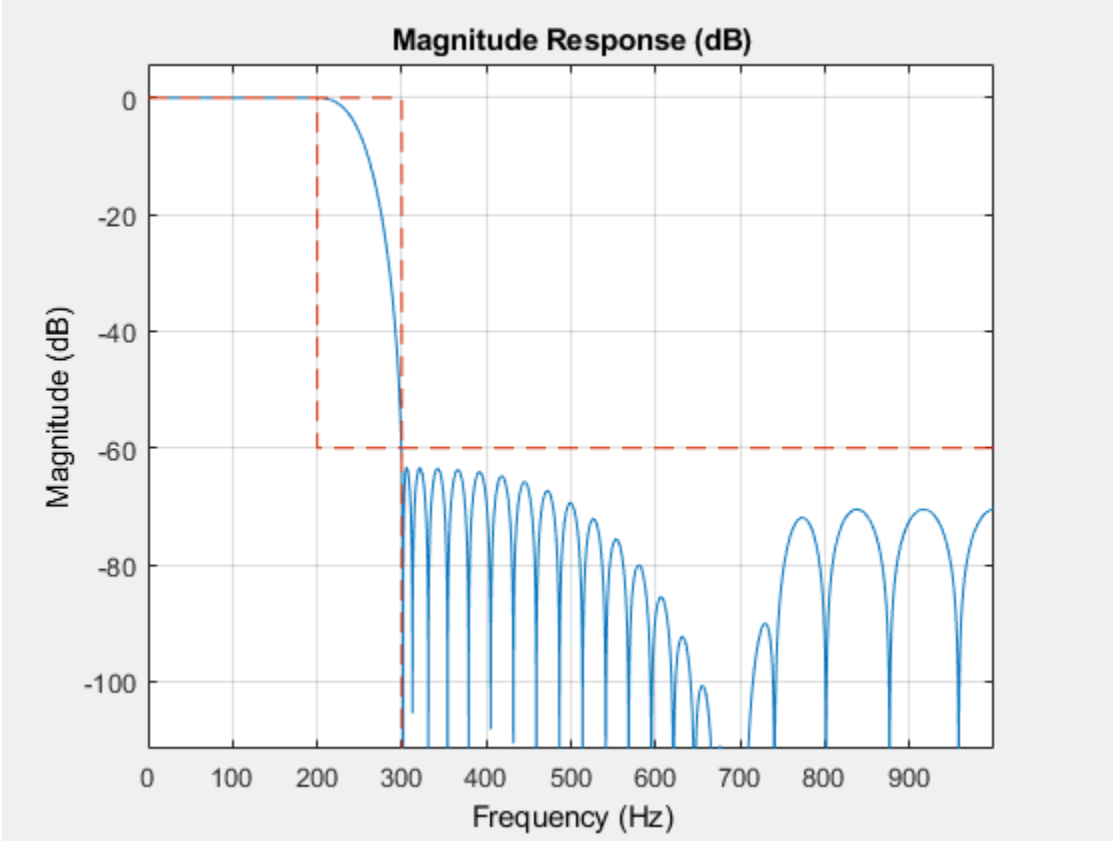
     '
```

```
fvtool(filtCasc)
```



Generate code to filter data using this design. You cannot generate C/C++ code from the `dsp.FilterCascade` object directly, but you can generate C/C++ code from the generated function. The function defines the filter stages and calls them in sequence. The function is saved in a file called my`Decimator.m` in the current directory.

```
generateFilteringCode(filtCasc,'myDecimator');
```

The my`Decimator` function creates a filter cascade and calls each stage object in turn.

```
type myDecimator
```

```
function y = myDecimator(x)
%MYDECIMATOR Construct filter cascade and process each stage
```

```

getNumStages

Package: dsp

Get number of stages in filter cascade

Syntax

```
getNumStages(FC)
```

Description

`getNumStages(FC)` returns the number of stages in the `dsp.FilterCascade` object, `FC`.

Examples

Find Number of Stages

This example shows how to query the number of stages in a filter cascade.

Create a filter cascade with two stages and call `getNumStages` on the cascade object.

```
    FC = cascade(dsp.FIRFilter,dsp.IIRFilter)
```

```
FC =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
```

```
    FCstages = getNumStages(FC)
```

```
FCstages = 2
```

Input Arguments

FC — Filter cascade
`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

See Also

Objects
`dsp.FilterCascade`

Functions
`addStage` | `generateFilteringCode` | `getNumStages` | `releaseStages` | `removeStage`

Introduced in R2014b

releaseStages

Package: `dsp`

Release locked state of all stages in cascade

Syntax

```
releaseStages(FC)
```

Description

`releaseStages(FC)` calls the `release` function of each individual stage in the `dsp.FilterCascade` System object `FC`.

For instance, if a `dsp.FilterCascade` object consists of a `dsp.FIRFilter` and a `dsp.FIRInterpolator` object, the `releaseStages` function calls the:

- `release` function of the `dsp.FIRFilter` object
- `release` function of the `dsp.FIRInterpolator` object

Examples

Release Stages of a Filter Cascade

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create and release stages of a filter cascade.

```
firfilt = dsp.FIRFilter;
y = firfilt(randn);
FC = dsp.FilterCascade(dsp.FIRInterpolator, firfilt);
isLocked(FC.Stage2)
```

```
ans = logical
   1

releaseStages(FC);
isLocked(FC.Stage2)

ans = logical
   0
```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

See Also

Objects

`dsp.FilterCascade`

Functions

`addStage` | `generateFilteringCode` | `getNumStages` | `releaseStages` | `removeStage`

Introduced in R2014b

removeStage

Package: `dsp`

Remove stage from filter cascade

Syntax

```
removeStage(FC)
removeStage(FC,stageId)
```

Description

`removeStage(FC)` removes the final stage of the `dsp.FilterCascade` System object `FC`.

`removeStage(FC,stageId)` removes the stage from stage position `stageId` of the filter cascade `FC`. All existing filter stages from `stageId` to the end of the cascade are shifted down in the cascade when the stage is removed.

Examples

Remove Filter Stage

Call removeStage with no arguments other than the filter cascade System object™. The function removes the last stage in the filter cascade.

```
FC2= dsp.FilterCascade(dsp.FIRFilter,dsp.IIRFilter)
```

```
FC2 =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
```

```
removeStage(FC2);
FC2

FC2 =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRFilter]
```

To remove a specific stage of the cascade, specify the index for that stage as an input argument. This example creates a filter cascade that has four stages, and then removes the third stage.

```
 FC4 = cascade(dsp.FIRInterpolator, dsp.FIRInterpolator, dsp.FIRDecimator, dsp.FIRDecir

FC4 =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRInterpolator]
    Stage2: [1x1 dsp.FIRInterpolator]
    Stage3: [1x1 dsp.FIRDecimator]
    Stage4: [1x1 dsp.FIRDecimator]

 removeStage(FC4,3);
 FC4

FC4 =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRInterpolator]
    Stage2: [1x1 dsp.FIRInterpolator]
    Stage3: [1x1 dsp.FIRDecimator]
```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

`stageId` — Index of filter stage to be removed
positive integer

Index of filter stage to be removed, specified as a positive integer. The function removes this stage from the filter cascade. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when the filter is removed.

dsp.FilteredXLMSFilter

Package: `dsp`

Filtered XLMS filter

Description

The `dsp.FilteredXLMSFilter` System object computes output, error and coefficients using filtered-x least mean square FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Create the `dsp.FilteredXLMSFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
fxlms = dsp.FilteredXLMSFilter
fxlms = dsp.FilteredXLMSFilter(len)
fxlms = dsp.FilteredXLMSFilter(Name,Value)
```

Description

`fxlms = dsp.FilteredXLMSFilter` returns a filtered-x least mean square FIR adaptive filter System object, `fxlms`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fxlms = dsp.FilteredXLMSFilter(len)` returns a `FilteredXLMSFilter` System object, `fxlms`, with the `Length` property set to `len`.

`fxlms = dsp.FilteredXLMSFilter(Name,Value)` returns a `FilteredXLMSFilter` System object, `fxlms`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Length` — Length of filter coefficients vector

`10` (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StepSize` — Adaptation step size

`0.1` (default) | positive scalar

Specify the adaptation step size factor as a positive numeric scalar.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LeakageFactor` — Adaptation leakage factor

`1` (default) | scalar

Specify the leakage factor used in a leaky adaptive filter as a numeric value between `0` and `1`, both inclusive. When the value is less than `1`, the System object implements a leaky adaptive algorithm. The default value is `1`, providing no leakage in the adapting method.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`SecondaryPathCoefficients` — Coefficients of the secondary path filter model
`[0.0051 -3.2506e-18 -0.0419 1.3210e-17 0.2885 0.4968 0.2885 1.3210e-17 -0.0419 -3.2506e-18 0.0051]` (default) | vector

Specify the coefficients of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value is a vector that represents the coefficients of a 10th-order FIR lowpass filter.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SecondaryPathEstimate` — Estimate of secondary path filter model
`[0.0051 -3.2506e-18 -0.0419 1.3210e-17 0.2885 0.4968 0.2885 1.3210e-17 -0.0419 -3.2506e-18 0.0051]` (default) | vector

Specify the estimate of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value equals to the `SecondayPathCoefficients` property value. This property is not tunable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialCoefficients` — Initial coefficients of filter
`0` (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LockCoefficients` — Locked status of coefficient updates
`false` (default) | `true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Tunable: Yes

Usage

Syntax

```
[y,err] = fxlms(x,d)
```

Description

`[y,err] = fxlms(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output `y` and the filter error `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `fxlms` filter, call `fxlms.Coefficients` after you pass the input and desired signal to the object.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the filtered XLMS filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input, `x` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The filtered XLMS filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal, `d`, can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

`y` — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

`err` — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The objective of the filtered XLMS filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the filtered XLMS filter coefficients, call `fxlms.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FilteredXLMSFilter`

msesim Estimated mean squared error for adaptive filters

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Active Noise Control of Random Noise Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate noise, create FIR primary path system model, generate observation noise, filter the primary path system model output with added noise, and create FIR secondary path system model.

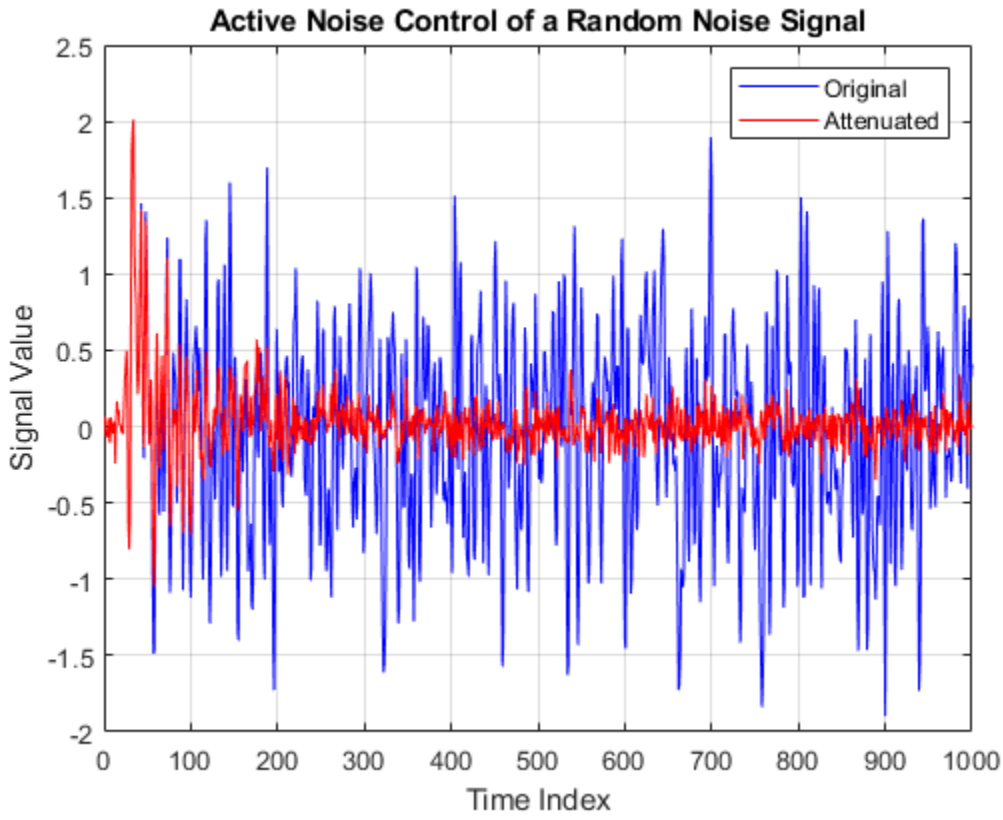
```
x  = randn(1000,1);
g  = fir1(47,0.4);
n  = 0.1*randn(1000,1);
d  = filter(g,1,x) + n;
b  = fir1(31,0.5);
```

Use the `dsp.FilteredXLMSFilter` System object™ to compute the filtered output and the filter error for the input and the signal to be canceled.

```
mu = 0.008;
fxlms = dsp.FilteredXLMSFilter(32, 'StepSize', mu, 'LeakageFactor', ...
     1, 'SecondaryPathCoefficients', b);
[y,e] = fxlms(x,d);
```

Plot the results.

```
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```



System Identification of FIR Filter Using Filtered XLMS Filter

Identify an unknown system by performing active noise control using a filtered-x LMS algorithm. The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter and the output of the unknown system (or the system to be identified). Once the error signal is minimal, the unknown system converges to the adaptive filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Initialization

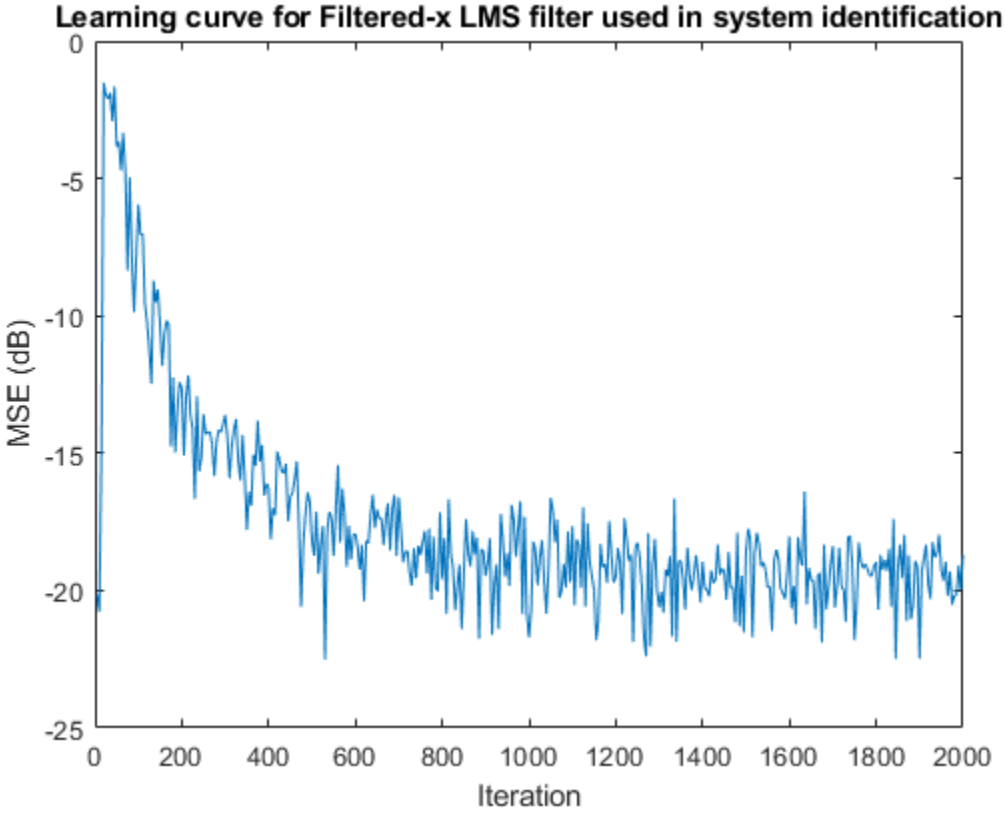
Create a `dsp.FIRFilter` System object that represents the system to be identified. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

Adaptive Filter

Create a `dsp.FilteredXLMSFilter` System object to create an adaptive filter that uses the filtered-x LMS algorithm. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the error between the output of the unknown system, `d`, and the output of the adaptive filter.

```
l = 32;
mu = 0.008;
m  = 5;
fxlms = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fxlms,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse))
xlabel('Iteration')
ylabel('MSE (dB)')
title('Learning curve for Filtered-x LMS filter used in system identification')
```



With each iteration of adaptation, the value of `simmse` decreases to a minimal value, indicating that the unknown system has converged to the adaptive filter.

dsp.FIRDecimator

Package: `dsp`

Polyphase FIR decimator

Description

The `dsp.FIRDecimator` System object resamples vector or matrix inputs along the first dimension. The object resamples at a rate *M* times slower than the input sampling rate, where *M* is the integer-valued downsampling factor. The decimation combines an FIR anti-aliasing filter with downsampling. The FIR decimator object uses a polyphase implementation of the FIR filter.

To resample vector or matrix inputs along the first dimension:

1. Create the `dsp.FIRDecimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
firdecim = dsp.FIRDecimator
firdecim = dsp.FIRDecimator(decimFactor,num)
firdecim = dsp.FIRDecimator( ___ ,Name,Value)
```

Description

`firdecim = dsp.FIRDecimator` returns an FIR decimator, `firdecim`, which applies an FIR filter with a cutoff frequency of `0.4*pi` radians/sample to the input and downsamples the filter output by factor of 2.

`firdecim = dsp.FIRDecimator(decimFactor,num)` returns an FIR decimator with the integer-valued `DecimationFactor` property set to `decimFactor` and the `Numerator` property set to `num`.

`firdecim = dsp.FIRDecimator( ___ ,Name,Value)` returns an FIR decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`DecimationFactor` — Decimation factor

2 (default) | positive integer

Decimation factor, specified as a positive integer. The FIR decimator reduces the sampling rate of the input by this factor. The number of input rows must be a multiple of the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumeratorSource` — FIR filter coefficient source

`'Property'` (default) | `'Input port'`

FIR filter coefficient source, specified as either:

- `'Property'` –– The numerator coefficients are specified through the `Numerator` property.
- `'Input port'` –– The numerator coefficients are specified as an input to the object algorithm.

`Numerator` — FIR filter coefficients

`fir1(35,0.4)` (default) | row vector

Specify the numerator coefficients of the FIR filter in powers of z^{-1}. The following equation defines the system function for a filter of length L:

$$H(z) = \sum_{l=0}^{L-1} b_l z^{-l}$$

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than 1/`DecimationFactor`. You can specify the filter coefficients as a vector in the supported data types.

Dependencies

This property applies when `NumeratorSource` is set to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Structure` — Filter structure
`'Direct form'` (default) | `'Direct form transposed'`

Specify the implementation of the FIR filter as either `Direct form` or `Direct form transposed`.

Fixed-Point Properties

`FullPrecisionOverride` — Full-precision override for fixed-point arithmetic
`true` (default) | `false`

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` –– The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` –– Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

`RoundingMethod` — Rounding method for fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `ProductDataType` set to `'Full precision'`, `AccumulatorDataType` set to `'Full precision'`, and `OutputDataType` set to `'Same as accumulator'`.

Under these conditions, the object operates in full precision mode.

`OverflowAction` — Overflow action for fixed-point operations

`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` –– The object wraps the result of its fixed-point operations.
- `'Saturate'` –– The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `OutputDataType` set to `'Same as accumulator'`, `ProductDataType` set to `'Full precision'`, and `AccumulatorDataType` set to `'Full precision'`

Under these conditions, the object operates in full precision mode.

`CoefficientsDataType` — Data type of FIR filter coefficients

`Same word length as input` (default) | `Custom`

Data type of the FIR filter coefficients, specified as:

- `Same word length as input` –– The word length of the coefficients is the same as that of the input. The fraction length is computed to give the best possible precision.
- `Custom` –– The coefficients data type is specified as a custom numeric type through the `CustomCoefficientsDataType` property.

`CustomCoefficientsDataType` — Word and fraction lengths of coefficients data type

`numerictype([],16,15)` (default) | custom numeric type

Word and fraction lengths of the coefficients data type, specified as an autosigned `numerictype` with a word length of 16 and a fraction length of 15.

Dependencies

This property applies when you set the `CoefficientsDataType` property to `Custom`.

`ProductDataType` — Data type of product output

`'Full precision'` (default) | `'Custom'` | `'Same as input'`

Data type of the product output in this object, specified as one of the following:

- `'Full precision'` –– The product output data type has full precision.
- `'Same as input'` –– The object specifies the product output data type to be the same as that of the input data type.
- `'Custom'` –– The product output data type is specified as a custom numeric type through the `CustomProductDataType` property.

For more information on the product output data type, see “Multiplication Data Types”.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomProductDataType` — Word and fraction lengths of product data type

`numerictype([],32,30)` (default) | custom numeric type

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `ProductDataType` to `'Custom'`.

`AccumulatorDataType` — Data type of accumulation operation

`'Full precision'` (default) | `'Same as input'` | `'Same as product'` | `'Custom'`

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` –– The accumulation operation has full precision.
- `'Same as product'` –– The object specifies the accumulator data type to be the same as that of the product output data type.
- `'Same as input'` –– The object specifies the accumulator data type to be the same as that of the input data type.
- `'Custom'` –– The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomAccumulatorDataType` — Word and fraction lengths of accumulator data type

`numerictype([],32,30)` (default) | custom numeric type

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `AccumulatorDataType` to `'Custom'`.

`OutputDataType` — Data type of object output

`'Same as accumulator'` (default) | `'Same as input'` | `'Same as product'` | `'Custom'`

Data type of the object output, specified as one of the following:

- `'Same as accumulator'` –– The output data type is the same as that of the accumulator output data type.

- `'Same as input'` –– The output data type is the same as that of the input data type.
- `'Same as product'` –– The output data type is the same as that of the product output data type.
- `'Custom'` –– The output data type is specified as a custom numeric type through the `CustomOutputDataType` property.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomOutputDataType` — Word and fraction lengths of output data type
`numerictype([],16,15)` (default) | custom numeric type

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `OutputDataType` to `'Custom'`.

Usage

Syntax

```
y = firdecim(x)
y = firdecim(x,num)
```

Description

`y = firdecim(x)` outputs the filtered and downsampled values, `y`, of the input signal, `x`.

`y = firdecim(x,num)` uses the FIR filter, `num`, to decimate the input signal. This configuration is valid only when the `'NumeratorSource'` property is set to `'Input port'`.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix of size *Ki*-by-*N*. The number of input rows, *Ki*, must be a multiple of the `DecimationFactor` property. The input columns represent the *N* independent channels.

This object supports variable-size input and does not support complex unsigned fixed-point inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

num — FIR filter coefficients

row vector

FIR filter coefficients, specified as a row vector.

Dependencies

This input is accepted only when the `'NumeratorSource'` property is set to `'Input port'`.

Data Types: `double`

Output Arguments

y — FIR decimator output

column vector | matrix

FIR decimated output, returned as a column vector or a matrix of size *Ki/M*-by-*N*, where *M* is the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRDecimator`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost for implementing filter System objects
polyphase	Polyphase decomposition of multirate filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
impz	Impulse response of discrete-time filter System object
coeffs	Filter coefficients

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Decimate a Sum of Sine Waves

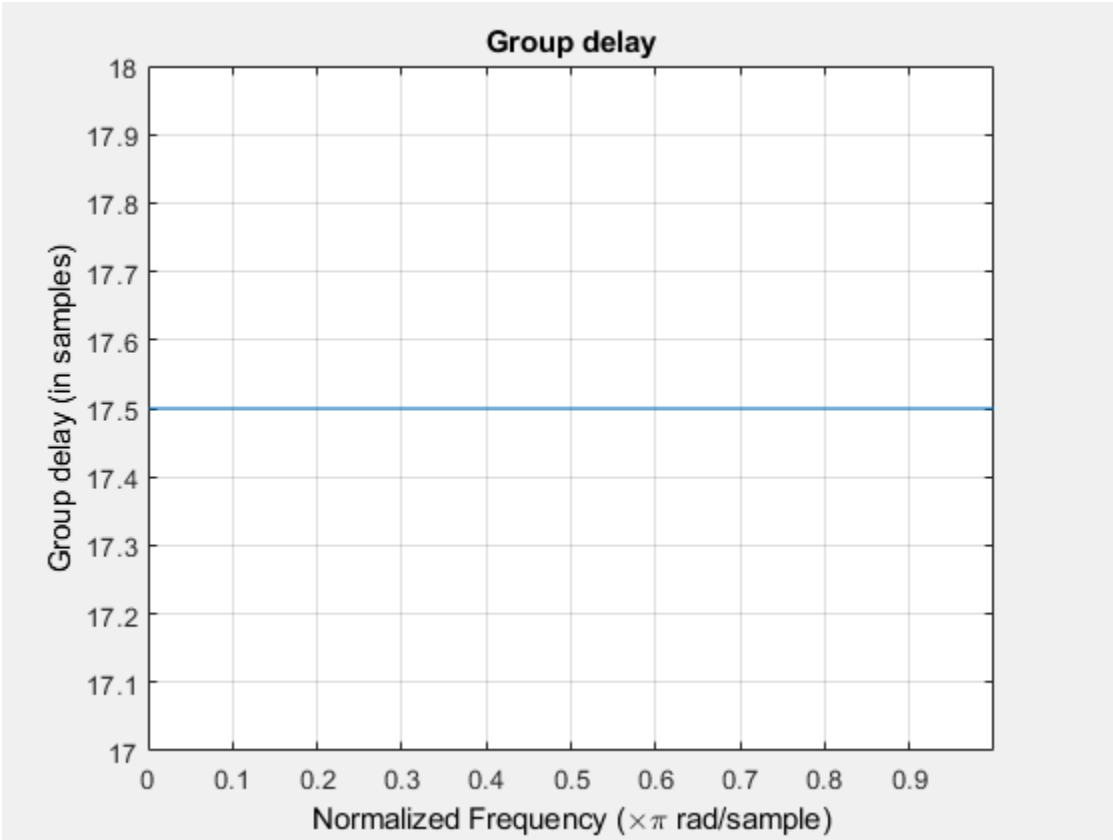
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example shows how to decimate a sum of sine waves with angular frequencies of pi/4 and 2pi/3 radians/sample by a factor of two. To prevent aliasing, the FIR decimator filters out the 2pi/3 radians/sample component before downsampling.

```
x = cos(pi/4*(0:95)')+sin(2*pi/3*(0:95)');
firdecim = dsp.FIRDecimator;
y = firdecim(x);
```

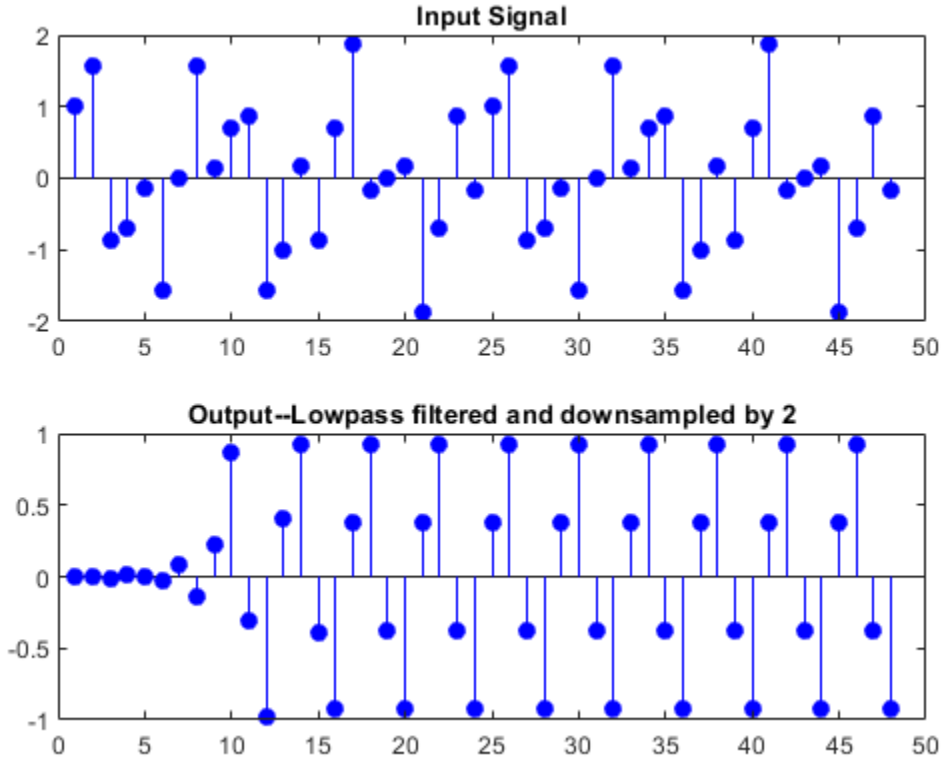
View group delay of default FIR filter

```
fvtool(fir1(35,0.4),1,'analysis','grpdelay');
```



Group delay of the default linear-phase FIR filter is 17.5 samples. Downsampling by a factor of two expect an approx. 8.75 sample delay in the output y with the initial filter states of zero

```
subplot(211);
stem(x(1:length(x)/2),'b','markerfacecolor',[0 0 1]);
title('Input Signal');
subplot(212);
stem(y,'b','markerfacecolor',[0 0 1]);
title('Output--Lowpass filtered and downsampled by 2');
```



Reduce the Sample Rate of an Audio Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

This example shows how to reduce the sampling rate of an audio signal by 1/2 and plays it.

```
afr = dsp.AudioFileReader('OutputDataType',...
  'single');
adw = audioDeviceWriter(22050/2);
firdecim = dsp.FIRDecimator;

while ~isDone(afr)
     frame = afr();
     y = firdecim(frame);
     adw(y);
end

release(afr);
pause(0.5);
release(adw);
```

More About

Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into M different subfilters, where M is the downsampling, or decimation factor. Let $h(n)$ denote the FIR filter impulse response of length L and $u(n)$ the input signal. Decimating the filter output by a factor of M is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^{L-1} h(l)u(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting $M=2$, the input values $u(0),u(2),u(4), \ldots$ are only combined with the filter coefficients $h(0),h(2),h(4),\ldots$, and the input values $u(1),u(3),u(5), \ldots$ are only combined with the filter coefficients $h(1),h(3),h(5),\ldots$. By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output. The following MATLAB code demonstrates how to construct the two polyphase subfilters for the default order 35 filter in the “Numerator” on page 4-0 property and the default “DecimationFactor” on page 4-0 property value of two:

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
     nzeros = M - rem(FiltLength, M);
     Num = [zeros(nzeros,1); Num];  % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of M , there are M phases and therefore M subfilters.

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Decimation block reference page. The object properties correspond to the block parameters, except:

- **Framing** – The FIR decimator object only supports `Maintain input frame rate`
- **Output buffer initial conditions** – The FIR decimator object does not support this parameter.
- **Rate options** – The FIR decimator object does not support this parameter.
- **Input processing** The FIR decimator object does not support this parameter.

Introduced in R2012a

dsp.FIRFilter

Package: `dsp`

Static or time-varying FIR filter

Description

The `dsp.FIRFilter` System object filters each channel of the input using static or time-varying FIR filter implementations.

To filter each channel of the input:

1. Create the `dsp.FIRFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
fir = dsp.FIRFilter
fir = dsp.FIRFilter(num)
fir = dsp.FIRFilter(Name,Value)
```

Description

`fir = dsp.FIRFilter` returns a finite impulse response (FIR) filter object, `fir`, which independently filters each channel of the input over time using a specified FIR filter implementation.

`fir = dsp.FIRFilter(num)` returns an FIR filter System object, `fir`, with the `Numerator` property set to `num`.

`fir = dsp.FIRFilter(Name,Value)` returns an FIR filter System object, `fir`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Structure` — Filter structure

`Direct form` (default) | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed` | `Lattice MA`

Specify the filter structure. You can specify the filter structure as one of `Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed` | `Lattice MA`.

`NumeratorSource` — Source of filter coefficients

`Property` (default) | `Input port`

Specify the source of the filter coefficients as `Property` or `Input port`. When you specify `Input port`, the filter object updates the time-varying filter once every frame.

Dependencies

This applies when you set the `Structure` to `Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed`.

`ReflectionCoefficientsSource` — Source of filter coefficients

`Property` (default) | `Input port`

Specify the source of the Lattice filter coefficients as `Property` or `Input port`. When you specify `Input port`, the filter object updates the time-varying filter once every frame.

Dependencies

This applies when you set the `Structure` to `Lattice MA`.

`Numerator` — Numerator coefficients

`[0.5 0.5]` (default) | row vector

Specify the filter coefficients as a real or complex numeric row vector.

Tunable: Yes

Dependencies

This property applies when you set the `NumeratorSource` property to `Property`, and the "Structure" on page 4-0 property is set to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ReflectionCoefficients` — Reflection coefficients of lattice filter structure

`[0.5 0.5]` (default) | row vector

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector.

Tunable: Yes

Dependencies

This property applies when you set the "Structure" on page 4-0 property to `Lattice MA`, and the `ReflectionCoefficientsSource` property to `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialConditions` — Initial conditions for the FIR filter

`0` (default) | scalar | vector | matrix

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you

specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

`FullPrecisionOverride` — Full precision override for fixed-point arithmetic

`true` (default) | `false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

`RoundingMethod` — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

Dependencies

This property applies only if the object is not in full precision mode.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

Dependencies

This property applies only if the object is not in full precision mode.

`CoefficientsDataType` — Coefficients word and fraction lengths
`Same word length as input` (default) | `Custom`

Specify the coefficients fixed-point data type as `Same word length as input` or `Custom`.

Dependencies

This property applies when you set the `NumeratorSource` property to `Property`.

`CustomCoefficientsDataType` — Custom coefficients word and fraction lengths
`numerictype(true,16,15)` (default) | numerictype

Specify the coefficients fixed-point type as a signed or unsigned `numerictype` object.

Dependencies

This property applies when you set the `CoefficientsDataType` property to `Custom`.

`ReflectionCoefficientsDataType` — Reflection coefficients word and fraction lengths
`Same word length as input` (default) | `Custom`

Specify the reflection coefficients fixed-point data type as `Same word length as input` or `Custom`.

Dependencies

This property applies when you set the `ReflectionCoefficientsSource` property to `Property`.

`CustomReflectionCoefficientsDataType` — Custom reflection coefficients word and fraction lengths
`numerictype(true,16,15)` (default) | numerictype

Specify the reflection coefficients fixed-point type as a signed or unsigned `numerictype` object.

Dependencies

This property applies when you set the `ReflectionCoefficientsDataType` property to `Custom`.

`ProductDataType` — Product word and fraction lengths
`Full precision` (default) | `Same as input` | `Custom`

Specify the product fixed-point data type as `Full precision`, `Same as input`, or `Custom`.

`CustomProductDataType` — Custom product word and fraction lengths
`numerictype(true,32,30)` (default) | numerictype

Specify the product fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

`AccumulatorDataType` — Accumulator word and fraction lengths
`Full precision` (default) | `Same as input` | `Same as product` | `Custom`

Specify the accumulator fixed-point data type to `Full precision`, `Same as input`, `Same as product`, or `Custom`.

`CustomAccumulatorDataType` — Custom accumulator word and fraction lengths
`numerictype(true,32,30)` (default) | numerictype

Specify the accumulator fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

`StateDataType` — State word and fraction lengths
`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the state fixed-point data type as one of `Same as input`, `Same as accumulator`, or `Custom`.

Dependencies

This property does not apply to any of the direct form or direct form I filter structures.

`CustomStateDataType` — Custom state word and fraction lengths
`numerictype(true,16,15)` (default) | numerictype

Specify the state fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the `StateDataType` property to `Custom`.

`OutputDataType` — Output word and fraction lengths
`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the output fixed-point data type as one of `Same as input`, `Same as accumulator`, or `Custom`.

`CustomOutputDataType` — Custom output word and fraction lengths
numerictype(true,16,15) (default) | numerictype

Specify the output fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the "OutputDataType" on page 4-0 property to `Custom`.

Usage

Syntax

```
y = fir(x)
y = fir(x,coeff)
```

Description

`y = fir(x)` applies an FIR filter to the real or complex input signal `x` to produce the output `y`.

`y = fir(x,coeff)` uses the time-varying coefficients, `coeff` , to filter the input signal `x` and produce the output `y` . You can use this option when you set the `NumeratorSource` or `ReflectionCoefficientsSource` property to `Input port`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. When the input data is of a fixed-point type, it must be signed when the structure is set to `Direct form symmetric` or `Direct form antisymmetric`. The FIR filter object operates on each channel of the input signal independently over successive calls to the object.

This System object supports variable-size input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

coeff — Filter coefficients

row vector

Time-varying filter coefficients, specified as a row vector. The data and coefficient inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`
Complex Number Support: Yes

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size and data type as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRFilter`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Filter coefficients
cost	Estimate cost for implementing filter System objects
grpdelay	Group delay response of discrete-time filter System object
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Lowpass Filter a Sinusoid Signal Using FIRFilter object

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components.

```
 t = (0:1000)'/8e3;
 xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);

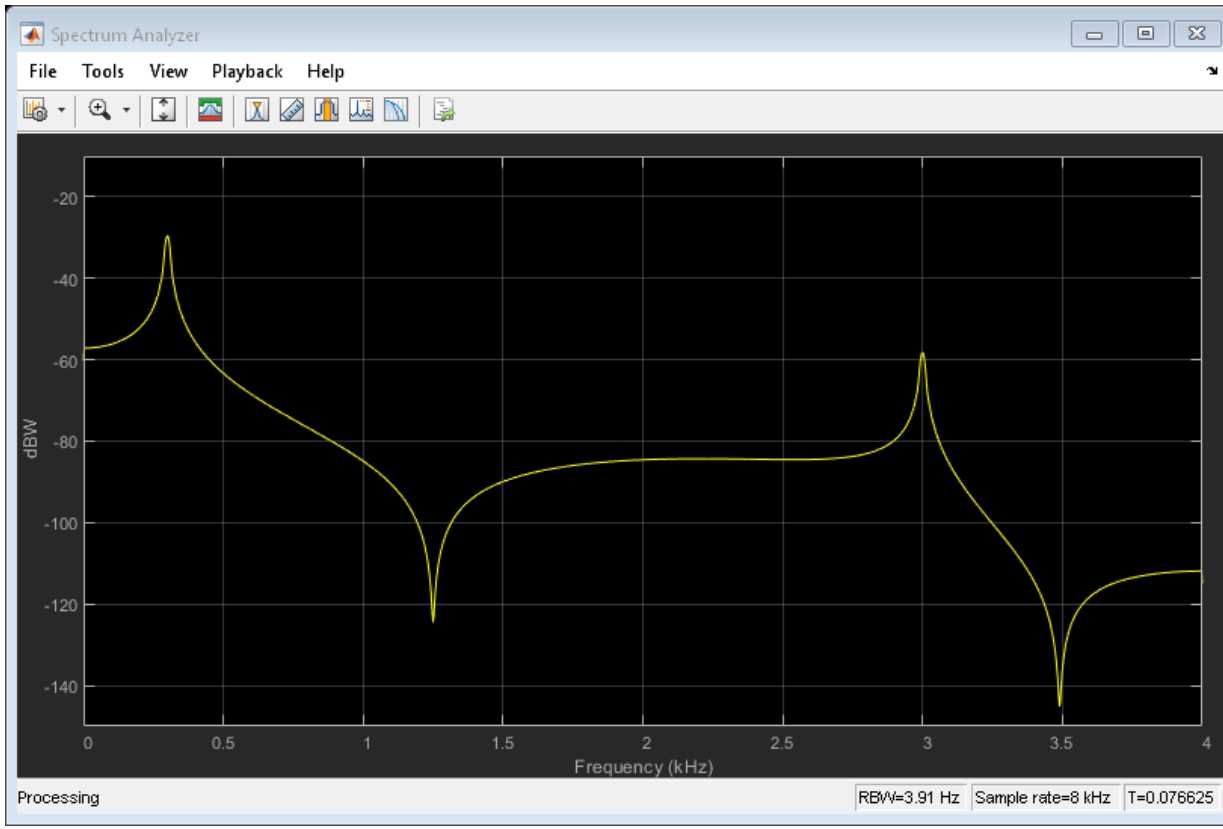
 sr = dsp.SignalSource;
 sr.Signal = xin;
 sink = dsp.SignalSink;

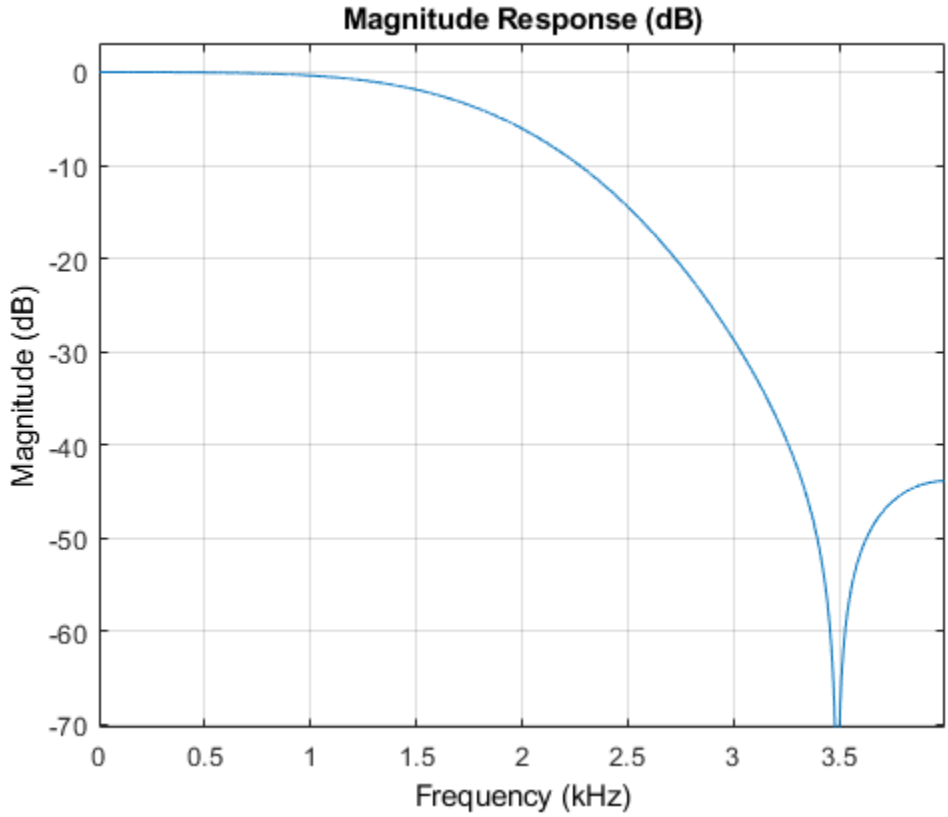
 fir = dsp.FIRFilter(fir1(10,0.5));

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80, 'PowerUnits','dBW',...
    'YLimits', [-150 -10]);
```

```
while ~isDone(sr)
      input = sr();
      filteredOutput = fir(input);
      sink(filteredOutput);
      sa(filteredOutput)
end

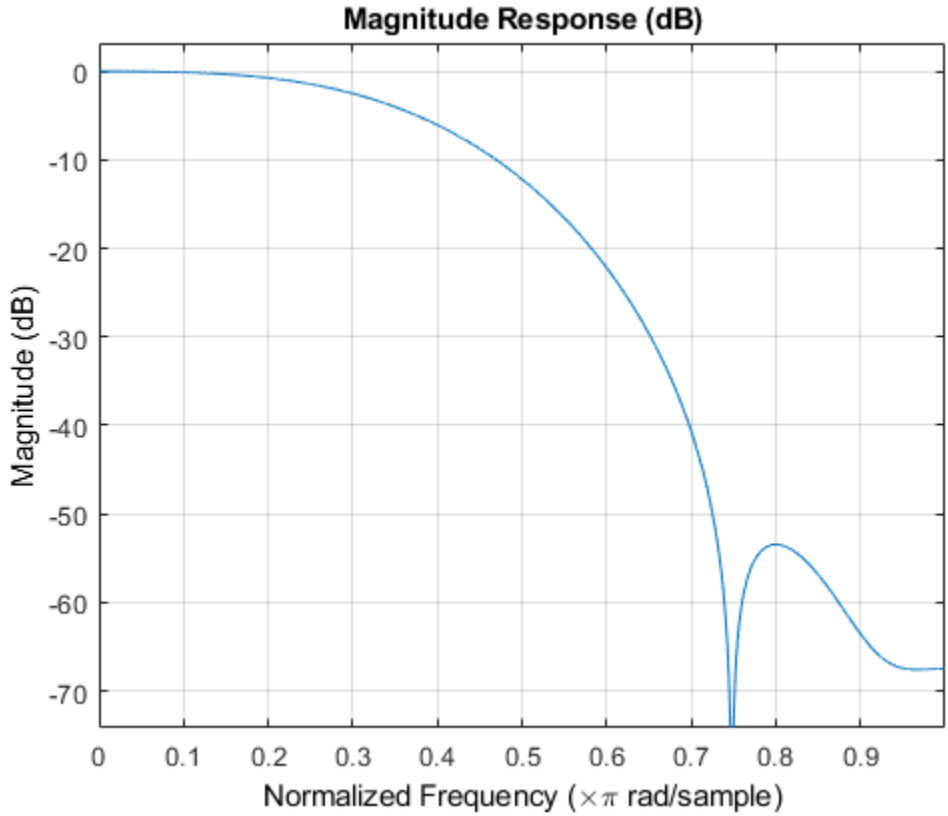
filteredResult = sink.Buffer;
fvtool(fir,'Fs',8000)
```





Design an FIR filter as a System object.

```
N = 10;
Fc = 0.4;
B = fir1(N,Fc);
fir1 = dsp.FIRFilter(B);
fvtool(fir1)
```



This can also be achieved by using `fdesign` as a constructor and `design` to design the filter.

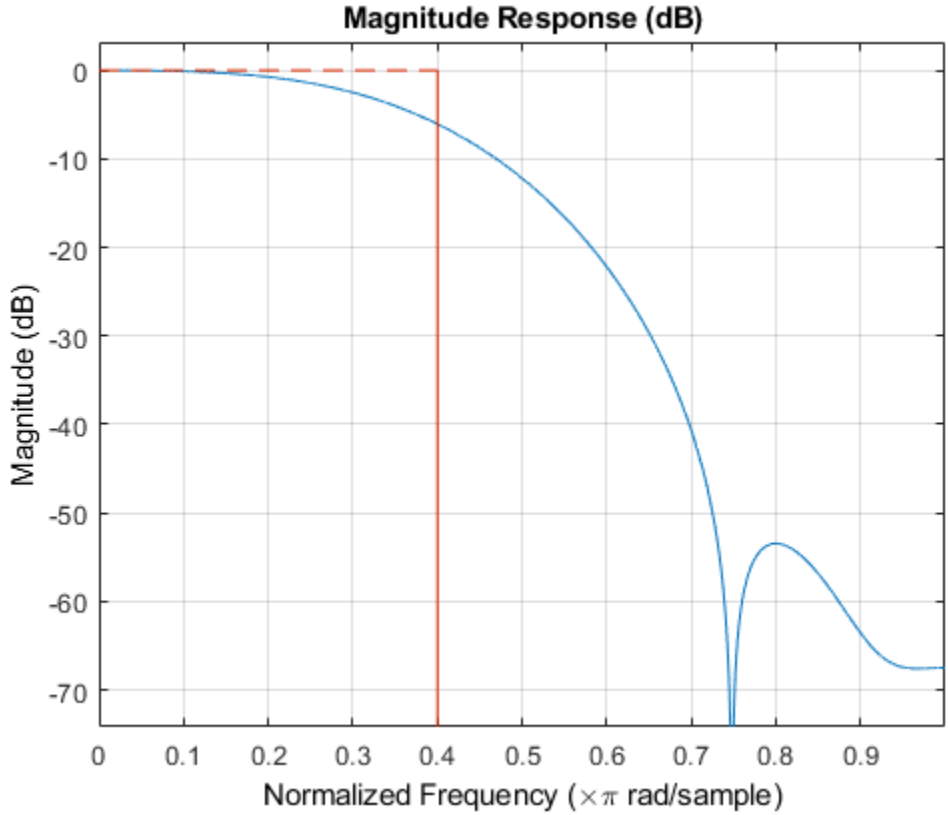
```
N = 10;
Fc = 0.4;
specLowpass = fdesign.lowpass('N,Fc',N,Fc);
fir2 = design(specLowpass,'systemobject',true)
fvtool(fir2);
```

```
fir2 =

  dsp.FIRFilter with properties:
```

```
            Structure: 'Direct form'
      NumeratorSource: 'Property'
            Numerator: [1x11 double]
    InitialConditions: 0

  Use get to show all properties
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete FIR Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

dsp.HDLFIRFilter

Package: `dsp`

Finite impulse response filter—optimized for HDL code generation

Description

The `dsp.HDLFIRFilter` System object models finite-impulse response filter architectures optimized for HDL code generation. The object accepts one input sample at a time, and provides an option for programmable coefficients. It provides a hardware-friendly interface with input and output control signals. To provide a cycle-accurate simulation of the generated HDL code, the object models architectural latency including pipeline registers and resource sharing.

The object provides three filter structures. The direct form systolic architecture provides a fully parallel implementation that makes efficient use of Intel and Xilinx DSP blocks. The direct form transposed architecture is a fully parallel implementation and is suitable for FPGA and ASIC applications. The partly-serial systolic architecture provides a configurable serial implementation that makes efficient use of FPGA DSP blocks. For a filter implementation that matches multipliers, pipeline registers, and pre-adders to the DSP configuration of your FPGA vendor, specify your target device when you generate HDL code.

All three structures optimize hardware resources by sharing multipliers for symmetric or antisymmetric filters. The parallel implementations also remove the multipliers for zero-valued coefficients such as in half-band filters and Hilbert transforms.

The latency between valid input data and the corresponding valid output data depends on the filter structure, serialization options, the number of coefficients and whether the coefficient values provide optimization opportunities.

For a FIR filter with multichannel or frame-based inputs, use the `dsp.FIRFilter` System object instead of this System object.

To filter input data with an HDL-optimized FIR filter:

1 Create the `dsp.HDLFIRFilter` object and set its properties.

2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
firFilt = dsp.HDLFIRFilter
firFilt = dsp.HDLFIRFilter(num)
firFilt = dsp.HDLFIRFilter( ___ ,Name,Value)
```

Description

`firFilt = dsp.HDLFIRFilter` creates an HDL-optimized discrete FIR filter System object, `firFilt`, with default properties.

`firFilt = dsp.HDLFIRFilter(num)` creates a filter with the `Numerator` property set to `num`.

`firFilt = dsp.HDLFIRFilter( ___ ,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

For example:

```
Numerator = firpm(10,[0,0.1,0.5,1],[1,1,0,0]);
fir = dsp.HDLFIRFilter(Numerator,'FilterStructure','Direct form transposed');
...
[dataOut,validOut] = fir(dataIn,validIn);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

Main

`NumeratorSource` — Source of filter coefficients

`'Property'` (default) | `'Input port (Parallel interface)'`

You can enter constant filter coefficients as a property or provide time-varying filter coefficients using an input argument.

Setting this property to `'Input port (Parallel interface)'` enables the `coeff` argument, and the `NumeratorPrototype` property. Specify a prototype to enable the object to optimize the filter implementation according to the symmetry of your coefficients. To use `'Input port (Parallel interface)'`, set the `FilterStructure` property to `'Direct form systolic'`.

`Numerator` — Discrete FIR filter coefficients

`[0.5 0.5]` (default) | real or complex vector

Discrete FIR filter coefficients, specified as a vector of real or complex values. You can also specify the vector as a workspace variable, or as a call to a filter design function. When the input data type is a floating-point type, the object casts the coefficients to the same data type as the input. When the input data type is an integer type or a fixed-point type, you can modify the coefficient data type by using the `CoefficientsDataType` property.

Example: `dsp.HDLFIRFIlter('Numerator',firpm(30,[0 0.1 0.2 0.5]*2,[1 1 0 0]))` defines coefficients using a linear-phase filter design function.

Dependencies

To enable this property, set `NumeratorSource` to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`NumeratorPrototype` — Prototype filter coefficients

`[]` (default) | real or complex vector

Prototype filter coefficients, specified as a vector of real or complex values. The prototype specifies a sample coefficient vector that is representative of the symmetry and zero-value locations of the expected input coefficients. If all of your input coefficient vectors have the

same symmetry and zero-value coefficient locations, set `NumeratorPrototype` to one of those vectors. If your coefficients are unknown or not expected to share symmetry or zero-value locations, set `NumeratorPrototype` to `[]`. The object uses the prototype to optimize the filter by sharing multipliers for symmetric or antisymmetric coefficients, and removing multipliers for zero-value coefficients.

Coefficient optimizations affect the expected size of the `coeff` input argument. Provide only the nonduplicate coefficients as the argument. For example, if you set the `NumeratorPrototype` property to a symmetric 14-tap filter, the object shares one multiplier between each pair of duplicate coefficients, so the object expects a vector of 7 values for the `coeff` argument. You must still provide zeros in the input `coeff` vector for the nonduplicate zero-value coefficients.

Dependencies

To enable this property, set `NumeratorSource` to `'Input port (Parallel interface)'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`FilterStructure` — HDL filter architecture

`'Direct form systolic'` (default) | `'Direct form transposed'` | `'Partly serial systolic'`

HDL filter architecture, specified as one of these structures:

- `'Direct form systolic'` — This architecture provides a fully parallel filter implementation that makes efficient use of Intel and Xilinx DSP blocks. For architecture and performance details, see “Fully Parallel Systolic Architecture” on page 2-618.
- `'Direct form transposed'` — This architecture is a fully parallel implementation that is suitable for FPGA and ASIC applications. For architecture and performance details, see “Fully Parallel Transposed Architecture” on page 2-620.
- `'Partly serial systolic'` — This architecture provides a serial filter implementation and options for tradeoffs between throughput and resource utilization. It makes efficient use of Intel and Xilinx DSP blocks. The object implements a serial L-coefficient filter with M multipliers and requires input samples that are at least N cycles apart, such that $L = N \times M$. You can specify either M or N. For this implementation, the object provides an output signal, `ready`, that indicates when the object is ready for new input data. For architecture and performance details, see “Partly Serial Systolic Architecture (1 < N < L)” on page 2-620 and “Fully Serial Systolic Architecture (N ≥ L)” on page 2-622.

All implementations share multipliers for symmetric and antisymmetric coefficients. The `'Direct form systolic'` and `'Direct form transposed'` structures also remove multipliers for zero-valued coefficients.

`SerializationOption` — Rule to define serial implementation
`'Minimum number of cycles between valid input samples'` (default) | `'Maximum number of multipliers'`

Specify the rule that the object uses to serialize the filter as one of:

- `'Minimum number of cycles between valid input samples'` – Specify a requirement for input data timing by using the `NumberOfCycles` property.
- `'Maximum number of multipliers'` – Specify a requirement for resource usage by using the `NumberOfMultipliers` property.

For a filter with L coefficients, the object implements a serial filter with not more than M multipliers and requires input samples that are at least N cycles apart, such that $L = N \times M$. The object applies coefficient optimizations after serialization, so the M or N values of the final filter implementation can be lower than the value that you specified.

Dependencies

To enable this property, set `FilterStructure` to `'Partly serial systolic'`.

`NumberOfCycles` — Serialization requirement for input timing
2 (default) | positive integer

Serialization requirement for input timing, specified as a positive integer. This property represents N, the minimum number of cycles between valid input samples. In this case, the object calculates $M = L/N$. To implement a fully-serial architecture, set `NumberOfCycles` to a value greater than the filter length, L, or to `Inf`.

The object applies coefficient optimizations after serialization, so the M and N values of the final filter can be lower than the value you specified.

Dependencies

To enable this property, set `FilterStructure` to `'Partly serial systolic'` and set `SerializationOption` to `'Minimum number of cycles between valid input samples'`.

`NumberOfMultipliers` — Serialization requirement for resource usage
2 (default) | positive integer

Serialization requirement for resource usage, specified as a positive integer. This property represents M, the maximum number of multipliers in the filter implementation. In this case, the object calculates $N = L/M$. If the input data is complex, the object allocates `floor(`M`/2)` multipliers for the real part of the filter and `floor(`M`/2)` multipliers for the imaginary part of the filter. To implement a fully-serial architecture, set `NumberOfMultipliers` to `1` for real input, or `2` for complex input.

The object applies coefficient optimizations after serialization, so the M and N values of the final filter can be lower than the value you specified.

Dependencies

To enable this property, set the `FilterStructure` to `'Partly serial systolic'`, and set `SerializationOption` to `'Maximum number of multipliers'`.

Data Types

`Rounding` — Rounding method for type-casting the output
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding method for type-casting the output, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'`, `'Round'`, or `'Zero'`. The rounding method is used when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the object ignores the `RoundingMethod` property. For more details, see “Rounding Modes”.

`OverflowAction` — Overflow handling for type-casting the output
`'Wrap'` (default) | `'Saturate'`

Overflow handling for type-casting the output, specified as `'Wrap'` or `'Saturate'`. Overflow handling is used when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the object ignores the `OverflowAction` property. For more details, see “Overflow Handling”.

`CoefficientsDataType` — Data type of discrete FIR filter coefficients
`'Same word length as input'` (default) | `numerictype` object

Data type of discrete FIR filter coefficients, specified as `'Same word length as input'` or a `numerictype` object. To specify a `numerictype` object, call `numerictype(s,w,f)`, where:

- `s` is `1` for signed and `0` for unsigned.
- `w` is the word length in bits.
- `f` is the number of fractional bits.

The object type-casts the filter coefficients of the discrete FIR filter to the specified data type. The quantization rounds to the nearest representable value and saturates on overflow. When the input data type is floating point, the object ignores the `Coefficients` property.

Dependencies

To enable this property, set `NumeratorSource` to `'Property'`.

`OutputDataType` — Data type of discrete FIR filter output
`'Full precision'` (default) | `'Same word length as input'` | `numerictype` object

Data type of discrete FIR filter output, specified as `'Same word length as input'`, `'Full precision'`, or a `numerictype` object. To specify a `numerictype` object, call `numerictype(s,w,f)`, where:

- `s` is `1` for signed and `0` for unsigned.
- `w` is the word length in bits.
- `f` is the number of fractional bits.

The object type-casts the output of the discrete FIR filter to the specified data type. The quantization uses the settings of the `RoundingMethod` and `OverflowAction` properties. When the input data type is floating point, the object ignores the `OutputDataType` property.

The object increases the word length for full precision inside each filter tap and casts the final output to the specified type. The maximum final internal data type (*WF*) depends on the input data type (*WI*), the coefficient data type (*WC*), and the number of coefficients (*L*) and is given by

WF = *WI* + *WC* + ceil(log2(*L*)).

When you specify a fixed set of coefficients, usually the actual full-precision internal word length is smaller than *WF* because the values of the coefficients limit the potential growth. When you use programmable coefficients, the object cannot calculate the dynamic range, and the internal data type is always *WF*.

Control Arguments

`ResetInputPort` — Enable reset input argument
`false` (default) | `true`

When you set this property to `true`, the object expects a value for the `reset` input argument. The reset signal implements a local synchronous reset of the data path registers.

For more reset considerations, see “Tips” on page 4-727.

`HDLGlobalReset` — Connect data path registers to generated HDL global reset signal
`false` (default) | `true`

Set this property to `true` to connect the generated HDL global reset signal to the data path registers. This property does not change the arguments of the object or modify simulation behavior in MATLAB. When this property is set to `false`, the generated HDL global reset clears only control path registers. The generated HDL global reset can be synchronous or asynchronous depending on your HDL code generation settings.

For more reset considerations, see “Tips” on page 4-727.

Usage

Syntax

```
[dataOut,validOut] = firFilt(dataIn,validIn)
[dataOut,validOut,ready] = firFilt(dataIn,validIn)
[dataOut,validOut] = firFilt(dataIn,validIn,coeff)
[dataOut,validOut] = firFilt(dataIn,validIn,reset)
```

Description

`[dataOut,validOut] = firFilt(dataIn,validIn)` filters the input data only when `validIn` is `true`.

`[dataOut,validOut,ready] = firFilt(dataIn,validIn)` returns `ready` set to `true` when the object is ready to accept new input data on the next call.

The object returns the `ready` argument only when you set the `FilterStructure` property to `'Partly serial systolic'`. For example:

```
firFilt = dsp.HDLFIRFilter(Numerator,...
            'FilterStructure','Partly serial systolic',...
            'SerializationOption','Minimum number of cycles between valid input samples
            'NumberOfCycles',8)
...
for k=1:length(dataIn)
    [dataOut,validOut,ready] = firFilt(dataIn(k),validIn(k));
```

`[dataOut,validOut] = firFilt(dataIn,validIn,coeff)` filters data using the coefficients, `coeff`. The object expects the `coeff` argument only when you set the `NumeratorSource` property to `'Input port (Parallel interface)'`. For example:

```
firFilt = dsp.HDLFIRFilter(NumeratorSource,'Input Port (Parallel interface)')
...
for k=1:length(dataIn)
    Numerator = myGetNumerator();  %calculate coefficients
    [dataOut,validOut] = firFilt(dataIn(k),validIn(k),Numerator);
```

`[dataOut,validOut] = firFilt(dataIn,validIn,reset)` filters data when `reset` is `false`. When `reset` is `true`, the object resets the filter registers. The object expects the `reset` argument only when you set the `ResetInputPort` property to `true`. For example:

```
firFilt = dsp.HDLFIRFilter(Numerator,'ResetInputPort',true)
...
% reset the filter
firFilt(0,false,true);
for k=1:length(dataIn)
    [dataOut,validOut] = firFilt(dataIn(k),validIn(k),false);
```

For more reset considerations, see “Tips” on page 4-727.

Input Arguments

`dataIn` — Input data

real or complex scalar

Input data, specified as a real or complex scalar. When the input data type is an integer type or fixed-point type, the object uses fixed-point arithmetic for internal calculations. `double` and `single` data types are accepted for simulation but not for HDL code generation.

Data Types: `fi` | `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`
Complex Number Support: Yes

`validIn` — Validity of input data

logical scalar

Validity of the input data, specified as a logical scalar. The `dataIn` argument is valid only when `validIn` is `1` (`true`).

Data Types: `logical`

`coeff` — Filter coefficients

real or complex vector

Filter coefficients, specified as a vector of real or complex values. You can change the input coefficients at any time. The size of the vector depends on the size and symmetry of the sample coefficients specified in the `NumeratorPrototype` property. The prototype specifies a sample coefficient vector that is representative of the symmetry and zero-value locations of the expected input coefficients. The object uses the prototype to optimize the filter by sharing multipliers for symmetric or antisymmetric coefficients, and removing multipliers for zero-value coefficients. Therefore, provide only the nonduplicate coefficients in the argument. For example, if you set the `NumeratorPrototype` property to a symmetric 14-tap filter, the object expects a vector of 7 values for the `coeff` argument. You must still provide zeros in the input `coeff` vector for the nonduplicate zero-value coefficients.

`double` and `single` data types are accepted for simulation but not for HDL code generation.

Dependencies

To enable this argument, set the `NumeratorSource` property to `'Input port (Parallel interface)'`.

Data Types: `fi` | `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`reset` — Clear data path state

logical scalar

When the `reset` argument is `true`, the object stops the current calculation and clears the internal state of the filter. The reset signal is synchronous and clears the data path and control path states. For more reset considerations, see “Tips” on page 4-727.

Dependencies

To enable this argument, set the `ResetInputPort` property to `true`.

Data Types: `logical`

Output Arguments

`dataOut` — Filtered output data

real or complex scalar

Filtered output data, returned as a real or complex scalar. When the input data is floating point, the output data inherits the data type of the input data. When the input data is an integer type or fixed-point type, the OutputDataType property determines the output data type.

Data Types: `fi` | `single` | `double`

`validOut` — Validity of output data

logical scalar

Validity of the output data, returned as a logical scalar. The object sets `validOut` to `1` (`true`) with each valid output data in the `dataOut` argument.

Data Types: `logical`

`ready` — Indication object is ready for new input data

logical scalar

Indication of whether the object is ready for new input data, returned as a logical scalar. The object sets this value to `true` to indicate that it is ready to accept new input data on the next call.

When using the partly-serial architecture, the object processes one sample at a time. If your design waits for the object to return `ready` set to `false` before de-asserting `validIn`, then one extra data input value arrives at the object. The object stores this extra data while processing the current data, and then does not set `ready` to `true` until the extra input is processed.

Dependencies

The object returns this value only when the `FilterStructure` property is set to `'Partly serial systolic'`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLFIRFilter

getLatency	Latency of FIR filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create HDL FIR Filter System Object with Default Settings

Create an HDL FIR filter System object with default settings.

```
firFilt = dsp.HDLFIRFilter;
```

Create an input signal of random noise, and allocate memory for outputs.

```
L = 100;
dataIn = randn(L,1);
dataOut = zeros(L,1);
validOut = false(L,1);
```

Call the object on the input signal, asserting that the input data is always valid. The object processes one data sample at a time.

```
for k=1:L
    [dataOut(k),validOut(k)] = firFilt(dataIn(k),true);
end
```

Implement a Partly-Serial Streaming FIR Filter

This example shows how to configure the `dsp.HDLFIRFilter` System object™ as a partly-serial 31-tap lowpass filter.

Design the filter coefficients. Then create an HDL FIR filter System object. Set the `FilterStructure` to `'Partly serial systolic'`. By default, the `SerializationOption` property is `'Minimum number of cycles between valid input samples'`, and so you must specify the serialization rule using the `NumberOfCycles` property. To share each multiplier between 10 coefficients, set the `NumberOfCycles` to 10.

```
numerator = firpm(30,[0 0.1 0.2 0.5]*2,[1 1 0 0]);
numCycles = 10;
firFilt = dsp.HDLFIRFilter('Numerator',numerator, ...
    'FilterStructure','Partly serial systolic','NumberOfCycles',numCycles);
```

This serial filter implementation requires 10 time steps to calculate each output. Create input signals `dataIn` and `validIn` such that new data is applied only every `NumberOfCycles` time steps.

```
L = 16;
x = fi(randn(L,1),1,16);
dataIn = zeros(L*numCycles,1,'like',x);
dataIn(1:numCycles:end) = x;
validIn = false(L*numCycles,1);
validIn(1:numCycles:end) = true;
```

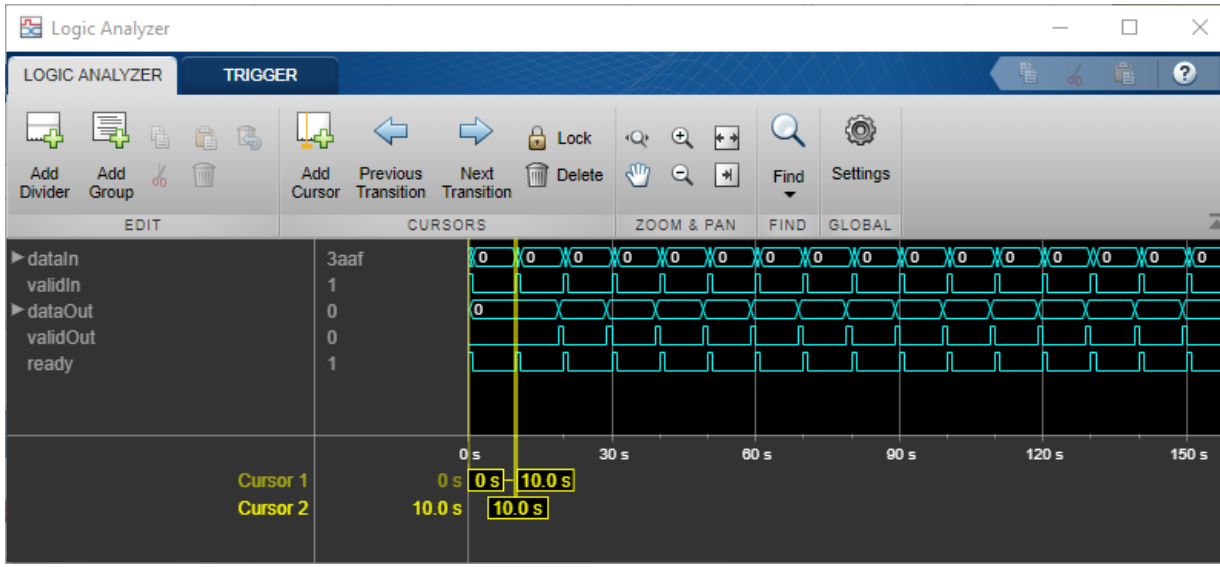
Create a `LogicAnalyzer` object to view the inputs and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',5, ...
    'SampleTime',1,'TimeSpan',length(dataIn));
tags = getDisplayChannelTags(la);
modifyDisplayChannel(la,tags{1},'Name','dataIn');
```

```
modifyDisplayChannel(la,tags{2},'Name','validIn');
modifyDisplayChannel(la,tags{3},'Name','dataOut');
modifyDisplayChannel(la,tags{4},'Name','validOut');
modifyDisplayChannel(la,tags{5},'Name','ready');
```

Call the filter System object on the input signals, and view the results in the Logic Analyzer. The object models HDL pipeline registers and resource sharing, so the waveform shows an initial delay before the object returns valid output samples.

```
for k=1:length(dataIn)
    [dataOut,validOut,ready] = firFilt(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut,ready)
end
```



Create HDL FIR Filter System Object for HDL Code Generation

To generate HDL code from a System object™, create a function that contains and calls the object.

Create Function

Write a function that creates and calls an 11-tap HDL FIR filter System object. You can generate HDL code from this function.

```
function [dataOut,validOut] = HDLFIR11Tap(dataIn, validIn)
%HDLFIR11Tap
% Process one sample of data by using the dsp.HDLFIRFilter System
% object.
% dataIn is a fixed-point scalar value.
% You can generate HDL code from this function.
    persistent fir
    if isempty(fir)
        Numerator = firpm(10,[0 0.1 0.5 1],[1 1 0 0]);
        fir = dsp.HDLFIRFilter('Numerator',Numerator);
    end
    [dataOut,validOut] = fir(dataIn,validIn);
end
```

Create Test Bench for Function

Clear the workspace, create an input signal of random noise, and allocate memory for outputs.

```
clear variables
clear HDLFIR11Tap
L = 200;
dataIn = fi(randn(L,1),1,16);
validIn = ones(L,'logical');
dataOut = zeros(L,1);
validOut = false(L,1);
```

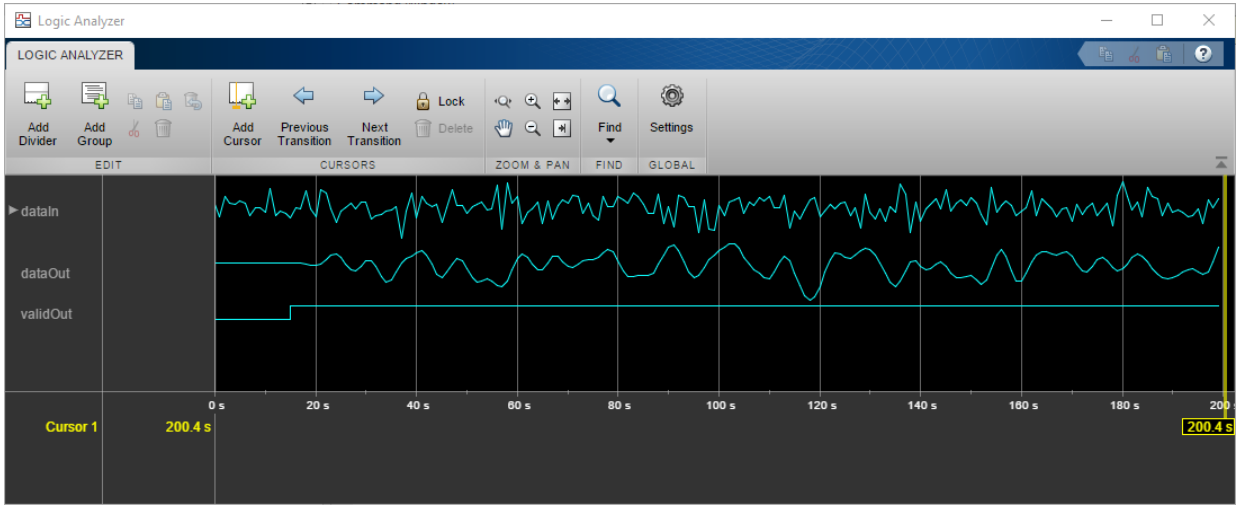
Call the function on the input signal.

```
for k = 1:L
    [dataOut(k),validOut(k)] = HDLFIR11Tap(dataIn(k), validIn(k));
end
```

Plot the signals with the Logic Analyzer.

```
la = dsp.LogicAnalyzer('NumInputPorts',3,'SampleTime',1,'TimeSpan',L);
tags = getDisplayChannelTags(la);
```

```
modifyDisplayChannel(la,tags{1},'Name','dataIn','Format','Analog','Height',50);
modifyDisplayChannel(la,tags{2},'Name','dataOut','Format','Analog','Height',50);
modifyDisplayChannel(la,tags{3},'Name','validOut');
la(dataIn,dataOut,validOut)
```



Explore Latency of HDL FIR Object

The latency of the `dsp.HDLFIRFilter` System object™ varies with filter structure, serialization options, and whether the coefficient values provide optimization opportunities. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output.

Create a `dsp.HDLFIRFilter` System object™ and request the latency. The default architecture is fully parallel systolic. The default data type for the coefficients is `'Same word length as input'`. Therefore, when you call the `getLatency` object function, you must specify an input data type. The object casts the coefficient values to the input data type, and then checks for symmetric coefficients. This `Numerator` has 31 symmetric coefficients, so the object optimizes for the shared coefficients, and implements 16 multipliers.

```
Numerator = firpm(30,[0 0.1 0.2 0.5]*2,[1 1 0 0]);
Input_type = numerictype(1,16,15); % object uses only the word length for coefficient t
```

```
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator);
L_sysp = getLatency(hdlfir,Input_type)
```

```
L_sysp = 23
```

Check the latency for a partly serial systolic implementation of the same filter. By default, the `SerializationOption` property is `'Minimum number of cycles between valid input samples'`, and so you must specify the serialization rule using the `NumberOfCycles` property. To share each multiplier between 8 coefficients, set the `NumberOfCycles` to 8. The object then optimizes based on the coefficient symmetry, so there are 16 unique coefficients shared 8 times each over 2 multipliers. This serial filter implementation requires input samples that are valid every 8 cycles.

```
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator,'FilterStructure','Partly serial systol
L_syss = getLatency(hdlfir,Input_type)
```

```
L_syss = 19
```

Check the latency of a nonsymmetric fully parallel systolic filter. The `Numerator` has 31 coefficients.

```
Numerator = sinc(0.4*[-30:0]);
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator);
L_sysp = getLatency(hdlfir,Input_type)
```

```
L_sysp = 37
```

Check the latency of the same nonsymmetric filter implemented as a partly serial systolic filter. In this case, specify the `SerializationOption` by the number of multipliers. The object implements a filter that has 2 multipliers and requires 8 cycles between input samples.

```
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator,'FilterStructure','Partly serial systol
                          'SerializationOption','Maximum number of multipliers','Numbe
L_syss = getLatency(hdlfir,Input_type)
```

```
L_syss = 25
```

Check the latency of a fully parallel transposed architecture. The latency for this filter structure is always 6 cycles.

```
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator,'FilterStructure','Direct form transpos
L_trans = getLatency(hdlfir,Input_type)
```

```
L_trans = 6
```

Tips

Reset Behavior

- By default, the `dsp.HDLFIRFilter` object connects the generated HDL global reset to only control path registers. The two reset properties, ResetInputPort and HDLGlobalReset, connect a reset signal to the data path registers. Resetting data path registers can reduce synthesis performance because of the additional routing and loading on the reset signal.
- The `ResetInputPort` property enables a `reset` argument when you call the object. The reset signal implements a local synchronous reset of the data path registers. For optimal use of FPGA resources, this option does not connect the reset signal to registers targeted to the DSP blocks of the FPGA.
- The `HDLGlobalReset` property connects the generated HDL global reset signal to the data path registers. This property does not change the arguments of the object or modify simulation behavior in MATLAB. The generated HDL global reset can be synchronous or asynchronous depending on your HDL code generation settings. Depending on your device, using the global reset may move registers out of the DSP blocks and increase resource use.
- When you set both the `ResetInputPort` and `HDLGlobalReset` properties to `true`, both the global and local reset signals clear the control and data path registers.

Algorithms

This System object implements the algorithms described on the Discrete FIR Filter HDL Optimized block reference page.

Compatibility Considerations

Changes to Serial Filter Properties

Behavior changed in R2019a

The options for configuring a serial filter architecture have changed. Prior to R2019a, you specified the serial implementation by setting a requirement for input timing. Now, you

can specify the serialization requirement based on either input timing (*N*) or resource usage (*M*).

Serial Filter Requirement	Configuration Prior to R2019a	Configuration After R2019a
Specify a serialization rule based on input timing, that is, *N* cycles.	• Set the `FilterStructure` property to `'Direct form systolic'`. • Set the `Sharing` property to `true`. • Set the `SharingFactor` property to *N*.	• Set the `FilterStructure` property to `'Partly serial systolic'`. • Set the `SerializationOption` property to `'Minimum number of cycles between valid input samples'`. • Set the `NumberOfCycles` property to *N*.
Specify a serialization rule based on resource usage, that is, *M* multipliers.	Serialization by resource usage is not supported prior to R2019a. However, you can calculate *N* based on your multiplier requirement. • Set the `FilterStructure` property to `'Direct form systolic'`. • Set the `Sharing` property to `true`. • Set the `SharingFactor` property to `ceil(NumCoeffs/`*M*`)`.	• Set the `FilterStructure` property to `'Partly serial systolic'`. • Set the `SerializationOption` property to `'Maximum number of multipliers'`. • Set the `NumberOfMultipliers` property to *M*.

`dsp.FIRFilter`

Introduced in R2017a

dsp.FIRHalfbandDecimator

Package: dsp

Halfband decimator

Description

The dsp.FIRHalfbandDecimator System object performs an efficient polyphase decimation of the input signal by a factor of two. You can use dsp.FIRHalfbandDecimator to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands. dsp.FIRHalfbandDecimator uses an FIR equiripple design to construct the halfband filters and a polyphase implementation to filter the input.

To filter and downsample your data:

1. Create the dsp.FIRHalfbandDecimator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
firhalfbanddecim = dsp.FIRHalfbandDecimator
firhalfbanddecim = dsp.FIRHalfbandDecimator(Name,Value)
```

Description

firhalfbanddecim = dsp.FIRHalfbandDecimator returns a halfband decimator, firhalfbanddecim, with the default settings. Under the default settings, the System object filters and downsamples the input data with a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

`firhalfbanddecim = dsp.FIRHalfbandDecimator(Name,Value)` returns a halfband decimator, with additional properties specified by one or more `Name,Value` pair arguments.

Example: `firhalfbanddecim = dsp.FIRHalfbandDecimator('Specification','Filter order and stopband attenuation')` creates an FIR halfband decimator object with filter order set to 52 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Specification` — Filter design parameters
`'Transition width and stopband attenuation'` (default) | `'Filter order and stopband attenuation'` | `'Filter order and transition width'` | `'Coefficients'`

Filter design parameters, specified as a character vector. When you set `Specification` to one of the following, you choose two of the three available design parameters to design the FIR Halfband filter.

- `'Transition width and stopband attenuation'` –– Transition width and stopband attenuation are the design parameters.
- `'Filter order and stopband attenuation'` –– Filter order and stopband attenuation are the design parameters.
- `'Filter order and transition width'` –– Filter order and transition width are the design parameters.

The filter is designed using the optimal equiripple filter design method.

When you set `Specification` to `'Coefficients'`, you specify the halfband filter coefficients directly through the `Numerator` property.

`FilterOrder` — Filter order

`52` (default) | even positive integer

Filter order, specified as an even positive integer.

Dependencies

This property applies when you set `Specification` to either `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Stopband attenuation

`80` (default) | positive real scalar

Stopband attenuation in dB, specified as a positive real scalar.

Dependencies

This property applies when you set `Specification` to either `'Filter order and stopband attenuation'` or `'Transition width and stopband attenuation'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TransitionWidth` — Transition width

`4100` (default) | positive real scalar

Transition width in Hz, specified as a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate.

Dependencies

This property applies when you set `Specification` to either `'Transition width and stopband attenuation'` or `'Filter order and transition width'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Numerator` — FIR halfband filter coefficients

`firhalfband('minorder',0.407,1e-4)` (default) | row vector

FIR halfband filter coefficients, specified as a row vector. The coefficients must comply with the FIR halfband impulse response format. For details on this format, see “Halfband

Filters” on page 4-744 and “FIR Halfband Filter Design”. If half the order of the filter, `(length(Numerator) - 1)/2`, is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 0.5. If half the order of the filter is odd, the sequence of alternating zeros with a 0.5 at the center starts at the second coefficient.

Dependencies

This property applies when you set `Specification` to `'Coefficients'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SampleRate` — Input sample rate

`44100` (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Data Types: `single` | `double`

Fixed-Point Properties

`CoefficientsDataType` — Word and fraction lengths of coefficients

`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

`RoundingMethod` — Rounding method for output fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
ylow = firhalfbanddecim(x)
[ylow,yhigh] = firhalfbanddecim(x)
```

Description

`ylow = firhalfbanddecim(x)` filters the input signal `x` using the FIR halfband filter, `firhalfbanddecim`, and downsamples the output by a factor of 2.

`[ylow,yhigh] = firhalfbanddecim(x)` computes the `ylow` and `yhigh`, of the analysis filter bank, `firhalfbanddecim` for input `x`. A *Ki*-by-*N* input matrix is treated as *N* independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `ylow` and `yhigh` are of the same size (*Ko*-by-*N*) and data type. *Ko* = *Ki*/2, where 2 is the decimation factor.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

This object supports variable-size input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

`ylow` — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of decimator output, returned as a column vector or a matrix. The output, `ylow` is a lowpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

`yhigh` — Highpass subband of decimator output

column vector | matrix

Highpass subband of decimator output, returned as a column vector or a matrix. The output, `yhigh` is a highpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRHalfbandDecimator`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost for implementing filter System objects
coeffs	Filter coefficients
polyphase	Polyphase decomposition of multirate filter

Common to All System Objects

step	Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

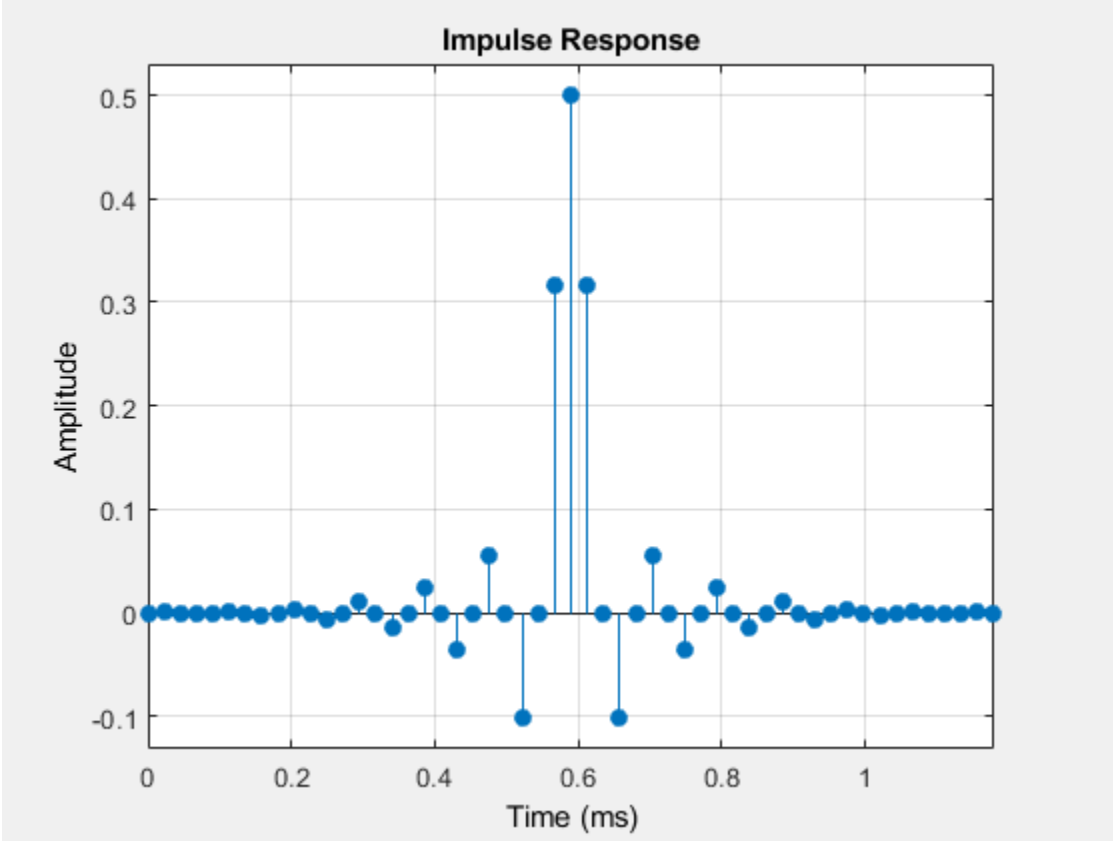
Impulse and Frequency Response of Halfband Decimation Filter

Create a lowpass halfband decimation filter for data sampled at 44.1 kHz. The output data rate is 1/2 the input sampling rate, or 22.05 kHz. Specify the filter order to be 52 with a transition width of 4.1 kHz.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbanddecim =dsp.FIRHalfbandDecimator('Specification',filterspec, ...
                                           'FilterOrder',Order, ...
                                           'TransitionWidth',TW, ...
                                           'SampleRate',Fs);
```

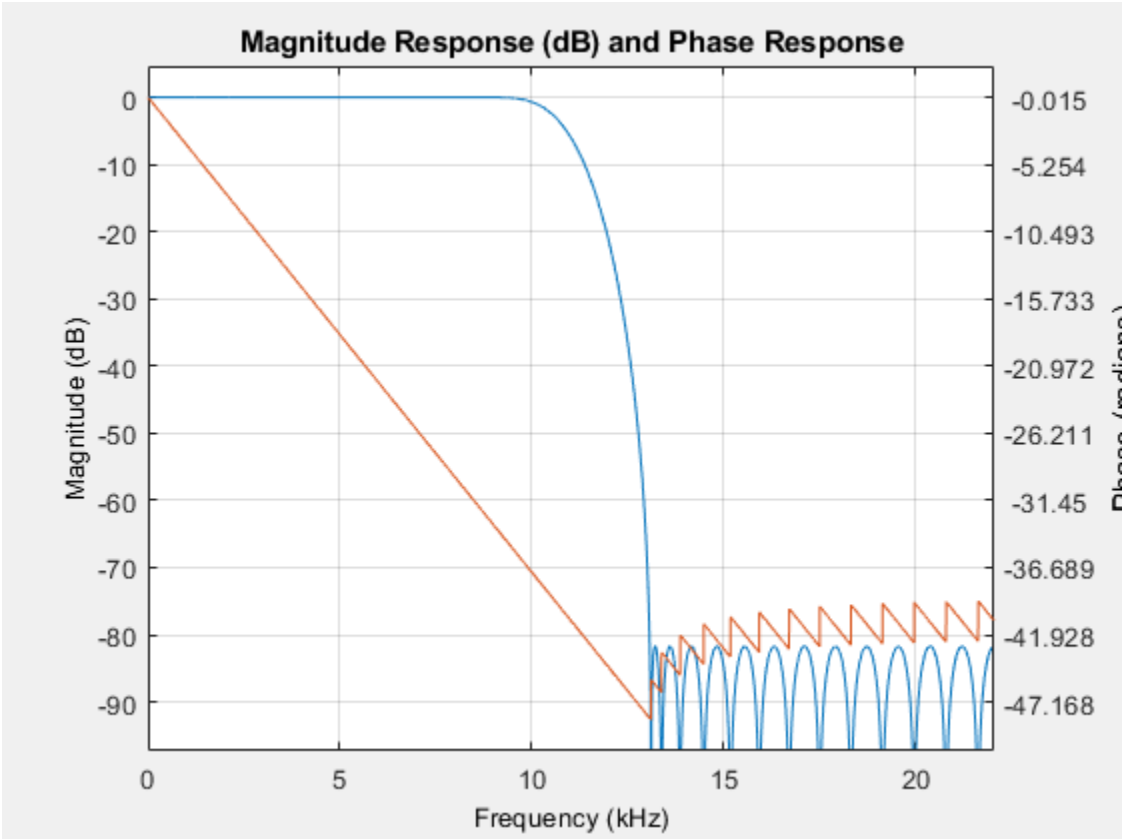
Plot the impulse response. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
fvtool(firhalfbanddecim,'Analysis','impulse')
```



Plot the magnitude and phase response.

```
fvtool(firhalfbanddecim,'Analysis','freq')
```



Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sampling rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

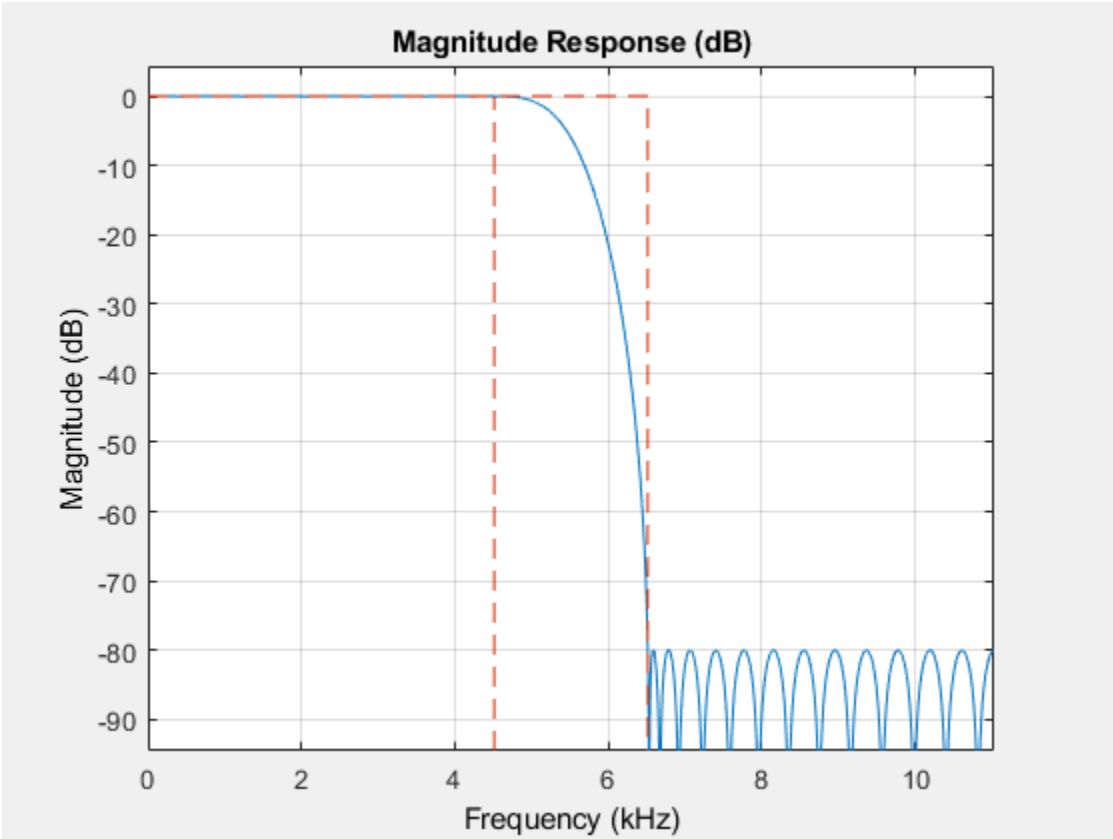
firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

adw = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```



Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
  audioframe = afr();
  xlo = firhalfbanddecim(audioframe);
  ylow = firhalfbandinterp(xlo);
  adw(ylow);
end
```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

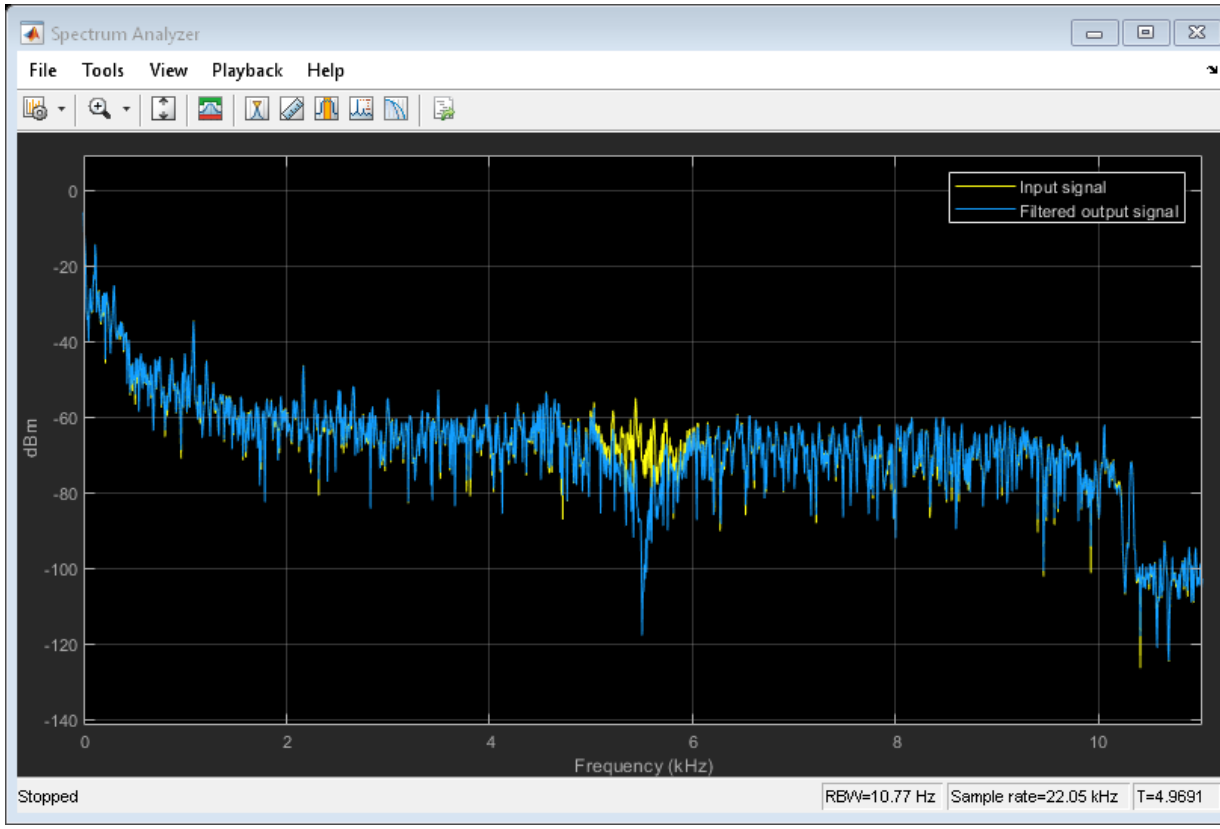
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank.

Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = firhalfbanddecim(audioInput);
    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```



Filter Input into Lowpass and Highpass Subbands

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```
hfirhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification','Transition width and stopband attenuation',...
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);
```

Filter a two-channel input into low and highpass subbands

```
x = randn(1024,2);
[ylow,yhigh] = step(hfirhalfbanddecim,x);
```

More About

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi}\int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at n=0. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi}\int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi}\int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at n=0.

`dsp.FIRHalfbandDecimator` uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-745 for more details.

Algorithms

Halfband Equiripple Design

`dsp.FIRHalfbandDecimator` uses a minimax FIR design to design a fullband linear phase filter with the desired specifications. The fullband filter is upsampled so that the even-indexed samples of the filter are replaced with zeros. The upsampling of the filter produces a halfband filter. Finally, the filter tap corresponding to the group delay of the filter in samples is set equal to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband Filters” on page 4-744. See [1] for a description of this filter design method using the Remez exchange algorithm.

Polyphase Implementation with Halfband Filters

`dsp.FIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters when you filter the input signal. The chief advantage of the polyphase implementation is that you can downsample the signal prior to filtering. This allows you to filter at the lower sampling rate.

Splitting a filter’s impulse response, *h(n)*, into two polyphase components results in an even polyphase component with *z*-transform

$$H_0(z) = \sum_n h(2n) z^{-n}.$$

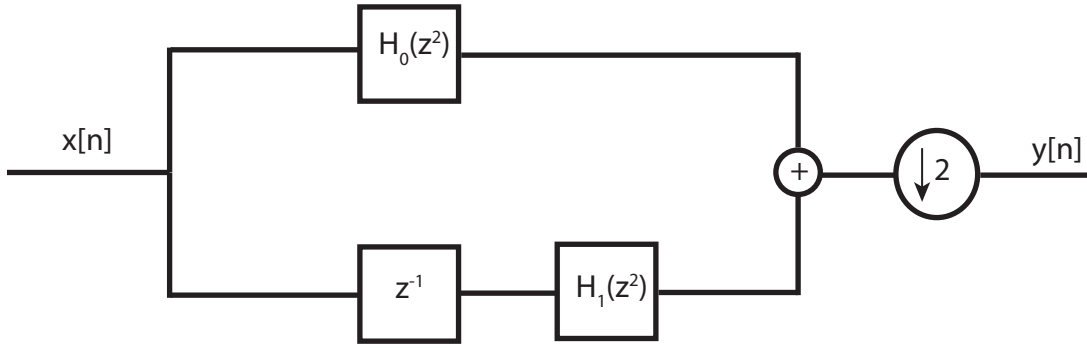
and an odd polyphase component with *z*-transform

$$H_1(z) = \sum_n h(2n+1) z^{-n}.$$

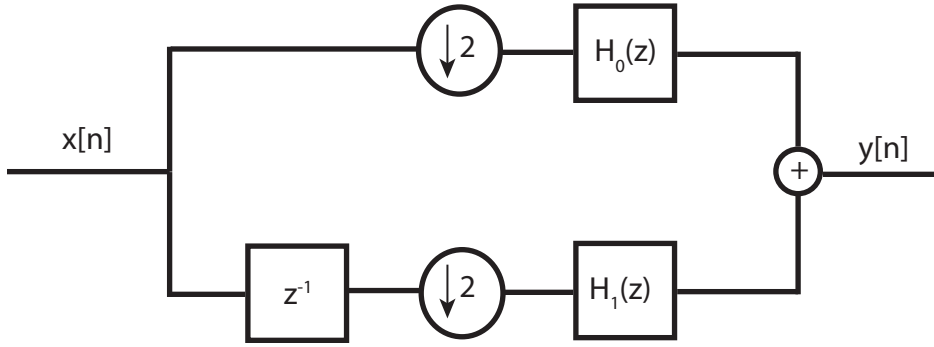
The *z*-transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1} H_1(z^2).$$

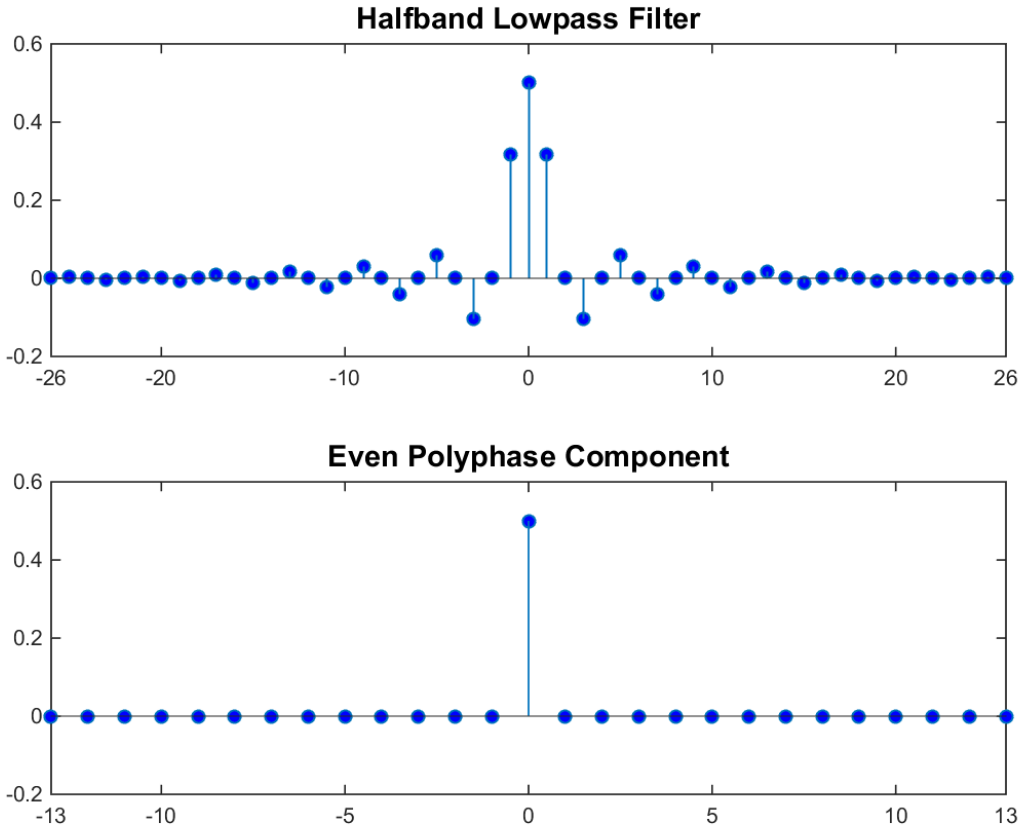
Graphically, you can represent filtering and input followed by downsampling by two with the following figure



Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This allows you to filter at the lower rate.

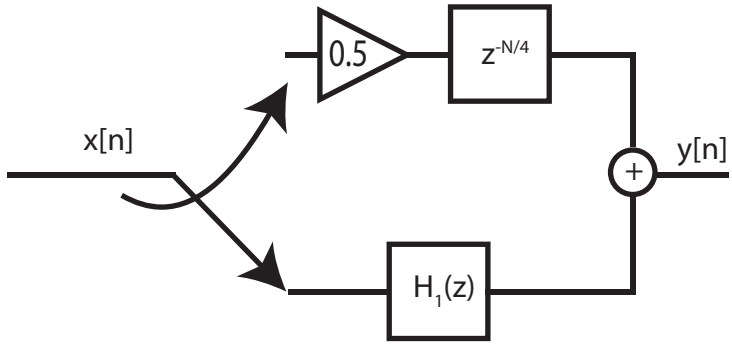


For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0. Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$ where N is the number of filter taps. This process is illustrated in the following figure.



The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband decimator, `dsp.FIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch. This is illustrated in the following figure where one polyphase component is replaced by a gain and delay.



The commutator switch takes input samples from a single branch and supplies every other sample to one of the two polyphase components for filtering. This halves the sampling rate of the input signal. Which polyphase component reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even depending on the filter half order. You can see this by inspecting the polyphase components of the following filters.

```
filterspec = 'Filter order and stopband attenuation' ;
halfOrderEven = dsp.FIRHalfbandDecimator('Specification',filterspec,...
    'FilterOrder',64,'StopbandAttenuation',80);
halfOrderOdd = dsp.FIRHalfbandDecimator('Specification',filterspec,...
    'FilterOrder', 54,'StopbandAttenuation',80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

To summarize, `dsp.FIRHalfbandDecimator`

- decimates the input prior to filtering and filters the even and odd polyphase components of the input separately with the even and odd polyphase components of the filter.
- exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

dsp.FIRHalfbandInterpolator

Package: `dsp`

Halfband interpolator

Description

The `dsp.FIRHalfbandInterpolator` System object performs efficient polyphase interpolation of the input signal using an upsampling factor of two. You can use `dsp.FIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands. `dsp.FIRHalfbandInterpolator` uses an FIR equiripple design to construct the halfband filters and a polyphase implementation to filter the input.

To upsample and interpolate your data:

1. Create the `dsp.FIRHalfbandInterpolator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator
firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name,Value)
```

Description

`firhalfbandinterp = dsp.FIRHalfbandInterpolator` returns a FIR halfband interpolation filter, `firhalfbandinterp`, with the default settings. Under the default settings, the System object upsamples and interpolates the input data using a halfband

frequency of `11025` Hz, a transition width of `4.1` kHz, and a stopband attenuation of `80` dB.

`firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name,Value)` returns a halfband interpolator, with additional properties specified by one or more `Name,Value` pair arguments.

Example: `firhalfbandinterp = dsp.FIRHalfbandInterpolator('Specification','Filter order and stopband attenuation')` creates an FIR halfband interpolator object with filter order set to 52 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Specification` — Filter design parameters
`'Transition width and stopband attenuation'` (default) | `'Filter order and stopband attenuation'` | `'Filter order and transition width'` | `'Coefficients'`

Filter design parameters, specified as a character vector. When you set `Specification` to one of the following, you choose two of the three available design parameters to design the FIR Halfband filter.

- `'Transition width and stopband attenuation'` –– Transition width and stopband attenuation are the design parameters.
- `'Filter order and stopband attenuation'` –– Filter order and stopband attenuation are the design parameters.
- `'Filter order and transition width'` –– Filter order and transition width are the design parameters.

The filter is designed using optimal equiripple filter design method.

When you set `Specification` to `'Coefficients'`, you specify the halfband filter coefficients directly through the `Numerator` property.

`FilterOrder` — Filter order

`52` (default) | even positive integer

Filter order, specified as an even positive integer.

Dependencies

This property applies when you set `Specification` to either `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Stopband attenuation

`80` (default) | positive real scalar

Stopband attenuation in dB, specified as a positive real scalar.

Dependencies

This property applies when you set `Specification` to either `'Filter order and stopband attenuation'` or `'Transition width and stopband attenuation'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TransitionWidth` — Transition width

`4100` (default) | positive real scalar

Transition width in Hz, specified as a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate.

Dependencies

This property applies when you set `Specification` to either `'Transition width and stopband attenuation'` or `'Filter order and transition width'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Numerator` — FIR halfband filter coefficients

`2*firhalfband('minorder',0.407,1e-4)` (default) | row vector

FIR halfband filter coefficients, specified as a row vector. The coefficients must comply with the FIR halfband impulse response format. For details on this format, see "Halfband Filters" on page 4-765 and "FIR Halfband Filter Design". If half the order of the filter, `(length(Numerator) - 1)/2` is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 1.0. If half the order of the filter is odd, the sequence of alternating zeros with a 1.0 at the center starts at the second coefficient.

Dependencies

This property applies when you set `Specification` to `'Coefficients'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`SampleRate` — Input sample rate

`44100` (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify a transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Data Types: `single` | `double`

`FilterBankInputPort` — Synthesis filter bank

`false` (default) | `true`

Synthesis filter bank, specified as either `false` or `true`. If this property is `false`, `dsp.FIRHalfbandInterpolator` is an interpolation filter for a single vector- or matrix-valued input when you call the algorithm. If this property is `true`, `dsp.FIRHalfbandInterpolator` is a synthesis filter bank and the algorithm accepts two inputs, the lowpass and highpass subbands to synthesize.

Fixed-Point Properties

`CoefficientsDataType` — Word and fraction lengths of coefficients

`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

`RoundingMethod` — Rounding method for output fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y = firhalfbandinterp(x1)
y = firhalfbandinterp(x1,x2)
```

Description

`y = firhalfbandinterp(x1)` upsamples by two and interpolates the input signal `x1` using the FIR halfband interpolator, `firhalfbandinterp`.

`y = firhalfbandinterp(x1,x2)` implements a halfband synthesis filter bank for the inputs `x1` and `x2`. `x1` is the lowpass output of a halfband analysis filter bank and `x2` is the highpass output of a halfband analysis filter bank. `dsp.FIRHalfbandInterpolator` implements a synthesis filter bank only when the `'FilterBankInputPort'` property is set to `true`.

Input Arguments

`x1` — Data input
column vector | matrix

Data input to the FIR halfband interpolator, specified as a column vector or a matrix. This signal is the lowpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

x2 — Second data input
column vector | matrix

Second data input to the synthesis filter bank, specified as a column vector or a matrix. This signal is the highpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Output of interpolator
column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRHalfbandInterpolator`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters

info	Information about filter System object
cost	Estimate cost for implementing filter System objects
coeffs	Filter coefficients
polyphase	Polyphase decomposition of multirate filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Impulse and Frequency Response of Halfband Interpolation Filter

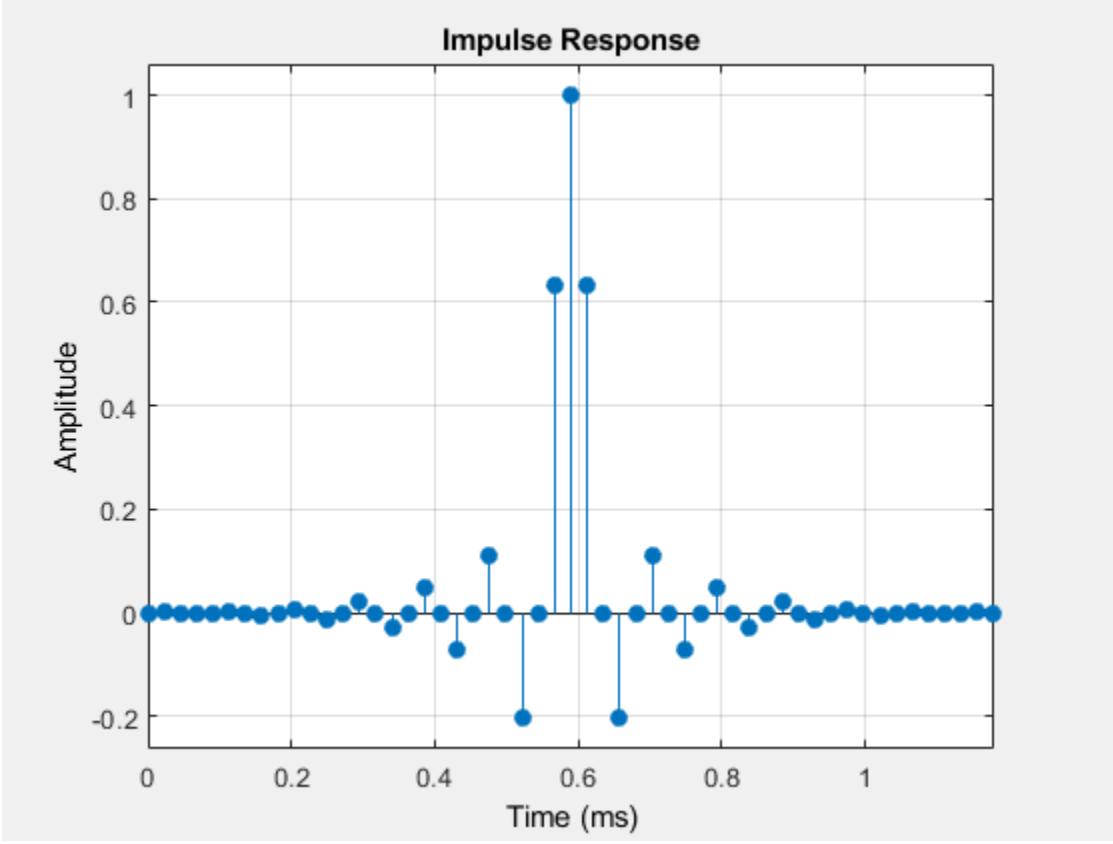
Create a lowpass halfband interpolation filter for upsampling data to 44.1 kHz. Specify a filter order of 52 and a transition width of 4.1 kHz.

```
Fs = 44.1e3;
InputSampleRate = Fs/2;
Order = 52;
TW = 4.1e3;
filterspec = 'Filter order and transition width';

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',InputSampleRate);
```

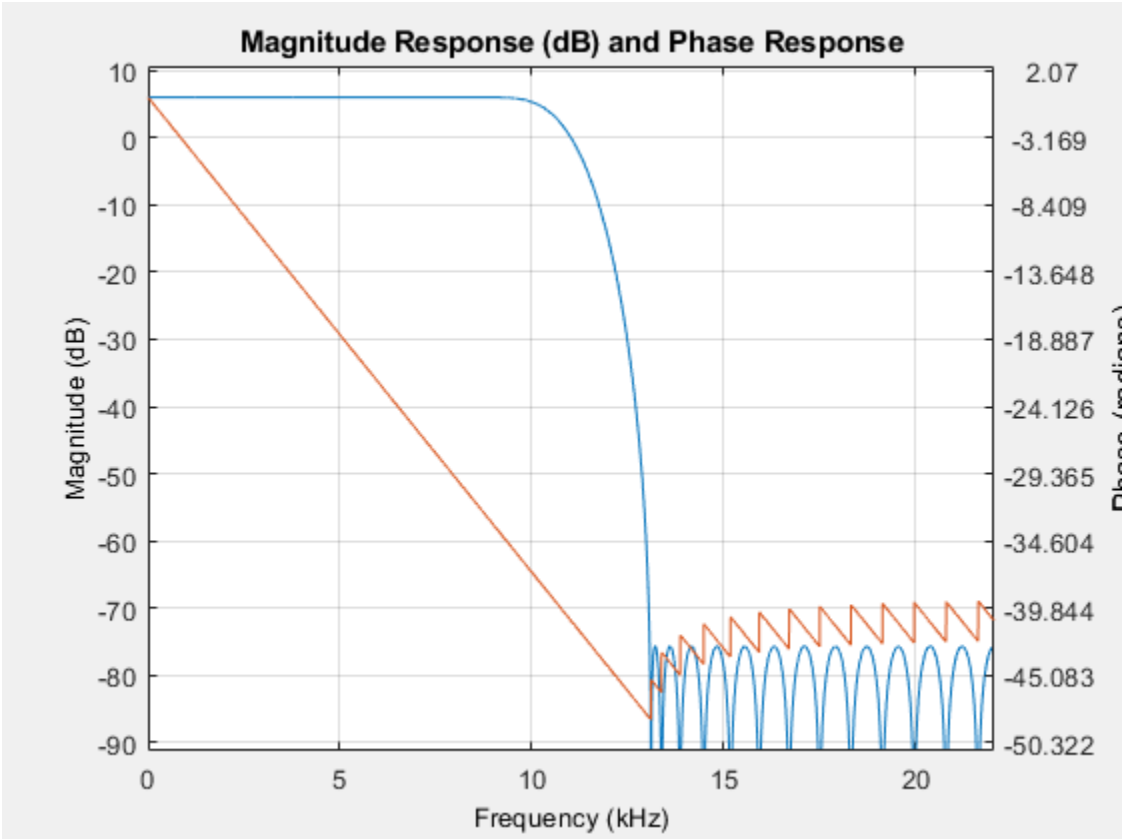
Plot the impulse response. The 0th order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
fvtool(firhalfbandinterp,'Analysis','Impulse');
```



Plot the magnitude and phase response.

```
fvtool(firhalfbandinterp,'Analysis','freq');
```



Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sampling rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

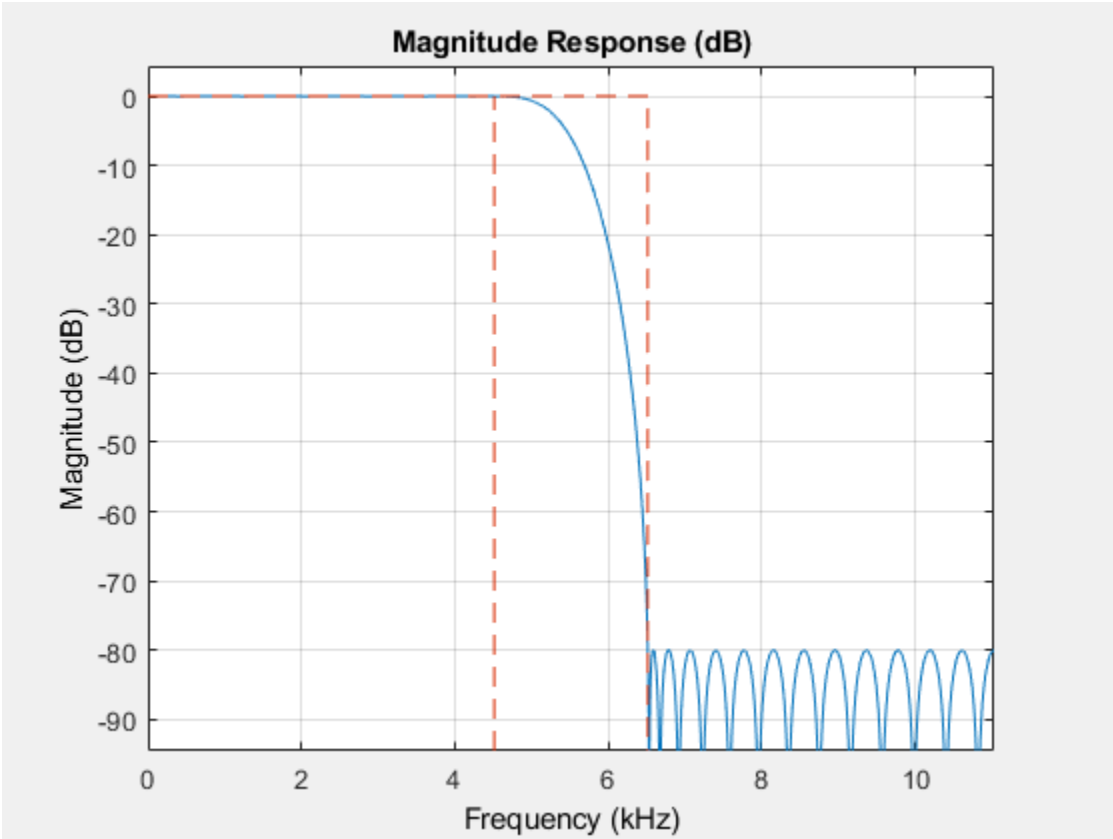
firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

adw = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```



Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
  audioframe = afr();
  xlo = firhalfbanddecim(audioframe);
  ylow = firhalfbandinterp(xlo);
  adw(ylow);
end
```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

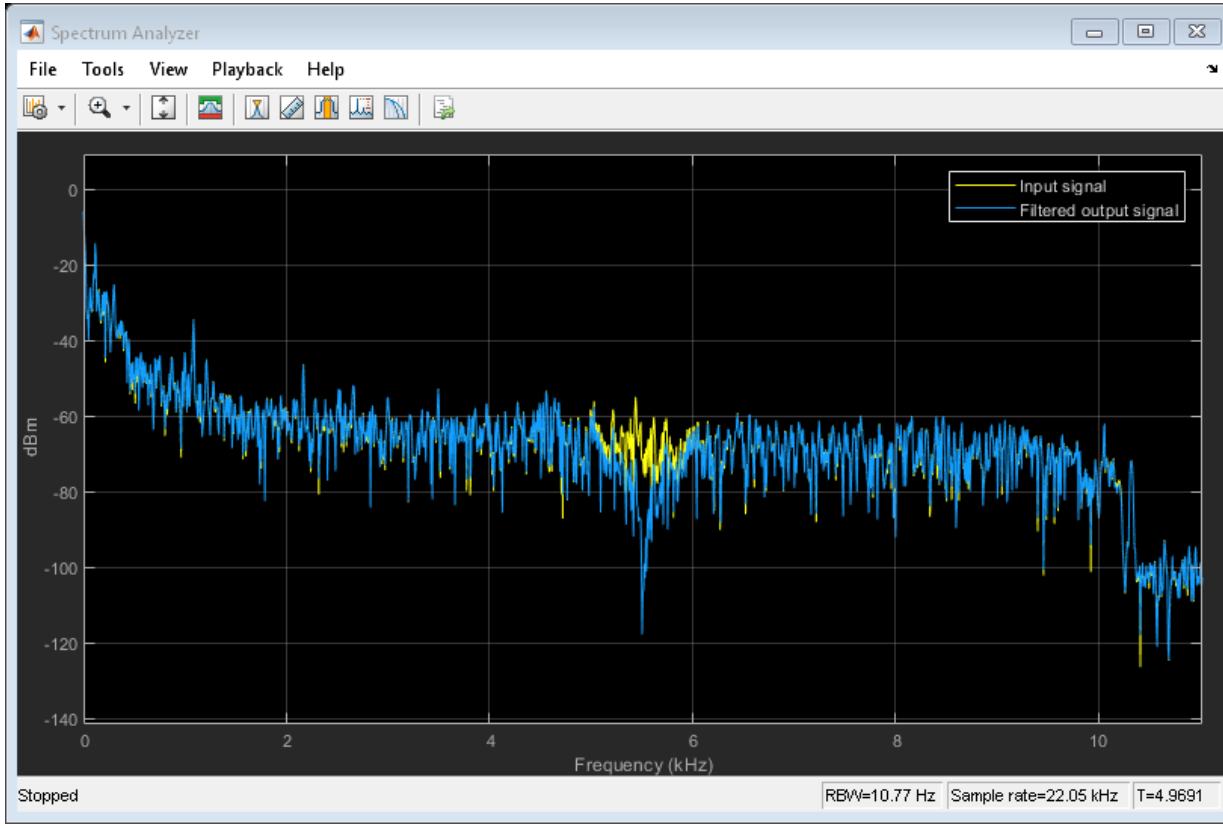
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank.

Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = firhalfbanddecim(audioInput);
    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```



Upsample and Interpolate Multichannel Input

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 52 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
                                                'Specification',filterspec,...
                                                'FilterOrder',Order,...
```

```
                                                'TransitionWidth',TW,...
                                                 'SampleRate',Fs);

x = randn(1024,4);
y = step(firhalfbandinterp,x);
```

More About

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi}\int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at n=0. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi}\int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi}\int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at n=0.

`dsp.FIRHalfbandInterpolator` uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-766 for more details.

Algorithms

Halfband Equiripple Design

`dsp.FIRHalfbandInterpolator` uses a minimax FIR design to design a fullband linear phase filter with the desired specifications. The fullband filter is upsampled so that the even-indexed samples of the filter are replaced with zeros. The upsampling of the filter produces a halfband filter. Finally, the filter tap corresponding to the group delay of the filter in samples is set equal to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in "Halfband Filters" on page 4-765. See [1] for a description of this filter design method using the Remez exchange algorithm.

The coefficients of the halfband interpolation filter are scaled by the interpolation factor, two, to preserve the output power of the signal.

Polyphase Implementation with Halfband Filters

`dsp.FIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters when you filter the input signal. You can use a polyphase implementation to move the upsampling operation after filtering. This allows you to filter at the lower sampling rate.

Splitting a filter's impulse response, *h(n)*, into two polyphase components results in an even polyphase component with *z*-transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

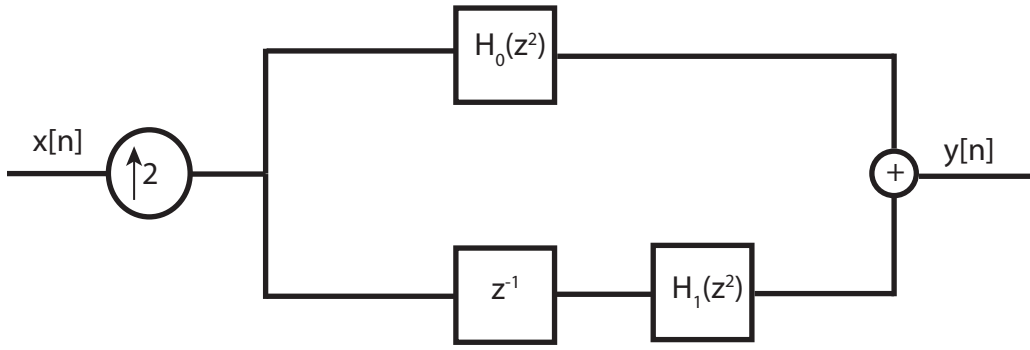
and an odd polyphase component with *z*-transform

$$H_1(z) = \sum_n h(2n+1)z^{-n}.$$

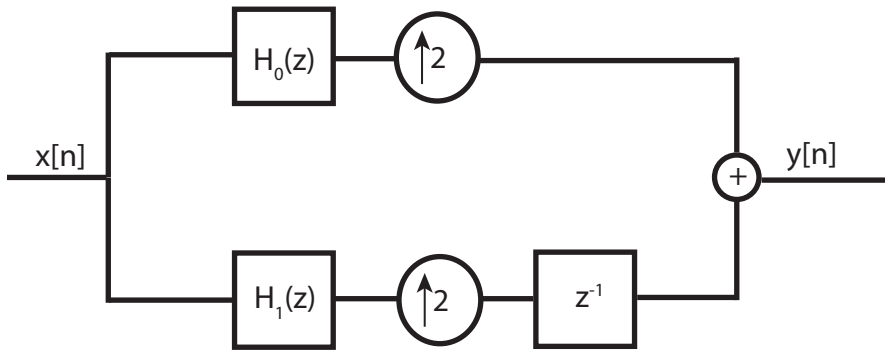
The *z*-transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2)\,.$$

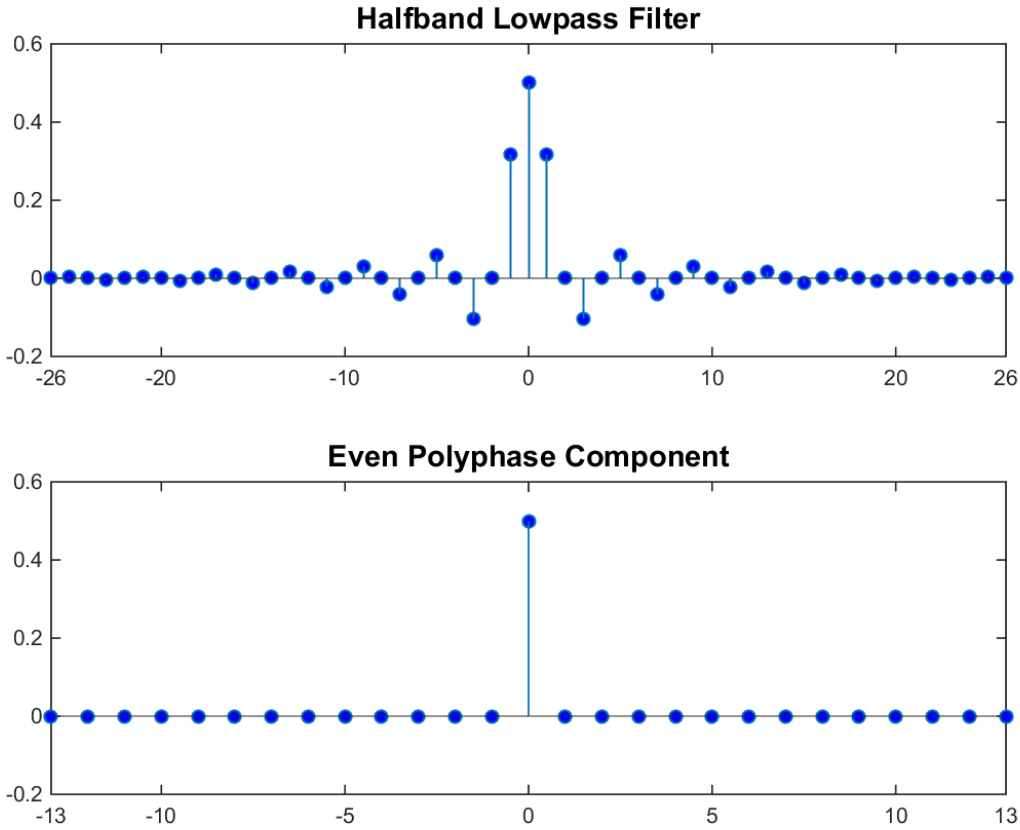
Graphically, you can represent upsampling by two followed by filtering with the following figure



Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

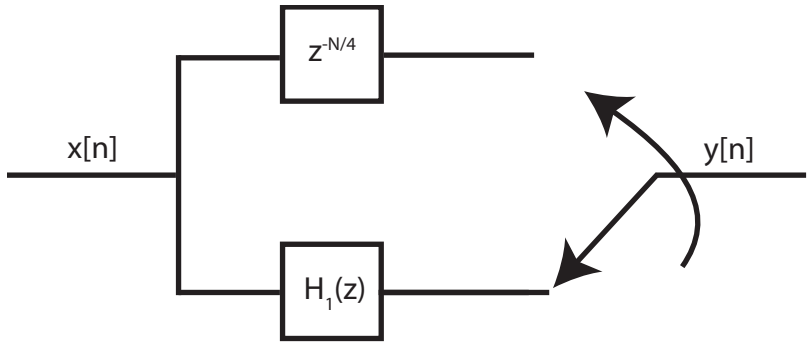


For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0. Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$, where N is the number of filter taps. This process is shown in the following figure.



The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband interpolator, `dsp.FIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure, where one polyphase component is replaced by a delay.



The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal. The polyphase component that reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even, depending on the filter half order. For an example of this behavior, inspect the polyphase components of the following filters.

```
filterspec = 'Filter order and stopband attenuation';
halfOrderEven = dsp.FIRHalfbandInterpolator('Specification',filterspec,...
    'FilterOrder',64,'StopbandAttenuation',80);
halfOrderOdd = dsp.FIRHalfbandInterpolator('Specification',filterspec,...
    'FilterOrder', 54,'StopbandAttenuation',80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

One of the polyphase components has a single nonzero coefficient indicating that it is a simple delay. To preserve the output power of the signal, the coefficients are scaled by the interpolation factor, two. To see this scaling, compare the polyphase components of a halfband interpolator with the coefficients of a halfband decimator.

```
hfirinterp = dsp.FIRHalfbandInterpolator;
hfirdecim = dsp.FIRHalfbandDecimator;
polyphase(hfirdecim)
polyphase(hfirinterp)
```

To summarize, `dsp.FIRHalfbandInterpolator`

- Filters the input before upsampling with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

dsp.FIRInterpolator

Package: `dsp`

Polyphase FIR interpolator

Description

The `dsp.FIRInterpolator` System object upsamples an input by the integer upsampling factor, *L*, followed by an FIR anti-imaging filter. The filter coefficients are scaled by the interpolation factor. A polyphase interpolation structure implements the filter. The resulting discrete-time signal has a sampling rate *L* times the original sampling rate.

To upsample an input:

1. Create the `dsp.FIRInterpolator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
firinterp = dsp.FIRInterpolator
firinterp = dsp.FIRInterpolator(interpFactor,num)
firinterp = dsp.FIRInterpolator( ___ ,Name,Value)
```

Description

`firinterp = dsp.FIRInterpolator` returns an FIR interpolator, `firinterp`, which upsamples an input signal by a factor of 3 and applies an FIR filter to interpolate the output.

`firinterp = dsp.FIRInterpolator(interpFactor,num)` returns an FIR interpolator with the integer-valued `InterpolationFactor` property set to `interpFactor` and the `Numerator` property set to `num`.

`firinterp = dsp.FIRInterpolator( ___ ,Name,Value)` returns an FIR interpolator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`InterpolationFactor` — Interpolation factor

3 (default) | positive integer

Specify the integer factor, *L*, by which to increase the sampling rate of the input signal. The polyphase implementation uses *L* polyphase subfilters to compute convolutions at the lower sample rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumeratorSource` — FIR filter coefficient source

`'Property'` (default) | `'Input port'`

FIR filter coefficient source, specified as either:

- `'Property'` –– The numerator coefficients are specified through the `Numerator` property.
- `'Input port'` –– The numerator coefficients are specified as an input to the object algorithm.

`Numerator` — FIR filter coefficients

`fir1(15,0.25)` (default) | row vector

Specify the numerator coefficients of the FIR anti-imaging filter as the coefficients of a polynomial in z^{-1}. Indexing from zero, the filter coefficients are:

$$H(z) = \sum_{n=0}^{N-1} b(n) z^{-n}$$

To act as an effective anti-imaging filter, the coefficients must correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the `InterpolationFactor`. The filter coefficients are scaled by the value of the `InterpolationFactor` property before filtering the signal. To form the L polyphase subfilters, `Numerator` is appended with zeros if necessary.

Dependencies

This property applies when `NumeratorSource` is set to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

`FullPrecisionOverride` — Full-precision override for fixed-point arithmetic

`true` (default) | `false`

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` –– The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` –– Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

`RoundingMethod` — Rounding method for fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `ProductDataType` set to `'Full precision'`, `AccumulatorDataType` set to `'Full precision'`, and `OutputDataType` set to `'Same as accumulator'`.

Under these conditions, the object operates in full precision mode.

`OverflowAction` — Overflow action for fixed-point operations

`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` –– The object wraps the result of its fixed-point operations.
- `'Saturate'` –– The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `OutputDataType` set to `'Same as accumulator'`, `ProductDataType` set to `'Full precision'`, and `AccumulatorDataType` set to `'Full precision'`

Under these conditions, the object operates in full precision mode.

`CoefficientsDataType` — Data type of FIR filter coefficients

`Same word length as input` (default) | `Custom`

Data type of the FIR filter coefficients, specified as:

- `Same word length as input` –– The word length of the coefficients is the same as that of the input. The fraction length is computed to give the best possible precision.

- `Custom` –– The coefficients data type is specified as a custom numeric type through the `CustomCoefficientsDataType` property.

`CustomCoefficientsDataType` — Word and fraction lengths of coefficients data type
`numerictype([],16,15)` (default) | custom numeric type

Word and fraction lengths of the coefficients data type, specified as an autosigned `numerictype` with a word length of 16 and a fraction length of 15.

Dependencies

This property applies when you set the `CoefficientsDataType` property to `Custom`.

`ProductDataType` — Data type of product output
`'Full precision'` (default) | `'Custom'` | `'Same as input'`

Data type of the product output in this object, specified as one of the following:

- `'Full precision'` –– The product output data type has full precision.
- `'Same as input'` –– The object specifies the product output data type to be the same as that of the input data type.
- `'Custom'` –– The product output data type is specified as a custom numeric type through the `CustomProductDataType` property.

For more information on the product output data type, see “Multiplication Data Types”.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomProductDataType` — Word and fraction lengths of product data type
`numerictype([],32,30)` (default) | custom numeric type

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `ProductDataType` to `'Custom'`.

`AccumulatorDataType` — Data type of accumulation operation
`'Full precision'` (default) | `'Same as input'` | `'Same as product'` | `'Custom'`

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` –– The accumulation operation has full precision.
- `'Same as product'` –– The object specifies the accumulator data type to be the same as that of the product output data type.
- `'Same as input'` –– The object specifies the accumulator data type to be the same as that of the input data type.
- `'Custom'` –– The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomAccumulatorDataType` — Word and fraction lengths of accumulator data type

`numerictype([],32,30)` (default) | custom numeric type

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `AccumulatorDataType` to `'Custom'`.

`OutputDataType` — Data type of object output

`'Same as accumulator'` (default) | `'Same as input'` | `'Same as product'` | `'Custom'`

Data type of the object output, specified as one of the following:

- `'Same as accumulator'` –– The output data type is the same as that of the accumulator output data type.
- `'Same as input'` –– The output data type is the same as that of the input data type.
- `'Same as product'` –– The output data type is the same as that of the product output data type.
- `'Custom'` –– The output data type is specified as a custom numeric type through the `CustomOutputDataType` property.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

`CustomOutputDataType` — Word and fraction lengths of output data type
`numerictype([],16,15)` (default) | custom numeric type

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `OutputDataType` to `'Custom'`.

Usage

Syntax

```
y = firinterp(x)
y = firinterp(x,num)
```

Description

`y = firinterp(x)` outputs the upsampled and filtered values, `y`, of the input signal, `x`.

`y = firinterp(x,num)` uses the FIR filter, `num`, to interpolate the input signal. This configuration is valid only when the `'NumeratorSource'` property is set to `'Input port'`.

Input Arguments

`x` — Data input
vector | matrix

Data input, specified as a vector or a matrix. A *Ki*-by-*N* input matrix is treated as *N* independent channels, and the System object interpolates each channel over the first dimension and generates a *Ki***L*-by-*N* output matrix, where *L* is the interpolation factor.

This object supports variable-size input and does not support complex unsigned fixed-point inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

`num` — FIR filter coefficients

row vector

FIR filter coefficients, specified as a row vector.

Dependencies

This input is accepted only when the `'NumeratorSource'` property is set to `'Input port'`.

Data Types: `double`

Output Arguments

y — FIR interpolator output

vector | matrix

FIR interpolator output, returned as a vector or a matrix of size *Ki***L*-by-*N*, where *L* is the interpolation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRInterpolator`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object

cost	Estimate cost for implementing filter System objects
polyphase	Polyphase decomposition of multirate filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
impz	Impulse response of discrete-time filter System object
coeffs	Filter coefficients

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Double the Sample Rate Using FIR Interpolator

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

This example shows how to double the sampling rate of an audio signal from 22.05 kHz to 44.1 kHz, and play the audio.

```
afr = dsp.AudioFileReader('OutputDataType',...
   'single');
adw = audioDeviceWriter(44100);
firinterp = dsp.FIRInterpolator(2, ...
   firpm(30, [0 0.45 0.55 1], [1 1 0 0]));

while ~isDone(afr)
     frame = afr();
     y = firinterp(frame);
     adw(y);
end

pause(1);
```

```
release(afr);
release(adw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Interpolation block reference page. The object properties correspond to the block parameters, except:

- The `FIRInterpolator` object does not have a property that corresponds to the **Input processing** parameter of the FIR Interpolation block.
- The **Rate options** block parameter is not supported by the `FIRInterpolator` object.

System Objects

`dsp.FIRDecimator` | `dsp.FIRRateConverter`

Topics

“Analysis Methods for Filter System Objects” on page 3-2

Introduced in R2012a

dsp.FIRRateConverter

Package: `dsp`

Sample rate converter

Description

The `dsp.FIRRateConverter` System object performs sampling rate conversion by a rational factor on a vector or matrix input. The FIR rate convertor cascades an interpolator with a decimator. The interpolator upsamples the input by the upsampling factor, *L*, followed by a lowpass FIR filter. The FIR filter acts both as an anti-imaging filter and an anti-aliasing filter prior to decimation. The decimator downsamples the output of upsampling and FIR filtering by the downsampling factor *M*. You must use upsampling and downsampling factors that are relatively prime, or coprime. The resulting discrete-time signal has a sampling rate *L/M* times the original sampling rate.

To perform sampling rate conversion:

1. Create the `dsp.FIRRateConverter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
firrc = dsp.FIRRateConverter
firrc = dsp.FIRRateConverter(L,M,NUM)
firrc = dsp.FIRRateConverter( ___ ,Name,Value)
```

Description

`firrc = dsp.FIRRateConverter` returns a FIR sample rate converter, `firrc`, that resamples an input signal at a rate 3/2 times the original sampling rate.

`firrc = dsp.FIRRateConverter(L,M,NUM)` returns an FIR sample rate converter, `firrc`, with the `InterpolationFactor` property set to `L`, the `DecimationFactor` property set to `M`, and the `Numerator` property set to `NUM`.

`firrc = dsp.FIRRateConverter( ___ ,Name,Value)` returns an FIR sample rate converter, with additional properties specified by one or more `Name,Value` pair arguments.

Example: `firrc = dsp.FIRRateConverter('FullPrecisionOverride','false')` enables the fixed-point data types to be controlled through the individual fixed-point property settings.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`InterpolationFactor` — Interpolation factor

3 (default) | positive integer

Interpolation factor, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DecimationFactor` — Decimation factor

2 (default) | positive integer

Decimation factor, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Numerator` — FIR filter coefficients
`firpm(70,[0 0.28 0.32 1],[1 1 0 0])` (default) | row vector

Specify the FIR filter coefficients in powers of z^{-1}. The length of filter coefficients must exceed the interpolation factor. Use a lowpass with normalized cutoff frequency no greater than `min(1/InterpolationFactor, 1/DecimationFactor)`. All initial filter states are zero.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

`FullPrecisionOverride` — Full precision override for fixed-point arithmetic
`true` (default) | `false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

`RoundingMethod` — Rounding method for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |.

Dependencies

This property applies only if the object is not in full precision mode.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as one of | `Wrap` | `Saturate` |.

Dependencies

This property applies only if the object is not in full precision mode.

`CoefficientsDataType` — Word and fraction lengths of filter coefficients
`Same word length as input` (default) | `Custom`

Specify the filter coefficient fixed-point data type as one of | `Same word length as input` | `Custom` |.

`CustomCoefficientsDataType` — Word and fraction lengths of filter coefficients
`numerictype([],16,15)` (default) | `numerictype`

Specify the filter coefficient fixed-point type as a `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when the `CoefficientsDataType` property is `Custom`.

`ProductDataType` — Product word and fraction lengths
`Full precision` (default) | `Same as input` | `Custom`

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |.

`CustomProductDataType` — Product word and fraction lengths
`numerictype([],32,30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when the `ProductDataType` property is `Custom`.

`AccumulatorDataType` — Accumulator word and fraction lengths
`Full precision` (default) | `Same as product` | `Same as input` | `Custom`

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype([],32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when the `AccumulatorDataType` property is `Custom`.

`OutputDataType` — Output word and fraction lengths
`Same as accumulator` (default) | `Same as product` | `Same as input` | `Custom`

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |.

`CustomOutputDataType` — Output word and fraction lengths
`numerictype([],16,15)` (default) | `numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when the `OutputDataType` property is `Custom`.

Usage

Syntax

```
y = firrc(x)
```

Description

`y = firrc(x)` resamples the input `x` and returns the resampled signal `y`.

Input Arguments

`x` — Data input
column vector | matrix

Data input, specified as a column vector or a matrix. The number of input rows must be a multiple of the decimation factor. An *M*-by-*N* matrix input is treated as *N* independent channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Resampled output

column vector | matrix

Resampled output, returned as a column vector or a matrix. The number of rows in the output signal is given by *MI*/*D*, where *M* is the number of input rows, *I* is the interpolation factor, and *D* is the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRRateConverter`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost for implementing filter System objects
coeffs	Filter coefficients
polyphase	Polyphase decomposition of multirate filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step	Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Resample a Signal using FIR Rate Converter

This example shows how to resample a 100 Hz sine wave signal by a factor of 3:2.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

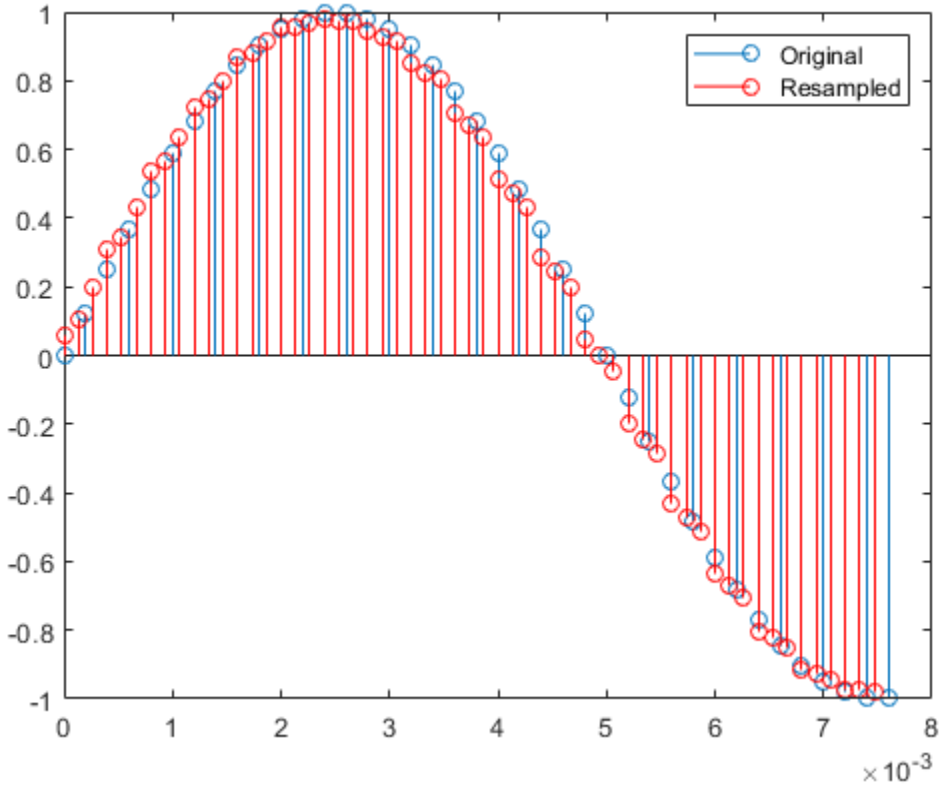
```
sine = dsp.SineWave(1, 100,'SampleRate', 5000,'SamplesPerFrame', 50);
```

Create a FIR rate converter filter. The default interpolation factor is 3 and decimation factor is 2.

```
firrc = dsp.FIRRateConverter;
input = sine();
output = firrc(input);
```

Plot the original and resampled signals.

```
ndelay = round(length(firrc.Numerator)/2/firrc.DecimationFactor);
indx = ndelay+1:length(output);
x = (0:length(indx)-1)/sine.SampleRate*firrc.DecimationFactor/firrc.InterpolationFactor
stem((0:38)/sine.SampleRate, input(1:39)); hold on;
stem(x, firrc.InterpolationFactor*output(indx),'r');
legend('Original','Resampled');
```



Resample and Play an Audio Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

This example shows how to resample and play an audio signal from 48 kHz to 32 kHz on a Windows® platform.

```
afr = dsp.AudioFileReader('audio48kHz.wav', ...
    'OutputDataType', 'single', ...
    'SamplesPerFrame', 300);
adw = audioDeviceWriter(32000);
```

Create an FIRRateConverter System object with interpolation factor = 2, decimation factor = 3. Default FIR filter coefficients define a lowpass filter with normalized cutoff frequency of 1/3.

```
firrc = dsp.FIRRateConverter(2,3);

while ~isDone(afr)
    audio1 = afr();
    audio2 = firrc(audio1);
    adw(audio2);
end

release(afr);
release(adw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Rate Conversion block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

dsp.FrequencyDomainAdaptiveFilter

Package: `dsp`

Compute output, error, and coefficients using frequency-domain FIR adaptive filter

Description

The `dsp.FrequencyDomainAdaptiveFilter` System object implements an adaptive finite impulse response (FIR) filter in the frequency domain using the fast block least mean squares (LMS) algorithm. The "Length" on page 4-0 and the "BlockLength" on page 4-0 properties specify the filter length and the block length values the algorithm uses. The "FFTCoefficients" on page 4-0 property contains the discrete Fourier transform of the current filter coefficients. The object offers the constrained and unconstrained versions of the algorithm with partitioned and non-partitioned modes. For details, see "Algorithms" on page 4-810.

To filter a signal using frequency-domain FIR adaptive filter:

1. Create the `dsp.FrequencyDomainAdaptiveFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
fdaf = dsp.FrequencyDomainAdaptiveFilter
fdaf = dsp.FrequencyDomainAdaptiveFilter(len)
fdaf = dsp.FrequencyDomainAdaptiveFilter( ___ ,Name,Value)
```

Description

`fdaf = dsp.FrequencyDomainAdaptiveFilter` returns a frequency domain FIR adaptive filter System object, `fdaf`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fdaf = dsp.FrequencyDomainAdaptiveFilter(len)` returns a frequency domain FIR adaptive filter object with the `Length` property set to `len`.

`fdaf = dsp.FrequencyDomainAdaptiveFilter(___,Name,Value)` returns a frequency domain FIR adaptive filter object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',0.1)` models a frequency-domain adaptive filter with a length of 32 taps and a step size of 0.1.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Method` — Method to calculate filter coefficients

`'Constrained FDAF'` (default) | `'Unconstrained FDAF'` | `'Partitioned constrained FDAF'` | `'Partitioned unconstrained FDAF'`

Method used to calculate the filter coefficients, specified as:

- `'Constrained FDAF'` –– Imposes a gradient constraint on the filter tap weights.
- `'Unconstrained FDAF'` –– No gradient constraint is imposed on the filter tap weights.
- `'Partitioned constrained FDAF'` –– Partitions the impulse response of the filter to reduce latency.

- `'Partitioned unconstrained FDAF'` –– Partitions the impulse response of the filter to reduce latency. No gradient constraint is imposed on the filter tap weights.

For more details, see “Algorithms” on page 4-810.

`Length` — Length of filter coefficients vector

32 (default) | positive, integer-valued scalar

Length of the FIR filter coefficients vector, specified as a positive, integer-valued scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`BlockLength` — Block length for coefficient updates

32 (default) | positive, integer-valued scalar

Block length for the coefficient updates, specified as a positive, integer-valued scalar. The adaptive filter processes the input data and the desired signal as a block of samples of length set by this property. For details on how this data is processed by the filter, see “Algorithms” on page 4-810. The length of the input vector must be divisible by the `BlockLength` property value. The default value of the `BlockLength` property is set to the value of the `Length` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StepSize` — Adaptation step size

1 (default) | real scalar in the range (0,1]

Adaptation step size factor, specified as a real scalar in the range (0,1]. Using a small step size ensures a small steady-state error. However, a small step size decreases the resulting convergence speed of the adaptive filter. Increasing the step size improves the convergence speed, at the cost of increased steady-state mean squared error. When the step size value is `1`, the algorithm provides the optimal tradeoff between the convergence speed and the steady-state mean squared error.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`LeakageFactor` — Adaptation leakage factor

1 (default) | scalar in the range [0,1]

Leakage factor used when implementing a leaky adaptive filter, specified as a scalar numeric value in the range [0,1]. When the value is less than 1, the System object implements a leaky adaptive algorithm. When the value is 1, the object provides no leakage in the adapting method.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`AveragingFactor` — Averaging factor for signal power

`0.9` (default) | real scalar in the range (0,1]

Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates, specified as a real scalar in the range (0,1].

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`Offset` — Offset for normalization terms

`0` (default) | nonnegative real scalar

Offset for the normalization terms in the coefficient updates, specified as a nonnegative real scalar value. This property value is used to avoid division by zero or division by very small numbers if any of the FFT input signal powers become very small.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitalPower` — Initial FFT input signal power

`1` (default) | positive numeric scalar

Initial common value of all of the FFT input signal powers, specified as a positive numeric scalar.

If you change this value once the object is locked, the change takes effect only after you reset the object.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialCoefficients` — Initial time-domain coefficients of filter

`0` (default) | scalar | vector

Initial time-domain coefficients of the adaptive filter, specified as a scalar or a vector of length equal to the `Length` property value. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients.

If you change this value once the object is locked, the change takes effect only after you reset the object.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LockCoefficients` — Locked status of coefficient updates

`false` (default) | `true`

Locked status of the coefficient updates, specified as:

- `false` –– The object continuously updates the filter coefficients.
- `true` –– The filter coefficients do not get updated and their values remain at the current value.

Tunable: Yes

Data Types: `logical`

`FFTCoefficients` — Current FFT coefficients of filter

`[]` (default) | row vector

This property is read-only.

Current discrete Fourier transform of the filter coefficients, returned as a row vector. For `'Constrained FDAF'` and `'Unconstrained FDAF'` algorithms, the length of this vector is equal to the sum of the `Length` value and the `BlockLength` value. This property is initialized to the FFT values of the `InitialCoefficients` property. To get the discrete Fourier transform of the filter coefficients, call the object, and access the `FFTCoefficients` property of the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Usage

Syntax

```
[y,err] = fdaf(x,d)
```

Description

`[y,err] = fdaf(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. The FFT of these filter weights can be obtained by accessing the `FFTCoefficients` property after calling the object algorithm.

Input Arguments

x — Data input

column vector

The signal to be filtered by the frequency-domain FIR adaptive filter. The input, `x`, and the desired signal, `d`, must have the same size and data type. The length of the input vector must be divisible by the “BlockLength” on page 4-0 property value.

The input, `x`, can be a variable-size signal as long as the frame length is a multiple of the `BlockLength`. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

column vector

The frequency domain adaptive filter adapts its filter weights to minimize the error, `err`, and converge the input signal, `x`, to the desired signal, `d`, as closely as possible.

The input signal and the desired signal must have the same size and data type. The length of the desired signal vector must be divisible by the `BlockLength` property value.

The input signal can be a variable-size signal as long as the frame length is a multiple of the `BlockLength`. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

column vector

Filtered output, returned as a column vector. The object adapts its filter weights to converge the input signal, `x`, to match the desired signal, `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

column vector

Difference between the output signal and the desired signal, returned as a column vector. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights which produce an output signal that matches the desired signal as closely as possible. For more details on how `err` is computed, see [2].

Data Types: `single` | `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

QPSK Adaptive Equalization With FIR Filter

Transmit a quadrature phase shift keying (QPSK) signal across a noisy transmission channel. Minimize the noise in the received signal using a frequency-domain adaptive filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

The QPSK signal, *s*, is transmitted across a noisy channel. The numerator and the denominator coefficients of the channel are contained in the vectors *b* and *a*, respectively. The received signal, *r,* obtained at the end of the transmission channel contains the transmitted QPSK signal and the noise added to the channel, *n*. The adaptive filter is used to extract the QPSK signal from the received noisy input. The desired signal, *d,* is the delayed version of the QPSK signal.

```
D = 16;
b  = exp(1i*pi/4)*[-0.7 1];
a  = [1 -0.7];
ntr = 1024;
s  = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n  = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r  = filter(b,a,s) + n;
x  = r(1+D:ntr+D);
d  = s(1:ntr);
```

Create a `dsp.FrequencyDomainAdaptiveFilter` object to model a frequency-domain adaptive filter of length 32 taps and a step size of 0.1. The adaptive filter accepts the delayed version of the received signal and the desired signal as inputs. The output of the adaptive filter is compared to the desired signal. The error between the two signals represents the noise added to the transmission channel. The adaptive filter updates its

coefficients until this error becomes minimal. To get the discrete Fourier transform of the filter coefficients, call the `fdaf` object, and access the FFTCoefficients property of this object.

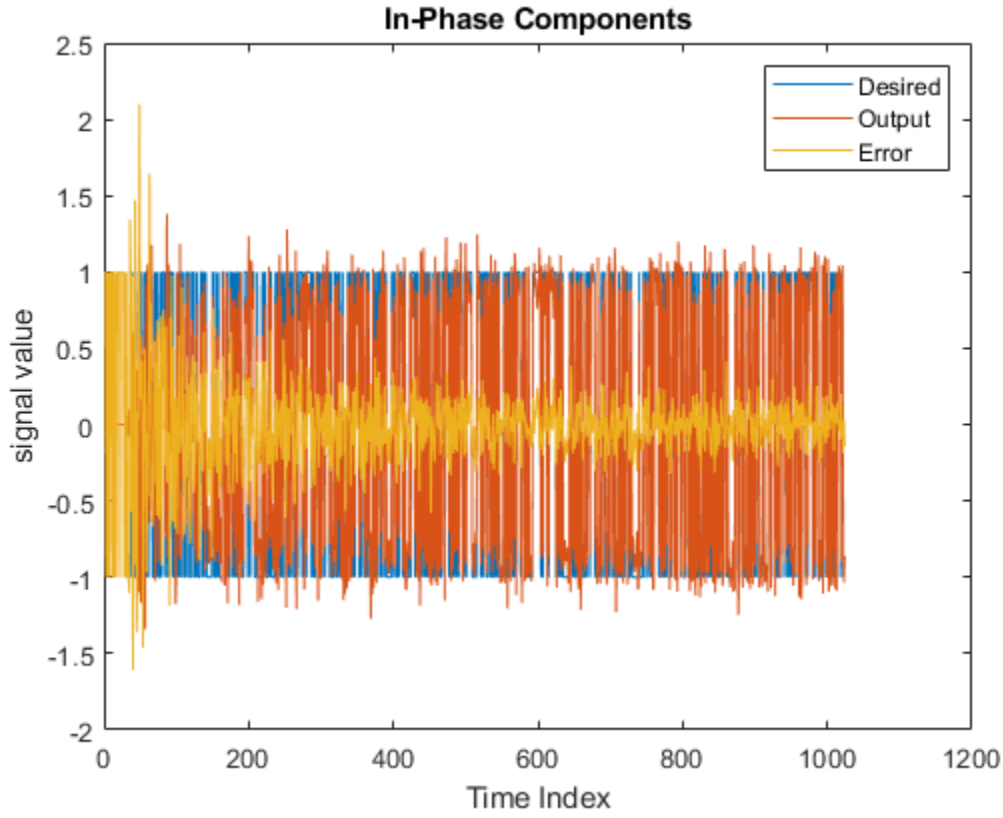
```
mu  = 0.1;
fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',mu);
[y,e] = fdaf(x,d);
fftCoeffs = fdaf.FFTCoefficients
```

```
fftCoeffs = 1×64 complex

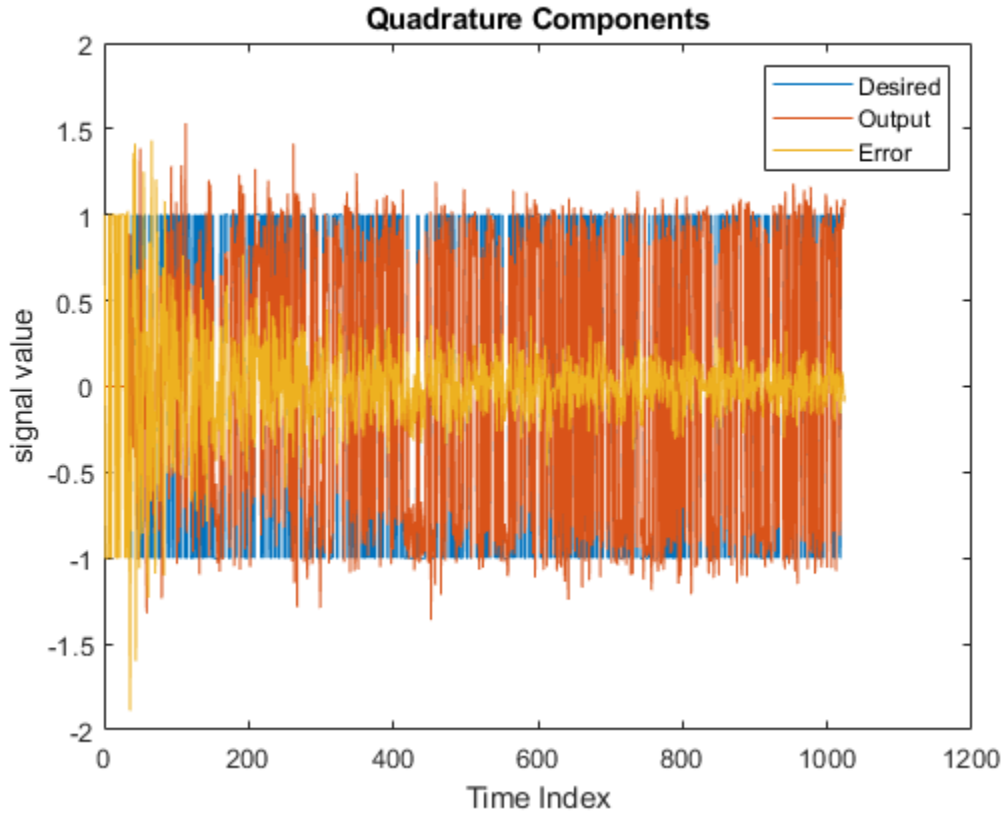
   0.6802 - 0.6847i  -0.2485 - 0.9427i  -0.9675 - 0.2123i  -0.5605 + 0.8002i   0.5748 -
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```
plot(1:ntr,real([d;y;e]))
legend('Desired','Output','Error')
title('In-Phase Components')
xlabel('Time Index'); ylabel('signal value')
```

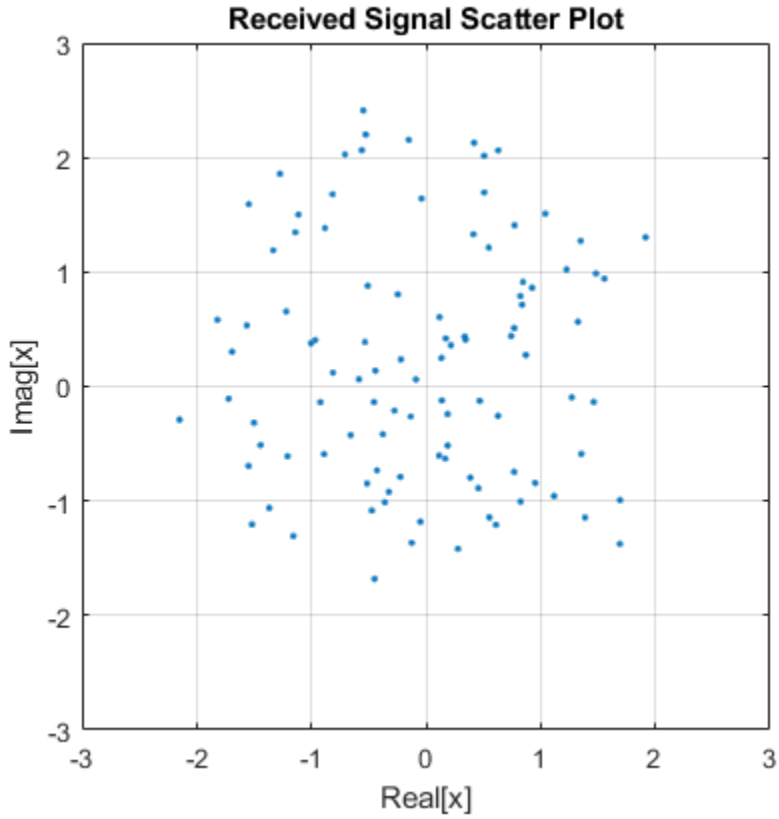


```
plot(1:ntr,imag([d;y;e]))
legend('Desired','Output','Error')
title('Quadrature Components')
xlabel('Time Index')
ylabel('signal value')
```

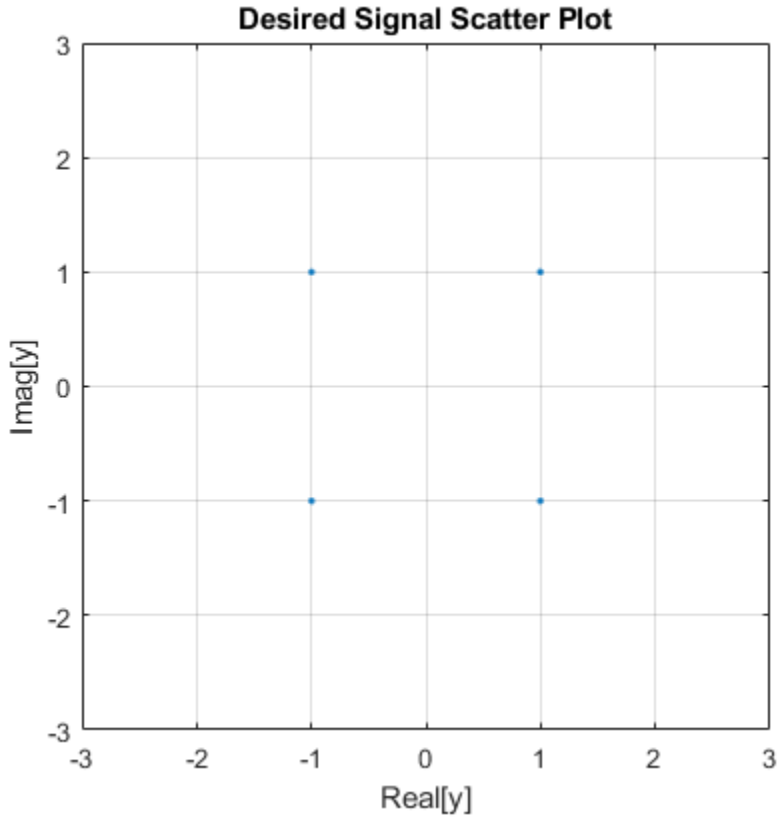


Create scatter plots of the received signal and the desired signal.

```
plot(x(ntr-100:ntr),'.')
axis([-3 3 -3 3])
title('Received Signal Scatter Plot')
axis('square')
xlabel('Real[x]')
ylabel('Imag[x]')
grid on
```

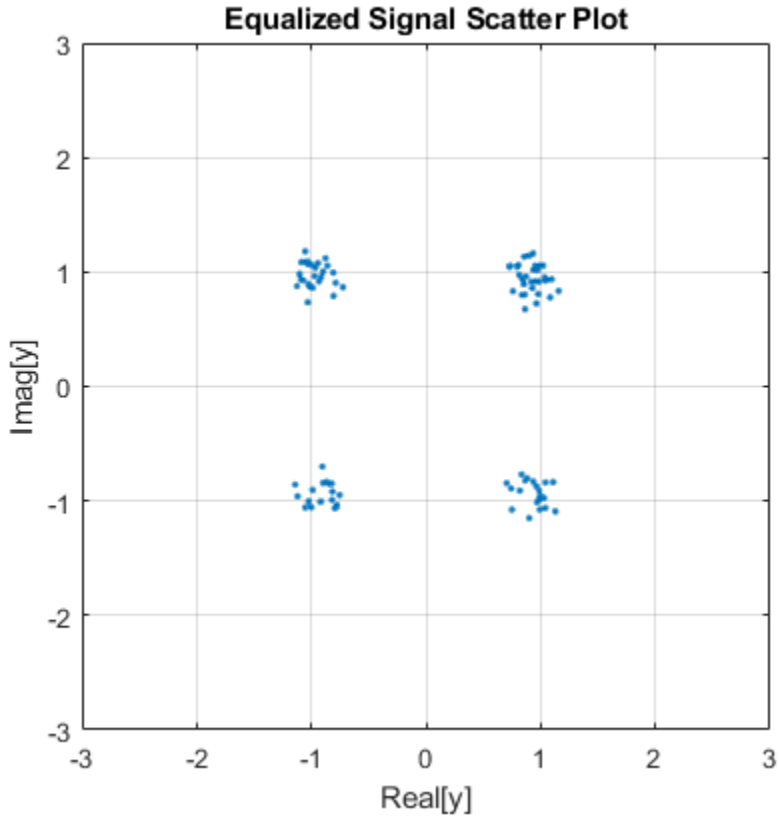


```
plot(d(ntr-100:ntr),'.')
axis([-3 3 -3 3])
title('Desired Signal Scatter Plot')
axis('square')
xlabel('Real[y]')
ylabel('Imag[y]')
grid on
```



The adaptive filter equalizes the received signal to eliminate noise. Plot the scatter plot of the equalized signal.

```
plot(y(ntr-100:ntr),'.')
axis([-3 3 -3 3])
title('Equalized Signal Scatter Plot')
axis('square')
xlabel('Real[y]')
ylabel('Imag[y]')
grid on
```



Estimate Coefficients of long FIR Filter using Frequency-Domain Adaptive Filter

Use a frequency-domain adaptive filter to estimate the coefficients of a long FIR filter. The FIR filter models the impulse response of a room. Use the partitioned mode in the frequency-domain adaptive filter to reduce filter latency.

Note: This example runs only in R2018a or later.

Initialization

Generate a long FIR impulse response of 8192 samples and assign the impulse response to a `dsp.FIRFilter` object, `room`. This object models the impulse response of a room. Create a `dsp.FrequencyDomainAdaptiveFilter` filter, `lmsfilt`, in partitioned constrained mode. Set the length of the filter to one-fourth the length of the impulse response of the room. Set the block length of the filter to 128 samples. Set the step size to 0.025, initial power to 0.01, averaging factor to 0.98, offset to 1, and the leakage factor to 1. Initialize a `dsp.ArrayPlot` object to view the filter coefficients. Initialize a `dsp.TimeScope` object to show the mean-squared error between the filter output and the desired signal.

```
fs = 16e3;
m = 8192;
[b,a] = cheby2(4,20,[0.1 0.7]);
impulseResponseGenerator = dsp.IIRFilter(...
    'Numerator', [zeros(1,6) b], ...
    'Denominator', a);
roomImpulseResponse = impulseResponseGenerator( ...
    (log(0.99*rand(1,m)+0.01).*sign(randn(1,m)).*exp(-0.002*(1:m)))');
roomImpulseResponse = roomImpulseResponse/norm(roomImpulseResponse);
room = dsp.FIRFilter('Numerator',roomImpulseResponse');

lmsfilt = dsp.FrequencyDomainAdaptiveFilter(...
    'Method','Partitioned constrained FDAF',...
    'Length',m/4, ...
    'BlockLength',128,...
    'StepSize',0.025, ...
    'InitialPower',0.01, ...
    'AveragingFactor',0.98,...
    'Offset',1,...
    'LeakageFactor',1);

FrameSize = lmsfilt.BlockLength; NIter = 2000;

AP = dsp.ArrayPlot('YLimits',[-0.2 .2],'ShowLegend',true, ...
    'Position',[0 0 560 420],'ChannelNames', ...
    {'Actual Coefficients','Estimated Coefficients'});

TS = dsp.TimeScope('SampleRate',fs,'TimeSpan',FrameSize*NIter/fs,...
    'TimeUnits','Seconds',...
    'YLimits',[-50 0],'Title','Learning curve',...
    'YLabel','dB', ...
    'BufferLength',FrameSize*NIter,...
```

```
    'ShowGrid',true);

signalmean = dsp.MovingAverage('SpecifyWindowLength',false);
```

Streaming

Generate a random input signal using the `randn` function. The frame size of the input matches the block length of the adaptive filter. The desired signal is the sum of the output of the FIR filter (room) and a white Gaussian noise signal. Pass the input signal and the desired signal to the adaptive filter. Compute the adaptive filter output and the error between the output and the desired signal.

Estimate the time-domain coefficients of the adaptive filter by taking the IFFT of the frequency-domain coefficients vector returned by the `lmsfilt.FFTCoefficients` property. Compare the estimated coefficients with the actual coefficients assigned to the FIR filter (room). Once the adaptive filter has converged its output to the desired signal, and minimized the error signal, the estimated coefficients match closely with the actual coefficients. This means that the adaptive filter has successfully adapted itself to model the impulse response of the FIR filter (room).

```
for k = 1:NIter
    x = randn(FrameSize,1);
    d = room(x) + 0.01*randn(FrameSize,1);
    [y,e] = lmsfilt(x,d);
    FFTCoeffs = lmsfilt.FFTCoefficients;
    w = ifft(FFTCoeffs,[],2,'symmetric');
    w = w(:,1:FrameSize) + w(:,FrameSize+1:end);
    w = reshape(w.',1,m/4);
    AP([roomImpulseResponse(1:m/4),w.']);
    TS(10*log10(signalmean(abs(e).^2)));
end
```

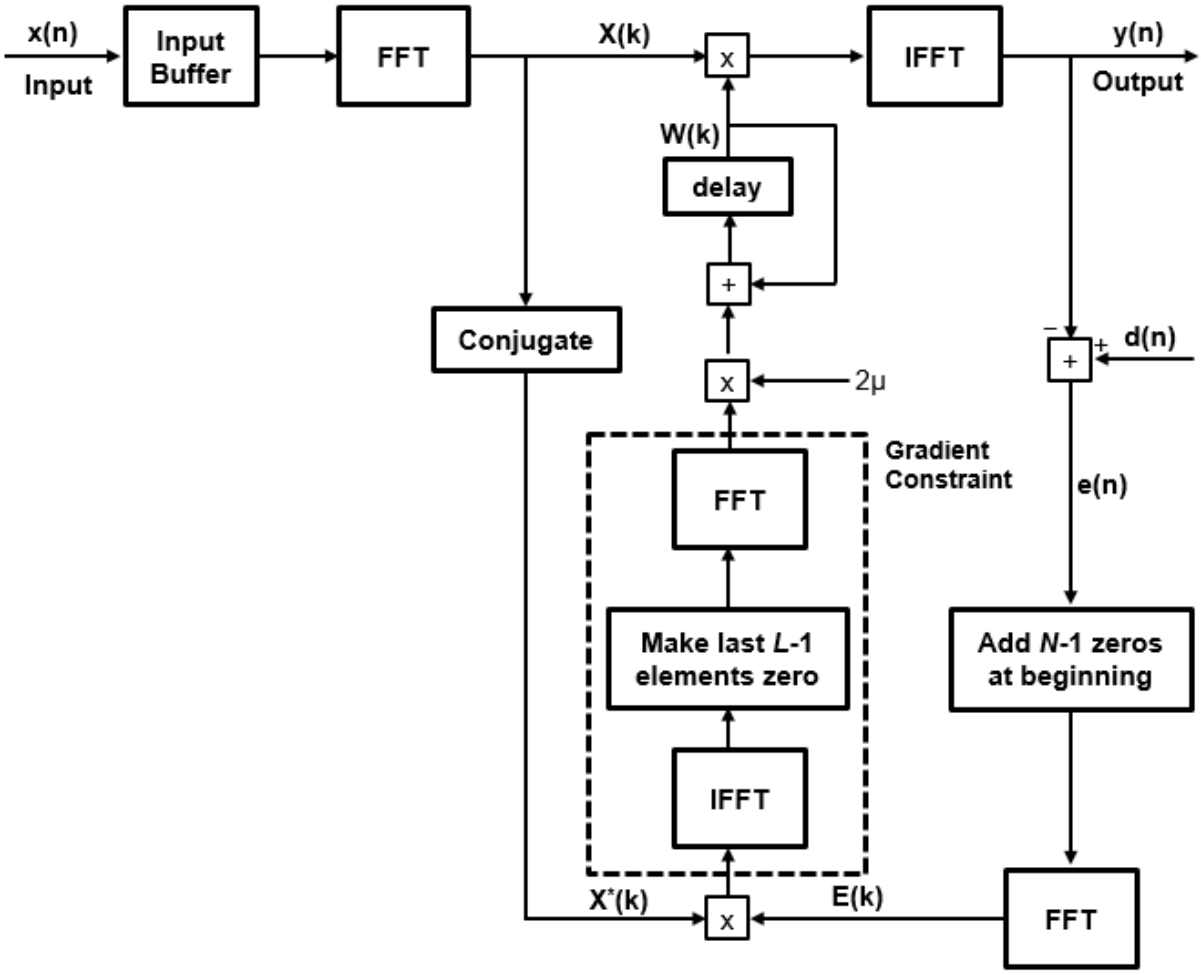
As the filter adapts with time, you can see in the time scope that the mean-squared error becomes minimal. Simultaneously, the estimated coefficients match the actual coefficients closely in the array plot.

Algorithms

Frequency-domain adaptive filtering consists of three steps - filtering, error estimation, and tap-weight adaptation. This algorithm implements FIR filtering in the frequency domain using the overlap-save or overlap-add method. For more implementation details of these two methods, see the “Algorithms” on page 4-828 section in the `dsp.FrequencyDomainFIRFilter` object page. The error estimation and the tap-weight adaptation are implemented using the fast block LMS algorithm (FBLMS).

Fast Block LMS Algorithm

The frequency-domain adaptive filter processes input data and the desired signal data as a block of samples using the fast block LMS (FBLMS) algorithm. Here is the block diagram of the frequency-domain adaptive filter using the FBLMS algorithm. The frequency-domain FIR filter in this diagram uses the overlap-save method.



where:

- N –– Filter length
- L –– Block length
- μ –– Step size parameter
- $x(n)$ –– Input signal
- $X(k)$ –– Transformed input signal in the frequency domain
- $d(n)$ –– Desired signal
- $e(n)$ –– Error between the desired signal and the filter output
- $E(n)$ –– Transformed error signal in the frequency domain
- $W(k)$ –– Tap-weights vector in the frequency domain

For more details on how the error is estimated and the tap-weights are adapted, see [2].

Constrained and Unconstrained FBLMS Algorithms

The previous diagram is the constrained version. If you remove the gradient constraint portion of the algorithm, you have the unconstrained FBLMS implementation. For details on the convergence behavior of both constrained and unconstrained variations, see [2].

Partitioned FBLMS Algorithm

The latency of the filter roughly equals the length of the FIR numerator. If the impulse response of the filter is very long, the latency becomes significantly large. The partitioned FBLMS algorithm reduces latency by partitioning the impulse response. The nonpartitioned frequency-domain FIR filtering is faster than the time-domain filtering for long impulse responses, at the cost of increased latency. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details on the implementation, see [2].

dsp.FrequencyDomainFIRFilter

Package: `dsp`

Filter input signal in frequency domain

Description

The `dsp.FrequencyDomainFIRFilter` System object implements frequency-domain, fast Fourier transform (FFT)-based filtering to filter a streaming input signal. In the time domain, the filtering operation involves a convolution between the input and the impulse response of the finite impulse response (FIR) filter. In the frequency domain, the filtering operation involves the multiplication of the Fourier transform of the input and the Fourier transform of the impulse response. The frequency-domain filtering is efficient when the impulse response is very long. You can specify the filter coefficients directly in the frequency domain by setting `NumeratorDomain` to `'Frequency'`.

This object uses the overlap-save and overlap-add methods to perform the frequency-domain filtering. For filters with a long impulse response length, the latency inherent to these two methods can be significant. To mitigate this latency, the `dsp.FrequencyDomainFIRFilter` object partitions the impulse response into shorter blocks and implements the overlap-save and overlap-add methods on these shorter blocks. To partition the impulse response, set the “PartitionForReducedLatency” on page 4-0 property to `true`. For more details on these two methods and on reducing latency through impulse response partitioning, see “Algorithms” on page 4-828.

To filter the input signal in the frequency domain:

1. Create the `dsp.FrequencyDomainFIRFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
fdf = dsp.FrequencyDomainFIRFilter
fdf = dsp.FrequencyDomainFIRFilter(num)
fdf = dsp.FrequencyDomainFIRFilter(Name,Value)
```

Description

`fdf = dsp.FrequencyDomainFIRFilter` creates a frequency domain FIR filter System object that filters each channel of the input signal independently over time in the frequency domain using the overlap-save or overlap-add method.

`fdf = dsp.FrequencyDomainFIRFilter(num)` creates a frequency domain FIR filter object with the "Numerator" on page 4-0 property set to `num`.

Example: `dsp.FrequencyDomainFIRFilter(fir1(400,2 * 2000 / 8000));`

`fdf = dsp.FrequencyDomainFIRFilter(Name,Value)` creates a frequency domain FIR filter System object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Example: `dsp.FrequencyDomainFIRFilter('Method','Overlap-add');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Method` — Frequency-domain filter method
`'Overlap-save'` (default) | `'Overlap-add'`

Frequency-domain filter method, specified as either `'Overlap-save'` or `'Overlap-add'`. For more details on these two methods, see “Algorithms” on page 4-828.

`NumeratorDomain` — Numerator domain

`'Time'` (default) | `'Frequency'`

Domain of the filter coefficients, specified as one of the following:

- `'Time'` –– Specify the time-domain filter numerator in the `Numerator` property.
- `'Frequency'` –– Specify the filter's frequency response in the `FrequencyResponse` property.

`Numerator` — FIR filter coefficients

`fir1(100,0.3)` (default) | row vector

FIR filter coefficients, specified as a row vector.

Tunable: Yes

Dependencies

This property applies when `NumeratorDomain` is set to `'Time'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`FrequencyResponse` — Filter frequency response

`fft(fir1(100,0.3),202)` (default) | row vector | matrix

Frequency response of the filter, specified as a row vector or a matrix. When `PartitionForReducedLatency` is `false`, `FrequencyResponse` must be a row vector. The FFT length is equal to the length of the `FrequencyResponse` vector. When `PartitionForReducedLatency` is `true`, `FrequencyResponse` must be a $2P$-by-N matrix, where P is the partition size, and N is the number of partitions.

Tunable: Yes

Dependencies

This property applies when `NumeratorDomain` is set to `'Frequency'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

`NumeratorLength` — Time-domain numerator length

`101` (default) | positive integer-valued scalar

Time-domain numerator length, specified as a positive integer-valued scalar.

Dependencies

This property applies when `NumeratorDomain` is set to `'Frequency'` and `PartitionForReducedLatency` is set to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FilterIsReal` — Flag to specify if filter is real

`true` (default) | `false`

Flag to specify if the filter coefficients are all real, specified as `true` or `false`.

Dependencies

This property applies when `NumeratorDomain` is set to `'Frequency'`.

`PartitionForReducedLatency` — Flag to partition numerator to reduce latency

`false` (default) | `true`

Flag to partition numerator to reduce latency, specified as one of the following:

- `false` –- The filter uses the traditional overlap-save or overlap-add method. The latency in this case is “FFTLength” on page 4-0 – length(“Numerator” on page 4-0) + 1.
- `true` –- In this mode, the object partitions the numerator into segments of length specified by the “PartitionLength” on page 4-0 property. The filter performs overlap-save or overlap-add on each partition, and combines the partial results to form the overall output. The latency is now reduced to the partition length.

`FFTLength` — FFT length

`[]` (default) | positive integer

FFT length, specified as a positive integer. The default value of this property, `[]`, indicates that the FFT length is equal to twice the numerator length. The FFT length must be greater than or equal to the numerator length.

Example: `64`

Dependencies

This property applies when you set `NumeratorDomain` property to `'Time'` and "PartitionForReducedLatency" on page 4-0 property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PartitionLength` — Numerator partition length

`32` (default) | positive integer

Numerator partition length, specified as a positive integer less than or equal to the length of the numerator.

Example: `40`

Example: `60`

Dependencies

This property applies when you set the `NumeratorDomain` property to `'Time'` and "PartitionForReducedLatency" on page 4-0 property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Latency` — Filter latency

`102` (default) | positive integer

This property is read-only.

Filter latency in samples, returned as an integer greater than 0. When "PartitionForReducedLatency" on page 4-0 is `false`, the latency is equal to "FFTLength" on page 4-0 – length("Numerator" on page 4-0) + 1. When `PartitionForReducedLatency` is `true`, the latency is equal to the partition length.

Data Types: `uint32`

Usage

Syntax

```
fdfOut = fdf(input)
```

Description

`fdfOut = fdf(input)` filters the input signal and outputs the filtered signal. The object filters each channel of the input signal independently over time in the frequency domain.

Input Arguments

`input` — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: `randn(164,4)`

Data Types: `single` | `double`

Output Arguments

`fdfOut` — Filtered output

vector | matrix

Filtered output, returned as a vector or matrix. The size, data type, and complexity of the output match those of the input.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FrequencyDomainFIRFilter

fvtool	Visualize frequency response of DSP filters

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Frequency Domain Filtering Using Overlap-Add and Overlap-Save

Filter input signal using overlap-add and overlap-save methods, and compare the outputs to the output of a FIR filter.

Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The impulse response has a length of 400.

```
impL    = 400;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL,2*Fcutoff/Fs);
```

Create two `dsp.FrequencyDomainFIRFilter` objects and a `dsp.FIRFilter` object. Set the numerator of all the three filters to `imp`. Delay the FIR output by the latency of the frequency-domain filter.

```
fdfOA = dsp.FrequencyDomainFIRFilter(imp,'Method','overlap-add');
fdfOS = dsp.FrequencyDomainFIRFilter(imp,'Method','overlap-save');
fir = dsp.FIRFilter('Numerator',imp);
dly = dsp.Delay('Length',fdfOA.Latency);
```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `dsp.TimeScope` object to view the filtered outputs.

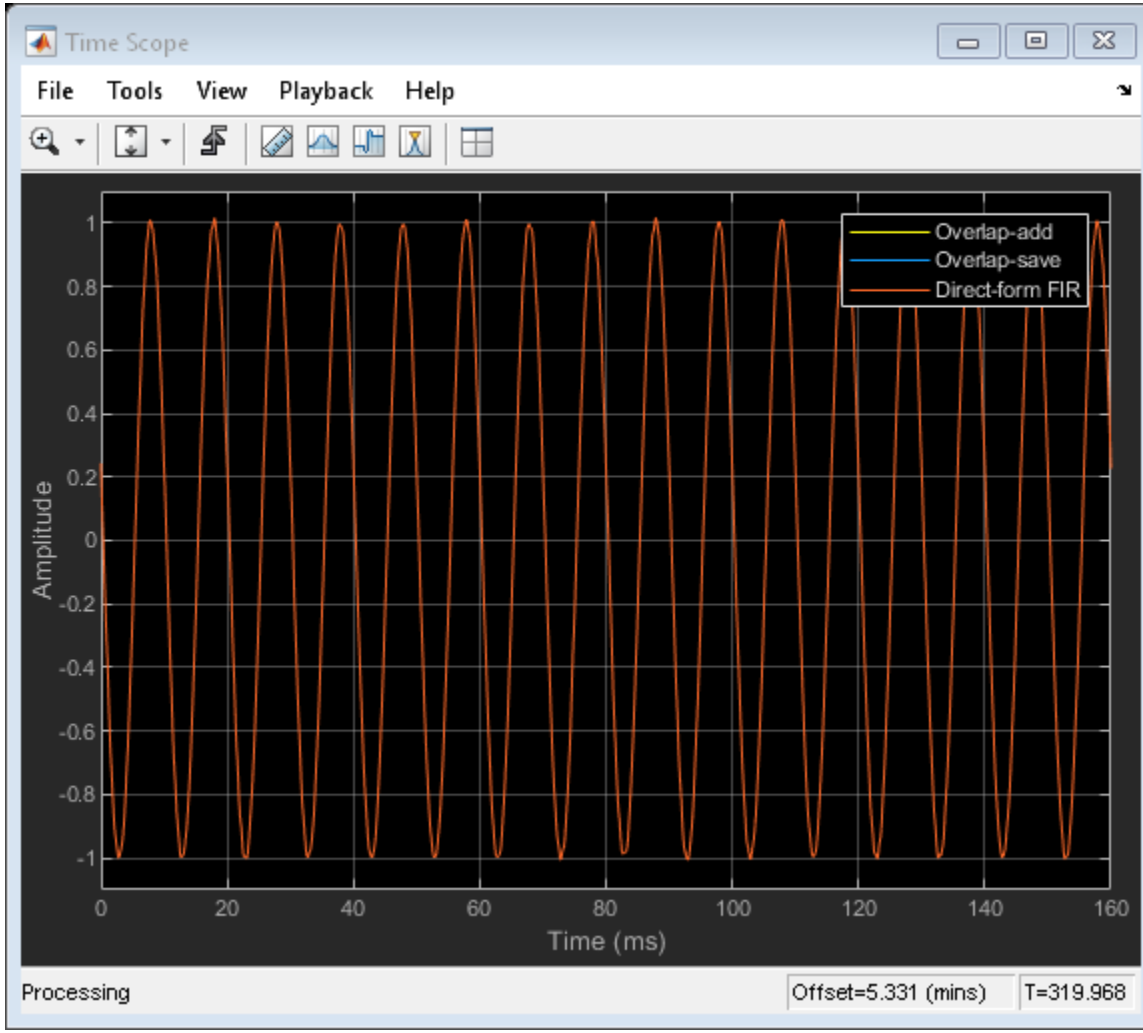
```
frameLen  = 256;

sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz  = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
ts = dsp.TimeScope('TimeSpanOverrunAction','Scroll',...
    'ShowGrid',true,'TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Overlap-save','Direct-form FIR'});
```

Streaming

Stream 1e4 frames of noisy input data. Pass this data through the frequency domain filters and the FIR filter. View the filtered outputs in the time scope.

```
numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01*randn(frameLen,1);
    yOA = fdfOA(x);
    yOS = fdfOS(x);
    yFIR = fir(dly(x));
    ts([yOA,yOS,yFIR]);
end
```



The outputs of all the three filters match exactly.

Reduce Latency Through Partitioned Numerator

Partition the impulse response length of a frequency domain FIR filter. Compare the outputs of the partitioned filter and the original filter.

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz and the cutoff frequency of the filter is 2 kHz. The impulse response is of length 4000.

```
impL    = 4000;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL,2 * Fcutoff / Fs);
```

Create a `dsp.FrequencyDomainFIRFilter` with coefficients set to the `imp` vector. The latency of this filter is given by $FFTLength - Length(Numerator) + 1$, which is equal to 4002. By default, FFT length is equal to twice the numerator length. This makes the latency proportional to the impulse response length.

```
fdfOS  = dsp.FrequencyDomainFIRFilter(imp,'Method','overlap-save');
fprintf('Frequency domain filter latency is %d samples\n',fdfOS.Latency);
```

```
Frequency domain filter latency is 4002 samples
```

Partition the impulse response to blocks of length 256. The latency after partitioning is proportional to the block length.

```
fdfRL  = dsp.FrequencyDomainFIRFilter(imp,'Method','overlap-save',...
    'PartitionForReducedLatency',true,...
    'PartitionLength',256);
fprintf('Frequency domain filter latency is %d samples\n',fdfRL.Latency);
```

```
Frequency domain filter latency is 256 samples
```

Compare the outputs of the two frequency domain filters. The latency of `fdfOS` is 4002, and the latency of `fdfRL` is 256. To compare the two outputs, delay the input to `fdfRL` by 4002 - 256 samples.

```
dly = dsp.Delay('Length',(fdfOS.Latency-fdfRL.Latency));
```

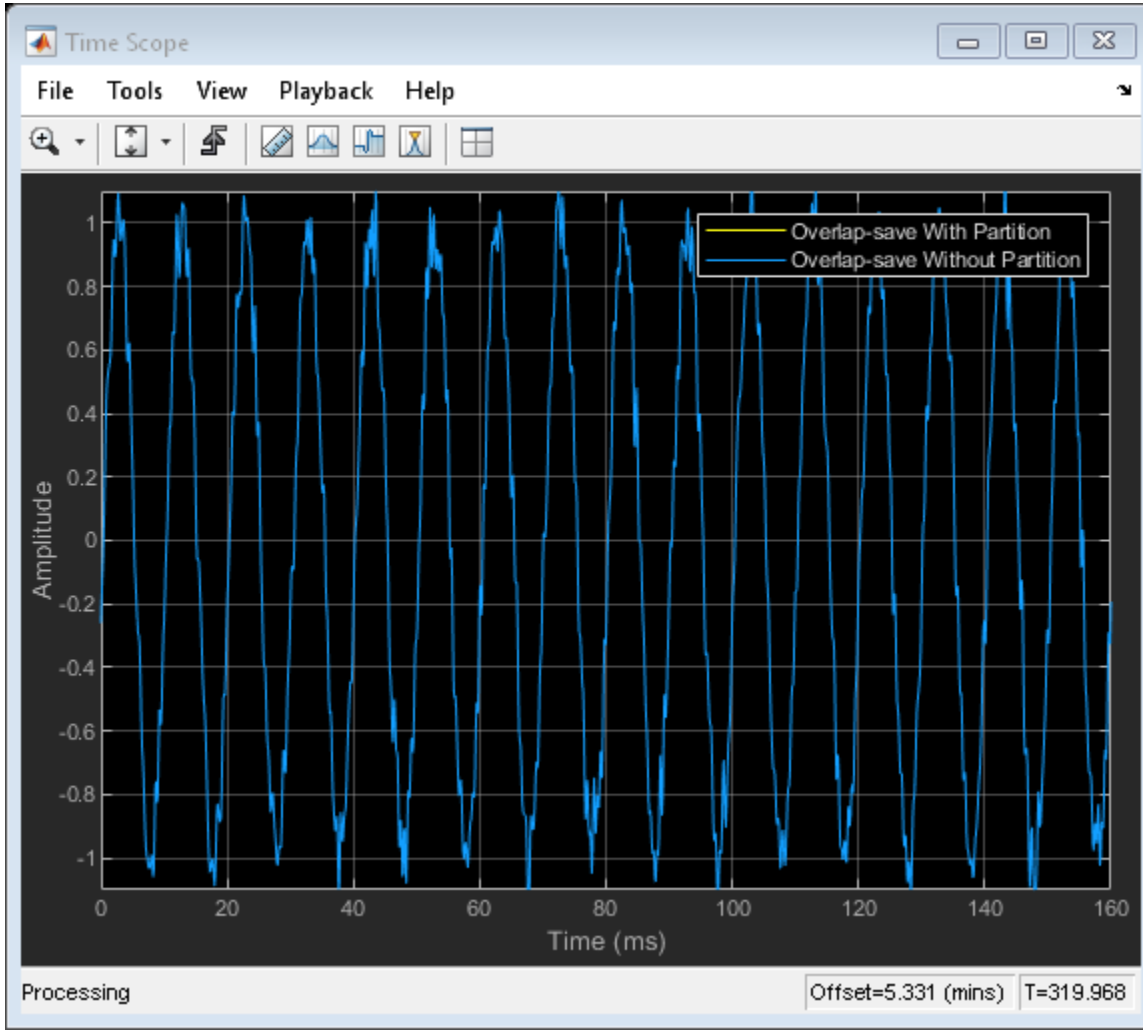
Create two `dsp.SineWave` objects. The sine waves have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `dsp.TimeScope` object to view the filtered outputs.

```
frameLen  = 256;
sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz  = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
```

```
ts = dsp.TimeScope('TimeSpanOverrunAction','Scroll',...
    'ShowGrid',true,'TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-save With Partition','Overlap-save Without Partition'});
```

Stream 1e4 frames of noisy input data. Pass this data through the two frequency domain filters. View the filtered outputs in the time scope.

```
numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + .1 * randn(frameLen,1);
    yRL = fdfRL(dly(x));
    yOS = fdfOS(x);
    ts([yRL,yOS]);
end
```



The outputs match exactly.

Specify Frequency Response of the Frequency-Domain FIR Filter

Specify the numerator coefficients of the frequency-domain FIR filter in the frequency domain. Filter the input signal using the overlap-add method. Compare the frequency-domain FIR filter output to the corresponding time-domain FIR filter output.

Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The time-domain impulse response has a length of 400. Compute the FFT of this impulse response and specify this response as the frequency response of the frequency-domain FIR filter. Set the time-domain numerator length, specified by the `NumeratorLength` property, to the number of elements in the time-domain impulse response.

```
impL    = 400;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL,2 * Fcutoff / Fs);
H   = fft(imp , 2 * numel(imp));
oa  = dsp.FrequencyDomainFIRFilter('NumeratorDomain','Frequency',...
    'FrequencyResponse', H,...
    'NumeratorLength',numel(imp),...
    'Method','overlap-add');
fprintf('Frequency domain filter latency is %d samples\n',oa.Latency);
```

```
Frequency domain filter latency is 402 samples
```

Create a `dsp.FIRFilter` System object? and specify the numerator as the time-domain coefficients computed using the `fir1` function, `imp`. Delay the FIR output by the latency of the frequency-domain FIR filter.

```
fir = dsp.FIRFilter('Numerator',imp);
dly = dsp.Delay('Length',oa.Latency);
```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `dsp.TimeScope` object to view the filtered outputs.

```
frameLen  = 256;

sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz  = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
```

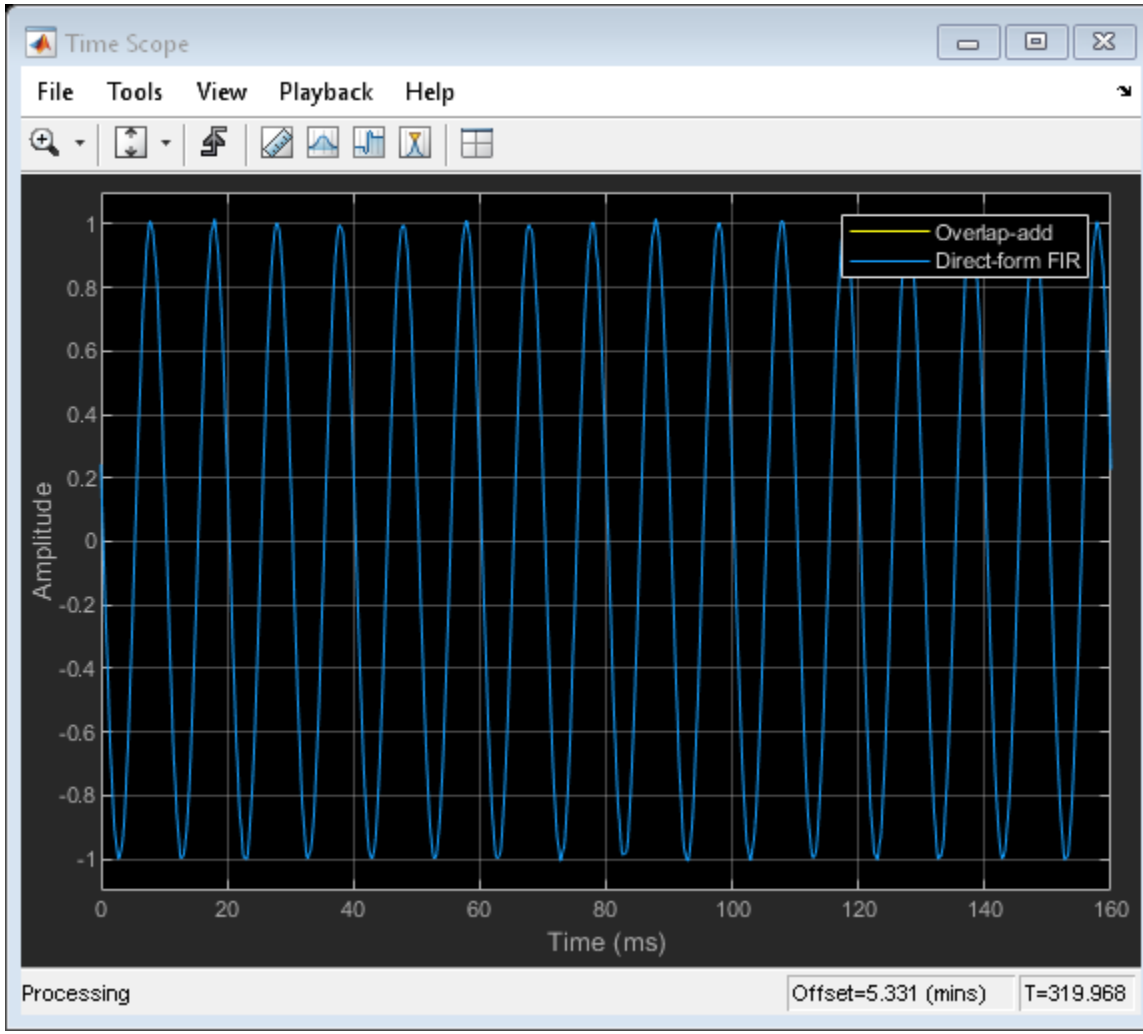
```
    'SamplesPerFrame',frameLen);

ts = dsp.TimeScope('TimeSpanOverrunAction','Scroll',...
    'ShowGrid',true,'TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Direct-form FIR'});
```

Streaming

Stream 1e4 frames of noisy input data. Pass this data through the frequency-domain FIR filter and the time-domain FIR filter. View the filtered outputs in the time scope.

```
numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01 * randn(frameLen,1);
    y1 = oa(x);
    y2 = fir(dly(x));
    ts([y1,y2]);
end
```



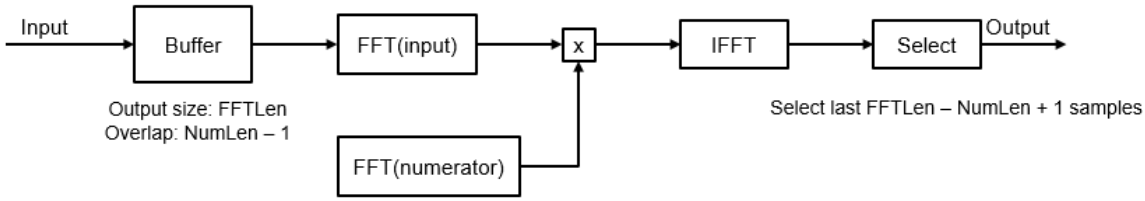
The outputs of both the filters match exactly.

Algorithms

Overlap-save and overlap-add are the two frequency-domain FFT-based filtering methods this algorithm uses.

Overlap-Save

The overlap-save method is implemented using the following approach:



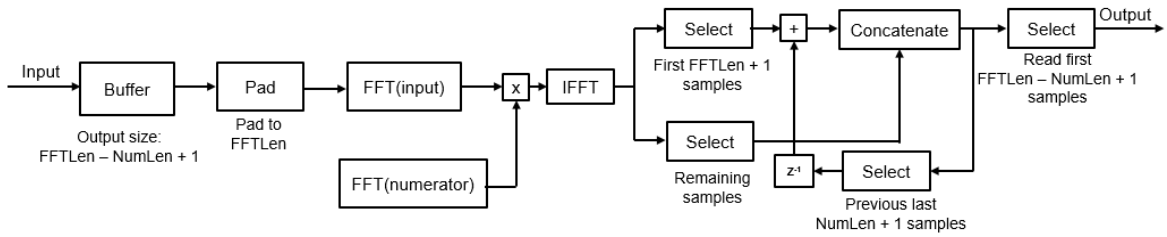
The input stream is partitioned into overlapping blocks of size *FFTLen*, with an overlap factor of *NumLen* – 1 samples. *FFTLen* is the FFT length and *NumLen* is the length of the FIR filter numerator. The FFT of each block of input samples is computed and multiplied with the length-*FFTLen* FFT of the FIR numerator. The inverse fast Fourier transform (IFFT) of the result is performed, and the last *FFTLen* – *NumLen* + 1 samples are saved. The remaining samples are dropped.

The latency of overlap-save is *FFTLen* – *NumLen* + 1. The first *FFTLen* – *NumLen* + 1 samples are equal to zero. The filtered value of the first input sample appears as the *FFTLen* – *NumLen* + 2 output sample.

Note that the FFT length must be larger than the numerator length, and is typically set to a value much greater than *NumLen*.

Overlap-Add

The overlap-add method is implemented using the following approach:



The input stream is partitioned into blocks of length *FFLen* – *NumLen* + 1, with no overlap between consecutive blocks. Similar to overlap-save, the FFT of the block is computed, and multiplied by the FFT of the FIR numerator. The IFFT of the result is then computed. The first *NumLen* + 1 samples are modified by adding the values of the last *NumLen* + 1 samples from the previous computed IFFT.

The latency of overlap-add is *FFTLen* – *NumLen* + 1. The first *FFTLen* – *NumLen* + 1 samples are equal to zero. The filtered value of the first input sample appears as the *FFTLen* – *NumLen* + 2 output sample.

Reduce Latency Through Impulse Response Partitioning

With an FFT length that is twice the length of the FIR numerator, the latency roughly equals the length of the FIR numerator. If the impulse response is very long, the latency becomes significantly large. However, frequency domain FIR filtering is still faster than the time-domain filtering. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details, see [1].

dsp.HampelFilter

Package: `dsp`

Filter outliers using Hampel identifier

Description

The `dsp.HampelFilter` System object detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers. For each sample of the input signal, the object computes the median of a window composed of the current sample and $\frac{Len-1}{2}$ adjacent samples on each side of current sample. *Len* is the window length you specify through the `WindowLength` property. The object also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see “Algorithms” on page 4-842.

To filter the input signal using a Hampel identifier:

1. Create the `dsp.HampelFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
hampFilt = dsp.HampelFilter
hampFilt = dsp.HampelFilter(Len)
hampFilt = dsp.HampelFilter(Len, Lim)
hampFilt = dsp.HampelFilter(Name,Value)
```

Description

`hampFilt = dsp.HampelFilter` returns a Hampel filter object, `hampFilt`, using the default properties.

`hampFilt = dsp.HampelFilter(Len)` sets the `WindowLength` property to `Len`.

`hampFilt = dsp.HampelFilter(Len, Lim)` sets the `WindowLength` property to `Len` and the `Threshold` property to `Lim`.

Example: `hampFilt = dsp.HampelFilter(11,2);`

`hampFilt = dsp.HampelFilter(Name,Value)` specifies properties using `Name,Value` pairs. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

If a property is listed as tunable, then you can change its value even when the object is locked.

`WindowLength` — Length of the sliding window

`11` (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the object computes the median and median absolute deviation of the data in the window.

Data Types: `single` | `double`

`Threshold` — Threshold for outlier detection

3 (default) | positive real scalar

Threshold for outlier detection, specified as a positive real scalar. For information on how this property is used to detect the outlier, see “Algorithms” on page 4-842.

Tunable: Yes

Data Types: `single` | `double`

Usage

Syntax

```
y = hampFilt(x)
[y,isOutlier] = hampFilt(x)
```

Description

`y = hampFilt(x)` detects and removes the outliers of each channel of the input signal, `x`, independently over time using the Hampel filter.

`[y,isOutlier] = hampFilt(x)` returns a logical array, `isOutlier`, in which each `true` element indicates that the corresponding element in the input is an outlier. `isOutlier` is the same size as the input and output vectors.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The object accepts multichannel inputs, that is, *m*-by-*n* size inputs, where $m \geq 1$, and $n > 1$. *m* is the number of samples in each frame (channel), and *n* is the number of channels. The object also accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Filtered data

vector | matrix

Filtered data, returned as a vector or a matrix.

Data Types: `single` | `double`

`isOutlier` — Indicate outlier

`true` | `false`

Logical array whose elements indicate if the corresponding element in the input array is an outlier. If an element in `isOutlier` is `true`, the corresponding element in the input array is an outlier.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Remove High-Frequency Noise Using Hampel Filter

Filter high-frequency noise from a noisy sine wave signal using a Hampel filter. Compare the performance of the Hampel filter with a median filter.

Initialization

Set up a `dsp.HampelFilter` and a `dsp.MedianFilter` object. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

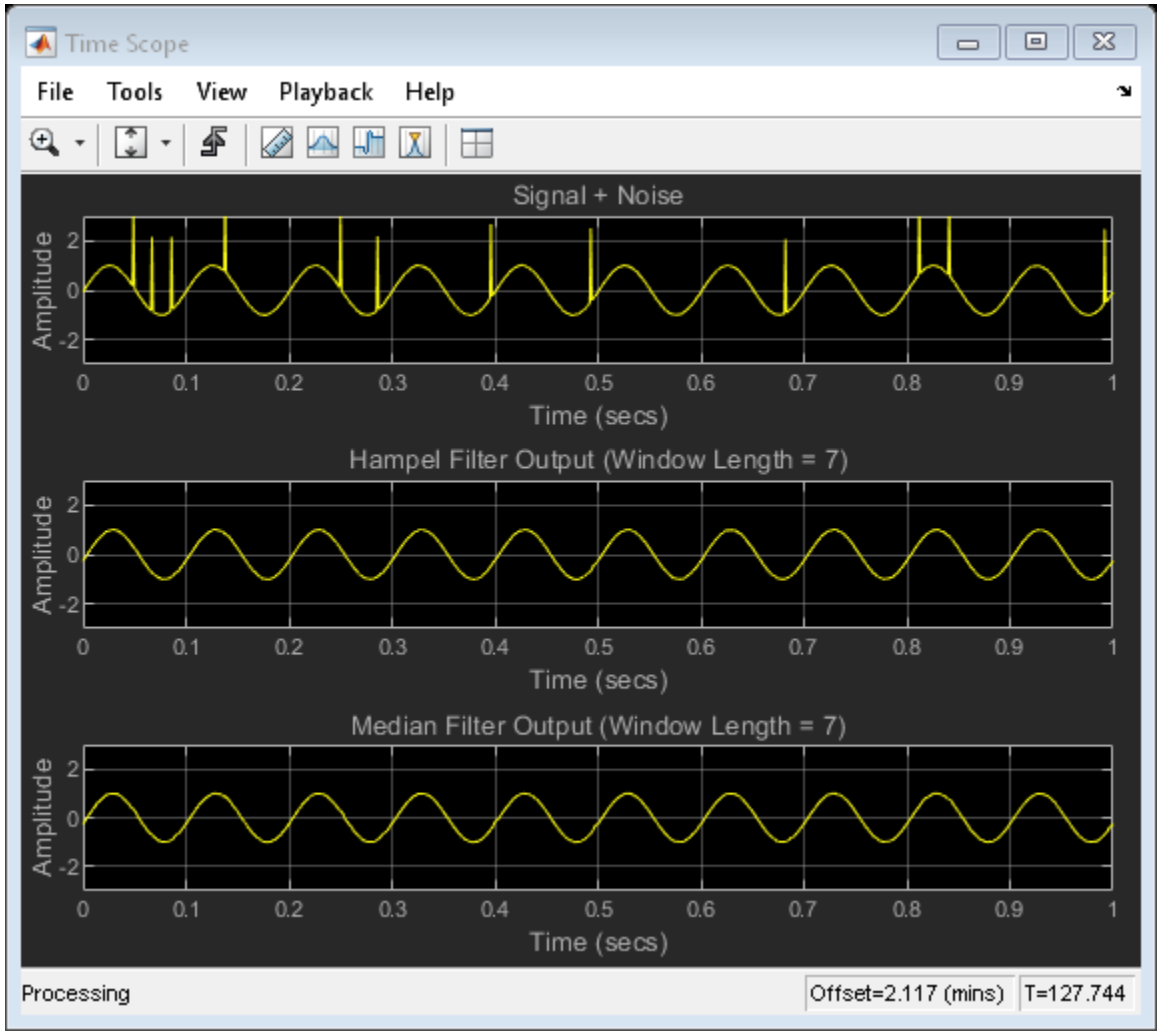
```
Fs = 1000;
hampFilt = dsp.HampelFilter(7);
medFilt = dsp.MedianFilter(7);
scope  = dsp.TimeScope('SampleRate',Fs, ...
    'TimeSpanOverrunAction','Scroll', ...
    'TimeSpan',1,'ShowGrid',true, ...
    'YLimits',[-3 3], ...
    'LayoutDimensions',[3 1], ...
    'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 7)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';
```

Filter the Noisy Sine Wave Using a Window of Length 7

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the Hampel filter and the median filter object to the signal. View the output on the time scope.

```
FrameLength = 256;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);

for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

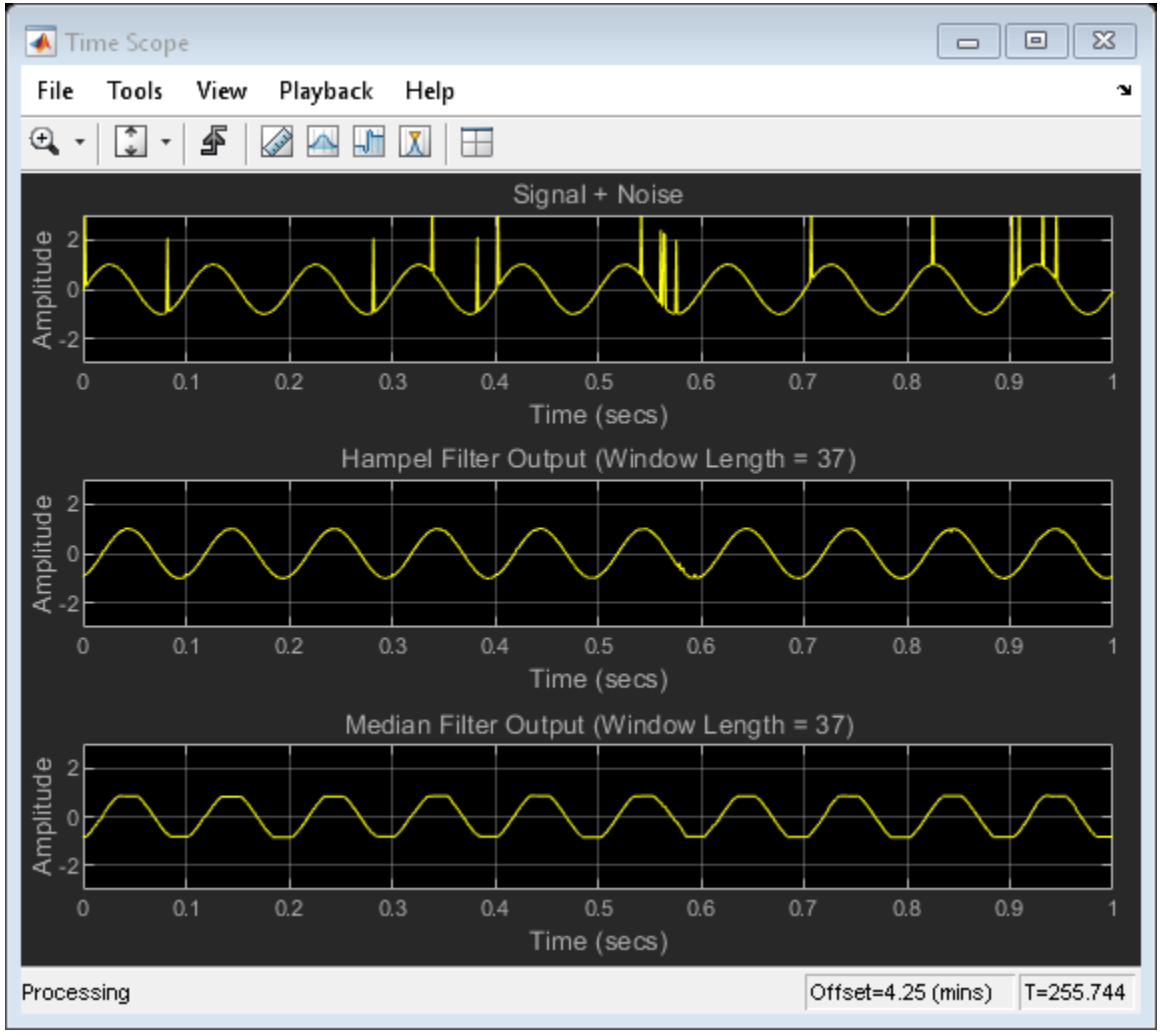


Both filters remove the high-frequency noise. However, when you increase the window length, the Hampel filter is preferred. Unlike the median filter, the Hampel filter preserves the shape of the sine wave even with large window lengths.

Filter the Noisy Sine Wave Using a Window of Length 37

Increase the window length of both the filters to 37. Filter the noisy sine wave and view the filtered output on the time scope. To change the window length of the filters, you must release the filter objects at the start of the processing loop.

```
release(hampFilt);
release(medFilt);
hampFilt.WindowLength = 37;
medFilt.WindowLength = 37;
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 37)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 37)';
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```



The median filter flattens the crests and troughs of the sine wave due to the median operation over a large window of data. The Hampel filter preserves the shape of the signal, in addition to removing the outliers.

Remove High-Frequency Noise from Gyroscope Data Using Hampel Filter

Remove the high-frequency outliers from a streaming signal using the `dsp.HampelFilter` System object?.

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The file contains three columns of data, with each column containing 7140 samples. The three columns represent the *x*-axis, *y*-axis, and *z*-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.HampelFilter` System object uses a window length of 11. Create a `dsp.TimeScope` object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,'Filename','LSM9DSHampelgyroData73.mat
    'VariableName','data');
hampFilt = dsp.HampelFilter(11);
scope = dsp.TimeScope('NumInputPorts',1,'SampleRate',119,'YLimits',[-300 300], ...
    'ChannelNames',{'Input','Filtered Output'},'TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.HampelFilter` System object. View the filtered *z*-axis data in the Time Scope.

```
for i = 1:10
    gyroData = reader();
    filteredData = hampFilt(gyroData);
    scope([gyroData(:,3),filteredData(:,3)]);
end
```

The Hampel filter removes all the outliers and preserves the shape of the signal.

More About

Hampel Identifier

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence $x_1, x_2, x_3, \ldots, x_n$ and a sliding window of length k, define point-to-point median and standard-deviation estimates using:

- Local median — $m_i = \text{median}(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \ldots, x_i, \ldots, x_{i+k-2}, x_{i+k-1}, x_{i+k})$
- Standard deviation — $\sigma_i = \kappa\text{median}(|x_{i-k} - m_i|, \ldots, |x_{i+k} - m_i|)$, where $\kappa = \frac{1}{\sqrt{2}\text{erfc}^{-1}(1/2)} \approx 1.4826$

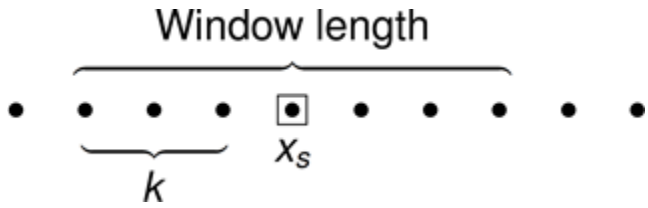
The quantity σ_i / κ is known as the median absolute deviation (MAD).

If a sample x_i is such that

$$|x_i - m_i| > n_\sigma \sigma_i$$

for a given threshold n_σ, then the Hampel identifier declares x_i an outlier and replaces it with m_i. If n_σ is 0, then the Hampel filter behaves as a regular median filter.

Algorithms

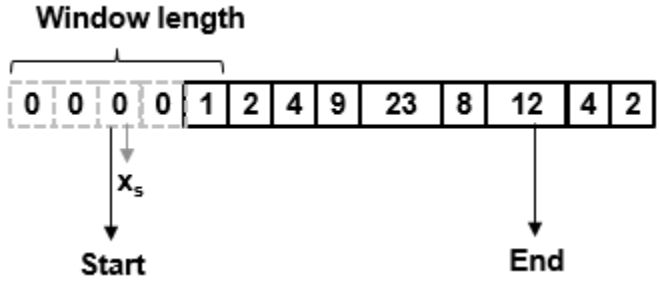


For a given sample of data, x_s, the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median, m_i, and standard deviation, σ_i, over the current window of data.
- Compares the current sample with $n_\sigma \times \sigma_i$, where n_σ is the threshold value. If $|x_s - m_i| > n_\sigma \times \sigma_i$, the filter identifies the current sample, x_s, as an outlier and replaces it with the median value, m_i.

Consider a frame of data that is passed into the Hampel filter.

In this example, the Hampel filter slides a window of length 5 (*Len*) over the data. The filter has a threshold value of 2 (n_σ). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with *Len* – 1 zeros. To compute the first sample of the output, the window centers on the $\left\lfloor \frac{Len-1}{2} + 1 \right\rfloor^{\text{th}}$ sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.



- Current sample: $x_s = 0$.
- Window of data: *win* = [0 0 0 0 1].
- Local median: m_i = median([0 0 0 0 1]) = 0.
- Median absolute deviation: mad_i = median($|x_{i-k} - m_i|$, ..., $|x_{i+k} - m_i|$). For this window of data, *mad* = median(|0 − 0|, ..., |1 − 0|) = 0.

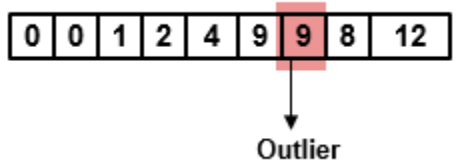
- Standard deviation: $\sigma_i = \kappa \times mad_i = 0$, where $\kappa = \frac{1}{\sqrt{2}\text{erfc}^{-1}(1/2)} \approx 1.4826$.
- The current sample, $x_s = 0$, does not obey the relation for outlier detection.

  $[|x_s - m_i| = 0] > [(n_\sigma \times \sigma_i) = 0]$

  Therefore, the Hampel filter outputs the current input sample, $x_s = 0$.

Repeat this procedure for every succeeding sample until the algorithm centers the window on the $\left[End - \frac{Len - 1}{2}\right]^{\text{th}}$ sample, marked as `End`. Because the window centered on the last $\frac{Len - 1}{2}$ samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:



The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

dsp.HDLChannelizer

Package: `dsp`

Polyphase filter bank and fast Fourier transform—optimized for HDL code generation

Description

The `dsp.HDLChannelizer` System object separates a broadband input signal into multiple narrowband output signals. It provides hardware speed and area optimization for streaming data applications. The object accepts scalar or vector input of real or complex data, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput by using vector input. The object implements a polyphase filter, with one subfilter per input vector element. The hardware implementation interleaves the subfilters, which results in sharing each filter multiplier (*FFT Length* / *Input Size*) times. The object implements the same pipelined Radix 2^2 FFT algorithm as the `dsp.HDLFFT` System object.

To channelize input data:

1. Create the `dsp.HDLChannelizer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
channelizer = dsp.HDLChannelizer
channelizer = dsp.HDLChannelizer(Name,Value)
```

Description

`channelizer = dsp.HDLChannelizer` returns a System object, `channelizer`, that implements a raised-cosine filter and an 8-point FFT.

`channelizer = dsp.HDLChannelizer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`NumFrequencyBands` — FFT length
8 (default) | integer power of two

FFT length, specified as an integer power of two. For HDL code generation, the FFT length must be between 2^3 and 2^{16}, inclusive.

`FilterCoefficients` — Polyphase filter coefficients
`[-0.032 0.121 0.318 0.482 0.546 0.482 0.318 0.121 -0.032]` (default) | vector of numeric values

Polyphase filter coefficients, specified as a vector of numeric values. If the number of coefficients is not a multiple of `NumFrequencyBands`, the object pads this vector with zeros. The default filter specification is a raised-cosine FIR filter, `rcosdesign(0.25,2,4,'sqrt')`. You can specify a vector of coefficients or a call to a filter design function that returns the coefficient values. Complex coefficients are not supported. By default, the object casts the coefficients to the same data type as the input.

`ComplexMultiplication` — HDL implementation of complex multipliers
`'Use 4 multipliers and 2 adders'` (default) | `'Use 3 multipliers and 5 adders'`

HDL implementation of complex multipliers, specified as either `'Use 4 multipliers and 2 adders'` or `'Use 3 multipliers and 5 adders'`. Depending on your synthesis tool and target device, one option may be faster or smaller.

Dependencies

This option applies only if you use the Radix 2^2 architecture.

`OutputSize` — Size of output data

`'Same as number of frequency bands'` (default) | `'Same as input size'`

Size of output data, specified as:

- `'Same as number of frequency bands'` — Output data is a 1-by-*M* vector, where *M* is the FFT length.
- `'Same as input size'` — Output data is an *M*-by-1 vector, where *M* is the input vector size.

The output order is bit natural for both output sizes.

`Normalize` — FFT scaling

`true` (default) | `false`

FFT output scaling, specified as either:

- `true` — The FFT implements an overall 1/*N* scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input.
- `false` — The FFT avoids overflow by increasing the word length by one bit at each stage.

`RoundingMethod` — Rounding mode used for internal fixed-point calculations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding mode used for fixed-point operations. The object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. Each FFT stage rounds after the twiddle factor multiplication but before the butterflies. Rounding can also occur when casting the coefficients and the output of the polyphase filter to the data types you specify.

`OverflowAction` — Overflow handling for internal fixed-point calculations

`'Wrap'` (default) | `'Saturate'`

“Overflow Handling” used for fixed-point operations. The object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. This option applies to casting the coefficients and the output of the polyphase filter to the data types you specify.

The FFT algorithm avoids overflow by either scaling the output of each stage (Normalize enabled), or by increasing the word length by 1 bit at each stage (`Normalize` disabled).

`CoefficientsDataType` — Data type of filter coefficients
`'Same word length as input'` (default) | `numerictype` object

The object casts the polyphase filter coefficients to this data type, using the rounding and overflow settings you specify. When you select `Inherit: Same word length as input` (default), the object selects the binary point using `fi()` best-precision rules.

`FilterOutputDataType` — Data type of output of polyphase filter
`'Same word length as input'` (default) | `'Full precision'` | `numerictype` object

Data type of the output of the polyphase filter, specified as `'Same word length as input'`, `'Full precision'`, or a `numerictype` object. The object casts the output of the polyphase filter (the input to the FFT) to this data type, using the rounding and overflow settings you specify. When you specify `'Same word length as input'`, the object selects a best-precision binary point by considering the values of your filter coefficients and the range of your input data type.

By default, the FFT logic does not change the data type. When you disable Normalize, the FFT algorithm avoids overflow by increasing the word length by 1 bit at each stage.

`ResetInputPort` — Enable reset argument
`false` (default) | `true`

Enable `reset` input argument to the object. When `reset` is `1` (true), the object stops calculation and clears all internal state.

`StartOutputPort` — Enable start output argument
`false` (default) | `true`

Enable `startOut` output argument of the object. When enabled, the object returns an additional output signal that is `1` (true) on the first cycle of each valid output frame.

`EndOutputPort` — Enable end output argument
`false` (default) | `true`

Enable `endOut` output argument of the object. When enabled, the object returns an additional output signal that is `1` (true) on the first cycle of each valid output frame.

Usage

Syntax

```
[dataOut,validOut] = channelizer(dataIn,validIn)
[dataOut,validOut] = channelizer(dataIn,validIn,reset)
[dataOut,startOut,endOut,validOut] = channelizer( ___ )
```

Description

`[dataOut,validOut] = channelizer(dataIn,validIn)` filters and computes a fast Fourier transform, and returns the frequency channels, `dataOut`, detected in the input signal, `dataIn`, when `validIn` is `1` (true). The `validIn` and `validOut` arguments are logical scalars that indicate the validity of the input and output signals, respectively.

`[dataOut,validOut] = channelizer(dataIn,validIn,reset)` returns the frequency channels, `dataOut`, detected in the input signal, `dataIn`, when `validIn` is `1` (true) and `reset` is `0` (false). When `reset` is `1` (true), the object stops the current calculation and clears all internal state.

To use this syntax, set the ResetInputPort property to `true`. For example:

```
channelizer = dsp.HDLChannelizer(...,'ResetInputPort',true);
...
[dataOut,validOut] = channelizer(dataIn,validIn,reset)
```

`[dataOut,startOut,endOut,validOut] = channelizer( ___ )` returns the frequency channels, `dataOut`, computed from the input arguments of any of the previous syntaxes. `startOut` is `1` (true) for the first sample of a frame of output data. `endOut` is `1` (true) for the last sample of a frame of output data.

To use this syntax, set the StartOutputPort and EndOutputPort properties to `true`. For example:

```
channelizer = dsp.HDLChannelizer(...,'StartOutputPort',true,'EndOutputPort',true);
...
[dataOut,startOut,endOut,validOut] = channelizer(dataIn,validIn)
```

Input Arguments

`dataIn` — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values. The vector size must be a power of 2 between 1 and 64 that is not greater than the number of channels (FFT length). `double` and `single` are allowed for simulation but not for HDL code generation.

The object does not accept `uint64` data.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

`validIn` — Validity of input data

`logical` scalar

Validity of input data, specified as a logical scalar. When `validIn` is `1` (true), the object captures the value on `dataIn`.

Data Types: `logical`

`reset` — Reset internal state

`logical` scalar

Reset internal state, specified as a logical scalar. When `reset` is `1` (true), the object stops the current calculation and clears internal state.

Dependencies

To enable this argument, set ResetInputPort to `true`.

Data Types: `logical`

Output Arguments

`dataOut` — Frequency channel output data

row vector

Frequency channel output data, returned as a row vector.

- If you set OutputSize to `'Same as number of frequency bands'` (default), the output data is a 1-by-*M* vector, where *M* is the FFT length.
- If you set `OutputSize` to `'Same as input size'`, the output data is an *M*-by-1 vector, where *M* is the input vector size.

The output order is bit natural for either output size. The data type is a result of the FilterOutputDataType and the FFT bit growth necessary to avoid overflow.

`validOut` — Validity of output data

`logical` scalar

Validity of output data, returned as a logical scalar. The object sets `validOut` to `1` (true) with each valid sample on `dataOut`.

Data Types: `logical`

`startOut` — First valid cycle of output data

`logical` scalar

First sample of output frame, returned as a logical scalar. The object sets `startOut` to `1` (true) during the first valid sample on `dataOut`.

Dependencies

To enable this argument, set StartOutputPort to `true`.

Data Types: `logical`

`endOut` — Last valid cycle of output data

`logical` scalar

Last sample of output frame, returned as a logical scalar. The object sets `endOut` to `1` (true) during the last valid sample on `dataOut`.

Dependencies

To enable this argument, set EndOutputPort to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLChannelizer

getLatency	Latency of FFT or channelizer calculation

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create Channelizer for HDL Generation

Create a function that contains a channelizer object and supports HDL code generation.

Create the specifications and input signal. The signal has 8 frequency channels.

```
N = 8;
loopCount = 1024;
offsets = [-40 -30 -20 10 15 25 35 -15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency', ...
     offsets+(-375:125:500),'SamplesPerFrame',loopCount);
spectrumAnalyzer = dsp.SpectrumAnalyzer('ShowLegend',true, ...
     'SampleRate',sinewave.SampleRate/N);
```

Write a function that creates and calls the channelizer System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLChannelizer8(yIn,validIn)
%HDLChannelizer8
% Process one sample of data using the dsp.HDLChannelizer System object
```

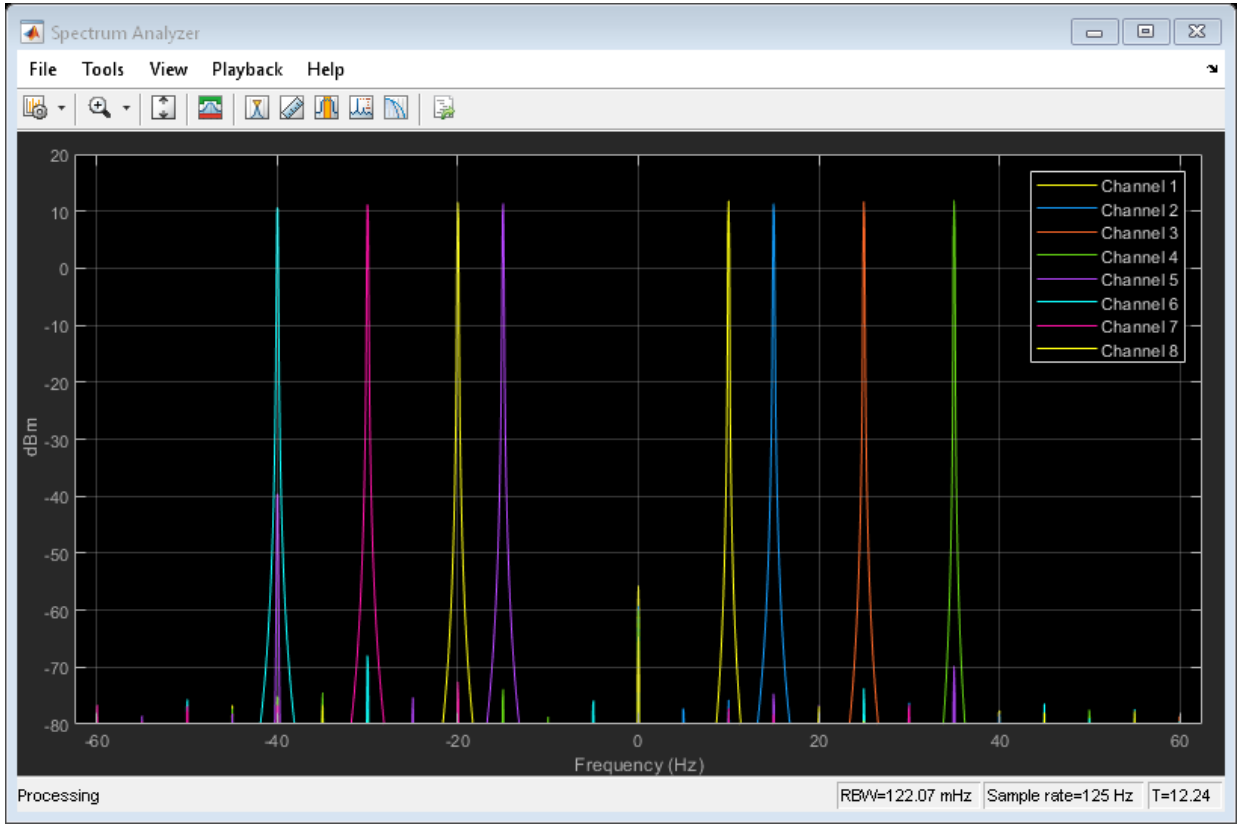
```
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent channelize8;
  coder.extrinsic('tf');
  coder.extrinsic('dsp.Channelizer');

  if isempty(channelize8)
    % Use filter coeffs from non-HDL channelizer, or supply your own.
    channelizer = coder.const(dsp.Channelizer('NumFrequencyBands',8));
    coeff = coder.const(tf(channelizer));
    channelize8 = dsp.HDLChannelizer('NumFrequencyBands',8,'FilterCoefficients',coeff);
  end
  [yOut,validOut] = channelize8(yIn,validIn);
end
```

Channelize the input data by calling the object for each data sample.

```
y = zeros(loopCount/N,N);
validOut = false(loopCount/N,1);
yValid = zeros(loopCount/(N*N),N);
for reps=1:20
   x = fi(sum(sinewave(),2),1,18);
   for loop=1:length(x)
      [y(loop,:),validOut(loop)]= HDLChannelizer8(x(loop),true);
   end
   yValid = y(validOut == 1,:);
   spectrumAnalyzer(yValid);
end
```



Explore Latency of the HDL Channelizer Object

The latency of the `dsp.HDLChannelizer` object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is measured as the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous. The number of filter coefficients does not affect the latency. Setting the output size equal to the input size reduces the latency because the samples are not saved and reordered.

Create a `dsp.HDLChannelizer` object and request the latency.

```
channelize = dsp.HDLChannelizer('NumFrequencyBands',512);
L512 = getLatency(channelize)
```

```
L512 = 1117
```

Request hypothetical latency information about a similar object with a different number of frequency bands (FFT length). The properties of the original object do not change.

```
L256 = getLatency(channelize,256)
```

```
L256 = 591
```

```
N = channelize.NumFrequencyBands
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(channelize,256,8)
```

```
L256v8 = 131
```

Enable scaling at each stage of the FFT. The latency does not change.

```
channelize.Normalize = true;
L512n = getLatency(channelize)
```

```
L512n = 1117
```

Request the same output size and order as the input data. The latency decreases because the object does not need to store and reorder the data before output. The default input size is scalar.

```
channelize.OutputSize = 'Same as input size';
L512r = getLatency(channelize)
```

```
L512r = 1083
```

Check the latency of a vector input implementation where the input and output are the same size. Specify the current value of the FFT length and a vector size of 8 samples. The latency decreases because the object computes results in parallel when the input is a vector.

```
L256rv8 = getLatency(channelize,channelize.NumFrequencyBands,8)
```

```
L256rv8 = 217
```

Algorithms

This object implements the algorithm described on the Channelizer HDL Optimized block reference page.

Latency

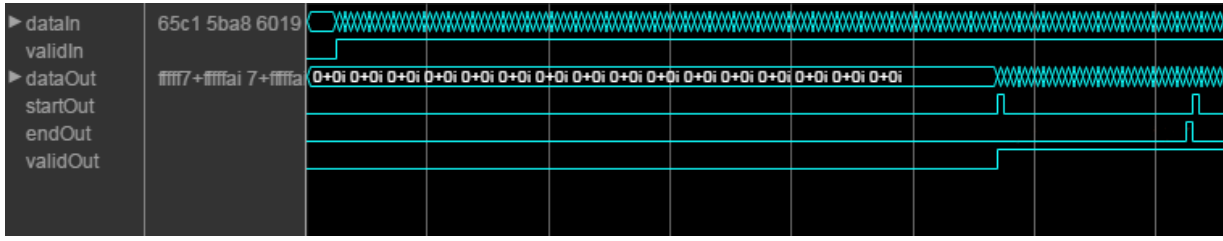
The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous. The filter coefficients do not affect the latency. Setting the output size equal to the input size reduces the latency, because the samples are not saved and reordered.

Control Signals

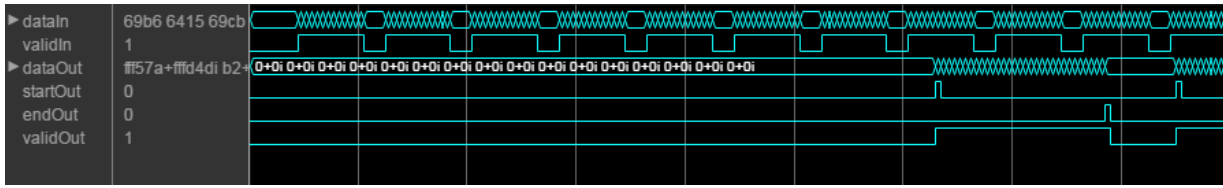
This diagram shows `validIn` and `validOut` signals for contiguous input data with a vector size of 16 and an FFT length of 512.

The diagram also shows the optional `startOut` and `endOut` signals that indicate frame boundaries. When enabled, `startOut` pulses for one cycle with the first `validOut` of the frame, and `endOut` pulses for one cycle with the last `validOut` of the frame.

If you apply continuous input frames (no gap in `validIn` between frames), the output will also be continuous, after the initial latency.



The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` signal is stored until a frame is filled. Then the data is output in a contiguous frame of *N* (FFT length) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16 samples.



Performance

These resource and performance data are the place-and-route results from the generated HDL targeted to a Xilinx Virtex 6 (XC6VLX240-1ff784) FPGA. The three examples in the tables use this configuration:

- FFT length (default) — 8
- Filter length — 96 coefficients
- 16-bit complex input data
- Coefficient and filter output data types (default) — Same as number of frequency bands
- Complex multiplication (default) — 4 multipliers, 2 adders
- Output scaling — Enabled
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options.

For scalar input, the design achieves a clock frequency of 346 MHz. The latency is 53 cycles. The subfilters share each multiplier eight (*N*) times. The design uses these resources.

Resource	Number Used
LUT	1591
FFS	2681
Xilinx LogiCORE DSP48	16

For four-sample vector input, the design achieves a clock frequency of 333 MHz. The latency is 31 cycles. The subfilters share each multiplier twice (*N*/*M*). The design uses these resources.

Resource	Number Used
LUT	1912
FFS	3986
Xilinx LogiCORE DSP48	56

For eight-sample vector input, the design achieves a clock frequency of 292 MHz. The latency is 20 cycles. When the input size is the same as the FFT length, the subfilters do not share any multipliers. The design uses these resources.

Resource	Number Used
LUT	1388
FFS	2302
Xilinx LogiCORE DSP48	110

dsp.HDLComplexToMagnitudeAngle

Package: dsp

Magnitude and phase angle of complex signal—optimized for HDL code generation

Description

The dsp.HDLComplexToMagnitudeAngle System object computes the magnitude and phase angle of a complex signal. It provides hardware-friendly control signals. The System object uses a pipelined coordinate rotation digital computer (CORDIC) algorithm to achieve an HDL-optimized implementation.

To compute the magnitude and phase angle of a complex signal:

1. Create the dsp.HDLComplexToMagnitudeAngle object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
HCMA = dsp.HDLComplexToMagnitudeAngle
HCMA = dsp.HDLComplexToMagnitudeAngle(Name,Value)
```

Description

HCMA = dsp.HDLComplexToMagnitudeAngle returns a dsp.HDLComplexToMagnitudeAngle System object, HCMA, that computes the magnitude and phase angle of a complex input signal.

HCMA = dsp.HDLComplexToMagnitudeAngle(Name,Value) sets properties of HCMA using one or more name-value pairs. Enclose each property name in single quotes.

Example: `cma = dsp.HDLComplexToMagnitudeAngle('AngleFormat','Radians')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`OutputValue` — Type of values to return

`'Magnitude and angle'` (default) | `'Magnitude'` | `'Angle'`

Type of output values to return, specified as `'Magnitude and angle'`, `'Magnitude'`, or `'Angle'`. You can choose for the object to return the magnitude of the input signal, or the phase angle of the input signal, or both.

`AngleFormat` — Format of phase angle output value

`'Normalized'` (default) | `'Radians'`

Format of the phase angle output value from the object, specified as:

- `'Normalized'` — Fixed-point format that normalizes the angle in the range [–1,1].
- `'Radians'` — Fixed-point values in the range [π,−π].

`ScaleOutput` — Scale output by inverse of CORDIC gain factor

`true` (default) | `false`

Scale output by the inverse of the CORDIC gain factor, specified as `true` or `false`.

Note If your design includes a gain factor later in the datapath, you can set `ScaleOutput` to `false`, and include the CORDIC gain factor in the later gain. For calculation of this gain factor, see “Algorithm” on page 4-868. The object replaces the first CORDIC iteration by mapping the input value onto the angle range [0,π/4]. Therefore, the initial rotation does not contribute a gain term.

`NumIterationsSource` — Source of `NumIterations`
`'Auto'` (default) | `'Property'`

Source of the `NumIterations` property for the CORDIC algorithm, specified as:

- `'Auto'` — Sets the number of iterations to one less than the input word length. If the input is `double` or `single`, the number of iterations is 16.
- `'Property'` — Uses the `NumIterations` property.

For details of the CORDIC algorithm, see “Algorithm” on page 4-868.

`NumIterations` — Number of CORDIC iterations
integer less than or equal to one less than the input word length

Number of CORDIC iterations that the object executes, specified as an integer. The number of iterations must be less than or equal to one less than the input word length.

For details of the CORDIC algorithm, see “Algorithm” on page 4-868.

Dependencies

To enable this property, set `NumIterationsSource` to `'Property'`.

Usage

Syntax

```
[mag,angle,validOut] = HCMA(X,validIn)
[mag,validOut] = HCMA(X,validIn)
[angle,validOut] = HCMA(X,validIn)
```

Description

`[mag,angle,validOut] = HCMA(X,validIn)` converts complex scalar `X` into its component magnitude and phase angle. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals, respectively.

`[mag,validOut] = HCMA(X,validIn)` returns only the component magnitude of `X`.

To use this syntax, set OutputValue to `'Magnitude'`.

Example: `HCMA = dsp.HDLComplextoMagnitudeAngle('OutputValue','Magnitude');`

`[angle,validOut] = HCMA(X,validIn)` returns only the component phase angle of `X`.

To use this syntax, set OutputValue to `'Angle'`.

Example: `HCMA = dsp.HDLComplextoMagnitudeAngle('OutputValue','Angle');`

Input Arguments

`X` — Input signal

complex scalar

Input signal, specified as a complex scalar value. `double` and `single` are allowed for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `single` | `double`

`validIn` — Validity of input signal

logical scalar

Validity of the input signal, specified as a logical scalar.

Data Types: `logical`

Output Arguments

`mag` — Magnitude component of input signal

scalar

Magnitude calculated from the complex input signal, returned as a scalar value with the same data type as the input signal.

`angle` — Phase angle component of input signal

scalar

Angle calculated from the complex input signal, returned as a scalar value with the same data type as the input signal. The format of this value depends on the AngleFormat property.

`validOut` — Validity of output components
logical scalar

Validity of the output components, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

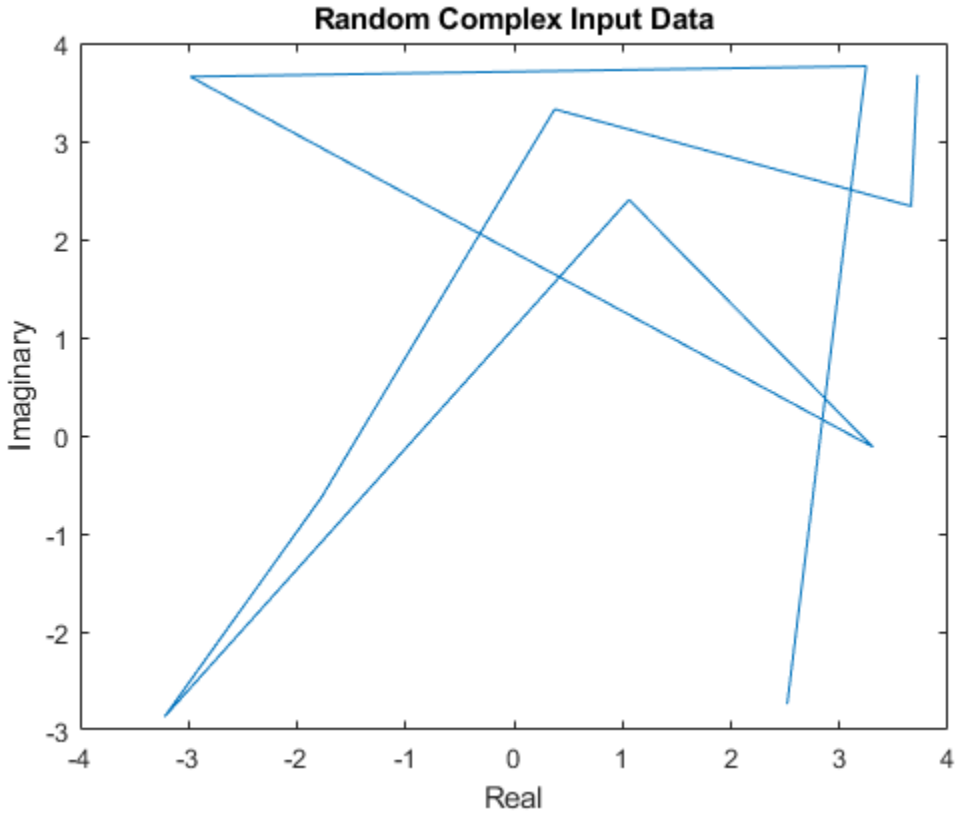
Compute Magnitude and Phase Angle of Complex Signal

Use the `dsp.HDLComplextoMagnitudeAngle` object to compute the magnitude and phase angle of a complex signal. The object uses a CORDIC algorithm for an efficient hardware implementation.

Choose word lengths and create random complex input signal. Then, convert the input signal to fixed-point.

```
a = -4;
b = 4;
inputWL = 16;
inputFL = 12;
numSamples = 10;
reData = ((b-a).*rand(numSamples,1)+a);
imData = ((b-a).*rand(numSamples,1)+a);
```

```
dataIn = (fi(reData+imData*1i,1,inputWL,inputFL));
figure
plot(dataIn)
title('Random Complex Input Data')
xlabel('Real')
ylabel('Imaginary')
```



Write a function that creates and calls the System object™. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [mag,angle,validOut] = Complex2MagAngle(yIn,validIn)
%Complex2MagAngle
% Converts one sample of complex data to magnitude and angle data.
% yIn is a fixed-point complex number.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent cma;
  if isempty(cma)
    cma = dsp.HDLComplexToMagnitudeAngle('AngleFormat','Radians');
  end
  [mag,angle,validOut] = cma(yIn,validIn);
end
```

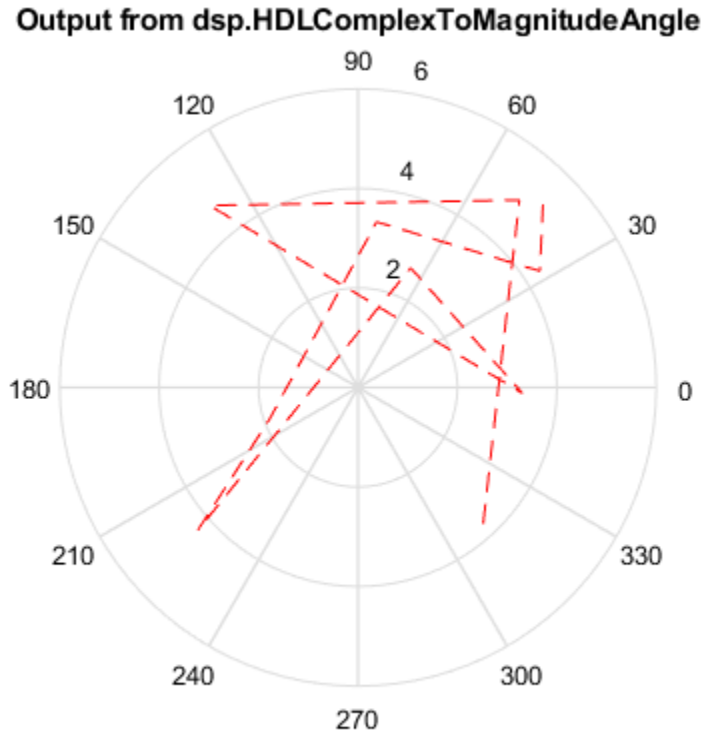
The number of CORDIC iterations determines the latency that the object takes to compute the answer for each input sample. The latency is `NumIterations+4`. In this example, `NumIterationsSource` is set to the default, `'Auto'`, so the object uses `inputWL-1` iterations. The latency is `inputWL+3`.

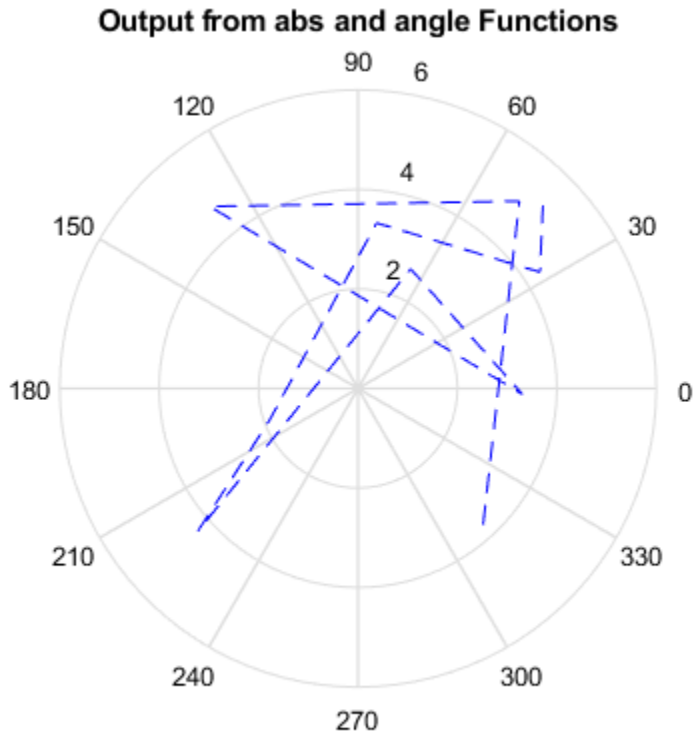
```
latency = inputWL+3;
mag = zeros(1,numSamples+latency);
ang = zeros(1,numSamples+latency);
validOut = false(1,numSamples+latency);
```

Call the function to convert each sample. After you apply all input samples, continue calling the function with invalid input to flush remaining output samples.

```
for ii = 1:1:numSamples
   [mag(ii),ang(ii),validOut] = Complex2MagAngle(dataIn(ii),true);
end
for ii = (numSamples+1):1:(numSamples+latency)
   [mag(ii),ang(ii),validOut(ii)] = Complex2MagAngle(fi(0+0*1i,1,inputWL,inputFL),false
end
% Remove invalid output values
mag = mag(validOut == 1);
ang = ang(validOut == 1);
figure
polar(ang,mag,'--r')   % Red is output from HDL-optimized System object
title('Output from dsp.HDLComplexToMagnitudeAngle')
magD = abs(dataIn);
angD = angle(dataIn);
```

```
figure
polar(angD,magD,'--b') % Blue is output from abs and angle functions
title('Output from abs and angle Functions')
```





Algorithms

CORDIC Algorithm

The CORDIC algorithm is a hardware-friendly method for performing trigonometric functions. It is an iterative algorithm that approximates the solution by converging toward the ideal point. The object uses CORDIC vectoring mode to iteratively rotate the input onto the real axis.

The Givens method for rotating a complex number $x+iy$ by an angle θ is as follows. The direction of rotation, d, is $+1$ for counterclockwise and -1 for clockwise.

$$x_r = x\cos\theta - dy\sin\theta$$
$$y_r = y\cos\theta + dx\sin\theta$$

For a hardware implementation, factor out the $\cos\theta$ to leave a $\tan\theta$ term.

$$x_r = \cos\theta(x - dy\tan\theta)$$
$$y_r = \cos\theta(y + dx\tan\theta)$$

To rotate the vector onto the real axis, choose a series of rotations of θ_n so that $\tan\theta_n = 2^{-n}$. Remove the $\cos\theta$ term so each iterative rotation uses only shift and add operations.

$$Rx_n = x_{n-1} - d_n y_{n-1} 2^{-n}$$
$$Ry_n = y_{n-1} + d_n x_{n-1} 2^{-n}$$

Combine the missing $\cos\theta$ terms from each iteration into a constant, and apply it with a single multiplier to the result of the final rotation. The output magnitude is the scaled final value of x. The output angle, z, is the sum of the rotation angles.

$$x_r = (\cos\theta_0\cos\theta_1 \ldots \cos\theta_n) Rx_N$$
$$z = \sum_{0}^{N} d_n\theta_n$$

Modified CORDIC Algorithm

The convergence region for the standard CORDIC rotation is ≈±99.7°. To work around this limitation, before doing any rotation, the object maps the input into the [0,π/4] range using the following algorithm.

```
if abs(x) > abs(y)
  input_mapped = [abs(x), abs(y)];
else
  input_mapped = [abs(y), abs(x)];
end
```

At each iteration, the object rotates the vector towards the real axis. The rotation is counterclockwise when y is negative, and clockwise when y is positive.

Quadrant mapping saves hardware resources and reduces latency by reducing the number of CORDIC pipeline stages by one. The CORDIC gain factor, *Kn*, therefore does not include the n=0, or cos(π/4) term.

$$K_n = cos\theta_1 ... cos\theta_n = \cos(26.565) \cdot \cos(14.036) \cdot \cos(7.125) \cdot \cos(3.576)$$

After the CORDIC iterations are complete, the object corrects the angle back to its original location. First it adjusts the angle to the correct side of π/4.

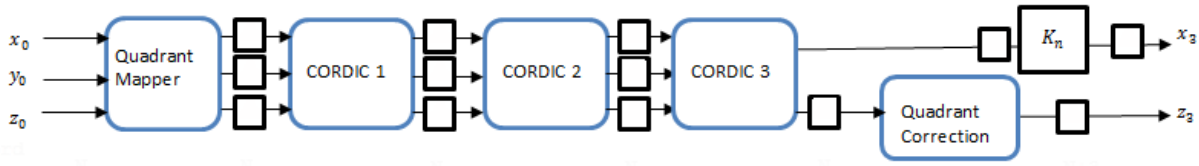
```
if abs(x) > abs(y)
  angle_unmapped = CORDIC_out;
else
  angle_unmapped = (pi/2) - CORDIC_out;
end
```

Then it flips the angle to the original quadrant.

```
if (x < 0)
  if (y < 0)
    output_angle = - pi + angle_unmapped;
  else
    output_angle = pi - angle_unmapped;
else
  if (y<0)
    output_angle = -angle_unmapped;
```

Architecture

The object generates a pipelined HDL architecture to maximize throughput. Each CORDIC iteration is done in one pipeline stage. The gain multiplier, if enabled, is implemented with Canonical Signed Digit (CSD) logic.

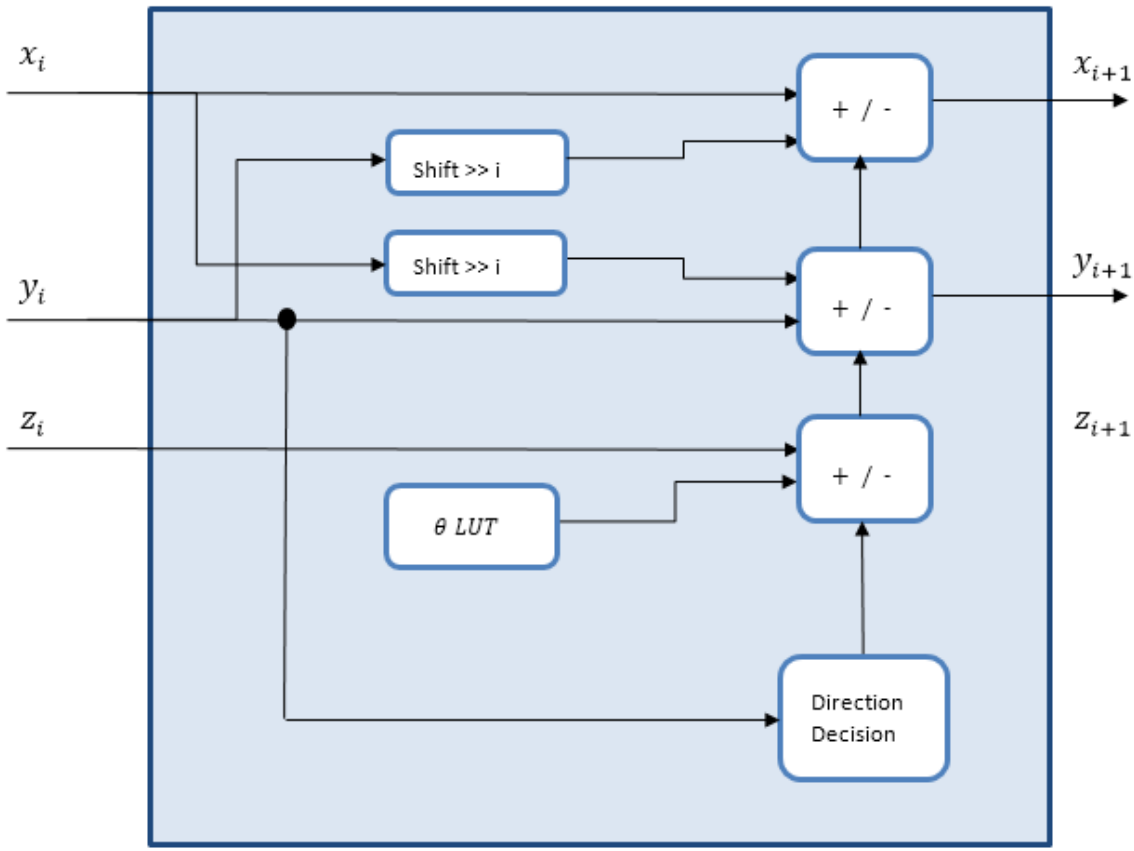


Input Word Length	Output Magnitude Word Length
fixdt(0,WL,FL)	fixdt(0,WL+2,FL)

Input Word Length	Output Magnitude Word Length
fixdt(1,WL,FL)	fixdt(1,WL+1,FL)

Input Word Length	Output Angle Word Length	
fixdt([ ],WL,FL)	Radians	fixdt(1,WL+3,WL)
	Normalized	fixdt(1,WL+3,WL+2)

The CORDIC logic at each pipeline stage implements one iteration. For each pipeline stage, the shift and angle rotation are constants.

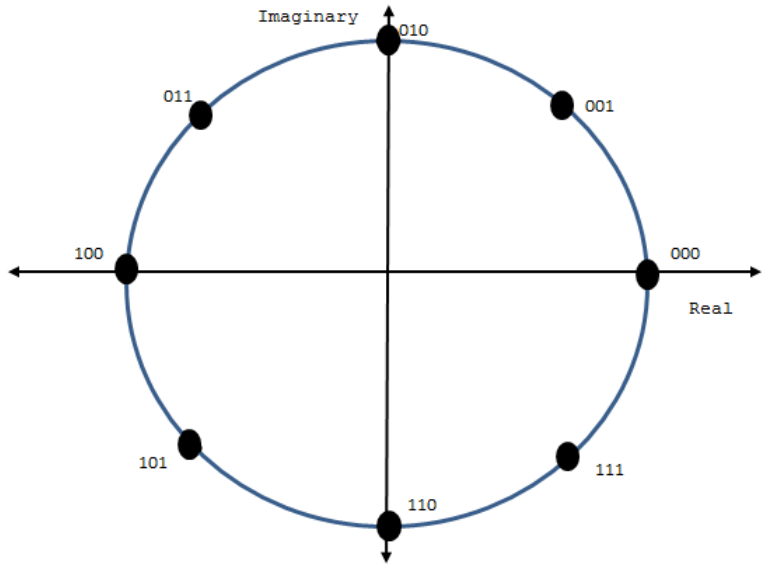


When you set `OutputValue` to `'Magnitude'`, the object does not generate HDL code for the angle accumulation and quadrant correction logic.

Normalized Angle Format

This format normalizes the fixed-point radian angle values around the unit circle. This is a more efficient use of bits than a range of [0,2π] radians. Normalized angle format also enables wraparound at 0/2π without additional detect and correct logic.

For example, representing the angle with 3 bits results in the following normalized values.



Using the mapping described in “Modified CORDIC Algorithm” on page 2-946, the object normalizes the angles across [0,π/4] and maps them to the correct octant at the end of the calculation.

Delay

The latency is NumIterations + 4 cycles from input to output. Each call to the object models one clock cycle.

When you set NumIterationsSource to `'Auto'`, the number of iterations is one less than the input word length and the latency is three more than the input word length. If the data type of the input is `double` or `single`, the number of iterations is 16 and the latency is 20.

Performance

Performance was measured for the default configuration, with output scaling disabled and `fixdt(1,16,12)` input. When the generated HDL code is synthesized into a Xilinx Virtex-6 (XC6VLX240T-1FFG1156) FPGA, the design achieves 260 MHz clock frequency. It uses the following resources.

Resource	Number Used
LUT	882
FFS	792
Xilinx LogiCORE DSP48	0
Block RAM (16K)	0

Performance of the synthesized HDL code varies depending on your target and synthesis options.

Introduced in R2014b

dsp.HDLFIRRateConverter

Package: `dsp`

Upsample, filter, and downsample—optimized for HDL code generation

Description

The `dsp.HDLFIRRateConverter` System object upsamples, filters, and downsamples input signals. It is optimized for HDL code generation and operates on one sample of each channel at a time. The object implements an efficient polyphase architecture to avoid unnecessary arithmetic operations and high intermediate sample rates.

The object upsamples by an integer factor of *L*, applies an FIR filter, and downsamples by an integer factor of *M*. The object accepts and returns control signal arguments for pacing the flow of samples. For detail of the flow control interface, see “Flow Control” on page 4-891.

To resample and filter input data:

1. Create the `dsp.HDLFIRRateConverter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
HDLFIRRC = dsp.HDLFIRRateConverter
HDLFIRRC = dsp.HDLFIRRateConverter(L,M,num)
HDLFIRRC = dsp.HDLFIRRateConverter( ___ ,Name,Value)
```

Description

`HDLFIRRC = dsp.HDLFIRRateConverter` returns a System object, `HDLFIRRC`, that resamples each channel of the input. The object upsamples by an integer factor of *L*, applies an FIR filter, and downsamples by an integer factor of *M*. The default *L/M* is 3/2.

`HDLFIRRC = dsp.HDLFIRRateConverter(L,M,num)` sets the `InterpolationFactor` property to `L`, the `DecimationFactor` property to `M`, and the `Numerator` property to `num`.

`HDLFIRRC = dsp.HDLFIRRateConverter( ___ ,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(L,M,Num,'ReadyPort',true,'RequestPort',true);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`InterpolationFactor` — Upsampling factor

3 (default) | positive integer scalar

Upsampling factor, *L*, specified as a positive integer.

`DecimationFactor` — Downsampling factor
2 (default) | positive integer scalar

Downsampling factor, M, specified as a positive integer scalar.

`Numerator` — FIR filter coefficients
`firpm(70,[0 .28 .32 1],[1 1 0 0])` (default) | vector in descending powers of z^{-1}

FIR filter coefficients, specified as a vector in descending powers of z^{-1}.

You can generate filter coefficients by using the Signal Processing Toolbox filter design functions, such as `fir1`. Design a lowpass filter with normalized cutoff frequency no greater than `min(1/L,1/M)`. The object initializes internal filter states to zero.

`ReadyPort` — Enable ready argument
`false` (default) | `true`

Enable `ready` output argument of the object. When enabled, the object returns a logical scalar value, `ready`, when you call the object. When `ready` is `1` (true), the object is ready for a new input sample the next time you call it.

`RequestPort` — Enable request argument
`false` (default) | `true`

Enable `request` input argument of the object. When `request` is `1` (true), the object returns a new output sample on the current call to the object.

`RoundingMethod` — Rounding mode used for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding mode used for fixed-point operations. This property does not apply when the input is `single` or `double` type. `'Simplest'` mode is not supported.

`OverflowAction` — Overflow mode used for fixed-point operations
`'Wrap'` (default) | `'Saturate'`

Overflow mode used for fixed-point operations. This property does not apply when the input is `single` or `double` type.

`CoefficientsDataType` — Data type of the FIR filter coefficients
`numerictype(1,16,16)` (default) | `numerictype(s,wl,fl)`

Data type of the FIR filter coefficients, specified as a `numerictype(s,wl,fl)` object with `signedness`, `word length`, and `fractional length` properties.

`OutputDataType` — Data type of the output data samples
`'Same word length as input'` (default) | `numerictype(s,wl,fl)` | `'Full precision'`

Data type of the output data samples, specified as '`Same word length as input`', '`Full precision`', or as a `numerictype(s,wl,fl)` object with `signedness`, `word length`, and `fractional length` properties.

Usage

Syntax

```
[dataOut,validOut] = HDLFIRRC(dataIn,validIn)
[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn)
[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn,request)
```

Description

`[dataOut,validOut] = HDLFIRRC(dataIn,validIn)` resamples `dataIn` according to the InterpolationFactor (*L*) and DecimationFactor (*M*) properties. To avoid dropped samples when using this syntax, apply new valid input samples, with `validIn` set to `true`, only every `ceil(L/M)` calls to the object. The object sets `validOut` to `true` when `dataOut` is a new valid sample.

`[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn)` resamples the input data and returns `ready` to indicate whether the object can accept a new sample on the next call.

This syntax applies when you set the ReadyPort property to `true`. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(...,'ReadyPort',true);
...
[dataOut,validOut,ready] = rateConverter(dataIn,validIn);
```

`[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn,request)` resamples the input data, indicates whether the object can accept a new sample, and, if `request` is `true`, returns the next available sample.

This syntax applies when you set the RequestPort property to `true`. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(...,'RequestPort',true);
...
[dataOut,validOut] = rateConverter(dataIn,validIn,request);
```

You can connect the `ready` output of a downstream object to the `request` input of an upstream object.

Input Arguments

`dataIn` — Data input

scalar or row vector

Data input, specified as a scalar, or as a row vector where each element represents an independent channel.

The data can be real or complex. `double` and `single` are allowed for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

`validIn` — Validity of input data

logical scalar

Validity of the input data, specified as a logical scalar.

When `validIn` is `1` (true), the object captures the value on `dataIn`. You can apply a valid data sample every `ceil(L/M)` calls to the object. You can use the optional `ready` output signal to indicate when the object can accept a new sample.

Data Types: `logical`

`request` — Request for a new output sample

logical scalar

Request for a new output sample, specified as a logical scalar.

When `request` is `1` (true), and a new output data sample is available, the object returns the sample with `validOut` set to `1` (true). If no sample is available, the object returns `validOut` set to `0` (false). The object accepts this argument when you set the RequestPort property to `true`.

Data Types: `logical`

Output Arguments

`dataOut` — Resampled and filtered data sample

scalar or row vector

Resampled and filtered data sample, returned as a scalar, or as a vector in which each element represents an independent channel. `double` and `single` are allowed for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

`validOut` — Validity of output data

logical scalar

Validity of the output data, returned as a logical scalar.

When `validOut` is `1` (true), the data output is valid. When `validOut` is `0` (false), the data output is not valid.

Data Types: `logical`

`ready` — Ready for a new input sample

logical scalar

Indicator that the object is ready for a new input sample, returned as a logical scalar.

The object returns `ready = 1` (true) to indicate that the object can accept a new input data sample on the next call. The object returns this additional output when you set the ReadyPort property to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Downsample Signal

Convert a signal from 48 kHz to 32 kHz by using the `dsp.HDLFIRRateConverter` System object™.

Define the sample rate and length of the input signal, and a 2 kHz cosine waveform. Set `validIn = true` for every sample.

```
Fs = 48e3;
Ns = 100;
t = (0:Ns-1).'/Fs;
dataIn = cos(2*pi*2e3*t);
validIn = true(Ns,1);
```

Preallocate `dataOut` and `validOut` signals for faster simulation.

```
dataOut = zeros(Ns,1);
validOut = false(Ns,1);
```

Create the System object. Configure it to perform rate conversion by a factor of 2/3, using an equiripple filter.

```
Numerator = firpm(70,[0 0.25 0.32 1],[1 1 0 0]);
firrc = dsp.HDLFIRRateConverter(2,3,Numerator);
```

Call the System object to perform the rate conversion and obtain each output sample.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

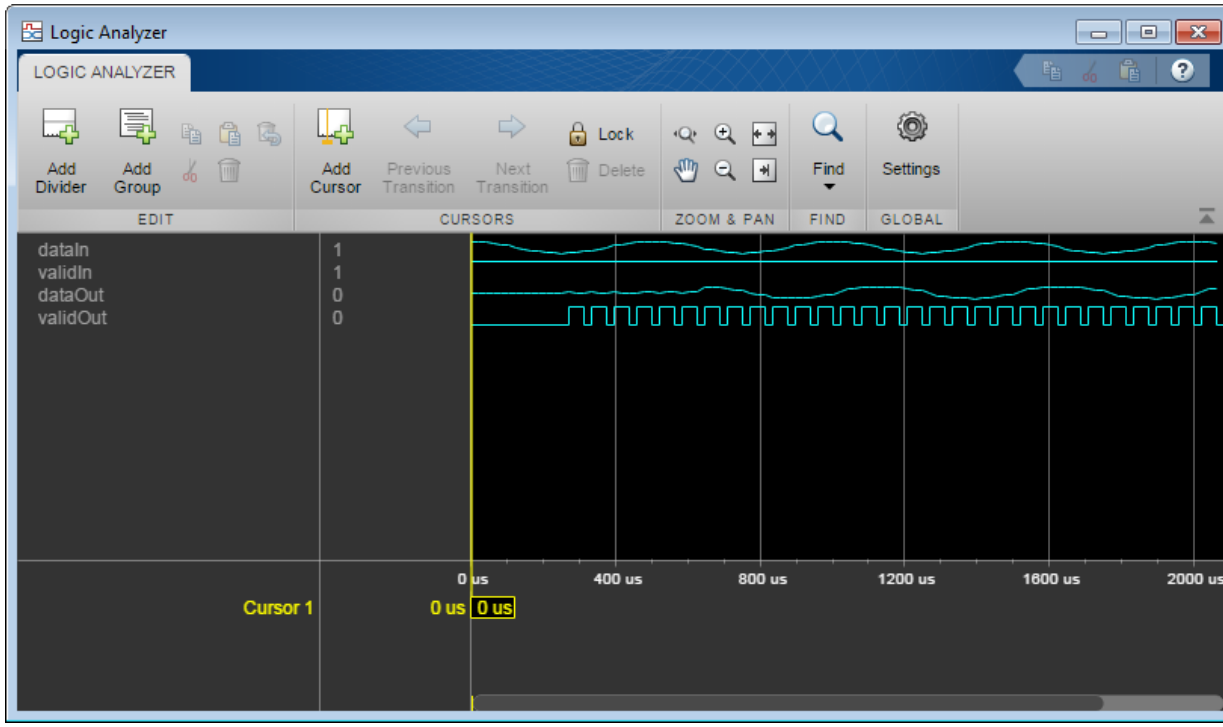
```
for k = 1:Ns
    [dataOut(k),validOut(k)] = firrc(dataIn(k),validIn(k));
end
```

Because the input sample rate is higher than the output sample rate, not every member of `dataOut` is valid. Use `validOut` to extract the valid samples from `dataOut`.

```
y = dataOut(validOut);
```

View the input and output signals with the Logic Analyzer.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',Ns/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
la(dataIn,validIn,dataOut,validOut)
```



Upsample Signal

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter` System object™. To avoid overrunning the object as the signal is upsampled, control the input rate manually.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1).'/Fs;
x = fi(cos(2*pi*1.2e6*t),1,16,14);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Calculate how often the object can accept a new input sample.

```
L = 5;
M = 2;
stepsPerInput = ceil(L/M);
numSteps = stepsPerInput*Ns;
```

Generate `dataIn` and `validIn` based on how often the object can accept a new sample.

```
dataIn = zeros(numSteps,1,'like',x);
dataIn(1:stepsPerInput:end) = x;
validIn = false(numSteps,1);
validIn(1:stepsPerInput:end) = true;
```

Create the System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter.

```
Numerator = firpm(70,[0 0.15 0.25 1],[1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator);
```

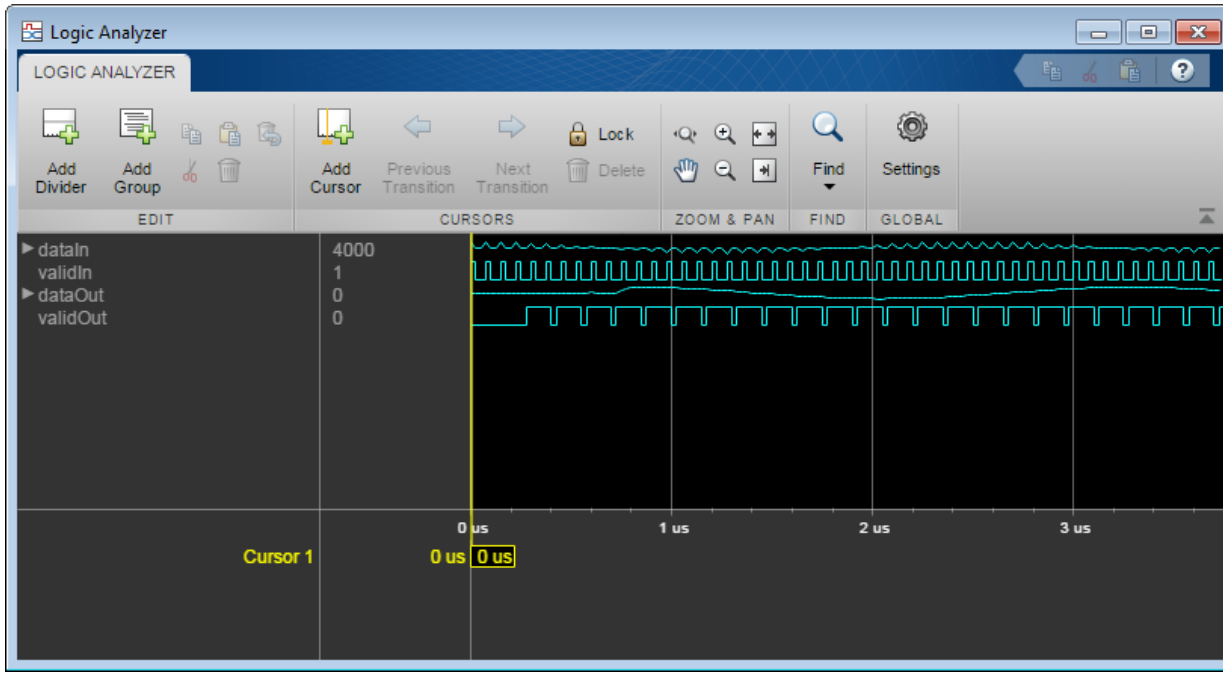
Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
```

Call the System object to perform the rate conversion and obtain each output sample. Call the Logic Analyzer to add each sample to the waveform display.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    [dataOut,validOut] = rateConverter(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut)
end
```



Control Input Rate When Upsampling

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter` System object™. Use the optional `ready` output signal to avoid overrunning the object as the data is upsampled. The `ready` signal indicates the object can accept a new data sample on the next call to the object.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform. Create a `SignalSource` object to provide data samples on demand.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1).'/Fs;
x = fi(cos(2*pi*1.2e6*t),1,16,14);
inputSource = dsp.SignalSource(x);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Determine the number of calls to the object needed to convert `Ns` samples.

```
L = 5;
M = 2;
numSteps = floor(Ns*L/M);
```

Create the HDL FIR rate converter System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter. Enable the optional `ready` output port.

```
Numerator = firpm(70,[0 0.15 0.25 1],[1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator,'ReadyPort',true);
```

Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',5,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
modifyDisplayChannel(la,5,'Name','ready')
```

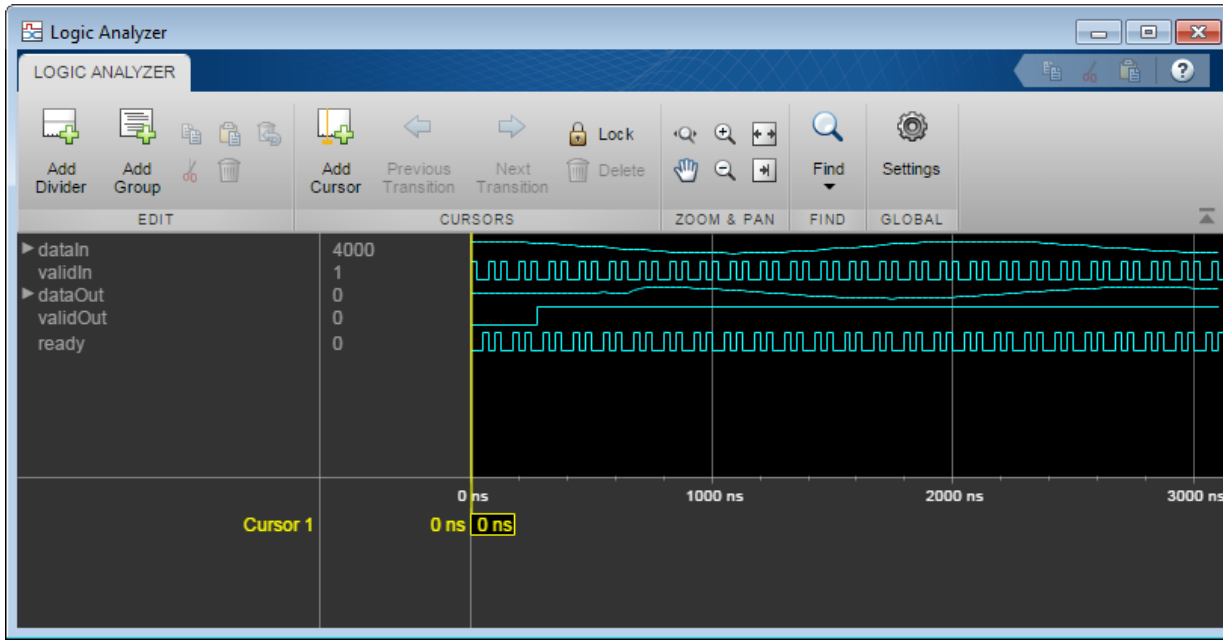
Initialize the `ready` signal. The object is always ready for input data on the first call.

```
ready = true;
```

Call the System object to perform the rate conversion and obtain each output sample. Apply a new input sample when the object indicates it is ready. Otherwise, set `validIn` to `false`.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    if ready
        dataIn = inputSource();
    end
    validIn = ready;
    [dataOut,validOut,ready] = rateConverter(dataIn,validIn);
    la(dataIn,validIn,dataOut,validOut,ready)
end
```



Control Output Rate When Upsampling

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter` System object™. Use the optional `request` input signal to control the output data rate. When the object receives the `request` signal, it returns a new output data sample. This example models a clock rate of 200 MHz by requesting an output sample every second call to the object.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform. Create a `SignalSource` object to provide data samples on demand.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1).'/Fs;
x = fi(cos(2*pi*1.2e6*t),1,16,14);
inputSource = dsp.SignalSource(x);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Determine the number of calls to the object needed to convert `Ns` samples.

```
L = 5;
M = 2;
numSteps = floor(2*Ns*L/M);
```

Create the HDL FIR rate converter System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter. Enable the optional `ready` and `request` ports.

```
Numerator = firpm(70,[0 0.15 0.25 1],[1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator,...
                                        'ReadyPort',true,...
                                        'RequestPort',true);
```

Create a **Logic Analyzer** to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',6,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','request')
modifyDisplayChannel(la,4,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,5,'Name','validOut')
modifyDisplayChannel(la,6,'Name','ready')
```

Generate a signal that requests a new output sample every second call to the object.

```
request = false(numSteps,1);
request(1:2:end) = true;
```

Initialize the `ready` signal. The object is always ready for input data on the first call.

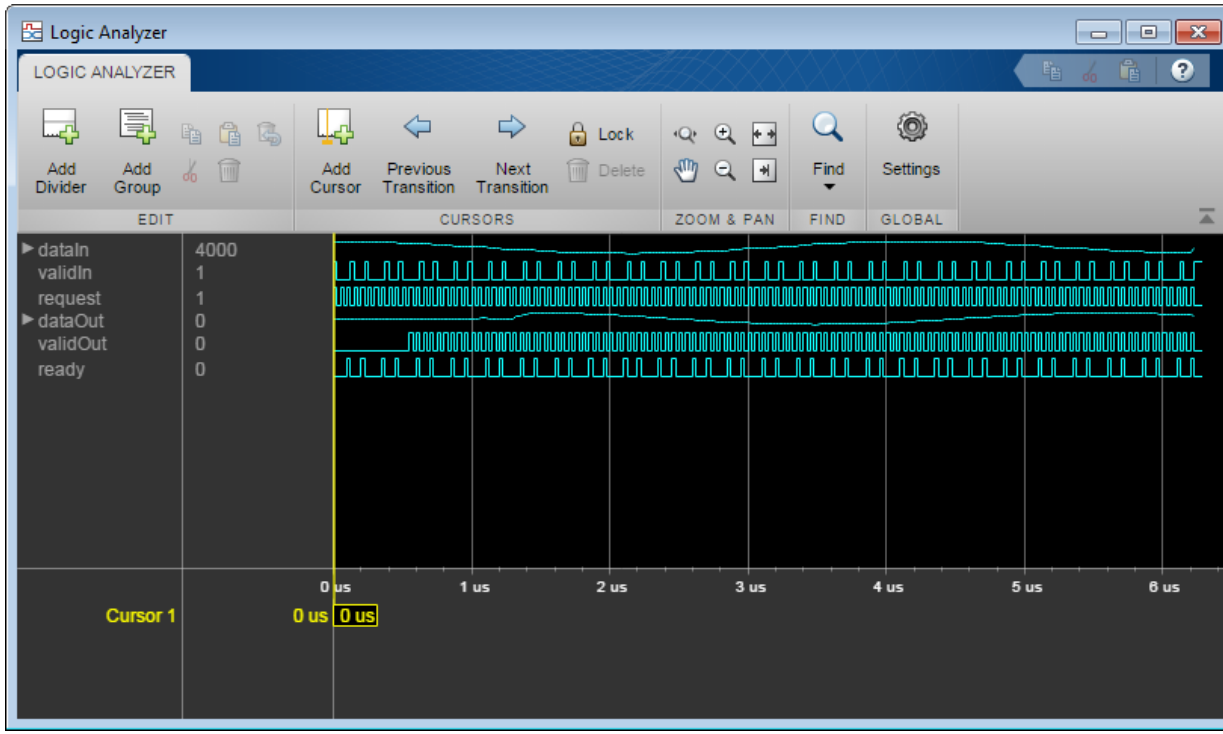
```
ready = true;
```

Call the System object to perform the rate conversion and obtain each output sample. Apply a new input sample when the object indicates it is ready. Otherwise, set `validIn` to `false`. The object returns valid output samples when `request` is set to `true`.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    if ready
```

```
        dataIn = inputSource();
    end
    validIn = ready;
    [dataOut,validOut,ready] = rateConverter(dataIn,validIn,request(k));
    la(dataIn,validIn,request(k),dataOut,validOut,ready)
end
```



Design for HDL Code Generation from HDL FIR Rate Converter

Create a rate conversion function targeted for HDL code generation, and a test bench to exercise it. The function converts a signal from 40 MHz to 100 MHz. To avoid overrunning the object, the test bench manually controls the input rate.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1).'/Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Calculate how often the object can accept a new data sample.

```
L = 5;
M = 2;
stepsPerInput = ceil(L/M);
numSteps = stepsPerInput*Ns;
```

Generate `dataIn` and `validIn` based on how often the object can accept a new sample.

```
dataIn = zeros(numSteps,1,'like',x);
dataIn(1:stepsPerInput:end) = x;
validIn = false(numSteps,1);
validIn(1:stepsPerInput:end) = true;
```

Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
```

Write a function that creates and calls the System object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

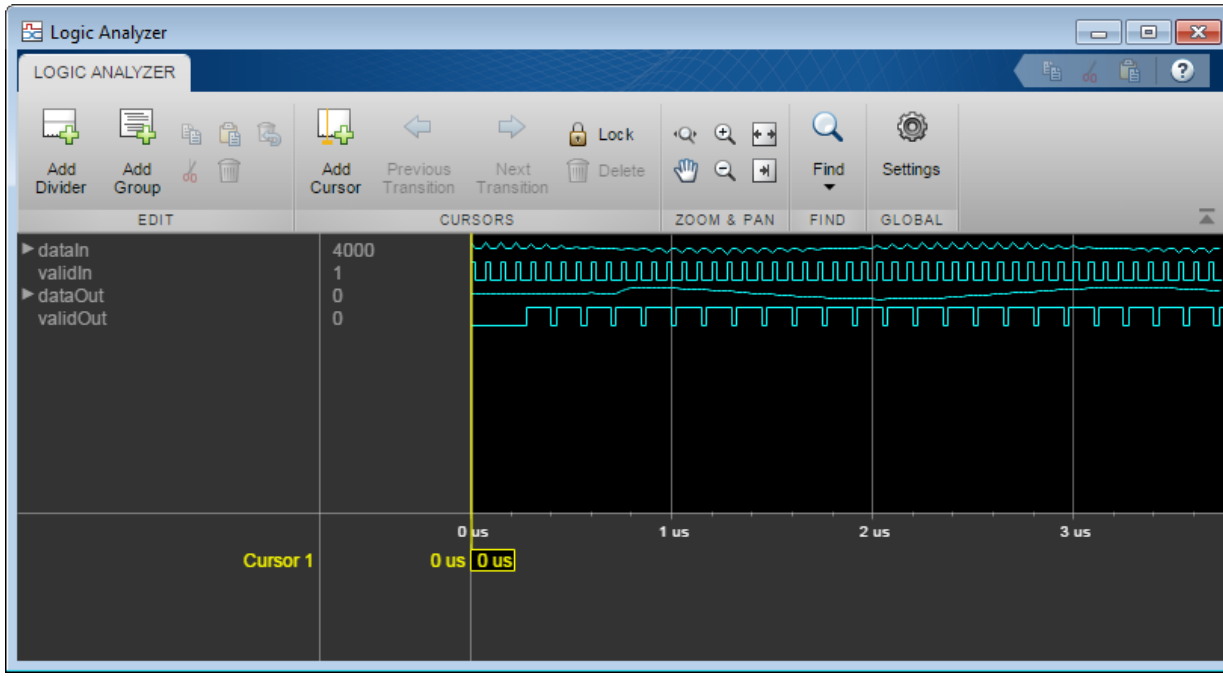
```
function [dataOut,validOut] = HDLFIRRC5_2(dataIn,validIn)
%HDLFIRRC5_2
% Processes one sample of data using the dsp.HDLFIRRateConverter System
% object. dataIn is a fixed-point scalar value. validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent firrc5_2;
  if isempty(firrc5_2)
    Numerator = firpm(70,[0,.15,.25,1],[1,1,0,0]);
    firrc5_2 = dsp.HDLFIRRateConverter(5,2,Numerator);
```

```
  end
  [dataOut,validOut] = firrc5_2(dataIn,validIn);
end
```

Resample the signal by calling the function for each data sample.

```
for k = 1:numSteps
    [dataOut,validOut] = HDLFIRRC5_2(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut)
end
```

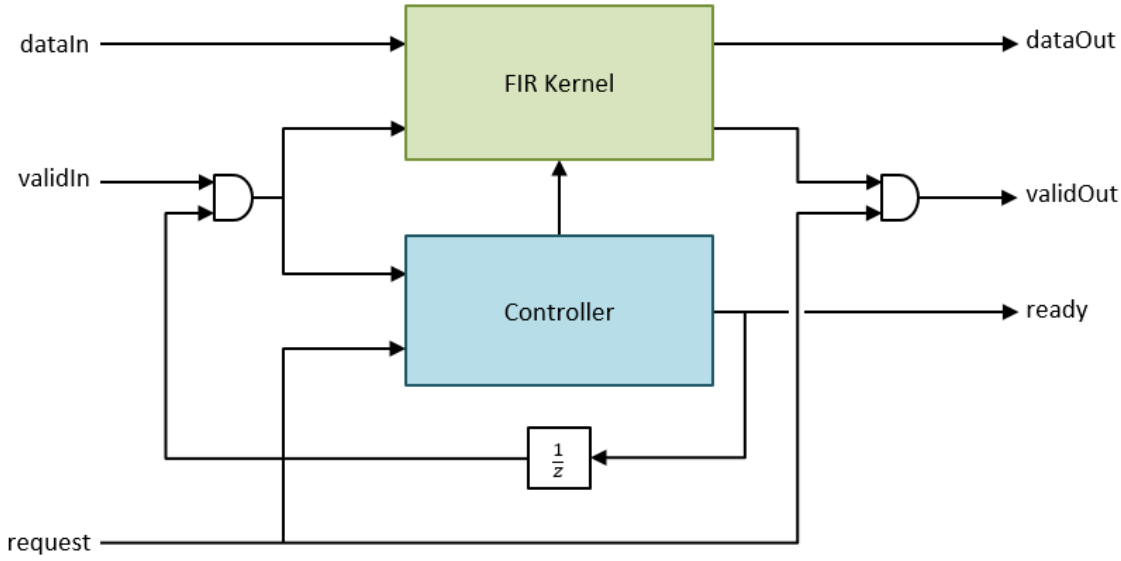


Algorithms

This object implements the algorithms described on the FIR Rate Conversion HDL Optimized block reference page.

Flow Control

The object accepts and returns control signal arguments for pacing the flow of samples. By default, the object uses `validIn` and `validOut` control signals. You can also enable a `ready` output signal and a `request` input signal.



The `ready` output indicates that the object can accept a new input data sample on the next call to to the object. When $L \geq M$, you can use the `ready` argument to achieve continuous output data samples. If you apply a new input sample after each time object returns `ready = true`, each call to the object returns a data output sample with `validOut = true`.

When you do not enable the `ready` argument, you can apply a valid data sample only every `ceil(L/M)` calls to the object. For example:

- $L/M = 4/5$ — You can apply a new input sample on every call.
- $L/M = 3/2$ — You can apply a new input sample on every other call.

When you enable the `request` input, the object returns the next output sample when `request` is `true` and a valid output sample is available. When you do not use `request`, the object returns output samples when they are available. Calls to the object that do not return a new sample return `validOut = false`.

You can connect `request` to the `ready` output of a downstream object.

`dsp.FIRRateConverter`

Introduced in R2015b

dsp.HDLFFT

Package: `dsp`

Fast Fourier transform — optimized for HDL code generation

Description

The HDL FFT System object provides two architectures to optimize either throughput or area. Use the streaming Radix 2^2 architecture for high-throughput applications. This architecture supports scalar or vector input data. You can achieve giga-sample-per-second (GSPS) throughput using vector input. Use the burst Radix 2 architecture for a minimum resource implementation, especially with large FFT sizes. Your system must be able to tolerate bursty data and higher latency. This architecture supports only scalar input data. The object accepts real or complex data, provides hardware-friendly control signals, and has optional output frame control signals.

To calculate the fast Fourier transform:

1. Create the `dsp.HDLFFT` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
FFT_N = dsp.HDLFFT
FFT_N = dsp.HDLFFT(Name,Value)
```

Description

`FFT_N = dsp.HDLFFT` returns an HDL FFT System object, `FFT_N`, that performs a fast Fourier transform.

`FFT_N = dsp.HDLFFT(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `fft128 = dsp.HDLFFT('FFTLength',128)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Architecture` — Hardware implementation
`'Streaming Radix 2^2'` (default) | `'Burst Radix 2'`

Hardware implementation, specified as either:

- `'Streaming Radix 2^2'` — Low-latency architecture. Supports giga-sample-per-second (GSPS) throughput when you use vector input.
- `'Burst Radix 2'`— Minimum resource architecture. Vector input is not supported when you select this architecture.

`ComplexMultiplication` — HDL implementation of complex multipliers
`'Use 4 multipliers and 2 adders'` (default) | `'Use 3 multipliers and 5 adders'`

HDL implementation of complex multipliers, specified as either `'Use 4 multipliers and 2 adders'` or `'Use 3 multipliers and 5 adders'`. Depending on your synthesis tool and target device, one option may be faster or smaller.

`BitReversedOutput` — Order of the output data
`true` (default) | `false`

Order of the output data, specified as either:

- `true` — The output channel elements are bit reversed relative to the input order.

- `false` — The output channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

`BitReversedInput` — Expected order of the input data
`false` (default) | `true`

Expected order of the input data, specified as either:

- `true` — The input channel elements are in bit-reversed order.
- `false` — The input channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

`Normalize` — Output scaling
`false` (default) | `true`

Output scaling, specified as either:

- `true` — The object implements an overall 1/*N* scale factor by dividing the output of each butterfly multiplication by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input.
- `false` — The object avoids overflow by increasing the word length by one bit after each butterfly multiplication. The bit growth is the same for both architectures.

`FFTLength` — Number of data points used for one FFT calculation
1024 (default) | integer power of 2 between 2^3 and 2^{16}

Number of data points used for one FFT calculation, specified as an integer power of 2 between 2^3 and 2^{16}. The object accepts FFT lengths outside this range, but they are not supported for HDL code generation.

`ResetInputPort` — Enable reset argument
`false` (default) | `true`

Enable `reset` input argument to the object. When `reset` is `true`, the object stops calculation and clears all internal state.

`StartOutputPort` — Enable start output argument
`false` (default) | `true`

Enable `startOut` output argument of the object. When enabled, the object returns an additional output signal that is `true` on the first cycle of each valid output frame.

`EndOutputPort` — Enable end output argument
`false` (default) | `true`

Enable `endOut` output argument of the object. When enabled, the object returns an additional output signal that is `true` on the first cycle of each valid output frame.

`RoundingMethod` — Rounding mode used for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding mode used for fixed-point operations. When the input is any integer or fixed-point data type, the FFT algorithm uses fixed-point arithmetic for internal calculations. This option does not apply when the input is single or double type. Rounding applies to twiddle factor multiplication and scaling operations.

Usage

Syntax

```
[Y,validOut] = FFT_N(X,validIn)
[Y,validOut,ready] = FFT_N(X,validIn)
[Y,startOut,endOut,validOut] = FFT_N(X,validIn)
[Y,validOut] = FFT_N(X,validIn,resetIn)
[Y,startOut,endOut,validOut] = FFT_N(X,validIn,resetIn)
```

Description

`[Y,validOut] = FFT_N(X,validIn)` returns the FFT, `Y`, of the input, `X`, when `validIn` is `true`. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals, respectively.

`[Y,validOut,ready] = FFT_N(X,validIn)` returns the fast Fourier transform (FFT) when using the burst Radix 2 architecture. The `ready` signal indicates when the object can accept input samples.

To use this syntax, set the Architecture property to `'Burst Radix 2'`. For example:

```
FFT_N = dsp.HDLFFT(___,'Architecture','Burst Radix 2');
...
[y,validOut,ready] = FFT_N(x,validIn)
```

`[Y,startOut,endOut,validOut] = FFT_N(X,validIn)` also returns frame control signals `startOut` and `endOut`. `startOut` is `true` on the first sample of a frame of output data. `endOut` is `true` for the last sample of a frame of output data.

To use this syntax, set the StartOutputPort and EndOutputPort properties to `true`. For example:

```
FFT_N = dsp.HDLFFT(___,'StartOutputPort',true,'EndOutputPort',true);
...
[y,startOut,endOut,validOut] = FFT_N(x,validIn)
```

`[Y,validOut] = FFT_N(X,validIn,resetIn)` returns the FFT when `validIn` is `true` and `resetIn` is `false`. When `resetIn` is `true`, the object stops the current calculation and clears all internal state.

To use this syntax set the ResetInputPort property to `true`. For example:

```
FFT_N = dsp.HDLFFT(___,'ResetInputPort',true);
...
[y,validOut] = FFT_N(x,validIn,resetIn)
```

`[Y,startOut,endOut,validOut] = FFT_N(X,validIn,resetIn)` returns the FFT, Y, using all optional control signals. You can use any combination of the optional port syntaxes.

Input Arguments

X — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values, in fixed-point or integer format. Vector input is supported with `'Streaming Radix 2^2'` architecture only. The vector size must be a power of 2 between 1 and 64, and not greater than the

FFT length. `double` and `single` are supported for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

`validIn` — Validity of input data
logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

`resetIn` — Reset internal state
logical scalar

Reset internal state, specified as a logical scalar. To enable this argument, set the ResetInputPort property to `true`.

Data Types: `logical`

Output Arguments

`Y` — Output data
scalar or column vector of real or complex values

Output data, returned as a scalar or column vector of real or complex values. The output format matches the format of the input data.

`ready` — Memory available for input data
logical scalar

Indication that the object has memory available for input data, returned as a logical scalar. This output is returned when you select `'Burst Radix 2'` architecture.

Data Types: `logical`

`startOut` — First sample of output frame
logical scalar

First sample of output frame, returned as a logical scalar. To enable this argument, set the StartOutputPort property to `true`.

Data Types: `logical`

`endOut` — Last sample of output frame
logical scalar

Last sample of output frame, returned as a logical scalar. To enable this argument, set the EndOutputPort property to `true`.

Data Types: `logical`

`validOut` — Validity of output data
logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLFFT

getLatency	Latency of FFT or channelizer calculation

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create FFT for HDL Generation

Create the specifications and input signal.

```
N = 128;
Fs = 40;
```

```
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,24);
```

Write a function that creates and calls the System object™. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [yOut,validOut] = HDLFFT128(yIn,validIn)
%HDLFFT128
% Processes one sample of FFT data using the dsp.HDLFFT System object(TM)
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

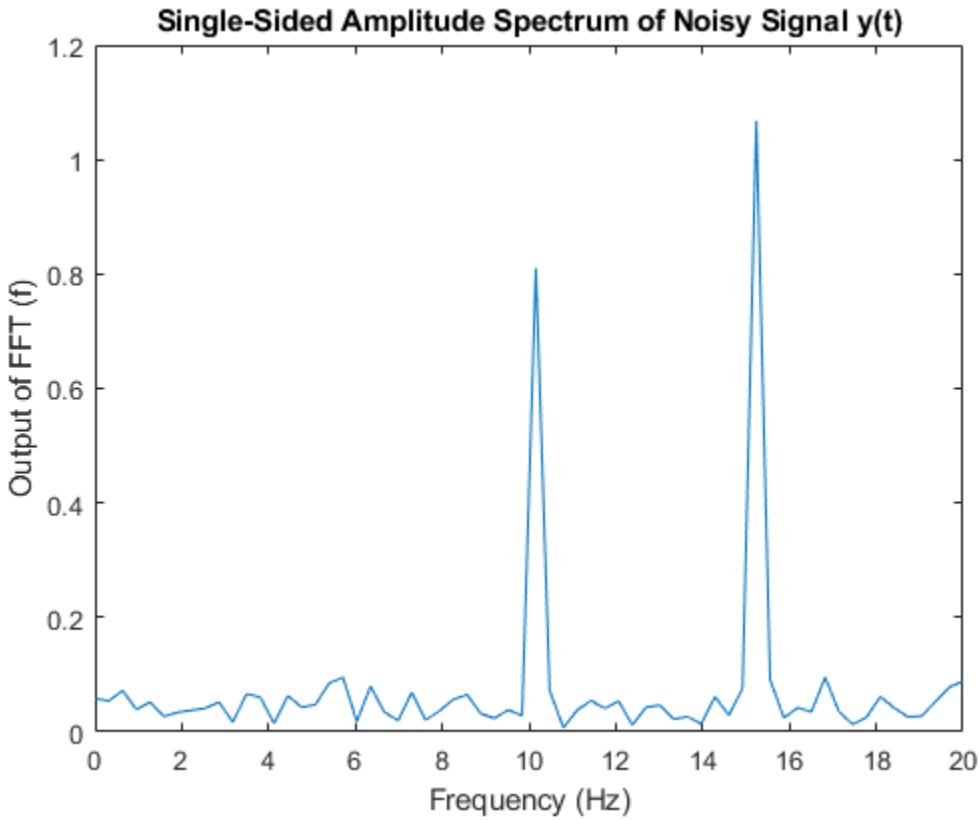
  persistent fft128;
  if isempty(fft128)
    fft128 = dsp.HDLFFT('FFTLength',128);
  end
  [yOut,validOut] = fft128(yIn,validIn);
end
```

Compute the FFT by calling the function for each data sample.

```
Yf = zeros(1,3*N);
validOut = false(1,3*N);
for loop = 1:1:3*N
    if (mod(loop, N) == 0)
        i = N;
    else
        i = mod(loop, N);
    end
    [Yf(loop),validOut(loop)] = HDLFFT128(complex(y_fixed(i)),(loop <= N));
end
```

Discard invalid data samples. Then plot the frequency channel results from the FFT.

```
Yf = Yf(validOut == 1);
Yr =  bitrevorder(Yf);
plot(Fs/2*linspace(0,1,N/2), 2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT (f)')
```



Create Vector-Input FFT for HDL Generation

Create specifications and input signal. This example uses a 128-point FFT and computes the transform over 16 samples at a time.

```
N = 128;
V = 16;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,24);
y_vect = reshape(y_fixed,V,N/V);
```

Write a function that creates and calls the System object™. The function does not need to know the vector size. The object saves the size of the input signal the first time you call it.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [yOut,validOut] = HDLFFT128V16(yIn,validIn)
%HDLFFT128V16
% Processes 16-sample vectors of FFT data
% yIn is a fixed-point column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent fft128v16;
  if isempty(fft128v16)
    fft128v16 = dsp.HDLFFT('FFTLength',128);
  end
  [yOut,validOut] = fft128v16(yIn,validIn);
end
```

Compute the FFT by passing 16-element vectors to the object. Use the `getLatency` function to find out when the first output data sample will be ready. Then, add the frame length to determine how many times to call the object. Because the object variable is inside the function, use a second object to call `getLatency`. Use the loop counter to flip `validIn` to `false` after N input samples.

```
tempfft = dsp.HDLFFT;
loopCount = getLatency(tempfft,N,V)+N/V;
Yf = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
```

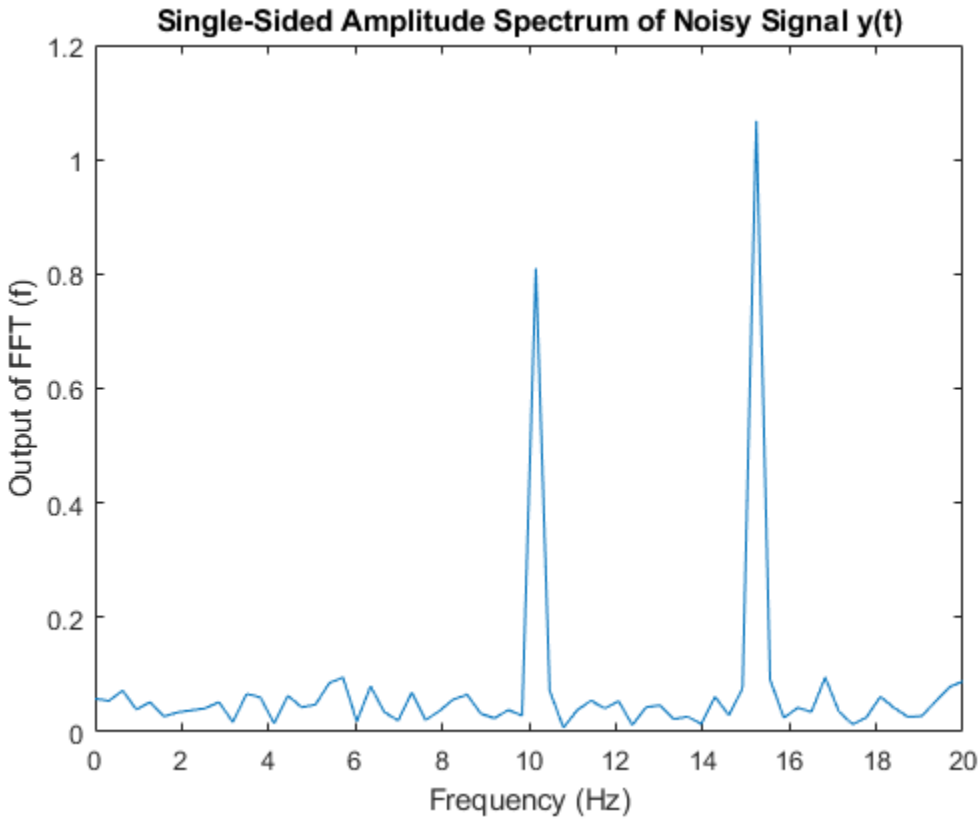
```
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
    [Yf(:,loop),validOut(loop)] = HDLFFT128V16(complex(y_vect(:,i)),(loop<=N/V));
end
```

Discard invalid output samples.

```
C = Yf(:,validOut==1);
Yf_flat = C(:);
```

Plot the frequency channel data from the FFT. The FFT output is in bit-reversed order. Reorder it before plotting.

```
Yr =  bitrevorder(Yf_flat);
plot(Fs/2*linspace(0,1,N/2),2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT (f)')
```



Explore Latency of HDL FFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

Create a new `dsp.HDLFFT` object and request the latency.

```
hdlfft = dsp.HDLFFT('FFTLength',512);
L512 = getLatency(hdlfft)
```

```
L512 = 599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change.

```
L256 = getLatency(hdlfft,256)
```

```
L256 = 329
```

```
N = hdlfft.FFTLength
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlfft,256,8)
```

```
L256v8 = 93
```

Enable scaling at each stage of the FFT. The latency does not change.

```
hdlfft.Normalize = true;
L512n = getLatency(hdlfft)
```

```
L512n = 599
```

Request the same output order as the input order. The latency increases because the object must collect the output before reordering.

```
hdlfft.BitReversedOutput = false;
L512r = getLatency(hdlfft)
```

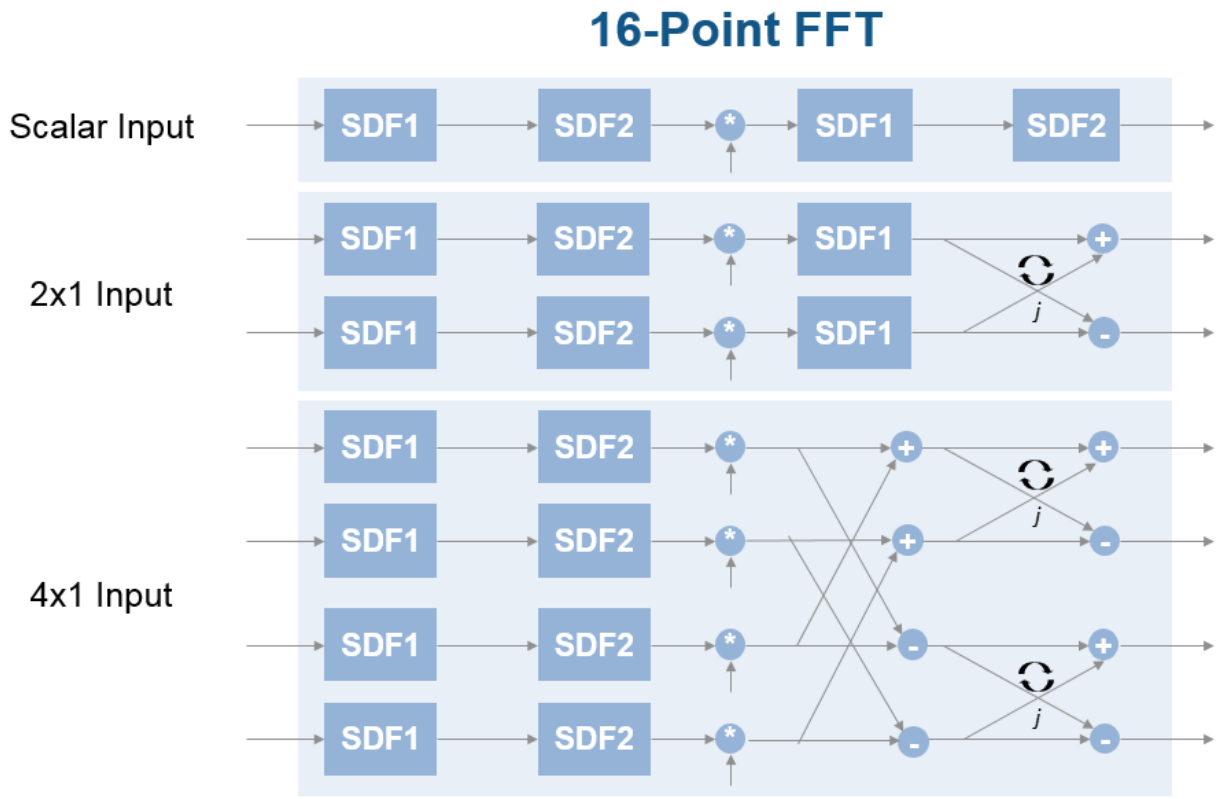
```
L512r = 1078
```

Algorithms

Streaming Radix 2^2

The streaming Radix 2^2 architecture implements a low-latency architecture. It saves resources compared to a streaming Radix 2 implementation by factoring and grouping the FFT equation. The architecture has $\log_4(N)$ stages. Each stage contains two single-path delay feedback (SDF) butterflies with memory controllers. When you use vector input,

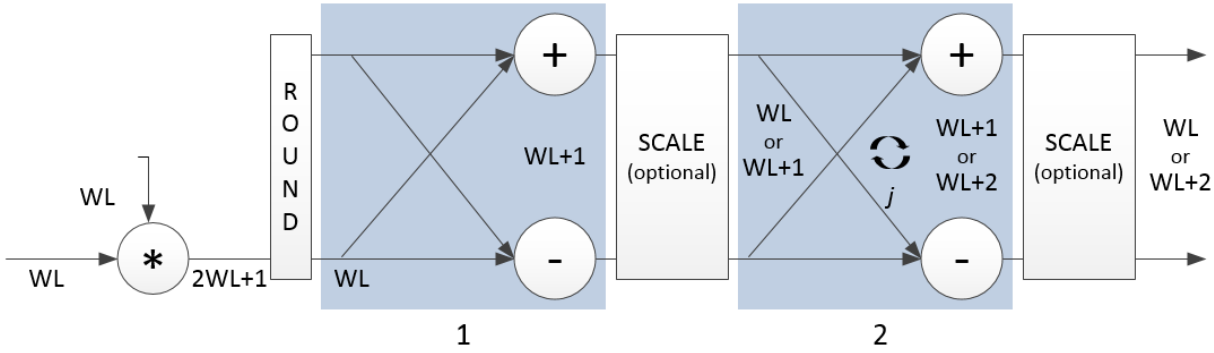
each stage operates on fewer input samples, so some stages reduce to a simple butterfly, without SDF.



The first SDF stage is a regular butterfly. The second stage multiplies the outputs of the first stage by *–j*. To avoid a hardware multiplier, the block swaps the real and imaginary parts of the inputs, and again swaps the imaginary parts of the resulting outputs. Each stage rounds the result of the twiddle factor multiplication to the input word length. The twiddle factors have two integer bits, and the rest of the bits are used for fractional bits. The twiddle factors have the same bit width as the input data, *WL*. The twiddle factors have two integer bits, and *WL*-2 fractional bits.

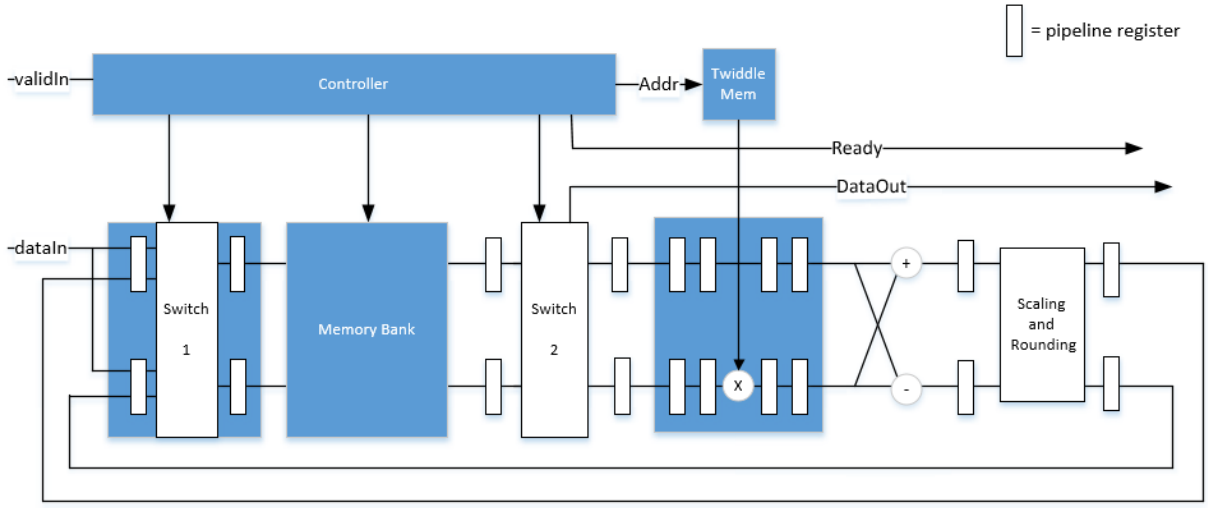
If you enable scaling, the algorithm divides the result of each butterfly stage by 2. Scaling at each stage avoids overflow, keeps the word length the same as the input, and results in an overall scale factor of 1/*N*. If scaling is disabled, the algorithm avoids overflow by

increasing the word length by 1 bit at each stage. The diagram shows the butterflies and internal word lengths of each stage, not including the memory.



Burst Radix 2

The burst Radix 2 architecture implements the FFT by using a single complex butterfly multiplier. The algorithm cannot start until it has stored the entire input frame, and it cannot accept the next frame until computations are complete. The output **ready** port indicates when the algorithm is ready for new data. The diagram shows the burst architecture, with pipeline registers.



Control Signals

The algorithm processes input data only when the input **valid** port is 1. Output data is valid only when the output **valid** port is 1.

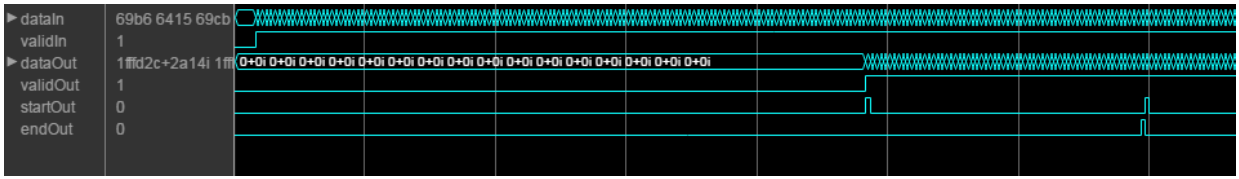
When the optional input **reset** port is 1, the algorithm stops the current calculation and clears all internal states. The algorithm begins new calculations when **reset** port is 0 and the input **valid** port starts a new frame.

Timing Diagram

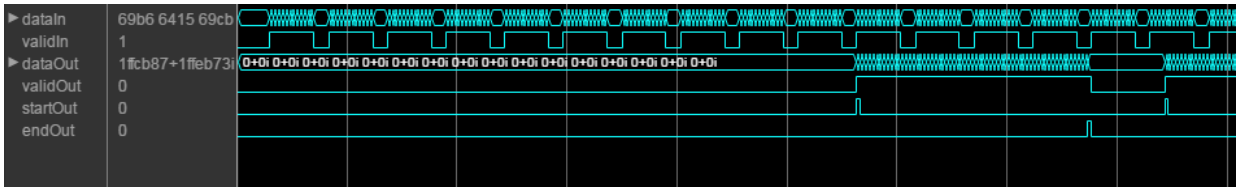
This diagram shows the input and output **valid** port values for contiguous scalar input data, streaming Radix 2^2 architecture, an FFT length of 1024, and a vector size of 16.

The diagram also shows the optional **start** and **end** port values that indicate frame boundaries. If you enable the **start** port, the **start** port value pulses for one cycle with the first valid output of the frame. If you enable the **end** port, the **start** port value pulses for one cycle with the last valid output of the frame.

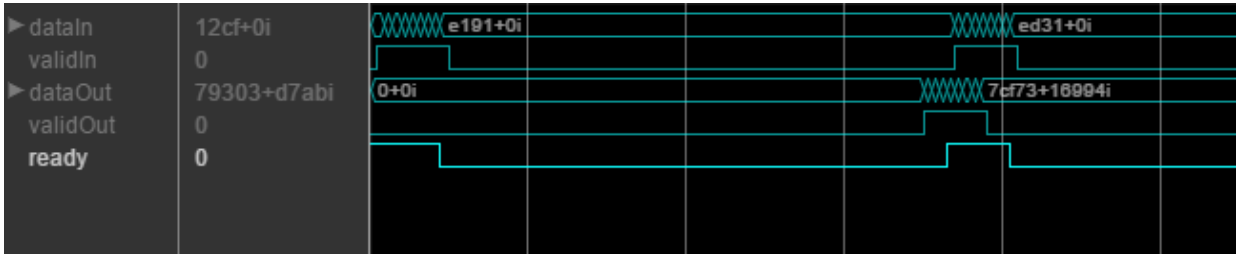
If you apply continuous input frames, the output will also be continuous after the initial latency.



The input **valid** port can be noncontiguous. Data accompanied by an input **valid** port is processed as it arrives, and the resulting data is stored until a frame is filled. Then the algorithm returns contiguous output samples in a frame of *N* (**FFT length**) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16.



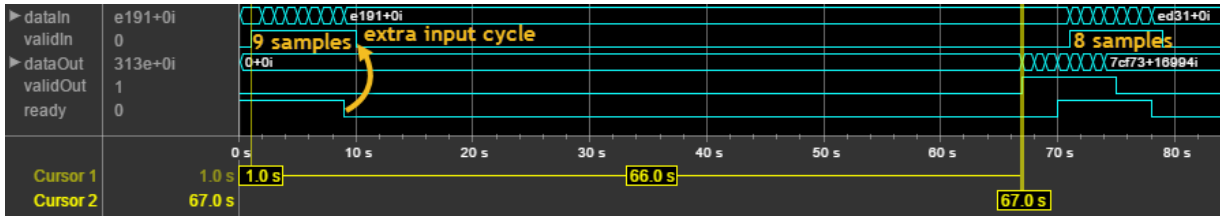
When you use the burst architecture, you cannot provide the next frame of input data until memory space is available. The **ready** port indicates when the algorithm can accept new input data.



Latency

The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

When using the burst architecture with a contiguous input, if your design waits for **ready** to output `0` before de-asserting the input **valid**, then one extra cycle of data arrives at the input. This data sample is the first sample of the next frame. The algorithm can save one sample while processing the current frame. Due to this one sample advance, the observed latency of the later frames (from input **valid** to output **valid**) is one cycle shorter than the reported latency. The latency is measured from the first cycle, when input **valid** is 1 to the first cycle when output **valid** is 1. The number of cycles between when **ready** port is 0 and the output **valid** port is 1 is always *latency – FFTLength*.



Performance

This resource and performance data is the synthesis result from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The examples in the tables have this configuration:

- 1024 FFT length (default)
- Complex multiplication using 4 multipliers, 2 adders
- Output scaling enabled
- Natural order input, Bit-reversed output
- 16-bit complex input data
- Clock enables minimized (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, reordering for a natural-order output uses more RAM than the default bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2^2 configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Number Used
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2^2 implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Number Used
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24
Block RAM (16K)	8

The block supports scalar input data only when implementing burst Radix 2 architecture. The burst design achieves 309 MHz clock frequency. The latency is 5811 cycles. The design uses these resources.

Resource	Number Used
LUT	971
FFS	1254
Xilinx LogiCORE DSP48	3
Block RAM (16K)	6

Blocks
FFT HDL Optimized

Introduced in R2014b

dsp.HDLIFFT

Package: `dsp`

Inverse fast Fourier transform — optimized for HDL code generation

Description

The HDL IFFT System object provides two architectures to optimize either throughput or area. Use the streaming Radix 2^2 architecture for high-throughput applications. This architecture supports scalar or vector input data. You can achieve giga-sample-per-second (GSPS) throughput using vector input. Use the burst Radix 2 architecture for a minimum resource implementation, especially with large FFT sizes. Your system must be able to tolerate bursty data and higher latency. This architecture supports only scalar input data. The object accepts real or complex data, provides hardware-friendly control signals, and has optional output frame control signals.

To calculate the inverse fast Fourier transform:

1. Create the `dsp.HDLIFFT` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
IFFT_N = dsp.HDLIFFT
IFFT_N = dsp.HDLIFFT(Name,Value)
```

Description

`IFFT_N = dsp.HDLIFFT` returns an HDL IFFT System object, `IFFT_N`, that performs a fast Fourier transform.

`IFFT_N = dsp.HDLIFFT(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `ifft128 = dsp.HDLIFFT('FFTLength',128)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Architecture` — Hardware implementation
`'Streaming Radix 2^2'` (default) | `'Burst Radix 2'`

Hardware implementation, specified as either:

- `'Streaming Radix 2^2'` — Low-latency architecture. Supports giga-sample-per-second (GSPS) throughput when you use vector input.
- `'Burst Radix 2'`— Minimum resource architecture. Vector input is not supported when you select this architecture.

`ComplexMultiplication` — HDL implementation of complex multipliers
`'Use 4 multipliers and 2 adders'` (default) | `'Use 3 multipliers and 5 adders'`

HDL implementation of complex multipliers, specified as either `'Use 4 multipliers and 2 adders'` or `'Use 3 multipliers and 5 adders'`. Depending on your synthesis tool and target device, one option may be faster or smaller.

`BitReversedOutput` — Order of the output data
`true` (default) | `false`

Order of the output data, specified as either:

- `true` — The output channel elements are bit reversed relative to the input order.

- `false` — The output channel elements are in linear order.

The IFFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

`BitReversedInput` — Expected order of the input data
`false` (default) | `true`

Expected order of the input data, specified as either:

- `true` — The input channel elements are in bit-reversed order.
- `false` — The input channel elements are in linear order.

The IFFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

`Normalize` — Output scaling
`true` (default) | `false`

Output scaling, specified as either:

- `true` — The object implements an overall 1/*N* scale factor by dividing the output of each butterfly multiplication by 2. This adjustment keeps the output of the IFFT in the same amplitude range as its input.
- `false` — The object avoids overflow by increasing the word length by one bit after each butterfly multiplication. The bit growth is the same for both architectures.

`FFTLength` — Number of data points used for one FFT calculation
1024 (default) | integer power of 2 between 2^3 and 2^{16}

Number of data points used for one FFT calculation, specified as an integer power of 2 between 2^3 and 2^{16}. The object accepts FFT lengths outside this range, but they are not supported for HDL code generation.

`ResetInputPort` — Enable reset argument
`false` (default) | `true`

Enable `reset` input argument to the object. When `reset` is `true`, the object stops calculation and clears all internal state.

`StartOutputPort` — Enable start output argument
`false` (default) | `true`

Enable `startOut` output argument of the object. When enabled, the object returns an additional output signal that is `true` on the first cycle of each valid output frame.

`EndOutputPort` — Enable end output argument
`false` (default) | `true`

Enable `endOut` output argument of the object. When enabled, the object returns an additional output signal that is `true` on the first cycle of each valid output frame.

`RoundingMethod` — Rounding mode used for fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding mode used for fixed-point operations. When the input is any integer or fixed-point data type, the IFFT algorithm uses fixed-point arithmetic for internal calculations. This option does not apply when the input is single or double type. Rounding applies to twiddle factor multiplication and scaling operations.

Usage

Syntax

```
[Y,validOut] = IFFT_N(X,validIn)
[Y,validOut,ready] = IFFT_N(X,validIn)
[Y,startOut,endOut,validOut] = IFFT_N(X,validIn)
[Y,validOut] = IFFT_N(X,validIn,resetIn)
[Y,startOut,endOut,validOut] = IFFT_N(X,validIn,resetIn)
```

Description

`[Y,validOut] = IFFT_N(X,validIn)` returns the inverse fast Fourier transform (IFFT), `Y`, of the input, `X`, when `validIn` is `true`. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals, respectively.

`[Y,validOut,ready] = IFFT_N(X,validIn)` returns the inverse fast Fourier transform (IFFT) when using the burst Radix 2 architecture. The `ready` signal indicates when the object can accept input samples.

To use this syntax, set the Architecture property to `'Burst Radix 2'`. For example:

```
IFFT_N = dsp.HDLIFFT(___,'Architecture','Burst Radix 2');
...
[y,validOut,ready] = IFFT_N(x,validIn)
```

`[Y,startOut,endOut,validOut] = IFFT_N(X,validIn)` also returns frame control signals `startOut` and `endOut`. `startOut` is `true` on the first sample of a frame of output data. `endOut` is `true` for the last sample of a frame of output data.

To use this syntax, set the StartOutputPort and EndOutputPort properties to `true`. For example:

```
IFFT_N = dsp.HDLIFFT(___,'StartOutputPort',true,'EndOutputPort',true);
...
[y,startOut,endOut,validOut] = IFFT_N(x,validIn)
```

`[Y,validOut] = IFFT_N(X,validIn,resetIn)` returns the IFFT, `Y`, when `validIn` is `true` and `resetIn` is `false`. When `resetIn` is `true`, the object stops the current calculation and clears all internal state.

To use this syntax, set the ResetInputPort property to `true`. For example:

```
IFFT_N = dsp.HDLIFFT(___,'ResetInputPort',true);
...
[y,validOut] = IFFT_N(x,validIn,resetIn)
```

`[Y,startOut,endOut,validOut] = IFFT_N(X,validIn,resetIn)` returns the IFFT, `Y`, using all optional control signals. You can use any combination of the optional port syntaxes.

Input Arguments

X — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values, in fixed-point or integer format. Vector input is supported with `'Streaming Radix 2^2'` architecture only. The vector size must be a power of 2 between 1 and 64 that is not greater than the

FFT length. `double` and `single` are supported for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

`validIn` — Validity of input data
logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

`resetIn` — Reset internal state
logical scalar

Reset internal state, specified as a logical scalar. To enable this argument, set the ResetInputPort property to `true`.

Data Types: `logical`

Output Arguments

`Y` — Output data
scalar or column vector of real or complex values

Output data, returned as a scalar or column vector of real or complex values. The output format matches the format of the input data.

`ready` — Memory available for input data
logical scalar

Indication that the object has memory available for input data, returned as a logical scalar. This output is returned when you select `'Burst Radix 2'` architecture.

Data Types: `logical`

`startOut` — First sample of output frame
logical scalar

First sample of output frame, returned as a logical scalar. To enable this argument, set the StartOutputPort property to `true`.

Data Types: `logical`

`endOut` — Last sample of output frame
logical scalar

Last sample of output frame, returned as a logical scalar. To enable this argument, set the EndOutputPort property to `true`.

Data Types: `logical`

`validOut` — Validity of output data
logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLIFFT

getLatency	Latency of FFT or channelizer calculation

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create IFFT for HDL Code Generation

Create the specifications and input signal. This example uses a 128-point FFT.

```
N = 128;
Fs = 40;
```

```
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,16);
noOp = zeros(1,'like',y_fixed);
```

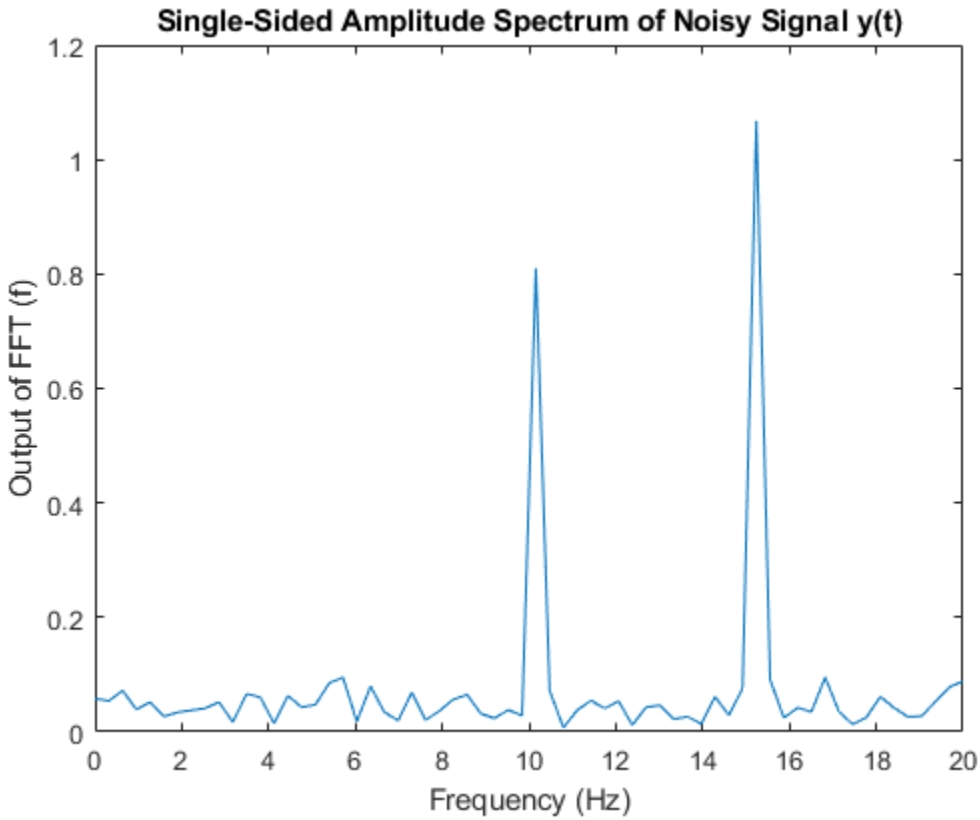
Compute the FFT of the signal to use as the input to the IFFT object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlfft = dsp.HDLFFT('FFTLength',N,'BitReversedOutput',false);
Yf = zeros(1,4*N);
validOut = false(1,4*N);
for loop = 1:1:N
         [Yf(loop),validOut(loop)] = hdlfft(complex(y_fixed(loop)),true);
end
for loop = N+1:1:4*N
      [Yf(loop),validOut(loop)] = hdlfft(complex(noOp),false);
end
Yf = Yf(validOut == 1);
```

Plot the single-sided amplitude spectrum.

```
plot(Fs/2*linspace(0,1,N/2),2*abs(Yf(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT (f)')
```



Select frequencies that hold the majority of the energy in the signal. The `cumsum` function does not accept fixed-point arguments, so convert the data back to `double`.

```
[Ysort,i] = sort(abs(double(transpose(Yf(1:N)))),1,'descend');
Ysort_d = double(Ysort);
CumEnergy = sqrt(cumsum(Ysort_d.^2))/norm(Ysort_d);
j = find(CumEnergy > 0.9, 1);
     disp(['Number of FFT coefficients that represent 90% of the ', ...
     'total energy in the sequence: ', num2str(j)])
Yin = zeros(N,1);
Yin(i(1:j)) = Yf(i(1:j));
```

```
Number of FFT coefficients that represent 90% of the total energy in the sequence: 4
```

Write a function that creates and calls the IFFT System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLIFFT128(yIn,validIn)
%HDLIFFT128
% Processes one sample of data using the dsp.HDLIFFT System object(TM)
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar.
% You can generate HDL code from this function.

  persistent ifft128;
  if isempty(ifft128)
    ifft128 = dsp.HDLIFFT('FFTLength',128);
  end
  [yOut,validOut] = ifft128(yIn,validIn);
end
```

Compute the IFFT by calling the function for each data sample.

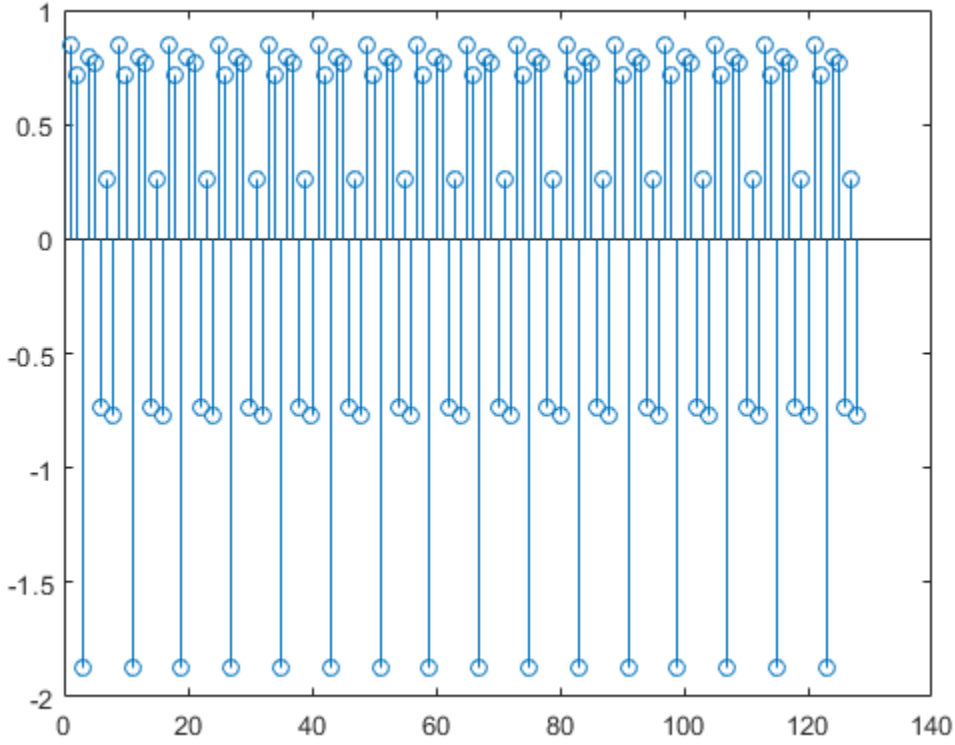
```
Xt = zeros(1,3*N);
validOut = false(1,3*N);
for loop = 1:1:N
    [Xt(loop),validOut(loop)] = HDLIFFT128(complex(Yin(loop)),true);
end
for loop = N+1:1:3*N
    [Xt(loop),validOut(loop)] = HDLIFFT128(complex(0),false);
end
```

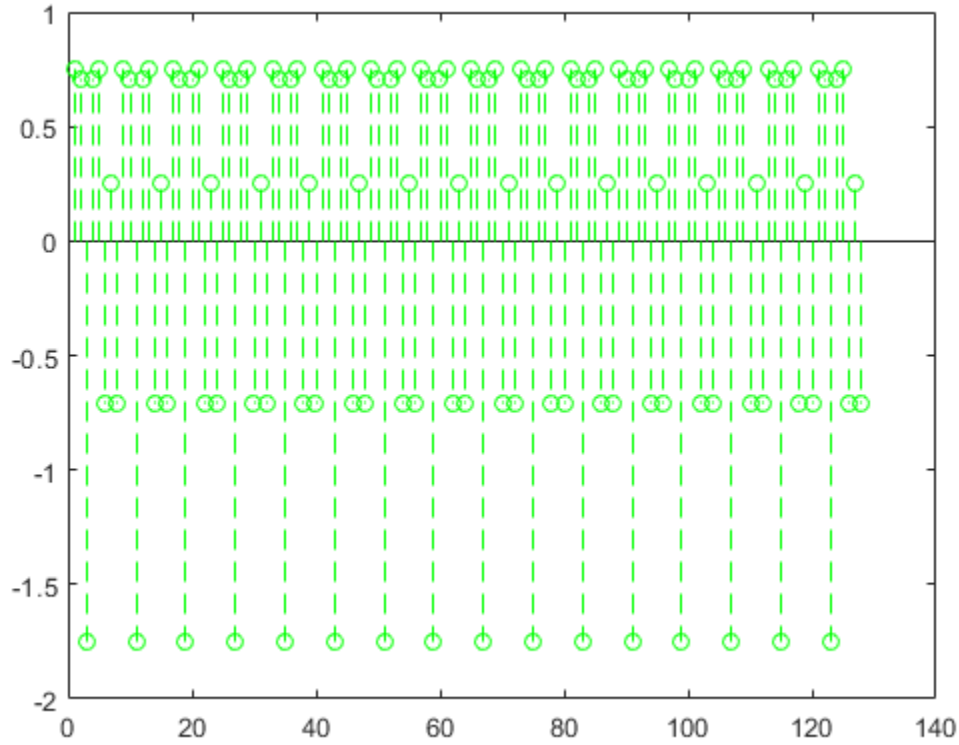
Discard invalid output samples. Then inspect the output and compare it with the input signal. The original input is in green.

```
Xt = Xt(validOut==1);
Xt = bitrevorder(Xt);
norm(x-transpose(Xt(1:N)))
figure
stem(real(Xt))
figure
stem(real(x),'--g')
```

```
ans =
```

```
0.7863
```





Create a Vector-Input IFFT for HDL Code Generation

Create the specifications and input signal. This example uses a 128-point FFT and computes the transform over 16 samples at a time.

```
N = 128;
V = 16;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
```

```
y_fixed = sfi(y,32,24);
y_vect = reshape(y_fixed,V,N/V);
```

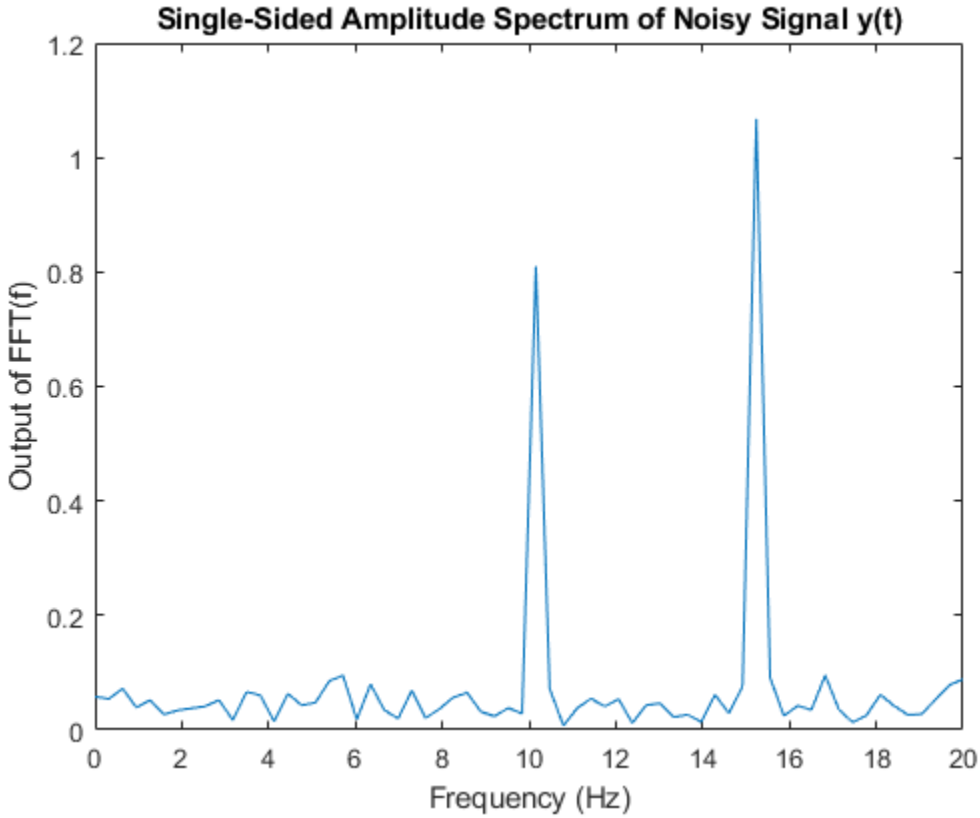
Compute the FFT of the signal, to use as the input to the IFFT object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlfft = dsp.HDLFFT('FFTLength',N);
loopCount = getLatency(hdlfft,N,V)+N/V;
Yf = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
       [Yf(:,loop),validOut(loop)] = hdlfft(complex(y_vect(:,i)),(loop<=N/V));
end
```

Plot the single-sided amplitude spectrum.

```
C = Yf(:,validOut==1);
Yf_flat = C(:);
Yr = bitrevorder(Yf_flat);
plot(Fs/2*linspace(0,1,N/2),2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT(f)')
```



Select frequencies that hold the majority of the energy in the signal. The `cumsum` function doesn't accept fixed-point arguments, so convert the data back to `double`.

```
[Ysort,i] = sort(abs(double(Yr(1:N))),1,'descend');
CumEnergy = sqrt(cumsum(Ysort.^2))/norm(Ysort);
j = find(CumEnergy > 0.9, 1);
     disp(['Number of FFT coefficients that represent 90% of the ', ...
     'total energy in the sequence: ', num2str(j)])
Yin = zeros(N,1);
Yin(i(1:j)) = Yr(i(1:j));
YinVect = reshape(Yin,V,N/V);
```

```
Number of FFT coefficients that represent 90% of the total energy in the sequence: 4
```

Write a function that creates and calls the IFFT System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLIFFT128V16(yIn,validIn)
%HDLFFT128V16
% Processes 16-sample vectors of FFT data
% yIn is a fixed-point column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent ifft128v16;
  if isempty(ifft128v16)
    ifft128v16 = dsp.HDLIFFT('FFTLength',128)
  end
  [yOut,validOut] = ifft128v16(yIn,validIn);
end
```

Compute the IFFT by calling the function for each data sample.

```
Xt = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
       [Xt(:,loop),validOut(loop)] = HDLIFFT128V16(complex(YinVect(:,i)),(loop<=N/V));
end
```

```
ifft128v16 =

  dsp.HDLIFFT with properties:

               FFTLength: 128
            Architecture: 'Streaming Radix 2^2'
    ComplexMultiplication: 'Use 4 multipliers and 2 adders'
        BitReversedOutput: true
         BitReversedInput: false
                Normalize: true
```

```
  Use get to show all properties
```

Discard invalid output samples. Then inspect the output and compare it with the input signal. The original input is in green.

```
C = Xt(:,validOut==1);
Xt = C(:);

Explore Latency of HDL IFFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

Create a new `dsp.HDLIFFT` object and request the latency.

```
hdlifft = dsp.HDLIFFT('FFTLength',512);
L512 = getLatency(hdlifft)
```

```
L512 = 599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change. When you do not specify a vector length, the function assumes scalar input data.

```
L256 = getLatency(hdlifft,256)
```

```
L256 = 329
```

```
N = hdlifft.FFTLength
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlifft,256,8)
```

```
L256v8 = 93
```

Enable scaling at each stage of the IFFT. The latency does not change.

```
hdlifft.Normalize = true;
L512n = getLatency(hdlifft)
```

```
L512n = 599
```

Request the same output order as the input order. This setting increases the latency because the object must collect the output before reordering.

```
hdlifft.BitReversedOutput = false;
L512r = getLatency(hdlifft)
```

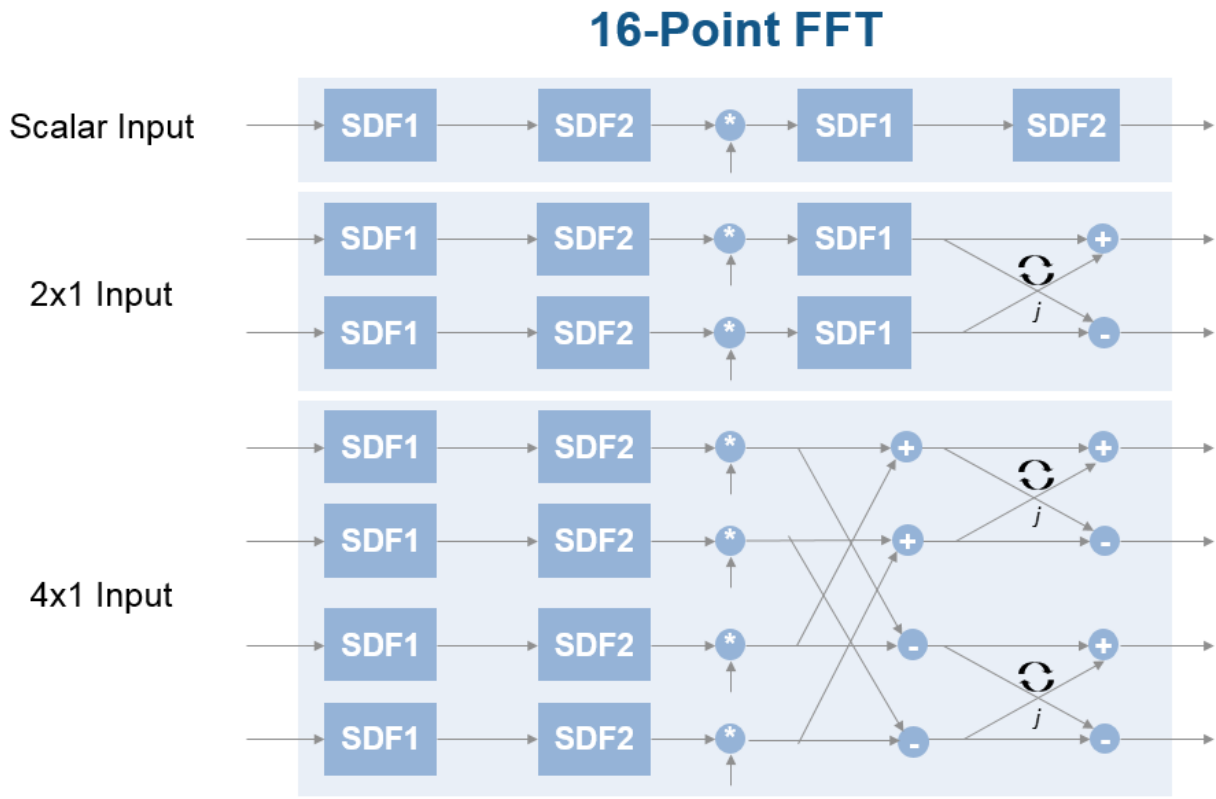
```
L512r = 1078
```

Algorithms

Streaming Radix 2^2

The streaming Radix 2^2 architecture implements a low-latency architecture. It saves resources compared to a streaming Radix 2 implementation by factoring and grouping the FFT equation. The architecture has $\log_4(N)$ stages. Each stage contains two single-path delay feedback (SDF) butterflies with memory controllers. When you use vector input,

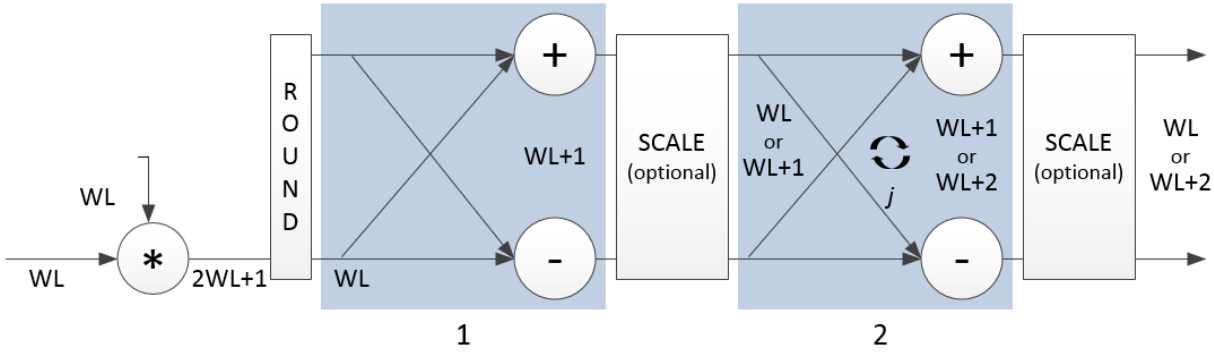
each stage operates on fewer input samples, so some stages reduce to a simple butterfly, without SDF.



The first SDF stage is a regular butterfly. The second stage multiplies the outputs of the first stage by *–j*. To avoid a hardware multiplier, the block swaps the real and imaginary parts of the inputs, and again swaps the imaginary parts of the resulting outputs. Each stage rounds the result of the twiddle factor multiplication to the input word length. The twiddle factors have two integer bits, and the rest of the bits are used for fractional bits. The twiddle factors have the same bit width as the input data, *WL*. The twiddle factors have two integer bits, and *WL*-2 fractional bits.

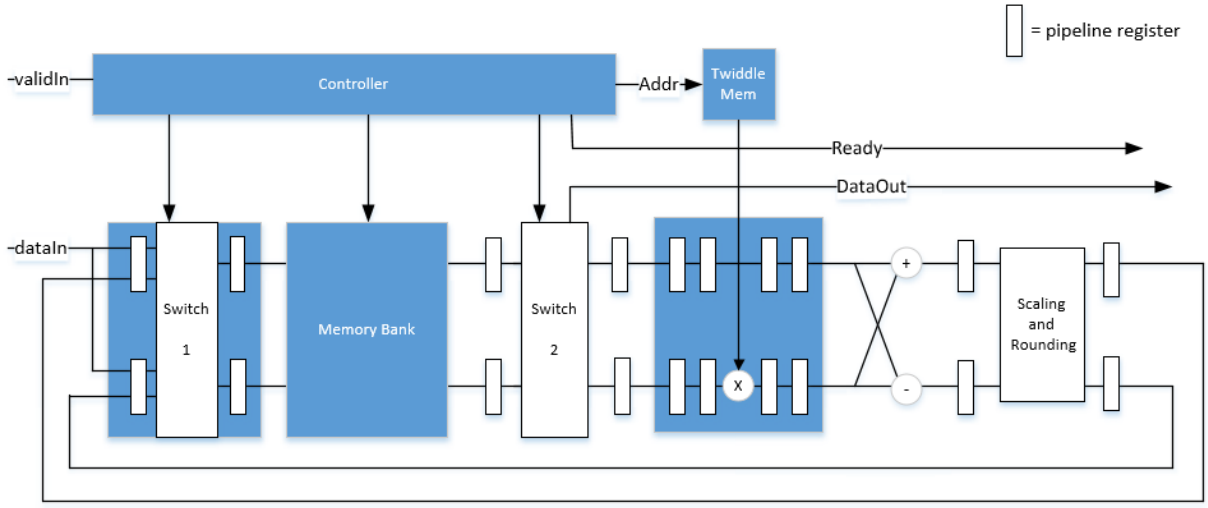
If you enable scaling, the algorithm divides the result of each butterfly stage by 2. Scaling at each stage avoids overflow, keeps the word length the same as the input, and results in an overall scale factor of 1/*N*. If scaling is disabled, the algorithm avoids overflow by

increasing the word length by 1 bit at each stage. The diagram shows the butterflies and internal word lengths of each stage, not including the memory.



Burst Radix 2

The burst Radix 2 architecture implements the FFT by using a single complex butterfly multiplier. The algorithm cannot start until it has stored the entire input frame, and it cannot accept the next frame until computations are complete. The output **ready** port indicates when the algorithm is ready for new data. The diagram shows the burst architecture, with pipeline registers.



Control Signals

The algorithm processes input data only when the input **valid** port is 1. Output data is valid only when the output **valid** port is 1.

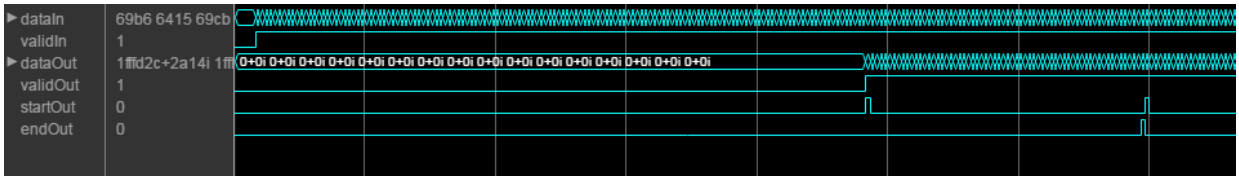
When the optional input **reset** port is 1, the algorithm stops the current calculation and clears all internal states. The algorithm begins new calculations when **reset** port is 0 and the input **valid** port starts a new frame.

Timing Diagram

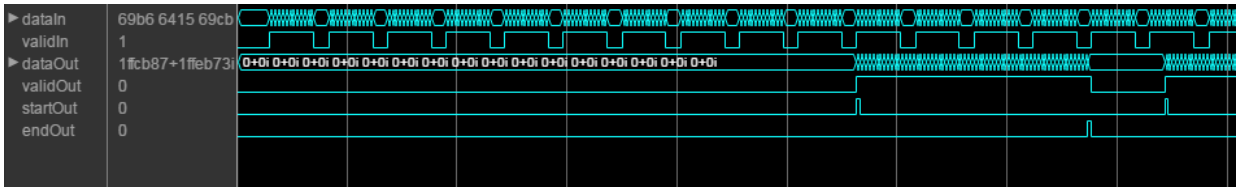
This diagram shows the input and output **valid** port values for contiguous scalar input data, streaming Radix 2^2 architecture, an FFT length of 1024, and a vector size of 16.

The diagram also shows the optional **start** and **end** port values that indicate frame boundaries. If you enable the **start** port, the **start** port value pulses for one cycle with the first valid output of the frame. If you enable the **end** port, the **start** port value pulses for one cycle with the last valid output of the frame.

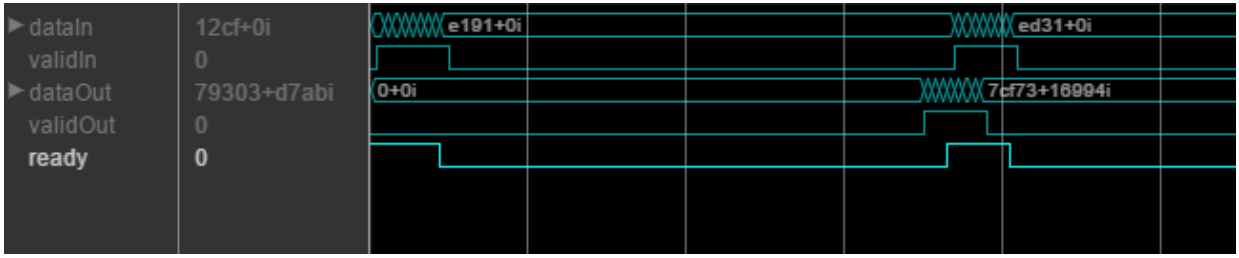
If you apply continuous input frames, the output will also be continuous after the initial latency.



The input **valid** port can be noncontiguous. Data accompanied by an input **valid** port is processed as it arrives, and the resulting data is stored until a frame is filled. Then the algorithm returns contiguous output samples in a frame of *N* (**FFT length**) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16.



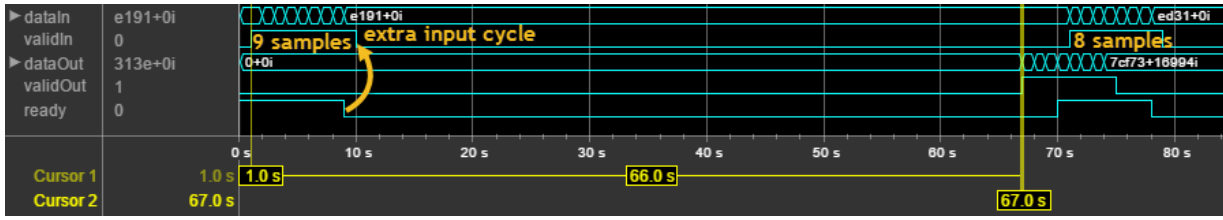
When you use the burst architecture, you cannot provide the next frame of input data until memory space is available. The **ready** port indicates when the algorithm can accept new input data.



Latency

The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

When using the burst architecture with a contiguous input, if your design waits for **ready** to output `0` before de-asserting the input **valid**, then one extra cycle of data arrives at the input. This data sample is the first sample of the next frame. The algorithm can save one sample while processing the current frame. Due to this one sample advance, the observed latency of the later frames (from input **valid** to output **valid**) is one cycle shorter than the reported latency. The latency is measured from the first cycle, when input **valid** is 1 to the first cycle when output **valid** is 1. The number of cycles between when **ready** port is 0 and the output **valid** port is 1 is always *latency – FFTLength*.



Performance

This resource and performance data is the synthesis result from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The examples in the tables have this configuration:

- 1024 FFT length (default)
- Complex multiplication using 4 multipliers, 2 adders
- Output scaling enabled
- Natural order input, Bit-reversed output
- 16-bit complex input data
- Clock enables minimized (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, reordering for a natural-order output uses more RAM than the default bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2^2 configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Number Used
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2^2 implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Number Used
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24
Block RAM (16K)	8

The block supports scalar input data only when implementing burst Radix 2 architecture. The burst design achieves 309 MHz clock frequency. The latency is 5811 cycles. The design uses these resources.

Resource	Number Used
LUT	971
FFS	1254
Xilinx LogiCORE DSP48	3
Block RAM (16K)	6

IFFT HDL Optimized

Introduced in R2014b

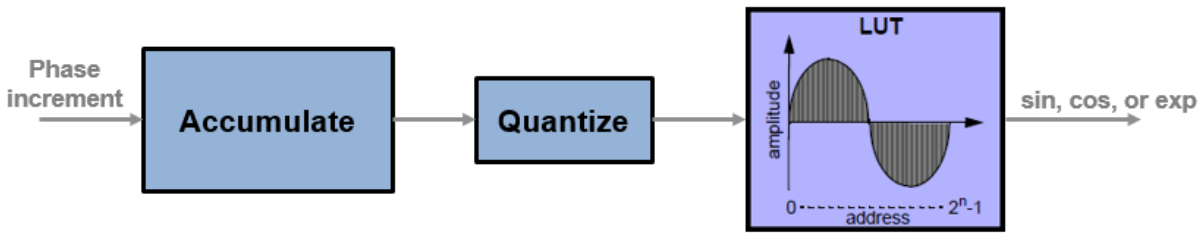
dsp.HDLNCO

Package: `dsp`

Generate real or complex sinusoidal signals—optimized for HDL code generation

Description

The HDL NCO System object generates real or complex sinusoidal signals, while providing hardware-friendly control signals. The object uses the same phase accumulation and lookup table algorithm as implemented in the NCO System object. When you use integer or fixed-point input signals, or use the object as a source with no input signal, the object uses quantized integer accumulation to create a sinusoid signal.



The HDL NCO System object provides these features:

- A lookup table compression option to reduce the lookup table size. This compression results in less than one LSB loss in precision. See “Lookup Table Compression” on page 4-954 for more information.
- An optional input argument for external dither.
- An optional reset argument that triggers a reset of the phase to its initial value during the sinusoid output generation.
- An optional output argument for the current NCO phase.

The System object does not support the property that allows the NCO HDL Optimized block to synthesize the lookup table to a ROM when using HDL Coder with an FPGA target.

Given a desired output frequency F_0, calculate the *phase increment* input value using

$$phaseincrement = (\frac{F_0 \cdot 2^N}{F_s})$$

where N is the accumulator word length and

$$F_s = \frac{1}{T_s} = \frac{1}{sampletime}$$

You can specify the phase increment using a property or an input argument.

The frequency resolution of an NCO is defined by

$$\Delta f = \frac{1}{T_s \cdot 2^N}\text{Hz}$$

Given a desired phase offset (in radians), calculate the *phase offset* input value using

$$phaseoffset = \frac{2^N \cdot desiredphaseoffset}{2\pi}$$

You can specify the phase offset using a property or an input argument.

When you use floating-point input signals, the object does not quantize the accumulation. Therefore, you must choose increment and offset values to represent a fraction of 2π without quantization.

To generate real or complex sinusoidal signals:

1. Create the `dsp.HDLNCO` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
hdlnco = dsp.HDLNCO
hdlnco = dsp.HDLNCO(Name,Value)
hdlnco = dsp.HDLNCO(Inc,'PhaseIncrementSource','Property')
```

Description

`hdlnco = dsp.HDLNCO` creates a numerically controlled oscillator (NCO) System object, `hdlnco`, that generates a real or complex sinusoidal signal. The amplitude of the generated signal is always 1.

`hdlnco = dsp.HDLNCO(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
hdlnco = dsp.HDLNCO('NumQuantizerAccumulatorBits',14, ...
                    'AccumulatorWL',17);
```

`hdlnco = dsp.HDLNCO(Inc,'PhaseIncrementSource','Property')` creates an NCO with the `PhaseIncrement` property set to `Inc`, an integer scalar. To use the PhaseIncrement property, set the PhaseIncrementSource property to `'Property'`. You can add other `Name,Value` pairs before or after `PhaseIncrementSource`.

Properties

Note This object supports floating point types for simulation but not for HDL code generation. When an input is fixed point or when all input arguments are disabled, the object computes the output waveform based on the fixed-point property settings. When a data input is floating point, the object computes a double-precision output waveform and ignores properties related to fixed-point settings (NumDitherBits, PhaseQuantization, NumQuantizerAccumulatorBits, LUTCompress, and the fixed-point data type properties).

When you switch to using a floating-point phase increment, you must adjust the value of the increment to account for the lack of phase quantization.

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

Waveform Generation

`PhaseIncrementSource` — Source of phase increment

`'Input port'` (default) | `'Property'`

You can set the phase increment with an input argument or by specifying a value for the property. Specify `'Property'` to configure the phase increment using the `PhaseIncrement` property. Specify `'Input port'` to set the phase increment using the `inc` argument.

`PhaseIncrement` — Phase increment for generated waveform

`100` (default) | scalar integer

Phase increment for generated waveform, specified as a scalar integer. If the increment is a fixed-point value, the object uses only the integer bits and ignores any fractional bits. `double` and `single` data types are supported for simulation but not for HDL code generation. When you use floating-point input signals, you must choose increment and offset values to represent a fraction of 2π,

Dependencies

This property applies when you set the `PhaseIncrementSource` property to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixdt([],N,0)`

`PhaseOffsetSource` — Source of phase offset

`'Input port'` (default) | `'Property'`

You can set the phase offset with an input argument or by specifying a value for the property. Specify `'Property'` to configure the phase increment using the `PhaseOffset` property. Specify `'Input port'` to set the phase increment using the `offset` argument.

`PhaseOffset` — Phase offset for generated waveform

`0` (default) | scalar integer

Phase offset for the generated waveform, specified as a scalar integer. If the offset is a fixed-point value, the object uses only the integer bits and ignores any fractional bits. `double` and `single` data types are supported for simulation but not for HDL code generation. When you use floating-point input signals, you must choose increment and offset values to represent a fraction of 2π.

Dependencies

This property applies when you set the `PhaseOffsetSource` property to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixdt([],N,0)`

`DitherSource` — Source of number of dither bits

`'Input port'` (default) | `'Property'` | `'None'`

You can set the number of dither bits from an input argument or from a property, or you can disable dither. Specify `'Property'` to configure the number of dither bits using the `NumDitherBits` property. Specify `'Input port'` to set the number of dither bits using the `dither` argument. Specify `'None'` to disable dither.

`NumDitherBits` — Bits used to express dither

`4` (default) | positive integer

Number of dither bits, specified as a positive integer.

Dependencies

This property applies when you set the `DitherSource` property to `'Property'`.

`PhaseQuantization` — Quantize accumulated phase

`true` (default) | `false`

Whether to quantize accumulated phase, specified as `true` or `false`. When this property is enabled, the object quantizes the result of the phase accumulator to a fixed bit-width. This quantized value is used to select a waveform value from the lookup table. Select the resolution of the lookup table using the `NumQuantizerAccumulatorBits` property.

The frequency resolution of an NCO is defined by $\Delta f = \frac{1}{T_s \cdot 2^N}\,\text{Hz}$.

When you disable this property, the object uses the accumulator data type as the address of the lookup table.

`NumQuantizerAccumulatorBits` — Bits used to express phase

12 (default) | scalar integer

Number of quantizer accumulator bits, specified as an integer scalar greater than 1 and less than the accumulator word length. This property must be less than or equal to 17 bits for HDL code generation. The lookup table of sine values has $2^{\texttt{NumQuantizerAccumulatorBits}-2}$ entries.

Dependencies

This property applies when you set `PhaseQuantization` to `true`.

`LUTCompress` — Lookup table compression

`false` (default) | `true`

By default, the object implements a noncompressed lookup table, and the output matches the output of the `dsp.NCO` System object. When you enable this option, the object implements a compressed lookup table. The Sunderland compression method reduces the size of the lookup table, losing less than one LSB of precision. The spurious free dynamic range (SFDR) is empirically 1-3 dB lower than the noncompressed case. The hardware savings of the compressed lookup table allow room to improve performance by increasing the word length of the accumulator and the number of quantize bits. For details of the compression method, see “Algorithms” on page 4-953.

`Waveform` — Type of output waveform

`'Sine'` (default) | `'Cosine'` | `'Complex exponential'` | `'Sine and cosine'`

Type of output waveform. If you select `'Sine'` or `'Cosine'`, the object returns a `sin` or `cos` value. If you select `'Complex exponential'`, the output value, `exp`, is of the form `sine + j*cosine`. If you select `'Sine and cosine'`, the object returns two values, `sin` and `cos`.

`PhasePort` — Return current phase

`false` (default) | `true`

Return the current phase along with the output waveform, when enabled.

Control Signals

`ResetAction` — Enable reset input argument
`false` (default) | `true`

When enabled, the object accepts a `reset` argument. When the `reset` argument is 1 (`true`), the object resets the accumulator to zero.

`ValidInputPort` — Enable valid input argument
`true` (default) | `false`

When enabled, the object accepts a `valid` argument. When the `valid` argument is 1 (`true`), the object increments the phase. When the `valid` argument is 0 (`false`), the phase is held.

Data Types

`OverflowAction` — Overflow mode for fixed-point operations
`'Wrap'` (default)

Overflow mode for fixed-point operations. `OverflowAction` is a read-only property with value `'Wrap'`.

`RoundingMethod` — Rounding mode for fixed-point operations
`'Floor'` (default)

Rounding mode for fixed-point operations. `RoundingMethod` is a read-only property with value `'Floor'`.

`AccumulatorDataType` — Accumulator data type
`'Binary point scaling'` (default)

Accumulator data type description. `AccumulatorDataType` is a read-only property with value `'Binary point scaling'`. The object defines the fixed-point data type using the `AccumulatorSigned`, `AccumulatorWL`, and `AccumulatorFL` properties.

`AccumulatorSigned` — Signed or unsigned accumulator data format
`'Signed'` (default)

Signed or unsigned accumulator data format. `AccumulatorSigned` is a read-only property with value `'Signed'`. All output is signed format.

`AccumulatorWL` — Accumulator word length
`16` (default) | scalar integer

Accumulator word length, in bits, specified as a scalar integer.

If `PhaseQuantization` is `false`, this property must be less than or equal to 17 bits for HDL code generation.

`AccumulatorFL` — Accumulator fraction length
`0` (default) | scalar integer

Accumulator fraction length, in bits. `AccumulatorFL` is a read-only property. The accumulator fraction length is zero bits. The accumulator operates on integers. If the phase increment is fixed-point type with a fractional part, the object ignores the fractional part.

`OutputDataType` — Output data type
`'Binary point scaling'` (default) | `'double'` | `'single'`

Output data type. If you specify `'Binary point scaling'`, the object defines the fixed-point data type using the `OutputSigned`, `OutputWL`, and `OutputFL` properties.

`OutputSigned` — Signed or unsigned output data format
`'Signed'` (default)

Signed or unsigned output data format. `OutputSigned` is a read-only property with value `'Signed'`. All output is signed format.

`OutputWL` — Output word length
`16` (default) | scalar integer

Output word length, in bits, specified as a scalar integer.

`OutputFL` — Output fraction length
`14` (default) | scalar integer

Output fraction length, in bits, specified as a scalar integer.

Usage

Syntax

```
[Y,ValidOut] = hdlnco(Inc,ValidIn)
[Y,ValidOut] = hdlnco
[Y,ValidOut] = hdlnco(Inc,Offset,Dither,ValidIn)
[Y,Phase,ValidOut] = hdlnco( ___ )
```

Description

The object returns the waveform value, `Y`, as a sine value, a cosine value, a complex exponential value, or a [`Sine,Cosine`] pair of values, depending on the Waveform property.

`[Y,ValidOut] = hdlnco(Inc,ValidIn)` returns a sinusoidal signal, `Y`, generated by the HDLNCO System object, using the phase increment, `Inc`. When `ValidIn` is `true`, `Inc` is added to the accumulator. The `Inc` argument is optional. Alternatively, you can specify the phase increment as a property.

`[Y,ValidOut] = hdlnco` returns a waveform, `Y`, using waveform parameters from properties rather than input arguments.

To use this syntax, set the PhaseIncrementSource, PhaseOffsetSource, and DitherSource properties to `'Property'` and ValidInputPort to `false`. These properties are independent of each other. For example:

```
hdlnco = dsp.HDLNCO('PhaseIncrementSource','Property', ...
       'PhaseIncrement',phIncr,...
       'PhaseOffset',phOffset,...
       'ValidInputPort',false,...
       'NumDitherBits',4)
```

`[Y,ValidOut] = hdlnco(Inc,Offset,Dither,ValidIn)` returns a waveform, `Y`, with phase increment, `Inc`, phase offset, `Offset`, and dither, `Dither`.

This syntax applies when you set the PhaseIncrementSource, PhaseOffsetSource, and DitherSource properties to `'Input port'`. These properties are independent of each other. You can mix and match the activation of these arguments. `PhaseIncrementSource` is `'Input port'` by default. For example:

```
hdlnco = dsp.HDLNCO('PhaseOffsetSource','Input port',...
                    'DitherSource','Input port')
for k = 1:1/Ts
   y(k) = hdlnco(phIncr,phOffset,ditherBits,true);
end
```

`[Y,Phase,ValidOut] = hdlnco( ___ )` returns a waveform, `Y`, and current phase, `Phase`.

To use this syntax, set the PhasePort property to `true`. This syntax can include any of the arguments from other syntaxes. For example:

```
hdlnco = dsp.HDLNCO('PhaseOffsetSource','Input port',...
                    'DitherSource','Input port',...
                    'PhasePort',true)
for k = 1:1/Ts
   [phase(k),y(k)] = hdlnco(phIncr,phOffset,ditherBits,true);
end
```

Input Arguments

`Inc` — Phase increment (optional)

scalar integer

Phase increment, specified as a scalar integer. If the phase increment is a fixed-point value, the object uses only the integer bits and ignores any fractional bits. `double` and `single` data types are supported for simulation but not for HDL code generation. When you use floating-point input signals, you must choose increment and offset values to represent a fraction of 2π.

Dependencies

The object accepts this argument when you set the PhaseIncrementSource property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixdt([],N,0)`

`ValidIn` — Enable signal (optional)

scalar

Control signal that enables NCO operation, specified as a `logical` scalar. When `ValidIn` is 1 (`true`), the object increments the phase. When `ValidIn` is 0 (`false`), the object holds the phase.

Dependencies

The object accepts this argument when you set the ValidInputPort property to `true`.

Data Types: `logical`

`Offset` — Phase offset

scalar integer

Phase offset, specified as a scalar integer. If the offset is a fixed-point value, the object uses only the integer bits and ignores any fractional bits. `double` and `single` data types are supported for simulation but not for HDL code generation. When you use floating-point input signals, you must choose increment and offset values to represent a fraction of 2π.

Dependencies

The object accepts this argument when you set the PhaseOffsetSource property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixdt([],N,0)`

`Dither` — Dither

scalar integer

Dither, specified as a scalar integer. `double` and `single` data types are supported for simulation but not for HDL code generation.

Dependencies

The object accepts this argument when you set the DitherSource property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixdt([],N,0)`

`Reset` — Reset accumulator (optional)

scalar

Control signal that resets the accumulator, specified as a scalar `logical`. When `Reset` is 1 (`true`), the object resets the accumulator to 0.

Dependencies

The object accepts this argument when you set the ResetAction property to `true`.

Data Types: `logical`

Output Arguments

Y — Generated waveform

scalar | [*Sine*,*Cosine*] pair

Generated waveform, returned as a scalar `sin` or `cos` value, as a scalar `exp` value representing `sine + j*cosine`, or as a pair of values, `[sin,cos]`. If any input is floating-point type, the object returns floating-point values, otherwise the object returns fixed-point values. Floating point types are supported for simulation but not for HDL code generation.

Dependencies

By default, the output waveform is a sine wave. The format of the output waveform depends on the Waveform property.

`ValidOut` — Indicates valid output data

scalar

Control signal that indicates whether the other output argument values are valid or not. When `validOut` is 1 (`true`), the values of `Y` and `Phase` are valid. When `validOut` is 0 (`false`), the values of `Y` and `Phase` are not valid.

Data Types: `logical`

Phase — Current phase of the NCO

scalar fixed-point or floating-point value

Current phase of the NCO, returned as a scalar of type `fixdt(1,M,-Z)`, where `M` is the number of quantized accumulator bits, and `Z` is the accumulator word length. If the input to the object is floating point, the object returns `Phase` as floating point. Floating point is supported for simulation but not for HDL code generation.

Dependencies

The object returns this argument when you set the PhasePort property to `true`.

Data Types: `single` | `double` | `fixdt(1,NumQuantizerAccumulatorBits,-AccumulatorWL)`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Design a HDL-Compatible NCO Source

This example shows how to design an HDL-compatible NCO source.

Write a function that creates and calls the System object™, based on the waveform requirements. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function yOut = HDLNCO510(validIn)
%HDLNCO510
% Generates one sample of NCO waveform using the dsp.HDLNCO System object(TM)
% validIn is a logical scalar value
% phase increment, phase offset, and dither are fixed.
% You can generate HDL code from this function.

  persistent nco510;
```

```
  if isempty(nco510)
  % Since calculation of the object parameters results in constant values, this
  % code is not included in the generated HDL. The generated HDL code for
  % the NCO object is initialized with the constant property values.

   F0 = 510;     % Target output frequency in Hz
   dphi = pi/2;  % Target phase offset
   df = 0.05;    % Frequency resolution in Hz
   minSFDR = 96; % Spurious free dynamic range(SFDR) in dB
   Ts = 1/4000;  % Sample period in seconds

   % Calculate the number of accumulator bits required for the frequency
   % resolution and the number of quantized accumulator bits to satisfy the SFDR
   % requirement.
   Nacc = ceil(log2(1/(df*Ts)));
   % Actual frequency resolution achieved = 1/(Ts*2^Nacc)
   Nqacc = ceil((minSFDR-12)/6);
   % Calculate the phase increment and offset to achieve the target frequency
   % and offset.
   phIncr = round(F0*Ts*2^Nacc);
   phOffset = 2^Nacc*dphi/(2*pi);
   nco510 = dsp.HDLNCO('PhaseIncrementSource','Property', ...
       'PhaseIncrement',phIncr,...
       'PhaseOffset',phOffset,...
       'NumDitherBits',4, ...
       'NumQuantizerAccumulatorBits',Nqacc,...
       'AccumulatorWL',Nacc);
  end

  yOut = nco510(validIn);

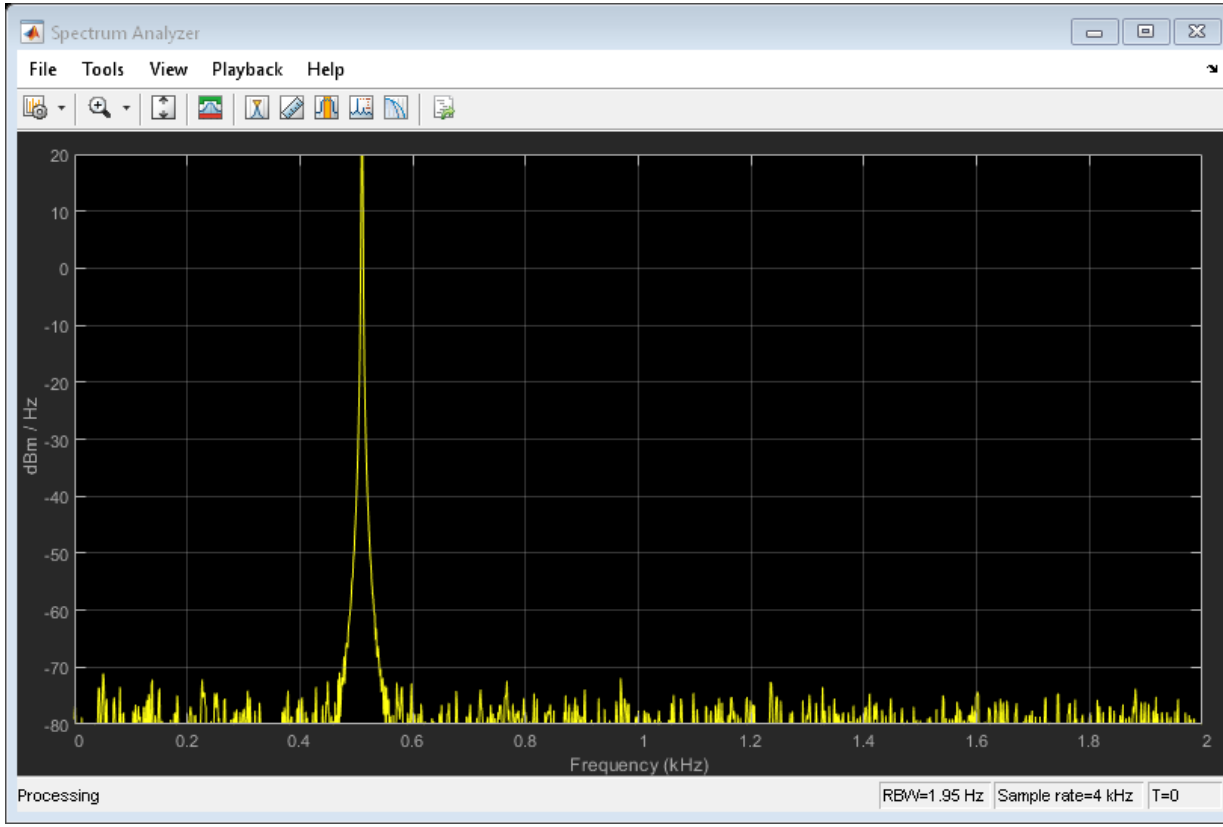
end
```

Call the object to generate data points in a sine wave. The input to the object is a valid control signal.

```
Ts = 1/4000;
y = zeros(1,1/Ts);
for k = 1:1/Ts
   y(k) = HDLNCO510(true);
end
```

Plot the mean-square spectrum of the 510 Hz sine wave generated by the NCO.

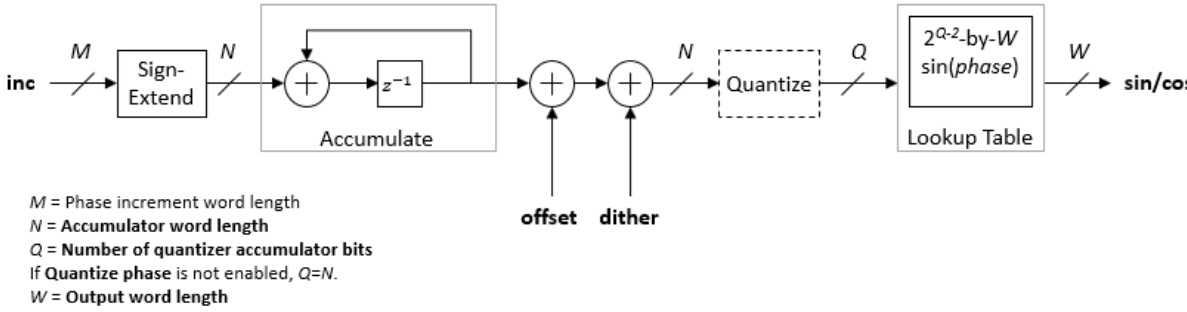
```
sa = dsp.SpectrumAnalyzer('SampleRate',1/Ts);
sa.SpectrumType = 'Power density';
sa.PlotAsTwoSidedSpectrum = false;
sa(y')
```



Algorithms

The NCO implementation depends on whether you enable the `LUTCompress` property.

Without lookup table compression, the object uses the same quarter-sine lookup table as the NCO block. The size of the LUT is $2^{\texttt{NumQuantizerAccumulatorBits}-2} \times \texttt{OutputWL}$ bits.



If you do not enable `PhaseQuantization`, then `NumQuantizerAccumulatorBits=AccumulatorWL`. Consider the impact on simulator memory and hardware resources when you select these parameters.

Lookup Table Compression

When you select lookup table (LUT) compression, the object applies the Sunderland compression method. Sunderland techniques use trigonometric identities to divide each phase of the quarter sine wave into three components and express it as:

$$\sin(A+B+C) = \sin(A+B)\cos(C) + \cos(A)\cos(B)\sin(C) - \sin(A)\sin(B)\sin(C)$$

If the quarter-sine phase has `Q-2` bits, then the phase components A and B have a word length of $LA=LB=$`ceil((Q-2)/3)`. Phase component C contains the remaining phase bits. If the phase has 12 bits, then the quarter sine phase has 10 bits, and the components are defined as:

- A, the four most significant bits

  $(0 \le A \le \frac{\pi}{2})$

- B, the next four bits

  $(0 \le B \le \frac{\pi}{2} \times 2^{-4})$

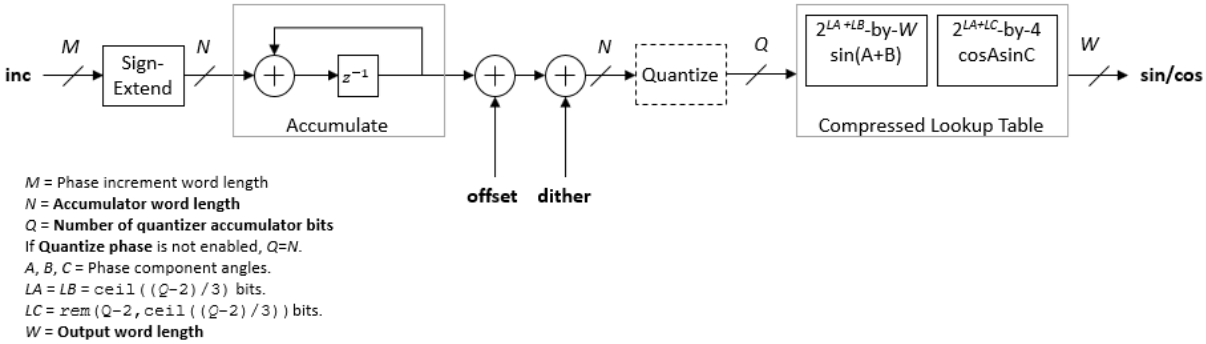
- C, the remaining two least significant bits

  $(0 \le C \le \frac{\pi}{2} \times 2^{-8})$

Given the relative sizes of A, B, and C, the equation can be approximated by:

$$\sin(A + B + C) \approx \sin(A + B) + \cos A \sin C$$

The object implements this equation with one LUT for $\sin(A + B)$ and one LUT for $\cos(A)\sin(C)$. The second term is a fine correction factor that you can truncate to fewer bits without losing precision. Therefore, the second LUT returns a four-bit result.



With the default accumulator size of 16 bits, and the default quantized phase width of 12 bits, the LUTs use $2^8 \times 16$ plus $2^6 \times 4$ bits (4.5 kb). A quarter sine lookup table uses $2^{10} \times 16$ bits (16 kb). This approximation is accurate within one LSB, resulting in an SNR of at least 60 dB on the output. See [1].

dsp.HighpassFilter

Package: dsp

FIR or IIR highpass filter

Description

The dsp.HighpassFilter System object independently filters each channel of the input over time using the given design specifications. You can set the FilterType property of dsp.HighpassFilter to 'FIR' or 'IIR' to implement the object as an FIR or IIR highpass filter.

To filter each channel of your input:

1. Create the dsp.HighpassFilter object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
HPF = dsp.HighpassFilter
HPF = dsp.HighpassFilter(Name,Value)
```

Description

HPF = dsp.HighpassFilter returns a minimum order FIR highpass filter, HPF, with the default filter settings. Calling the object with the default property settings filters the input data with a stopband frequency of 8 kHz, a passband frequency of 12 kHz, a stopband attenuation of 80 dB, and a passband ripple of 0.1 dB.

HPF = dsp.HighpassFilter(Name,Value) returns a highpass filter, with additional properties specified by one or more Name,Value pair arguments. Name is the property

name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`SampleRate` — Input sample rate

`44100` (default) | positive real scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of `'SampleRate'` and a positive real scalar.

Data Types: `single` | `double`

`FilterType` — Filter type

`'FIR'` (default) | `'IIR'`

Filter type, specified as one of the following options:

- `'FIR'` — The object designs an FIR highpass filter.
- `'IIR'` — The object designs an IIR highpass (biquad) filter.

`DesignForMinimumOrder` — Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as the comma-separated pair consisting of `'DesignForMinimumOrder'` and a logical value. If this property is `true`, then `dsp.HighpassFilter` designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is `false`, then the object designs filters with the order that you specify in the `FilterOrder`

property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

`FilterOrder` — Order of the FIR or IIR filter

`50` (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of `'FilterOrder'` and a positive integer scalar.

Dependencies

Specifying a filter order is only valid when the value of `'DesignForMinimumOrder'` is `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandFrequency` — Filter stopband edge frequency

`8000` (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of `'StopbandFrequency'` and a real positive scalar. The value of the stopband edge frequency in Hz must be less than the passband frequency.

Dependencies

You can specify the stopband edge frequency only when `'DesignForMinimumOrder'` is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandFrequency` — Filter passband edge frequency

`12000` (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair consisting of `'PassbandFrequency'` and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the `SampleRate` and greater than `StopbandFrequency`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Minimum attenuation in the stopband

`80` (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of `'StopbandAttenuation'` and a real positive scalar. Minimum attenuation in the stopband defaults to `80` dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandRipple` — Maximum ripple of filter response in the passband
`0.1` (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of `'PassbandRipple'` and a real positive scalar. Maximum ripple of filter response defaults to `0.1` dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

`RoundingMethod` — Rounding method for output fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

`CoefficientsDataType` — Word and fraction lengths of coefficients
`numerictype([],16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

Usage

Syntax

```
y = HPF(x)
```

Description

`y = HPF(x)` highpass filters the input signal, `x`. `y` is a highpass-filtered version of `x`.

Input Arguments

x — Noisy data input

vector | matrix

Noisy data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length. This object accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.HighpassFilter`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Filter coefficients
cost	Estimate cost for implementing filter System objects
grpdelay	Group delay response of discrete-time filter System object
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
measure	Measure frequency response characteristics of filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Impulse and Frequency Response of FIR and IIR Highpass Filters

Create a minimum order FIR highpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 12 kHz, a stopband frequency of 8 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 12e3;
Fstop = 8e3;
```

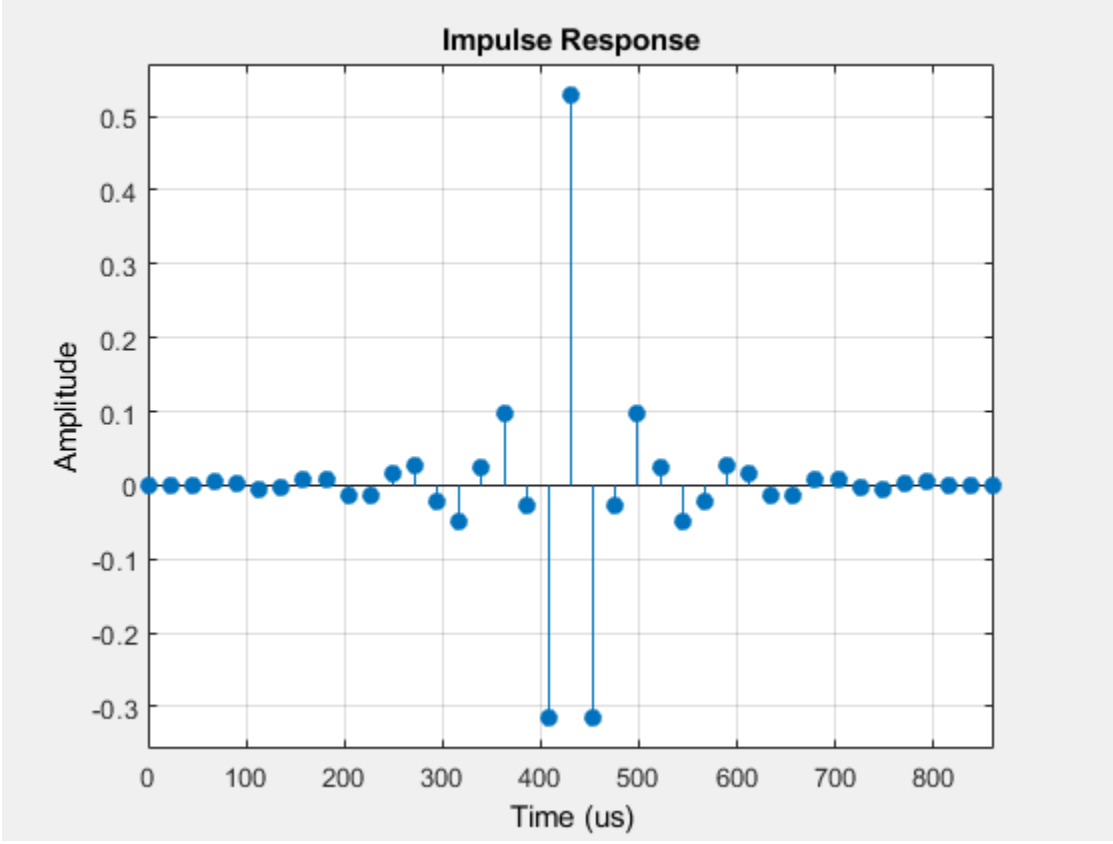
```
Rp = 0.1;
Astop = 80;
FIRHPF = dsp.HighpassFilter('SampleRate',Fs,...
                            'FilterType',filtertype,...
                            'PassbandFrequency',Fpass,...
                            'StopbandFrequency',Fstop,...
                            'PassbandRipple',Rp,...
                            'StopbandAttenuation',Astop);
```

Design a minimum order IIR highpass filter with the same properties as the FIR highpass filter. Use `clone` to create a system object with the same properties as the FIR Highpass filter. Change the `FilterType` property of the cloned filter to `IIR`.

```
IIRHPF = clone(FIRHPF);
IIRHPF.FilterType = 'IIR';
```

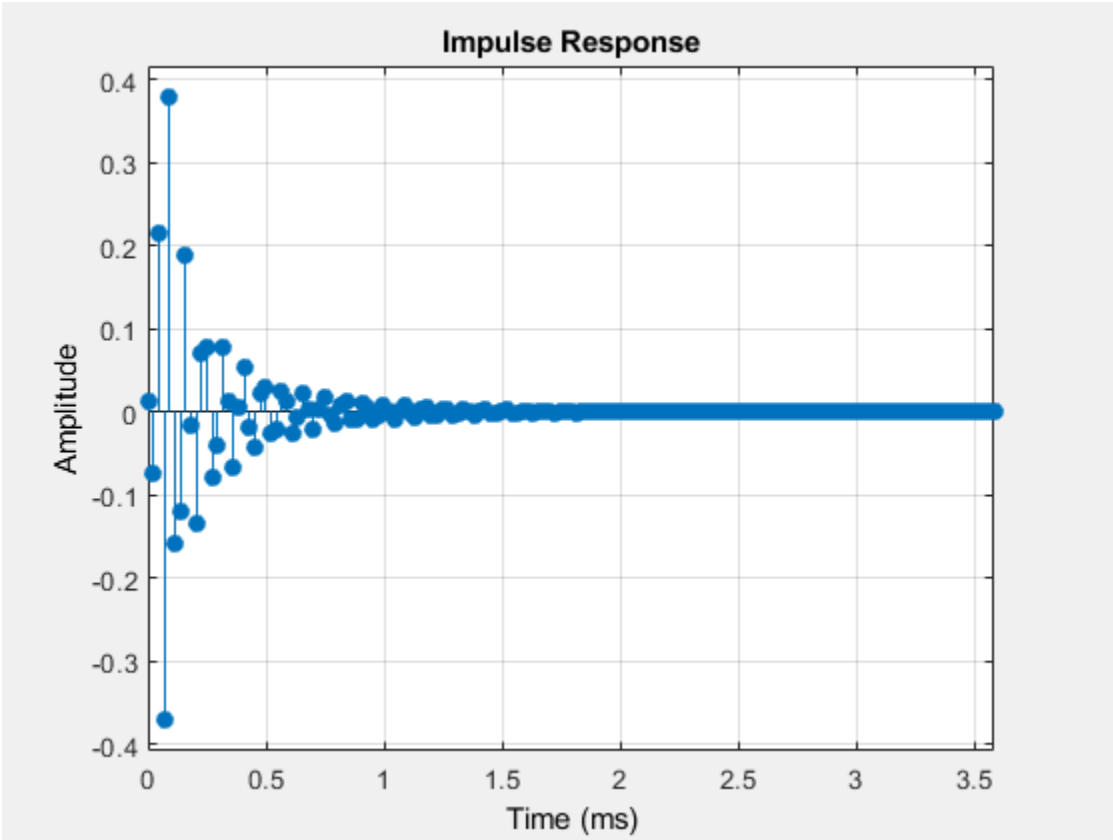
Plot the impulse response of the FIR highpass filter. The zeroth order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR highpass filter is a causal FIR filter

```
fvtool(FIRHPF,'Analysis','impulse')
```



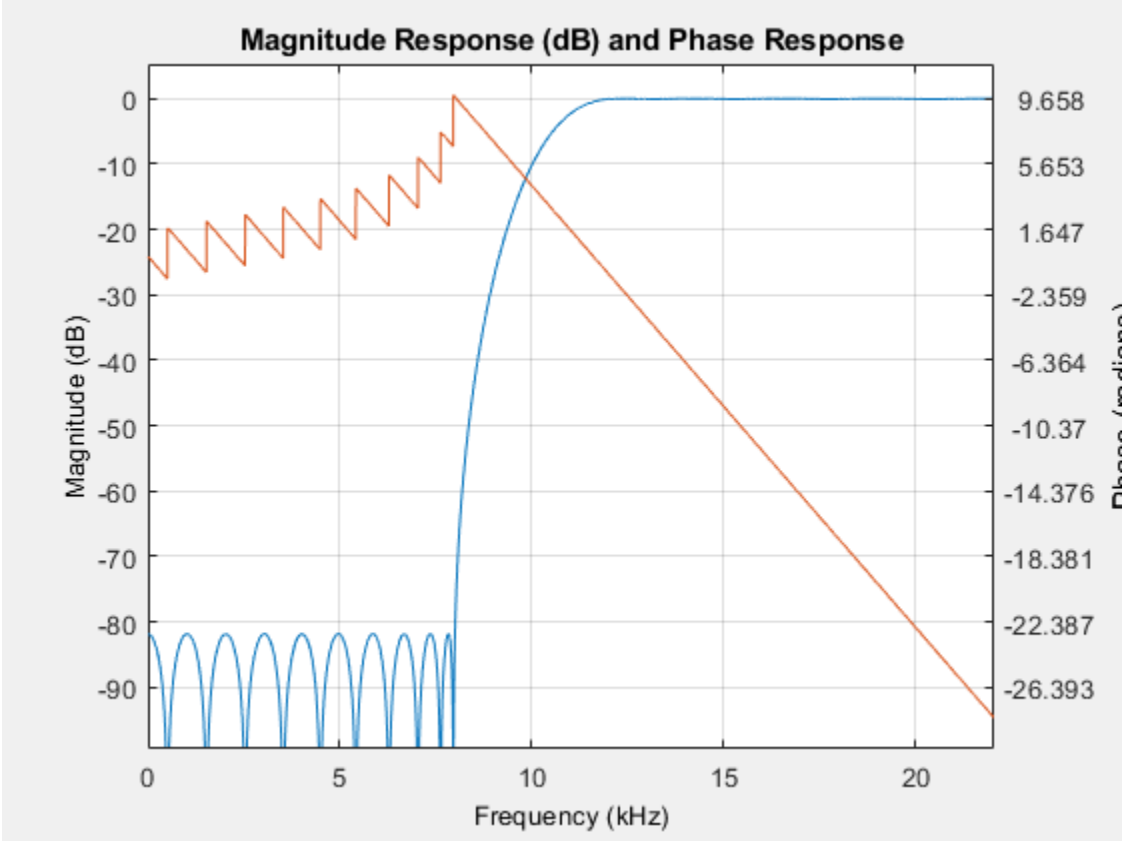
Plot the impulse response of the IIR highpass filter.

```
fvtool(IIRHPF,'Analysis','impulse')
```



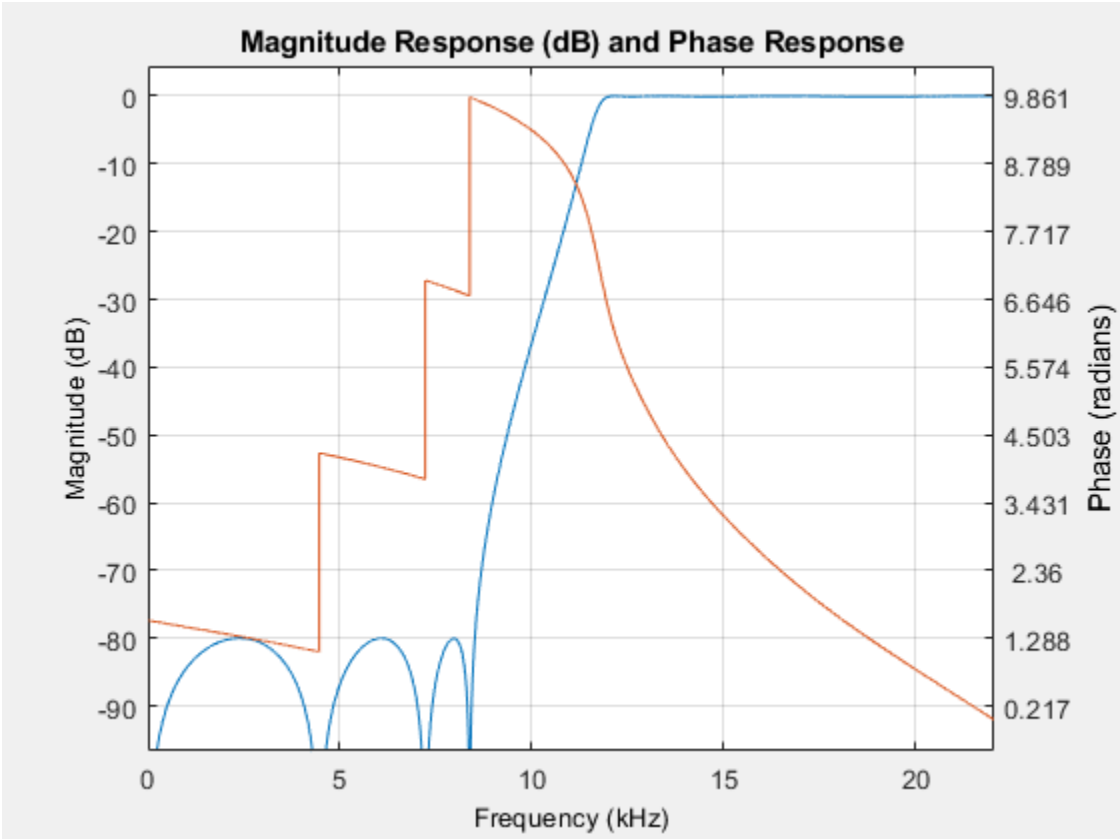
Plot the magnitude and phase response of the FIR highpass filter.

```
fvtool(FIRHPF,'Analysis','freq')
```



Plot the magnitude and phase response of the IIR highpass filter.

```
fvtool(IIRHPF,'Analysis','freq')
```



Calculate the cost of implementing the FIR highpass filter.

```
cost(FIRHPF)
```

```
ans = struct with fields:
                  NumCoefficients: 39
                        NumStates: 38
    MultiplicationsPerInputSample: 39
          AdditionsPerInputSample: 38
```

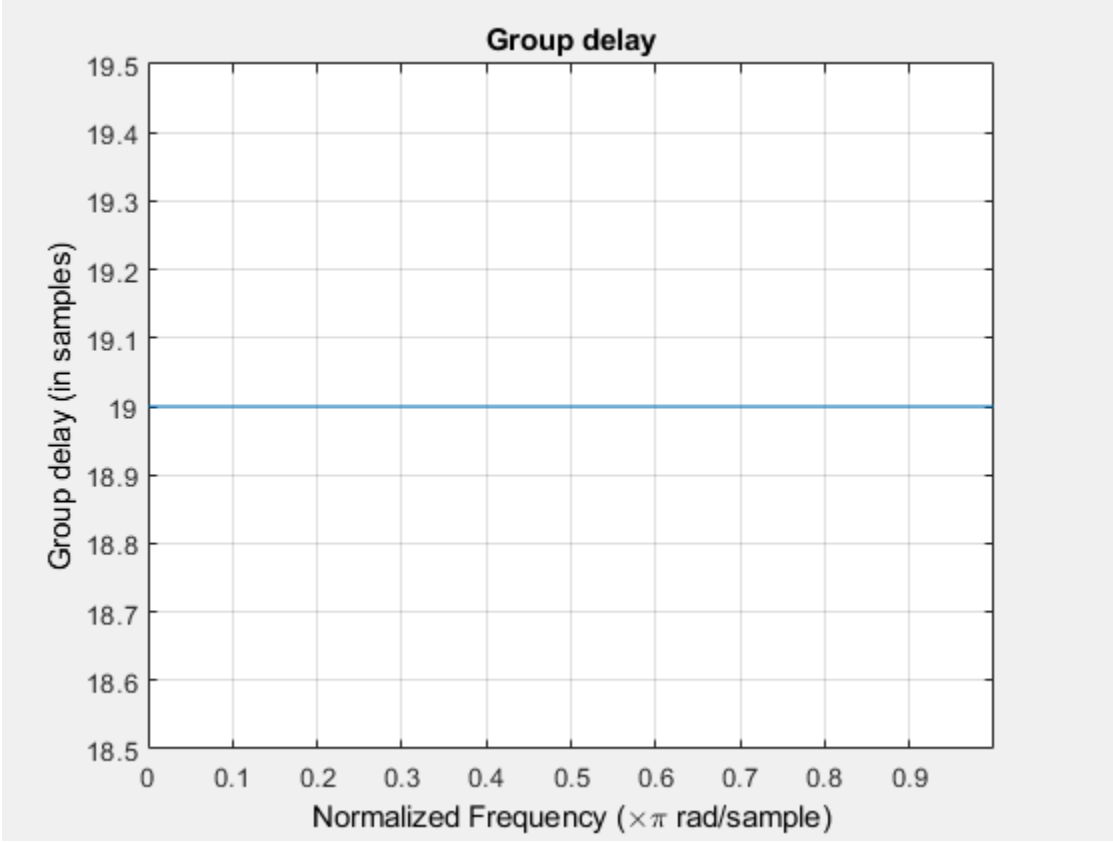
Calculate the cost of implementing the IIR highpass filter. The IIR filter is more efficient to implement than its FIR counterpart.

```
cost(IIRHPF)
```

```
ans = struct with fields:
                  NumCoefficients: 18
                       NumStates: 14
    MultiplicationsPerInputSample: 18
          AdditionsPerInputSample: 14
```

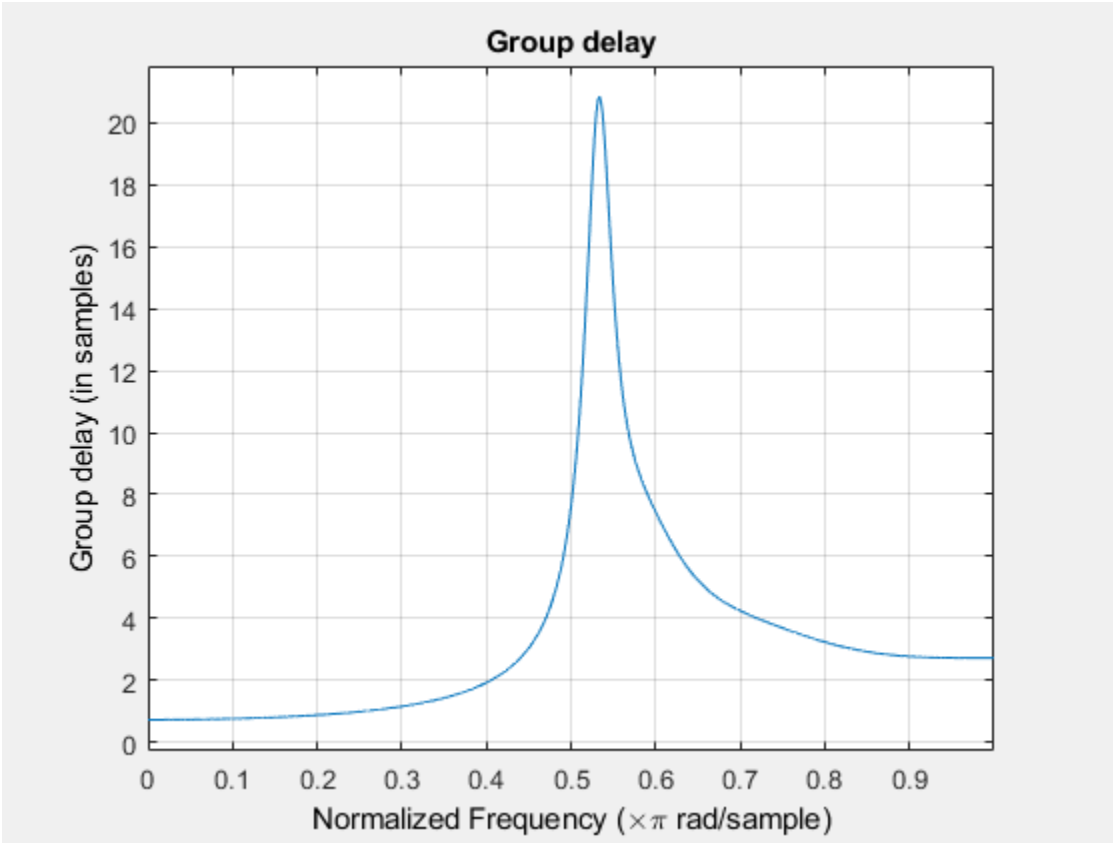
Calculate the group delay of the FIR highpass filter.

```
grpdelay(FIRHPF)
```



Calculate the group delay of the IIR highpass filter. The FIR filter has a constant group delay (linear phase) while its IIR counterpart does not.

```
grpdelay(IIRHPF)
```



Filter White Gaussian Noise with an IIR Highpass filter

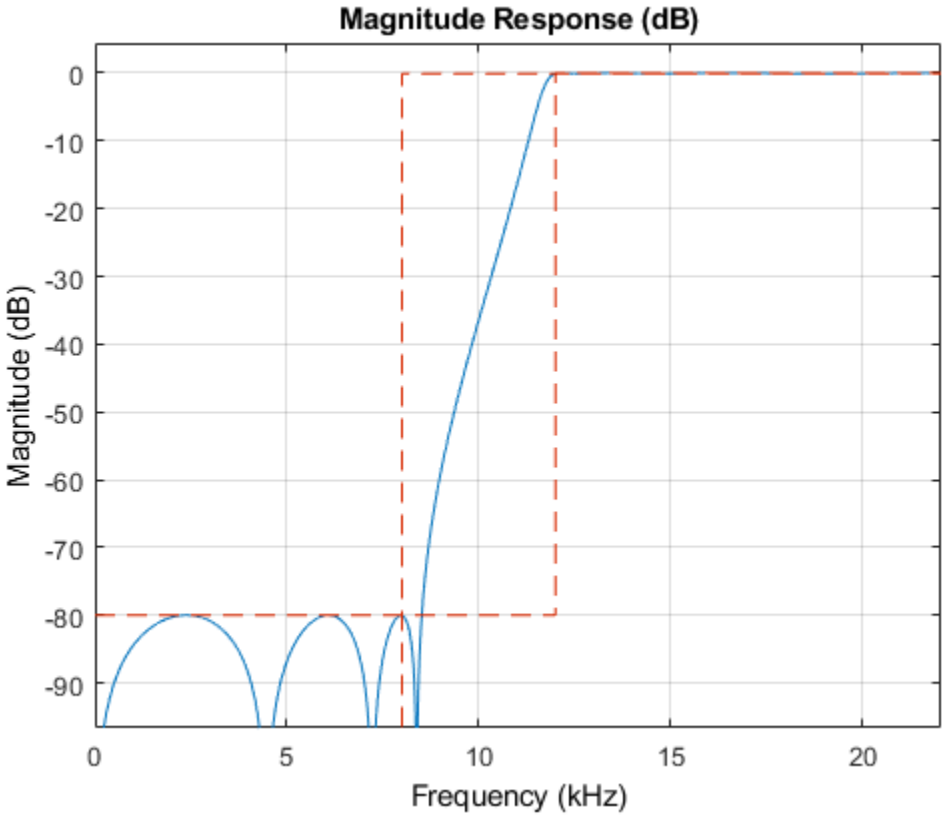
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the IIR highpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 12 kHz, the stopband frequency is 8 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;
filtertype = 'IIR';
Fpass = 12e3;
Fstop = 8e3;
Rp = 0.1;
Astop = 80;
hpf = dsp.HighpassFilter('SampleRate',Fs,...
                         'FilterType',filtertype,...
                         'PassbandFrequency',Fpass,...
                         'StopbandFrequency',Fstop,...
                         'PassbandRipple',Rp,...
                         'StopbandAttenuation',Astop);
```

View the magnitude response of the highpass filter.

```
fvtool(hpf)
```



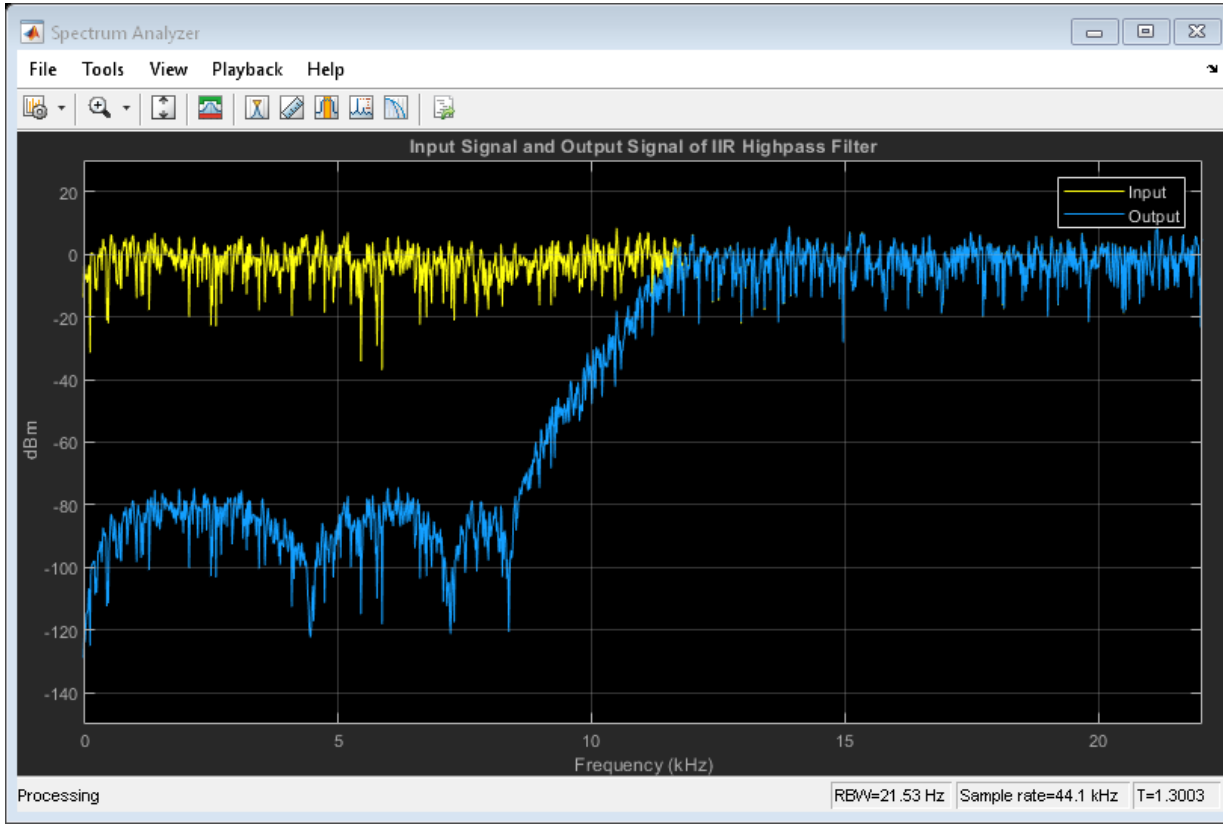
Create a spectrum analyzer object.

```
sa = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
           [-150 30],...
           'Title',...
           'Input Signal and Output Signal of IIR Highpass Filter');
sa.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);
```

```
    Output = hpf(Input);
    sa([Input,Output]);
end
```



Measure Frequency Response Characteristics of Highpass Filter

Measure the frequency response characteristics of a highpass filter. Create a `dsp.HighpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
HPF = dsp.HighpassFilter
```

```
HPF =
  dsp.HighpassFilter with properties:

              FilterType: 'FIR'
    DesignForMinimumOrder: true
        StopbandFrequency: 8000
        PassbandFrequency: 12000
      StopbandAttenuation: 80
           PassbandRipple: 0.1000
              SampleRate: 44100

  Show all properties
```

```
HPFMeas = measure(HPF)
```

```
HPFMeas =
Sample Rate      : 44.1 kHz
Stopband Edge    : 8 kHz
6-dB Point       : 10.418 kHz
3-dB Point       : 10.8594 kHz
Passband Edge    : 12 kHz
Stopband Atten.  : 81.8558 dB
Passband Ripple  : 0.08066 dB
Transition Width : 4 kHz
```

Algorithms

FIR Highpass Filter

When the `FilterType` property is set to `'FIR'`, the `dsp.HighpassFilter` object acts as a FIR highpass filter. In this configuration, `dsp.HighpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct form` structure. You can use `measure` to verify that the design meets the prescribed specifications.

IIR Highpass Filter

When the `FilterType` property is set to `'IIR'`, the `dsp.HighpassFilter` object acts as an IIR highpass filter. In this configuration, this object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to set up a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the `dsp.HighpassFilter` System object. You can use `measure` to verify that the design meets the prescribed specifications.

System Objects
`dsp.LowpassFilter`

Topics
“Analysis Methods for Filter System Objects” on page 3-2

Introduced in R2015a

dsp.Histogram

Package: `dsp`

(To be removed) Histogram of input or sequence of inputs

Description

The `Histogram` object generates a histogram for an input or a sequence of inputs.

Note The `dsp.Histogram` System object will be removed in a future release. Use the `histcounts` function instead. For more information, see “Compatibility Considerations” on page 4-982.

To generate a histogram for an input or a sequence of inputs:

1. Create the `dsp.Histogram` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
hist = dsp.Histogram
hist = dsp.Histogram(min,max,numbins)
hist = dsp.Histogram(Name,Value)
```

Description

`hist = dsp.Histogram` returns a histogram object, `hist`, that computes the frequency distribution of the elements in each input matrix.

`hist = dsp.Histogram(min,max,numbins)` returns a histogram object, `hist`, with the `LowerLimit` property set to `min`, `UpperLimit` property set to `max`, and `NumBins` property set to `numbins`.

`hist = dsp.Histogram(Name,Value)` returns a histogram object, `hist`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`LowerLimit` — Lower boundary

`0` (default) | real scalar

Specify the lower boundary of the lowest-valued bin as a real-valued scalar. `NaN` and `Inf` are not valid values for this property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`UpperLimit` — Upper boundary

`10` (default) | real scalar

Specify the upper boundary of the highest-valued bin as a real-valued scalar. `NaN` and `Inf` are not valid values for this property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`NumBins` — Number of bins in histogram
`11` (default) | positive integer

Specify the number of bins in the histogram.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Dimension` — Dimension
`Column` (default) | `All`

Specify how the histogram calculation is performed over the data as `All` or `Column`.

`Normalize` — Enable output vector normalization
`false` (default) | `true`

Specify whether the histogram object normalizes the output vector, *v*, so that *sum*(*v*) = 1. When you set this property to `true`, the output vector is normalized. When you set it to `false`, the object supports fixed-point operations and does not use this property for normalization.

`RunningHistogram` — Enable calculation over successive calls to algorithm
`false` (default) | `true`

Set this property to `true` to enable running histogram calculations for the input elements over successive calls to the algorithm. Set this property to `false` to compute a histogram for the current input.

`ResetInputPort` — Enable resetting in running histogram mode
`false` (default) | `true`

Set this property to `true` to enable resetting the running histogram. When you set the property to `true`, specify a reset input to the object algorithm that resets the running histogram. When this property is `false`, the histogram object does not reset.

Dependencies

This property applies when you set the `RunningHistogram` property to `true`.

`ResetCondition` — Reset condition for running histogram mode
`Non-zero` (default) | `Rising edge` | `Falling edge` | `Either edge`

Specify the event that resets the running histogram as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

Dependencies

This property applies when you set the `ResetInputPort` property to `true`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

`ProductDataType` — Product word and fraction lengths
`Same as input` (default) | `Custom`

Specify the product fixed-point data type as `Same as input` or `Custom`.

`CustomProductDataType` — Custom product word and fraction lengths
`numerictype([],32,30)` (default) | numerictype

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

`AccumulatorDataType` — Accumulator word and fraction lengths
`Same as input` (default) | `Same as product` | `Custom`

Specify the accumulator fixed-point data type as one of `Same as product`, `Same as input`, or `Custom` |.

`CustomAccumulatorDataType` — Custom accumulator word and fraction lengths
`numerictype([],32,30)` (default) | numerictype

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

Usage

Syntax

```
y = hist(x)
y = hist(x,r)
```

Description

`y = hist(x)` returns a histogram `y` for the input data `x` . When the `RunningHistogram` property is `true`, `y` corresponds to the histogram of the input elements over successive calls to the algorithm.

`y = hist(x,r)` resets the histogram state based on the reset signal, `r` and the object's `ResetCondition` property. You can reset the histogram state only when the `RunningHistogram` and the `ResetInputPort` properties are `true`.

Input Arguments

`x` — Data input
vector | matrix | *N*-D array

Data input, specified as a vector, matrix, or *N*-D array. If `x` is a matrix, each column is treated as an independent channel.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

`r` — Reset signal
scalar

Reset signal, specified as a scalar. The reset signal resets the histogram state based on the value of `r` and the object's `ResetCondition` property.

Dependencies

You can reset the histogram state only when the `RunningHistogram` and the `ResetInputPort` properties are `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `logical`

Output Arguments

y — Histogram output

scalar | vector

Histogram output of the input signal, returned as a scalar, vector, or matrix. The output depends on the setting of `Dimension`:

- `'Column'` –– The object computes the histogram value of each input channel. If the input is a column vector, the output is a scalar. If the input is a multichannel signal, the output signal is 1-by-*N* vector, where *N* is the number of input channels.
- `'All'` –– The object computes the histogram value over all input channels.

Data Types: `single` | `double` | `uint32`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Compute Histogram of Sequence

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compute a histogram with four bins, for possible input values 1 through 4.

```
hist = dsp.Histogram(1,4,4);
y = hist([1 2 2 3 3 3 4 4 4 4]')
```

```
y = 4×1

     1
     2
     3
     4
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Histogram block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.
- The **Find histogram over** block parameter corresponds to the “Dimension” on page 4-0 property of the object.

Compatibility Considerations

`dsp.Histogram` System object will be removed

Warns starting in R2019b

The `dsp.Histogram` System object will be removed in a future release. Use the `histcounts` function instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage (R2016b or Later)	Discouraged Usage (Before R2016b)	Recommended Replacement

`x = [1 2 2 3 3 3 4 4 4 4];`

dsp.IDCT

Package: `dsp`

(To be removed) Inverse discrete cosine transform (IDCT)

Note The `dsp.IDCT` System object™ will be removed in a future release. Use `idct` instead. For more information, see “Compatibility Considerations”.

Description

The `IDCT` object computes the inverse discrete cosine transform (IDCT) of an input.

To compute the IDCT of an input:

1. Define and set up your IDCT object. See “Construction” on page 4-984.
2. Call `step` to compute the IDCT of an input according to the properties of `dsp.IDCT`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`idct = dsp.IDCT` returns a inverse discrete cosine transform (IDCT) object, `idct`. This object computes the IDCT of a real or complex input signal using the `Table lookup` method.

`idct = dsp.IDCT('PropertyName',PropertyValue,...)` returns an inverse discrete cosine transform (IDCT) object, `idct`, with each property set to the specified value.

Properties

`SineComputation`

Method to compute sines and cosines

Specify how the IDCT object computes the trigonometric function values as `Trigonometric function` or `Table lookup`. You must set this property to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` property to `Table lookup`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

`SineTableDataType`

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

`CustomSineTableDataType`

Sine table word length

Specify the sine table fixed-point type as a signed, unscaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numerictype(true,16)`.

`ProductDataType`

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numerictype(true,32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numerictype(true,32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision` , `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the “OutputDataType” on page 4-0 property to `Custom`. The default is`numerictype(true,16,15)`.

Methods

step Inverse discrete cosine transform (IDCT) of input

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Analyze the Energy Content in a Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
dct = dsp.DCT;
X = dct(x);
```

Set the DCT coefficients which represent less than 0.1% of the total energy to 0 and reconstruct the sequence using IDCT.

```
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end
```

```
disp(['Number of DCT coefficients that represent 99.9%',...
    'of the total energy in the sequence: ',num2str(ii)]);
```

```
Number of DCT coefficients that represent 99.9%of the total energy in the sequence: 10
```

```
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
idct = dsp.IDCT;
xt = idct(XXt);
plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
    'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the IDCT block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`dsp.IDCT` System object will be removed

Warns starting in R2019a

The `dsp.IDCT` System object will be removed in a future release. Use `idct` instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

If your code has this form (R2016b or later):	If your code has this form (prior to R2016b):	Use this code instead:

`idctObj = dsp.IDCT;`
`xt = idctObj(X);`
 	
The variable, *X* represents the DCT of a time-domain signal.
	`idctObj = dsp.IDCT;`
	`xt = step(idctObj,X);`
		`xt = idct(X);`

Extended Capabilities

Functions
`idct`

System Objects
`dsp.FFT` | `dsp.IFFT`.

Introduced in R2012a

step

System object: `dsp.IDCT`
Package: `dsp`

Inverse discrete cosine transform (IDCT) of input

Syntax

```
Y = step(idct,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(idct,X)` computes the inverse discrete cosine transform, `Y` , of input `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.IFFT

Package: `dsp`

Inverse discrete Fourier transform (IDFT)

Description

The `dsp.IFFT` System object computes the inverse discrete Fourier transform (IDFT) of the input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen from FFTW [1], [2]

To compute the IFFT of the input:

1. Create the `dsp.IFFT` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
ift = dsp.IFFT
ift = dsp.IFFT(Name,Value)
```

Description

`ift = dsp.IFFT` returns an `IFFT` object, `ift`, that computes the IDFT of a column vector or *N*-D array. For column vectors or N-D arrays, the `IFFT` object computes the IDFT along the first dimension of the array. If the input is a row vector, the `IFFT` object computes a row of single-sample IDFTs and issues a warning.

`ift = dsp.IFFT(Name,Value)` returns an `IFFT` object, `ift`, with each property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`FFTImplementation` — FFT implementation
`Auto` (default) | `Radix-2` | `FFTW`

Specify the implementation used for the FFT as `Auto`, `Radix-2`, or `FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

`BitReversedInput` — Enable bit-reversed order interpretation of input elements
`false` (default) | `true`

Set this property to `true` if the order of Fourier transformed input elements to the `IFFT` object are in bit-reversed order. The default is `false`, which denotes linear ordering.

Dependencies

This property applies only when the `FFTLengthSource` property is `Auto`.

`ConjugateSymmetricInput` — Enable conjugate symmetric interpretation of input
`false` (default) | `true`

Set this property to `true` if the input is conjugate symmetric to yield real-valued outputs. The discrete Fourier transform of a real valued sequence is conjugate symmetric, and setting this property to `true` optimizes the IDFT computation method. Setting this property to `false` for conjugate symmetric inputs may result in complex output values with nonzero imaginary parts. This occurs due to rounding errors. Setting this property to `true` for nonconjugate symmetric inputs results in invalid outputs.

Dependencies

This property applies only when the `FFTLengthSource` property is `Auto`.

`Normalize` — Enable dividing output by FFT length

`true` (default) | `false`

Specify whether to divide the IFFT output by the FFT length. The default is `true` and each element of the output is divided by the FFT length.

`FFTLengthSource` — Source of FFT length

`Auto` (default) | `Property`

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal.

Dependencies

This property applies only when both the `BitReversedInput` and `ConjugateSymmetricInput` properties are `false`.

`FFTLength` — FFT length

`64` (default) | integer

Specify the FFT length as an integer greater than or equal to 2.

This property must be a power of two if any of these conditions apply:

- The input is a fixed-point data type.
- The FFTImplementation property is `Radix-2`.

Dependencies

This property applies when you set the `BitReversedInput` and `ConjugateSymmetricInput` properties to `false`, and the `FFTLengthSource` property to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WrapInput` — Boolean value of wrapping or truncating input
`true` (default) | `false`

Wrap input data when `FFTLength` is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given `FFTLength` is shorter than the input length. If this property is set to false, truncation of the input data to the `FFTLength` occurs before the FFT operation.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

`SineTableDataType` — Sine table word and fraction lengths
`Same word length as input` (default) | `Custom`

Specify the sine table data type as `Same word length as input` or `Custom`.

`CustomSineTableDataType` — Sine table word and fraction lengths
`numerictype([],16)` (default) | numerictype

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `SineTableDataType` property to `Custom`.

`ProductDataType` — Product word and fraction lengths
`Full precision` (default) | `Same as input` | `Custom`

Specify the product data type as `Full precision`, `Same as input`, or `Custom`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype([],32,30)` (default) | numerictype

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

`AccumulatorDataType` — Accumulator word and fraction lengths
`Full precision` (default) | `Same as input` | `Same as product` | `Custom`

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype([],32,30)` (default) | numerictype

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

`OutputDataType` — Output word and fraction lengths
`Full precision` (default) | `Same as input` | `Custom`

Specify the output data type as `Full precision`, `Same as input`, or `Custom`.

`CustomOutputDataType` — Output word and fraction lengths
`numerictype([],16,15)` (default) | numerictype

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage

Syntax

```
y = ift(x)
```

Description

`y = ift(x)` computes the inverse discrete Fourier transform (IDFT) , `y`, of the input `x` along the first dimension of `x`.

Input Arguments

x — Data input

vector | matrix | *N*-D array

Data input, specified as a vector, matrix, or *N*-D array.

When the `FFTLengthSource` property is `Auto`, the length of `x` along the first dimension must be a positive integer power of two. When the `FFTLengthSource` property is `'Property'`, the length of `x` along the first dimension can be any positive integer and the `FFTLength` property must be a positive integer power of two.

Variable-size input signals are only supported when the `FFTLengthSource` property is set to `'Auto'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Inverse discrete Fourier transform of input signal

vector | matrix | *N*-D array

Inverse discrete Fourier transform of input signal, returned as a vector, matrix, or *N*-D array.

When `FFTLengthSource` property is set to `'Auto'`, the FFT length is same as the number of rows in the input signal. When `FFTLengthSource` property is set to `'Property'`, the FFT length is specified through the `FFTLength` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj(x))`.

Consider a time-domain signal $x[n]$, which is defined over the finite time interval $0 \le n \le N-1$. The energy of the signal $x[n]$ is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT coefficients, $X[k]$, are considered signal values in the frequency domain. The energy of the signal $x[n]$ in the frequency-domain is therefore the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N}\sum_{k=0}^{N-1}|X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1}|x[n]|^2 = \frac{1}{N}\sum_{k=0}^{N-1}|X[k]|^2$$

Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLengthSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2, so select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,'PhaseOffset',10,...
    'SampleRate',44100,'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW','ConjugateSymmetricInput',true);
rng(1);
```

Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients that constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;
```

```
    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort(((1/L)*FFTCoeffMagSq),1,'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReconstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
```

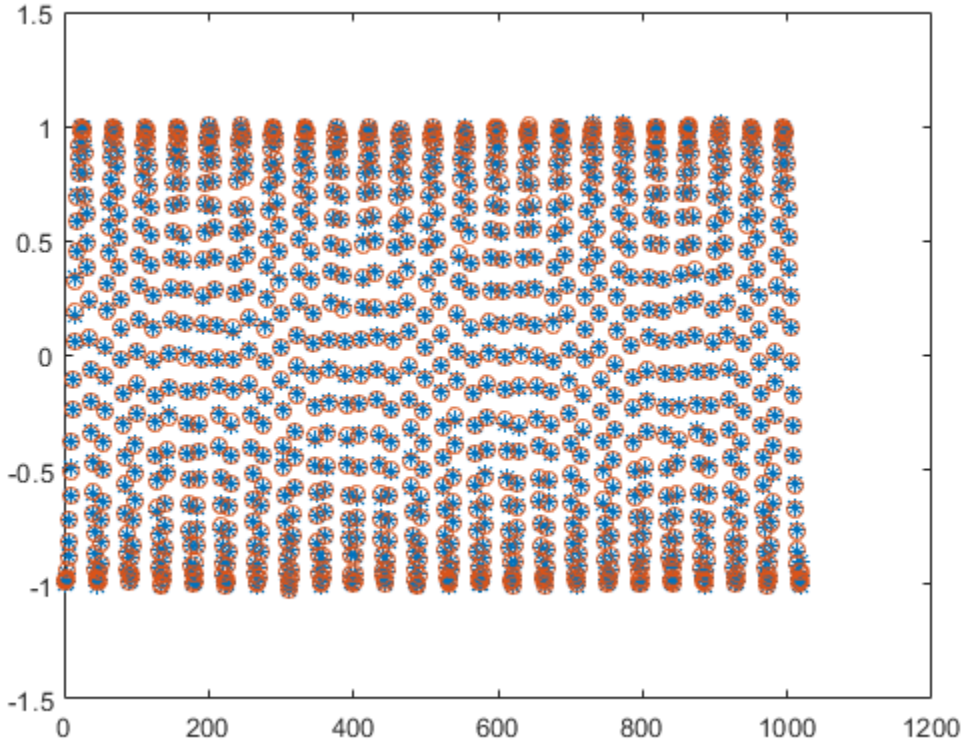
```
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input,'*');
hold on;
plot(ReconstrSignal,'o');
hold off;
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the IFFT block reference page. The object properties correspond to the block parameters, except the **Output sampling mode** parameter is not supported by `dsp.IFFT`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - `FFTImplementation` is set to `'FFTW'`.
  - `FFTImplementation` is set to `'Auto'`, `FFTLengthSource` is set to `'Property'`, and `FFTLength` is not a power of two.

  Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Introduced in R2012a

dsp.IIRFilter

Package: `dsp`

Infinite impulse response (IIR) filter

Description

The `dsp.IIRFilter` System object filters each channel of the input using the specified filter. You can specify the filter to have a `'Direct form I'`, `'Direct form I transposed'`, `'Direct form II'`, or `'Direct form II transposed'` structure.

Use the “Numerator” on page 4-0 and “Denominator” on page 4-0 properties to specify the coefficients of the filter numerator and denominator coefficients. In addition to these coefficients, you can also specify nonzero initial filter states through the “InitialConditions” on page 4-0 property.

To filter a signal using an IIR filter:

1. Create the `dsp.IIRFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
iir = dsp.IIRFilter
iir = dsp.IIRFilter(Name,Value)
```

Description

`iir = dsp.IIRFilter` creates an infinite impulse response (IIR) filter System object that independently filters each channel of the input over time using a specified IIR filter implementation.

`iir = dsp.IIRFilter(Name,Value)` creates an IIR filter object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: iir = dsp.IIRFilter('Structure','Direct form I');

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Structure` — IIR filter structure

`'Direct form II transposed'` (default) | `'Direct form I'` | `'Direct form I transposed'` | `'Direct form II'`

IIR filter structure, specified as `'Direct form I'`, `'Direct form I transposed'`, `'Direct form II'`, or `'Direct form II transposed'`.

`Numerator` — Numerator coefficients

`[1 1]` (default) | row vector

Numerator coefficients, specified as a row vector.

Example: `[0.0296 0.1775 0.4438 0.5918 0.4438 0.1775 0.0296]`

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`Denominator` — Denominator coefficients

`[1 0.1]` (default) | row vector

Denominator coefficients, specified as a row vector.

Example: `[1.0000 -0.0000 0.7777 -0.0000 0.1142 -0.0000 0.0018]`

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`InitialConditions` — Initial conditions

`0` (default) | scalar | vector | matrix

Initial conditions of the filter states, specified as one of the following:

- scalar –– The object initializes all delay elements in the filter to the scalar value.
- vector –– The length of the vector equals the number of delay elements in the filter. Each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector to each channel of the input signal.
- matrix –– The number of rows in the matrix must equal the number of delay elements in the filter. The number of columns in the matrix must equal the number of channels in the input. Each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

The number of filter states equals max(N,M) – 1, where N is the number of poles, and M is the number of zeros.

Tunable: Yes

Dependencies

This property applies only when you set the "Structure" on page 4-0 property to `'Direct form II'` or `'Direct form II transposed'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`NumeratorInitialConditions` — Initial conditions on zeros side

`0` (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the zeros, specified as one of the following:

- scalar –– The object initializes all delay elements on the zeros side in the filter to the scalar value.
- vector –– The length of the vector equals the number of delay elements on the zeros side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the zeros side. The object applies the same vector of initial conditions to each channel of the input signal.
- matrix –– The number of rows in the matrix must equal the number of delay elements on the zeros side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

The number of filter states equals max(N,M) – 1, where N is the number of poles, and M is the number of zeros, respectively.

Tunable: Yes

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to `'Direct form I'` or `'Direct form I transposed'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`DenominatorInitialConditions` — Initial conditions on poles side

`0` (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the poles, specified as one of the following:

- scalar –– The object initializes all delay elements on the poles side in the filter to the scalar value.
- vector –– The length of the vector equals the number of delay elements on the poles side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the poles side. The object applies the same vector of initial conditions to each channel of the input signal.

- matrix –– The number of rows in the matrix must equal the number of delay elements on the poles side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

The number of filter states equals max(N,M) – 1, where N is the number of poles, and M is the number of zeros, respectively.

Tunable: Yes

Dependencies

This property applies only when you set the "Structure" on page 4-0 property to `'Direct form I'` or `'Direct form I transposed'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

Fixed-Point Properties

`RoundingMethod` — Rounding method

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Select the rounding mode for fixed-point operations.

`OverflowAction` — Overflow action

`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` –– The object wraps the result of its fixed-point operations.
- `'Saturate'` –– The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

`StateDataType` — State data type

`'Same as input'` (default) | `'Custom'`

State data type, specified as one of the following:

- `'Same as input'` –– The state data type is same as the input data type.
- `'Custom'` –– The state output data type is an autosigned numeric type through the "CustomStateDataType" on page 4-0 property.

`CustomStateDataType` — State word and fraction lengths
`numerictype([],16,15)` (default)

State word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set "StateDataType" on page 4-0 to `'Custom'`.

`NumeratorCoefficientsDataType` — Data type of numerator coefficients
`'Same word length as input'` (default) | `'Custom'`

Data type of numerator coefficients, specified as one of the following:

- `'Same word length as input'` –– The word length of the numerator coefficients is the same as the input word length. The fraction length is chosen to give the best possible precision.
- `'Custom'` –– The data type of the numerator coefficients is the autosigned numeric type specified by the "CustomNumeratorCoefficientsDataType" on page 4-0 property.

`CustomNumeratorCoefficientsDataType` — Word and fraction lengths of the numerator coefficients
`numerictype([],16,15)` (default)

Word and fraction lengths of the numerator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set "NumeratorCoefficientsDataType" on page 4-0 to `'Custom'`.

`DenominatorCoefficientsDataType` — Data type of the denominator coefficients
`'Same word length as input'` (default) | `'Custom'`

Data type of the denominator coefficients, specified as one of the following:

- `'Same word length as input'` –– The word length of the denominator coefficients is the same as that of the input word length. The fraction length is chosen to give the best possible precision.
- `'Custom'` –– The data type of the denominator coefficients is the autosigned numeric type specified by the "CustomDenominatorCoefficientsDataType" on page 4-0 property.

`CustomDenominatorCoefficientsDataType` — Word and fraction lengths of denominator coefficients

`numerictype([],16,15)` (default)

Word and fraction lengths of denominator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set "DenominatorCoefficientsDataType" on page 4-0 to `'Custom'`.

`NumeratorProductDataType` — Numerator product data type

`'Full precision'` (default) | `'Same as input'` | `'Custom'`

Data type of the output of a product operation in the numerator polynomial of the IIR filter, specified as one of the following:

- `'Full precision'` –– The object computes the numerator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Same as input'` –– The product output data type is the same as the input data type.
- `'Custom'` –– The product output data type is the custom numeric type specified by the "CustomNumeratorProductDataType" on page 4-0 property. The rounding method and the overflow action are specified by the "RoundingMethod" on page 4-0 and "OverflowAction" on page 4-0 properties.

`CustomNumeratorProductDataType` — Numerator product word and fraction lengths

`numerictype([],32,30)` (default)

Numerator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “NumeratorProductDataType” on page 4-0 to `'Custom'`.

`DenominatorProductDataType` — Denominator product data type

`'Full precision'` (default) | `'Same as input'` | `'Custom'`

Data type of the output of a product operation in the denominator polynomial of the IIR filter, specified as one of the following:

- `'Full precision'` –– The object computes the denominator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Same as input'` –– The product output data type is the same as the input data type.
- `'Custom'` –– The product output data type is custom numeric type specified by the “CustomDenominatorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

`CustomDenominatorProductDataType` — Denominator product word and fraction lengths

`numerictype([],32,30)` (default)

Denominator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “DenominatorProductDataType” on page 4-0 to `'Custom'`.

`NumeratorAccumulatorDataType` — Numerator accumulator data type

`'Full precision'` (default) | `'Same as input'` | `'Same as product'` | `'Custom'`

Data type of the output of an accumulation operation in the numerator polynomial of the IIR filter, specified as one of the following:

- `'Full precision'` –– The object computes the numerator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point

numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.

- `'Same as input'` –– The accumulator data type is the same as the input data type.
- `'Same as product'` –– The accumulator data type is the same as the product output data type.
- `'Custom'` –– The accumulator data type is the custom numeric type specified by the "CustomNumeratorAccumulatorDataType" on page 4-0 property. The rounding method and the overflow action are specified by the "RoundingMethod" on page 4-0 and "OverflowAction" on page 4-0 properties.

`CustomNumeratorAccumulatorDataType` — Numerator accumulator word and fraction lengths

`numerictype([],32,30)` (default)

Numerator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set "NumeratorAccumulatorDataType" on page 4-0 to `'Custom'`.

`DenominatorAccumulatorDataType` — Denominator accumulator data type

`'Full precision'` (default) | `'Same as input'` | `'Same as product'` | `'Custom'`

Data type of the output of an accumulation operation in the denominator polynomial of the IIR filter, specified as one of the following:

- `'Full precision'` –– The object computes the denominator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Same as input'` –– The accumulator data type is the same as the input data type.
- `'Same as product'` –– The accumulator data type is the same as the product output data type.
- `'Custom'` –– The accumulator data type is the custom numeric type specified by the "CustomDenominatorAccumulatorDataType" on page 4-0 property. The rounding method and the overflow action are specified by the "RoundingMethod" on page 4-0 and "OverflowAction" on page 4-0 properties.

`CustomDenominatorAccumulatorDataType` — Denominator accumulator word and fraction lengths

`numerictype([],32,30)` (default)

Denominator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set "DenominatorAccumulatorDataType" on page 4-0 to `'Custom'`.

`OutputDataType` — Output data type

`'Same as input'` (default) | `'Full precision'` | `'Custom'`

Data type of the output of the `dsp.IIRFilter` object, specified as one of the following:

- `'Same as input'` –– The output data type is the same as the input data type.
- `'Full precision'` –– The object computes the output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Custom'` –– The output data type is the custom numeric type specified by the "CustomOutputDataType" on page 4-0 property. The rounding method and the overflow action are specified by the "RoundingMethod" on page 4-0 and "OverflowAction" on page 4-0 properties.

`CustomOutputDataType` — Output word and fraction lengths

`numerictype([],16,15)` (default)

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set "OutputDataType" on page 4-0 to `'Custom'`.

`MultiplicandDataType` — Multiplicand data type

`'Same as input'` (default) | `'Custom'`

Multiplicand data type, specified as one of the following:

- `'Same as input'` –– The multiplicand data type is the same as the input data type.
- `'Custom'` –– The multiplicand data type is the autosigned numeric type specifies by the “CustomMultiplicandDataType” on page 4-0 property.

`CustomMultiplicandDataType` — Multiplicand output word and fraction lengths
`numerictype([],16,15)` (default)

Multiplicand output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “MultiplicandDataType” on page 4-0 to `'Custom'`.

Usage

Syntax

```
iirOut = iir(input)
```

Description

`iirOut = iir(input)` filters the input signal using the specified filter to produce the filtered output. The System object filters each column of the input signal independently over time.

Input Arguments

`input` — Data input
vector | matrix

Data input that is filtered, specified as a vector or matrix.

Example: `randn(34,24)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

`iirOut` — Filtered output
vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the outpout match that of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.IIRFilter

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
impz	Impulse response of discrete-time filter System object
phasez	Unwrapped phase response for filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.IIRFilter.helpFilterAnalysis` in the MATLAB command prompt. For the corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Filter Noisy Signal Using IIR Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

View the magnitude response of the IIR filter. Use the `Spectrum Analyzer` to display the power spectrum of the output signal.

Initialization

```
x = randn(2048,1);
x = x-mean(x);
src = dsp.SignalSource;
src.Signal = x;
sink = dsp.SignalSink;

N = 10;
Fc = 0.4;
[b,a] = butter(N,Fc);
iir = dsp.IIRFilter('Numerator',b,'Denominator',a);

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent',80,'PowerUnits','dBW',...
    'YLimits',[-220 -10]);
```

Filter the Signal

```
while ~isDone(src)
  input = src();
  output = iir(input);
  sa(output)
  sink(output);
end

Result = sink.Buffer;
fvtool(iir,'Fs',8000)
```

Design an IIR Filter

This example shows the two ways of designing an IIR filter.

Design the filter using `fdesign` and `design`.

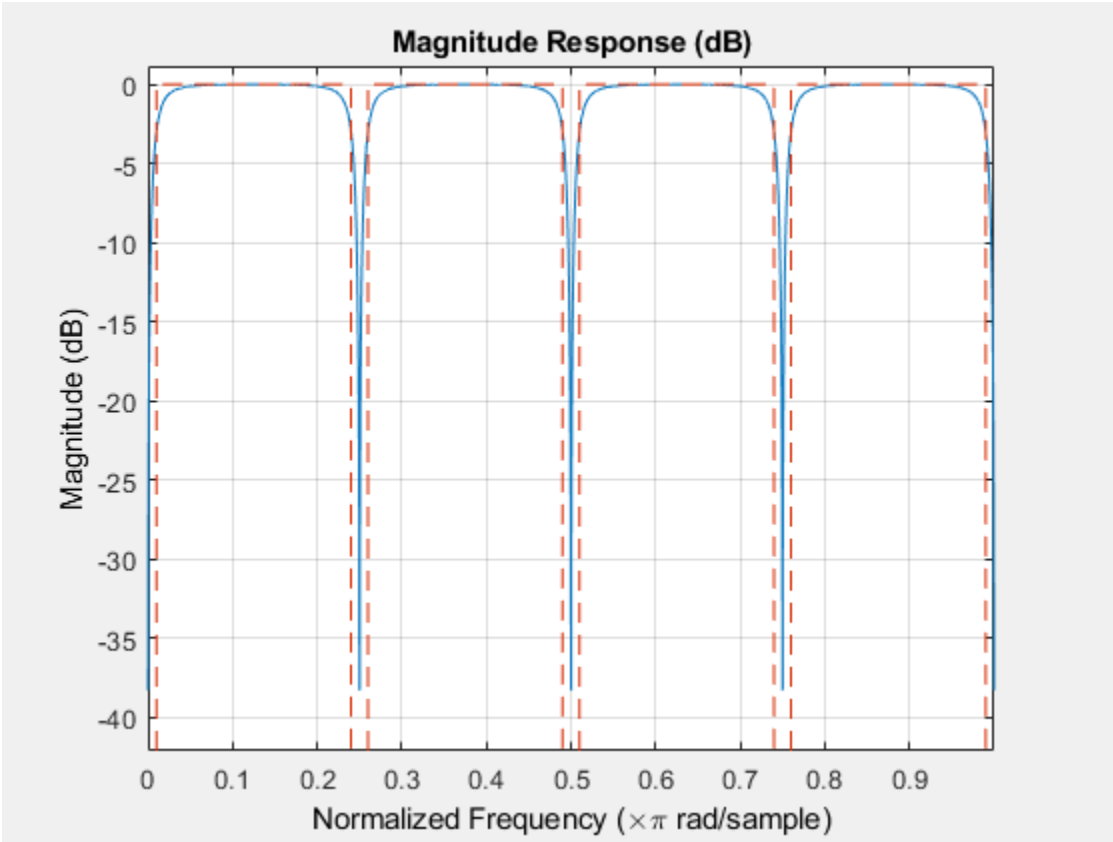
```
D = fdesign.comb('notch','N,BW',8,0.02);
iir = design(D,'systemobject',true)
```

```
iir =
  dsp.IIRFilter with properties:
```

```
            Structure: 'Direct form II'
            Numerator: [0.8878 0 0 0 0 0 0 0 -0.8878]
          Denominator: [1 0 0 0 0 0 0 0 -0.7757]
    InitialConditions: 0

  Show all properties
```

```
fvtool(iir);
```



Design the filter using filter coefficients.

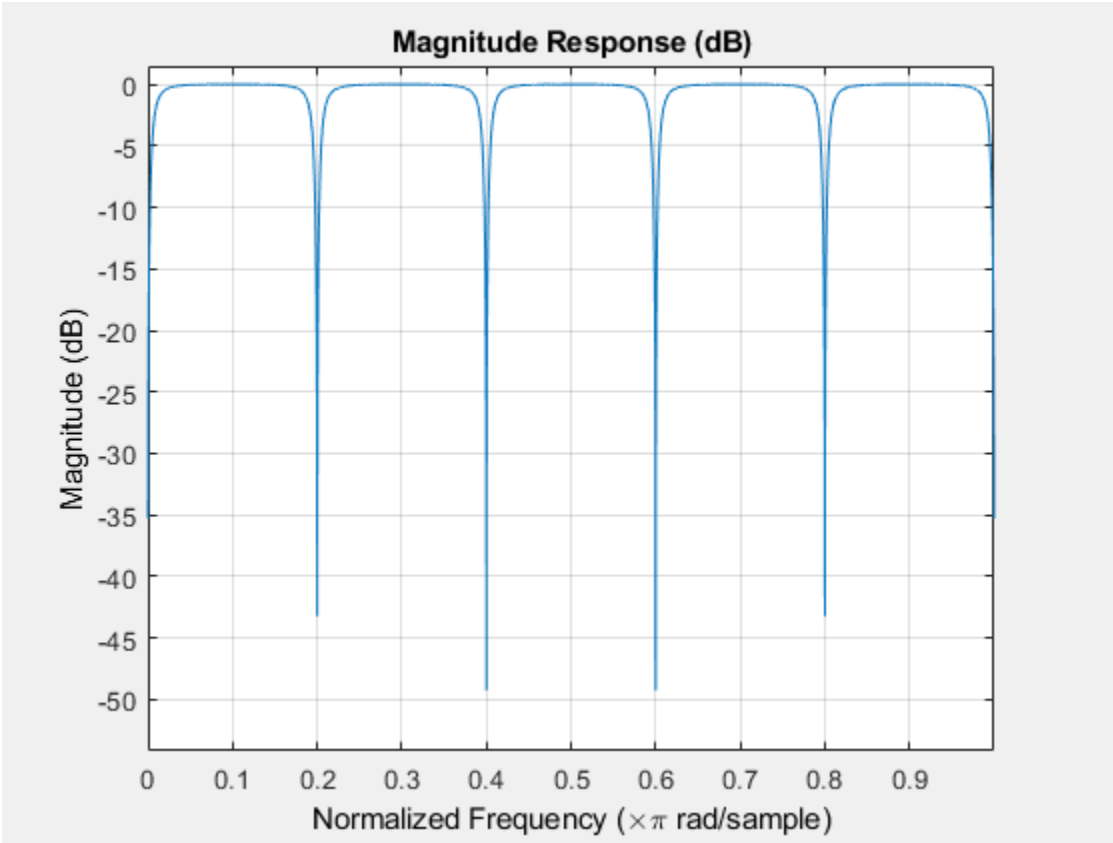
```
b = [0.9 zeros(9,1)' -0.9];
a = [1 zeros(9,1)' -0.8];
iir = dsp.IIRFilter('Numerator',b,'Denominator',a)
```

```
iir =
  dsp.IIRFilter with properties:

              Structure: 'Direct form II transposed'
              Numerator: [0.9000 0 0 0 0 0 0 0 0 0 -0.9000]
            Denominator: [1 0 0 0 0 0 0 0 0 0 -0.8000]
      InitialConditions: 0

  Show all properties
```

```
fvtool(iir);
```



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

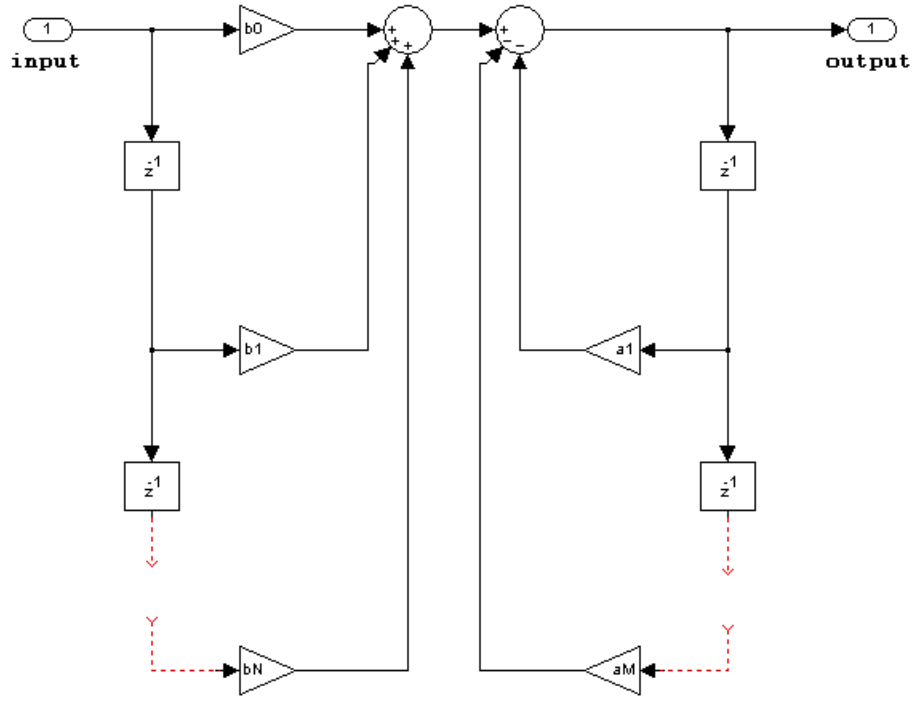
- Only the `Numerator` and `Denominator` properties are tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The `dsp.IIRFilter` System object supports the following filter structures. The diagrams in each section show the data types used in the filter structures for fixed-point signals. You can set the data types using the fixed-point properties of the object.

Direct form I



The following constraints apply when the `Structure` property is set to `'Direct form I'`:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- The State data type cannot be specified for this structure. Doing so is not possible because the input and output states have the same data types as the input and output buffers.

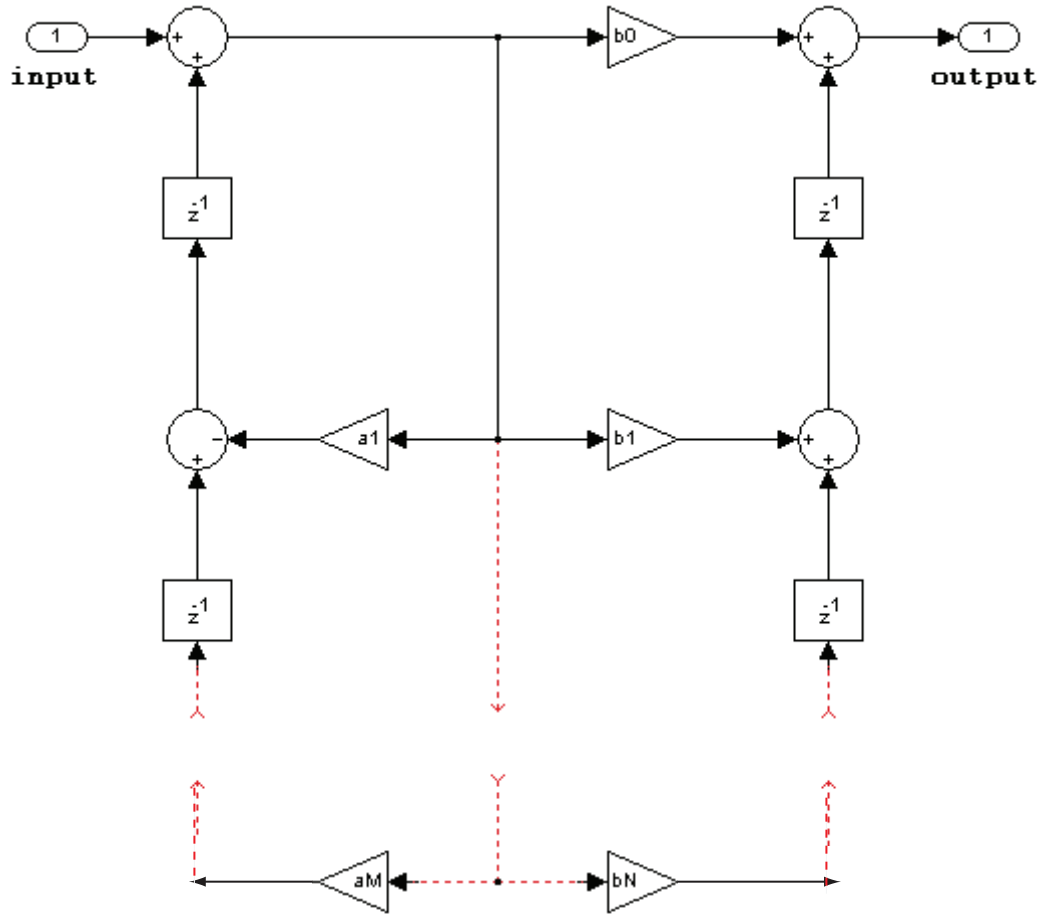
Direct form I transposed



The following constraints apply when the `Structure` property is set to `'Direct form I transposed'`:

- Inputs can be real or complex.

- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.

dsp.IIRHalfbandDecimator

Package: `dsp`

Decimate by factor of two using polyphase IIR

Description

The `dsp.IIRHalfbandDecimator` System object performs efficient polyphase decimation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the `dsp.IIRHalfbandDecimator` object to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

To filter and downsample your data:

1. Create the `dsp.IIRHalfbandDecimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
iirhalfbanddecim = dsp.IIRHalfbandDecimator
iirhalfbanddecim = dsp.IIRHalfbandDecimator(Name,Value)
```

Description

`iirhalfbanddecim = dsp.IIRHalfbandDecimator` returns a halfband decimator, `iirhalfbanddecim`, with the default settings. Under the default settings, the System object filters and downsamples the input data with a halfband frequency of `22050` Hz, a transition width of `4100` Hz, and a stopband attenuation of `80` dB.

`iirhalfbanddecim = dsp.IIRHalfbandDecimator(Name,Value)` returns an IIR halfband decimator, with additional properties specified by one or more `Name,Value` pair arguments.

Example: `iirhalfbanddecim = dsp.IIRHalfbandDecimator('Specification','Filter order and stopband attenuation')` creates an IIR halfband decimator object with filter order set to `9` and stopband attenuation set to `80` dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Specification` — Filter design parameters

`'Transition width and stopband attenuation'` (default) | `'Filter order and stopband attenuation'` | `'Filter order and transition width'` | `'Coefficients'`

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to `'Coefficients'`, you can specify the coefficients directly.

`FilterOrder` — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to `'Elliptic'`, then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to `'Quasi-linear phase'`, then `FilterOrder` must be a multiple of four.

Dependencies

This property applies when you set `Specification` to `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB.

Dependencies

This property applies only when you set `Specification` to `'Filter order and stopband attenuation'` or `'Transition width and stopband attenuation'`.

Data Types: `single` | `double`

`TransitionWidth` — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate.

Dependencies

This property applies only when you set `Specification` to `'Transition width and stopband attenuation'` or `'Filter order and transition width'`.

Data Types: `single` | `double`

`DesignMethod` — Design method

`'Elliptic'` (default) | `'Quasi-linear phase'`

Design method for the IIR halfband filter, specified as `'Elliptic'` or `'Quasi-linear phase'`. When the property is set to `'Quasi-linear phase'`, the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response.

Dependencies

This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

`SampleRate` — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz.

Dependencies

This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

Data Types: `single` | `double`

`Structure` — Internal allpass filter implementation structure

`'Minimum multiplier'` (default) | `'Wave Digital Filter'`

Internal allpass filter implementation structure, specified as `'Minimum multiplier'` or `'Wave Digital Filter'`.

This property is not tunable.

Dependencies

This property applies only when you set `'Specification'` to `'Coefficients'`. Each structure uses a different coefficients set, independently stored in the corresponding object property.

`AllpassCoefficients1` — Allpass polynomial filter coefficients of first branch

`[0.1284563; 0.7906755]` (default) | `[0.1284563 0.1534; 0.7906755 0.6745]`

Allpass polynomial filter coefficients of the first branch, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Minimum multiplier'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`AllpassCoefficients2` — Allpass polynomial filter coefficients of second branch

`[0.4295667]` (default) | `[0.7906755 0.1534]`

Allpass polynomial filter coefficients of the second branch, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Minimum multiplier'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WDFCoefficients1` — Allpass filter coefficients of first branch in Wave Digital Filter form

`[0.1284563; 0.7906755]` (default) | `[0.1284563 0.1534; 0.7906755 0.6745]`

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Wave Digital Filter'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WDFCoefficients2` — Allpass filter coefficients of second branch in Wave Digital Filter form

`[0.4295667]` (default) | `[0.7906755 0.1534]`

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as the comma-separated pair consisting of `'WDFCoefficients2'` and a *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set `'Specification'` to `'Coefficients'` and `'Structure'` to `'Wave Digital Filter'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`HasPureDelayBranch` — Make first branch a pure delay

`false` (default) | `true`

Flag to make the first allpass branch a delay, specified as a logical scalar. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

`Delay` — Length of delay

1 (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `HasPureDelayBranch` to 1.

Data Types: `single` | `double`

`HasTrailingFirstOrderSection` — Treat the last section of the second branch as first order
`false` (default) | `true`

Option to treat the last section of the second branch as first order, specified as a logical scalar. When this property is 1 and the coefficients of the second branch are in an *N*-by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to `0`, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an *N*-by-1 matrix, this property is ignored.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Usage

Syntax

```
ylow = iirhalfbanddecim(x)
[ylow,yhigh] = iirhalfbanddecim(x)
```

Description

`ylow = iirhalfbanddecim(x)` filters the input signal, `x`, using the IIR halfband filter, `iirhalfbanddecim`, and downsamples the output by a factor of 2.

`[ylow,yhigh] = iirhalfbanddecim(x)` computes the `ylow` and `yhigh`, of the analysis filter bank, `iirhalfbanddecim` for input `x`. A *Ki*-by-*N* input matrix is treated as *N* independent channels. The System object generates two power-complementary output

signals by adding and subtracting the two polyphase branch outputs respectively. `ylow` and `yhigh` are of the same size (*Ko*-by-*N*) and data type. *Ko* = *Ki*/2, where 2 is the decimation factor.

Input Arguments

`x` — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The number of rows in the input signal must be even since the decimation factor is always 2 for this object. If the input is a matrix, each column is treated as an independent channel.

Data Types: `single` | `double`

Output Arguments

`ylow` — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of decimator output, returned as a column vector or a matrix. The output, `ylow` is a lowpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double`

`yhigh` — Highpass subband of decimator output

column vector | matrix

Highpass subband of decimator output, returned as a column vector or a matrix. The output, `yhigh` is a highpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.IIRHalfbandDecimator`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost for implementing filter System objects
polyphase	Polyphase decomposition of multirate filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Frequency Response of Quasi-Linear Phase IIR Halfband Decimator

Create a minimum-order lowpass IIR halfband decimation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

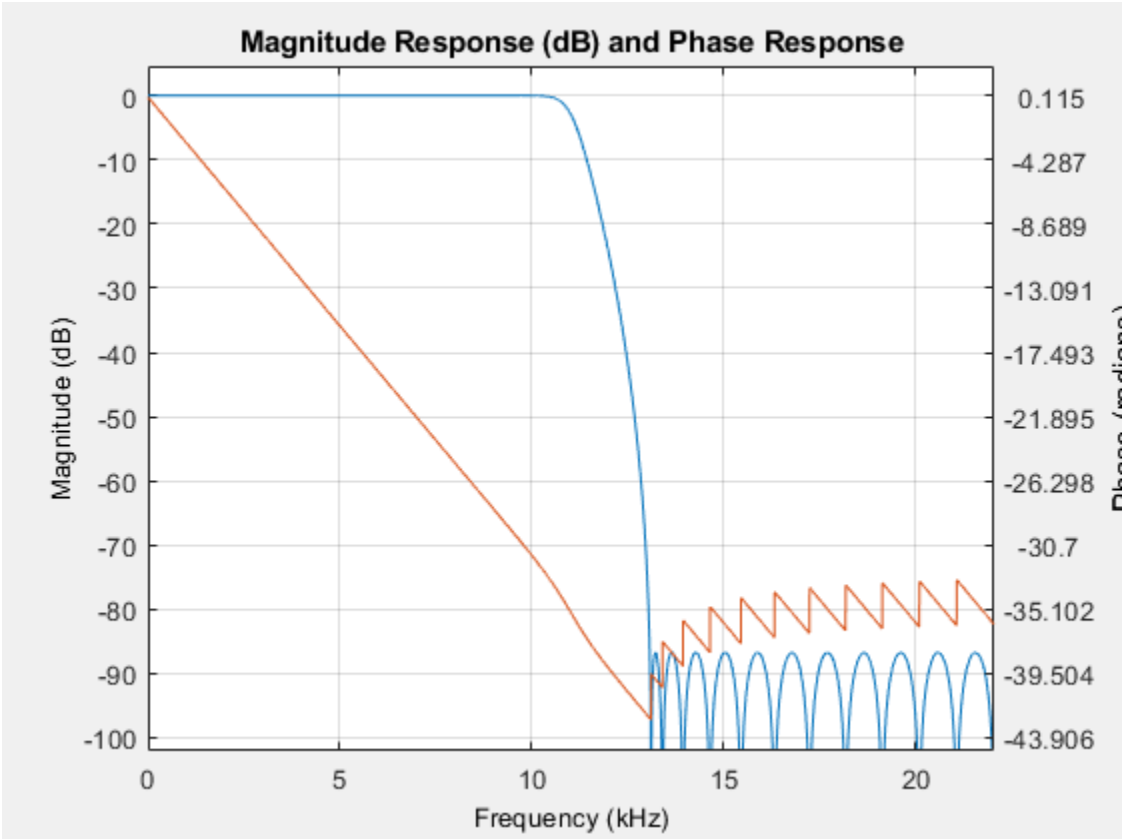
```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
                        'DesignMethod', 'Quasi-linear phase');
```

Obtain the filter coefficients.

```
c = coeffs(IIRHalfbandDecim);
```

Plot the magnitude and phase response.

```
fvtool(IIRHalfbandDecim,'Analysis','freq')
```



Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;

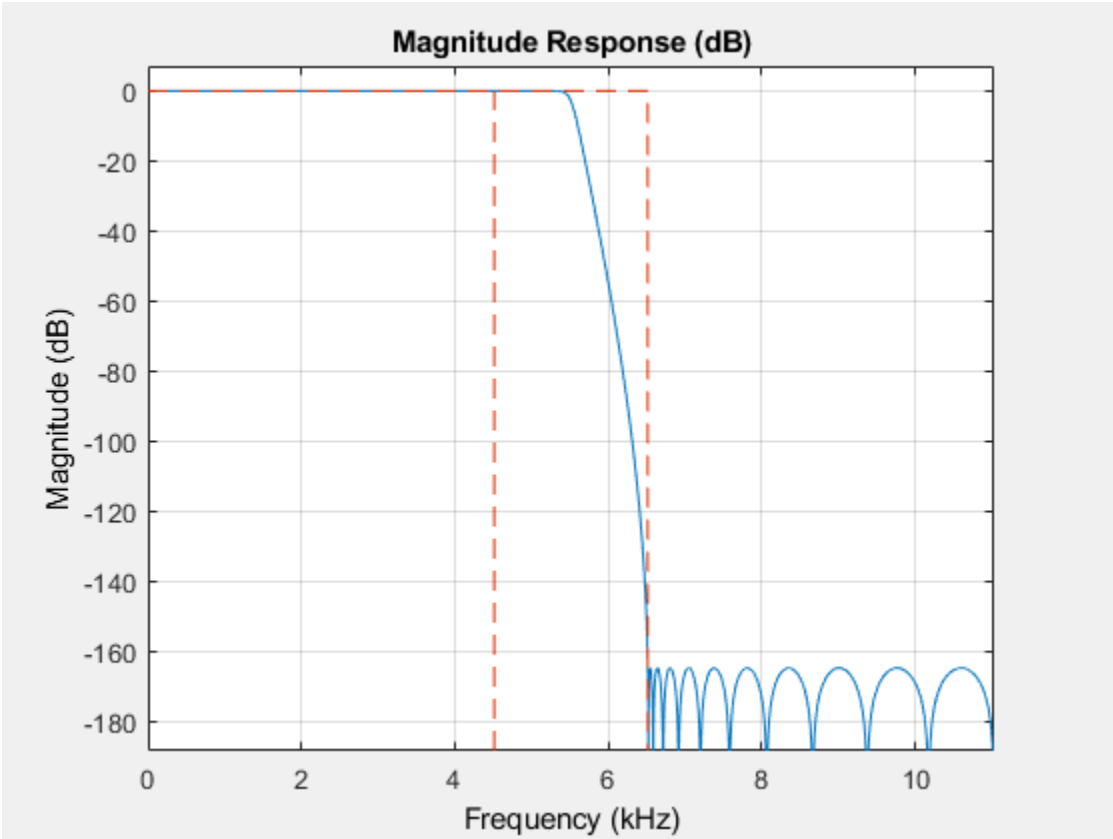
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```



Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
  audioframe = afr();
  xlo = IIRHalfbandDecim(audioframe);
  ylow = IIRHalfbandInterp(xlo);
  ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

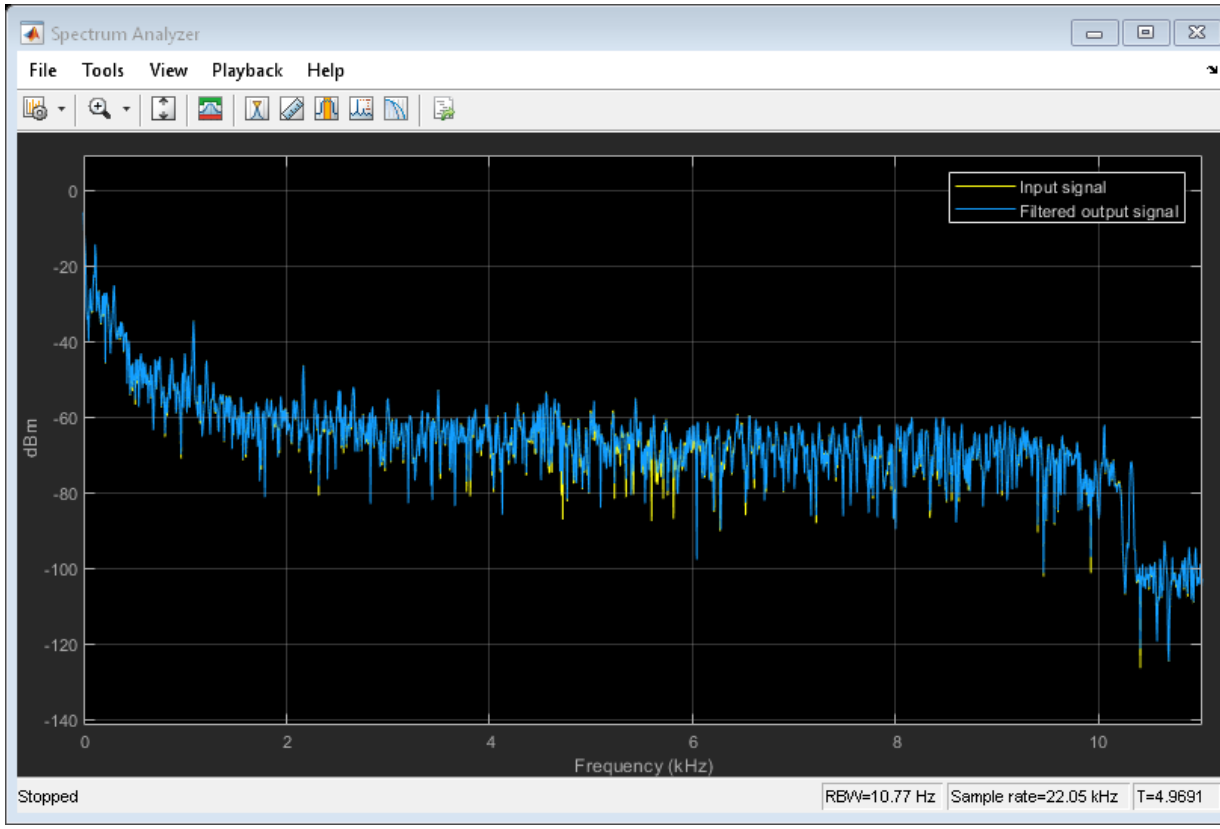
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank.

Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```



Filter Input into Lowpass and Highpass Subbands

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```
IIRHalfbanddecim = dsp.IIRHalfbandDecimator(...
    'Specification','Transition width and stopband attenuation',...
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);
```

Filter a two-channel input into lowpass and highpass subbands.

```
x = randn(1024,2);
[ylow,yhigh] = IIRHalfbanddecim(x);
```

Algorithms

Polyphase Implementation with Halfband Filters

When you filter your signal, `dsp.IIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters. You can use the polyphase implementation to move the downsample operation before filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5*[A_1(z^2) + z^{-1}A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

Quasi-Linear Phase Design

To achieve a near-linear phase response for IIR halfband filters, make one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for the quasi-linear phase IIR halfband filter are

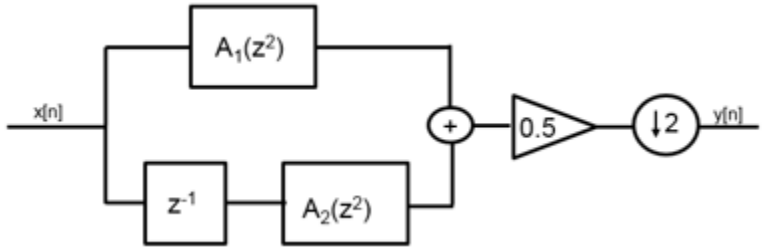
$$A_1(z) = z^{-k}$$

where k is the length of the delay.

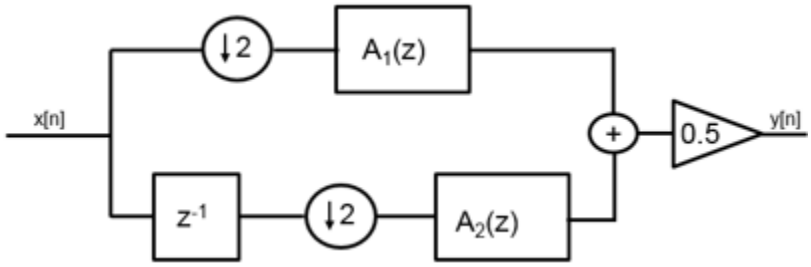
$$A_2(z) = \prod_{K=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{K=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

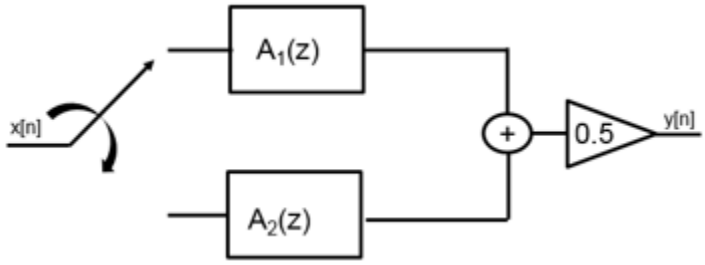
This figure represents filtering and downsampling the input by two.



Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This change enables you to filter at the lower rate.



To implement the halfband decimator efficiently, `dsp.IIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch.

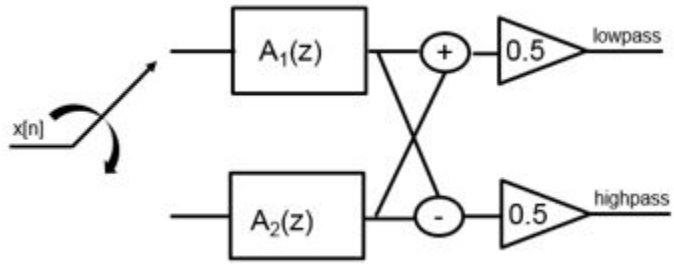


Analysis Filter Bank

The transfer function of the complementary highpass filter branch of the analysis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

Graphically, you can represent the analysis filter bank as follows.



`dsp.IIRHalfbandDecimator` generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively.

To summarize, `dsp.IIRHalfbandDecimator`

- Decimates the input prior to filtering.
- Acts as an analysis filter bank.
- Has non-linear phase response and uses few coefficients with elliptic design method.
- Has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

dsp.IIRHalfbandInterpolator

Package: `dsp`

Interpolate by a factor of two using polyphase IIR

Description

The `dsp.IIRHalfbandInterpolator` System object performs efficient polyphase interpolation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use `dsp.IIRHalfbandInterpolator` object to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To upsample and interpolate your data:

1. Create the `dsp.IIRHalfbandInterpolator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
iirhalfbandinterp = dsp.IIRHalfbandInterpolator
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(Name,Value)
```

Description

`iirhalfbandinterp = dsp.IIRHalfbandInterpolator` returns an IIR halfband interpolation filter, `iirhalfbandinterp`, with the default settings. Under the default settings, the System object upsamples and interpolates the input data using a halfband frequency of `22050` Hz, a transition width of `4100` Hz, and a stopband attenuation of `80` dB.

`iirhalfbandinterp = dsp.IIRHalfbandInterpolator(Name,Value)` returns an IIR halfband interpolator, with additional properties specified by one or more `Name,Value` pair arguments.

Example: `iirhalfbandinterp = dsp.IIRHalfbandInterpolator('Specification','Filter order and stopband attenuation')` creates an IIR halfband interpolator object with filter order set to `9` and stopband attenuation set to `80` dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Specification` — Filter design parameters

`'Transition width and stopband attenuation'` (default) | `'Filter order and stopband attenuation'` | `'Filter order and transition width'` | `'Coefficients'`

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to `'Coefficients'`, you can specify the coefficients directly.

`FilterOrder` — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to `'Elliptic'`, then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to `'Quasi-linear phase'`, then `FilterOrder` must be a multiple of four.

Dependencies

This property applies when you set `Specification` to `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB.

Dependencies

This property applies only when you set `Specification` to `'Filter order and stopband attenuation'` or `'Transition width and stopband attenuation'`.

Data Types: `single` | `double`

`TransitionWidth` — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate.

Dependencies

This property applies only when you set `Specification` to `'Transition width and stopband attenuation'` or `'Filter order and transition width'`.

Data Types: `single` | `double`

`DesignMethod` — Design method

`'Elliptic'` (default) | `'Quasi-linear phase'`

Design method for the IIR halfband filter, specified as `'Elliptic'` or `'Quasi-linear phase'`. When the property is set to `'Quasi-linear phase'`, the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response.

Dependencies

This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

`SampleRate` — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz.

Dependencies

This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

Data Types: `single` | `double`

`FilterBankInputPort` — Option to use object as synthesis filter bank

`false` (default) | `true`

Option to use object as synthesis filter bank, specified as a logical value. If this property is `false`, `dsp.IIRHalfbandInterpolator` acts as an interpolator. If this property is `true`, then `dsp.IIRHalfbandInterpolator` acts as a synthesis filter bank and the algorithm accepts two inputs: the lowpass and highpass subbands.

Dependencies

This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

`Structure` — Filter structure used in coefficient mode

`'Minimum multiplier'` (default) | `'Wave Digital Filter'`

Internal allpass filter implementation structure, specified as `'Minimum multiplier'` or `'Wave Digital Filter'`. Each structure uses a different coefficients set, independently stored in the corresponding object property.

This property is not tunable.

Dependencies

This property applies only when you set `'Specification'` to `'Coefficients'`.

`AllpassCoefficients1` — Allpass polynomial filter coefficients of first branch

`[0.1284563; 0.7906755]` (default) | `[0.1284563 0.1534; 0.7906755 0.6745]`

Allpass polynomial filter coefficients of the first branch, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Minimum multiplier'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`AllpassCoefficients2` — Allpass polynomial filter coefficients of second branch

`[0.4295667]` (default) | `[0.7906755 0.1534]`

Allpass polynomial filter coefficients of the second branch, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Minimum multiplier'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WDFCoefficients1` — Allpass filter coefficients of first branch in Wave Digital Filter form

`[0.1284563; 0.7906755]` (default) | `[0.1284563 0.1534; 0.7906755 0.6745]`

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Wave Digital Filter'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`WDFCoefficients2` — Allpass filter coefficients of second branch in Wave Digital Filter form

`[0.4295667]` (default) | `[0.7906755 0.1534]`

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Wave Digital Filter'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`HasPureDelayBranch` — Make the first branch a pure delay

`false` (default) | `true`

Flag to make the first allpass branch a delay, specified as a logical scalar. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

`Delay` — Length of the delay

1 (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

Dependencies

This property is applicable only when you set `'Specification'` to `'Coefficients'` and `HasPureDelayBranch` to 1.

Data Types: `single` | `double`

`HasTrailingFirstOrderSection` — Make the last section of the second branch as first order

`false` (default) | `true`

Option to treat the last section of the second branch as first order, specified as a logical scalar. When this property is 1 and the coefficients of the second branch are in an *N*-by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to `0`, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an *N*-by-1 matrix, this property is ignored.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Usage

Syntax

```
y = iirhalfbandinterp(x1)
y = iirhalfbandinterp(x1,x2)
```

Description

`y = iirhalfbandinterp(x1)` upsamples by two and interpolates the input signal `x1` using the IIR halfband interpolator, `iirhalfbandinterp`.

`y = iirhalfbandinterp(x1,x2)` implements a halfband synthesis filter bank for the inputs `x1` and `x2`. `x1` is the lowpass output of a halfband analysis filter bank and `x2` is the highpass output of a halfband analysis filter bank. `dsp.IIRHalfbandInterpolator` implements a synthesis filter bank only when the `FilterBankInputPort` property is `true`.

Input Arguments

x1 — Data input

column vector | matrix

Data input to the IIR halfband interpolator, specified as a column vector or a matrix. This signal is the lowpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Data Types: `single` | `double`

x2 — Second data input

column vector | matrix

Second data input to the synthesis filter bank, specified as a column vector or a matrix. This signal is the highpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

Data Types: `single` | `double`

Output Arguments

y — Output of interpolator
column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.IIRHalfbandInterpolator`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost for implementing filter System objects
polyphase	Polyphase decomposition of multirate filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Frequency response of Quasi-linear Phase IIR Halfband Interpolator

Create a minimum order lowpass IIR half-band interpolation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

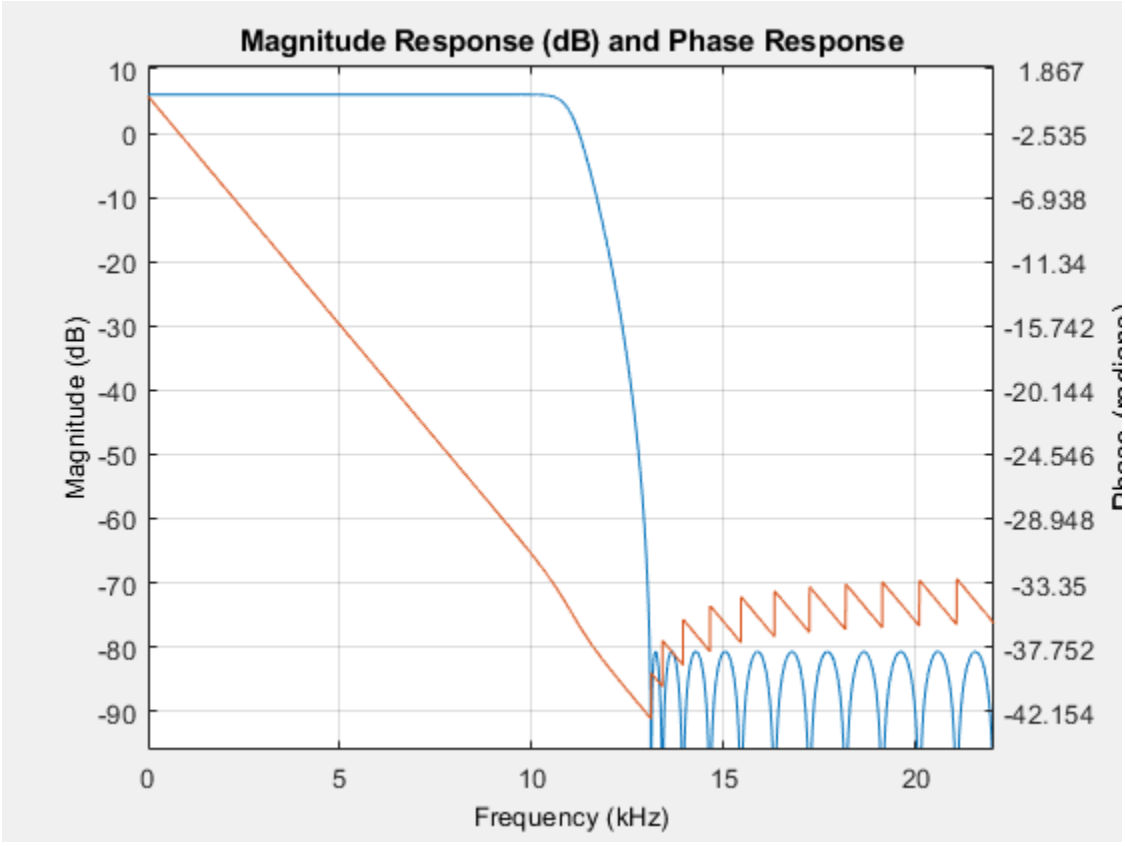
```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
                        'DesignMethod', 'Quasi-linear phase');
```

Obtain filter coefficients

```
c = coeffs(IIRHalfbandInterp);
```

Plot the Magnitude and Phase response

```
fvtool(IIRHalfbandInterp,'Analysis','freq')
```



Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;

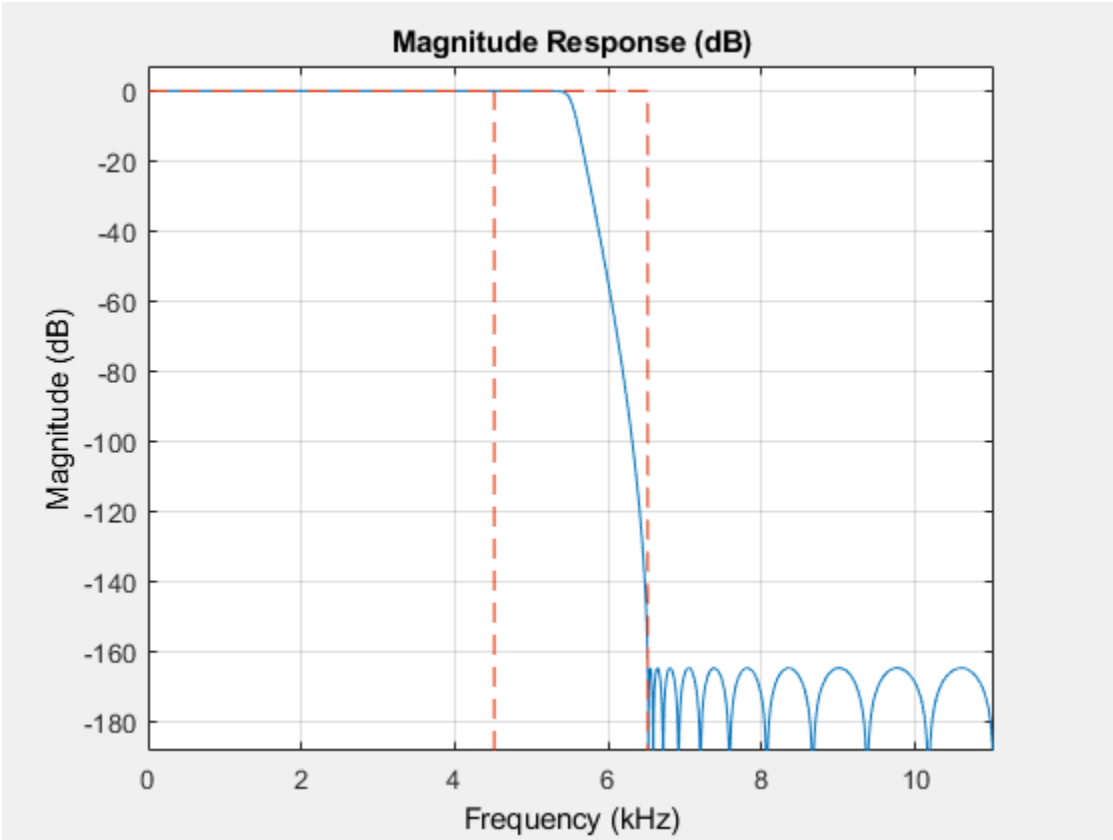
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```



Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
  audioframe = afr();
  xlo = IIRHalfbandDecim(audioframe);
  ylow = IIRHalfbandInterp(xlo);
  ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Note: The `dsp.AudioFileReader` and `audioDeviceWriter` System objects are not supported in MATLAB Online.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

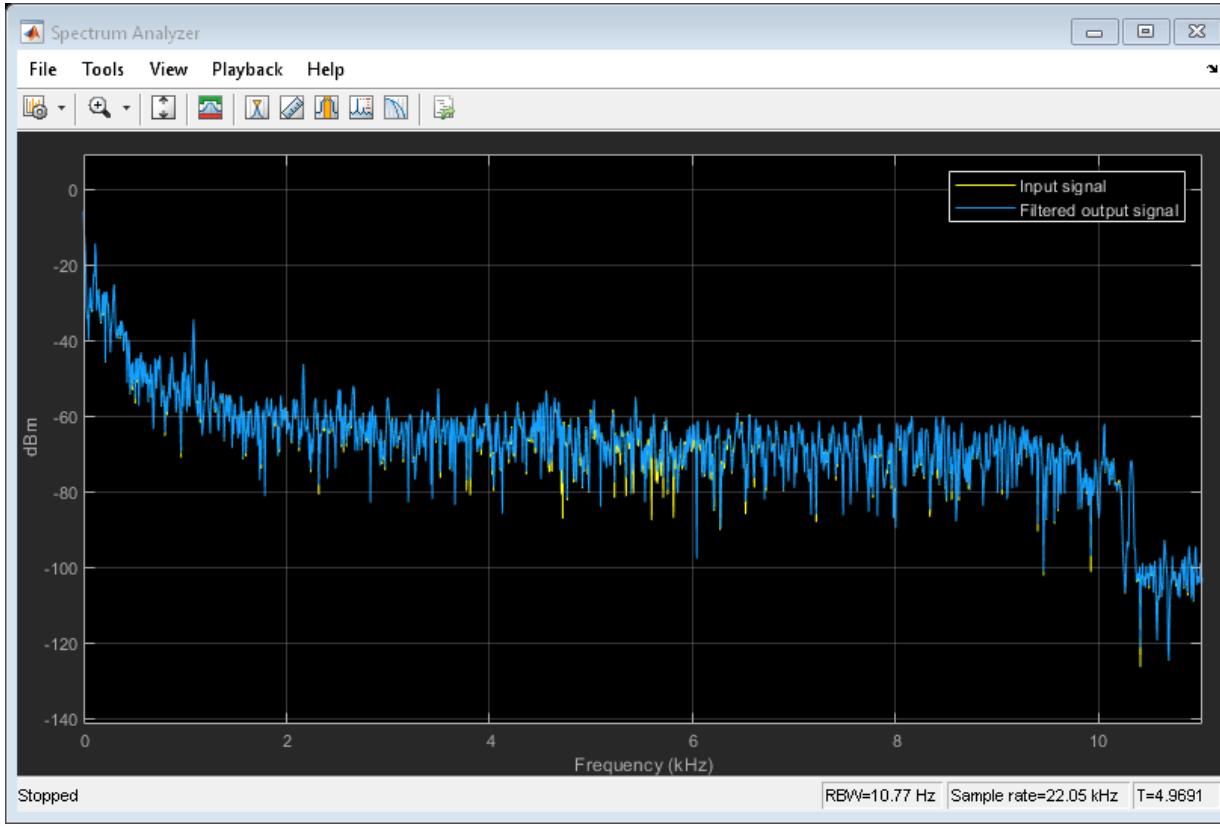
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank.

Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```



Upsample and Interpolate Multichannel Input with IIR Halfband Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 51 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
```

```
Order = 51;
TW = 4.1e3;
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(...
                                                'Specification',filterspec,...
                                                'FilterOrder',Order,...
                                                'TransitionWidth',TW,...
                                                 'SampleRate',Fs);

x = randn(1024,4);
y = iirhalfbandinterp(x);
```

Algorithms

Polyphase Implementation with Halfband Filters

When you filter your signal, `dsp.IIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters. You can use a polyphase implementation to move the upsampling operation after filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5*[A_1(z^2) + z^{-1}A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

Quasi-Linear Phase Design

A near-linear phase response for IIR halfband filters is achieved by making one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for quasi-linear phase IIR halfband filter are

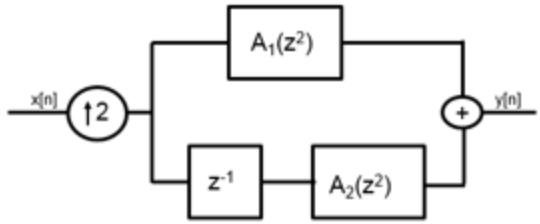
$$A_1(z) = z^{-k}$$

where, k is the length of the delay.

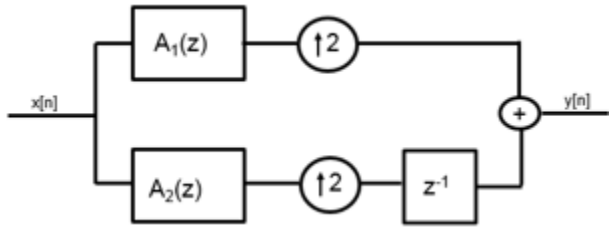
$$A_2(z) = \prod_{K=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{K=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

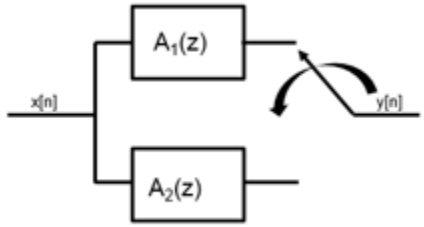
Graphically, you can represent upsampling by two followed by filtering with the following figure



Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.



To efficiently implement the halfband interpolator, `dsp.IIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. The commutator switch operates at twice the input sample rate. This is shown in the following figure:



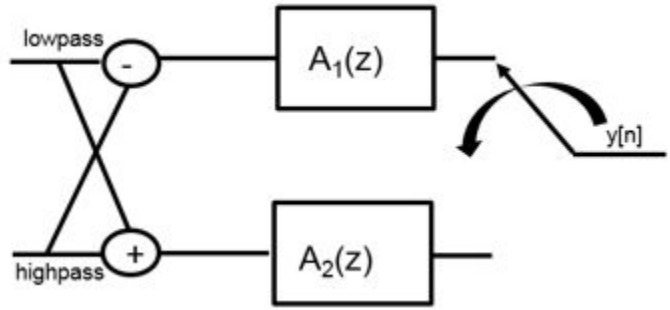
The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal.

Synthesis Filter Bank

Transfer function of the complementary high-pass filter branch of the synthesis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

Graphically, you can represent the synthesis filter bank as



`dsp.IIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To summarize, `dsp.IIRHalfbandInterpolator`

- Filters the input before upsampling
- acts as a synthesis filter bank
- has non-linear phase response and uses few coefficients with elliptic design method

- has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

dsp.Interpolator

Package: `dsp`

Linear or polyphase FIR interpolation

Description

The `dsp.Interpolator` System object interpolates values between real-valued input samples using linear or polyphase FIR interpolation. Specify which values to interpolate by providing a vector of interpolation points. An interpolation point of 1 refers to the first sample in the input. To interpolate the value halfway between the second and third sample in the input, specify an interpolation point of 2.5. Interpolation points that are not within the valid range are replaced with the closest value in the valid range.

To interpolate a real-valued input signal:

1. Create the `dsp.Interpolator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
interp = dsp.Interpolator
interp = dsp.Interpolator(Name,Value)
```

Description

`interp = dsp.Interpolator` creates an interpolation System object, `interp`, to interpolate values between real-valued input samples using linear interpolation.

`interp = dsp.Interpolator(Name,Value)` creates an interpolation System object, `interp`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: interp = dsp.Interpolator('InterpolationPointsSource','Input port')

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`InterpolationPointsSource` — Source of interpolation points

`'Property'` (default) | `'Input port'`

Method to specify the interpolation points, specified as one of the following:

- `'Property'` — Specify the interpolation points through the “InterpolationPoints” on page 4-0 property.
- `'Input port'` — Pass the interpolation points as an input to the System object algorithm.

`InterpolationPoints` — Interpolation points

`[1.1;4.8;2.67;1.6;3.2]` (default) | vector | matrix | *N*-D array

Interpolation points, specified as a vector, matrix, or an *N*-D array. The valid range of the values in the interpolation vector is from 1 to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is `[2;3.1;-2.1]`, the valid range of interpolation points is from 1 to 3. If you specify a `[-1;1.5;2;2.5;3;3.5]` vector of interpolation points, the interpolator object clips `-1` to 1 and `3.5` to 3. This clipping results in the interpolation points `[1 1.5 2 2.5 3 3]`.

For details on the dimension of the interpolation points array and how that influences the dimension of the output, see the tables in the “ipts” on page 4-0 input of the System object.

Tunable: Yes

Dependencies

This property applies only when you set the “InterpolationPointsSource” on page 4-0 property to `'Property'`.

`Method` — Interpolation method

`'Linear'` (default) | `'FIR'`

Interpolation method, specified as one of the following:

- `'Linear'` –– The object interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.
- `'FIR'` –– The object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. If the input has insufficient low-rate samples to perform FIR interpolation, the interpolator object performs linear interpolation. For more details, see the “FilterHalfLength” on page 4-0 property.

`FilterHalfLength` — Half-length of interpolation filter

3 (default) | integer scalar greater than 0

For a filter half-length of *P*, the polyphase FIR subfilters have length 2*P*. FIR interpolation always requires 2*P* low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires *P* low-rate samples below and *P* low-rate samples above the interpolation point.
- If the interpolation point corresponds to a low-rate sample, the 2*P*-sample requirement includes the low-rate sample.
- If the input has less than *2P* neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input `[1 4 1 4 1 4 1 4]`, upsampling by a factor of 4 results in equally spaced interpolation points, `InterP = [1:0.25:8]`. The points `InterP(9:12)` are `[3.0 3.25 3.5 3.75]`. If you set `FilterHalfLength` to 2, interpolating at these points uses the 4 low-rate samples from the input with indices `(2,3,4,5)`. If you set `FilterHalfLength` to 4, the interpolator object uses linear interpolation, because the input does not have enough low-rate samples to perform FIR interpolation.

The longer the `FilterHalfLength` property, the better the quality of the interpolation. However, increasing the filter half-length increases computation time and requires more low-rate samples below and above the interpolation point. In general, setting the `FilterHalfLength` property between 4 and 6 provides a reasonably accurate interpolation.

Dependencies

This property applies only when you set the "Method" on page 4-0 property to `'FIR'`.

`InterpolationPointsPerSample` — Upsampling factor

3 (default) | integer scalar greater than 0

Upsampling factor, specified as an integer scalar greater than 0. An upsampling factor of L inserts L – 1 zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with `InterpolationPointsPerSample` subfilters of length $2P$, where P is the value you specify in the "FilterHalfLength" on page 4-0 property. For nL low-rate samples in the upsampled input, where $n=1,2,...$, the interpolator object uses exactly one of the `InterpolationPointsPerSample` subfilters to interpolate at the points $nL+i/L$, where i = 0, 1, 2, ..., L – 1.

If you specify interpolation points that do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. Suppose you set the `InterpolationPointsPerSample` property to 4 and interpolate at the points `[3 3.2 3.4 3.6 3.8]`. The interpolator object uses the first polyphase subfilter for the points `[3.0 3.2]`, the second subfilter for the point `3.4`, the third subfilter for the point `3.6`, and the fourth subfilter for the point `3.8`.

Dependencies

This property applies only when you set the "Method" on page 4-0 property to `'FIR'`.

`Bandwidth` — Normalized input bandwidth

`0.5` (default) | real scalar greater than 0 and less than or equal to 1

Bandwidth to which the interpolated output samples must be constrained, specified as a real scalar greater than 0 and less than or equal to 1. A value of 1 equals the Nyquist frequency, or half the sampling frequency, Fs. Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above $Fs/4$, you can specify a value of 0.5 for the `Bandwidth` property.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to `'FIR'`.

Usage

Syntax

```
interpOut = interp(input)
interpOut = interp(input,ipts)
```

Description

`interpOut = interp(input)` outputs the interpolated sequence, `interpOut`, of the input vector or matrix *input*, as specified in the “InterpolationPoints” on page 4-0 property. Each column of `input` is treated as an independent channel of the input.

`interpOut = interp(input,ipts)` outputs the interpolated sequence as specified by `ipts`.

To specify the interpolation points, set the “InterpolationPointsSource” on page 4-0 property to `'Input port'`.

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
ipts = 1:0.1:length(x1);
interp = dsp.Interpolator('InterpolationPointsSource','Input port');
interpOut = interp(x1',ipts');
```

Input Arguments

`input` — Data input
vector | matrix | *N*-D array

Input that is interpolated by the object, specified as a vector, matrix, or *N*-D array.

Example: t = 0:0.0001:0.0511; input = sin(2*pi*20*t);

Data Types: `single` | `double`

`ipts` — Interpolation points

vector | matrix | *N*-D array

Interpolation array I_{Pts}, specified as a vector, matrix, or *N*-D array. The interpolation array represents the points in time at which to interpolate values of the input signal. An entry of 1 in I_{Pts} refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. In most cases, when I_{Pts} is a vector, it can be of any length.

Valid values in the interpolation array I_{Pts} range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector `D`, all entries of I_{Pts} must range from 1 to 5. I_{Pts} cannot contain entries such as 7 or –9, because `D` does not have a seventh or ninth entry.

The algorithm replaces any out-of-range values in I_{Pts} with the closest value in the valid range (from 1 to the number of input samples). Then it performs the interpolation using the clipped version of I_{Pts}.

Consider the following input data and interpolation points vector:

- `D = [11 22 33 44]'`
- $\texttt{I}_{\texttt{Pts}}$ `= [10 2.6 -3]'`

Because `D` has four samples, valid interpolation points range from 1 to 4. The algorithm clips interpolation point 10 down to to 4 and the point –3 up to 1. The result is the clipped interpolation vector $\texttt{I}_{\texttt{PtsClipped}}$ `= [4 2.6 1]'`.

Depending on the dimension of the input and the dimension of I_{Pts}, the algorithm applies I_{Pts} to the input in one of the following ways:

- If I_{Pts} is an array, the object applies I_{Pts} across the first dimension of an *N*-D array, resulting in an *N*-D array output.
- If I_{Pts} is a vector, the object applies I_{Pts} to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

The following tables summarize how the object applies the interpolation array I_{Pts} to all the possible types of inputs. The table also shows the resulting output dimensions.

This table describes the behavior when `InterpolationPointsSource` is set to `'Property'`.

Input Dimensions	Valid Dimensions of Interpolation Array I_{Pts}	How Object Applies I_{Pts} to Input	Output Dimensions
M-by-*N*-by-*K* matrix	*P*-by-1 column	Applies I_{Pts} to the first dimension of the input	*P*-by-*N*-by-*K* array
	P-by-*N*-by-*K* matrix	Applies each column element of I_{Pts} to the corresponding column of the input matrix	*P*-by-*N*-by-*K* array
M-by-*N* matrix	1-by-*N* row	Applies each column element of I_{Pts} to the corresponding column of the input matrix	1-by-*N* row
	P-by-1 column	Applies I_{Pts} to each input column	*P*-by-*N* matrix
	P-by-*N* matrix	Applies the columns of I_{Pts} to the corresponding columns of the input matrix	
M-by-1 column	1-by-*P* row (the algorithm treats I_{Pts} as a column)	Applies I_{Pts} to the input column	*P*-by-1 column
	P-by-1 column		
1-by-*N* row (not recommended)	1-by-*N* row	Not applicable. Object copies input vector.	1-by-*N* row, a copy of the input vector
	P-by-1 column		*P*-by-*N* matrix, where each row is a copy of the input vector
	P-by-*N* matrix		

This table describes the behavior when `InterpolationPointsSource` is set to `'Input port'`.

Input Dimensions	Valid Dimensions of Interpolation Array I_{Pts}	How Object Applies I_{Pts} to Input	Output Dimensions
M-by-*N*-by-*K* matrix	Column vector of length *P*	Applies I_{Pts} to the first dimension of the input	*P*-by-*N*-by-*K* array
	P-by-*N*-by-*K* matrix	Applies each column element of I_{Pts} to the corresponding column of the input matrix	*P*-by-*N*-by-*K* array
M-by-*N* matrix	1-by-*N* row	Applies each column element of I_{Pts} to the corresponding column of the input matrix	1-by-*N* row
	P-by-1 column	Applies I_{Pts} to each input column	*P*-by-*N* matrix
	P-by-*N* matrix	Applies the columns of I_{Pts} to the corresponding columns of the input matrix	
M-by-1 column	1-by-*P* row	Applies I_{Pts} to the input column	*P*-by-1 column
	P-by-1 column		
1-by-*N* row (not recommended)	1-by-*N* row	Not applicable. Object copies input vector.	1-by-*N* row, a copy of the input vector
	P-by-1 column		*P*-by-*N* matrix, where each row is a copy of the input vector
	P-by-*N* matrix		

Example: ipts = [1:10];

Data Types: `single` | `double`

Output Arguments

`interpOut` — Interpolated sequence

vector | matrix | *N*-D array

Interpolated sequence, returned as a vector, matrix, or *N*-D array. The dimension of the output depends on the dimensions of the input and the interpolation points array. For more details on the dimensions, see the tables in “ipts” on page 4-0 .

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

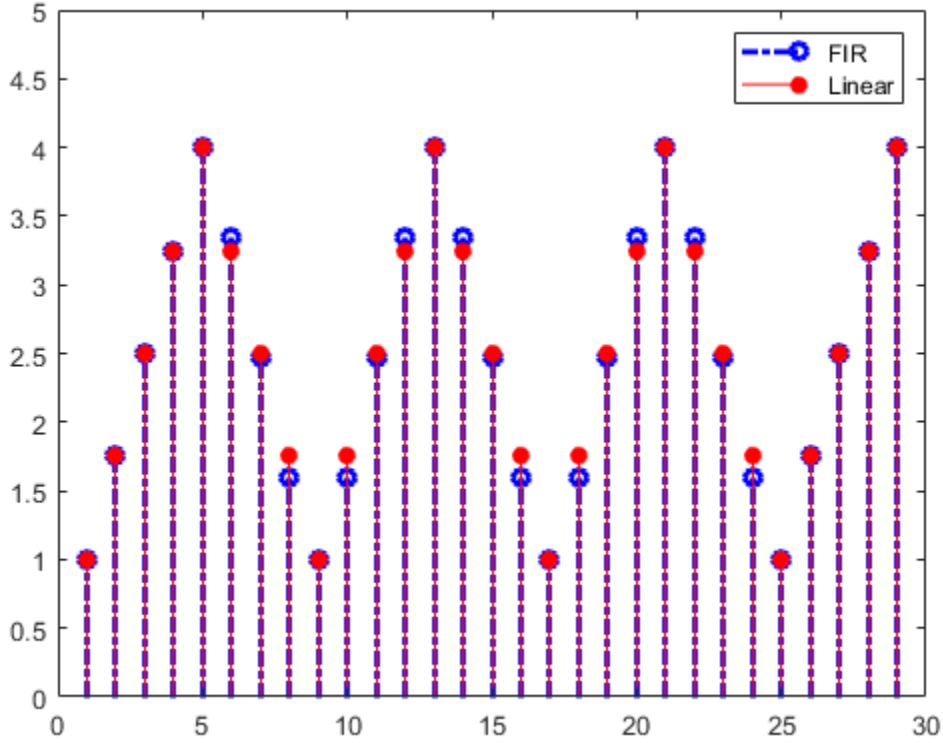
Examples

Compare Linear Interpolation with FIR Interpolation

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
x = [1 4];
x = repmat(x,1,4);
x1 = 1:0.25:8;
firInterp = dsp.Interpolator('Method','FIR','FilterHalfLength',2,...
'InterpolationPoints',x1','InterpolationPointsPerSample',4);
linInterp = dsp.Interpolator('InterpolationPoints',x1');
OutFIR = firInterp(x');
```

```
OutLin = linInterp(x');
stem(OutFIR,'b-.','linewidth',2);
hold on;
stem(OutLin,'r','markerfacecolor',[1 0 0]);
axis([0 30 0 5]);
legend('FIR','Linear','Location','Northeast');
```

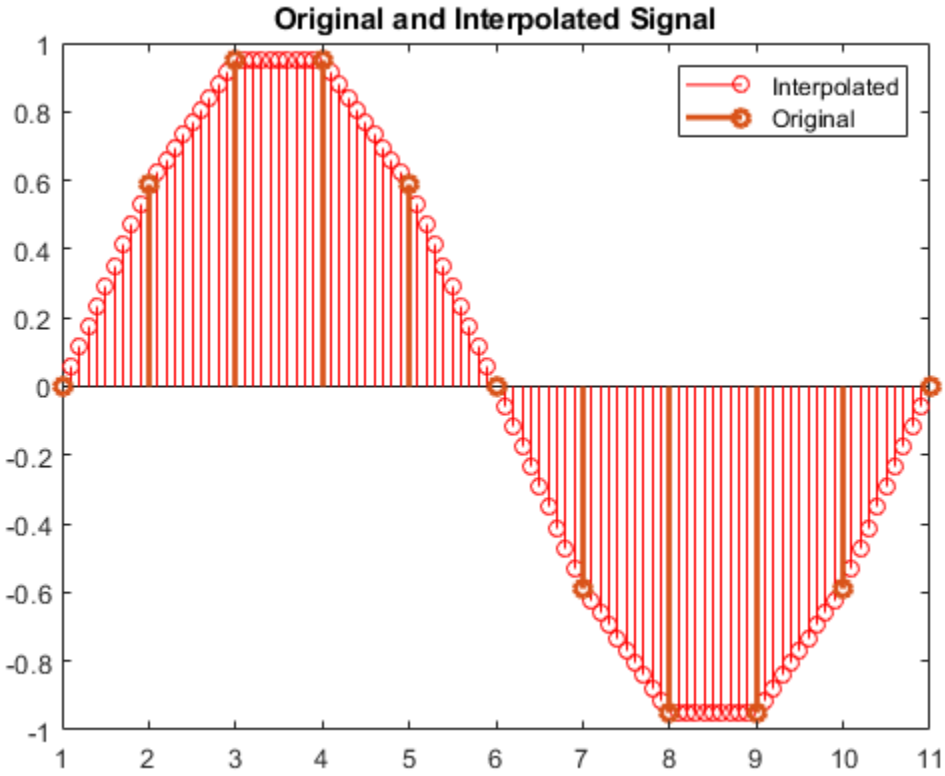


The interpolation points at indices 1 to 5 and 25 to 29 do not have enough low-rate samples surrounding them to use FIR interpolation with the specified filter length. Therefore, the interpolator object uses linear interpolation instead.

Interpolate a Sinusoid with Linear Interpolation

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
I = 1:0.1:length(x1);
interp = dsp.Interpolator('InterpolationPointsSource',...
    'Input port');
y = interp(x1',I');
stem(I',y, 'r');
title('Original and Interpolated Signal');
hold on;
stem(x1, 'Linewidth', 2);
legend('Interpolated','Original');
```



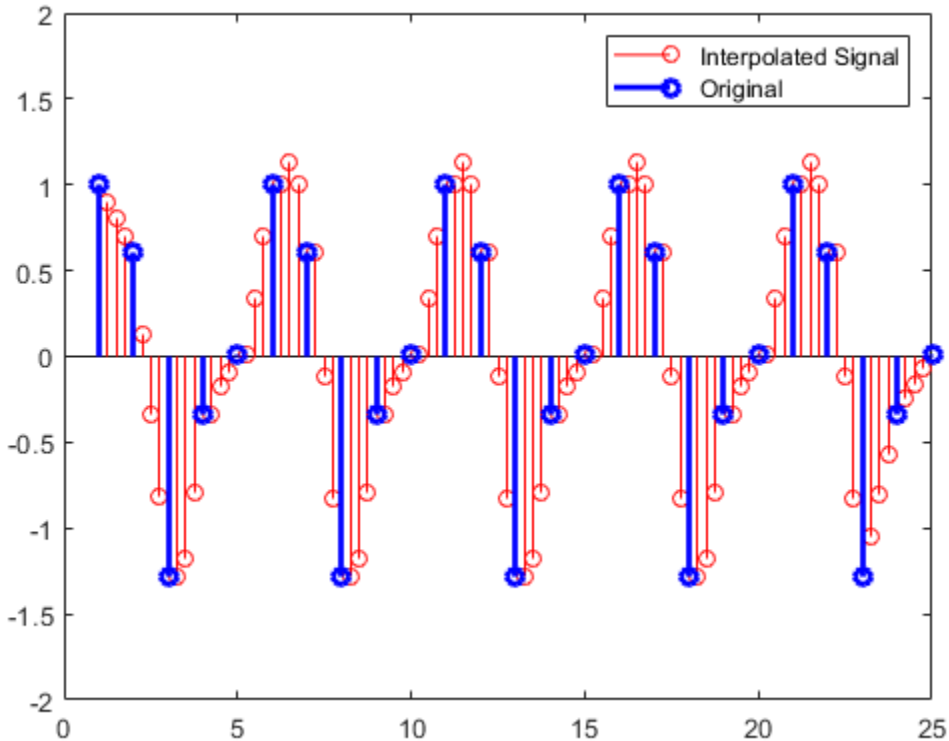
Interpolate a Sum of Sinusoids

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Interpolate a sum of sinusoids with FIR interpolation, and with 'Input port' as the source of interpolation points.

```
Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
```

```
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
interp = dsp.Interpolator('Method','FIR',...
'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = interp(x1',I');
stem(I,y,'r');
hold on;
axis([0 25 -2 2]);
stem(x1,'b','linewidth',2);
legend('Interpolated Signal','Original',...
'Location','Northeast');
```



Determine the Polyphase Subfilters of an FIR Interpolator

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

The `dsp.Interpolator` object with the `Method` property set to `'FIR'` models a polyphase FIR Interpolator. The polyphase implementation splits the lowpass FIR filter impulse response into several subfilters. Each subfilter occupies a specific narrow frequency band. This example shows how to determine the polyphase subfilters.

The default upsampling factor and the default polyphase half-length is 3. Using these values, design the linear phase FIR filter by using the `intfilt` function. The filter returned is of length 2 * *P* * *L* -1, where *P* is the upsampling factor and *L* is the filter half length.

```
interp = dsp.Interpolator('Method','FIR');
L = interp.InterpolationPointsPerSample;
P = interp.FilterHalfLength;
FiltCoeffs = intfilt(L,P,interp.Bandwidth);
FiltLen=length(FiltCoeffs);
FiltCols = ceil(FiltLen/2/L);
```

The filter needs 2*P*L coefficients. Prepending a zero does not affect the filter magnitude.

```
FiltCoeffs = [zeros(FiltCols*2*L-FiltLen,1); FiltCoeffs(:)];
```

Each column of `PolyPhaseCoeffs` is a polyphase subfilter.

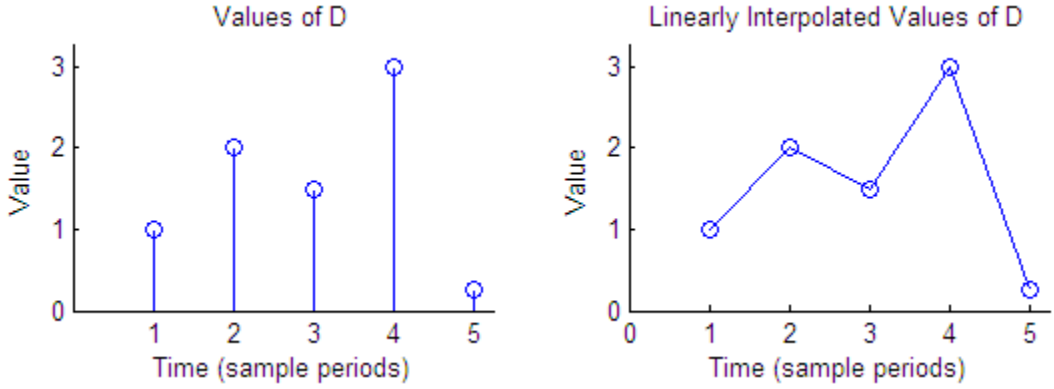
```
PolyPhaseCoeffs  = reshape(FiltCoeffs,FiltCols,2*L)';
```

Algorithms

Linear Interpolation Mode

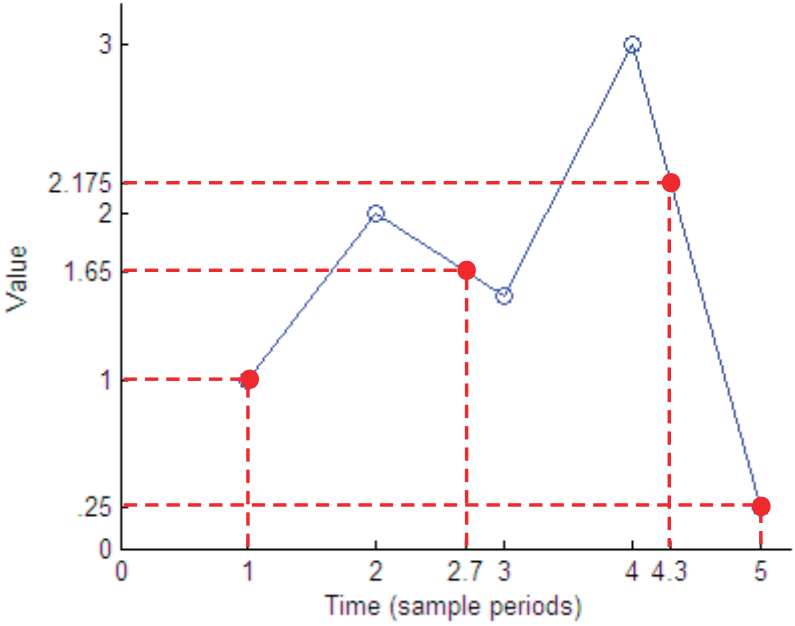
In the linear interpolation mode, the algorithm interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

Suppose the input signal is `D = [1 2 1.5 3 0.25]'` . The left plot shows the samples in `D` and the right plot shows the linearly interpolated values between the samples in `D`.



When the interpolation points are out of range, the algorithm clips the invalid interpolation points. Consider an input signal, `D = [1 2 1.5 3 0.25]'` , and an interpolation vector, I_{Pts} `= [-4 2.7 4.3 10]'`. The interpolated output is given by `[1 1.65 2.175 0.25]'`.

Interpolated Values of D at Clipped Interpolation Points



D = [1 2 1.5 3 0.25]'
I_{pts} = [-4 2.7 4.3 10]'

Valid interpolation points range from 1 to 5, so -4 is clipped to 1 and 10 is clipped to 5.

Clipped I_{pts} = [1 2.7 4.3 5]'

Output = [1 1.65 2.175 0.25]'

FIR Interpolation Mode

In the FIR interpolation mode, the algorithm interpolates data values using an FIR interpolation filter. The FIR filter is implemented using a polyphase structure. A polyphase implementation *splits* the lowpass FIR filter impulse response into a number of different subfilters.

Let L represent the number of interpolation points per sample, or the upsampling factor. Let P represent the half length of the polyphase subfilters. Indexing from zero, if $h(n)$ is the impulse response of the FIR filter, the kth subfilter is:

$$h_k(n) = h(k + nL) \quad k = 0, 1, \ldots, L - 1 \quad n = 0, 1, \ldots, 2P - 1$$

The table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object.

Coefficients	Polyphase Subfilter
h(0),h(3),h(6), ..., h(15)	$h_0(n)$
h(1),h(4),h(7), ..., h(16)	$h_1(n)$
h(2),h(5),h(8), ..., h(17)	$h_2(n)$

An upsampling factor of L inserts L – 1 zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter.

dsp.KalmanFilter

Package: `dsp`

Estimate system measurements and states using Kalman filter

Description

The `dsp.KalmanFilter` System object is an estimator used to recursively obtain a solution for linear optimal filtering. This estimation is made without precise knowledge of the underlying dynamic system. The Kalman filter implements the following linear discrete-time process with state, x, at the k^{th} time-step:
$x(k) = Ax(k-1) + Bu(k-1) + w(k-1)$ (state equation). This measurement, z, is given as:
$z(k) = Hx(k) + v(k)$ (measurement equation).

The Kalman filter algorithm computes the following two steps recursively:

- Prediction: Process parameters x (state) and P (state error covariance) are estimated using the previous state.
- Correction: The state and error covariance are corrected using the current measurement.

To filter each channel of the input:

1. Create the `dsp.KalmanFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
kalman = dsp.KalmanFilter
kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance,
MNCovariance, CIMatrix)
```

```
kalman = dsp.KalmanFilter(Name,Value)
```

Description

`kalman = dsp.KalmanFilter` returns the Kalman filter System object, `kalman`, with default values for the parameters.

`kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance, CIMatrix)` returns a Kalman filter System object, `kalman`. The `StateTransitionMatrix` property is set to `STMatrix`, the `MeasurementMatrix` property is set to `MMatrix`, the `ProcessNoiseCovariance` property is set to `PNCovariance`, the `MeasurementNoiseCovariance` property is set to `MNCovariance`, and the `ControlInputMatrix` property is set to `CIMatrix`.

`kalman = dsp.KalmanFilter(Name,Value)` returns an Kalman filter System object, `kalman`, with each property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`StateTransitionMatrix` — Model of state transition

1 (default) | scalar | square matrix

Specify A in the state equation that relates the state at the previous time step to the state at current time step. A is a square matrix with each dimension equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ControlInputMatrix` — Model of relation between control input and states

1 (default) | column vector

Specify B in the state equation that relates the control input to the state. B is a column vector with a number of rows equal to the number of states.

Dependencies

This property is activated only when the `ControlInputPort` property value is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MeasurementMatrix` — Model of relation between states and measurement output

`1` (default) | row vector

Specify H in the measurement equation that relates the states to the measurements. H is a row vector with a number of columns equal to the number of measurements.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ProcessNoiseCovariance` — Covariance of process noise

`0.1` (default) | scalar | square matrix

Specify Q as a square matrix with each dimension equal to the number of states. Q is the covariance of the white Gaussian process noise, w, in the state equation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`MeasurementNoiseCovariance` — Covariance of measurement noise

`0.1` (default) | scalar | square matrix

Specify R as a square matrix with each dimension equal to the number of states. R is the covariance of the white Gaussian process noise, v, in the measurement equation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialStateEstimate` — Initial value for states

`0` (default) | scalar | column vector

Specify an initial estimate of the states of the model as a column vector with length equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialErrorCovarianceEstimate` — Initial value for state error covariance
`0.1` (default) | scalar | square matrix

Specify an initial estimate for covariance of the state error, as a square matrix with each dimension equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DisableCorrection` — Disable port for filters
`false` (default) | `true`

Specify as a scalar logical value, disabling System object filters from performing the correction step after the prediction step in the Kalman filter algorithm.

`ControlInputPort` — Presence of a control input
`true` (default) | `false`

Specify if the control input is present, using a scalar logical value. The default value is `true`.

Usage

Syntax

```
[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = kalman(z,u)
```

Description

`[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = kalman(z,u)` carries out the iterative Kalman filter algorithm over measurements `z` and control inputs `u`. The columns in `z` and `u` are treated as inputs to separate parallel filters, whose correction (or update) step can be disabled by the `DisableCorrection` property. The values returned are estimated measurements `zEst`, estimated states `xEst`, MSE of estimated states `MSE_Est`, predicted measurements `zPred`, predicted states `xPred`, and MSE of predicted states `MSE_Pred`.

Input Arguments

z — Measurement input

vector | matrix

Measurement input, specified as a vector or a matrix.

The ratio of the number of rows of the measurement input to the number of rows of the `MeasurementMatrix` property must be equal to the ratio of the number of rows of the control input to the number of columns of the `ControlInputMatrix` property.

The measurement signal can be a variable-size input. Once the object is locked, you can change the size of each input channel, but the number of channels cannot change.

Data Types: `single` | `double`

u — Control input

vector | matrix

Control input, specified as a vector or a matrix.

The ratio of the number of rows of the control input to the number of columns of the `ControlInputMatrix` property must be equal to the ratio of the number of rows of the measurement input to the number of rows of the `MeasurementMatrix` property.

The control signal can be a variable-size input. Once the object is locked, you can change the size of each input channel, but the number of channels cannot change.

Data Types: `single` | `double`

Output Arguments

zEst — Estimated measurements

vector | matrix

Estimated measurements, returned as a vector or matrix.

Data Types: `single` | `double`

xEst — Estimated state

vector | matrix

Estimated state, returned as a vector or matrix.

Data Types: `single` | `double`

`MSE_Est` — MSE of estimated states
scalar | column vector

Mean-squared error of estimated states, returned as a scalar or column vector. If the input is a row vector, the MSE of the estimated states is a scalar.

Data Types: `single` | `double`

`zPred` — Predicted measurements
vector | matrix

Predicted measurements, returned as a vector or a matrix.

Data Types: `single` | `double`

`xPred` — Predicted states
vector | matrix

Predicted states, returned as a vector or a matrix.

Data Types: `single` | `double`

`MSE_Pred` — MSE of predicted states
scalar | column vector

Mean-squared error of predicted states, returned as a scalar or a column vector. If the input is a row vector, the MSE of the estimated states is a scalar.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm

release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Estimate Changing Scalar

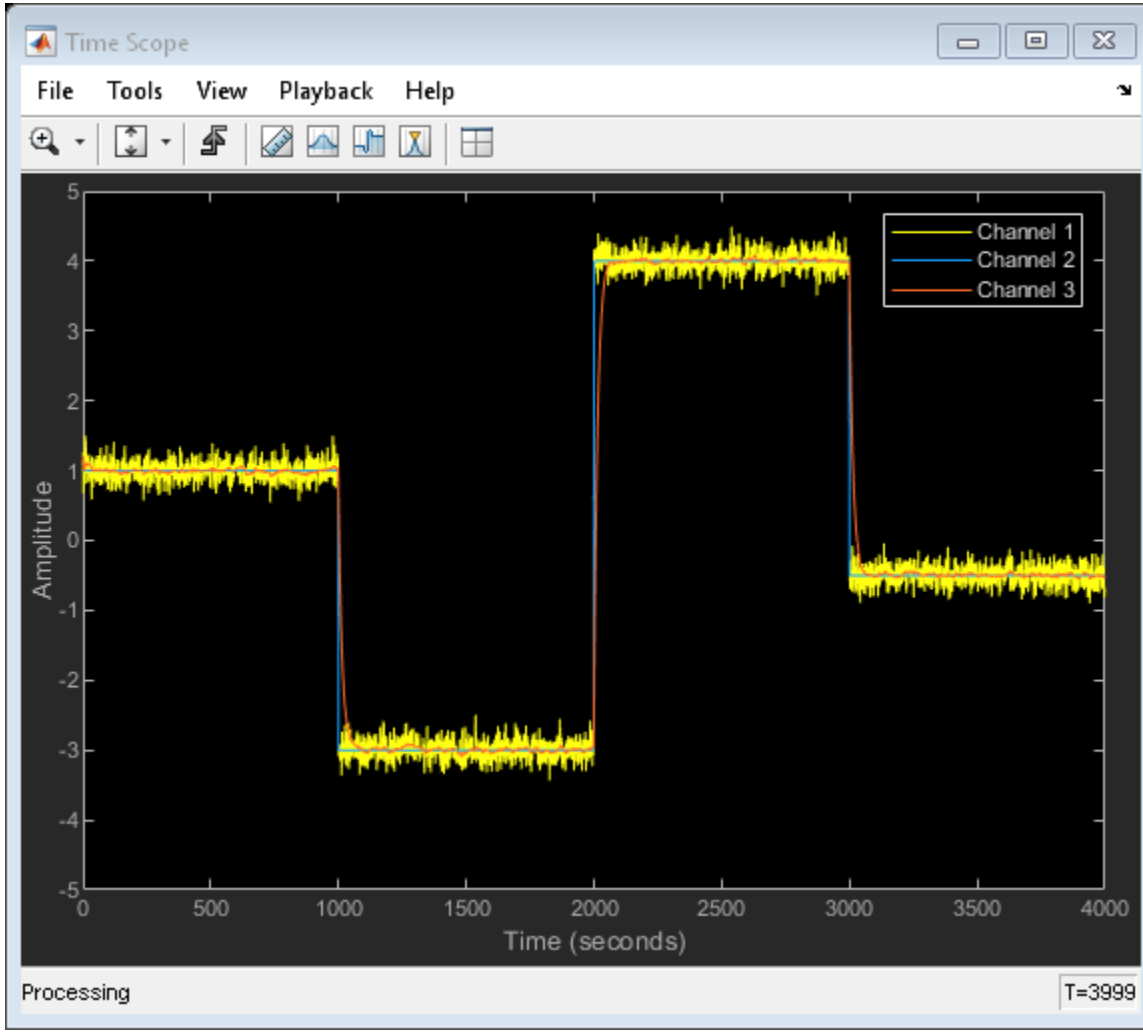
Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Create the System objects for the changing scalar input, the Kalman filter, and the scope (for plotting).

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
src.Signal = [ones(numSamples/4,1);-3*ones(numSamples/4,1);...
    4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
tScope = dsp.TimeScope('NumInputPorts',3,'TimeSpan',numSamples, ...
    'TimeUnits','Seconds','YLimits',[-5 5], ...
    'ShowLegend',true); % Create the Time Scope
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance',R,...
    'InitialStateEstimate',5,...
    'InitialErrorCovarianceEstimate',1,...
    'ControlInputPort',false); %Create Kalman filter
```

Add noise to the scalar, and pass the result to the Kalman filter. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
   trueVal = src();
   noisyVal = trueVal + sqrt(R)*randn;
   estVal = kalman(noisyVal);
   tScope(noisyVal,trueVal,estVal);
end
```



Disable the Correction Step in the Kalman Filter Algorithm

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

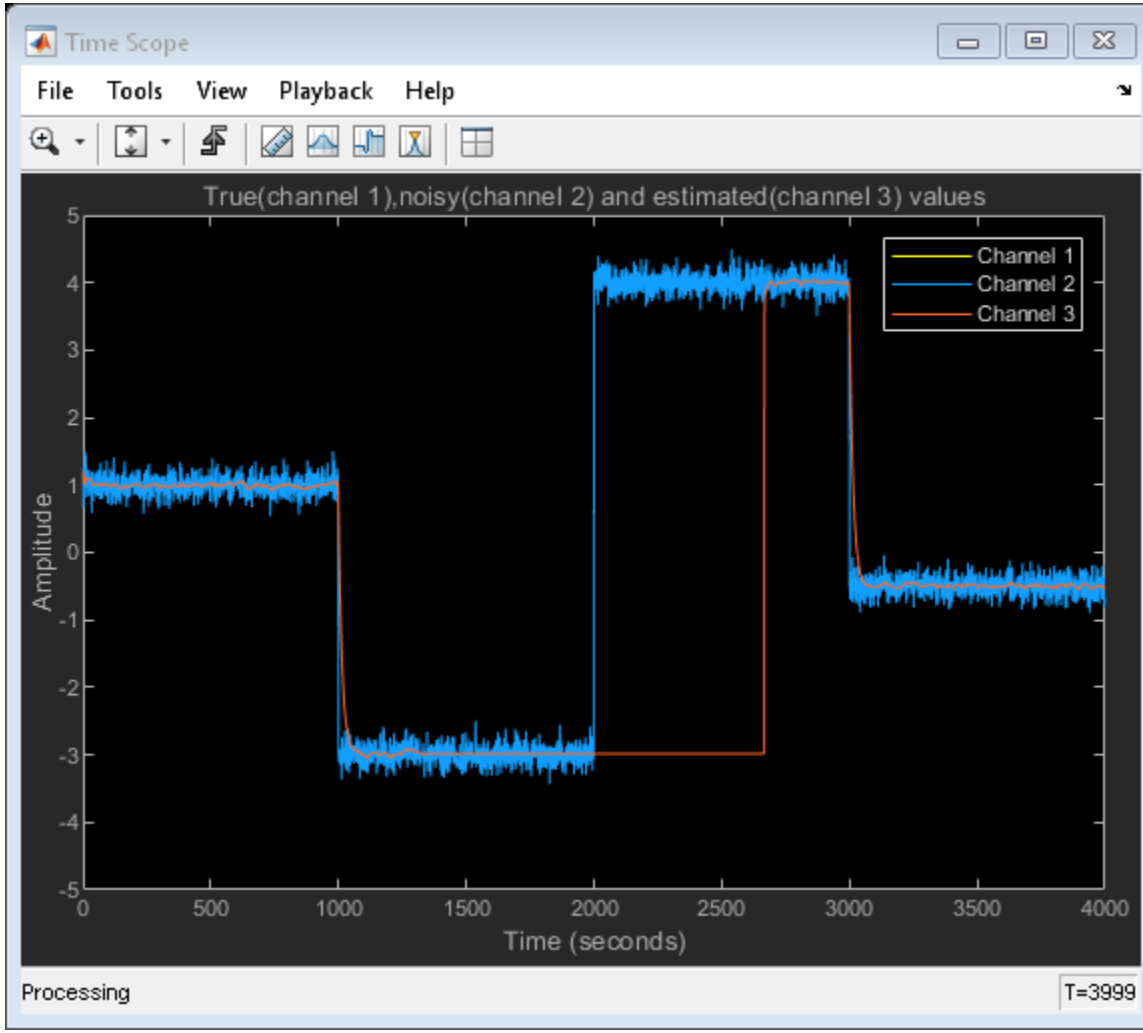
Create the signal, Kalman Filter, and Time Scope System objects.

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
src.Signal = [  ones(numSamples/4,1);-3*ones(numSamples/4,1);...
              4*ones(numSamples/4,1);-0.5*ones(numSamples/4,1)];
tScope = dsp.TimeScope('NumInputPorts',3,'TimeSpan',numSamples, ...
          'TimeUnits','Seconds','YLimits',[-5 5],...
          'Title',['True(channel 1),noisy(channel 2) and ',...
          'estimated(channel 3) values'], ...
          'ShowLegend', true);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance',0.0001,...
          'MeasurementNoiseCovariance',R,...
          'InitialStateEstimate',5,...
          'InitialErrorCovarianceEstimate',1,...
          'ControlInputPort',false);
ctr = 0;
```

Add noise to the signal. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = kalman(noisyVal);
    tScope(trueVal,noisyVal,estVal);

    % Disabling the correction step of second filter for the middle
    % one-third of the simulation
    if ctr == floor(numSamples/3)
        kalman.DisableCorrection = true;
    end
    if ctr == floor(2*numSamples/3)
        kalman.DisableCorrection = false;
    end
    ctr = ctr + 1;
end
```



Use a Single System object to Track Multiple Scalar Values

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Create the signal where the columns are the two scalar values to be tracked. Also create the Kalman Filter, and the Time Scopes.

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
sig1 = [  ones(numSamples/4,1);   -3*ones(numSamples/4,1);...
         4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
sig2 = [-2*ones(numSamples/4,1);   4*ones(numSamples/4,1);...
        -3*ones(numSamples/4,1); 1.5*ones(numSamples/4,1)];

src.Signal = [sig1, sig2];

tScope1 = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
           'TimeUnits', 'Seconds', 'YLimits',[-5 5], ...
           'Title', ['True(channel 1), noisy(channel 2) and ',...
           'estimated(channel 3) values'], ...
           'ShowLegend', true);
tScope2 = clone(tScope1);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance', R,...
    'InitialStateEstimate', -3,...
    'InitialErrorCovarianceEstimate', 1,...
    'ControlInputPort',false);
```

Add noise to the signal. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn(1,2);
    estVal = kalman(noisyVal);
           % Plot results of first channel on Time Scope
    tScope1(trueVal(:,1),noisyVal(:,1),estVal(:,1));
           % Plot results of second channel on Time Scope
    tScope2(trueVal(:,2),noisyVal(:,2),estVal(:,2));
end
```

Use Unit Step to Track Ramp Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

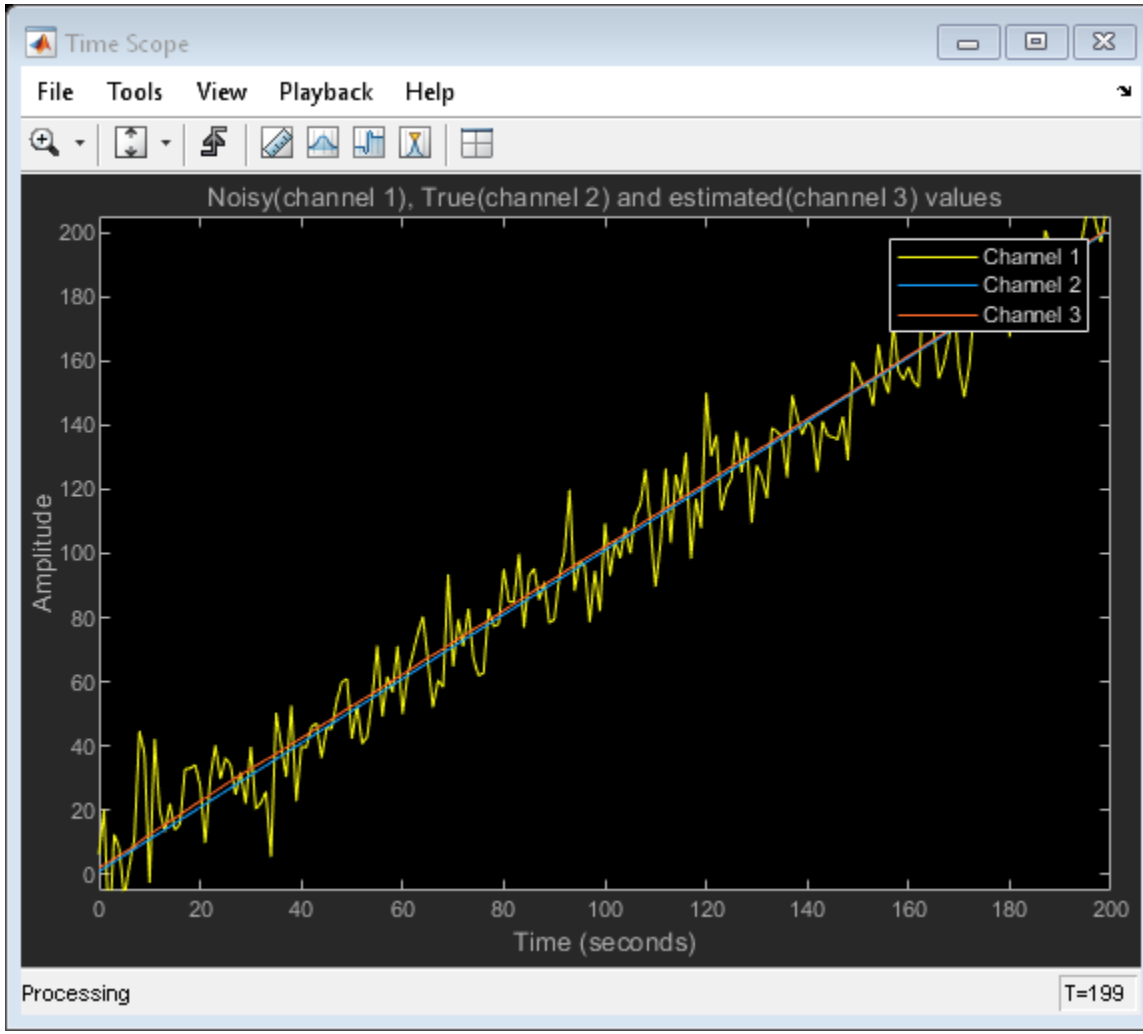
Use a unit step as the control input to track a ramp signal. Create the ramp signal to be tracked, the control input, the Time Scope, and the Kalman Filter.

```
numSamples = 200;
R = 100;
src = dsp.SignalSource;
src.Signal = (1:numSamples)';
control = dsp.SignalSource;
control.Signal = ones(numSamples,1);

tScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
    'TimeUnits', 'Seconds', 'YLimits',[-5 205], ...
    'Title', ['Noisy(channel 1), True(channel 2) and ',...
    'estimated(channel 3) values'], ...
    'ShowLegend', true);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance', R,...
    'InitialStateEstimate', 1,...
    'InitialErrorCovarianceEstimate', 1);
```

Add noise to the signal. Filter the signal using kalman filter. View the output using time scope.

```
while(~isDone(src))
    trueVal = src();
    ctrl = control();
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = kalman(noisyVal,ctrl);
    tScope(noisyVal,trueVal,estVal);
end
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Kalman Filter block reference page. The object properties correspond to the block parameters.

dsp.LDLFactor

Package: `dsp`

Factor square Hermitian positive definite matrices into components

Description

The `LDLFactor` object factors square Hermitian positive definite matrices into lower, upper, and diagonal components. The object uses only the lower triangle of S.

To factor these matrices into lower, upper, and diagonal components:

1. Define and set up your LDL factor object. See “Construction” on page 4-1103.
2. Call `step` to factor the matrices according to the properties of `dsp.LDLFactor`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ldl = dsp.LDLFactor` returns an LDL factor System object, `ldl`, that computes unit lower triangular `L` and diagonal `D` such that `S` = LDL for square, symmetric/Hermitian, positive definite input matrix `S`.

`ldl = dsp.LDLFactor('PropertyName',PropertyValue,...)` returns an `LDL` factor System object, `ldl`, with each specified property set to the specified value.

Properties

Fixed-Point Properties

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

`CustomIntermediateProductDataType`

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

`IntermediateProductDataType`

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

`ProductDataType`

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as: `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

Methods

step	Decompose matrix into components

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Decompose a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Decompose a square Hermitian positive definite matrix using LDL factor.

```
A = gallery('randcorr',5);
ldl = dsp.LDLFactor;
y = ldl(A);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LDL Factorization block reference page. The object properties correspond to the block parameters, except:
No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

Extended Capabilities

`dsp.LUFactor`

Introduced in R2012a

step

System object: `dsp.LDLFactor`
Package: `dsp`

Decompose matrix into components

Syntax

```
Y = step(ldl,S)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ldl,S)` decomposes the matrix `S` into lower, upper, and diagonal components. The output `Y` is a composite matrix with the `L` as its lower triangular part and `D` as the diagonal and `L'` as its upper triangular part. If `S` is not positive definite the output `Y` is not a valid factorization.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LevinsonSolver

Package: `dsp`

Solve linear system of equations using Levinson-Durbin recursion

Description

The `LevinsonSolver` object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

1. Define and set up your System object. See “Construction” on page 4-1109.
2. Call `step` to solve the system of equations according to the properties of `dsp.LevinsonSolver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`levinson = dsp.LevinsonSolver` returns a System object, `levinson`, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

`levinson = dsp.LevinsonSolver('PropertyName',PropertyValue,...)` returns a Levinson-Durbin object, `levinson`, with each specified property set to the specified value.

Properties

`AOutputPort`

Enable polynomial coefficients output

Set this property to `true` to output the polynomial coefficients *A*. Both `AOutputPort` and `KOutputPort` properties cannot be `false` at the same time. For scalar inputs, set the `AOutputPort` property to `true`. The default is `false`.

`KOutputPort`

Enable reflection coefficients output

Set this property to `true` to output the reflection coefficients *K*. You cannot set both the `AOutputPort` and `KOutputPort` properties to `false` at the same time. For scalar inputs, you must set the `KOutputPort` property to `false`. The default is `true`.

`PredictionErrorOutputPort`

Enable prediction error output

Set this property to `true` to output the prediction error. The default is `false`.

`ZerothLagZeroAction`

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select `Ignore` or `Use zeros`. The default is `Use zeros`.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as `Wrap`, `Saturate`. The default is `Wrap`.

`ACoefficientDataType`

A coefficient word and fraction lengths

This constant property has a value of `Custom`.

`CustomACoefficientDataType`

A coefficient word and fraction lengths

Specify the *A* coefficient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16,15)`.

`KCoefficientDataType`

K coefficient word and fraction lengths

This constant property has a value of `Custom`.

`CustomKCoefficientDataType`

K coefficient word and fraction lengths

Specify the *K* coefficient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16,15)`.

`PredictionErrorDataType`

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

`CustomPredictionErrorDataType`

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType` property is `Custom`. The default is `numerictype([],16,15)`.

`ProductDataType`

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. The default is `Custom`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

Methods

step Reflection coefficients corresponding to columns of input

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Compute Polynomial Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients.

```
levinson = dsp.LevinsonSolver;
levinson.AOutputPort = true;
levinson.KOutputPort = false;
x = (1:100)';
ac = dsp.Autocorrelator(...
'MaximumLagSource', 'Property', ...
'MaximumLag', 10);
a = ac(x);
c = levinson(a); % Compute polynomial coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Levinson-Durbin block reference page. The object properties correspond to the block parameters, except:
Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.Autocorrelator`

Introduced in R2012a

step

System object: `dsp.LevinsonSolver`
Package: `dsp`

Reflection coefficients corresponding to columns of input

Syntax

```
K = step(levinson,X)
A = step(levinson,X)
[A, K] = step(levinson,X)
[..., P] = step(levinson,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`K = step(levinson,X)` returns reflection coefficients `K` corresponding to the columns of input `X`. `X` is typically a column or matrix of autocorrelation coefficients with lag `0` as the first element.

`A = step(levinson,X)` returns polynomial coefficients `A` when the `AOutputPort` property is `true` and the `KOutputPort` property is `false`.

`[A, K] = step(levinson,X)` returns polynomial coefficients `A` and reflection coefficients `K` when both the `AOutputPort` and `KOutputPort` properties are `true`.

`[..., P] = step(levinson,X)` also returns the error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LMSFilter

Package: `dsp`

Compute output, error, and weights of LMS adaptive filter

Description

The `dsp.LMSFilter` System object implements an adaptive finite impulse response (FIR) filter that converges an input signal to the desired signal using one of the following algorithms:

- LMS
- Normalized LMS
- Sign-Data LMS
- Sign-Error LMS
- Sign-Sign LMS

For more details on each of these methods, see “Algorithms” on page 4-1170.

The filter adapts its weights until the error between the primary input signal and the desired signal is minimal. The mean square of this error (MSE) is computed using the `msesim` function. The predicted version of the MSE is determined using a Wiener filter in the `msepred` function. The `maxstep` function computes the maximum adaptation step size, which controls the speed of convergence.

For an overview of the adaptive filter methodology, and the most common applications the adaptive filters are used in, see “Overview of Adaptive Filters and Applications”.

To filter a signal using an adaptive FIR filter:

1. Create the `dsp.LMSFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
lms = dsp.LMSFilter
lms = dsp.LMSFilter(L)
lms = dsp.LMSFilter(Name,Value)
```

Description

`lms = dsp.LMSFilter` returns an LMS filter object, `lms`, that computes the filtered output, filter error, and the filter weights for a given input and a desired signal using the least mean squares (LMS) algorithm.

`lms = dsp.LMSFilter(L)` returns an LMS filter object with the “Length” on page 4-0 property set to `L`.

`lms = dsp.LMSFilter(Name,Value)` returns an LMS filter object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with the previous input argument.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`Method` — Method to calculate filter weights
`'LMS'` (default) | `'Normalized LMS'` | `'Sign-Data LMS'` | `'Sign-Error LMS'` | `'Sign-Sign LMS'`

Method to calculate filter weights, specified as one of the following:

- `'LMS'` –– Solves the Weiner-Hopf equation and finds the filter coefficients for an adaptive filter.
- `'Normalized LMS'` –– Normalized variation of the LMS algorithm.
- `'Sign-Data LMS'` –– Correction to the filter weights at each iteration depends on the sign of the input `x`.
- `'Sign-Error LMS'` –– Correction applied to the current filter weights for each successive iteration depends on the sign of the error, `err`.
- `'Sign-Sign LMS'` –– Correction applied to the current filter weights for each successive iteration depends on both the sign of `x` and the sign of `err`.

For more details on the algorithms, see “Algorithms” on page 4-1170.

`Length` — Length of FIR filter weights vector
`32` (default) | positive integer

Length of the FIR filter weights vector, specified as a positive integer.

Example: 64

Example: 16

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StepSizeSource` — Method to specify adaptation step size
`'Property'` (default) | `'Input port'`

Method to specify the adaptation step size, specified as one of the following:

- `'Property'` –– The property “StepSize” on page 4-0 specifies the size of each adaptation step.
- `'Input port'` –– Specify the adaptation step size as one of the inputs to the object.

`StepSize` — Adaptation step size
`0.1` (default) | non-negative scalar

Adaptation step size factor, specified as a non-negative scalar. For convergence of the normalized LMS method, the step size must be greater than 0 and less than 2.

A small step size ensures a small steady state error between the output “y” on page 4-0 and the desired signal “d” on page 4-0 . If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size.

Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Tunable: Yes

Dependencies

This property applies when you set "StepSizeSource" on page 4-0 to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LeakageFactor` — Leakage factor used in leaky LMS method

`1` (default) | `[0 1]`

Leakage factor used when implementing the leaky LMS method, specified as a scalar in the range `[0 1]`. When the value equals 1, there is no leakage in the adapting method. When the value is less than 1, the filter implements a leaky LMS method.

Example: 0.5

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialConditions` — Initial conditions of filter weights

`0` (default) | scalar | vector

Initial conditions of filter weights, specified as a scalar or a vector of length equal to the value of the "Length" on page 4-0 property. When the input is real, the value of this property must be real.

Example: 0

Example: [1 3 1 2 7 8 9 0 2 2 8 2]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`AdaptInputPort` — Flag to adapt filter weights

`false` (default) | `true`

Flag to adapt filter weights, specified as one of the following:

- `false` –– The object continuously updates the filter weights.
- `true` –– An adaptation control input is provided to the object when you call its algorithm. If the value of this input is non-zero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

`WeightsResetInputPort` — Flag to reset filter weights
`false` (default) | `true`

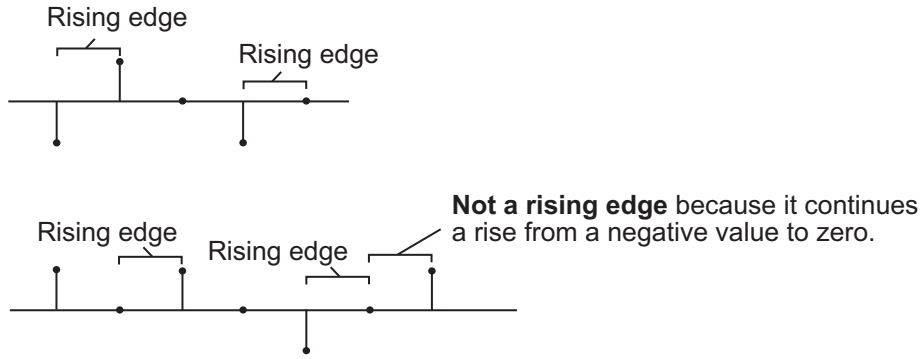
Flag to reset filter weights, specified as one of the following:

- `false` –– The object does not reset weights.
- `true` –– A reset control input is provided to the object when you call its algorithm. This setting enables the "WeightsResetCondition" on page 4-0 property. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input provided to the object algorithm.

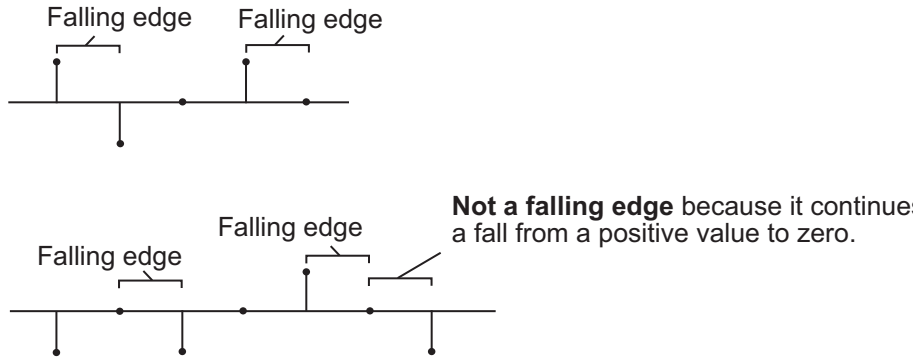
`WeightsResetCondition` — Event to reset filter weights
`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Event that triggers the reset of the filter weights, specified as one of the following. The object resets the filter weights whenever a reset event is detected in its reset input.

- `'Non-zero'` –– Triggers a reset operation at each sample, when the reset input is not zero.
- `'Rising edge'` –– Triggers a reset operation when the reset input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `'Falling edge'` –– Triggers a reset operation when the reset input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.



- `'Either edge'` –– Triggers a reset operation when the reset input is a rising edge or a falling edge.

The object resets the filter weights based on the value of this property and the reset input `r` provided to the object algorithm.

Dependencies

This property applies when you set the “WeightsResetInputPort” on page 4-0 property to `true`.

`WeightsOutput` — Method to output adapted filter weights

`'Last'` (default) | `'None'` | `'All'`

Method to output adapted filter weights, specified as one of the following:

- `'Last'` (default) — The object returns a column vector of weights corresponding to the last sample of the data frame. The length of the weights vector is the value given by the "Length" on page 4-0 property.
- `'All'` — The object returns a *FrameLength*-by-*Length* matrix of weights. The matrix corresponds to the full sample-by-sample history of weights for all *FrameLength* samples of the input values. Each row in the matrix corresponds to a set of LMS filter weights calculated for the corresponding input sample.
- `'None'` — This setting disables the weights output.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

`OverflowAction` — Overflow action for fixed-point operations

`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` –- The object wraps the result of its fixed-point operations.
- `'Saturate'` –- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

`StepSizeDataType` — Step size word length and fraction length settings

`'Same word length as first input'` (default) | `'Custom'`

Step size word length and fraction length settings, specified as one of the following:

- `'Same word length as first input'` –- The object specifies the word length of step size to be the same as that of the first input. The fraction length is computed to get the best possible precision.

- `'Custom'` –– The step size data type is specified as a custom numeric type through the "CustomStepSizeDataType" on page 4-0 property.

For more information on the step size data type this object uses, see the "Fixed Point" on page 4-1173 section.

`CustomStepSizeDataType` — Word and fraction lengths of step size
`numerictype([],16,15)` (default)

Word and fraction lengths of the step size, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: numerictype([],32)

Dependencies

This property applies under the following conditions:

- "StepSizeSource" on page 4-0 property set to `'Property'` and "StepSizeDataType" on page 4-0 set to `'Custom'`.
- `StepSizeSource` property set to `'Input port'`.

`LeakageFactorDataType` — Leakage factor word length and fraction length settings
`'Same word length as first input'` (default) | `'Custom'`

Leakage factor word length and fraction length settings, specified as one of the following:

- `'Same word length as first input'` –– The object specifies the word length of leakage factor to be the same as that of the first input. The fraction length is computed to get the best possible precision.
- `'Custom'` –– The leakage factor data type is specified as a custom numeric type through the "CustomLeakageFactorDataType" on page 4-0 property.

For more information on the leakage factor data type this object uses, see the "Fixed Point" on page 4-1173 section.

`CustomLeakageFactorDataType` — Word and fraction lengths of the leakage factor
`numerictype([],16,15)` (default)

Word and fraction lengths of the leakage factor, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: numerictype([],32)

Dependencies

This property applies when you set the "LeakageFactorDataType" on page 4-0 property to `'Custom'`.

`WeightsDataType` — Weights word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Weights word length and fraction length settings, specified as one of the following:

- `'Same as first input'` –– The object specifies the data type of the filter weights to be the same as that of the first input.
- `'Custom'` –– The data type of filter weights is specified as a custom numeric type through the "CustomWeightsDataType" on page 4-0 property.

For more information on the filter weights data type this object uses, see the "Fixed Point" on page 4-1173 section.

`CustomWeightsDataType` — Word and fraction lengths of filter weights

`numerictype([],16,15)` (default)

Word and fraction lengths of the filter weights, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: numerictype([],32,20)

Dependencies

This property applies when you set the "WeightsDataType" on page 4-0 property to `'Custom'`.

`EnergyProductDataType` — Energy product word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Energy product word length and fraction length settings, specified as one of the following:

- `'Same as first input'` –– The object specifies the data type of the energy product to be the same as that of the first input.

- `'Custom'` –– The data type of the energy product is specified as a custom numeric type through the "CustomEnergyProductDataType" on page 4-0 property.

For more information on the energy product data type this object uses, see the "Fixed Point" on page 4-1173 section.

Dependencies

This property applies when you set the "Method" on page 4-0 property to `'Normalized LMS'`.

`CustomEnergyProductDataType` — Word and fraction lengths of energy product

`numerictype([],32,20)` (default)

Word and fraction lengths of the energy product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the "Method" on page 4-0 property to `'Normalized LMS'` and "EnergyProductDataType" on page 4-0 property to `'Custom'`.

`EnergyAccumulatorDataType` — Energy accumulator word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Energy accumulator word length and fraction length settings, specified as one of the following:

- `'Same as first input'` –– The object specifies the data type of the energy accumulator to be the same as that of the first input.
- `'Custom'` –– The data type of the energy accumulator is specified as a custom numeric type through the "CustomEnergyAccumulatorDataType" on page 4-0 property.

For more information on the energy accumulator data type this object uses, see the "Fixed Point" on page 4-1173 section.

Dependencies

This property applies when you set the "Method" on page 4-0 property to `'Normalized LMS'`.

`CustomEnergyAccumulatorDataType` — Word and fraction lengths of energy accumulator

`numerictype([],32,20)` (default)

Word and fraction lengths of the energy accumulator, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the "Method" on page 4-0 property to `'Normalized LMS'` and "EnergyAccumulatorDataType" on page 4-0 property to `'Custom'`.

`ConvolutionProductDataType` — Convolution product word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Convolution product word length and fraction length settings, specified as one of the following:

- `'Same as first input'` –– The object specifies the data type of the convolution product to be the same as that of the first input.
- `'Custom'` –– The data type of the convolution product is specified as a custom numeric type through the "CustomConvolutionProductDataType" on page 4-0 property.

For more information on the convolution product data type this object uses, see the "Fixed Point" on page 4-1173 section.

`CustomConvolutionProductDataType` — Word and fraction lengths of convolution product

`numerictype([],32,20)` (default)

Word and fraction lengths of the convolution product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the "ConvolutionProductDataType" on page 4-0 property to `'Custom'`.

`ConvolutionAccumulatorDataType` — Convolution accumulator word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Convolution accumulator word length and fraction length settings, specified as one of the following:

- `'Same as first input'` –– The object specifies the data type of the convolution accumulator to be the same as that of the first input.
- `'Custom'` –– The data type of the convolution accumulator is specified as a custom numeric type through the "CustomConvolutionAccumulatorDataType" on page 4-0 property.

For more information on the convolution accumulator data type this object uses, see the "Fixed Point" on page 4-1173 section.

`CustomConvolutionAccumulatorDataType` — Word and fraction lengths of convolution accumulator

`numerictype([],32,20)` (default)

Word and fraction lengths of the convolution accumulator, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the "ConvolutionAccumulatorDataType" on page 4-0 property to `'Custom'`.

`StepSizeErrorProductDataType` — Step size error product word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Step size error product word length and fraction length settings, specified as one of the following:

- `'Same as first input'` –– The object specifies the data type of the step size error product to be the same as that of the first input.
- `'Custom'` –– The data type of the step size error product is specified as a custom numeric type through the "CustomStepSizeErrorProductDataType" on page 4-0 property.

For more information on the step size error product data type this object uses, see the “Fixed Point” on page 4-1173 section.

`CustomStepSizeErrorProductDataType` — Word and fraction lengths of step size error product

`numerictype([],32,20)` (default)

Word and fraction lengths of the step size error product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “StepSizeErrorProductDataType” on page 4-0 property to `'Custom'`.

`WeightsUpdateProductDataType` — Filter weights update product word length and fraction length settings

`'Same as first input'` (default) | `'Custom'`

Word and fraction length settings of the filter weights update product, specified as one of the following:

- `'Same as first input'` –– The object specifies the data type of the filter weights update product to be the same as that of the first input.
- `'Custom'` –– The data type of the filter weights update product is specified as a custom numeric type through the “CustomWeightsUpdateProductDataType” on page 4-0 property.

For more information on the filter weights update product data type this object uses, see the “Fixed Point” on page 4-1173 section.

`CustomWeightsUpdateProductDataType` — Word and fraction lengths of filter weights update product

`numerictype([],32,20)` (default)

Word and fraction lengths of the filter weights update product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “WeightsUpdateProductDataType” on page 4-0 property to `'Custom'`.

`QuotientDataType` — Quotient word length and fraction length settings
`'Same as first input'` (default) | `'Custom'`

Quotient word length and fraction length settings, specified as one of the following:

- `'Same as first input'` –– The object specifies the quotient data type to be the same as that of the first input.
- `'Custom'` –– The quotient data type is specified as a custom numeric type through the "CustomQuotientDataType" on page 4-0 property.

For more information on the quotient data type this object uses, see the "Fixed Point" on page 4-1173 section.

Dependencies

This property applies when you set the "Method" on page 4-0 property to `'Normalized LMS'`.

`CustomQuotientDataType` — Word and fraction lengths of quotient
`numerictype([],32,20)` (default)

Word and fraction lengths of the filter weights update product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the "Method" on page 4-0 property to `'Normalized LMS'` and "QuotientDataType" on page 4-0 property to `'Custom'`.

Usage

Syntax

```
[y,err,wts] = lms(x,d)
[y,err] = lms(x,d)
[ ___ ] = lms(x,d,mu)
[ ___ ] = lms(x,d,a)
[ ___ ] = lms(x,d,r)
[y,err,wts] = lms(x,d,mu,a,r)
```

Description

`[y,err,wts] = lms(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y`, the filter error in `err`, and the estimated filter weights in `wts`. The LMS filter object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`[y,err] = lms(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err` when the "WeightsOutput" on page 4-0 property is set to `'None'`.

`[ ___ ] = lms(x,d,mu)` filters the input signal, `x`, using `d` as the desired signal and `mu` as the step size, when the "StepSizeSource" on page 4-0 property is set to `'Input port'`. These inputs can be used with either of the previous sets of outputs.

`[ ___ ] = lms(x,d,a)` filters the input signal, `x`, using `d` as the desired signal and `a` as the adaptation control when the "AdaptInputPort" on page 4-0 property is set to `true`. When `a` is nonzero, the System object continuously updates the filter weights. When `a` is zero, the filter weights remain constant.

`[ ___ ] = lms(x,d,r)` filters the input signal, `x`, using `d` as the desired signal and `r` as a reset signal when the "WeightsResetInputPort" on page 4-0 property is set to `true`. The "WeightsResetCondition" on page 4-0 property can be used to set the reset trigger condition. If a reset event occurs, the System object resets the filter weights to their initial values.

`[y,err,wts] = lms(x,d,mu,a,r)` filters the input signal, `x`, using `d` as the desired signal, `mu` as the step size, `a` as the adaptation control, and `r` as the reset signal, and returns the filtered output in `y`, the filter error in `err`, and the adapted filter weights in `wts`.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the LMS filter. The input, `x`, and the desired signal, `d` must have the same size, data type, and complexity. If the input is fixed-point, the data type must be signed and must have the same word length as the desired signal.

The input, `x` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

`d` — Desired signal

scalar | column vector

The LMS filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size, data type, and complexity. If the desired signal is fixed-point, the data type must be signed and must have the same word length as the data input.

The input, `d` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

`mu` — Step size

nonnegative scalar

Adaptation step size factor, specified as a scalar, nonnegative numeric value. For convergence of the normalized LMS method, the step size should be greater than 0 and less than 2. The data type of the step size input must match the data type of `x` and `d`. If the data type is fixed-point, the data type must be signed.

A small step size ensures a small steady state error between the output `y` and the desired signal `d`. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Dependencies

This input is required when the “StepSizeSource” on page 4-0 property is set to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

a — Adaptation control

scalar

Adaptation control input that controls how the filter weights are updated. If the value of this input is non-zero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

Dependencies

This input is required when the "AdaptInputPort" on page 4-0 property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

r — Reset signal

scalar

Reset signal that resets the filter weights based on the values of the "WeightsResetCondition" on page 4-0 property.

Dependencies

This input is required when the "WeightsResetInputPort" on page 4-0 property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the

adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights that produce an output signal that matches closely with the desired signal. For more details on how `err` is computed, see "Algorithms" on page 4-1170.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

`wts` — Adaptive filter weights
scalar | column vector

Adaptive filter weights, returned as a scalar or a column vector of length specified by the value in "Length" on page 4-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.LMSFilter

maxstep	Maximum step size for LMS adaptive filter convergence
msepred	Predicted mean squared error for LMS adaptive filter
msesim	Estimated mean squared error for adaptive filters

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Predict Mean Squared Error for LMS Filter

The mean squared error (MSE) measures the average of the squares of the errors between the desired signal and the primary signal input to the adaptive filter. Reducing

this error converges the primary input to the desired signal. Determine the predicted value of MSE and the simulated value of MSE at each time instant using the `msepred` and `msesim` functions. Compare these MSE values with each other and with respect to the minimum MSE and steady-state MSE values. In addition, compute the sum of the squares of the coefficient errors given by the trace of the coefficient covariance matrix.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Initialization

Create a `dsp.FIRFilter` System object™ that represents the unknown system. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

LMS Filter

Create a `dsp.LMSFilter` System object to create a filter that adapts to output the desired signal. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the simulated MSE between the output of the unknown system, `d`, and the output of the adaptive filter. The variable `mse` gives the corresponding predicted value.

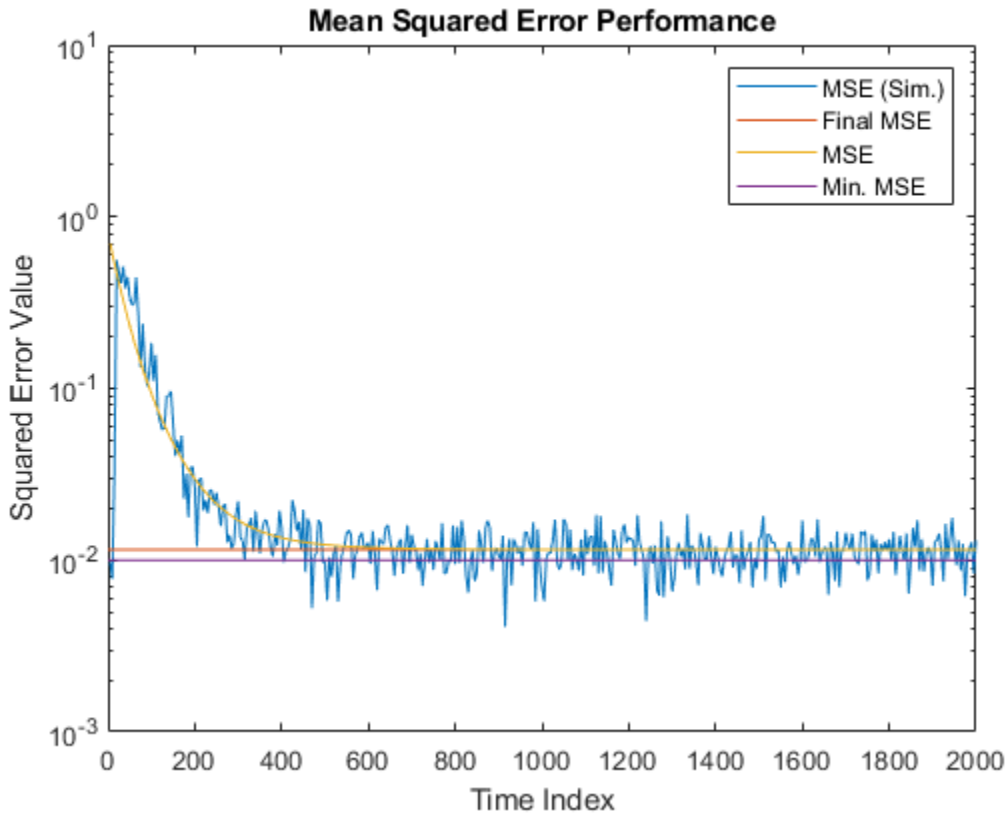
```
l = 32;
mu = 0.008;
m  = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
```

Plot the MSE Results

Compare the values of simulated MSE, predicted MSE, minimum MSE, and the final MSE. The final MSE value is given by the sum of minimum MSE and excess MSE.

```
nn = m:m:size(x,1);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
    (emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse])
title('Mean Squared Error Performance')
axis([0 size(x,1) 0.001 10])
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE')
xlabel('Time Index')
ylabel('Squared Error Value')
```



The predicted MSE follows the same trajectory as the simulated MSE. Both these trajectories converge with the steady-state (final) MSE.

Plot the Coefficient Trajectories

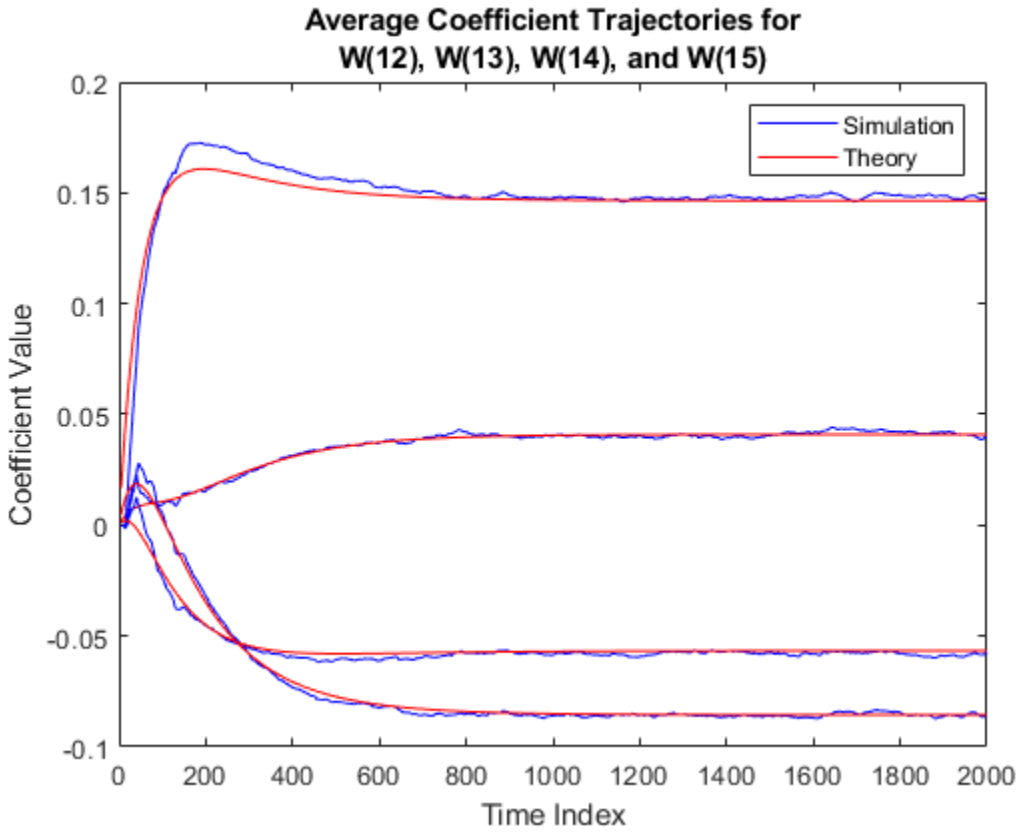
`meanWsim` is the mean value of the simulated coefficients given by `msesim`. `meanW` is the mean value of the predicted coefficients given by `msepred`.

Compare the simulated and predicted mean values of LMS filter coefficients 12,13,14, and 15.

```
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r')
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'}
```

```
PlotTitle = 2x1 cell array
    {'Average Coefficient Trajectories for'}
    {'W(12), W(13), W(14), and W(15)'      }
```

```
title(PlotTitle)
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Coefficient Value')
```

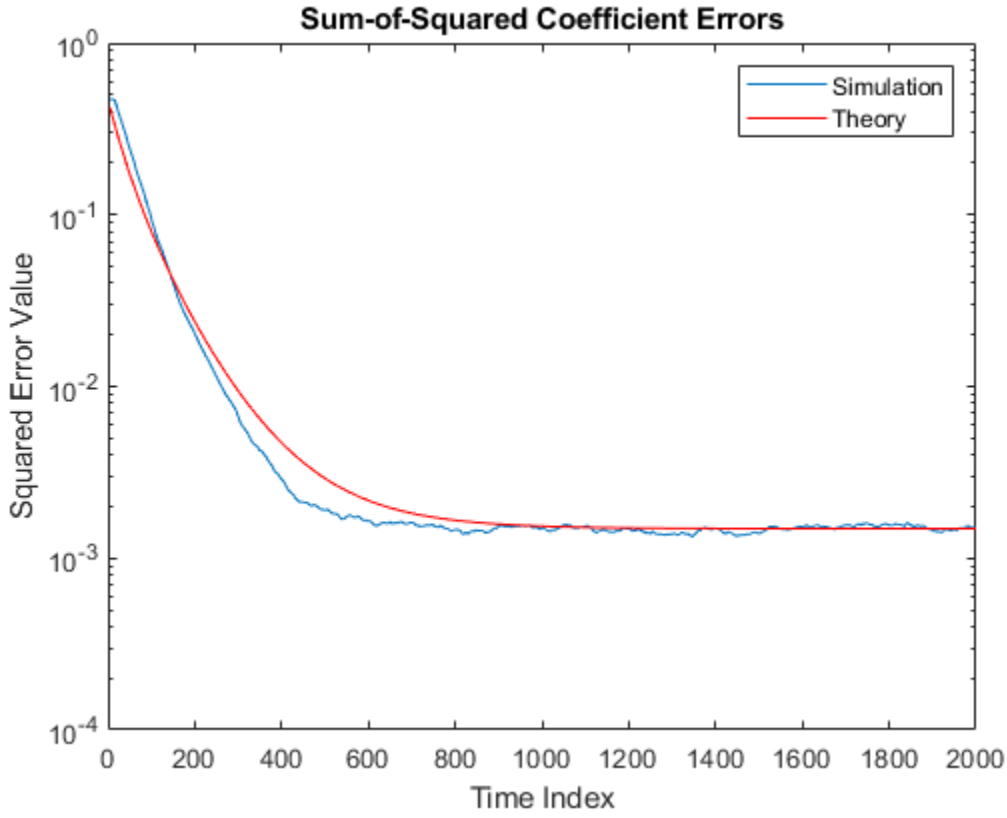


In steady state, both the trajectories converge.

Sum of Squared Coefficient Errors

Compare the sum of the squared coefficient errors given by `msepred` and `msesim`. These values are given by the trace of the coefficient covariance matrix.

```
semilogy(nn,traceKsim,nn,traceK,'r')
title('Sum-of-Squared Coefficient Errors')
axis([0 size(x,1) 0.0001 1])
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Squared Error Value')
```



Compute Maximum Step of LMS Adaptive Filter

The `maxstep` function computes the maximum step size of the adaptive filter. This step size keeps the filter stable at the maximum possible speed of convergence. Create the primary input signal, `x`, by passing a signed random signal to an IIR filter. Signal `x` contains 50 frames of 2000 samples each frame. Create an LMS filter with 32 taps and a step size of 0.1.

```
x = zeros(2000,50);
IIRFilter = dsp.IIRFilter('Numerator',sqrt(0.75),'Denominator',[1 -0.5]);
for k = 1:size(x,2)
  x(:,k) = IIRFilter(sign(randn(size(x,1),1)));
```

```
end
mu = 0.1;
LMSFilter = dsp.LMSFilter('Length',32,'StepSize',mu);
```

Compute the maximum adaptation step size and the maximum step size in mean-squared sense using the `maxstep` function.

```
[mumax,mumaxmse] = maxstep(LMSFilter,x)
```

```
mumax = 0.0625
```

```
mumaxmse = 0.0536
```

System Identification of FIR Filter Using LMS Algorithm

System identification is the process of identifying the coefficients of an unknown system using an adaptive filter. The general layout of the process is shown in “System Identification –– Using an Adaptive Filter to Identify an Unknown System”. The main components involved are:

- The adaptive filter algorithm. In this example, set the `Method` property of `dsp.LMSFilter` to `'LMS'`, to choose the LMS adaptive filter algorithm.
- An unknown system or process to adapt to. In this example, the filter designed by `fircband` is the unknown system.
- Appropriate input data to exercise the adaptation process. In terms of the generic LMS model, these are the desired signal $d(k)$ and the input signal $x(k)$.

The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter, $y(k)$, and the output of the unknown system (or the system to be identified), $d(k)$. Once the error signal is minimal, the adapted filter resembles the unknown system. The coefficients of both the filters match closely.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `fircband` function to design the filter coefficients. The filter designed is a lowpass filter constrained to 0.2 ripple in the stopband.

```
filt = dsp.FIRFilter;
filt.Numerator = fircband(12,[0 0.4 0.5 1], [1 1 0 0], [1 0.2],...
{'w' 'c'});
```

Pass the signal, `x` to the FIR filter. The desired signal, `d`, is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
x = 0.1*randn(250,1);
n = 0.01*randn(250,1);
d = filt(x) + n;
```

Adaptive Filter

With the unknown filter designed and the desired signal in place, construct and apply the adaptive LMS filter object to identify the unknown filter.

Preparing the adaptive filter object requires that you provide starting values for estimates of the filter coefficients and the LMS step size (`mu`). You could start with estimated coefficients of some set of nonzero values. This example uses zeros for the 12 initial filter weights. Set the `InitialConditions` property of `dsp.LMSFilter` to the desired initial values of the filter weights. For the step size, 0.8 is a good compromise between being large enough to converge well within the 250 iterations (250 input sample points) and small enough to create an accurate estimate of the unknown filter.

Create a `dsp.LMSFilter` object to create an adaptive filter that uses the LMS adaptive algorithm. Set the length of the adaptive filter to 13 taps and the step size to 0.8.

```
mu = 0.8;
lms = dsp.LMSFilter(13,'StepSize',mu)
```

```
lms =
  dsp.LMSFilter with properties:

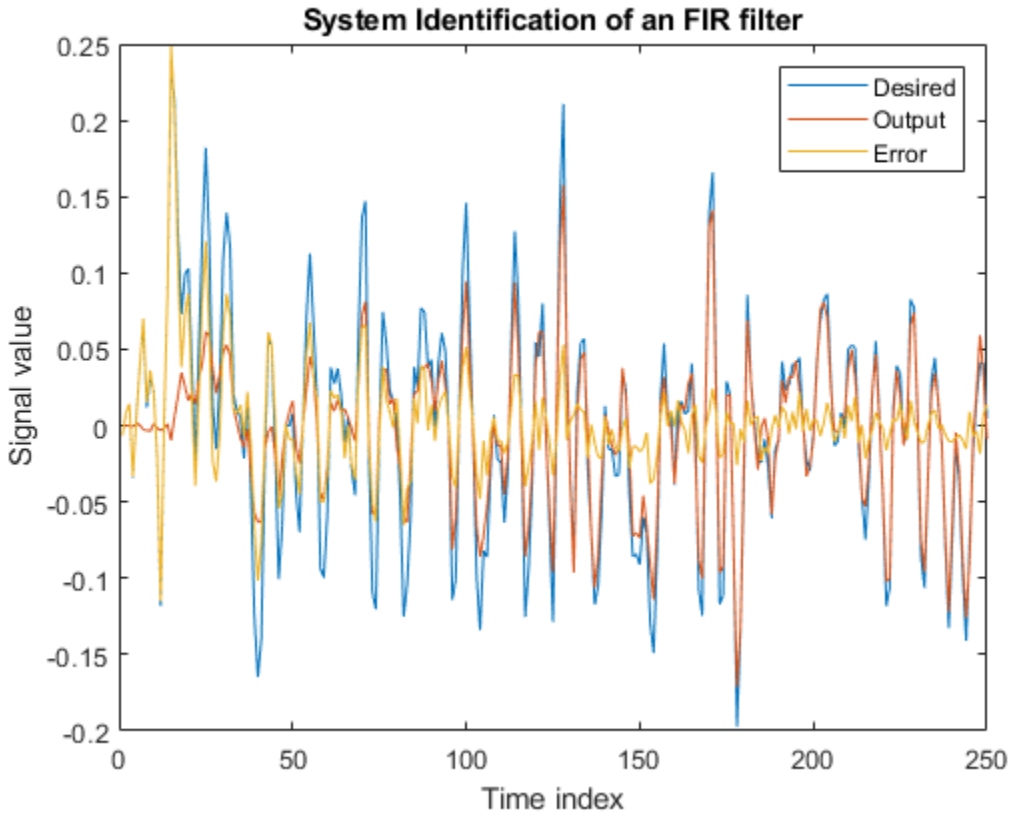
                  Method: 'LMS'
                  Length: 13
          StepSizeSource: 'Property'
                StepSize: 0.8000
           LeakageFactor: 1
       InitialConditions: 0
          AdaptInputPort: false
  WeightsResetInputPort: false
           WeightsOutput: 'Last'

  Show all properties
```

Pass the primary input signal, `x`, and the desired signal, `d`, to the LMS filter. Run the adaptive filter to determine the unknown system. The output, `y`, of the adaptive filter is the signal converged to the desired signal, `d`, thereby minimizing the error, `e`, between the two signals.

Plot the results. The output signal does not match the desired signal as expected, making the error between the two non-trivial.

```
[y,e,w] = lms(x,d);
plot(1:250, [d,y,e])
title('System Identification of an FIR filter')
legend('Desired','Output','Error')
xlabel('Time index')
ylabel('Signal value')
```

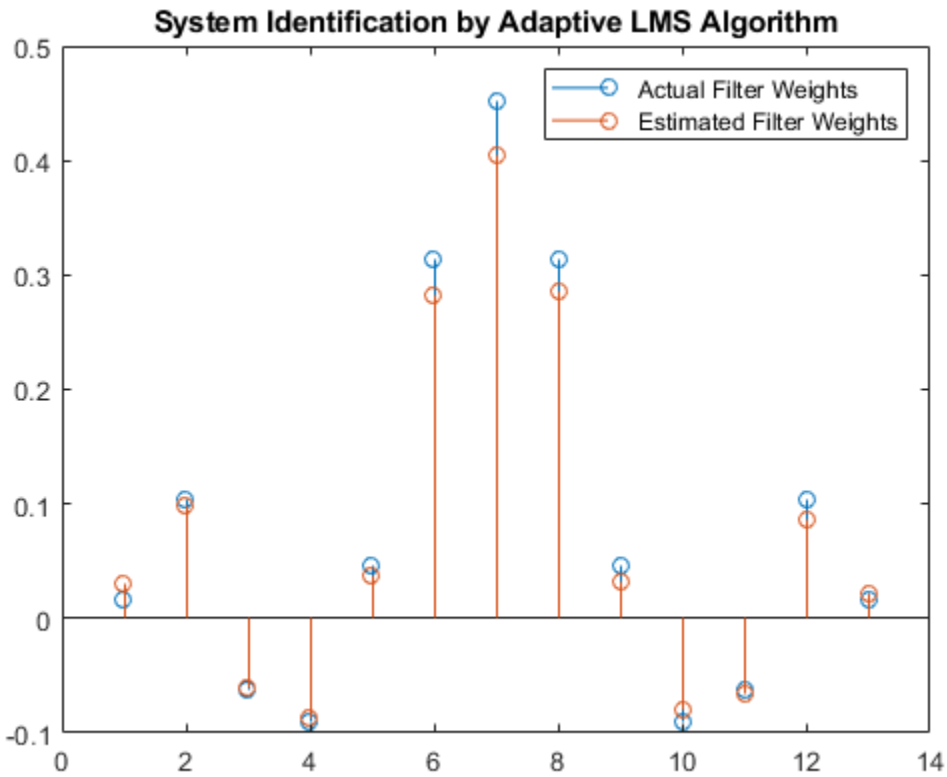


Compare the Weights

The weights vector, `w`, represents the coefficients of the LMS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the adaptive filter.

The estimated filter weights do not closely match the actual filter weights, confirming the results seen in the previous signal plot.

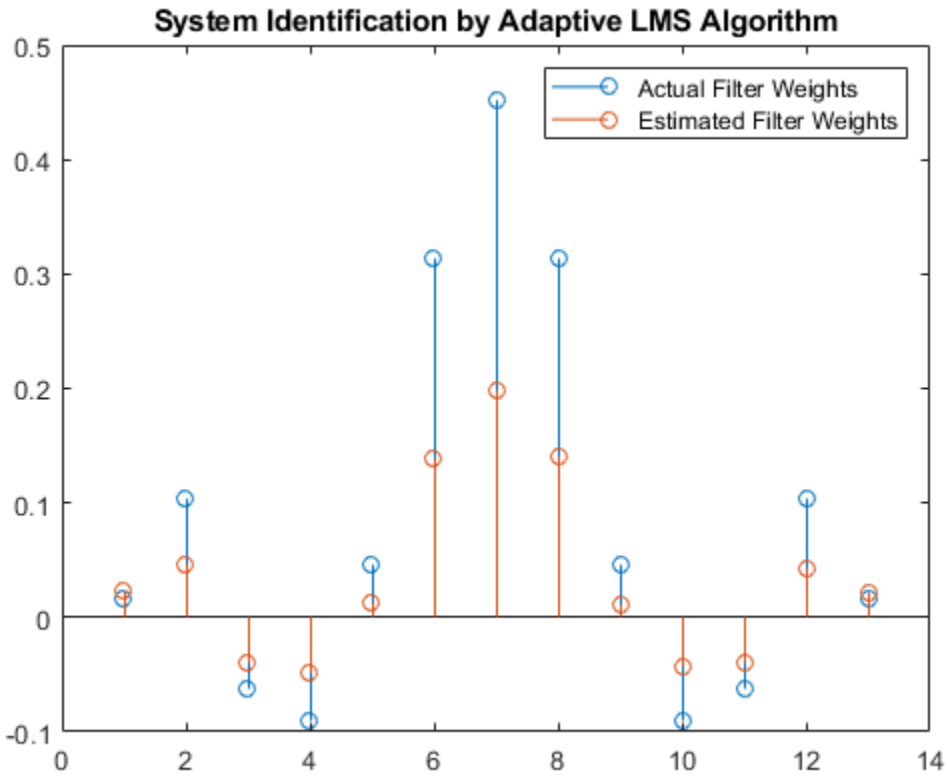
```
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual Filter Weights','Estimated Filter Weights',...
       'Location','NorthEast')
```



Changing the Step Size

As an experiment, try changing the step size to `0.2`. Repeating the example with `mu = 0.2` results in the following stem plot. The filters have not converged and estimated weights fail to approximate the actual weights closely.

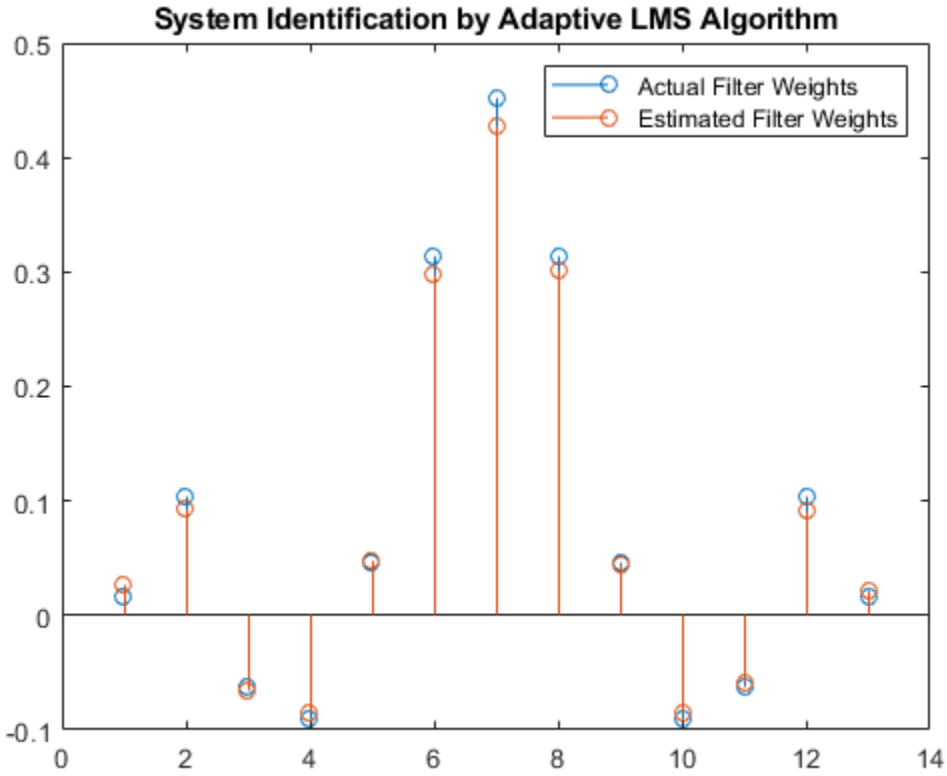
```
mu = 0.2;
lms = dsp.LMSFilter(13,'StepSize',mu);
[~,~,w] = lms(x,d);
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual Filter Weights','Estimated Filter Weights',...
       'Location','NorthEast')
```



Increase the Number of Data Samples

Increase the frame size of the desired signal. Even though this increases the computation involved, the LMS algorithm now has more data that can be used for adaptation. With 1000 samples of signal data and a step size of 0.2, the coefficients are aligned closer than before, indicating an improved convergence.

```
release(filt);
x = 0.1*randn(1000,1);
n = 0.01*randn(1000,1);
d = filt(x) + n;
[y,e,w] = lms(x,d);
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual Filter Weights','Estimated Filter Weights',...
       'Location','NorthEast')
```

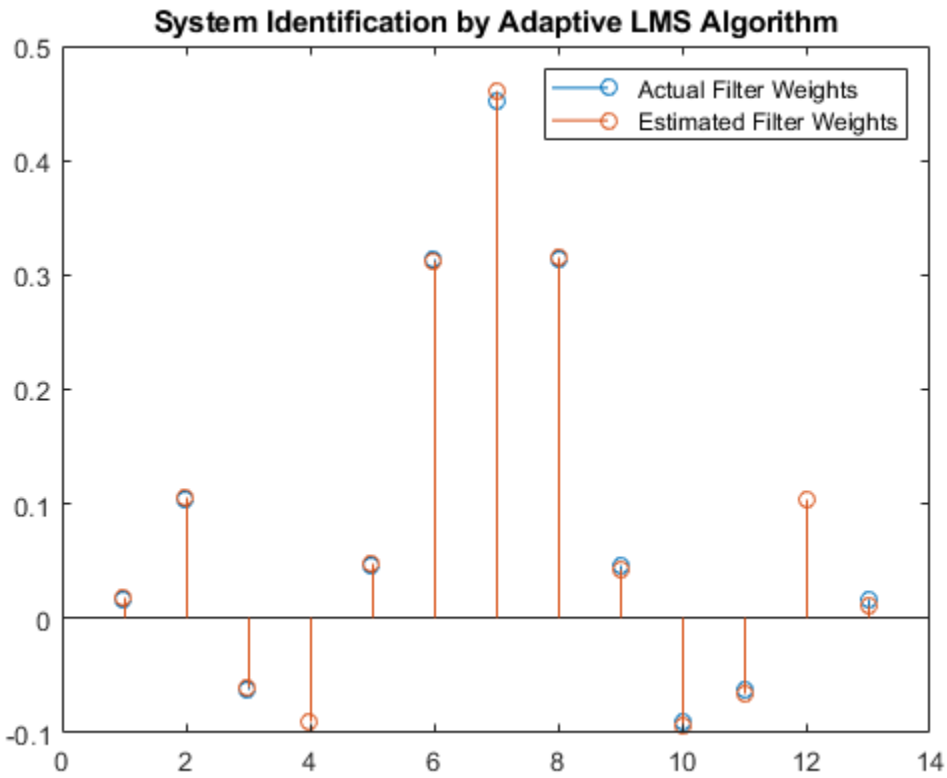


Further increase the number of data samples by inputing the data through iterations. Run the algorithm on 4000 samples of data, passed to the LMS algorithm in batches of 1000 samples, over 4 iterations.

Compare the filter weights. The weights of the LMS filter match very closely to the weights of the FIR filter indicating a good convergence.

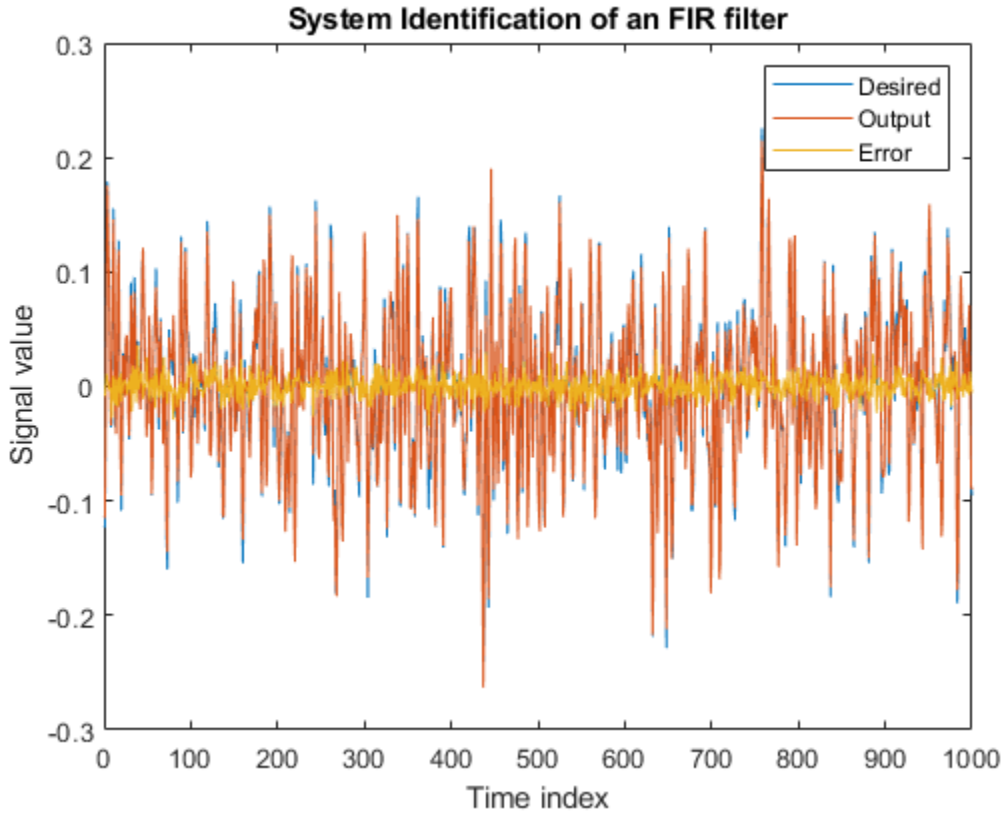
```
release(filt);
n = 0.01*randn(1000,1);
for index = 1:4
  x = 0.1*randn(1000,1);
  d = filt(x) + n;
  [y,e,w] = lms(x,d);
end
```

```
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual Filter Weights','Estimated Filter Weights',...
       'Location','NorthEast')
```



The output signal matches the desired signal very closely, making the error between the two very close to zero.

```
plot(1:1000, [d,y,e])
title('System Identification of an FIR filter')
legend('Desired','Output','Error')
xlabel('Time index')
ylabel('Signal value')
```



System Identification of FIR Filter Using Normalized LMS Algorithm

To improve the convergence performance of the LMS algorithm, the normalized variant (NLMS) uses an adaptive step size based on the signal power. As the input signal power changes, the algorithm calculates the input power and adjusts the step size to maintain an appropriate value. Thus the step size changes with time. As a result, the normalized algorithm converges more quickly with fewer samples in many cases. For input signals that change slowly over time, the normalized LMS can represent a more efficient LMS approach.

For an example using the LMS approach, see “System Identification of FIR Filter Using LMS Algorithm”.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `fircband` function to design the filter coefficients. The filter designed is a lowpass filter constrained to 0.2 ripple in the stopband.

```
filt = dsp.FIRFilter;
filt.Numerator = fircband(12,[0 0.4 0.5 1], [1 1 0 0], [1 0.2],...
{'w' 'c'});
```

Pass the signal, `x`, to the FIR filter. The desired signal, `d`, is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
x = 0.1*randn(1000,1);
n = 0.001*randn(1000,1);
d = filt(x) + n;
```

Adaptive Filter

To use the normalized LMS algorithm variation, set the `Method` property on the `dsp.LMSFilter` to `'Normalized LMS'`. Set the length of the adaptive filter to 13 taps and the step size to 0.2.

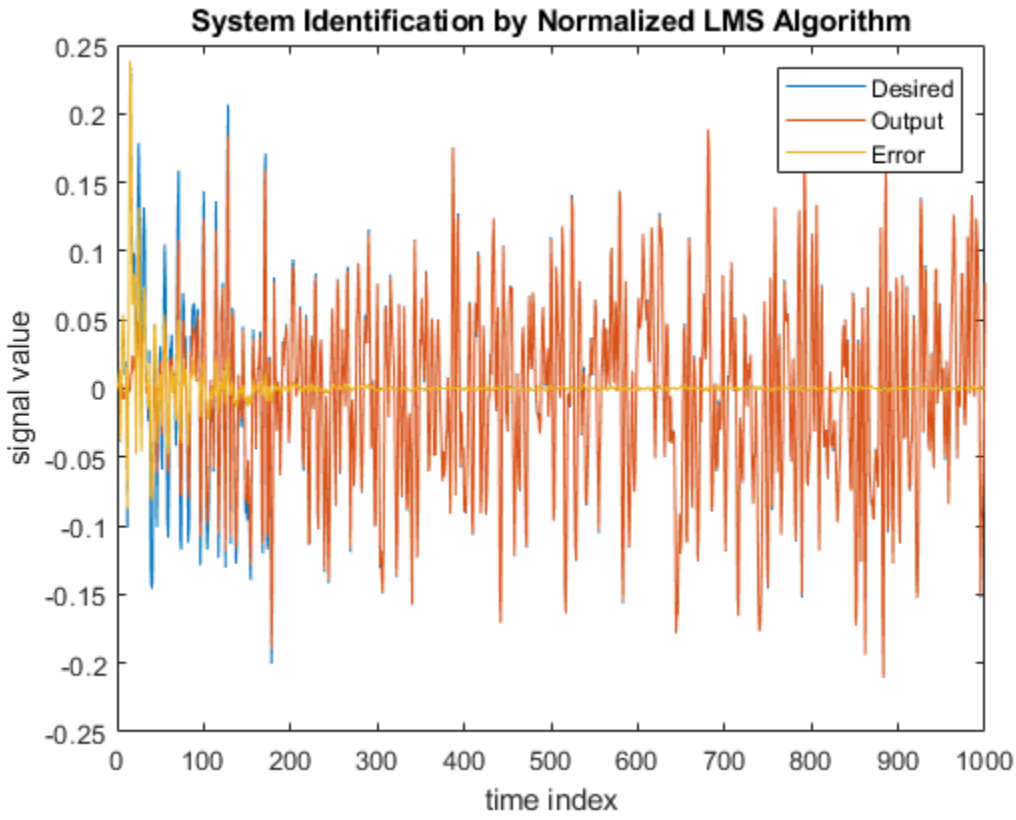
```
mu = 0.2;
lms = dsp.LMSFilter(13,'StepSize',mu,'Method',...
   'Normalized LMS');
```

Pass the primary input signal, `x`, and the desired signal, `d`, to the LMS filter.

```
[y,e,w] = lms(x,d);
```

The output, `y`, of the adaptive filter is the signal converged to the desired signal, `d`, thereby minimizing the error, `e`, between the two signals.

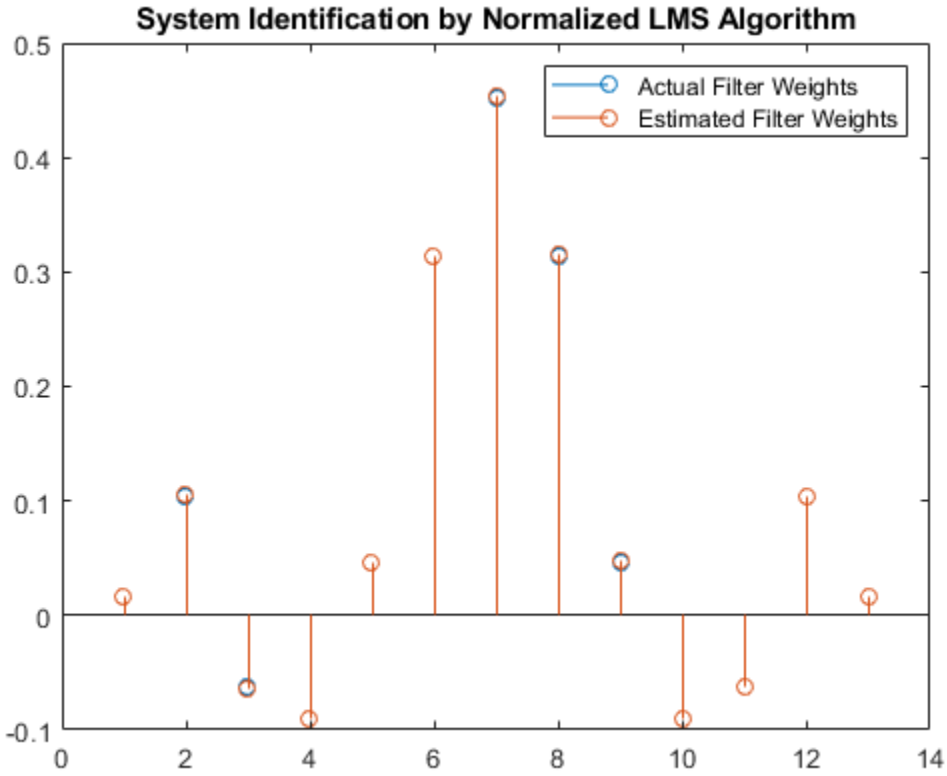
```
plot(1:1000, [d,y,e])
title('System Identification by Normalized LMS Algorithm')
legend('Desired','Output','Error')
xlabel('time index')
ylabel('signal value')
```



Compare the Adapted Filter to the Unknown System

The weights vector, w, represents the coefficients of the LMS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the adaptive filter.

```
stem([(filt.Numerator).' w])
title('System Identification by Normalized LMS Algorithm')
legend('Actual Filter Weights','Estimated Filter Weights',...
       'Location','NorthEast')
```



Compare Convergence Performance between LMS Algorithm and Normalized LMS Algorithm

An adaptive filter adapts its filter coefficients inorder to match the coefficients of the unknown system. The objective is to minimize the error signal between the output of the unknown system and the output of the adaptive filter. For the same input, when these two outputs converge and match closely, the coefficients of the two filters are said to match closely. The adaptive filter at this state resembles the unknown system. This example compares the rate at which this convergence happens for the two LMS algorithms - normalized LMS algorithm, LMS algorithm with no normalization.

Unknown System

Create a `dsp.FIRFilter` that represents the unknown system. Pass the signal, `x`, as an input to the unknown system. The desired signal, `d`, is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
filt = dsp.FIRFilter;
filt.Numerator = fircband(12,[0 0.4 0.5 1], [1 1 0 0], [1 0.2],...
{'w' 'c'});
x = 0.1*randn(1000,1);
n = 0.001*randn(1000,1);
d = filt(x) + n;
```

Adaptive Filter

Choose an adaptation step size of 0.2, and set the length of the adaptive filter to 13 taps.

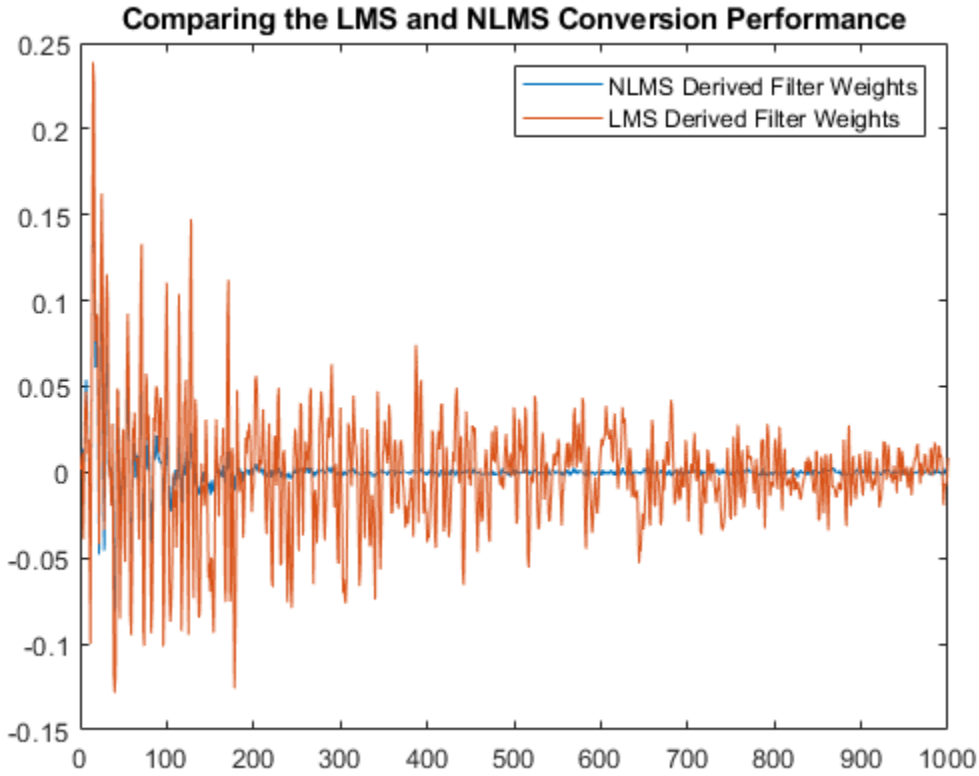
```
mu = 0.2;
lms_normalized = dsp.LMSFilter(13,'StepSize',mu,...
    'Method','Normalized LMS');
lms_nonnormalized = dsp.LMSFilter(13,'StepSize',mu,...
    'Method','LMS');
```

Pass the primary input signal, `x`, and the desired signal, `d`, to both the variations of the LMS algorithm. The variables, `e1` and `e2`, represent the error between the desired signal and the output of the normalized and non normalized filters, respecitvely.

```
[~,e1,~] = lms_normalized(x,d);
[~,e2,~] = lms_nonnormalized(x,d);
```

Plot the error signals for both the variations. When you compare, the error signal for the NLMS variant converges to zero much faster than the error signal for the LMS variant. The normalized version adapts in far fewer iterations to a result almost as good as the non normalized version.

```
plot([e1,e2]);
title('Comparing the LMS and NLMS Conversion Performance');
legend('NLMS Derived Filter Weights', ...
       'LMS Derived Filter Weights','Location', 'NorthEast');
```



Cancel Noise Using LMS Filter

Cancel additive noise, n, added to an unknown system using an LMS adaptive filter. The LMS filter adapts its coefficients until its transfer function matches the transfer function of the unknown system as closely as possible. The difference between the output of the adaptive filter and the output of the unknown system represents the error signal, e. Minimizing this error signal is the objective of the adaptive filter.

The unknown system and the LMS filter process the same input signal, x, and produce outputs d and y, respectively. If the coefficients of the adaptive filter match the coefficients of the unknown system, the error, e, in effect represents the additive noise.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

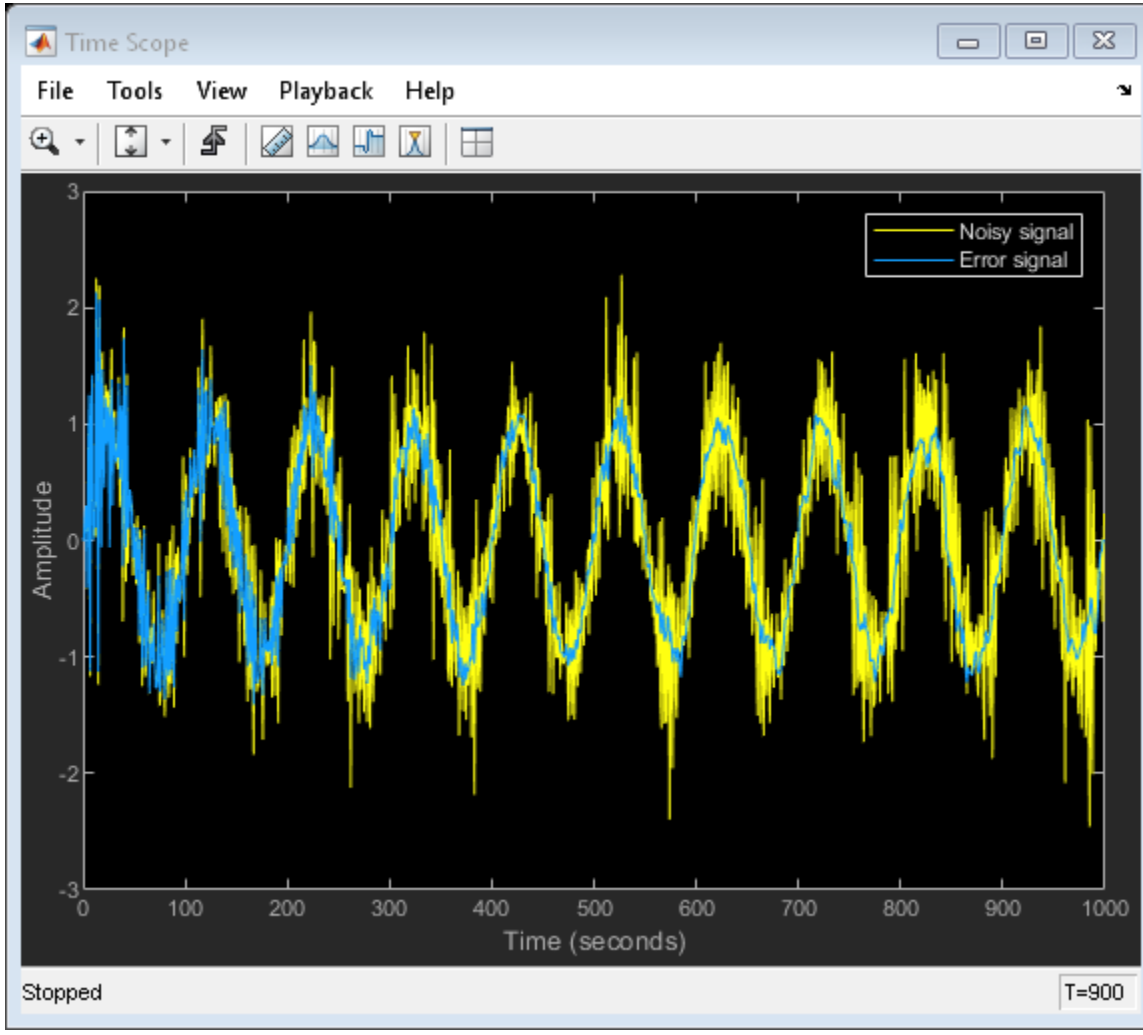
Initialization

Create a `dsp.FIRFilter` System object to represent the unknown system. Create a `dsp.LMSFilter` object and set the length to 11 taps and the step size to 0.05. Create a sine wave to represent the noise added to the unknown system. View the signals in a time scope.

```
FrameSize = 100;
NIter = 10;
lmsfilt2 = dsp.LMSFilter('Length',11,'Method','Normalized LMS', ...
    'StepSize',0.05);
firfilt2 = dsp.FIRFilter('Numerator', fir1(10,[.5, .75]));
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);
TS = dsp.TimeScope('TimeSpan',FrameSize*NIter,'TimeUnits','Seconds',...
    'YLimits',[-3 3],'BufferLength',2*FrameSize*NIter, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Noisy signal', 'Error signal'});
```

Create a random input signal, *x* and pass the signal to the FIR filter. Add a sine wave to the output of the FIR filter to generate the noisy signal, *d*. The signal, *d* is the output of the unknown system. Pass the noisy signal and the primary input signal to the LMS filter. View the noisy signal and the error signal in the time scope.

```
for k = 1:NIter
    x = randn(FrameSize,1);
    d = firfilt2(x) + sinewave();
    [y,e,w] = lmsfilt2(x,d);
    TS([d,e])
end
release(TS)
```



The error signal, `e`, is the sinusoidal noise added to the unknown system. Minimizing the error signal minimizes the noise added to the system.

Noise Cancellation Using Sign-Data LMS Algorithm

When the amount of computation required to derive an adaptive filter drives your development process, the sign-data variant of the LMS (SDLMS) algorithm might be a very good choice as demonstrated in this example.

In the standard and normalized variations of the LMS adaptive filter, coefficients for the adapting filter arise from the mean square error between the desired signal and the output signal from the unknown system. Using the sign-data algorithm changes the mean square error calculation by using the sign of the input data to change the filter coefficients.

When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ. If the error is negative, the new coefficients are again the previous coefficients minus the error multiplied by μ — note the sign change.

When the input is zero, the new coefficients are the same as the previous set.

In vector form, the sign-data LMS algorithm is:

$$w(k+1) = w(k) + \mu e(k)\mathrm{sgn}(x(k)),$$

where,

$$\mathrm{sgn}(x(k)) = \begin{cases} 1, & x(k) > 0 \\ 0, & x(k) = 0 \\ -1, & x(k) < 0 \end{cases}$$

with vector w containing the weights applied to the filter coefficients and vector $\boldsymbol{x}$ containing the input data. The vector $\boldsymbol{e}$ is the error between the desired signal and the filtered signal. The objective of the SDLMS algorithm is to minimize this error. Step size is represented by μ.

As you specify μ smaller, the correction to the filter weights gets smaller for each sample and the SDLMS error falls more slowly. Larger μ changes the weights more for each step so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\mathrm{InputSignalPower}\}},$$

where, N is the number of samples in the signal. Also, define μ as a power of two for efficient computing.

Note: How you set the initial conditions of the sign-data algorithm profoundly influences the effectiveness of the adaptation. Because the algorithm essentially quantizes the input signal, the algorithm can become unstable easily.

A series of large input values, coupled with the quantization process may result in the error growing beyond all bounds. You restrain the tendency of the sign-data algorithm to get out of control by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the `Method` property of `dsp.LMSFilter` to `'Sign-Data LMS'`. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation –– Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $d(k)$, the desired signal. The noise cancellation process removes the noise, leaving the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation –– Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter, and then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal+fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-data algorithm.

To prepare the `dsp.LMSFilter` object for processing, set the weight initial conditions (`InitialConditions`) and mu (`StepSize`) for the object. As noted earlier in this

section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path.

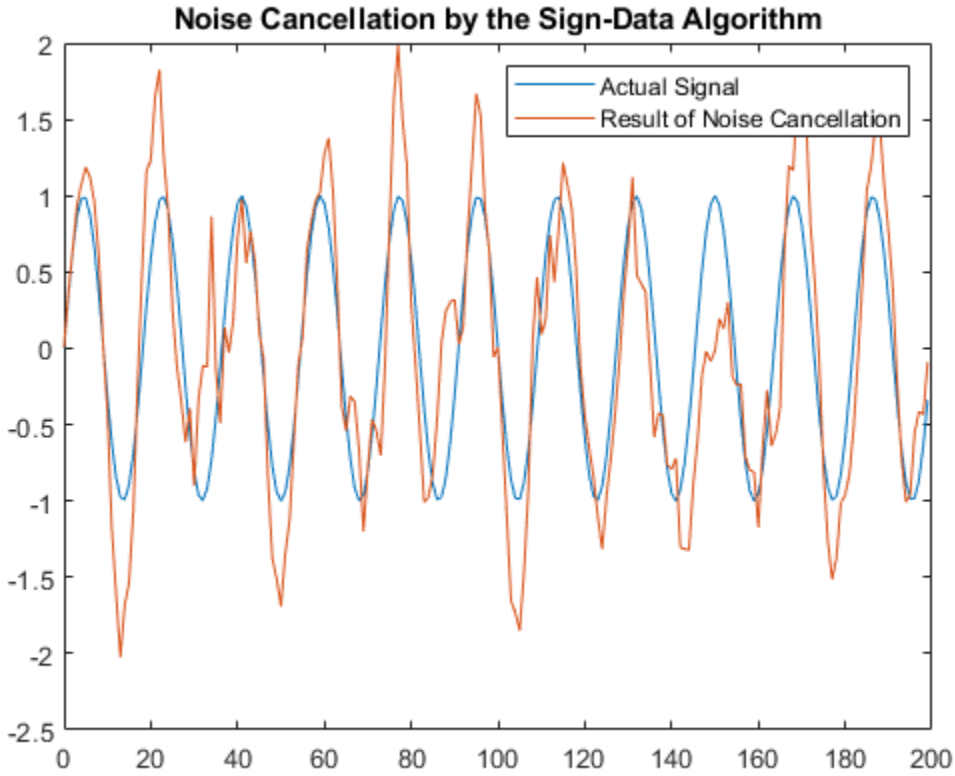
In “System Identification of FIR Filter Using LMS Algorithm” on page 4-1140, you constructed a default filter that sets the filter coefficients to zeros. In most cases that approach does not work for the sign-data algorithm. The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively.

For this example, start with the coefficients in the filter you used to filter the noise (`filt.Numerator`), and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).'-0.01; % Set the filter initial conditions.
mu = 0.05;          % Set the step size for algorithm updating.
```

With the required input arguments for `dsp.LMSFilter` prepared, construct the LMS filter object, run the adaptation, and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Data LMS',...
   'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:L-1,signal(1:L),0:L-1,e(1:L));
title('Noise Cancellation by the Sign-Data Algorithm');
legend('Actual Signal','Result of Noise Cancellation',...
       'Location','NorthEast');
```



When `dsp.LMSFilter` runs, it uses far fewer multiply operations than either of the LMS algorithms. Also, performing the sign-data adaptation requires only bit shifting multiplies when the step size is a power of two.

Although the performance of the sign-data algorithm as shown in the next figure is quite good, the sign-data algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the signal after processing is a very good match to the input signal, but the algorithm could very easily grow without bound rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and mu (`StepSize`), or even the lowpass filter you used to create the correlated noise can cause noise cancellation to fail and the algorithm to become useless.

Noise Cancellation Using Sign-Error LMS (SELMS) Algorithm

In the standard and normalized variations of the LMS adaptive filter, the coefficients for the adapting filter arise from calculating the mean square error between the desired signal and the output signal from the unknown system, and applying the result to the current filter coefficients. Using the sign-error algorithm replaces the mean square error calculation by using the sign of the error to modify the filter coefficients.

When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ. If the error is negative, the new coefficients are again the previous coefficients minus the error multiplied by μ — note the sign change. When the input is zero, the new coefficients are the same as the previous set.

In vector form, the sign-error LMS algorithm is

$$w(k+1) = w(k) + \mu \text{sgn}(e(k))(x(k)),$$

where,

$$\text{sgn}(e(k)) = \begin{cases} 1, & e(k) > 0 \\ 0, & e(k) = 0 \\ -1, & e(k) < 0 \end{cases}$$

with vector $\boldsymbol{w}$ containing the weights applied to the filter coefficients and vector $\boldsymbol{x}$ containing the input data. The vector $\boldsymbol{e}$ is the error between the desired signal and the filtered signal. The objective of the SELMS algorithm is to minimize this error. Step size is represented by μ.

As you specify μ smaller, the correction to the filter weights gets smaller for each sample and the SELMS error falls more slowly. Larger μ changes the weights more for each step so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}}$$

where, N is the number of samples in the signal. Also, define μ as a power of two for efficient computation.

Note: How you set the initial conditions of the sign-error algorithm profoundly influences the effectiveness of the adaptation. Because the algorithm essentially quantizes the error signal, the algorithm can become unstable easily.

A series of large error values, coupled with the quantization process may result in the error growing beyond all bounds. You restrain the tendency of the sign-error algorithm to get out of control by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the `Method` property of `dsp.LMSFilter` to `'Sign-Error LMS'`. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation –– Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $d(k)$, the desired signal. The noise cancellation process removes the noise, leaving the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation –– Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter, and then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal+fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-error algorithm.

To prepare the `dsp.LMSFilter` object for processing, set the weight initial conditions (`InitialConditions`) and `mu` (μ, `StepSize`) for the object. As noted earlier in this section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path.

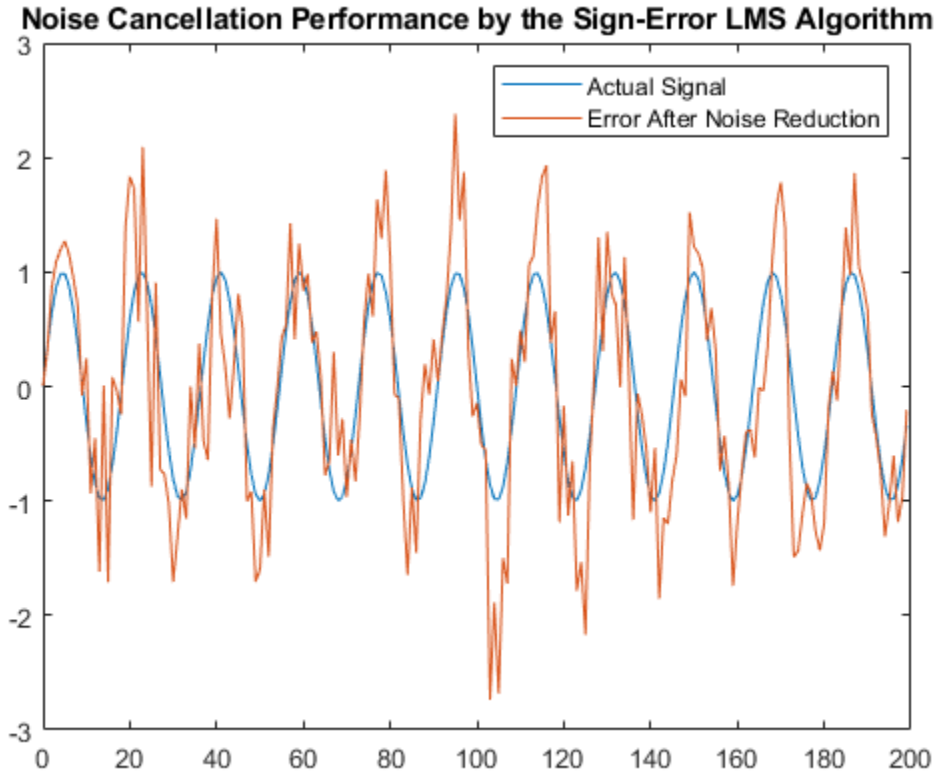
In “System Identification of FIR Filter Using LMS Algorithm” on page 4-1140, you constructed a default filter that sets the filter coefficients to zeros. In most cases that approach does not work for the sign-error algorithm. The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively.

For this example, start with the coefficients in the filter you used to filter the noise (`filt.Numerator`) and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).'-0.01; % Set the filter initial conditions.
mu = 0.05; % Set the step size for algorithm updating.
```

With the required input arguments for `dsp.LMSFilter` prepared, run the adaptation and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Error LMS',...
   'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:199,signal(1:200),0:199,e(1:200));
title('Noise Cancellation Performance by the Sign-Error LMS Algorithm');
legend('Actual Signal','Error After Noise Reduction',...
       'Location','NorthEast')
```



When the sign-error LMS algorithm runs, it uses far fewer multiply operations than either of the LMS algorithms. Also, performing the sign-error adaptation requires only bit shifting multiplies when the step size is a power of two.

Although the performance of the sign-error algorithm as shown in the next figure is quite good, the sign-error algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the signal after processing is a very good match to the input signal, but the algorithm could very easily become unstable rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and mu (`StepSize`), or even the lowpass filter you used to create the correlated noise can cause noise cancellation to fail and the algorithm to become useless.

Noise Cancellation Using Sign-Sign LMS Algorithm

The sign-sign LMS algorithm (SSLMS) replaces the mean square error calculation with using the sign of the input data to change the filter coefficients. When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ. If the error is negative, the new coefficients are again the previous coefficients minus the error multiplied by μ — note the sign change. When the input is zero, the new coefficients are the same as the previous set.

In essence, the algorithm quantizes both the error and the input by applying the sign operator to them.

In vector form, the sign-sign LMS algorithm is

$$w(k+1) = w(k) + \mu \text{sgn}(e(k))\text{sgn}(x(k)),$$

where,

$$\text{sgn}(z(k)) = \begin{cases} 1, & z(k) > 0 \\ 0, & z(k) = 0 \\ -1, & z(k) < 0 \end{cases}$$

$$z(k) = e(k)\text{sgn}(x(k))$$

Vector $\boldsymbol{w}$ contains the weights applied to the filter coefficients and vector $\boldsymbol{x}$ contains the input data. The vector $\boldsymbol{e}$ is the error between the desired signal and the filtered signal. The objective of the SSLMS algorithm is to minimize this error. Step size is represented by μ.

As you specify μ smaller, the correction to the filter weights gets smaller for each sample and the SSLMS error falls more slowly. Larger μ changes the weights more for each step so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}}$$

where, N is the number of samples in the signal. Also, define μ as a power of two for efficient computation

Note

How you set the initial conditions of the sign-sign algorithm profoundly influences the effectiveness of the adaptation. Because the algorithm essentially quantizes the input signal and the error signal, the algorithm can become unstable easily.

A series of large error values, coupled with the quantization process may result in the error growing beyond all bounds. You restrain the tendency of the sign-sign algorithm to get out of control by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the `Method` property of `dsp.LMSFilter` to `'Sign-Sign LMS'`. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation –– Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $d(k)$, the desired signal. The noise cancellation process removes the noise, leaving the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation –– Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter, then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-sign algorithm.

To prepare the `dsp.LMSFilter` object for processing, set the weight initial conditions (`InitialConditions`) and `mu` (μ, `StepSize`) for the object. As noted earlier in this

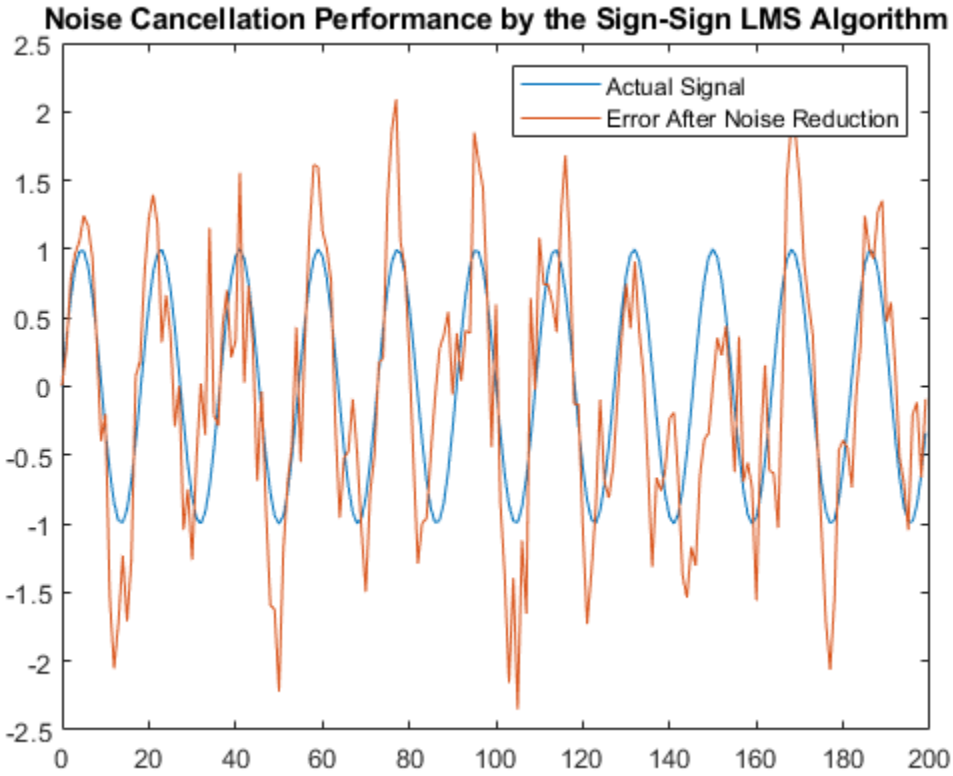
section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path. In “System Identification of FIR Filter Using LMS Algorithm” on page 4-1140, you constructed a default filter that sets the filter coefficients to zeros. Usually that approach does not work for the sign-sign algorithm.

The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively. For this example, you start with the coefficients in the filter you used to filter the noise (`filt.Numerator`), and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).' -0.01; % Set the filter initial conditions.
mu = 0.05;
```

With the required input arguments for `dsp.LMSFilter` prepared, run the adaptation and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Sign LMS',...
   'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:199,signal(1:200),0:199,e(1:200));
title('Noise Cancellation Performance by the Sign-Sign LMS Algorithm');
legend('Actual Signal','Error After Noise Reduction',...
       'Location','NorthEast')
```



When `dsp.LMSFilter` runs, it uses far fewer multiply operations than either of the LMS algorithms. Also, performing the sign-sign adaptation requires only bit shifting multiplies when the step size is a power of two.

Although the performance of the sign-sign algorithm as shown in the above figure is quite good, the sign-sign algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the signal after processing is a very good match to the input signal, but the algorithm could very easily become unstable rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and mu (`StepSize`), or even the lowpass filter you used to create the correlated noise can cause noise cancellation to fail and the algorithm to become useless.

Access Full History of LMS Filter Weights

Note: This example runs only in R2017a or later. If you are using a release earlier than R2017a, the object does not output a full sample-by-sample history of filter weights. If you are using a release earlier than R2016b, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Initialize the `dsp.LMSFilter` System object and set the `WeightsOutput` property to `'All'`. This setting enables the LMS filter to output a matrix of weights with dimensions `[FrameLength Length]`, corresponding to the full sample-by-sample history of weights for all `FrameLength` samples of input values.

```
FrameSize = 15000;
lmsfilt3 = dsp.LMSFilter('Length',63,'Method','LMS', ...
    'StepSize',0.001,'LeakageFactor',0.99999, ...
    'WeightsOutput','All'); % full Weights history

w_actual = fir1(64,[0.5 0.75]);
firfilt3 = dsp.FIRFilter('Numerator',w_actual);
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);

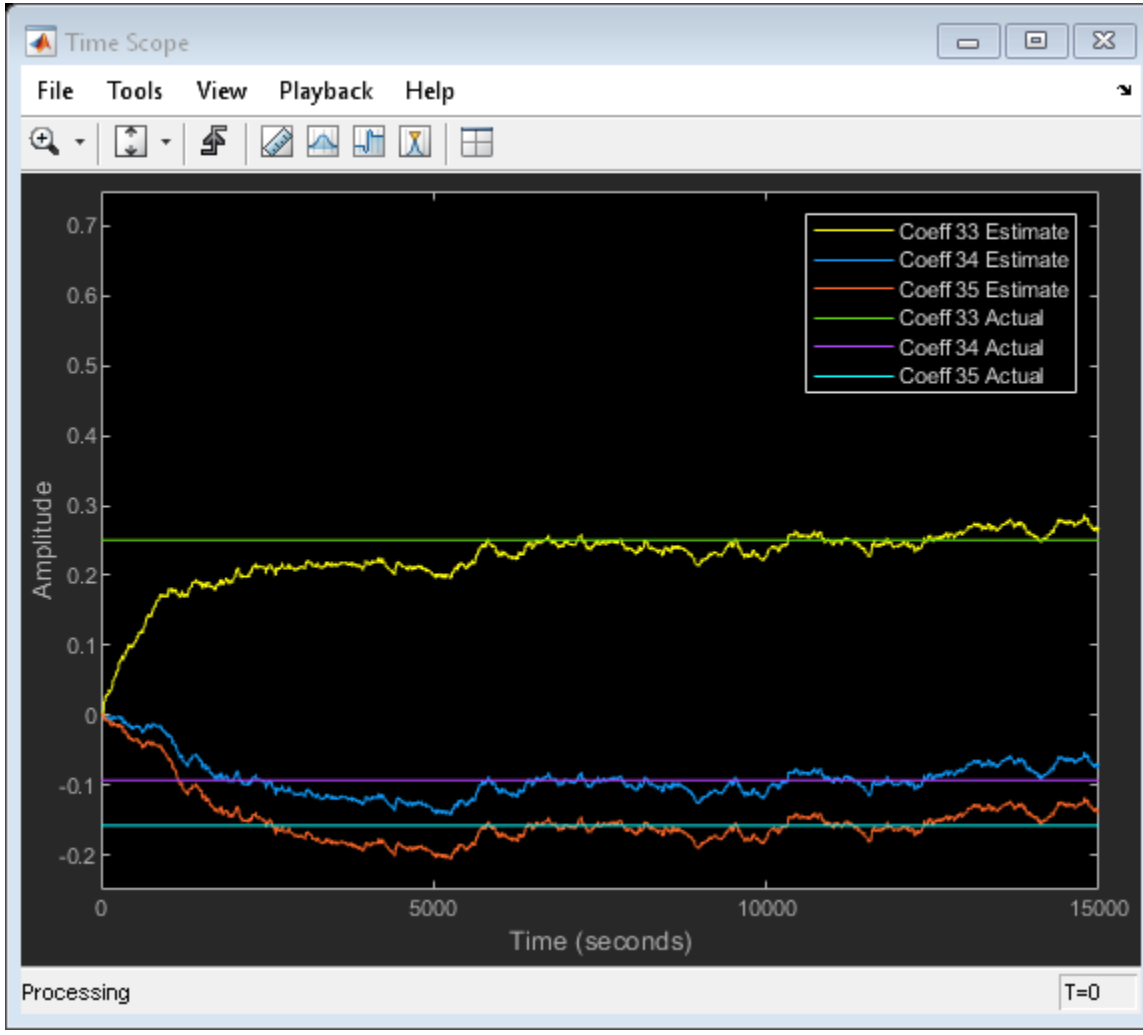
TS = dsp.TimeScope('TimeSpan',FrameSize,'TimeUnits','Seconds', ...
    'YLimits',[-0.25 0.75],'BufferLength',2*FrameSize, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Coeff 33 Estimate','Coeff 34 Estimate','Coeff 35 Estimate', ...
    'Coeff 33 Actual','Coeff 34 Actual','Coeff 35 Actual'});
```

Run one frame and output the full adaptive weights history, `w`.

```
x = randn(FrameSize,1);       % Input signal
d = firfilt3(x) + sinewave(); % Noise + Signal
[~,~,w] = lmsfilt3(x,d);
```

Each row in `w` is a set of weights estimated for the respective input sample. Each column in `w` gives the complete history of a specific weight. Plot the actual weight and the entire history of the 33rd, 34th, and 35th weight. In the plot, you can see that the estimated weight output eventually converges with the actual weight as the adaptive filter receives input samples and continues to adapt.

```
idxBeg = 33;
idxEnd = 35;
TS([w(:,idxBeg:idxEnd), repmat(w_actual(idxBeg:idxEnd),FrameSize,1)])
```



Algorithms

The LMS filter algorithm is defined by the following equations.

$$y(n) = \mathbf{w}^T(n-1)\mathbf{u}(n)$$
$$e(n) = d(n) - y(n)$$
$$\mathbf{w}(n) = \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)$$

The various LMS adaptive filter algorithms available in this System object are defined as:

- LMS –– Solves the Weiner-Hopf equation and finds the filter coefficients for an adaptive filter.

  $$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\mathbf{u}^*(n)$$
- Normalized LMS –– Normalized variation of the LMS algorithm.

  $$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

  In Normalized LMS, to overcome potential numerical instability in the update of the weights, a small positive constant, ε, has been added in the denominator. For double-precision floating-point input, ε is 2.2204460492503131e-016. For single-precision floating-point input, ε is 1.192092896e-07. For fixed-point input, ε is 0.
- Sign-Data LMS –– Correction to the filter weights at each iteration depends on the sign of the input **u**(n).

  $$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\text{sign}(\mathbf{u}(n))$$

  where **u**(n) is real.
- Sign-Error LMS –– Correction applied to the current filter weights for each successive iteration depends on the sign of the error, e(n).

  $$f(\mathbf{u}(n), e(n), \mu) = \mu\text{sign}(e(n))\mathbf{u}^*(n)$$
- Sign-Sign LMS –– Correction applied to the current filter weights for each successive iteration depends on both the sign of **u**(n) and the sign of e(n).

  $$f(\mathbf{u}(n), e(n), \mu) = \mu\text{sign}(e(n))\text{sign}(\mathbf{u}(n))$$

  where **u**(n) is real.

The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{u}^*(n)$	The complex conjugate of the vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter weight estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
μ	The adaptation step size
α	The leakage factor ($0 < \alpha \leq 1$)
ε	A constant that corrects any potential numerical instability that occurs during the update of weights.

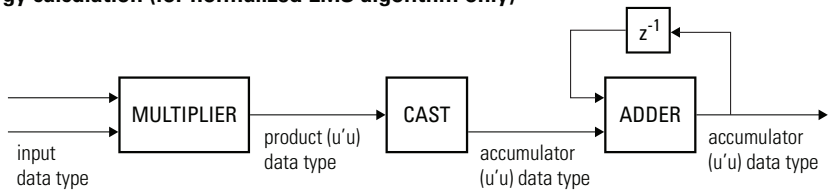
The following diagrams show the data types used within the `dsp.LMSFilter` object for fixed-point signals. The table summarizes the definitions of the variables used in the diagrams:

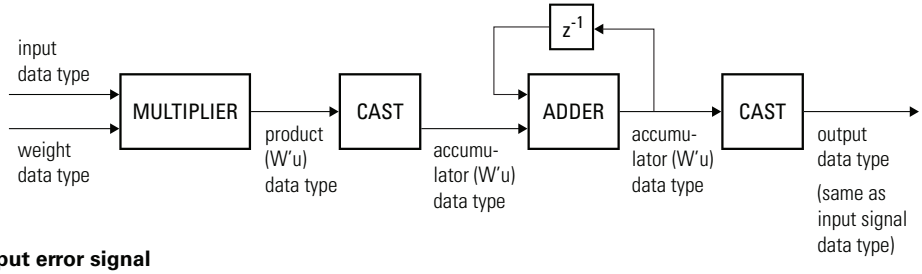
Variable	Definition
u	Input vector
W	Vector of filter weights
μ	Step size
e	Error
Q	Quotient, $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$
Product **u**'**u**	Product data type in Energy calculation diagram
Accumulator **u**'**u**	Accumulator data type in Energy calculation diagram
Product **W**'**u**	Product data type in Convolution diagram
Accumulator **W**'**u**	Accumulator data type in Convolution diagram
Product $\mu \cdot e$	Product data type in Product of step size and error diagram
Product $Q \cdot \mathbf{u}$	Product and accumulator data type in Weight update diagram. [1]

[1]The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

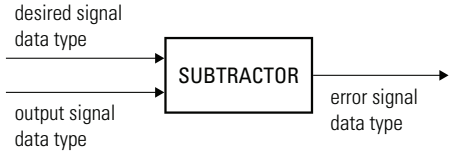
Energy calculation (for normalized LMS algorithm only)



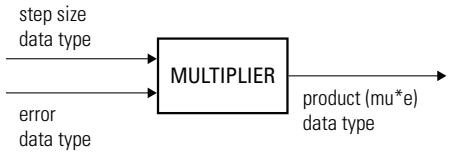
Convolution



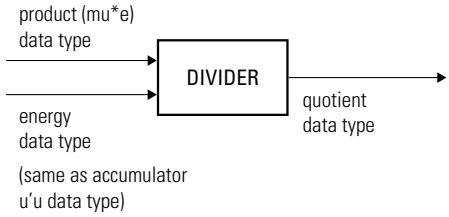
Output error signal



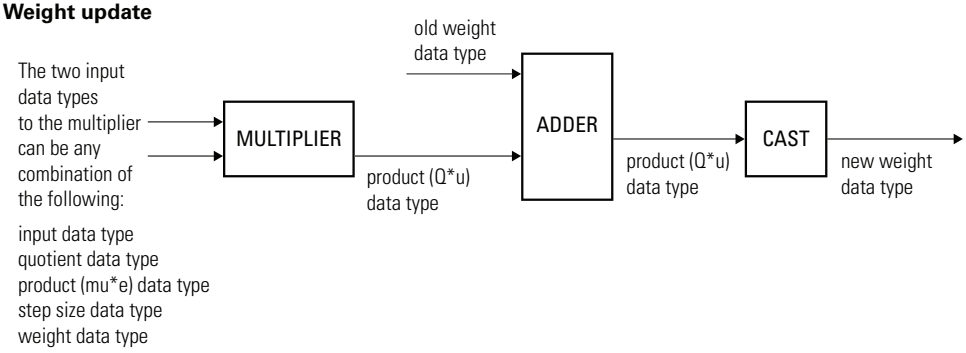
Product of step size and error (for LMS and Sign-Data LMS algorithms only)



Quotient (for normalized LMS only)



Weight update



You can set the data type of the properties, weights, products, quotient, and accumulators in the System object properties. Fixed-point inputs, outputs, and System object properties must have the following characteristics:

- The input signal and the desired signal must have the same word length, but their fraction lengths can differ.
- The step size and leakage factor must have the same word length, but their fraction lengths can differ.

- The output signal and the error signal have the same word length and the same fraction length as the desired signal.
- The quotient and the product output of the **u**'**u**, **W**'**u**, $\mu \cdot e$, and $Q \cdot \mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.
- The accumulator data type of the **u**'**u** and **W**'**u** operations must have the same word length, but their fraction lengths can differ.

The output of the multiplier is in the product output data type if at least one of the inputs to the multiplier is real. If both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

dsp.LogicAnalyzer

Package: `dsp`

Visualize, measure, and analyze transitions and states over time

Description

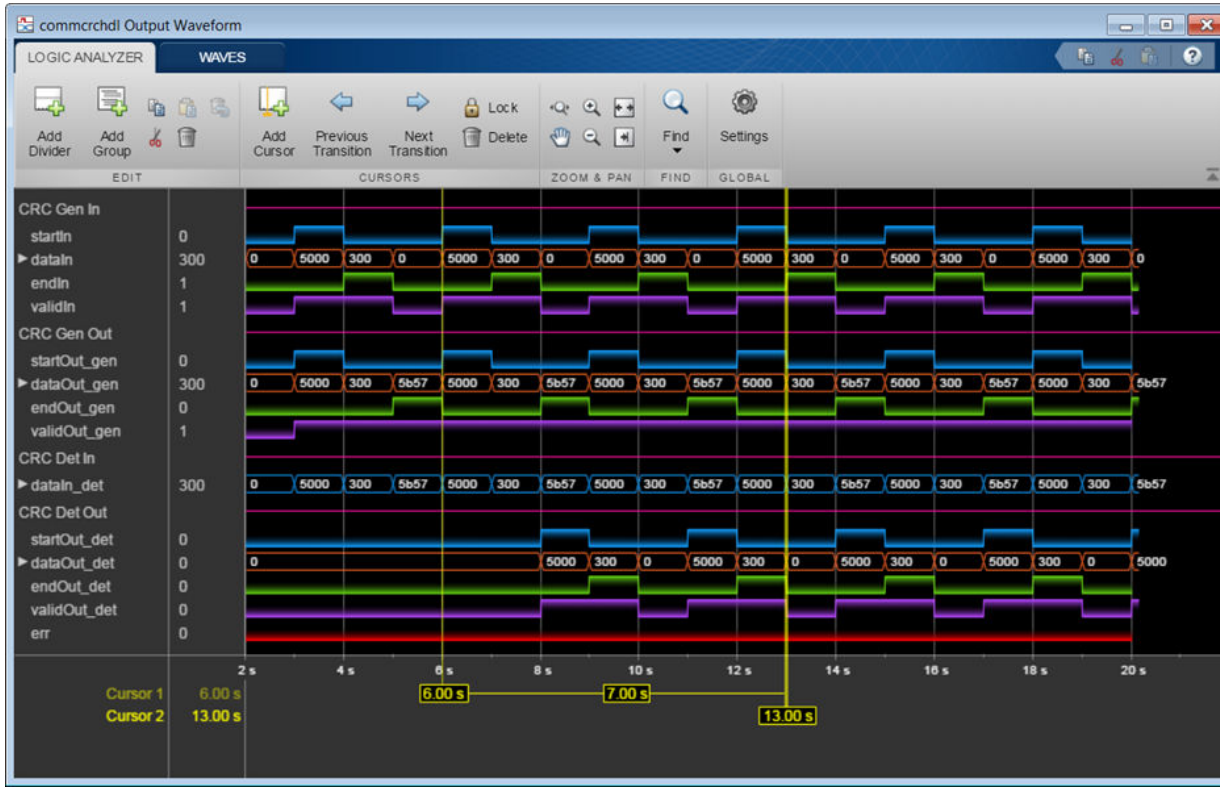
The Logic Analyzer System object displays the transitions in time-domain signals. Using `dsp.LogicAnalyzer`, you can:

- Debug and analyze models
- Trace and correlate 96 signals simultaneously
- Detect and analyze timing violations
- Trace system execution
- Detect signal changes using triggers

To display the transitions of signals in the Logic Analyzer:

1. Create the `dsp.LogicAnalyzer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).



For more information about how to configure and customize the Logic Analyzer, see **Logic Analyzer**.

Creation

Syntax

```
scope = dsp.LogicAnalyzer
scope = dsp.LogicAnalyzer(Name,Value)
```

Description

`scope = dsp.LogicAnalyzer` creates a Logic Analyzer System object, `scope`.

`scope = dsp.LogicAnalyzer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example, `scope = dsp.LogicAnalyzer('BackgroundColor','White','NumInputPorts',4)`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`BackgroundColor` — Background color for display

`'Black'` (default) | `'White'`

Background color of the display, specified as `'Black'` or `'White'`.

Tunable: Yes

Data Types: `char` | `string`

`DisplayChannelColor` — Color for channels in display

`[0.0588 1 1]` (default) | RGB triplet

Color for channels in the display, specified as an RGB triplet.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, `[0.4 0.6 0.7]`.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`DisplayChannelFontSize` — Font size for channels in display

`10` (default) | nonnegative scalar integer

Font size for channels in the display, in points, specified as a nonnegative integer.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`DisplayChannelFormat` — Format for channels in display

`'Automatic'` (default) | `'Analog'` | `'Digital'`

Format for channels in the display, specified as one of the following:

- `'Automatic'` — Displays floating-point signals in `Analog` format and integer and fixed-point signals in `Digital` format. Boolean signals are displayed as zero or one.
- `'Analog'` — Shows values as an analog plot.
- `'Digital'` — Shows values as digital transitions.

Tunable: Yes

Data Types: `char` | `string`

`DisplayChannelHeight` — Channel height in display

`12` (default) | positive real scalar

Channel height in the display, in pixels, specified as a positive real scalar in the range [8, 200].

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`DisplayChannelRadix` — Base used to display values

`'Hexadecimal'` (default) | `'Binary'` | `'Octal'` | `'Signed decimal'` | `'Unsigned decimal'`

This property applies only to fixed-point (`fi`) values.

Tunable: Yes

Data Types: `char` | `string`

`DisplayChannelSpacing` — Spacing between channels in display (pixels)

4 (default) | positive integer

Spacing between channels in the display, in pixels, specified as a positive scalar integer.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`Name` — Caption to display on scope window

`'Logic Analyzer'` (default) | character vector | string scalar

Caption to display on the scope window, specified as a character vector or string.

Tunable: Yes

Data Types: `char` | `string`

`NumInputPorts` — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

`Position` — Scope window position

`[left bottom width height]` vector

Position of the scope window on your screen, in pixels, specified as a `[left bottom width height]` vector. The default position depends on your screen resolution. By default, the scope window appears in the center of your screen, with a width of `800` pixels and height of `600` pixels.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`SampleTime` — Input sample time

1 (default) | scalar

Sample time of inputs in seconds, specified as a finite numeric scalar. The same sample time is used for all inputs.

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`TimeDisplayOffset` — Time display offset
`0` (default) | nonnegative scalar

Time display offset in seconds, specified as a nonnegative scalar.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`TimeSpan` — Time span
`10` | positive scalar

Time span in seconds, specified as a positive scalar. The *x*-axis limits are calculated as follows:

- Minimum *x*-axis limit = min(`TimeDisplayOffset`)
- Maximum *x*-axis limit = max(`TimeDisplayOffset`) + `TimeSpan`

`TimeDisplayOffset` and `TimeSpan` are the values of their respective properties.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

Usage

Syntax

```
scope(signal)
scope(signal1,signal2,...signalN)
```

Description

`scope(signal)` displays the signal `signal` in the Logic Analyzer scope.

`scope(signal1,signal2,...signalN)` displays multiple signals in the Logic Analyzer when you set the `NumInputPorts` property to `N`. Each signal can have different data types and dimensions.

Input Arguments

`signal` — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.LogicAnalyzer`. Signals can have different data types and dimensions.

Integers are supported up to 64 bits and fixed-point signals are supported up to 128 bits.

Example: `scope(signal1,signal2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `struct` | `table` | `cell`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.LogicAnalyzer

addCursor	Add cursor to Logic Analyzer
addDivider	Add divider to Logic Analyzer
addWave	Add wave to Logic Analyzer
deleteCursor	Delete Logic Analyzer cursor
deleteDisplayChannel	Delete Logic Analyzer channel
getCursorInfo	Return settings for Logic Analyzer cursor
getCursorTags	Return all Logic Analyzer cursor tags
getDisplayChannelInfo	Return settings for Logic Analyzer display channel
getDisplayChannelTags	Return all Logic Analyzer display channel tags
modifyCursor	Modify properties of Logic Analyzer cursor
modifyDisplayChannel	Modify properties of Logic Analyzer display channel
moveDisplayChannel	Move position of Logic Analyzer display channel

Specific to Scopes

show	Display scope window
hide	Hide scope window
isVisible	Determine visibility of scope

Common to All System Objects

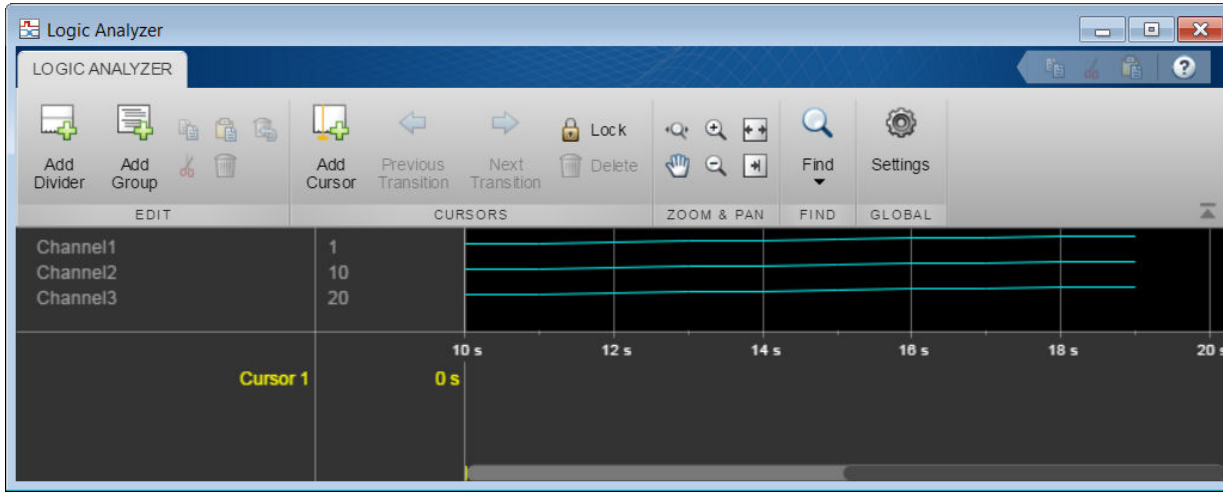
step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Display Simple Ramp Signals

Create a `dsp.LogicAnalyzer` object. Call the scope in a loop to display the signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);
for ii = 1:20
    scope(ii,10*ii,20*ii);
end
```



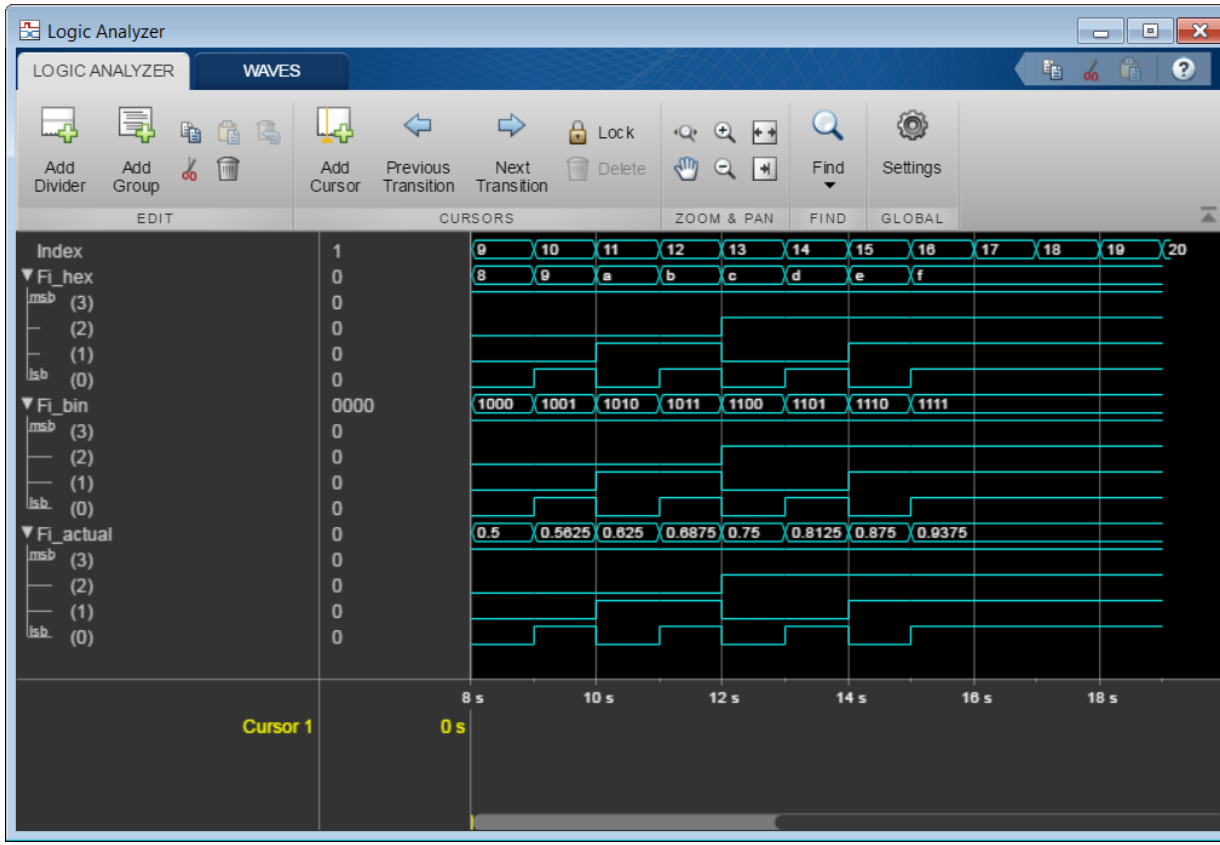
Display Fixed-Point Signals

Create a `dsp.LogicAnalyzer` object with four channels. Call `modifyDisplayChannel` to set the radix of each of the channels. Run the scope in a loop to display the waves.

```
scope = dsp.LogicAnalyzer('NumInputPorts',4,'DisplayChannelFormat','Digital');
scope.TimeSpan = 12;

modifyDisplayChannel(scope,1,'Name','Index','Radix','Unsigned decimal');
modifyDisplayChannel(scope,2,'Name','Fi_hex','Radix','Hexadecimal');
modifyDisplayChannel(scope,3,'Name','Fi_bin','Radix','Binary');
modifyDisplayChannel(scope,4,'Name','Fi_actual','Radix','Signed decimal');

for ii = 1:20
    fival = fi((ii-1)/16,0,4,4);
    scope(ii,fival,fival,fival);
end
```



Display Vector, Complex, and Enumerated Signals

Define a `WeekDaysInt` class to hold an enumerated list of weekday values. Create and save the following class definition file.

```
classdef WeekDaysInt < int32
  enumeration
    Monday(1), Tuesday(2), Wednesday(3), Thursday(4), Friday(5)
  end
end
```

Create a `dsp.LogicAnalyzer` object and configure the vector, complex, and enumerated data signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',6);
waves = getDisplayChannelTags(scope);

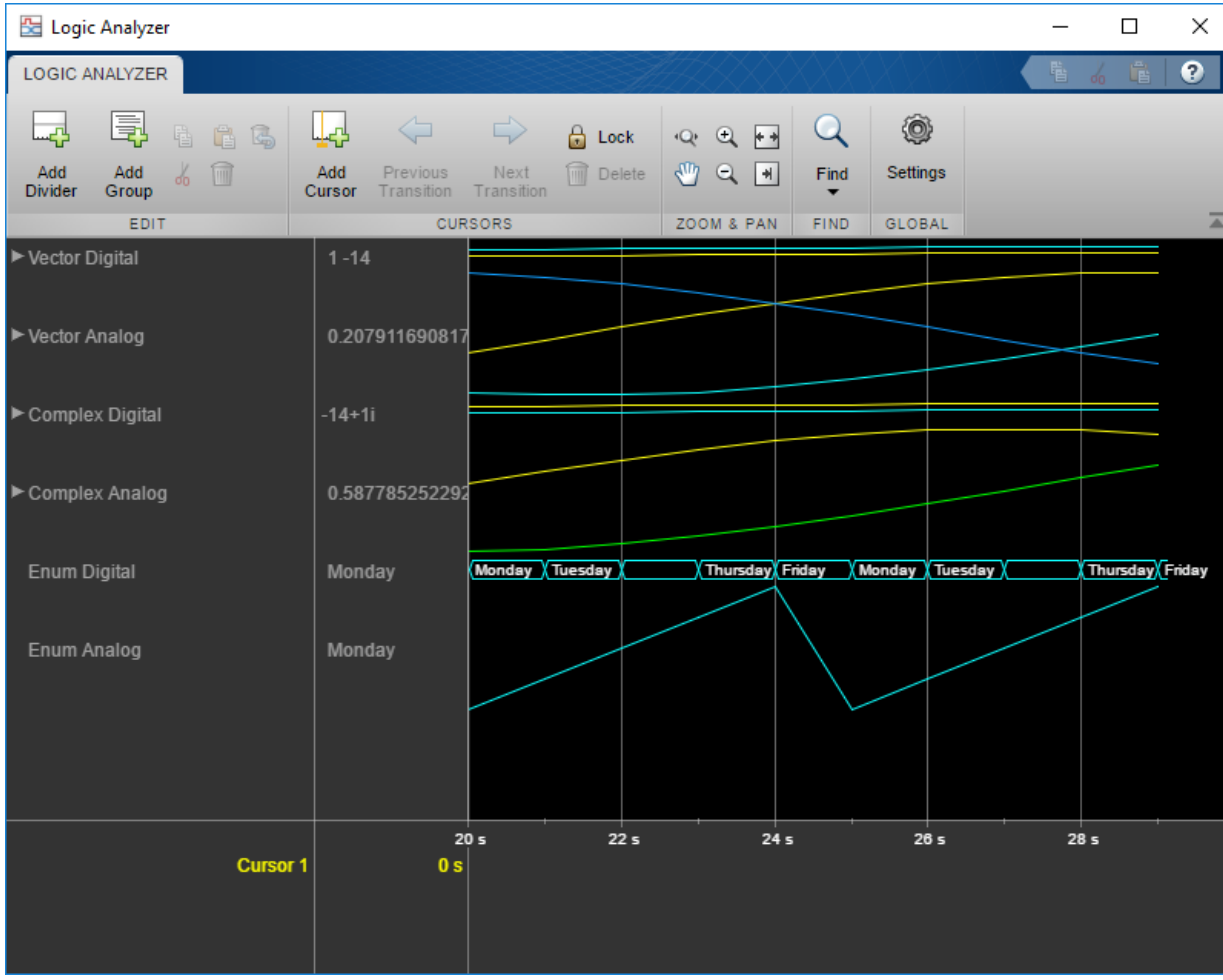
modifyDisplayChannel(scope,waves{1},'InputChannel',1,'Name','Vector Digital');
modifyDisplayChannel(scope,waves{2},'InputChannel',2,'Name','Vector Analog',...
    'Format','Analog','Height',80);
modifyDisplayChannel(scope,waves{3},'InputChannel',3,'Name','Complex Digital');
modifyDisplayChannel(scope,waves{4},'InputChannel',4,'Name','Complex Analog',...
    'Format','Analog','Height',80,'Color','Green');
modifyDisplayChannel(scope,waves{5},'InputChannel',5,'Name','Enum Digital');
modifyDisplayChannel(scope,waves{6},'InputChannel',6,'Name','Enum Analog',...
    'Format','Analog','Height',80);
```

Call the scope object in a loop to display the signals.

```
stop = 30;
for count = 1:stop
    sinValVec       = sin(count/stop*2*pi);
    cosValVec       = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);
    sinValReal      = sin((count+2)/stop*2*pi);
    cosValImag      = cos((count+2)/stop*2*pi);

    % Create a weekday enumerated value by wrapping the index
    day = WeekDaysInt(1+mod(count-1,5));

    scope(...
          [count (count-(stop/2))],...              % digital vector
          [sinValVec cosValVec cosValVecOffset],... % analog vector
          complex((count-(stop/2)),count),...       % digital complex
          complex(sinValReal, cosValImag),...       % analog complex
          day,...                                   % digital enum
          day...                                    % analog enum
          )
end
```



Tips

To close the logic analyzer window and clear its associated data, use the MATLAB `clear` function.

Introduced in R2013a

dsp.LowerTriangularSolver

Package: `dsp`

Solve lower-triangular matrix equation

Description

The `LowerTriangularSolver` object solves $LX = B$ for X when L is a square, lower-triangular matrix with the same number of rows as B.

To solve $LX = B$ for X:

1. Create the `dsp.LowerTriangularSolver` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
lowtriang = dsp.LowerTriangularSolver
lowtriang = dsp.LowerTriangularSolver(Name,Value)
```

Description

`lowtriang = dsp.LowerTriangularSolver` returns a linear system solver, `lowtriang`, used to solve the linear system $LX = B$, where L is a lower (or unit-lower) triangular matrix.

`lowtriang = dsp.LowerTriangularSolver(Name,Value)` returns a linear system solver, `lowtriang`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`OverwriteDiagonal` — Replace diagonal elements of input with ones
`false` (default) | `true`

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, *L*, with ones. This property is useful when matrix *L* is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the *D* matrix.

`RealDiagonalElements` — Indicate that diagonal of complex input is real
`false` (default) | `true`

When you set this property to `true`, the linear system solver optimizes computation speed if the input *L* is complex, but its diagonal elements are real. Set this property to either `true` or `false`.

Dependencies

This property applies only when you set the `OverwriteDiagonal` property to `false`.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

`OverflowAction` — Overflow action for fixed-point operations
`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

`ProductDataType` — Data type of product
`Full precision` (default) | `Same as input` | `Custom`

Specify the product data type as `Full precision`, `Same as input`, or `Custom`.

`CustomProductDataType` — Product word and fraction lengths
`numerictype([],32,30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `ProductDataType` property to `Custom`.

`AccumulatorDataType` — Data type of accumulator
`Full precision` (default) | `Same as first input` | `Same as product` | `Custom`

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`.

`CustomAccumulatorDataType` — Accumulator word and fraction lengths
`numerictype([],32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `AccumulatorDataType` property to `Custom`.

`OutputDataType` — Data type of output
`Same as first input` (default) | `Custom`

Specify the output data type as `Same as first input` or `Custom`.

`CustomOutputDataType` — Output word and fraction lengths
`numerictype([],16,15)` (default) | `numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `OutputDataType` property to `Custom`.

Usage

Syntax

```
X = lowtriang(L,B)
```

Description

`X = lowtriang(L,B)` computes the solution, X, of the matrix equation $LX = B$, where L is a square, lower-triangular matrix with the same number of rows as the matrix B.

Input Arguments

L — Lower-triangular matrix

matrix

Lower-triangular square matrix of size M-by-M.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

B — Input B

vector | matrix

Input B in the equation $LX = B$, where `B` is an M-by-N matrix.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

X — Solution of the equation

vector | matrix

Solution of the $LX = B$ equation, returned as an M-by-N output matrix. The object uses only the elements in the lower triangle of input L and ignores the upper elements. When you set `OverwriteDiagonal` to `true`, the object replaces the elements on the diagonal of the input, L, with ones.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Solve a Lower Triangular Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
lowtriang = dsp.LowerTriangularSolver;
u = tril(rand(4, 4));
b = rand(4, 1);
```

Check that result is the solution to the linear equations.

```
x1 = u\b
```

```
x1 = 4×1

    0.5177
    4.5810
   -3.4853
```

```
    9.6147

x = lowtriang(u, b)

x = 4×1

    0.5177
    4.5810
   -3.4853
    9.6147
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Forward Substitution block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

System Objects
`dsp.UpperTriangularSolver`

Introduced in R2012a

dsp.LowpassFilter

Package: dsp

FIR or IIR lowpass filter

Description

The dsp.LowpassFilter object independently filters each channel of the input over time using the given design specifications. You can set the FilterType property of dsp.LowpassFilter to 'FIR' or 'IIR' to implement the object as a FIR or IIR lowpass filter.

To filter each channel of your input:

1. Create the dsp.LowpassFilter object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

Creation

Syntax

```
LPF = dsp.LowpassFilter
LPF = dsp.LowpassFilter(Name,Value)
```

Description

LPF = dsp.LowpassFilter returns a minimum order FIR lowpass filter, LPF, with the default filter settings. Calling the object with the default property settings filters the input data with a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

LPF = dsp.LowpassFilter(Name,Value) returns a lowpass filter, with additional properties specified by one, or more Name,Value pair arguments. Name is the property

name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

`SampleRate` — Input sample rate

`44100` (default) | real positive scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of `'SampleRate'` and a real positive scalar.

Data Types: `single` | `double`

`FilterType` — Filter type

`'FIR'` (default) | `'IIR'`

Filter type, specified as one of the following options:

- `'FIR'` — The object designs an FIR lowpass filter.
- `'IIR'` — The object designs an IIR lowpass (biquad) filter.

`DesignForMinimumOrder` — Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as the comma-separated pair consisting of `'DesignForMinimumOrder'` and a logical value. If this property is `true`, then `dsp.LowpassFilter` designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is `false`, then the object designs filters with the order that you specify in the `FilterOrder`

property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

`FilterOrder` — Order of the FIR or IIR filter

`50` (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of `'FilterOrder'` and a positive integer scalar.

Dependencies

Specifying a filter order is only valid when the value of `'DesignForMinimumOrder'` is `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandFrequency` — Filter passband edge frequency

`8000` (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair of `'PassbandFrequency'` and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the `SampleRate`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandFrequency` — Filter stopband edge frequency

`12000` (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of `'StopbandFrequency'` and a real positive scalar. The value of the stopband edge frequency in Hz must be less than half the `SampleRate`.

Dependencies

You can specify the stopband edge frequency only when `'DesignForMinimumOrder'` is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PassbandRipple` — Maximum ripple of filter response in the passband

`0.1` (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of `'PassbandRipple'` and a real positive scalar. Maximum ripple of filter response defaults to `0.1` dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`StopbandAttenuation` — Minimum attenuation in the stopband
`80` (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of `'StopbandAttenuation'` and a real positive scalar. Minimum attenuation in the stopband defaults to `80` dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

`RoundingMethod` — Rounding method for output fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

`CoefficientsDataType` — Word and fraction lengths of coefficients
`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

Usage

Syntax

```
y = LPF(x)
```

Description

`y = LPF(x)` lowpass filters the input signal, `x`. `y` is a lowpass-filtered version of `x`.

Input Arguments

x — Noisy data input

vector | matrix

Noisy data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length. This object accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.LowpassFilter`

freqz	Frequency response of filter
fvtool	Visualize frequency response of DSP filters
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Filter coefficients
cost	Estimate cost for implementing filter System objects
grpdelay	Group delay response of discrete-time filter System object
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
measure	Measure frequency response characteristics of filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Impulse and Frequency Response of FIR and IIR Lowpass Filters

Create a minimum-order FIR lowpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 8e3;
Fstop = 12e3;
```

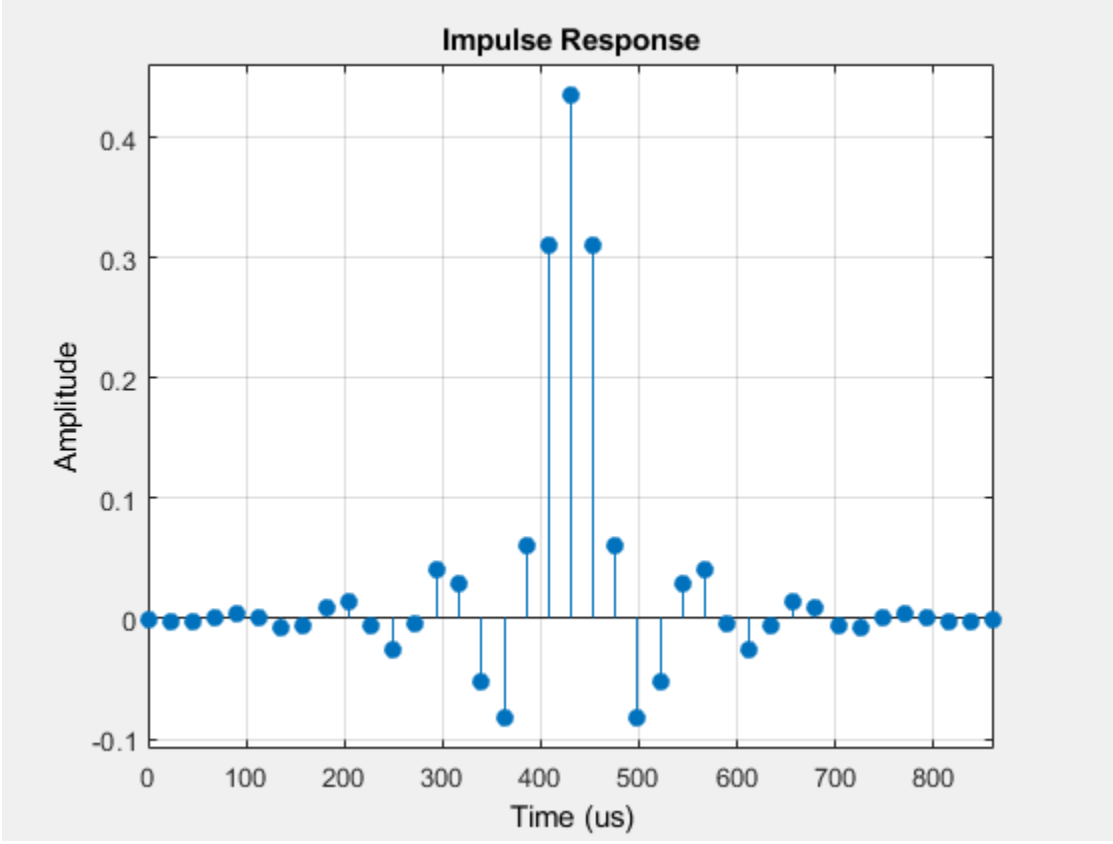
```
Rp = 0.1;
Astop = 80;
FIRLPF = dsp.LowpassFilter('SampleRate',Fs, ...
                           'FilterType',filtertype, ...
                           'PassbandFrequency',Fpass, ...
                           'StopbandFrequency',Fstop, ...
                           'PassbandRipple',Rp, ...
                           'StopbandAttenuation',Astop);
```

Design a minimum-order IIR lowpass filter with the same properties as the FIR lowpass filter. Change the `FilterType` property of the cloned filter to `IIR`.

```
IIRLPF = clone(FIRLPF);
IIRLPF.FilterType = 'IIR';
```

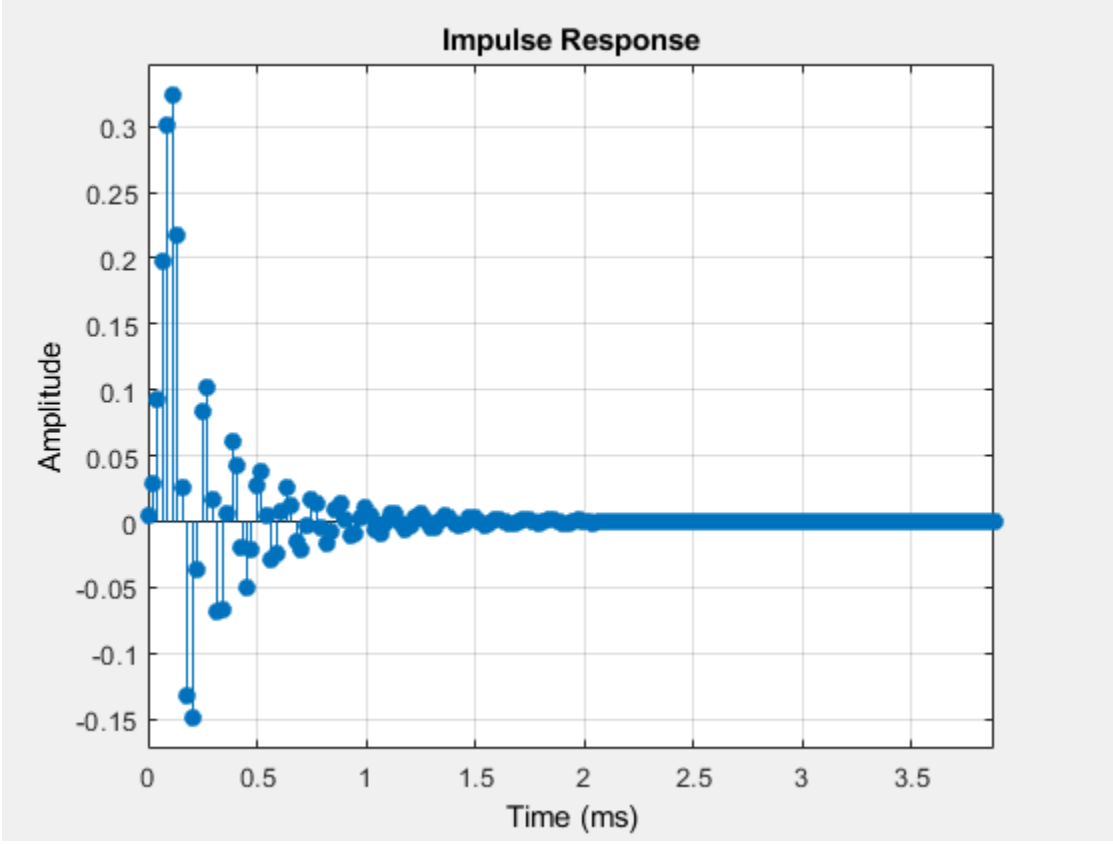
Plot the impulse response of the FIR lowpass filter. The zeroth-order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR lowpass filter is a causal FIR filter.

```
fvtool(FIRLPF,'Analysis','impulse')
```



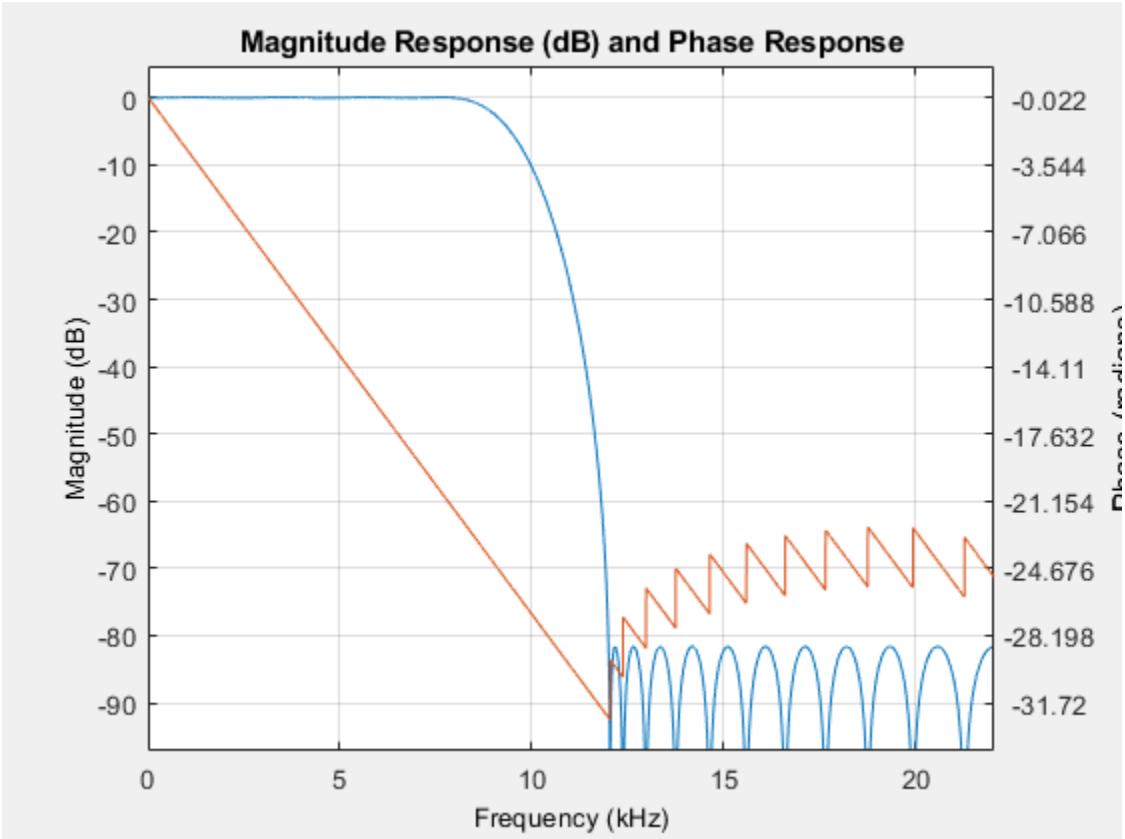
Plot the impulse response of the IIR lowpass filter.

```
fvtool(IIRLPF,'Analysis','impulse')
```



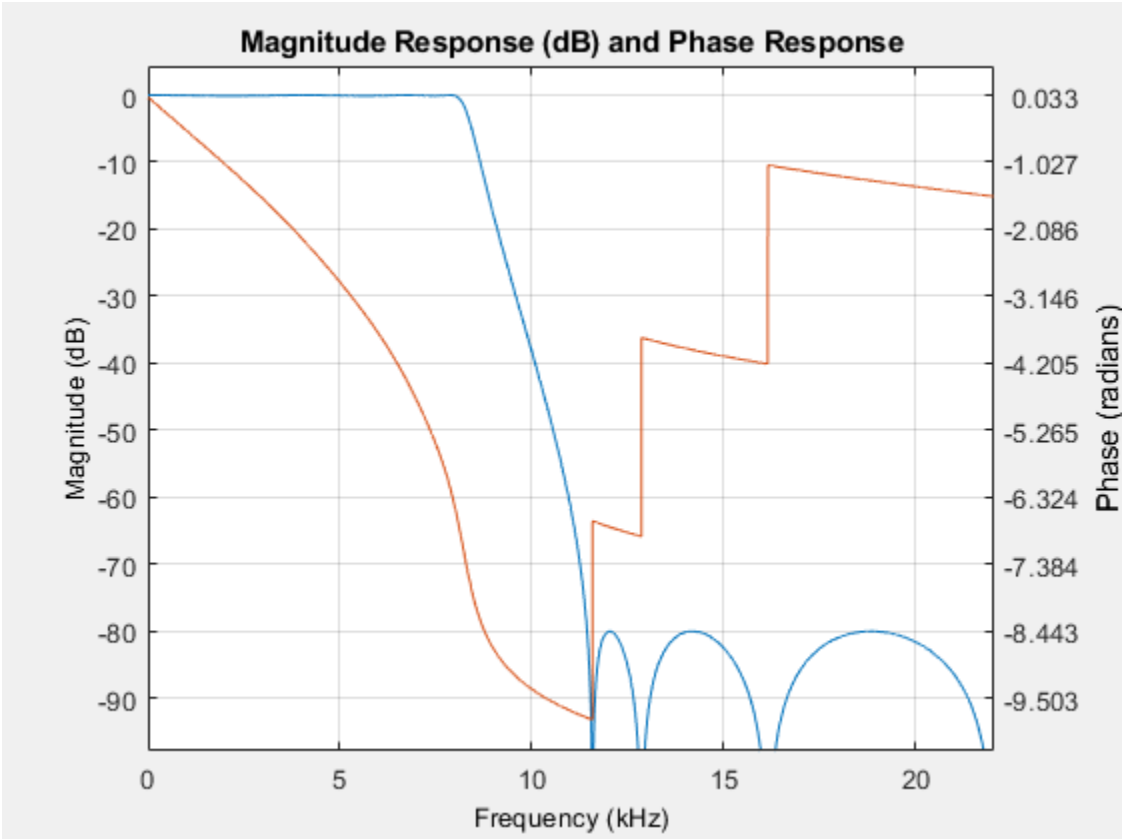
Plot the magnitude and phase response of the FIR lowpass filter.

```
fvtool(FIRLPF,'Analysis','freq')
```



Plot the magnitude and phase response of the IIR lowpass filter.

```
fvtool(IIRLPF,'Analysis','freq')
```



Calculate the cost of implementing the FIR lowpass filter.

```
cost(FIRLPF)
```

```
ans = struct with fields:
                  NumCoefficients: 39
                       NumStates: 38
    MultiplicationsPerInputSample: 39
          AdditionsPerInputSample: 38
```

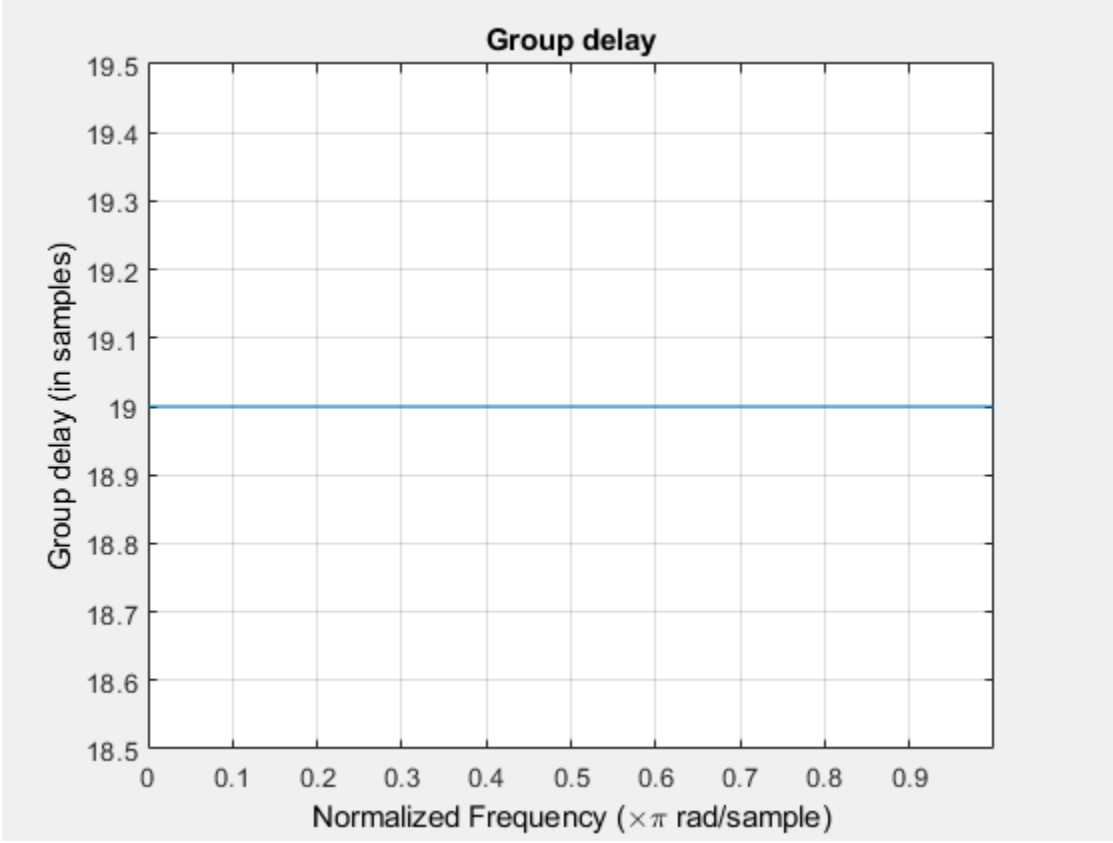
Calculate the cost of implementing the IIR lowpass filter. The IIR filter is more efficient to implement than the FIR filter.

```
cost(IIRLPF)
```

```
ans = struct with fields:
                  NumCoefficients: 18
                       NumStates: 14
    MultiplicationsPerInputSample: 18
          AdditionsPerInputSample: 14
```

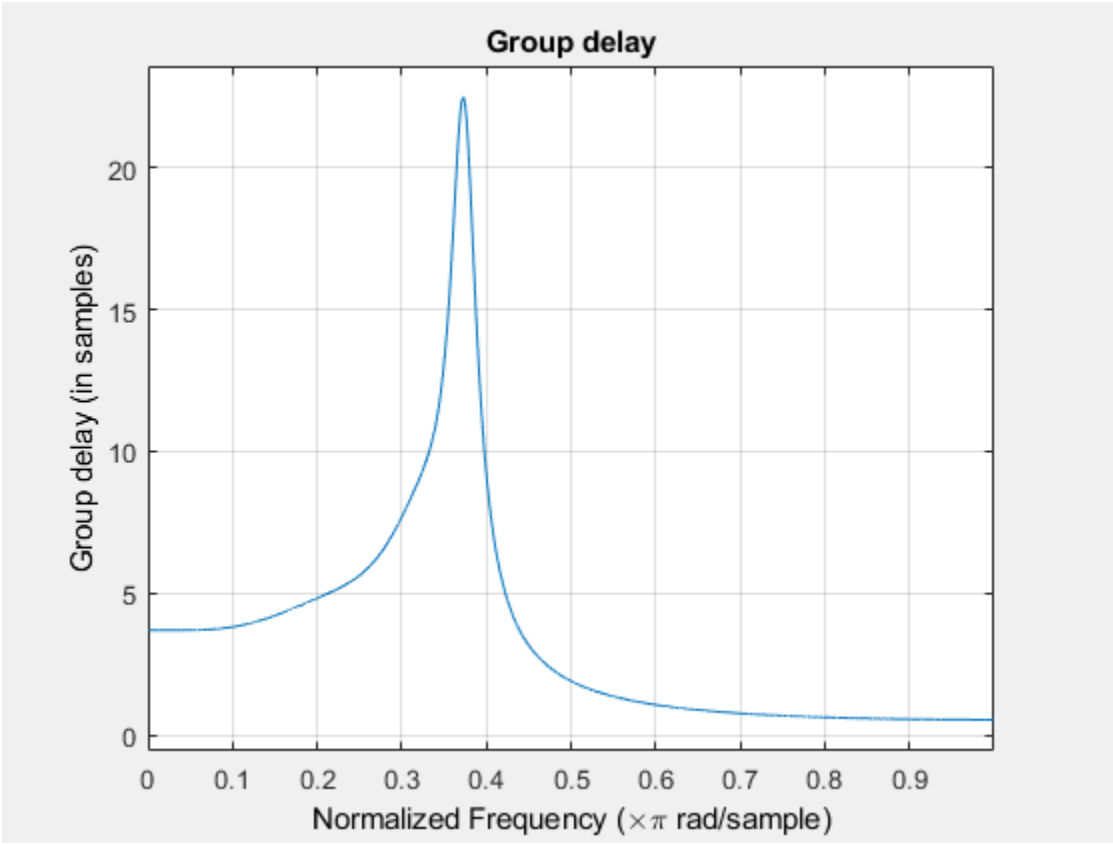
Calculate the group delay of the FIR lowpass filter.

```
grpdelay(FIRLPF)
```



Calculate the group delay of the IIR lowpass filter. The FIR filter has a constant group delay (linear phase), while its IIR counterpart does not.

```
grpdelay(IIRLPF)
```



Filter White Gaussian Noise Signal With Lowpass Filter

Create a lowpass filter with default properties.

```
LPF = dsp.LowpassFilter;
```

Create a spectrum analyzer object.

```
hSA = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
           [-150 30],...
           'Title',...
```

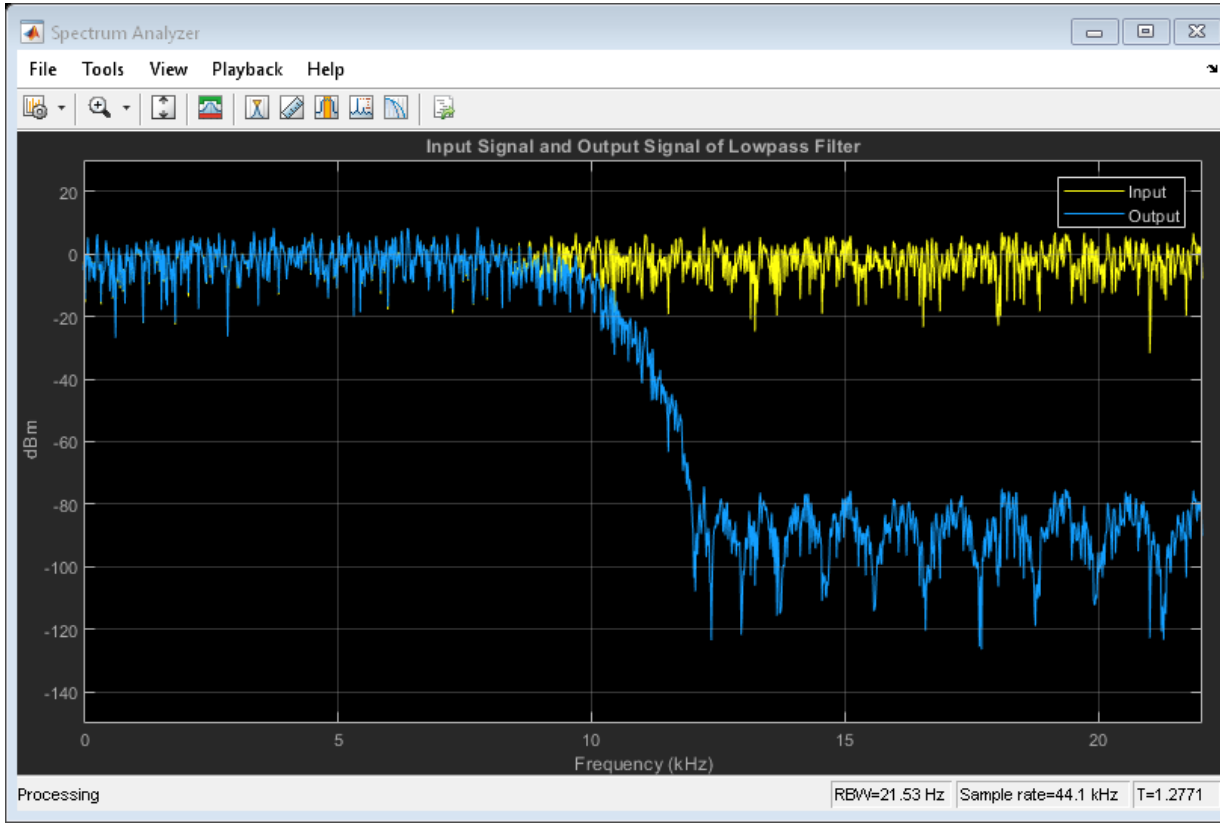
```
            'Input Signal and Output Signal of Lowpass Filter');
hSA.ChannelNames = {'Input','Output'};
```

Implement `step` on `LPF` to filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = step(LPF,Input);

    step(hSA,[Input,Output]);
end
```



Filter White Gaussian Noise

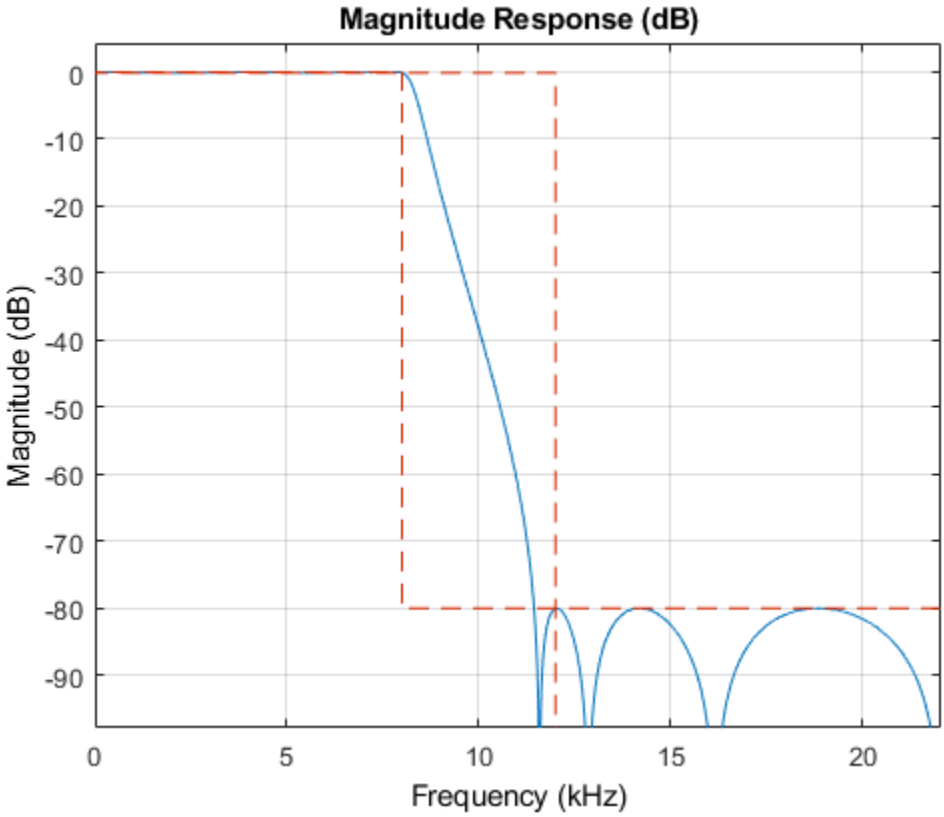
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the IIR lowpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 8 kHz, the stopband frequency is 12 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;
filtertype = 'IIR';
Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
Astop = 80;
LPF = dsp.LowpassFilter('SampleRate',Fs,...
                        'FilterType',filtertype,...
                        'PassbandFrequency',Fpass,...
                        'StopbandFrequency',Fstop,...
                        'PassbandRipple',Rp,...
                        'StopbandAttenuation',Astop);
```

View the magnitude response of the lowpass filter.

```
fvtool(LPF)
```



Create a spectrum analyzer object.

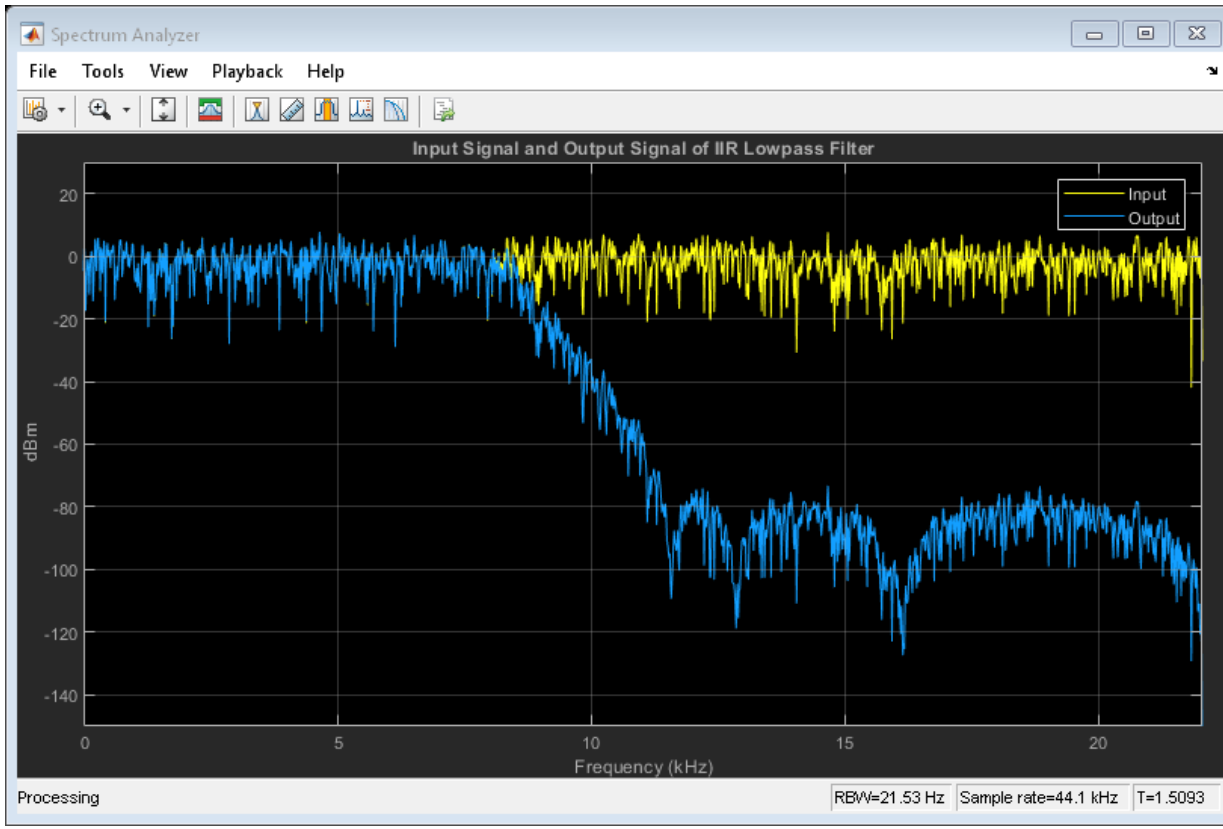
```
hSA = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
           [-150 30],...
           'Title',...
           'Input Signal and Output Signal of IIR Lowpass Filter');
hSA.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);
```

```
    Output = LPF(Input);

    hSA([Input,Output]);
end
```



Measure Frequency Response Characteristics of Lowpass Filter

Measure the frequency response characteristics of a lowpass filter. Create a `dsp.LowpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
LPF = dsp.LowpassFilter
```

```
LPF =
  dsp.LowpassFilter with properties:

               FilterType: 'FIR'
    DesignForMinimumOrder: true
        PassbandFrequency: 8000
        StopbandFrequency: 12000
           PassbandRipple: 0.1000
      StopbandAttenuation: 80
               SampleRate: 44100

  Show all properties
```

```
LPFMeas = measure(LPF)
```

```
LPFMeas =
Sample Rate      : 44.1 kHz
Passband Edge    : 8 kHz
3-dB Point       : 9.1311 kHz
6-dB Point       : 9.5723 kHz
Stopband Edge    : 12 kHz
Passband Ripple  : 0.08289 dB
Stopband Atten.  : 81.6141 dB
Transition Width : 4 kHz
```

Algorithms

FIR Lowpass Filter

When the `FilterType` property is set to `'FIR'`, the `dsp.LowpassFilter` object acts as a FIR lowpass filter.

In this configuration, `dsp.LowpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct form` structure. You can use `measure` to verify that the design meets the prescribed specifications.

IIR Lowpass Filter

When the `FilterType` property is set to `'IIR'`, the `dsp.LowpassFilter` object acts as an IIR lowpass filter. In this configuration, the object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to setup a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the `dsp.LowpassFilter` System object. You can use `measure` to verify that the design meets the prescribed specifications.

dsp.LPCToAutocorrelation

Package: `dsp`

(To be removed) Convert linear prediction coefficients to autocorrelation coefficients

---

Note `dsp.LPCToAutocorrelation` will be removed in a future release. Use `poly2ac` from Signal Processing Toolbox™ instead. For more information, see "Compatibility Considerations".

Description

The `LPCToAutocorrelation` System object converts linear prediction coefficients to autocorrelation coefficients.

To convert LPC to autocorrelation coefficients:

1. Define and set up your LPC to autocorrelation object. See "Construction" on page 4-1216.
2. Call `step` to convert LPC according to the properties of `dsp.LPCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2ac = dsp.LPCToAutocorrelation` returns an LPC to autocorrelation System object, `lpc2ac`, that converts linear prediction coefficients (LPC) to autocorrelation coefficients.

`lpc2ac = dsp.LPCToAutocorrelation('PropertyName',PropertyValue,...)` returns an LPC to autocorrelation conversion object, `lpc2ac`, with each specified property set to the specified value.

Properties

`PredictionErrorInputPort`

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes that the prediction error power is `1`. The default is `false`.

`NonUnityFirstCoefficientAction`

Action to take when first LPC coefficient is not `1`

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not `1`. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

step Autocorrelation coefficients from LPC coefficients

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Convert LPC To Autocorrelation Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert the linear prediction coefficients to autocorrelation coefficients.

```
a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711].';
lpc2ac = dsp.LPCToAutocorrelation;
ac = lpc2ac(a);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC/RC to Autocorrelation block reference page. The object properties correspond to the block parameters, except:
The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to `LPC to autocorrelation`.

Compatibility Considerations

`dsp.LPCToAutocorrelation` System object will be removed

Warns starting in R2019a

`dsp.LPCToAutocorrelation` System object will be removed in a future release. Use `poly2ac` instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

If your code has this form (R2016b or later):	If your code has this form (prior to R2016b):	Use this code instead:

`a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711]';`
`lpcToAC = dsp.LPCToAutocorrelation;`
`ACObj = lpcToAC(a)`
 	
or
 	
`a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711]';`
`lpcToAC = dsp.LPCToAutocorrelation('PredictionErrorInputPort',true);`
`p = 0.2;`
`ACObj = lpcToAC(a,p)`
 	
In the first example, the default prediction error, *p* is 1.
	`a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711]';`
	`lpcToAC = dsp.LPCToAutocorrelation;`
	`ACObj = step(lpcToAC,a)`
	
	or
	
	`a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711]';`
	`lpcToAC = dsp.LPCToAutocorrelation('PredictionErrorInputPort',true);`
	`p = 0.2;`
	`ACObj = step(lpcToAC,a,p)`
		`a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711]';`
		`p = 1.0;`
		`ACFn = poly2ac(a,p)`
		
		or
		
		`a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711]';`
		`p = 0.2;`
		`ACFn = poly2ac(a,p)`
		
		The `poly2ac` function expects prediction error as the second input while the default instance of the `dsp.LPCToAutocorrelation` System object does not accept such an input. By default, the object uses a prediction error of 1.0.
		
		When you set the `PredictionErrorInputPort` property to `true`, the object accepts the prediction error as the second input.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

Functions
`poly2ac`

Introduced in R2012a

step

System object: `dsp.LPCToAutocorrelation`
Package: `dsp`

Autocorrelation coefficients from LPC coefficients

Syntax

```
AC = step(lpc2ac,A)
AC = step(lpc2ac,A,P)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`AC = step(lpc2ac,A)` converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. The object assumes a prediction error power of `1`.

`AC = step(lpc2ac,A,P)` when you set the `PredictionErrorInputPort` property to `true`, converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. This conversion uses `P` as the prediction error power. `P` must be a row vector with same number of columns as `A`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToCepstral

Package: `dsp`

(To be removed) Convert linear prediction coefficients to cepstral coefficients

Note `dsp.LPCToCepstral` will be removed in a future release. For more information, see "Compatibility Considerations".

Description

The `LPCToCepstral` object converts linear prediction coefficients to cepstral coefficients.

To convert LPC to cepstral coefficients:

1. Define and set up your LPC to cepstral converter. See "Construction" on page 4-1223.
2. Call `step` to convert LPC according to the properties of `dsp.LPCToCepstral`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2cc = dsp.LPCToCepstral` returns an LPC to cepstral converter object, `lpc2cc`, that converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs).

`lpc2cc = dsp.LPCToCepstral('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an LPC to cepstral converter object, `lpc2cc`, with each specified property set to the specified value.

Properties

`PredictionErrorInputPort`

Enable prediction error power input

Choose how to set the prediction error power. When you set this property to `true`, you must specify the prediction error as a second input to the `step` method. When you set this property to `false`, the object assumes the prediction error power is 1. The default is `false`.

`CepstrumLengthSource`

Source of cepstrum length

Select how to specify the length of cepstral coefficients: `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, the length of each channel of the cepstral coefficients output is the same as the length of each channel of the input LPC coefficients. The default is `Property`.

`CepstrumLength`

Number of output cepstral coefficients

Set the length of the output cepstral coefficients vector as a scalar numeric integer. This property applies when you set the `CepstrumLengthSource` property to `Property`. The default is `10`.

`NonUnityFirstCoefficientAction`

LPC coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not `1`. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

step	Cepstral coefficients from columns of input LPC coefficients

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Convert LPC To Cepstral Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
levinson = dsp.LevinsonSolver;
levinson.AOutputPort = true; % Output polynomial coefficients
ac = dsp.Autocorrelator;
ac.MaximumLagSource = 'Property';
ac.MaximumLag = 9; % Compute autocorrelation lags between [0:9]
lpc2cc = dsp.LPCToCepstral;
x = (1:100)';
a = ac(x);
```

Compute LPC coefficients.

```
A = levinson(a);
```

Convert LPC to CC.

```
CC = lpc2cc(A);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from Cepstral Coefficients block reference page. The object properties correspond to the block parameters, except:
The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to `LPCs to cepstral coefficients`.

Compatibility Considerations

`dsp.LPCToCepstral` System object will be removed

Warns starting in R2019a

`dsp.LPCToCepstral` System object will be removed in a future release.

Introduced in R2012a

step

System object: `dsp.LPCToCepstral`
Package: `dsp`

Cepstral coefficients from columns of input LPC coefficients

Syntax

```
CC = step(lpc2cc,A)
CC = step(lpc2cc,A,P)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`CC = step(lpc2cc,A)` computes the cepstral coefficients, `CC`, from the columns of input linear prediction coefficients, `A`. The object assumes the prediction error power is `1`.

`CC = step(lpc2cc,A,P)` when you set the `PredictionErrorInputPort` property to `true`, computes the cepstral coefficients, `CC`, from the columns of input linear prediction coefficients, `A`. This conversion uses `P` as the prediction error power.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToLSF

Package: dsp

(To be removed) Convert linear prediction coefficients to line spectral frequencies

Note dsp.LPCToLSF will be removed in a future release. Use poly2lsf from Signal Processing Toolbox™ instead. For more information, see “Compatibility Considerations”.

Description

The LPCToLSF object converts linear prediction coefficients to line spectral frequencies.

To convert LPC to LSF:

1. Define and set up your LPC to LSF converter. See “Construction” on page 4-1228.
2. Call step to convert LPC according to the properties of dsp.LPCToLSF. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

lpc2lsf = dsp.LPCToLSF returns a System object, lpc2lsf, that converts linear prediction coefficients (LPCs) to line spectral frequencies (LSFs).

lpc2lsf = dsp.LPCToLSF('*PropertyName*',*PropertyValue*,...) returns an LPC to LSF System object, lpc2lsf, with each specified property set to the specified value.

Properties

`NumCoarseGridPoints`

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, `n`, used for finding line spectral pairs (LSP) values as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (–1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. To compute LSF outputs, the object computes the arc cosine of the LSPs, outputting values ranging from 0 to pi radians. The object divides the interval (–1, 1) into `n` subintervals and looks for roots in each subinterval. If you set *n* too small in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is `64`. This property is tunable.

`NumBisects`

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, `k`, used in the Chebyshev polynomial root finding method, where each line spectral pair (LSP) output is within

$$\frac{1}{(n \cdot 2^k)}$$

of the actual LSP value. Here *n* is the value of the `NumCoarseGridPoints` property, and the object searches a maximum of $k \cdot (n - 1)$ points for finding the roots. You must set the `NumBisects` property value *k*, to a positive scalar integer. The default is `4`. This property is tunable.

`ExceptionOutputPort`

Produces output with validity status of LSF output

Set this property to `true` to return a second output that indicates whether the computed LSF values are valid. The output is a vector with a length equal to the number of channels. A logical value of `1` indicates valid output. A logical value of `0` indicates invalid output. The LSF outputs are invalid when the object fails to find all the LSF values or when the input LPCs are unstable. The default is `false`.

`OverwriteInvalidOutput`

Enable overwriting invalid output with previous output

Specify the action that the System object should take for invalid LSF outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object does not take any action on invalid outputs and ignores the outputs.

`FirstOutputValuesSource`

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies when you set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When you set this property to `Auto`, the object uses a default value for the first output. The default value corresponds to the LSF representation of an allpass filter.

`FirstOutputValues`

Value of the first output

Specify a numeric vector of LSF values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, you can set this property to a matrix with the same number of channels as the input, or one vector that is applied to every channel. The default is an empty vector. This property applies when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

`NonUnityFirstCoefficientAction`

Action to take when first LPC coefficient is not `1`

Specify the action the object takes when the first coefficient of each channel of the LPC input is not `1` as `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

reset	Reset values for overwriting invalid outputs to their initial values
step	Convert LPC coefficients to line spectral frequencies

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Convert LPC Coefficients To LSF Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert LPC to LSF coefficients

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
lpc2lsf = dsp.LPCToLSF;
y = lpc2lsf(a);
display(y);
```

```
y = 5×1

    0.7842
    1.5605
    1.8776
    1.8984
    2.3593
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Output** block parameter. The object only supports LSF outputs in the range (0,∏)

Compatibility Considerations

`dsp.LPCToLSF` System object will be removed

Warns starting in R2019a

`dsp.LPCToLSF` System object will be removed in a future release. Use `poly2lsf` instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

If your code has this form (R2016b or later):	If your code has this form (prior to R2016b):	Use this code instead:

`a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';`
`lpc2lsf = dsp.LPCToLSF`
`lsfObj = lpc2lsf(a)`
	`a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';`
	`lpc2lsf = dsp.LPCToLSF`
	`lsfObj = step(lpc2lsf,a)`
		`a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';`
		`lsfFn = poly2lsf(a)`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

Functions
`poly2lsf`

Introduced in R2012a

reset

Reset values for overwriting invalid outputs to their initial values

Syntax

```
reset(lpc2lsf)
```

Description

`reset(lpc2lsf)` resets the values for overwriting the invalid outputs to their initial values.

step

System object: `dsp.LPCToLSF`
Package: `dsp`

Convert LPC coefficients to line spectral frequencies

Syntax

```
LSF = step(lpc2lsf,A)
[..., STATUS] = step(lpc2lsf,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`LSF = step(lpc2lsf,A)` converts the `LPC` coefficients, `A` , to line spectral frequencies, `LSF`, in the range (0 pi). The System object operates along the columns of the input `A`.

`[..., STATUS] = step(lpc2lsf,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToLSP

Package: `dsp`

(To be removed) Convert linear prediction coefficients to line spectral pairs

---

Note `dsp.LPCToLSP` will be removed in a future release. Use `poly2lsf` instead. For more information, see “Compatibility Considerations”.

Description

The `LPCToLSP` object converts linear prediction coefficients to line spectral pairs.

To convert LPC to LSP:

1. Define and set up your LPC to LSP converter. See “Construction” on page 4-1236.
2. Call `step` to convert LPC according to the properties of `dsp.LPCToLSP`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2lsp = dsp.LPCToLSP` returns a System object, `lpc2lsp`, that converts linear prediction coefficients (LPCs) to line spectral pairs (LSPs).

`lpc2lsp = dsp.LPCToLSP('PropertyName',PropertyValue,...)` returns an `LPC` to `LSF` System object, `lpc2lsp`, with each specified property set to the specified value.

Properties

`NumCoarseGridPoints`

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, *n*, used for finding line spectral pairs (LSP) values, as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (–1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. The object divides the interval (–1, 1) into *n* subintervals and looks for roots in each subinterval. If *n* is set to too small a number in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is `64`. This property is tunable.

`NumBisects`

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, *k*, that the Chebyshev polynomial uses in the root finding method. For each line spectral pair (LSP) the output is within

$$\frac{1}{n \cdot 2^k}$$

of the actual LSP value. Here *n* is the value of the `NumCoarseGridPoints` property and the object searches a maximum of

$$k \cdot (n-1)$$

points for finding the roots. The `NumBisects` property value *k*, must be a positive scalar integer. The default is `4`. This property is tunable.

`ExceptionOutputPort`

Produces output with validity status of LSP output

Set this property to `true` to return a second output that indicates whether the computed LSP values are valid. The object outputs a vector length equal to the number of channels. A logical value of `1` indicates the output is valid. A logical value of `0` indicates the output is invalid. The LSP outputs are invalid when the object fails to find all the LSP values or when the input LPCs are unstable. The default is `false`.

`OverwriteInvalidOutput`

Enable overwriting invalid output with previous output

Specify the action that the object takes for invalid LSP outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object takes no action on invalid outputs and ignores the outputs.

`FirstOutputValuesSource`

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies only when you set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When this property is `Auto`, the object uses a default value for the first output. The default value corresponds to the LSP representation of an allpass filter.

`FirstOutputValues`

Value of first output

Specify a numeric vector of LSP values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, set this property can to a matrix with the same number of channels as the input or one vector that you apply to every channel. The default is an empty vector. This property applies only when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

`NonUnityFirstCoefficientAction`

First coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not equal to `1`. Specify as one of `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

reset	Reset values for overwriting invalid outputs to their initial values
step	Convert linear prediction coefficients to line spectral pairs

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Convert LPC To LSP Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert the linear prediction coefficients to line spectral pairs.

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
lpc2lsp = dsp.LPCToLSP;
y = lpc2lsp(a); % Convert to LSP coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:
No object property corresponds to the **Output** block parameter. The object only supports LSP outputs.

Compatibility Considerations

`dsp.LPCToLSP` System object will be removed

Warns starting in R2019a

dsp.LPCToLSP System object will be removed in a future release. Use poly2lsf instead.
