void logFcn(rtwC_API_ModelMappingInfo *mmi, time_T *tPtr);

```

These files use the C API to access signal and parameter data in the code that you generate from the example model.

3. Set model configuration parameters **Header file** and **Source files** to `#include "ex_myHandHdr.h"` and `ex_myHandCode.c`, respectively.

```

set_param('rtwdemo_basicsc', 'CustomHeaderCode', '#include "ex_myHandHdr.h"')
set_param('rtwdemo_basicsc', 'CustomSource', 'ex_myHandCode.c')

```

4. Select model configuration parameter **MAT-file Logging**. The generated executable runs only until the simulation stop time (which you set in the model configuration parameters).

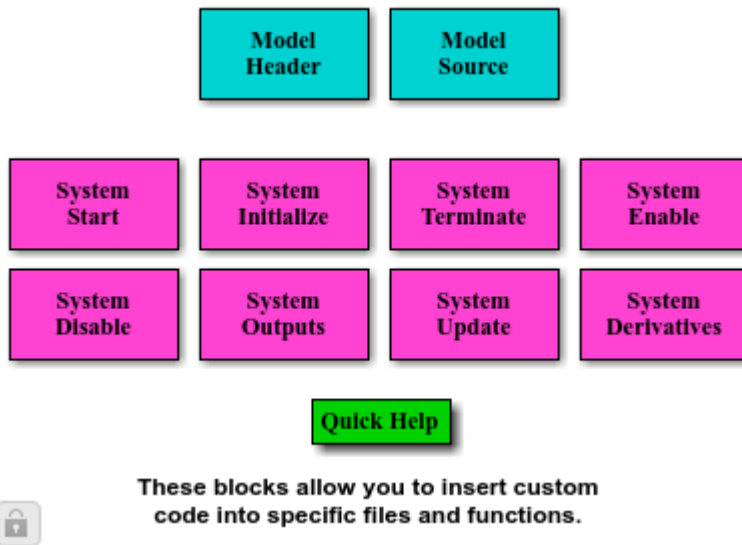

```
set_param('rtwdemo_basicsc','MatFileLogging','on')
```

5 Select C API model configuration parameters **parameters**, **signals**, **states**, and **root-level I/O**.

```
set_param('rtwdemo_basicsc','RTWCAPIParams','on')
set_param('rtwdemo_basicsc','RTWCAPISignals','on')
set_param('rtwdemo_basicsc','RTWCAPIStates','on')
set_param('rtwdemo_basicsc','RTWCAPIRootIO','on')
```

5. Load the Custom Code block library.

```
custcode
```

6. Add a System Outputs block to the model.

```
add_block('custcode/System Outputs','rtwdemo_basicsc/System Outputs')
```

7. In the System Outputs block dialog box, set **System Outputs Function Execution Code** to this code:

```
{
rtwdemo_basicsc_U.input2++;
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

8. In the block dialog box, set **System Outputs Function Exit Code** to this code:

```
{
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
logFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

Alternatively, to configure the System Outputs block, at the command prompt, use these commands:

```
temp.TLCFile = 'custcode';
temp.Location = 'System Outputs Function';
temp.Middle = sprintf(['\nrtwdemo_basicsc_U.input2++;'...
    '\nrtwCAPI_ModelMappingInfo *MMI = '...
    '&(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);'...
    '\ntuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));\n}']);
temp.Bottom = sprintf(['\nrtwCAPI_ModelMappingInfo *MMI = '...
    '&(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);'...
    '\nlogFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));\n}']);
set_param('rtwdemo_basicsc/System Outputs', 'RTWdata', temp)
```

9. Generate code.

```
rtwbuild('rtwdemo_basicsc')

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

10. In the code generation report, view the interface file `rtwdemo_basicsc_capi.c`. This file initializes the arrays of structures that you can use to interact with data items through the C API. For example, in the array of structures `rtBlockSignals`, the first structure (index 0) describes the test-pointed output signal of the Gain block in the model.

```
file = fullfile('rtwdemo_basicsc_grt_rtw', 'rtwdemo_basicsc_capi.c');
rtwmodbtype(file, '/* Block output signal information */', ...
    '/* Individual block tuning', 1, 0)

/* Block output signal information */
```

```

static const rtwCAPI_Signals rtBlockSignals[] = {
    /* addrMapIndex, sysNum, blockPath,
     * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
     */
    { 0, 0, TARGET_STRING("rtwdemo_basicsc/Gain"),
      TARGET_STRING(""), 0, 0, 0, 0, 0, 0 },

    {
        0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
    }
};

```

The fields of the structure, such as `addrMapIndex`, indicate indices into other arrays of structures, such as `rtDataAddrMap`, that describe the characteristics of the signal. These characteristics include the address of the signal data (a pointer to the data), the numeric data type, and the dimensions of the signal.

11. In the file `rtwdemo_basicsc.c`, view the code algorithm in the model step function. The algorithm first executes the code that you specified in the System Outputs block.

```

file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* user code (Output function Body) */',...
    '/* Logic: '<Root>/Log0p' incorporates:',1,0)

/* user code (Output function Body) */

/* System '<Root>' */
{
    rtwdemo_basicsc_U.input2++;
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
    tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}

/* DataStoreWrite: '<Root>/DSWrite' incorporates:
 * Constant: '<Root>/Constant1'
 * Constant: '<Root>/Constant2'
 * Inport: '<Root>/In1'

}

/* Model terminate function */
void rtwdemo_basicsc_terminate(void)
{
    /* (no terminate code required) */
}

```

This code first perturbs the input signal `input2` by incrementing the value of the signal each time the `step` function executes. The code then uses the built-in macro `rtmGetDataMapInfo` to extract model mapping information from the model data structure `rtwdemo_basicsc_M`. The pointer `MMI` points to the extracted mapping information, which allows the functions `tuneFcn` and `logFcn` to access the information contained in the arrays of structures that the C API file `rtwdemo_basicsc_capi.c` defines.

12. View the function `tuneFcn` in the file `ex_myHandCode.c`. This function uses the C API (through the model mapping information `mmi`) and a pointer to the simulation time to print the value of the parameter `K1` at specific times during code execution. When the simulation time reaches 5 seconds, the function changes the parameter value in memory. By using a `switch case` block, the function can access the parameter data whether the data type is `int8` or `double`.

13. View the code algorithm in the model `step` function again. Near the end of the function, the algorithm executes the code that you specified in the System Outputs block. This code calls the function `logFcn`.

```

rtwdemodbtype(file, '/* user code (Output function Trailer) */', ...
    '/* Matfile logging */', 1, 0)

/* user code (Output function Trailer) */

```

```
/* System '<Root>' */
{
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_bascisc_M).mmi);
    logFcn(MMI, rtmGetTPtr(rtwdemo_bascisc_M));
}
```

14. View the function `logFcn` in the file `ex_myHandCode.c`. The function uses the C API to print the value of the test-pointed signal. The function can access the signal data whether the data type is `single` or `double`.

15. At the command prompt, run the generated executable `rtwdemo_bascisc.exe`.

```
system('rtwdemo_bascisc')
```

The parameter and signal values appear in the Command Window output.

For more information about data interfaces, including the C API, see “Data Exchange Interfaces” (Simulink Coder).

## Standard Data Structures in the Generated Code

By default, signal lines, block parameters, states, and other model data appear in the generated code as fields of standard structures. For general information, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder).

The table shows some common data structures in the generated code. The name of the structure type and, if applicable, structure variable in the code that you generate from a model depends on the model settings. Regardless of the settings, the name of the structure type in the code contains the short name from the **Short Name of Structure Type** column in the table.

### Data Structures Generated for a Model

| Short Name of Structure Type | Data Represented in the Structure       |
|------------------------------|-----------------------------------------|
| ExtU                         | Data from root Inport blocks            |
| ExtY                         | Data from root Outport blocks           |
| B                            | Block output signals                    |
| ConstB                       | Block outputs that have constant values |
| P                            | Block parameters                        |
| ConstP                       | Constant parameters                     |
| DW                           | Discrete block states                   |
| XDis                         | Status of enabled subsystems            |

For additional structures, see “System-generated identifiers” (Simulink Coder).

You can exclude data from appearing in these structures by using:

- Direct application of storage classes. For example, you can use storage classes to represent signals, tunable parameters, and states as individual global variables. For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99.
- Configuration parameters, such as those on the **Optimization** pane in the Configuration Parameters dialog box. You can adjust these configuration parameters to control the default representation of data. For more information, see “Model Configuration Parameters: Code Generation Optimization” (Simulink Coder).

## Control Characteristics of Data Structures (Embedded Coder)

To control the characteristics of the standard data structures, use the information in the table.

| Name                           | How to Change Name                                                                                                                                                                                                                                                                                        |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Structure types                | Specify a naming rule to use for the types. Set a value for <b>Configuration Parameters &gt; Global types</b> .                                                                                                                                                                                           |
| Global structure variables     | Specify a naming rule with <b>Configuration Parameters &gt; Global variables</b> .                                                                                                                                                                                                                        |
| Names of structure fields      | By default, the name of each structure field derives from the name of the data item in the model (for example, the name of a block state, which you specify by using the <b>State name</b> block parameter). Specify a naming rule with <b>Configuration Parameters &gt; Field name of global types</b> . |
| Data types of structure fields | Use <code>Simulink.AliasType</code> objects and data type replacement to rename primitive types for the corresponding data items in the model. See “Control Data Type Names in Generated Code” on page 35-2.                                                                                              |

For more information about configuration parameters that control names and other identifiers in the generated code, see “Customize Generated Identifiers” on page 88-21.

## Use the Real-Time Model Data Structure

The code generator uses the real-time model (RT\_MODEL) data structure. This structure is also referred to as the `rtModel` data structure. You can access `rtModel` data by using a set of macros analogous to the `ssSetxxx` and `ssGetxxx` macros that S-functions use to access `SimStruct` data, including noninlined S-functions compiled by the code generator.

You need to use the set of macros `rtmGetxxx` and `rtmSetxxx` to access the real-time model data structure. The `rtModel` is an optimized data structure that replaces `SimStruct` as the top level data structure for a model. The `rtmGetxxx` and `rtmSetxxx` macros are used in the generated code as well as from the `main.c` or `main.cpp` module. If you are customizing `main.c` or `main.cpp` (either a static file or a generated file), you need to use `rtmGetxxx` and `rtmSetxxx` instead of the `ssSetxxx` and `ssGetxxx` macros.

Usage of `rtmGetxxx` and `rtmSetxxx` macros is the same as for the `ssSetxxx` and `ssGetxxx` versions, except that you replace `SimStruct` S by real-time model data structure `rtM`. The following table lists `rtmGetxxx` and `rtmSetxxx` macros that are used in `grt_main.c` and `grt_main.cpp`.

### Macros for Accessing the Real-Time Model Data Structure

| rtm Macro Syntax                                   | Description                                                                                         |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>rtmGetX(rtm)</code>                          | Get the derivatives of block continuous states                                                      |
| <code>rtmGetOffsetTimePtr(RT_MDL rtm)</code>       | Return the pointer to vector that stores sample time offsets of the model associated with rtm       |
| <code>rtmGetNumSampleTimes(RT_MDL rtm)</code>      | Get the number of sample times that a block has                                                     |
| <code>rtmGetPerTaskSampleHitsPtr(RT_MDL)</code>    | Return a pointer to NumSampleTime × NumSampleTime matrix                                            |
| <code>rtmGetRTWExtModeInfo(RT_MDL rtm)</code>      | Return an external mode information data structure of the model (used internally for external mode) |
| <code>rtmGetRTWLogInfo(RT_MDL)</code>              | Return a data structure used by code generator logging (internal use only)                          |
| <code>rtmGetRTWRTModelMethodsInfo(RT_MDL)</code>   | Return a data structure of real-time model methods information (internal use only)                  |
| <code>rtmGetRTWSolverInfo(RT_MDL)</code>           | Return data structure containing solver information of the model (internal use only)                |
| <code>rtmGetSampleHitPtr(RT_MDL)</code>            | Return a pointer to Sample Hit flag vector                                                          |
| <code>rtmGetSampleTime(RT_MDL rtm, int TID)</code> | Get task sample time                                                                                |
| <code>rtmGetSampleTimePtr(RT_MDL rtm)</code>       | Get pointer to a task sample time                                                                   |
| <code>rtmGetSampleTimeTaskIDPtr(RT_MDL rtm)</code> | Get pointer to a task ID                                                                            |
| <code>rtmGetSimTimeStep(RT_MDL)</code>             | Return simulation step type ID (MINOR_TIME_STEP, MAJOR_TIME_STEP)                                   |
| <code>rtmGetStepSize(RT_MDL)</code>                | Return the fundamental step size of the model                                                       |
| <code>rtmGetT(RT_MDL, t)</code>                    | Get the current simulation time                                                                     |
| <code>rtmSetT(RT_MDL, t)</code>                    | Set the time of the next sample hit                                                                 |
| <code>rtmGetTaskTime(RT_MDL, tid)</code>           | Get the current time for the current task                                                           |
| <code>rtmGetTFinal(RT_MDL)</code>                  | Get the simulation stop time                                                                        |
| <code>rtmSetTFinal(RT_MDL, finalT)</code>          | Set the simulation stop time                                                                        |
| <code>rtmGetTimingData(RT_MDL)</code>              | Return a data structure used by timing engine of the model (internal use only)                      |

| <b>rtm Macro Syntax</b>                     | <b>Description</b>                                                                                   |
|---------------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>rtmGetTPtr(RT_MDL)</code>             | Return a pointer to the current time                                                                 |
| <code>rtmGetTStart(RT_MDL)</code>           | Get the simulation start time                                                                        |
| <code>rtmIsContinuousTask(rtm)</code>       | Determine whether a task is continuous                                                               |
| <code>rtmIsMajorTimeStep(rtm)</code>        | Determine whether the simulation is in a major step                                                  |
| <code>rtmIsSampleHit(RT_MDL, tid)</code>    | Determine whether the sample time is hit                                                             |
| <code>rtmGetErrorStatus(rtm)</code>         | Get the current error status                                                                         |
| <code>rtmSetErrorStatus(rtm, val)</code>    | Set the current error status                                                                         |
| <code>rtmGetErrorStatusPointer(rtm)</code>  | Return a pointer to the current error status                                                         |
| <code>rtmGetStopRequested(rtm)</code>       | Return whether a stop is requested                                                                   |
| <code>rtmGetBlockIO(rtm)</code>             | Get the block I/O data structure                                                                     |
| <code>rtmSetBlockIO(rtm, val)</code>        | Set the block I/O data structure                                                                     |
| <code>rtmGetContStates(rtm)</code>          | Get the continuous states data structure                                                             |
| <code>rtmSetContStates(rtm, val)</code>     | Set the continuous states data structure                                                             |
| <code>rtmGetDefaultParam(rtm)</code>        | Get the default parameters data structure                                                            |
| <code>rtmSetDefaultParam(rtm, val)</code>   | Set the default parameters data structure                                                            |
| <code>rtmGetPrevZCSigState(rtm)</code>      | Get the previous zero-crossing signal state data structure                                           |
| <code>rtmSetPrevZCSigState(rtm, val)</code> | Set the previous zero-crossing signal state data structure                                           |
| <code>rtmGetRootDWork(rtm)</code>           | Get the DWork data structure                                                                         |
| <code>rtmSetRootDWork(rtm, val)</code>      | Set the DWork data structure                                                                         |
| <code>rtmGetU(rtm)</code>                   | Get the root inputs data structure (when root inputs are passed as part of the model data structure) |
| <code>rtmSetU(rtm, val)</code>              | Set the root inputs data structure (when root inputs are passed as part of the model data structure) |

| <b>rtm Macro Syntax</b>        | <b>Description</b>                                                                                     |
|--------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>rtmGetY(rtm)</code>      | Get the root outputs data structure (when root outputs are passed as part of the model data structure) |
| <code>rtmSetY(rtm, val)</code> | Set the root outputs data structure (when root outputs are passed as part of the model data structure) |

## How Generated Code Exchanges Data with an Environment

To use the code that you generate from a model, you call the generated entry-point functions such as `step` and `initialize`. The environment in which you call these functions must provide input signal data and, depending on your application, scheduling information. The generated algorithm then calculates output data that the calling environment can use. The environment and the algorithm can exchange this data through global variables or through formal parameters (arguments).

The set of input and output data and the exchange mechanisms constitute the interfaces of the entry-point functions. When you understand the default interfaces and how to control them, you can:

- Write code that calls the generated code.
- Generate reusable (reentrant) code that you can call multiple times in a single application.
- Integrate the generated code with other, external code in your application.

In a model, root-level Inport and Outport blocks represent the primary inputs and outputs of the block algorithm. By default, the code generator aggregates these blocks into standard structures that store input and output data.

For information about how the generated code stores internal data, which does not participate in the model interface, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-68.

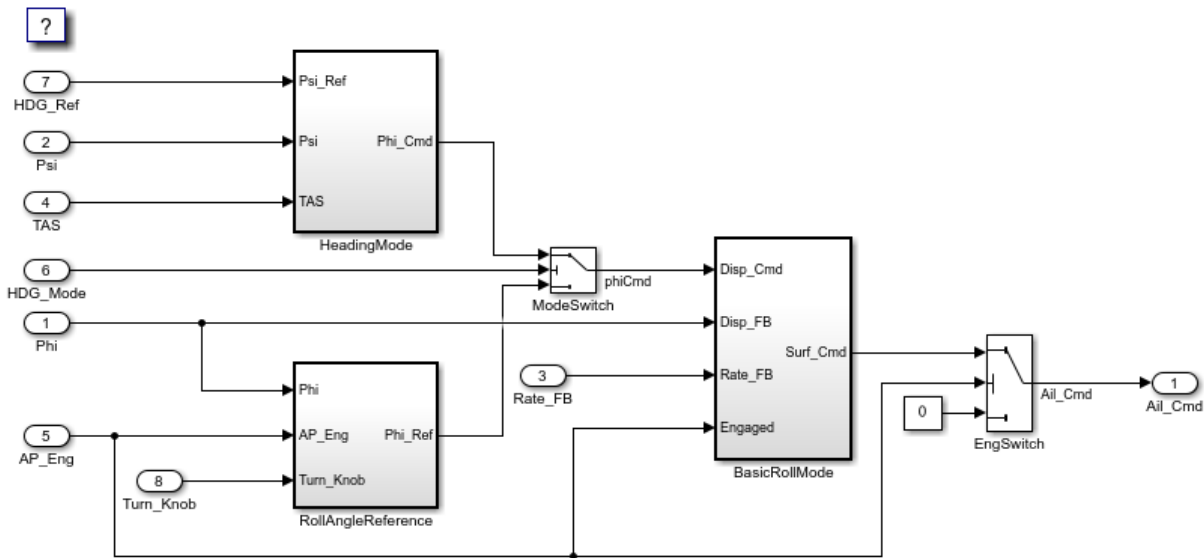

### Data Interfaces in the Generated Code

This example shows how the generated code exchanges data with an environment.

#### Explore Example Model

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```

Copyright 1990-2019 The MathWorks, Inc.

At the root level, the model has a number of Inport blocks and one Outport block.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```
set_param('rtwdemo_roll', 'SystemTargetFile', 'grt.tlc')
```

Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting `Nonreusable` function means that the generated code is not reusable (not reentrant).

For this example, to generate simpler code, clear the **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```
set_param('rtwdemo_roll', 'MatFileLogging', 'off')
```

### Generate Nonreusable Code

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Inspect the file `rtwdemo_roll.h`. The file defines a structure type that represents input data and a type that represents output data.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
    /* External inputs (root inport signals with default storage) */,...
    '} ExtY_rtwdemo_roll_T;',1,1)

/* External inputs (root inport signals with default storage) */
typedef struct {
    real32_T Phi;           /* '<Root>/Phi' */
    real32_T Psi;          /* '<Root>/Psi' */
    real32_T Rate_FB;     /* '<Root>/Rate_FB' */
    real32_T TAS;         /* '<Root>/TAS' */
    boolean_T AP_Eng;     /* '<Root>/AP_Eng' */
    boolean_T HDG_Mode;   /* '<Root>/HDG_Mode' */
    real32_T HDG_Ref;     /* '<Root>/HDG_Ref' */
    real32_T Turn_Knob;   /* '<Root>/Turn_Knob' */
} ExtU_rtwdemo_roll_T;

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
    real32_T Ail_Cmd;     /* '<Root>/Ail_Cmd' */
} ExtY_rtwdemo_roll_T;
```

Each field corresponds to an Inport or Outport block at the root level of the model. The name of each field derives from the name of the block.

The file also defines a structure type, the *real-time model data structure*, whose single field stores a run-time indication of whether the generated code has encountered an error during execution.

```
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
    /* Block states (default storage) */',1,0)

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
    const char_T *errorStatus;
};
```

When you modify model configuration parameters to suit your application, this structure can also contain other data that pertain to the entire model, such as scheduling information.

For the structure type that represents the real-time model data structure, the file `rtwdemo_roll_types.h` creates an alias (typedef) that the generated code later uses to allocate memory for the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll_types.h');
rtwdemodbtype(file,'/* Forward declaration for rtModel */',...
    'RT_MODEL_rtwdemo_roll_T;',1,1)
```

```
/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;
```

Using these structure types, the file `rtwdemo_roll.c` defines (allocates memory for) global structure variables that store input and output data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,...
    '/* External inputs (root inport signals with default storage) */',...
    '= &rtwdemo_roll_M;',1,1)
```

```
/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;
```

```
/* External outputs (root outputs fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;
```

```
/* Real-time model */
RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M;
```

The file `rtwdemo_roll.h` declares these structure variables. Your external code can include (`#include`) this file, whose general name is `model.h` where `model` is the name of the model, to access data that participate in the model interface.

In `rtwdemo_roll.c`, the `model_step` function, which represents the primary model algorithm, uses a `void void` interface (without arguments).

```
rtwdemo_dbtype(file,...
    /* Model step function */,'void rtwdemo_roll_step(void)',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(void)
```

In the function definition, the algorithm reads input data and writes output data by directly accessing the global structure variables. For example, near the end of the algorithm, the code for the EngSwitch block reads the value of the AP\_Eng field (which represents an input) and, based on that value, conditionally writes a constant value to the Ail\_Cmd field (which represents an output).

```
rtwdemo_dbtype(file,'if (rtwdemo_roll_U.AP_Eng) {' , '      }',1,1)
```

```
if (rtwdemo_roll_U.AP_Eng) {
    /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
    /* Saturate: '<S1>/CmdLimit' */
    if (rtwdemo_roll_Y.Ail_Cmd > 15.0F) {
        /* Sum: '<S1>/Sum2' incorporates:
         * Output: '<Root>/Ail_Cmd'
         */
        rtwdemo_roll_Y.Ail_Cmd = 15.0F;
    } else {
        if (rtwdemo_roll_Y.Ail_Cmd < -15.0F) {
            /* Sum: '<S1>/Sum2' incorporates:
             * Output: '<Root>/Ail_Cmd'
             */
            rtwdemo_roll_Y.Ail_Cmd = -15.0F;
        }
    }
}
```

Due to the `void void` interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call reads and writes input and output data to the same global structure variables, resulting in data corruption and unintentional interaction between the calls.

The model initialization function, `rtwdemo_roll_initialize`, initializes input and output data to zero. The function also initializes the error status. The function directly accesses the global variables, which means the function is not reentrant.

```
rtwdemo_dbtype(file,'/* Model initialize function */',...
    'rtmSetErrorStatus(rtwdemo_roll_M, (NULL));',1,1)
```

```
/* Model initialize function */
void rtwdemo_roll_initialize(void)
{
    /* Registration code */

    /* initialize error status */
    rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

    rtwdemodbtype(file, ' /* external inputs */',...
        ' /* SystemInitialize for Atomic SubSystem:',1,0)

    /* external inputs */
    (void)memset(&rtwdemo_roll_U, 0, sizeof(ExtU_rtwdemo_roll_T));

    /* external outputs */
    rtwdemo_roll_Y.Ail_Cmd = 0.0F;
}
```

### Generate Reusable Code

You can configure the generated code as reentrant, which means that you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions exchange input, output, and other model data through formal parameters (pointer arguments). With these pointer arguments, each call can read inputs and write outputs to a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to Reusable function.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Reusable function')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')

### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the input data, the output data, and additional data in the form of a `DWork` substructure (which stores, for example, block states such as the state of a Discrete-Time Integrator block).

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
    '/* External data declarations for dependent source files */',1,0)

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
    const char_T *errorStatus;
    ExtU_rtwdemo_roll_T *inputs;
    ExtY_rtwdemo_roll_T *outputs;
    DW_rtwdemo_roll_T *dwork;
};

```

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the input and output structures.

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Model data allocation function */',...
    'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)

```

```

/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)

```

In `rtwdemo_roll.c`, the model step function accepts an argument that represents the real-time model data structure.

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,...
    '/* Model step function */','void rtwdemo_roll_step',1,1)

```

```

/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

```

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```

rtwdemodbtype(file,...
    '*rtwdemo_roll_DW =','rtwdemo_roll_M->outputs;',1,1)

```

```

DW_rtwdemo_roll_T *rtwdemo_roll_DW = ((DW_rtwdemo_roll_T *)
    rtwdemo_roll_M->dwork);
ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
    rtwdemo_roll_M->inputs;
ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
    rtwdemo_roll_M->outputs;

```

Then, to access the input and output data stored in global memory, the algorithm interacts with these local variables.

```

rtwdemodbtype(file, ' if (rtwdemo_roll_U->AP_Eng) {' , ...
    ' /* End of Switch: '<Root>/EngSwitch' */',1,1)

if (rtwdemo_roll_U->AP_Eng) {
    /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
    /* Saturate: '<S1>/CmdLimit' */
    if (rtwdemo_roll_Y->Ail_Cmd > 15.0F) {
        /* Sum: '<S1>/Sum2' incorporates:
         * Output: '<Root>/Ail_Cmd'
         */
        rtwdemo_roll_Y->Ail_Cmd = 15.0F;
    } else {
        if (rtwdemo_roll_Y->Ail_Cmd < -15.0F) {
            /* Sum: '<S1>/Sum2' incorporates:
             * Output: '<Root>/Ail_Cmd'
             */
            rtwdemo_roll_Y->Ail_Cmd = -15.0F;
        }
    }

    /* End of Saturate: '<S1>/CmdLimit' */
    /* End of Outputs for SubSystem: '<Root>/BasicRollMode' */
} else {
    /* Sum: '<S1>/Sum2' incorporates:
     * Constant: '<Root>/Zero'
     * Output: '<Root>/Ail_Cmd'
     */
    rtwdemo_roll_Y->Ail_Cmd = 0.0F;
}

```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```
rtwdemoDbType(file,...
    /* Model initialize function */, 'void rtwdemo_roll_initialize', 1, 1)

/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

## Configure Data Interface

To control the characteristics of the data interface in the generated code, see “Control Data and Function Interface in Generated Code” on page 33-60.

## Control Data and Function Interface in Generated Code

To use the code that you generate from a model, you call generated entry-point functions such as `step` and `initialize`. The calling environment and the generated functions exchange input and output data through global variables or through formal parameters (arguments). This data and the exchange mechanisms constitute the interfaces of the entry-point functions. For information about the default interfaces for reentrant and nonreentrant models in the generated code, see “How Generated Code Exchanges Data with an Environment” on page 33-51.

By controlling the interfaces that appear in the generated code, you can:

- Minimize the modifications that you must make to existing code.
- Generate stable interfaces that do not change or minimally change when you make changes to the model.
- Generate code that exchanges data more efficiently (for example, by using pointers and pass-by-reference arguments for nonscalar data).

### Control Type Names, Field Names, and Variable Names of Standard I/O Structures (Embedded Coder)

By default, for nonreentrant code, Inport blocks at the root level of the model appear in the generated code as fields of a global structure variable. Similarly, Outport blocks appear in a different structure. For reentrant code, depending on your setting for model configuration parameter **Pass root-level I/O**, the code generator can also package input and output data into standard structures.

With Embedded Coder, you can control these names. See “Control Characteristics of Data Structures (Embedded Coder)” (Simulink Coder).

### Control Names of Generated Entry-Point Functions (Embedded Coder)

To use the generated code, you write code that calls generated entry-point functions. For example, entry-point functions include `model_step`, `model_initialize`, and top-level functions generated from an export-function model. To control the names of the model entry-point functions, use the Code Mappings editor (requires Embedded Coder) to apply a combination of these techniques:

- On the **Function Defaults** tab, specify default naming rules for categories of entry-point functions by applying function customization templates in the Code Mappings editor. With this technique, a naming rule applies to functions in a category. For more information, see “Configure Default Code Generation for Functions” on page 32-15.
- On the **Functions** tab, specify names for individual entry-point functions by either directly editing the **Function Name** column or through a configuration dialog box opened from the **Function Preview** column. Names that you specify override default naming rules specified by function customization templates. For more information, see “Customize Generated C Function Interfaces” on page 40-2

## Control Data Interface for Nonreentrant Code

When you set the model configuration parameter **Code interface packaging** to `Nonreusable function` (the default), generated entry-point functions are not reentrant. Typically, the functions exchange data with the calling environment through direct access to global variables.

### Configure Inport or Outport Block as Separate Global Variable

To remove the block from the standard I/O structures by creating a separate global variable, apply a storage class, such as `ExportedGlobal` or `ExportToFile`, to the signal that the block represents.

- To specify a default storage class for Inport blocks and a different default for Outport blocks, use the Code Mappings editor. As you add such blocks to the model, they acquire the storage class that you specify. You do not need to configure each individual block.

For this technique, you must have Embedded Coder.

- To override the default for an individual block, apply a different storage class by using other tools such as the Model Data Editor or the Property Inspector. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

For an example, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder). For general information about storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).

### **Configure Generated Code to Read or Write to Global Variables Defined by External Code**

If your calling code already defines a global variable that you want the generated code to use as input data or use to store output data, you can reuse the variable by preventing the code generator from duplicating the definition. Apply a storage class to the corresponding Inport or Outport block in the model. Choose a storage class that specifies an imported data scope, such as `ImportedExtern` or `ImportFromFile`. For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19.

### **Package Multiple Inputs or Outputs into Custom Structure**

You can configure a single Inport or Outport block to appear in the generated code as a custom structure that contains multiple input or output signals. You can also configure the block to appear as a substructure of the default I/O structures or as a separate structure variable.

Configure the block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object.

- To generate the bus signal as a substructure in the standard I/O structures, leave the block storage class at the default setting, `Auto`. If you have Embedded Coder, in the Code Mappings editor, on the **Data Defaults** tab, set the storage class for categories **Inports** and **Outports** to `Default`.
- To generate the bus signal as a separate global structure variable, apply a storage class such as `ExportedGlobal` or `ExportToFile`.

For more information about grouping signals into custom structures in the generated code, see “Organize Data into Structures in Generated Code” on page 33-201.

### **Configure Inport or Outport Block as Function Call (Embedded Coder)**

If your external code defines a function that returns input data for the generated code or accepts output data that the generated code produces, you can configure an Inport or Outport block so that the generated code calls the function instead of accessing a global variable. Apply the Embedded Coder storage class `GetSet`. For more information, see “Access Data Through Functions with Storage Class `GetSet`” on page 37-42.

## Pass Inputs and Outputs Through Function Arguments (Embedded Coder)

With Embedded Coder, you can optionally configure the model step (execution) function to access root-level input and output through arguments instead of directly reading and writing to global variables. Completely control the argument characteristics such as name, order, and passing mechanism (by reference or by value). This level of configuration can help to integrate generated code with your external code.

To pass inputs and outputs through arguments, in the Configure C Step Function interface dialog box, select **Configure arguments for Step function prototype**. Each Inport and Outport block at the root level of the model appears in the code as an argument of the execution function. For more information, see “Customize Generated C Function Interfaces” on page 40-2.

## Configure Referenced Model Inputs and Outputs as Global Variables (void-void)

By default, for a nonreentrant referenced model, the generated code passes root-level input and output through function arguments. A nonreentrant referenced model is one in which you set model configuration parameter **Total number of instances allowed per top model** to One.

To pass this data through global variables instead (for a void-void interface), in the referenced model, apply storage classes such as `ExportedGlobal` and `ExportToFile` to root-level Inport and Outport blocks.

- To apply a default storage class to such blocks, use the Code Mapping Editor, which requires Embedded Coder. With this technique, as you add such blocks to the model, the blocks acquire the default storage class, preserving the void-void interface. For more information, see “Configure Default Code Generation for Data” on page 32-8.
- To override the default storage class, apply storage classes directly to individual blocks by using the Model Data Editor. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99.
- For an example that requires Embedded Coder, see “Establish Data Ownership in a System of Components” on page 34-15.

## Control Data Interface for Reentrant Code

When you set **Code interface packaging** to `Reusable` function, generated entry-point functions are reentrant. The functions exchange data with the calling environment through formal parameters (arguments). By default, each root-level Inport and Outport

block appears in the generated code as a separate argument instead of a field of the standard I/O structures.

- To reduce the number of arguments, see “Reduce Number of Arguments by Using Structures” (Simulink Coder).
- To control the data types of the arguments, see “Control Data Types of Arguments” (Simulink Coder).

## **Prevent Unintended Changes to the Interface**

Some changes that you make to a model change the entry-point function interfaces in the generated code. For example, if you change the name of the model, the names of the functions can change. If you configure the model code to exchange data through arguments, when you add or remove Inport or Outport blocks or change the names of the blocks, the corresponding arguments can change.

For easier maintenance of your calling code, prevent changes to the interfaces of the entry-point functions.

- If you exchange input and output data through arguments, configure the generated code to package Inport and Outport blocks into structures instead of allowing each block to appear as a separate argument (the default). Then, when you add or remove Inport or Outport blocks, or change their properties such as name and data type, the fields of the structures change, but the function interfaces do not change. See “Reduce Number of Arguments by Using Structures” on page 33-65.
- Set the data types of Inport and Outport blocks explicitly instead of using an inherited data type setting (which these blocks use by default). Inherited data type settings can cause the blocks to use different data types depending on the data types of upstream and downstream signals. For more information about configuring data types, see “Control Signal Data Types” (Simulink).
- With Embedded Coder, specify function names that do not depend on the model name. If you specify a naming rule with a function customization template, do not use the token \$R in the rule. See “Control Names of Generated Entry-Point Functions (Embedded Coder)” (Simulink Coder).

## Reduce Number of Arguments by Using Structures

Reducing the number of arguments of a function can improve the readability of the code and reduce consumption of stack memory. To create a structure argument that can pass multiple pieces of data at one time, use these techniques:

- Manually combine multiple Inport or Outport blocks so that they appear in the generated code as fields of a structure or substructure of a standard data structure. The generated entry-point function or functions accept the address of the structure as a separate argument or as a substructure (field) of the standard I/O structures.

Replace the Inport or Outport blocks with a single block, and configure the new block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object. See “Organize Data into Structures in Generated Code” on page 33-201 and `Simulink.importExternalCTypes`.

- When you generate reentrant code with Embedded Coder, configure Inport and Outport blocks to appear in aggregated structures by default. Set model configuration parameter **Pass root-level I/O as** to a setting other than `Individual` arguments.
  - To package Inport and Outport blocks into the real-time model data structure, select `Part of model data structure`. The code generator aggregates the blocks into the default I/O structures to which the real-time model data structure points. The generated entry-point function or functions accept the real-time model data structure as a single argument. If you choose this setting, the function has the smallest number of arguments.
  - To aggregate Inport blocks into a structure and Outport blocks into a different structure, select `Structure reference`. The generated entry-point function or functions accept the address of each structure as an argument. Another argument accepts the real-time model data structure. If you choose this setting, the inputs and outputs are more identifiable in the function interfaces.

With this setting, if you remove the root-level Inport blocks or the root-level Outport blocks, the function signature can change. Similarly, the signature can change if you add a root-level Inport or Outport block to a model that does not include such blocks.

- For more control over the characteristics of the structures, set **Pass root-level I/O as** to `Part of model data structure`. Then, set the default storage class for

Inport and Outport blocks to a structured storage class that you create. With this technique:

- You can create a single structure for the blocks or create two separate structures.
- You can control the names of the structure types.
- The structures appear as substructures of the real-time model data structure. You must set **Pass root-level I/O as** to `Part of model data structure`.

Create the storage class by using the Embedded Coder Dictionary (see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2). Apply the storage class by using the Code Mappings editor (see “Configure Default Code Generation for Data” on page 32-8).

For more information, see “Pass root-level I/O as” (Simulink Coder).

## Control Data Types of Arguments

You can configure the generated entry-point functions to exchange data through arguments. For a scalar or array argument, to control the name of the primitive data type, use a `Simulink.AliasType` object to either set the data type of the corresponding block or to configure data type replacements for the entire model. These techniques require Embedded Coder. For more information, see “Control Data Type Names in Generated Code” on page 35-2.

## Promote Data Item to the Interface

By default, the code generator assumes that Inport and Outport blocks at the root level of the model constitute the data interface of the model. You can promote an arbitrary signal, block parameter, or block state to the interface so that other systems and components can access it. See “Promote Internal Data to the Interface” on page 33-81.

## How Generated Code Stores Internal Signal, State, and Parameter Data

To calculate outputs from inputs, the generated code stores some internal data in global memory. A signal that does not connect to a root-level input or output (Inport or Outport block) is internal data.

Internal data can also include:

- A block state such as the state of a Unit Delay block. The algorithm must retain the state value between execution cycles, so the generated code typically stores states in global memory (for example, as a global variable or a field of a global structure variable).
- A block parameter, such as the **Gain** parameter of a Gain block, whose value the code generator cannot inline in the code. For example, the code generator cannot inline the value of a nonscalar parameter.
- The status indicator of a conditionally executed subsystem such as an enabled subsystem.

For more efficient code, you can configure optimizations such as **Configuration Parameters > Default parameter behavior** and **Configuration Parameters > Signal storage reuse** that attempt to eliminate storage for internal data. However, the optimizations cannot eliminate storage for some data, which consume memory in the generated code.

When you understand the default format in which the generated code stores internal data, you can:

- Make signals accessible and parameters tunable by default. You can then interact with and monitor the code during execution.
- Generate efficient production code by eliminating storage for internal data and, depending on your hardware and build toolchain, controlling the placement in memory of data that the optimizations cannot eliminate.
- Promote pieces of internal data to the model interface so that other components and systems can access that data.

For information about how the generated code exchanges data with a calling environment through interfaces, see “How Generated Code Exchanges Data with an Environment” on page 33-51.

## Internal Data in the Generated Code

This example shows how the generated code stores internal data such as block states.

### Explore Example Model

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```

The model contains internal signals that do not connect to root-level Inport or Outport blocks. Some of the signals have a name, such as the `phiCmd` signal.

The model also contains some blocks that maintain state data. For example, in the `BasicRollMode` subsystem, a Discrete-Time Integrator block labeled `Integrator` maintains a state.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```
set_param('rtwdemo_roll', 'SystemTargetFile', 'grt.tlc')
```

Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting `Nonreusable` function means that the generated code is not reusable (reentrant).

For this example, generate simpler code by clearing **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```
set_param('rtwdemo_roll','MatFileLogging','off')
```

### Generate Nonreusable Code

Set these configuration parameters:

- Set **Default parameter behavior** to Tunable.
- Clear **Signal storage reuse**.

```
set_param('rtwdemo_roll','DefaultParameterBehavior','Tunable',...
          'OptimizeBlockIOStorage','off')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')

### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

The file `rtwdemo_roll.h` defines several structure types that represent internal data. For example, the `block` input and output structure defines one field for each internal signal in the model. Each field name derives from the name of the block that generates the signal or, if you specify a name for the signal, from the name of the signal.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
              '/* Block signals (default storage) */',{' B_rtwdemo_roll_T;',1,1)

/* Block signals (default storage) */
typedef struct {
    real32_T phiCmd;           /* '<Root>/ModeSwitch' */
    real32_T Abs;             /* '<S3>/Abs' */
    real32_T FixPtUnitDelay1; /* '<S7>/FixPt Unit Delay1' */
    real32_T Xnew;           /* '<S7>/Enable' */
    real32_T TKSwitch;       /* '<S3>/TKSwitch' */
    real32_T RefSwitch;      /* '<S3>/RefSwitch' */
}
```

```

real32_T Integrator;          /* '<S1>/Integrator' */
real32_T DispLimit;         /* '<S1>/DispLimit' */
real32_T Sum;               /* '<S1>/Sum' */
real32_T DispGain;         /* '<S1>/DispGain' */
real32_T RateLimit;        /* '<S1>/RateLimit' */
real32_T Sum1;             /* '<S1>/Sum1' */
real32_T RateGain;         /* '<S1>/RateGain' */
real32_T Sum2;             /* '<S1>/Sum2' */
real32_T CmdLimit;         /* '<S1>/CmdLimit' */
real32_T IntGain;          /* '<S1>/IntGain' */
real32_T hdgError;         /* '<S2>/Sum' */
real32_T DispGain_a;       /* '<S2>/DispGain' */
real32_T Product;          /* '<S2>/Product' */
boolean_T NotEngaged;      /* '<S3>/NotEngaged' */
boolean_T TKThreshold;     /* '<S3>/TKThreshold' */
boolean_T RefThreshold2;   /* '<S3>/RefThreshold2' */
boolean_T RefThreshold1;   /* '<S3>/RefThreshold1' */
boolean_T Or;              /* '<S3>/Or' */
boolean_T NotEngaged_e;    /* '<S1>/NotEngaged' */
} B_rtwdemo_roll_T;

```

The file defines a structure type, the `DWork` structure, to represent block states such as the state of the Discrete-Time Integrator block.

```

rtwdemodbtype(file,...
    /* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)

/* Block states (default storage) for system '<Root>' */
typedef struct {
    real32_T FixPtUnitDelay1_DSTATE; /* '<S7>/FixPt Unit Delay1' */
    real32_T Integrator_DSTATE;      /* '<S1>/Integrator' */
    int8_T Integrator_PrevResetState; /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;

```

The file defines a structure type to represent parameter data. Each tunable block parameter in the model, such as the **Gain** parameter of a Gain block, appears as a field of this structure. If a block parameter acquires its value from a MATLAB variable or a Simulink.Parameter object, the variable or object appears as a field, not the block parameter.

The file also defines a structure type, the *real-time model data structure*, whose single field represents a run-time indication of whether the generated code has encountered an error during execution.

```
rtwdemodbtype(file, /* Real-time Model Data Structure */ , ...  
              /* Block parameters (default storage) */ , 1, 0)
```

```
/* Real-time Model Data Structure */  
struct tag_RTM_rtwdemo_roll_T {  
    const char_T *errorStatus;  
};
```

For the structure type that represents the real-time model data structure, the file `rtwdemo_roll_types.h` creates an alias that the generated code later uses to allocate memory for the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw', 'rtwdemo_roll_types.h');  
rtwdemodbtype(file, /* Forward declaration for rtModel */ , ...  
              'RT_MODEL_rtwdemo_roll_T', 1, 1)
```

```
/* Forward declaration for rtModel */  
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;
```

Using these structure types, the file `rtwdemo_roll.c` defines (allocates memory for) global structure variables that store internal data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw', 'rtwdemo_roll.c');  
rtwdemodbtype(file, /* Block signals (default storage) */ , ...  
              '= &rtwdemo_roll_M;', 1, 1)
```

```
/* Block signals (default storage) */  
B_rtwdemo_roll_T rtwdemo_roll_B;
```

```
/* Block states (default storage) */  
DW_rtwdemo_roll_T rtwdemo_roll_DW;
```

```
/* External inputs (root inport signals with default storage) */  
ExtU_rtwdemo_roll_T rtwdemo_roll_U;
```

```
/* External outputs (root outports fed by signals with default storage) */  
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;
```

```
/* Real-time model */
```

```
RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M;
```

The model step function, which represents the primary model algorithm, uses a void void interface (with no arguments).

```
rtwdemodbtype(file,...
    /* Model step function */, 'void rtwdemo_roll_step(void)', 1, 1)
```

```
/* Model step function */
void rtwdemo_roll_step(void)
```

In the function definition, the algorithm performs calculations and stores intermediate results in the signal and state structures by directly accessing the global variables. The algorithm also reads parameter data from the corresponding global variable. For example, in the BasicRollMode subsystem, the code generated for the Integrator block reads and writes signal, state, and parameter data from the structures.

```
rtwdemodbtype(file, /* DiscreteIntegrator: '<S1>/Integrator' */, ...
    /* End of DiscreteIntegrator: '<S1>/Integrator' */, 1, 1)

/* DiscreteIntegrator: '<S1>/Integrator' */
if (rtwdemo_roll_B.NotEngaged_e || (rtwdemo_roll_DW.Integrator_PrevResetState
    != 0)) {
    rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
}

if (rtwdemo_roll_DW.Integrator_DSTATE >= rtwdemo_roll_P.intLim) {
    rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.intLim;
} else {
    if (rtwdemo_roll_DW.Integrator_DSTATE <= rtwdemo_roll_P.Integrator_LowerSat)
    {
        rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_LowerSat;
    }
}

rtwdemo_roll_B.Integrator = rtwdemo_roll_DW.Integrator_DSTATE;
```

Due to the void void interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call writes data to the global structure variables and the subsequent call can read that data, resulting in unintentional interference between the calls.

The model initialization function `rtwdemo_roll_initialize` initializes all of the internal data to zero. The function also initializes the error status by calling a specialized macro function. The initialization function directly accesses the global variables, which means that the function is not reentrant.

```
rtwdemodbtype(file, /* Model initialize function */ , ...
    'sizeof(DW_rtwdemo_roll_T));', 1, 1)
```

```
/* Model initialize function */
void rtwdemo_roll_initialize(void)
{
    /* Registration code */

    /* initialize error status */
    rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

    /* block I/O */
    (void) memset((void *) &rtwdemo_roll_B, 0,
        sizeof(B_rtwdemo_roll_T));

    /* states (dwork) */
    (void) memset((void *)&rtwdemo_roll_DW, 0,
        sizeof(DW_rtwdemo_roll_T));
```

The function then initializes the block states in the `DWork` structure to the initial values that the block parameters in the model specify. Two of the three states in the model have tunable initial values, so the code initializes them by reading data from the parameters structure.

```
rtwdemodbtype(file, ...
    /* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */ , ...
    /* Model terminate function */ , 1, 0)

/* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */
/* InitializeConditions for UnitDelay: '<S7>/FixPt Unit Delay1' */
rtwdemo_roll_DW.FixPtUnitDelay1_DSTATE = rtwdemo_roll_P.LatchPhi_vinit;

/* End of SystemInitialize for SubSystem: '<Root>/RollAngleReference' */

/* SystemInitialize for Atomic SubSystem: '<Root>/BasicRollMode' */
/* InitializeConditions for DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
rtwdemo_roll_DW.Integrator_PrevResetState = 0;
```

```

    /* End of SystemInitialize for SubSystem: '<Root>/BasicRollMode' */
}

```

## Generate Reusable Code

You can configure the generated code as reentrant, which means you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions accept internal data through formal parameters (pointer arguments). With these pointer arguments, each call can maintain internal data in a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to Reusable function.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Reusable function')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')

### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll

```

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the internal data, and primary input and output data in the form of `ExtU` and `ExtY` substructures (the fields of which represent Inport and Outport blocks at the root level of the model).

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
    '/* External data declarations for dependent source files */',1,0)

```

```

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
    const char_T *errorStatus;
    B_rtwdemo_roll_T *blockIO;
    P_rtwdemo_roll_T *defaultParam;
    ExtU_rtwdemo_roll_T *inputs;
    ExtY_rtwdemo_roll_T *outputs;
    boolean_T paramIsMallocated;
    DW_rtwdemo_roll_T *dwork;
};

```

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the `DWork` structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file, /* Model data allocation function */ , ...
    'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)
```

```
/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)
```

The model `step` function accepts an argument that represents the real-time model data structure.

```
rtwdemodbtype(file, /* Model step function */ , 'void rtwdemo_roll_step',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```
rtwdemodbtype(file, /*rtwdemo_roll_P_e =', 'rtwdemo_roll_M->outputs;',1,1)
```

```
P_rtwdemo_roll_T *rtwdemo_roll_P_e = ((P_rtwdemo_roll_T *)
    rtwdemo_roll_M->defaultParam);
B_rtwdemo_roll_T *rtwdemo_roll_B = ((B_rtwdemo_roll_T *)
    rtwdemo_roll_M->blockIO);
DW_rtwdemo_roll_T *rtwdemo_roll_DW = ((DW_rtwdemo_roll_T *)
    rtwdemo_roll_M->dwork);
ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
    rtwdemo_roll_M->inputs;
ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
    rtwdemo_roll_M->outputs;
```

Then, to access the internal data stored in global memory, the algorithm interacts with these local variables.

```

rtwdemodbtype(file, /* DiscreteIntegrator: '<S1>/Integrator' */ , ...
    /* End of DiscreteIntegrator: '<S1>/Integrator' */ , 1, 1)

/* DiscreteIntegrator: '<S1>/Integrator' */
if (rtwdemo_roll_B->NotEngaged_e ||
    (rtwdemo_roll_DW->Integrator_PrevResetState != 0)) {
    rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->Integrator_IC;
}

if (rtwdemo_roll_DW->Integrator_DSTATE >= rtwdemo_roll_P_e->intLim) {
    rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->intLim;
} else {
    if (rtwdemo_roll_DW->Integrator_DSTATE <=
        rtwdemo_roll_P_e->Integrator_LowerSat) {
        rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->Integrator_LowerSat;
    }
}

rtwdemo_roll_B->Integrator = rtwdemo_roll_DW->Integrator_DSTATE;

```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```

rtwdemodbtype(file, ...
    /* Model initialize function */ , 'void rtwdemo_roll_initialize' , 1, 1)

/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

```

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

### Eliminate Internal Data with Code Generation Optimizations

For more efficient code that consumes less memory, select the optimizations, such as **Default parameter behavior**, that you cleared earlier.

```

set_param('rtwdemo_roll', 'DefaultParameterBehavior', 'Inlined' , ...
    'OptimizeBlockIOStorage', 'on' , ...
    'LocalBlockOutputs', 'on')

```

In this example, for simpler code, set **Code interface packaging** to Nonreusable function.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Nonreusable function')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Now, `rtwdemo_roll.h` does not define a structure for block inputs and outputs. For all of the internal signals in the model, the optimizations either eliminated storage or created local function variables instead of global structure fields.

The optimizations were not able to eliminate storage for the three block states, so the file continues to define the `DWork` structure type.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
    /* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)

/* Block states (default storage) for system '<Root>' */
typedef struct {
    real32_T FixPtUnitDelay1_DSTATE;    /* '<S7>/FixPt Unit Delay1' */
    real32_T Integrator_DSTATE;        /* '<S1>/Integrator' */
    int8_T Integrator_PrevResetState;  /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;
```

The code generated for the Discrete-Time Integrator block now stores state and output data only in the `DWork` structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Update for DiscreteIntegrator: '<S1>/Integrator''',...
    /* End of Update for DiscreteIntegrator: '<S1>/Integrator' */',1,1)

/* Update for DiscreteIntegrator: '<S1>/Integrator' incorporates:
 * Gain: '<S1>/IntGain'
 */
rtwdemo_roll_DW.Integrator_DSTATE += 0.5F * rtb_TKSwitch * 0.025F;
if (rtwdemo_roll_DW.Integrator_DSTATE >= 5.0F) {
    rtwdemo_roll_DW.Integrator_DSTATE = 5.0F;
```

```

} else {
    if (rtwdemo_roll_DW.Integrator_DSTATE <= -5.0F) {
        rtwdemo_roll_DW.Integrator_DSTATE = -5.0F;
    }
}

rtwdemo_roll_DW.Integrator_PrevResetState = (int8_T)rtb_NotEngaged_f;

```

The optimizations also eliminated storage for the block parameters in the model. For example, in the Discrete-Time Integrator block, the **Upper saturation limit** and **Lower saturation limit** parameters are set to `intLim` and `-intLim`. `intLim` is a Simulink.Parameter object that stores the value 5. In the code generated for the Discrete-Time Integrator, these block parameters and `intLim` appear as inlined literal numbers `5.0F` and `-5.0F`.

If a model contains a parameter that the code generator cannot inline directly (for example, an array parameter), the code defines a structure type that represents the data. This *constant parameters* structure uses the `const` storage type qualifier, so some build toolchains can optimize the assembly code further.

## Local Variables in the Generated Code

When you select the optimization **Configuration Parameters > Enable local block outputs**, the code generator attempts to yield more efficient code by representing internal signals as local variables instead of fields of a global structure. If the memory consumed by local variables risks exceeding the stack space available on your target hardware, consider indicating the maximum stack size by setting **Configuration Parameters > Maximum stack size (bytes)**. For more information, see “Maximum stack size (bytes)” (Simulink Coder).

## Appearance of Test Points in the Generated Code

A *test point* is a signal that is stored in a unique memory location. For information about including test points in your model, see “Test Points” (Simulink).

When you generate code for models that include test points, the build process allocates a separate memory buffer for each test point. By default, test points are stored as members of a standard data structure such as `model_B`.

If you have Embedded Coder:

- You can control the default representation of test points by specifying code generation settings for the **Internal data** category of data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 32-8).
- You can specify that the build process ignore test points in the model, allowing optimal buffer allocation, by using the “Ignore test point signals” (Simulink Coder) parameter. Ignoring test points facilitates transitioning from prototyping to deployment and avoids accidental degradation of generated code due to workflow artifacts. See “Ignore test point signals” (Simulink Coder).

Virtual buses do not appear in generated code, even when associated with a test point. To display a bus in generated code, use a nonvirtual bus or a virtual bus converted to a nonvirtual bus by a Signal Conversion block.

## Appearance of Workspace Variables in the Generated Code

Workspace variables are variables that you use to specify block parameter values in a model. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary.

When you set **Default parameter behavior** to `Tunable`, by default, workspace variables appear in the generated code as tunable fields of the global parameters structure. If you use such a variable to specify multiple block parameter values, the variable appears as a single field of the global parameters structure. The code does not create multiple fields to represent the block parameters. Therefore, tuning the field value during code execution changes the mathematical behavior of the model in the same way as tuning the value of the MATLAB variable or parameter object during simulation.

If you have Embedded Coder, you can control the default representation of workspace variables by specifying code generation settings for categories of parameter data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 32-8).

- The **Model parameters** category applies to variables that you store in a model workspace.
- The **External parameter objects** category applies to variables that you store in the base workspace or a data dictionary.

## Promote Internal Data to the Interface

By default, the code generator assumes that other systems and components in your application do not need to access internal data. For example, internal data are subject to optimizations that can eliminate them from the generated code. For prototyping and testing purposes, you can access internal data by clearing the optimizations or by configuring test points and applying storage classes (see “Preserve Variables in Generated Code” on page 33-3). For optimized production code, configure individual data items to appear in the generated code as part of the model interface.

### Data That You Can Promote

Depending on the reentrancy of the generated code, that is, the setting that you choose for **Code interface packaging**, you can configure each data item in a model to participate in the interface by appearing in the code as one of these entities:

- A global symbol, such as a global variable or a call to a specialized function
- A formal parameter (argument) of the generated entry-point functions

The table shows the mechanisms that each category of data can use to participate in the interface.

| Category of Data                   | Appear as Global Symbol        | Appear as Argument of Entry-Point Function                                                                                             |
|------------------------------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Root-level Inport or Outport block | Only for a nonreentrant model. | Yes.                                                                                                                                   |
| Signal connecting two blocks       | Only for a nonreentrant model. | Only for a reentrant model and only as a field of a structure.<br><br>Alternatively, connect the signal to a root-level Outport block. |
| Block state                        | Only for a nonreentrant model. | Only for a reentrant model and only as a field of a structure.                                                                         |

| Category of Data                                                            | Appear as Global Symbol | Appear as Argument of Entry-Point Function                     |
|-----------------------------------------------------------------------------|-------------------------|----------------------------------------------------------------|
| Data store such as a Data Store Memory block                                | Yes.                    | Only for a reentrant model and only as a field of a structure. |
| Block parameter or parameter object such as <code>Simulink.Parameter</code> | Yes.                    | Only as a field of a structure.                                |

### Single-Instance Algorithm

For a single-instance algorithm (you set **Code interface packaging** to **Nonreusable function**), apply storage classes directly to individual data items by using the Model Data Editor or the Property Inspector. With a directly applied storage class, a data item appears in the code as a global symbol such as a global variable. The storage class also prevents optimizations from eliminating storage for the data item.

You can apply storage classes to signals, block states, and block parameters. (For block parameters, you apply storage classes indirectly through parameter objects such as `Simulink.Parameter`). However, for a signal, consider connecting the signal to an Outputport block at the root level of the model. Then, optionally, you can apply a storage class to the block. In the block diagram, the Outputport block shows that the signal represents a system output.

For more information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99.

### Reentrant Algorithm

For a reentrant algorithm (you set **Code interface packaging** to **Reusable function**), use different techniques to configure data items to appear in the code as formal parameters (arguments) of the generated entry-point functions.

- For an internal signal, directly apply the storage class `Model default` (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99). If you have Embedded Coder, in the Code Mapping Editor, for the **Internal data** category, set the default storage class to `Default` or to a structured storage class that you define in an Embedded Coder Dictionary (see “Create Code Definitions for Use as Default Code Generation Settings” on page 30-2). Alternatively, configure the signal as a test point (see “Appearance of Test Points in the Generated Code” on

page 33-79). By default, the signal appears as a field of one of the standard data structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-68). If you do not want the signal to appear in production code, use a test point so that you can later select the model configuration parameter **Ignore test point signals**.

Alternatively, connect the signal to an Outport block at the root level of the model. Connecting the signal to a root-level Outport block prevents optimizations from eliminating the signal from the code. To help with signal routing in a large model, use Goto and From blocks.

- For a block parameter, create a parameter object such as `Simulink.Parameter` and directly apply a storage class other than `Auto` to the object. The storage class prevents optimizations from inlining the parameter value in the code.

With the storage class, the parameter is shared between instances of the model, which are calls to the entry-point functions. The functions access the parameter data directly, as a global symbol, not an argument. You cannot configure a parameter to appear in the code as an argument, so you cannot enable each instance of the model to use a different value for the parameter.

For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

## Control Default Representation of Internal Data (Embedded Coder)

By default, the code generator aggregates internal data that optimizations cannot eliminate, such as most state data, into standard structures such as the `DWork` structure. With Embedded Coder, you can control how the generated code stores this data.

### Control Placement of Data in Memory by Inserting Pragmas

Use the Code Mapping Editor to specify a default memory section for each category of data such as states and signals (**Internal data**). In the generated code, your custom pragmas or other decorations surround the data definitions and declarations.

You can also partition the structures according to atomic subsystems in your model so that you can specify different default memory sections for the data of subroutines and other algorithmic subcomponents.

For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 41-2.

### **Control Names of Types, Fields, and Global Variables for Standard Data Structures**

You can control some characteristics of the standard data structures. For more information, see “Control Characteristics of Data Structures (Embedded Coder)” (Simulink Coder).

For additional control over structure characteristics, such as placement in generated code files, create your own structured storage class by using the Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. The storage class removes the data from the standard structures, creating other structures that you can more finely control. For more information about applying default storage classes to categories of data, see “Configure Default Code Generation for Data” on page 32-8. For more information about creating a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2.

### **Organize Data into Structures According to Subcomponents**

- In the standard data structures, to create substructures that contain the data for a single-instance (nonreentrant) subroutine or subcomponent, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set **Function packaging** to `Reusable` function. For more information, see “Generate Modular Function Code for Nonvirtual Subsystems” on page 40-51.

Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `Multiple`. For more information, see “Code Generation of Referenced Models” on page 4-2.

- To create separate, standalone structures that contain the data for a multi-instance (reentrant) subroutine or subcomponent, in the model, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set **Function packaging** to `Nonreusable` function and select **Function with separate data**. For more information, see “Generate Modular Function Code for Nonvirtual Subsystems” on page 40-51.

Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, choose one of these techniques:

- Set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to One. For more information, see “Code Generation of Referenced Models” on page 4-2.
- Set **Total number of instances allowed per top model** to Multiple and create a structured storage class by using an Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. To create a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2. To apply the storage class to categories of data, see “Configure Default Code Generation for Data” on page 32-8.

### **Organize Signal and Parameter Data into Meaningful, Custom Structures and Substructures**

To organize arbitrary signals and parameters into custom structures and substructures, create nonvirtual bus signals and parameter structures. Optionally, to prevent optimizations from eliminating the data from the code, set the storage class of a bus signal or parameter structure to a value other than Auto (the default setting).

As you add blocks to the model, you must explicitly place each new signal and parameter into a bus or a structure.

For more information, see “Organize Data into Structures in Generated Code” on page 33-201.

### **Create Separate Global Variables Instead of Structure Fields**

To make a category of internal data appear in the generated code as separate, unstructured global variables instead of fields of a standard data structure, apply an unstructured storage class to the data category by using the Code Mapping Editor. For example, apply the storage class `ExportedGlobal`. However, if you generate multi-instance, reentrant code by setting the configuration parameter **Code interface packaging** to a value other than `Nonreusable function`, you cannot use this technique for some categories of data (see “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder)).

To apply default storage classes to categories of data by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 32-8. To choose a storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).

## **Choose Storage Class for Controlling Data Representation in Generated Code**

A storage class is a code generation setting that you apply to model data, such as signals, block parameters, and states. Use storage classes to control the appearance of data elements in the generated code.

The table shows built-in storage classes that you can choose. These storage classes come with Simulink Coder.

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto               | <p>Auto is the default storage class setting for each data element in a model. The data element is subject to code generation optimizations, which can eliminate the element from the code or change the representation of the element. For information about these optimizations, such as those on the <b>Configuration Parameters &gt; Code Generation &gt; Optimization</b> pane, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder).</p> <p>Optimizations cannot eliminate some data, such as most block states, from the code. This remaining data acquire a default storage class that you specify with the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 32-8—requires Embedded Coder). If you leave the storage class setting in the Code Mapping Editor at the default value, <b>Default</b>, the data element appears as a field of a standard data structure (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-68).</p> <p>If optimizations cannot eliminate the data element, the name of the element in the code is based on naming rules that you specify with model configuration parameters (see “Identifier Format Control” on page 50-22—requires Embedded Coder).</p> <p>Use this storage class to enable optimizations to operate on the data</p> |

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | element, potentially generating more efficient code.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Model default      | <p>The data element acquires the corresponding default storage class that you specify with the Code Mapping Editor. The name of the data element in the code is the same as the name in the model.</p> <p>Use this storage class to prevent optimizations from eliminating storage for a data element (see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder)).</p>                                                                 |
| ExportedGlobal     | <p>Generate a global variable definition and declaration. The name of the variable is the name of the data element. The code declares the variable in the generated file <i>model.h</i>, which you can include (<code>#include</code>) in your external code.</p>                                                                                                                                                                                                        |
| ImportedExtern     | <p>Generate code that reads from and writes to a global variable defined by your external code. The generated code declares the variable in the generated file <i>model_private.h</i> so that the model entry-point functions can read and write to the variable.</p> <p>Use this storage class to make a data element in a model represent a global variable that your external code defines. The generated algorithmic code uses the variable without defining it.</p> |

| Storage Class Name    | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ImportedExternPointer | <p>Generate code that reads from and writes to a global pointer variable defined by your external code. The generated code declares the variable in the generated file <i>model_private.h</i> and reads and writes to the data by dereferencing the pointer.</p> <p>Use this storage class when your external code defines a data element and provides a pointer for accessing that data.</p> |

If you have Embedded Coder, you can choose additional built-in storage classes, shown in the next table.

| Storage Class Name | Description                                                                                                                                                                                   | Use for Signal or State Data | Use for Parameter Data |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| BitField           | <p>Generate a structure that stores Boolean data in named bit fields. For an example, see “Bitfields” on page 24-88.</p> <p>You cannot use this storage class in the Code Mapping Editor.</p> | Yes                          | Yes                    |

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Use for Signal or State Data | Use for Parameter Data |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| CompilerFlag       | <p>Supports preprocessor conditionals defined via compiler flag or option. See “Generate Preprocessor Conditionals for Variant Systems” on page 25-40.</p> <p>If you build the generated code by using Embedded Coder (you clear <b>Configuration Parameters &gt; Generate code only</b>), to specify the compiler option, you can use the model configuration parameter <b>Configuration Parameters &gt; Code Generation &gt; Custom Code &gt; Additional build information &gt; Defines</b>. See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).</p> | No                           | Yes                    |
| Const              | Generate a global variable definition and declaration with the <code>const</code> type qualifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | No                           | Yes                    |
| ConstVolatile      | Generate a global variable definition and declaration with the <code>const</code> and <code>volatile</code> type qualifiers. For an example, see “Type Qualifiers” on page 24-15.                                                                                                                                                                                                                                                                                                                                                                                                                 | No                           | Yes                    |
| Define             | Generate a macro ( <code>#define</code> directive) such as <code>#define myParam 5</code> . For an example, see “Macro Definitions ( <code>#define</code> )” on page 24-70.                                                                                                                                                                                                                                                                                                                                                                                                                       | No                           | Yes                    |
| ExportToFile       | Generate a global variable definition and declaration. You can specify the names of the files that define and declare the variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Yes                          | Yes                    |

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Use for Signal or State Data | Use for Parameter Data |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| FileScope          | <p>Generate a global variable definition and declaration with the <code>static</code> type qualifier. In the generated code, the scope of the variable is limited to the current file, which is typically <code>model.c</code>.</p> <p>In a model reference hierarchy, if a referenced model uses a parameter object (such as <code>Simulink.Parameter</code>) that you create in the base workspace or a data dictionary, you cannot apply <code>FileScope</code> to the object. As a workaround, move the parameter object into the model workspace of the referenced model. Then, you can use <code>FileScope</code>.</p> | Yes                          | Yes                    |
| GetSet             | <p>Generate code that interacts with data by calling your custom accessor functions. Your external code defines the data and provides the function definitions. For examples, see “Access Data Through Functions with Storage Class <code>GetSet</code>” on page 37-42.</p>                                                                                                                                                                                                                                                                                                                                                  | Yes                          | Yes                    |
| ImportedDefine     | <p>Generate code that uses a macro (<code>#define</code> directive) defined in a header file in your external code. For an example, see “Macro Definitions (<code>#define</code>)” on page 24-70.</p>                                                                                                                                                                                                                                                                                                                                                                                                                        | No                           | Yes                    |
| ImportFromFile     | <p>Generate code that reads from and writes to a global variable defined by your external code. Similar to <code>ExportToFile</code>, but the generated code does not define the variable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               | Yes                          | Yes                    |

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                     | Use for Signal or State Data | Use for Parameter Data |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| Reusable           | <p>Generate more efficient code that stores intermediate calculations of a data path (a series of connected blocks) in a single, reused global variable. For an example, see “Specify Buffer Reuse by Using Simulink.Signal Objects” on page 69-19.</p> <p>You can apply this storage class only to a <code>Simulink.Signal</code> object that represents multiple signal lines in a model.</p> | Yes                          | No                     |
| Struct             | <p>Generate a global structure whose name you can specify. For examples, see “Organize Parameter Data into a Structure by Using the Struct Storage Class” on page 37-23 and “Structures of Signals” on page 24-80.</p> <p>You cannot use this storage class in the Code Mapping Editor.</p>                                                                                                     | Yes                          | Yes                    |
| Volatile           | <p>Generate a global variable definition and declaration with the <code>volatile</code> type qualifier.</p>                                                                                                                                                                                                                                                                                     | Yes                          | Yes                    |
| Localizable        | <p>For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove the variables from the generated code. For an example, see “Generate Local Variables with Localizable Storage Class” on page 37-98.</p>                                           | Yes (signals not states)     | No                     |

These storage classes are examples of storage classes that you can add to an Embedded Coder Dictionary. These examples are defined and made available when you prepare a model for code generation with the Quick Start tool.

| Storage Class Name | Description                                                                                                                                                                                                                                                                                                                                                                                                    | Use for Signal or State Data | Use for Parameter Data |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------------|
| ParamStruct        | Generate global structures that contain parameter data. In a hierarchy of components (referenced models or atomic subsystems), you can use this example storage class to create a corresponding hierarchy of parameter structures. This storage class appears only in the Code Mapping Editor for data category <b>Model parameters</b> after preparing a model for code generation with the Quick Start tool. | No                           | Yes                    |
| SignalStruct       | Generate global structures that contain signal or state data. In a hierarchy of components (referenced models or atomic subsystems), you can use this example storage class to create a corresponding hierarchy of signal and state structures. This storage class appears only in the Code Mapping Editor after preparing a model for code generation with the Quick Start tool.                              | Yes                          | No                     |

When you generate reentrant, multi-instance code, limitations and restrictions apply if you want to use storage classes. See “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder).

### Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)

After you apply some storage classes, such as `ExportToFile`, you can specify additional settings such as declaration (header) and definition file names. In the Code Mapping Editor, to access these additional settings, you use the Property Inspector.

With other storage classes, you cannot specify additional settings.

- These built-in Simulink Coder storage classes do not allow you to specify additional settings:
  - ExportedGlobal
  - ImportedExtern
  - ImportedExternPointer
- The built-in Embedded Coder storage classes typically allow you to specify declaration and definition file names.
- For the `ExportToFile` storage class, the definition file setting is honored only for single-instance models. The setting is ignored for reusable multi-instance models because the data definition is handled at the parent level.
- When you create a storage class with the Custom Storage Class Designer, you can choose whether the user of the storage class can specify additional settings. See “Allow Users of Storage Class to Specify Property Value” on page 37-32.

## Specify Default `#include` Syntax for Header Files That Declare Data (Embedded Coder)

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19). You then use the **Header file** custom attribute to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify **Header file**, you can omit delimiters (`"` or `<>`) and use only the file name. You can then control the default delimiters that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters > Code Generation > Code Placement > #include file delimiters** to `#include <header.h>`.

## Storage Class Limitations

- When you use storage classes in the Code Mappings editor (Embedded Coder), some limitations apply. See “Constraints” on page 32-34.
- Data objects cannot use an Embedded Coder storage class and a multiword data type.

- For Embedded Coder storage classes in models that use referenced models:
  - If you apply a grouped storage class to multiple data items, the storage class **Data scope** property must be set to **Imported** and you must provide the data declaration in an external header file. Grouped storage classes use a single variable in the generated code to represent multiple data objects. For example, the storage classes **BitField** and **Struct** are grouped storage classes.
  - If a parameter object exists in the base workspace or a data dictionary, and a referenced model uses the object, you cannot apply the storage class **FileScope**. As a workaround, move the object into the model workspace of the referenced model. Then, you can use **FileScope**.
- You cannot apply the storage class **FileScope** to data items used by a data exchange interface (C API, external mode, or ASAP2) or MAT-file logging. File-scoped data is not externally accessible.

## Use Storage Classes in Reentrant, Multi-Instance Models and Components

The code that you generate from a model or component (referenced model or subsystem) is multi-instance code if it allows your application to maintain multiple independent instances of the component during execution. For example, you can generate reentrant, multi-instance code from an entire model by setting the model configuration parameter **Code interface packaging** to `Reusable function`. For general information about multi-instance models and components, see “Code Reuse” (Simulink Coder).

Under some circumstances, applying storage classes can:

- Prevent you from generating multi-instance code.
- Cause some data elements to appear in the generated code as singletons, which means that each instance of the model or component directly accesses the same shared, global data, creating dependencies between the instances.

To avoid errors and unexpected generation of single-instance code and singleton data, observe the guidelines and limitations below.

### Directly Applied Storage Classes

When you apply a storage class directly to a data element (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder)):

- To generate multi-instance code, you must apply the storage class only to parameter objects, global data stores, shared local data stores, and root-level I/O.
- The storage class yields only singleton data.

### Storage Classes Applied by Default

When you apply a default storage class by using the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 32-8—requires Embedded Coder):

- For these data categories, you can generate only singleton data:
  - **Model parameters**
  - **External parameter objects**

- **Global data stores**
- **Shared local data stores**
- For **Internal data**, you can generate only instance-specific data, which means each instance of the model or component operates on a separate copy of the data. For this category, you must use the example storage class `SignalStruct`, which appears after preparing a model for code generation with the Quick Start tool. Alternatively, you can create and use your own structured storage class by using an Embedded Coder Dictionary.

## Apply Storage Classes to Individual Signal, State, and Parameter Data Elements

A storage class is a code generation setting that you apply to a data item (signal, block parameter, or state) in a model. When you directly apply it to a data item, a storage class:

- Causes the data item to appear in the generated code as a global symbol, typically a global variable.
- Prevents optimizations such as **Default parameter behavior** and **Signal storage reuse** from eliminating the data item from the generated code.
- With Embedded Coder, you can configure the format in which the generated code stores or otherwise defines the data item. For example, you can apply the storage type qualifiers `const` or `volatile` or configure a parameter data item to appear as a macro (`#define`).

Directly apply storage classes to individual data items to:

- Tune parameters and monitor signals and states during execution.
- Configure data placement in memory through memory sections.
- Generate code that exchanges data (for example, global variables) with your external code.

For information about applying storage classes to categories of data by default, by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 32-8.

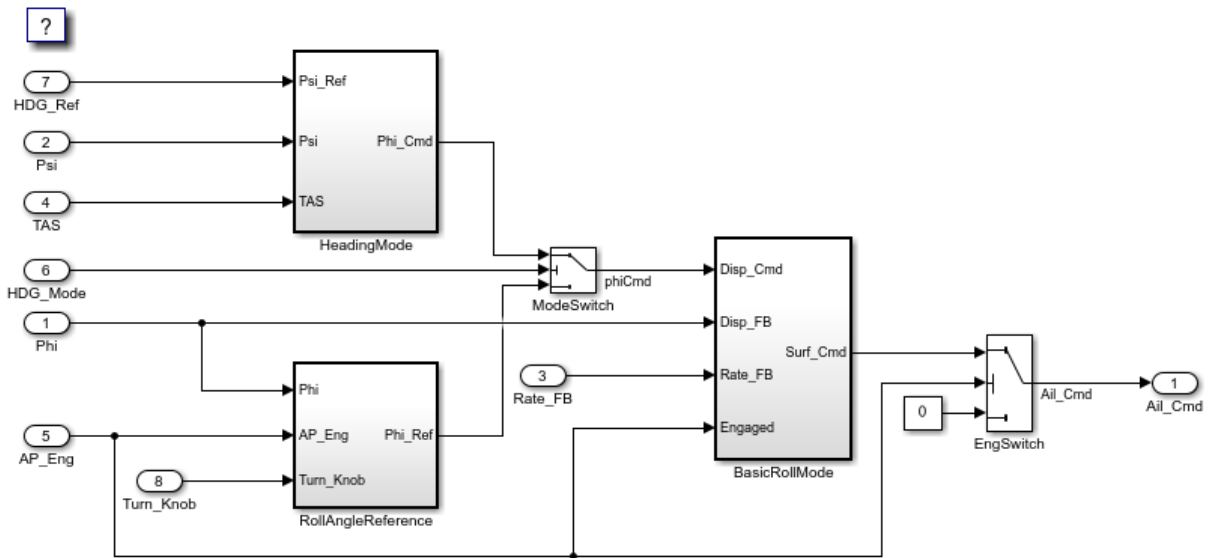

### Apply Storage Classes to Data Items

This example shows how to apply storage classes to a signal, a block state, and a block parameter in a model.

#### Explore Example Model

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```

Copyright 1990-2019 The MathWorks, Inc.

Navigate into the BasicRollMode subsystem.

`open_system('rtwdemo_roll/BasicRollMode')`

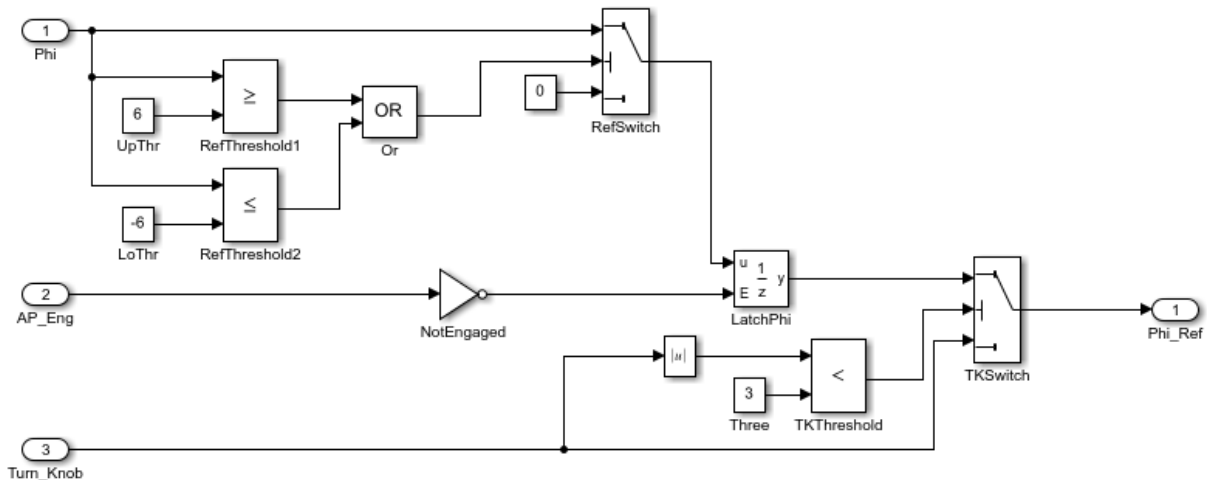

Copyright 1990-2019 The MathWorks, Inc.

The subsystem contains an Integrator block, which maintains a piece of state data.

From the root level of the model, navigate into the RollAngleReference subsystem.

```
open_system('rtwdemo_roll/RollAngleReference')
```

Copyright 1990-2019 The MathWorks, Inc.

The subsystem contains a Constant block labeled UpThr.

In this example, you configure the state and output signal of the Integrator block and the **Constant value** parameter of the Constant block to appear in the generated code as separate global variables.

### Apply Storage Classes

- 1 Navigate to the root level of the model.
- 2 Open the **Simulink Coder** App. When prompted, change the system target file to `grt.tlc`.
- 3 Click the Model Data Editor tab.
- 4 In the Model Data Editor, click the **Change scope** button. This expands
- 5 the lists of data to include data items in the subsystems.
- 6 Select the **Signals** tab.

- 7 Set the **Change view** drop-down list to Code.
- 8 In the **Filter contents** box, enter `integrator`.
- 9 Optionally, use the **Name** column to specify a name for the output signal of the Integrator block, such as `mySignal`.
- 10 Use the **Storage Class** column to apply storage class `ExportedGlobal`.
- 11 Select the **States** tab.
- 12 Optionally, use the **Name** column to specify a name for the state, such as `myState`.
- 13 Use the **Storage Class** column to apply storage class `ExportedGlobal`.
- 14 Select the **Parameters** tab. You cannot apply a storage class directly to a block parameter. You must create a parameter object, such as `Simulink.Parameter`, use the object to set the value of the block parameter, and apply the storage class to the object.
- 15 Set the **Change view** drop-down list to Design.
- 16 In the **Filter contents** box, enter `UpThr`.
- 17 Use the **Value** column to change the parameter value from 6 to `UpThr`.
- 18 While editing the parameter value, next to `UpThr`, click the action button (with three vertical dots) and select **Create**.
- 19 In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter` and click **OK**. A `Simulink.Parameter` object named `UpThr` appears in the base workspace.
- 20 In the `UpThr` property dialog box, set **Value** to 6 and **Storage class** to `ExportedGlobal`. Click **OK**.

Alternatively, you can use these commands at the command prompt to configure the signal, state, and parameter data.

```
% Configure signal
portHandles = get_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'PortHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'Name', 'mySignal')
set_param(outportHandle, 'StorageClass', 'ExportedGlobal')

% Configure state
set_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'StateName', 'myState')
set_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'StateStorageClass', 'ExportedGlobal')
```

```
% Configure parameter
set_param('rtwdemo_roll/RollAngleReference/UpThr','Value','UpThr')
UpThr = Simulink.Parameter(6);
UpThr.StorageClass = 'ExportedGlobal';
```

## Generate and Inspect Code

Generate code from the model.

```
set_param('rtwdemo_roll','SystemTargetFile','grt.tlc')
rtwbuild('rtwdemo_roll')

### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
### Simulink cache artifacts for 'rtwdemo_roll' were created in 'H:\Documents\MATLAB\ex
```

Inspect the file `rtwdemo_roll.c`. The file defines the global variables.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Exported block signals */','real32_T myState;',1,1)
```

```
/* Exported block signals */
real32_T mySignal;                                /* '<S1>/Integrator' */

/* Exported block parameters */
real32_T UpThr = 6.0F;                            /* Variable: UpThr
* Referenced by: '<S3>/UpThr'
*/

/* Exported block states */
real32_T myState;                                /* '<S1>/Integrator' */
```

The file `rtwdemo_roll.h` declares the variables. To access these variables, your external code can include (`#include`) this header file.

In `rtwdemo_roll.c`, search the file for the names of the variables, such as `UpThr`. The model algorithm in the `rtwdemo_roll_step` function reads and writes to the variables.

## Built-In Storage Classes You Can Choose

The default storage class setting for a data item is `Auto`, which means the code generator determines how the item appears in the code. For a list of built-in storage classes that you

can choose, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).

## Decide Where to Store Storage Class Specification

For each individual signal or state data item (including Data Store Memory blocks) to which you directly apply a storage class, Simulink stores your storage class specification either in the model file or in the properties of a signal data object (`Simulink.Signal`), which you create in the base workspace, a model workspace, or a data dictionary. To apply a storage class to a block parameter, you must create a parameter data object (such as `Simulink.Parameter`) and specify the storage class in the object.

- When you apply a storage class to a signal or state in a model, for example, by using the Model Data Editor or the Property Inspector, you store the storage class specification in the model file.

If you use this technique, you cannot control other characteristics of the data item, such as data type, by using an external signal data object.

- When you create a signal or parameter data object, you apply the storage class by using the `CoderInfo` property of the object. The value of the property is a `Simulink.CoderInfo` object, whose `StorageClass` property you use to specify the storage class. After you associate the data item in the model with the object, the data item acquires the storage class from the object.

For signals, states, and Data Store Memory blocks, to decide whether to store the storage class specification in the model or in a data object, see “Store Design Attributes of Signals and States” (Simulink).

## Apply Storage Classes to Output Blocks by Using the Model Data Editor

You can use the Model Data Editor to apply a storage class directly to a root-level Output block or to the input signal that drives the block.

- To store the storage class specification in the Output block, use the **Inports/Outputs** tab in the Model Data Editor. When you use this technique, the specification remains after you delete the input signal that drives the block. Use this technique to configure the model interface before you develop the internal algorithm.
- To store the specification in the input signal that drives the block, use the **Signals** tab in the Model Data Editor.

## Techniques to Apply Storage Classes Interactively

To apply storage classes to multiple data items in a list that you can search, sort, and filter, use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**) as shown in “Apply Storage Classes to Data Items” on page 33-99.

To apply a storage class while focusing on a single signal, block state, or parameter, use the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), the Signal Properties dialog box (for a signal), or the block dialog box (for a state or parameter). Under **Code Generation**, apply the storage class.

- For a parameter, first set the value of the parameter to the name that you want to use for the required parameter object. Then, create and configure the parameter object as shown in “Create Tunable Calibration Parameter in the Generated Code” on page 33-140.
- For a signal, state, or Data Store Memory block, first give the signal or state a name, which the code generator uses as the name of the corresponding global symbol. Then, either specify a storage class using **Storage class** (in which case the model file stores the specification) or create a signal data object as shown in “Use Data Objects in Simulink Models” (Simulink) and apply a storage class to the object.

## Techniques to Apply Storage Classes Programmatically

- For a block parameter, use `set_param` to set the value of the parameter. Use other commands to create and configure the properties of the required parameter object. For an example, see “Create Tunable Calibration Parameter in the Generated Code” on page 33-140.
- For a signal, use `get_param` or `find_system` to return a handle to the block port that generates the signal. Use the parameters of the handle to name the signal, then apply the storage class directly (see “Apply Storage Class Directly to Signal Line” (Simulink Coder)) or configure the signal to acquire settings, including the storage class, from a signal object (see “Use Data Objects in Simulink Models” (Simulink)).
- For an Inport block, configure the signal line that exits the block. For an Output block, configure the block or the signal line that enters the block. For an example, see “Design Data Interface by Configuring Inport and Output Blocks” on page 33-230.
- For a block state, use `set_param` to interact with the block. Name the state, then apply the storage class directly (see “Apply Storage Class Directly to Block State” (Simulink Coder)) or configure the state to acquire the storage class from a signal object (see “Use Data Objects in Simulink Models” (Simulink)).

- For a Data Store Memory block, use `set_param` to interact with the block. Because the data store already has a name, you do not need to specify a name. Apply the storage class directly by using the `StateStorageClass` parameter or configure the data store to acquire the storage class from a signal object.

To interact with a signal or parameter data object that you store in a model workspace or data dictionary, use the programmatic interface of the workspace or dictionary. See “Interact With Variables Programmatically” (Simulink).

### Apply Storage Class Directly to Signal Line

This example shows how to programmatically apply a storage class directly to a signal line.

- 1 Open the example model `rtwdemo_secondOrderSystem`.

```
rtwdemo_secondOrderSystem
```

- 2 Get a handle to the output of the block named Force: `f(t)`.

```
portHandles = ...  
    get_param('rtwdemo_secondOrderSystem/Force: f(t)', 'PortHandles');  
outportHandle = portHandles.Output;
```

- 3 Set the name of the corresponding signal to `ForceSignal`.

```
set_param(outportHandle, 'Name', 'ForceSignal')
```

- 4 Set the storage class of the signal to `ExportedGlobal`.

```
set_param(outportHandle, 'StorageClass', 'ExportedGlobal')
```

- 5 Generate code from the model. The code declares and defines a global variable `ForceSignal` to represent the signal.

### Apply Storage Class Directly to Block State

This example shows how to programmatically apply a storage class to a block state.

- 1 Open the example model `rtwdemo_basicsc`.

```
rtwdemo_basicsc
```

- 2 Name the state of the Delay block as `myState`.

```
set_param('rtwdemo_basicsc/Delay', 'StateName', 'myState')
```

- 3 Set the storage class of the state to ExportedGlobal.

```
set_param('rtwdemo_basicsc/Delay',...
         'StateStorageClass','ExportedGlobal')
```

- 4 Generate code from the model. The code declares and defines a global variable myState to represent the state.

## Parameter Object Configuration Quick Reference Diagram

This diagram shows the code generation and storage class options that control the representation of parameter objects in the generated code.

## Use Enumerated Data in Generated Code

### In this section...

“Enumerated Data Types” on page 33-108

“Specify Integer Data Type for Enumeration” on page 33-108

“Customize Enumerated Data Type” on page 33-110

“Control Enumerated Type Implementation in Generated Code” on page 33-115

“Type Casting for Enumerations” on page 33-117

“Enumerated Type Limitations” on page 33-118

### Enumerated Data Types

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code. The following is a MATLAB class definition for an enumerated data type named `BasicColors`, which is used in the examples in this section.

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
end
```

For basic information about enumerated data types and their use in Simulink models, see “Use Enumerated Data in Simulink Models” (Simulink). For information about enumerated data types in Stateflow charts, see “Define Enumerated Data Types” (Stateflow).

### Specify Integer Data Type for Enumeration

When you specify a data type for your enumeration, you can:

- Control the size of enumerated data types in the generated code by specifying a superclass.

- Reduce RAM/ROM usage.
- Improve code portability.
- Improve integration with legacy code.

You can specify these integer data types:

- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `Simulink.IntEnumType`. Specify values in the range of the signed integer for your hardware platform.

### Use a Class Definition in a MATLAB File

To specify an integer data type size, derive your enumeration class from the integer data type.

```
classdef Colors < int8
    enumeration
        Red(0)
        Green(1)
        Blue(2)
    end
end
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red      ((Colors)0)
#define Green   ((Colors)1)
#define Blue    ((Colors)2)
```

### Use the Function `Simulink.defineIntEnumType`

To specify an integer data type size, specify the name-value pair `StorageType` as the integer data type.

```
Simulink.defineIntEnumType('Colors', {'Red', 'Green', 'Blue'}, ...
[0;1;2], 'StorageType', 'int8')
```

The code generator generates this code:

```
typedef int8_T Colors;  
  
#define Red      ((Colors)0)  
#define Green   ((Colors)1)  
#define Blue    ((Colors)2)
```

## Customize Enumerated Data Type

When you generate code from a model that uses enumerated data, you can implement these static methods to customize the behavior of the type during simulation and in generated code:

- `getDefaultValue` — Specifies the default value of the enumerated data type.
- `getDescription` — Specifies a description of the enumerated data type.
- `getHeaderFile` — Specifies a header file where the type is defined for generated code.
- `getDataScope` — Specifies whether generated code exports or imports the enumerated data type definition to or from a separate header file.
- `addClassNameToEnumNames` — Specifies whether the class name becomes a prefix in generated code.

The first of these methods, `getDefaultValue`, is relevant to both simulation and code generation, and is described in “Specify a Default Enumerated Value” (Simulink). The other methods are relevant only to code generation. To customize the behavior of an enumerated type, include a version of the method in the `methods(Static)` section of the enumeration class definition. If you do not want to customize the type, omit the `methods(Static)` section. The table summarizes the methods and the data to supply for each one.

| Static Method   | Purpose                                                                                                            | Default Value Without Implementing Method            | Custom Return Value                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| getDefaultValue | Specifies the default enumeration member for the class.                                                            | First member specified in the enumeration definition | A character vector containing the name of an enumeration member in the class (see "Instantiate Enumerations" (Simulink)).                                                                                                                                                                                                                                                                                  |
| getDescription  | Specifies a description of the enumeration class.                                                                  | ' '                                                  | A character vector containing the description of the type.                                                                                                                                                                                                                                                                                                                                                 |
| getHeaderFile   | Specifies the name of a header file. The method <code>getDataScope</code> determines the significance of the file. | ' '                                                  | A character vector containing the name of the header file that defines the enumerated type.<br><br>By default, the generated <code>#include</code> directive uses the preprocessor delimiter <code>"</code> instead of <code>&lt;</code> and <code>&gt;</code> . To generate the directive <code>#include &lt;myTypes.h&gt;</code> , specify the custom return value as <code>'&lt;myTypes.h&gt;'</code> . |

| Static Method           | Purpose                                                                                                                                                                                                           | Default Value Without Implementing Method | Custom Return Value                        |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|--------------------------------------------|
| getDataScope            | Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method <code>getHeaderFile</code> to specify the generated or included header file that defines the type. | 'Auto'                                    | One of: 'Auto', 'Exported', or 'Imported'. |
| addClassNameToEnumNames | Specifies whether to prefix the class name in generated code.                                                                                                                                                     | false                                     | true or false.                             |

### Specify a Description

To specify a description for an enumerated data type, include this method in the `methods(Static)` section of the enumeration class:

```
function retVal = getDescription()
% GETDESCRIPTION Optional description of the data type.
    retVal = 'description';
end
```

Substitute a MATLAB character vector for *description*. The generated code that defines the enumerated type includes the specified description.

### Import Type Definition in Generated Code

To prevent generated code from defining an enumerated data type, which allows you to provide the definition in an external file, include these methods in the `methods(Static)` section of the enumeration class:

```
function retVal = getHeaderFile()
% GETHEADERFILE Specifies the file that defines this type in generated code.
% The method getDataScope determines the significance of the specified file.
    retVal = 'imported_enum_type.h';
end
```

```

function retVal = getDataScope()
% GETDATASCOPE Specifies whether generated code imports or exports this type.
% Return one of:
% 'Auto':    define type in model_types.h, or import if header file specified
% 'Exported': define type in a generated header file
% 'Imported': import type definition from specified header file
% If you do not define this method, DataScope is 'Auto' by default.
retVal = 'Imported';
end

```

Instead of defining the type in `model_types.h`, which is the default behavior, generated code imports the definition from the specified header file using a `#include` statement like:

```
#include "imported_enum_type.h"
```

Generating code does not create the imported header file. You must provide the header file, using the file name specified by the method `getHeaderFile`, that defines the enumerated data type.

To create a Simulink enumeration that corresponds to your existing C-code enumeration, use the `Simulink.importExternalCTypes` function.

### Export Type Definition in Generated Code

To generate a separate header file that defines an enumerated data type, include these methods in the `methods(Static)` section of the enumeration class:

```

function retVal = getDataScope()
% GETDATASCOPE Specifies whether generated code imports or exports this type.
% Return one of:
% 'Auto':    define type in model_types.h, or import if header file specified
% 'Exported': define type in a generated header file
% 'Imported': import type definition from specified header file
% If you do not define this method, DataScope is 'Auto' by default.
retVal = 'Exported';
end

function retVal = getHeaderFile()
% GETHEADERFILE Specifies the file that defines this type in generated code.
% The method getDataScope determines the significance of the specified file.
retVal = 'exported_enum_type.h';
end

```

Generated code exports the enumerated type definition to the generated header file `exported_enum_type.h`.

## Add Prefixes To Class Names

By default, enumerated values in generated code have the same names that they have in the enumeration class definition. Alternatively, your code can prefix every enumerated value in an enumeration class with the name of the class. You can use this technique to prevent identifier conflicts or to improve the readability of the code. To specify class name prefixing, include this method in the methods (Static) section of an enumeration class:

```
function retVal = addClassNameToEnumNames()
    % ADDCLASSNAMETOENUMNAMES Specifies whether to add the class name
    % as a prefix to enumeration member names in generated code.
    % Return true or false.
    % If you do not define this method, no prefix is added.
    retVal = true;
end
```

Specify the return value as `true` to enable class name prefixing or as `false` to suppress prefixing. If you specify `true`, each enumerated value in the class appears in generated code as *EnumTypeName\_EnumName*. For the example enumeration class `BasicColors` in “Enumerated Data Types” on page 33-108, the data type definition in generated code might look like this:

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
    BasicColors_Red = 0,          /* Default value */
    BasicColors_Yellow = 1,
    BasicColors_Blue = 2,
} BasicColors;

#endif
```

The enumeration class name `BasicColors` appears as a prefix for each of the enumerated names.

## Control Use of Duplicate Enumeration Member Names

When you import the enumeration data from a header file, you can control the use of duplicate enumeration member names during code generation. Duplicate enumeration member names improve the readability of the code. Use the model configuration parameter **Duplicate enumeration member names** (Simulink Coder) to allow duplicate enumeration member names in different enumeration types during code generation or to generate an error or a warning message. You can use duplicate enumeration member names only if two enumerations have the same `StorageType` and have these specifications:

- DataScope set to 'Imported'
- StorageType set to 'int8', 'int16', 'int32', 'uint8', or 'uint16'
- Value is the same

For example:

```
typedef int32_T enum {  
    Red = 0,  
    Yellow = 1,  
    Blue = 2,  
}A;
```

```
typedef int32_T enum {  
    Black = 0,  
    Yellow = 1,  
    White = 2,  
}B;
```

You can have a Yellow enumeration member in enumeration A and B without prefixing the member name with a class name to improve the readability of your code.

## Control Enumerated Type Implementation in Generated Code

Suppose that you define an enumerated type `BasicColors`. You can specify that the generated code implement the type definition by using:

- An enum block. The native integer type of your hardware is the underlying integer type for the enumeration members.
- A typedef statement and a series of `#define` macros. The typedef statement bases the enumerated type name on a specific integer data type, such as `int8`. The macros associate the enumeration members with the underlying integer values.

### Implement Enumerated Type by Using enum Block

To implement the type definition by using an enum block:

- In Simulink, define the enumerated type by using a `classdef` block in a script file. Derive the enumeration from the type `Simulink.IntEnumType`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Do not specify the property `StorageType`.

When you generate code, the type definition appears in an enum block.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
    Red = 0,          /* Default value */
    Yellow,
    Blue,
} BasicColors;

#endif
```

### Implement Enumerated Type Using a Specific Integer Type

To implement the type definition using a typedef statement and #define macros:

- In Simulink, define the enumerated type using a `classdef` block in a script file. Derive the enumeration from a specific integer type such as `int8`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Specify the property `StorageType` using a specific integer type such as `int8`.

When you generate code, the type definition appears as a typedef statement and a series of #define macros.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef int8_T BasicColors;

#define Red ((BasicColors)0)          /* Default value */
#define Yellow ((BasicColors)1)
#define Blue ((BasicColors)2)

#endif
```

By default, the generated file `model_types.h` contains enumerated type definitions.

## Type Casting for Enumerations

### Safe Casting

A Simulink Data Type Conversion block accepts a signal of integer type. The block converts the input to one of the underlying values of an enumerated type.

If the input value does not match an underlying value of an enumerated type value, Simulink inserts a safe cast to replace the input value with the enumerated type default value.

### Enable and Disable Safe Casting

You can enable or disable safe casting for enumerations during code generation for a Simulink Data Type Conversion block or a Stateflow block.

To control safe casting, enable or disable the **Saturate on integer overflow** block parameter. The parameter works as follows:

- **Enabled:** Simulink replaces a nonmatching input value with the default value of the enumerated values during simulation. The software generates a safe cast function during code generation.
- **Disabled:** For a nonmatching input value, Simulink generates an error during simulation. The software omits the safe cast function during code generation. In this case, the code is more efficient. However, the code may be more vulnerable to run-time errors.

### Safe Cast Function in Generated Code

This example shows how the safe cast function `int32_T ET08_safe_cast_to_BasicColors` for the enumeration `BasicColors` appears in generated code when generated for 32-bit hardware.

```
static int32_T ET08_safe_cast_to_BasicColors(int32_T input)
{
    int32_T output;
    /* Initialize output value to default value for BasicColors (Red) */
    output = 0;
    if ((input >= 0) && (input <= 2)) {
        /* Set output value to input value if it is a member of BasicColors */
        output = input;
    }
}
```

```
    return output;  
}
```

Through this function, the enumerated type's default value is used if the input value does not match one of underlying values of the enumerated type's values.

If the block's **Saturate on integer overflow** parameter is disabled, this function does not appear in generated code.

## Enumerated Type Limitations

- Generated code does not support logging enumerated data.

## Data Stores in Generated Code

### In this section...

“About Data Stores” on page 33-119

“Generate Code for Data Store Memory Blocks” on page 33-119

“Storage Classes for Data Store Memory Blocks” on page 33-120

“Data Store Buffering in Generated Code” on page 33-122

“Data Stores Shared by Instances of a Reusable Model” on page 33-125

“Structures in Generated Code Using Data Stores” on page 33-126

### About Data Stores

A data store contains data that is accessible in a model hierarchy at or below the level in which the data store is defined. Data stores can allow subsystems and referenced models to share data without having to use I/O ports to pass the data from level to level. See “Data Stores with Data Store Memory Blocks” (Simulink) for information about data stores in Simulink. This section provides additional information about data store code generation.

### Generate Code for Data Store Memory Blocks

To control the code generated for a Data Store Memory block, apply a storage class to the data store. You can associate a Data Store Memory block with a signal object that you store in a workspace or data dictionary, and control code generation for the block by applying the storage class to the object:

- 1 On the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **Data Stores** tab.
- 3 Begin editing the name of the target Data Store Memory block by clicking the corresponding row in the **Name** column.
- 4 Next to the name, click the button  and select **Create and Resolve**.
- 5 In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Optionally, use the **Location** drop-down list to choose a workspace for storing the resulting `Simulink.Signal` object.

- 6 Click **Create**. The `Simulink.Signal` object, which has the same name as the data store, appears in the target workspace. Simulink selects the block parameter **Data store name must resolve to Simulink signal object**.

The property dialog box for the object opens.

- 7 Use the **Storage class** drop-down list to apply the target storage class.

---

**Note** When a Data Store Memory block is associated with a signal object, the mapping between the **Data store name** and the signal object name must be one-to-one. If two or more identically named entities map to the same signal object, the name conflict is flagged as an error at code generation time. See “Resolve Conflicts in Configuration of Signal Objects for Code Generation” (Simulink) for more information.

---

## Storage Classes for Data Store Memory Blocks

You can control how Data Store Memory blocks in your model are stored and represented in the generated code by assigning storage classes and type qualifiers. You do this in almost exactly the same way you assign storage classes and type qualifiers for block states.

Data Store Memory blocks, like block states, have `Auto` storage class by default, and their memory is stored within the `DWork` vector. The symbolic name of the storage location is based on the data store name.

You can generate code from multiple Data Store Memory blocks that have the same data store name, subject to the following restriction: *at most one* of the identically named blocks can have a storage class other than `Auto`. An error is reported if this condition is not met.

For blocks with `Auto` storage class, the code generator produces a unique symbolic name for each block to avoid name clashes. For Data Store Memory blocks with storage classes other than `Auto`, the generated code uses the data store name as the symbol.

In the following model, a Data Store Write block writes to memory declared by the Data Store Memory block `myData`:

To control the storage declaration for a Data Store Memory block, use the **Code Generation > Signal object class** and **Code Generation > Storage class** drop-down lists of the Data Store Memory block dialog box. Set **Signal object class** to **Simulink.Signal** (the default), and choose a storage class from the **Storage class** drop-down list. The next figure shows the Data Store Memory block dialog box for the preceding model.

To apply storage classes to data stores, you can alternatively use the **Data Stores** tab in the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**).

Data Store Memory blocks are nonvirtual because code is generated for their initialization in `.c` and `.cpp` files and their declarations in header files. The following table shows how the code generated for the Data Store Memory block in the preceding model differs for different storage classes. The table gives the variable declarations and `MdlOutputs` code generated for the `myData` block.

| Storage Class                                                                       | Declaration                                                                                                                                                                                                             | Code                                          |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| Auto or Model default<br>(when Code Mapping Editor specifies Default storage class) | In <code>model.h</code><br><pre>typedef struct D_Work_tag {     real_T myData; } D_Work;</pre><br>In <code>model.c</code> or <code>model.cpp</code><br><pre>/* Block states (auto storage) */ D_Work model_DWork;</pre> | <pre>model_DWork.myData = rtb_SineWave;</pre> |
| ExportedGlobal                                                                      | In <code>model.c</code> or <code>model.cpp</code><br><pre>/* Exported block states */ real_T myData;</pre><br>In <code>model.h</code><br><pre>extern real_T myData;</pre>                                               | <pre>myData = rtb_SineWave;</pre>             |
| ImportedExtern                                                                      | In <code>model_private.h</code><br><pre>extern real_T myData;</pre>                                                                                                                                                     | <pre>myData = rtb_SineWave;</pre>             |
| ImportedExternPointer                                                               | In <code>model_private.h</code><br><pre>extern real_T *myData;</pre>                                                                                                                                                    | <pre>(*myData) = rtb_SineWave;</pre>          |

For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99.

## Data Store Buffering in Generated Code

A Data Store Read block is a nonvirtual block that copies the value of the data store to its output buffer when it executes. Since the value is buffered, downstream blocks connected to the output of the data store read utilize the same value, even if a Data Store Write block updates the data store in between execution of two of the downstream blocks.

The next figure shows a model that uses blocks whose priorities have been modified to achieve a particular order of execution:

```

/* local block i/o variables */
real_T rtb_DataStoreRead;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A; Buffer the value of A

/* Abs: '<Root>/Abs1' incorporates:
 * DataStoreRead: '<Root>/Data Store Read'
 */
y1 = fabs(A); Use A (whose value equals
the buffered value at this point

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Inport: '<Root>/In1'
 */
A = u1; Update the value of A

/* Abs: '<Root>/Abs' */
y2 = fabs(rtb_DataStoreRead); Consistently use the same buffered
value as before the update to A

```

The following execution order applies:

- 1 The block Data Store Read buffers the current value of the data store A at its output.
- 2 The block Abs1 uses the buffered output of Data Store Read.
- 3 The block Data Store Write updates the data store.
- 4 The block Abs uses the buffered output of Data Store Read.

Because the output of Data Store Read is a buffer, both Abs and Abs1 use the same value: the value of the data store at the time that Data Store Read executes.

The next figure shows another example:

```

real_T rtb_DataStoreRead;

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Constant: '<Root>/Constant'
 */
A = DoBufferDSMRead2_P.Constant_Value;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A; Buffer the value of A

/* Outputs for atomic SubSystem: '<Root>/Atomic Subsystem' */
DoBufferDSMRead_AtomicSubsystem(); We don't do a global analysis to
detect if this function writes to A

/* end of Outputs for SubSystem: '<Root>/Atomic Subsystem' */

/* Outport: '<Root>/Out1' incorporates:
 * Sum: '<Root>/Sum'
 */
Use the buffered value of A
DoBufferDSMRead2_Y.Out1 = rtb_DataStoreRead + DoBufferDSMRead2_B.Abs;

```

In this example, the following execution order applies:

- 1 The block Data Store Read buffers the current value of the data store A at its output.
- 2 Atomic Subsystem executes.
- 3 The Sum block adds the output of Atomic Subsystem to the output of Data Store Read.

Simulink assumes that Atomic Subsystem might update the data store, so Simulink buffers the data store. Atomic Subsystem executes after Data Store Read buffers its output, and the buffer provides a way for the Sum block to use the value of the data store as it was when Data Store Read executed.

In some cases, the code generator determines that it can optimize away the output buffer for a Data Store Read block, and the generated code refers to the data store directly, rather than a buffered value of it. The next figure shows an example:

```

/* Model step function */
void DONTbufferDSMRead_step(void)
{
    /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
     *   Inport: '<Root>/In1'
     */
    A = u1;

    /* Abs: '<Root>/Abs' incorporates:
     *   DataStoreRead: '<Root>/Data Store Read'
     */
    y2 = fabs(A);
}

```

In the generated code, the argument of the `fabs()` function is the data store `A` rather than a buffered value.

## Data Stores Shared by Instances of a Reusable Model

You can use a data store to share a piece of data between the instances of a reusable referenced model (see “Share Data Among Referenced Model Instances” (Simulink)) or a model that you configure to generate reentrant code (by setting the configuration

parameter **Code interface packaging** to Reusable function). If you implement the data store as a Data Store Memory block and select the **Share across model instances** parameter:

- By default, the data store appears in the generated code as a separate global symbol.
- If you have Embedded Coder, to restrict access such that only the code generated from the model can use the data store, configure the data store to appear as `static` by applying the storage class `FileScope`. For more information about `FileScope` and other storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-87.

## Structures in Generated Code Using Data Stores

If you use more than one data store to provide global access to multiple signals in generated code, you can combine the signals into a single structure variable by using one data store. This combination of signal data can help you integrate the code generated from a model with other existing code that requires the data in a structure format.

This example shows how to store several model signals in a structure in generated code using a single data store. To store multiple signals in a data store, you configure the data store to accept a composite signal, such as a nonvirtual bus signal or an array of nonvirtual bus signals.

### Explore Example Model

- 1 Open the example model `ex_bus_struct_in_code`.

The model contains three subsystems that perform calculations on the inputs from the top level of the model. In each subsystem, a Data Store Memory block stores an intermediate calculated signal.

- 2 Generate code with the model. In the code generation report, view the file `ex_bus_struct_in_code.c`. The code defines a global variable for each data store.

```
real_T BioBTURate;  
real_T CoalBTURate;  
real_T GasBTURate;
```

Suppose that you want to integrate code generated from the example model with other existing code. Suppose also that the existing code requires access to data from the three data stores in a single structure variable. You can use a data store to assemble the target data in a structure in generated code.

## Configure Data Store

Configure a data store to contain multiple signals by creating a bus type to use as the data type of the data store. Define the bus type using the same hierarchy of elements as the structure that you want to appear in generated code.

- 1 Open the Bus Editor tool.

buseditor

- 2 Define a new bus type `Raw_BTU_Rate` with one element for each of the three target signals. Name the elements `BioBTU`, `GasBTU`, and `CoalBTU`.

- 3 At the top level of the example model, add a Data Store Memory block.
- 4 On the **Modeling** tab, click **Model Data Editor**.
- 5 In the Model Data Editor, inspect the **Data Stores** tab.
- 6 For the new Data Store Memory block, use the **Name** column to set the data store name to `Raw_BTU_Data`.
- 7 Use the **Data Type** column to set the data type of the data store to **Bus : Raw\_BTU\_Rate**.
- 8 Set the **Change view** drop-down list to **Code**.
- 9 Use the **Storage Class** column to apply the storage class `ExportedGlobal`.

## Write to Data Store Elements

To write to a specific element of a data store, use a Data Store Write block. On the **Element Assignment** tab in the dialog box, you can specify to write to a single element, a collection of elements, or the entire contents of a data store.

- 1 Open the **Biomass Calc** subsystem.
- 2 Delete the Data Store Memory block `BioBTURate`.
- 3 In the block dialog box for the Data Store Write block, set **Data store name** to `Raw_BTU_Data`.

- 4 On the **Element Assignment** tab, under **Signals in the bus**, expand the contents of the data store `Raw_BTU_Data`. Click the element `BioBTU`, and then click **Select**. Click **OK**.

- 5 Modify the **Gas Calc** and **Coal Calc** subsystems similarly.
  - Delete the Data Store Memory block in each subsystem.
  - In each Data Store Write block dialog box, set **Data store name** to `Raw_BTU_Data`.
  - In the **Gas Calc** subsystem, use the Data Store Write block to write to the data store element `GasBTU`. In the **Coal Calc** subsystem, write to the element `CoalBTU`.

## Generate Code with Data Store Structure

- 1 Generate code for the example model.
- 2 In the code generation report, view the file `ex_bus_struct_in_code_types.h`. The code defines a structure that corresponds to the bus type `Raw_BTU_Rate`.

```
typedef struct {  
    real_T BioBTU;  
    real_T GasBTU;  
    real_T CoalBTU;  
} Raw_BTU_Rate;
```

- 3 View the file `ex_bus_struct_in_code.c`. The code represents the data store with a global variable `Raw_BTU_Data` of the structure type `Raw_BTU_Rate`. In the model step function, the code assigns the data from the calculated signals to the fields of the global variable `Raw_BTU_Data`.

## Specify Single-Precision Data Type for Embedded Application

When you want code that uses only single precision, such as when you are targeting a single-precision processor, you can use model configuration parameters and block parameters to prevent the introduction of `double` in the model.

To design and validate a single-precision model, see “Validate a Floating-Point Embedded Model” (Simulink). If you have Fixed-Point Designer, you can use the Single Precision Converter app (see “Single-Precision Design for Simulink” (Fixed-Point Designer)).

### Use single Data Type as Default for Underspecified Types

This example shows how to avoid introducing a double-precision data type in code generated for a single-precision hardware target.

If you specify an inherited data type for signals, but data type propagation rules cannot determine data types for the signals, the signal data types default to `double`. You can use a model configuration parameter to specify the default data type as `single`.

#### Explore Example Model

Open the example model `rtwdemo_underspecified_datatype` and configure it to show the generated names of blocks.

```
model = 'rtwdemo_underspecified_datatype';  
load_system(model)  
set_param(model, 'HideAutomaticNames', 'off')  
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

The root inports In2, In3, and In4 specify `Inherit: Auto` for the **Data type** block parameter. The downstream blocks also use inherited data types.

### Generate Code with `double` as Default Data Type

The model starts with the configuration parameter **System target file** set to `ert.tlc`, which requires Embedded Coder. Set **System target file** to `grt.tlc` instead.

```
set_param(model, 'SystemTargetFile', 'grt.tlc')
```

Generate code from the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_underspecified_datatype
### Successful completion of build procedure for model: rtwdemo_underspecified_datatype
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the double data type to define the variables In2, In3, and In4 because the Inport data types are underspecified in the model.

```
cfile = fullfile('rtwdemo_underspecified_datatype_grt_rtw',...
    'rtwdemo_underspecified_datatype.h');
rtwdemodbtype(cfile,...
    /* External inputs (root inport signals with default storage) */',...
    /* External outputs (root outports fed by signals with default storage) */',...
    1, 0);

/* External inputs (root inport signals with default storage) */
typedef struct {
    int8_T In1;                /* '<Root>/In1' */
    real_T In2;                /* '<Root>/In2' */
    real_T In3;                /* '<Root>/In3' */
    real_T In4;                /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;
```

### Generate Code with single as Default Data Type

Open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select `single` in the **Default for underspecified data type** drop-down list.

Alternatively, enable the optimization at the command prompt.

```
set_param(model, 'DefaultUnderspecifiedDataType', 'single');
```

Generate code from the model.

```
rtwbuild(model)

### Starting build procedure for model: rtwdemo_underspecified_datatype
### Successful completion of build procedure for model: rtwdemo_underspecified_datatype
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the single data type to define the variables In2, In3, and In4.

```
rtwdemodbtype(cfile,...
    /* External inputs (root inport signals with default storage) */',...
    /* External outputs (root outports fed by signals with default storage) */',...
    1, 0);

/* External inputs (root inport signals with default storage) */
```

```
typedef struct {  
    int8_T In1;           /* '<Root>/In1' */  
    real32_T In2;        /* '<Root>/In2' */  
    real32_T In3;        /* '<Root>/In3' */  
    real32_T In4;        /* '<Root>/In4' */  
} ExtU_rtwdemo_underspecified_d_T;
```

## Tune Phase Parameter of Sine Wave Block During Code Execution

Under certain conditions, you cannot configure the **Phase** parameter of a Sine Wave block to appear in the generated code as a tunable global variable (for more information, see the block reference page). This example shows how to generate code so that you can tune the phase during execution.

Create the model `ex_phase_tunable` by using a Digital Clock block.

```
open_system('ex_phase_tunable')
```

Set **Default parameter behavior** to `Tunable` so that the parameters of the Sine Wave block appear in the generated code as tunable fields of the global parameter structure.

```
set_param('ex_phase_tunable', 'DefaultParameterBehavior', 'Tunable')
```

Generate code from the model.

```
rtwbuild('ex_phase_tunable')
```

```
### Starting build procedure for model: ex_phase_tunable
### Successful completion of code generation for model: ex_phase_tunable
```

In the code generation report, view the file `ex_phase_tunable.c`. The code algorithm in the model `step` function calculates the Sine Wave block output. The parameters of the block, including **Phase**, appear in the code as tunable structure fields.

```
file = fullfile('ex_phase_tunable_grt_rtw', 'ex_phase_tunable.c');
rtwdemodbtype(file, '/* Outport: '<Root>/Out1' incorporates:', ...
    'ex_phase_tunable_P.SineWave_Bias;', 1, 1)
```

```
/* Outport: '<Root>/Out1' incorporates:
 * DigitalClock: '<Root>/Digital Clock'
 * Sin: '<Root>/Sine Wave'
 */
```

```
ex_phase_tunable_Y.Out1 = sin(ex_phase_tunable_P.SineWave_Freq *  
    ((ex_phase_tunable_M->Timing.clockTick1+  
        ex_phase_tunable_M->Timing.clockTickH1* 4294967296.0)) * 1.0) +  
    ex_phase_tunable_P.SineWave_Phase) * ex_phase_tunable_P.SineWave_Amp +  
    ex_phase_tunable_P.SineWave_Bias;
```

During code execution, you can assign new values to the structure field that corresponds to the **Phase** parameter.

## Switch Between Output Waveforms During Code Execution for Waveform Generator Block

This example shows how to generate code that enables you to switch between stimulus waveforms during code execution.

For a Waveform Generator block, you cannot make the parameters of a waveform, such as amplitude and phase shift, tunable in the generated code. Instead, you can generate code that enables you to choose an active waveform from a set of waveform variants that you specify in the block. During execution of the code, you activate a variant by adjusting the value of a global structure field.

You must set the model configuration parameter **Default parameter behavior** to **Tunable**. Then, by default, block parameters in the model appear tunable in the generated code. These parameters can consume large amounts of memory for a large model.

Create the model `ex_switch_waveform`.

```
open_system('ex_switch_waveform')
```

In the Waveform Generator block, configure this waveform:

```
square(amp,10,0,dutyCycle)
```

In the base workspace, create the variables `amp` and `dutyCycle`.

```
amp = 2.71;
dutyCycle = 50;
```

This waveform represents the baseline stimulus that you want the application to use at the start of execution.

Suppose that, during execution, you want to observe the effects of changing the waveform frequency from 10 to 15 and the phase shift from 0 to 0.5. In the Waveform Generator block, add these waveform variants:

```
square(amp,10,0.5,dutyCycle)
square(amp,15,0,dutyCycle)
square(amp,15,0.5,dutyCycle)
```

Set the model configuration parameter **Default parameter behavior** to Tunable.

```
set_param('ex_switch_waveform','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('ex_switch_waveform')
```

```
### Starting build procedure for model: ex_switch_waveform
### Successful completion of code generation for model: ex_switch_waveform
```

The generated file `ex_switch_waveform.h` defines the standard structure type that stores tunable parameter data for the model. The structure contains a field whose value represents the active waveform.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform.h');
rtwdemodbtype(file,'/* Parameters (default storage) */',...
    '/* Real-time Model Data Structure */',1,0)

/* Parameters (default storage) */
struct P_ex_switch_waveform_T_ {
    real_T WaveformGeneratorStimulus_Select;
    /* Mask Parameter: WaveformGeneratorStimulus_Select
    * Referenced by: '<S1>/Switch'
    */
    real_T GainControlSystem_Gain; /* Expression: 3.5
    * Referenced by: '<Root>/Gain (Control System)
    */
};
```

The file `ex_switch_waveform_data.c` defines a global structure variable and initializes the field value to 1. This value represents the baseline waveform.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform_data.c');
rtwdemodbtype(file,'/* Block parameters (default storage) */',';',1,1)
```

```

/* Block parameters (default storage) */
P_ex_switch_waveform_T ex_switch_waveform_P = {
  /* Mask Parameter: WaveformGeneratorStimulus_Select
   * Referenced by: '<S1>/Switch'
   */
  1.0,

  /* Expression: 3.5
   * Referenced by: '<Root>/Gain (Control System)'
   */
  3.5
};

```

The file `ex_switch_waveform.c` defines the model execution function. The function uses a `switch` statement to determine the value of the active waveform, and then calculates the value of the root-level Output block, `Out1`.

```

file = fullfile('ex_switch_waveform_grt_rtw', 'ex_switch_waveform.c');
rtwdemodbtype(file, 'switch ((int32_T)', ...
  'ex_switch_waveform_Y.Out1 =', 1, 1)

switch ((int32_T)ex_switch_waveform_P.WaveformGeneratorStimulus_Select) {
  case 1:
    temp = temp - floor(temp) <= 0.5 ? 2.71 : -2.71;
    break;

  case 2:
    temp = temp_0 - floor(temp_0) <= 0.5 ? 2.71 : -2.71;
    break;

  case 3:
    temp = temp_1 - floor(temp_1) <= 0.5 ? 2.71 : -2.71;
    break;

  default:
    temp = frequencyVar - floor(frequencyVar) <= 0.5 ? 2.71 : -2.71;
    break;
}

/* End of MultiPortSwitch: '<S1>/MultiportSwitch' */

/* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain (Control System)'

```

```
*/  
ex_switch_waveform_Y.Out1 = ex_switch_waveform_P.GainControlSystem_Gain * temp;
```

During code execution, to change the active waveform, adjust the value of the structure field in the global parameters structure.

## Create Tunable Calibration Parameter in the Generated Code

A calibration parameter is a value stored in global memory that an algorithm reads for use in calculations but does not write to. Calibration parameters are tunable because you can change the stored value during algorithm execution. You create calibration parameters so that you can:

- Determine an optimal parameter value by tuning the parameter and monitoring signal values during execution.
- Efficiently adapt an algorithm to different execution conditions by overwriting the parameter value stored in memory. For example, you can use the same control algorithm for multiple vehicles of different masses by storing different parameter values in each vehicle's engine control unit.

In Simulink, create a `Simulink.Parameter` object to represent a calibration parameter. You use the parameter object to set block parameter values, such as the **Gain** parameter of a Gain block. To control the representation of the parameter object in the generated code, you apply a storage class to the object.

To make block parameters accessible in the generated code by default, for example for rapid prototyping, set **Default parameter behavior** (see “Default parameter behavior” (Simulink Coder)) to **Tunable**. For more information, see “Preserve Variables in Generated Code” on page 33-3.

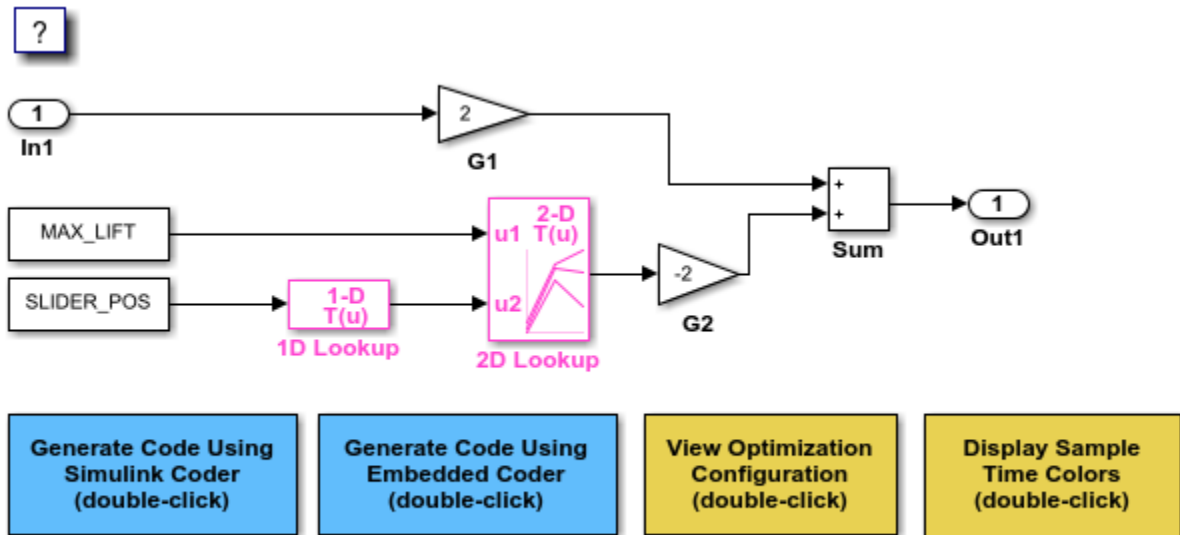

### Represent Block Parameter as Tunable Global Variable

This example shows how to create tunable parameter data by representing block parameters as global variables in the generated code.

#### Configure Block Parameter by Using Parameter Object

Open the example model `rtwdemo_paraminline` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```

Copyright 1994-2019 The MathWorks, Inc.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the G1 Gain block. The Model Data Editor highlights the row that corresponds to the **Gain** parameter of the block.

In the Model Data Editor **Value** column, change the gain value from 2 to myGainParam.

Next to myGainParam, click the action button (with three vertical dots) and select **Create**.

In the Create New Data block dialog box, set **Value** to Simulink.Parameter(2). Click **Create**. A Simulink.Parameter object myGainParam stores the parameter value, 2, in the base workspace.

In the myGainParam dialog box, set **Storage class** to ExportedGlobal and click **OK**. This storage class causes the parameter object to appear in the generated code as a tunable global variable.

Alternatively, to create the parameter object and configure the model, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G1','Gain','myGainParam')
myGainParam = Simulink.Parameter(2);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
```

Use the Model Data Editor to create a parameter object, myOtherGain, for the G2 Gain block. Apply the storage class ExportedGlobal.

Alternatively, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G2','Gain','myOtherGain')
myOtherGain = Simulink.Parameter(-2);
myOtherGain.CoderInfo.StorageClass = 'ExportedGlobal';
```

### Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The generated file `rtwdemo_paraminline.h` contains extern declarations of the global variables `myGainParam` and `myOtherGain`. You can include (`#include`) this header file so that your code can read and write the value of the variable during execution.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.h');
rtwdemodbtype(file,...
    'extern real_T myGainParam;', 'Referenced by: '<Root>/G2'',1,1)

extern real_T myGainParam;          /* Variable: myGainParam
    * Referenced by: '<Root>/G1'
    */
extern real_T myOtherGain;         /* Variable: myOtherGain
    * Referenced by: '<Root>/G2'
```

The file `rtwdemo_paraminline.c` allocates memory for and initializes `myGainParam` and `myOtherGain`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,...
    '/* Exported block parameters */', 'Referenced by: '<Root>/G2'',1,1)
```

```

/* Exported block parameters */
real_T myGainParam = 2.0;          /* Variable: myGainParam
                                   * Referenced by: '<Root>/G1'
                                   */
real_T myOtherGain = -2.0;        /* Variable: myOtherGain
                                   * Referenced by: '<Root>/G2'

```

The generated code algorithm in the model `step` function uses `myGainParam` and `myOtherGain` for calculations.

```

rtwdemoDbType(file,...
    /* Model step function */, /* Model initialize function */,1,0)

/* Model step function */
void rtwdemo_paraminline_step(void)
{
    /* Output: '<Root>/Out1' incorporates:
     * Gain: '<Root>/G1'
     * Gain: '<Root>/G2'
     * Inport: '<Root>/In1'
     * Sum: '<Root>/Sum'
     */
    rtwdemo_paraminline_Y.Out1 = myGainParam * rtwdemo_paraminline_U.In1 +
        myOtherGain * -75.0;
}

```

## Apply Storage Class When Block Parameter Refers to Numeric MATLAB Variable

If you use a numeric variable to set the value of a block parameter, you cannot apply a storage class to the variable. As a workaround, you can convert the variable to a parameter object, and then apply a storage class to the object. To convert the variable to a parameter object, choose one of these techniques:

- On the Model Data Editor **Parameters** tab, with **Change view** set to Code, find the row that corresponds to the variable. In the **Storage Class** column, from the drop-down list, select **Convert to parameter object**. The Model Data Editor converts the variable to a parameter object. Then, use the **Storage Class** column to apply a storage class to the object.

You can also use this technique in the Model Explorer.

- Use the Data Object Wizard (see “Create Data Objects for a Model Using Data Object Wizard” (Simulink)). In the Wizard, select the **Parameters** check box. The Wizard converts variables to objects. Then, apply storage classes to the objects, for example, by using the Model Data Editor or the Model Explorer.

## Create Storage Class That Represents Calibration Parameters (Embedded Coder)

This example shows how to create a storage class that yields a calibration parameter in the generated code. The storage class causes each parameter object (`Simulink.Parameter`) to appear as a global variable with special decorations such as keywords and pragmas.

In the generated code, the calibration parameters must appear as global variables defined in a file named `calPrms.c` and declared in `calPrms.h`. The variable definitions must look like these definitions:

```
#pragma SEC(CALPRM)

const volatile float param1 = 3.0F;
const volatile float param2 = 5.0F;
const volatile float param3 = 7.0F;

#pragma SEC()
```

The variables use the keywords `const` and `volatile`. The pragma `#pragma SEC(CALPRM)` controls the placement of the variables in memory. To implement the pragma, variable definitions must appear in a contiguous block of code.

Also, the generated code must include an ASAP2 (a2l) description of each parameter.

### Create Package for Storing Storage Class and Memory Section Definitions

Now, create a package in your current folder by copying the example package `+SimulinkDemos`. The package stores the definitions of `Parameter` and `Signal` classes that you later use to apply the storage class to data elements in models. Later, the package also stores the definitions of the storage class and an associated memory section.

- 1 Set your current MATLAB folder to a writable location.
- 2 Copy the `+SimulinkDemos` package folder into your current folder. Name the copy `+myPackage`.

```
copyfile(fullfile(matlabroot,...
    'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
    '+myPackage','f')
```

- 3 Navigate inside the +myPackage folder to the file Signal.m to edit the definition of the Signal class.
- 4 Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section looks like this:

```
methods
function setupCoderInfo(h)
    % Use custom storage classes from this package
    useLocalCustomStorageClasses(h, 'myPackage');
end
end % methods
```

- 5 Save and close the file.
- 6 Navigate inside the +myPackage folder to the file Parameter.m to edit the definition of the Parameter class. Uncomment the methods section that defines the method setupCoderInfo and replace 'packageName' with 'myPackage'.
- 7 Save and close the file.

### Create Storage Class and Memory Section

- 1 Set your current folder to the folder that contains the package folder +myPackage.
- 2 Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

- 3 In the Custom Storage Class Designer, on the **Memory Sections** tab, click **New**.
- 4 For the new memory section, set properties according to the table.

| Property                   | Value               |
|----------------------------|---------------------|
| <b>Name</b>                | CalMem              |
| <b>Statements Surround</b> | Group of variables  |
| <b>Pre Statement</b>       | #pragma SEC(CALPRM) |
| <b>Post Statement</b>      | #pragma SEC()       |
| <b>Is const</b>            | Select              |
| <b>Is volatile</b>         | Select              |

- 5 Click **Apply**.
- 6 On the **Custom Storage Class** tab, click **New**.

- 7 For the new storage class, set properties according to the table.

| Property               | Value     |
|------------------------|-----------|
| <b>Name</b>            | CalParam  |
| <b>For signals</b>     | Clear     |
| <b>Data scope</b>      | Exported  |
| <b>Header File</b>     | calPrms.h |
| <b>Definition File</b> | calPrms.c |
| <b>Memory Section</b>  | CalMem    |

- 8 Click **OK**. In response to the message about saving changes, click **Yes**.

### Set Default Parameter Object to myPackage.Parameter

To make applying the storage class easier, use the Model Explorer to change the default parameter object from `Simulink.Parameter` to `myPackage.Parameter`.

- At the command prompt, open the Model Explorer.
 

```
daexplr
```
- In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- In the Model Explorer toolbar, click the arrow next to the **Add Simulink Parameter** button. In the drop-down list, select **Customize class lists**.
- In the **Customize class lists** dialog box, under **Parameter classes**, select the check box next to **myPackage.Parameter**. Click **OK**.
- In the Model Explorer toolbar, click the arrow next to the **Add Simulink Parameter** button. In the drop-down list, select **myPackage Parameter**.

A `myPackage.Parameter` object appears in the base workspace. You can delete this object.

Now, when you use tools such as the Model Data Editor to create parameter objects, Simulink creates `myPackage.Parameter` objects instead of `Simulink.Parameter` objects.

### Apply Storage Class

In the example model `rtwdemo_roll`, the `BasicRollMode` subsystem represents a PID controller. Configure the P, I, and D parameters as calibration parameters.

- 1 Open the model.

```
rtwdemo_roll
```

- 2 In the model, navigate into the BasicRollMode subsystem.
- 3 In the Apps gallery, click **Embedded Coder**.
- 4 Underneath the block diagram, open the Model Data Editor by selecting the **Model Data Editor** tab.
- 5 In the Model Data Editor, select the **Parameters** tab and update the block diagram.

Now, the data table contains rows that correspond to workspace variables used by the Gain blocks (which represent the P, I, and D parameters of the controller).

- 6 In the Model Data Editor, next to the **Filter contents** box, activate the **Filter using selection** button.
- 7 In the model, select the three Gain blocks.
- 8 In the **Filter contents** box, enter model workspace.

The variables that the Gain blocks use are in the model workspace.

- 9 In the data table, select the three rows and, in the **Storage Class** column for a row, select Convert to parameter object.

The Model Data Editor converts the workspace variables to myPackage.Parameter objects. Now, you can apply a storage class to the objects.

- 10 In the **Storage Class** column for a row, select CalParam.

### Configure Generation of ASAP2 Interface

Configure the model to generate a2l files. Select **Configuration Parameters > Code Generation > Interface > ASAP2 interface**.

### Generate and Inspect Code

- 1 Generate code from the model.
- 2 In the code generation report, inspect the calPrms.c file. The file defines the calibration parameters.

```
/* Exported data definition */
#pragma SEC(CALPRM)

/* Definition for custom storage class: CalParam */
const volatile real32_T dispGain = 0.75F;
const volatile real32_T intGain = 0.5F;
const volatile real32_T rateGain = 2.0F;
```

```
#pragma SEC()
```

The file `calPrms.h` declares the parameters.

- 3 Inspect the interface file `rtwdemo_roll.a2l`. The file contains information about each parameter, for example, for `dispGain`.

```
/begin CHARACTERISTIC
/* Name                */      dispGain
/* Long Identifier     */      ""
/* Type               */      VALUE
/* ECU Address        */      0x0000 /* @ECU_Address@dispGain@ */
/* Record Layout     */      Scalar_FLOAT32_IEEE
/* Maximum Difference */      0
/* Conversion Method  */      rtwdemo_roll_CM_single
/* Lower Limit       */      -3.4E+38
/* Upper Limit       */      3.4E+38
/end CHARACTERISTIC
```

## Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)

You can generate code that initializes a tunable parameter with a value calculated from some system constants (macros). For example, you can generate this code, which initializes a tunable parameter `totalVol` with a value calculated from macros `numVessels` and `vesInitVol`:

```
#define numVessels 16
#define vesInitVol 18.2

double totalVol = numVessels * vesInitVol;
```

This initialization technique preserves the mathematical relationship between the tunable parameter and the system constants, which can make the generated code more readable and easier to maintain. To generate this code:

- 1 Create parameter objects that represent the system constants.

```
numVessels = Simulink.Parameter(16);
vesInitVol = Simulink.Parameter(18.2);
```

- 2 Configure the objects to use the storage class `Define`, which yields a macro in the generated code.

```
numVessels.CoderInfo.StorageClass = 'Custom';
numVessels.CoderInfo.CustomStorageClass = 'Define';
```

```
vesInitVol.CoderInfo.StorageClass = 'Custom';
vesInitVol.CoderInfo.CustomStorageClass = 'Define';
```

- 3 Create another parameter object that represents the tunable parameter. Configure the object to use the storage class `ExportedGlobal`, which yields a global variable in the generated code.

```
totalVol = Simulink.Parameter;
totalVol.CoderInfo.StorageClass = 'ExportedGlobal';
```

- 4 Set the value of `totalVol` by using the expression `numVessels * vesInitVol`. To specify that the generated code preserve the expression, use the `slexpr` function.

```
totalVol.Value = slexpr('numVessels * vesInitVol');
```

- 5 Use `totalVol` to set block parameter values in your model. The code that you generate from the model initializes the tunable parameter with a value based on the system constants.

For more information and limitations about using an expression to set the value of a `Simulink.Parameter` object, see “Set Variable Value by Using a Mathematical Expression” (Simulink).

## Code Generation Impact of Storage Location for Parameter Objects

You can create a parameter object in the base workspace, a model workspace, or a data dictionary. However, when you end your MATLAB session, variables in the base workspace are deleted. To determine where to store parameter objects and other variables that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models” (Simulink).

The location of a parameter object can impact the file placement of the corresponding data definition in the generated code.

- If you place a parameter object in the base workspace or a data dictionary, the code generator assumes that the corresponding parameter data (for example, a global variable) belongs to the system from which you generate code, not to a specific component in the system. For example, if a model in a model reference hierarchy uses a parameter object with a storage class other than `Auto`, the data definition appears in

the code generated for the top model in the hierarchy, not in the code generated for the model that uses the object.

However, if you have Embedded Coder, some storage classes enable you to specify the name of the model that owns a piece of data. When you specify an owner model, the code generated for that model defines the data. For more information about data ownership, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.

- If you place a parameter object in a model workspace, the code generator assumes that the model owns the data. If you generate code from a reference hierarchy that includes the containing model, the data definition appears in the code generated for the containing model.

For more information about data ownership, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.

- If you apply a storage class other than `Auto` to a parameter object, the object appears in the generated code as a global symbol. Therefore, in a model reference hierarchy, two such objects in different model workspaces or dictionaries cannot have the same name. The name of each object must be unique throughout the model hierarchy.

However, if you have Embedded Coder, you can use the storage class `FileScope` to prevent name clashes between parameter objects in different model workspaces. See “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19.

If you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.

## Configure Accessibility of Signal Data

When you tune the value of a parameter during algorithm execution, you monitor or capture output signal values to analyze the results of the tuning. To represent signals in the generated code as accessible data, you can use techniques such as test points and storage classes. See “Preserve Variables in Generated Code” on page 33-3.

## Programmatic Interfaces for Tuning Parameters

You can configure the generated code to include:

- A C application programming interface (API) for tuning parameters independent of external mode. The generated code includes extra code so that you can write your own

code to access parameter values. See “Exchange Data Between Generated and External Code Using C API” on page 57-2.

- A Target Language Compiler API for tuning parameters independently of external mode. See “Parameter Functions” (Simulink Coder).

## Set Tunable Parameter Minimum and Maximum Values

It is a best practice to specify minimum and maximum values for tunable parameters.

You can specify these minimum and maximum values:

- In the block dialog box that uses the parameter object. Use this technique to store the minimum and maximum information in the model.
- By using the properties of a `Simulink.Parameter` object that you use to set the parameter value. Use this technique to store the minimum and maximum information outside the model.

For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).

## Considerations for Other Modeling Goals

| Goal                                                                                                        | Considerations and More Information                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Apply storage type qualifiers <code>const</code> and <code>volatile</code>                                  | If you have Embedded Coder, to generate the storage type qualifiers, see “Protect Global Data with <code>const</code> and <code>volatile</code> Type Qualifiers” on page 41-17.                                      |
| Prevent name clashes between parameters in different components by applying the keyword <code>static</code> | If you have Embedded Coder, use the storage class <code>FileScope</code> or a similar storage class that you create. See “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-87. |
| Generate ASAP2 ( <code>a2l</code> ) description                                                             | You can generate an <code>a2l</code> file that uses the ASAP2 standard to describe your calibration parameters. For more information, see “Define ASAP2 Information for Parameters and Signals” on page 58-4.        |

| Goal                                                             | Considerations and More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generate AUTOSAR XML (arxml) description                         | If you have Embedded Coder, you can generate an arxml file that describes calibration parameters used by models that you configure for the AUTOSAR standard. See “Model AUTOSAR Calibration Parameters and Lookup Tables” (AUTOSAR Blockset).                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Store lookup table data for calibration                          | <p>To store lookup table data for calibration according to the ASAP2 or AUTOSAR standards (for example, STD_AXIS, COM_AXIS, or CURVE), you can use <code>Simulink.LookupTable</code> and <code>Simulink.Breakpoint</code> objects in lookup table blocks.</p> <p>However, some limitations apply. See <code>Simulink.LookupTable</code>. To work around the limitations of <code>Simulink.LookupTable</code> and <code>Simulink.Breakpoint</code> objects, use <code>Simulink.Parameter</code> objects instead.</p> <p>For more information, see “Define ASAP2 Information for Parameters and Signals” on page 58-4 and “Configure Lookup Tables for AUTOSAR Measurement and Calibration” (AUTOSAR Blockset).</p> |
| Use pragmas to store parameter data in specific memory locations | If you have an Embedded Coder license, to generate code that includes custom pragmas, use storage classes and memory sections. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 41-2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Limitations for Block Parameter Tunability in Generated Code

A block parameter, MATLAB variable, or `Simulink.Parameter` object is tunable if it appears in the generated code as data stored in memory, such as a global variable. For example, when you apply the storage class `ExportedGlobal` to a parameter object, the parameter object appears tunable in the generated code. When you set **Default parameter behavior** to `Tunable`, MATLAB variables and parameter objects appear tunable in the generated code. By definition, model arguments also appear tunable.

Under certain conditions, the code generator cannot maintain tunability of a parameter, variable, object, or expression. In this case, the code generator inlines the numeric value, preventing you from changing the value during code execution.

To detect these conditions in your model, set the model configuration parameter **Detect loss of tunability** (see “Detect loss of tunability” (Simulink)) to `warning` or `error`.

### Tunable Expression Limitations

You can specify block parameter values as expressions that use `Simulink.Parameter` objects or workspace variables. For example, you can use the expression `5 * gainParam`. For general information about using expressions to set block parameter values, see “Use Mathematical Expressions, MATLAB Functions, and Custom Functions” (Simulink). For limitations with respect to expressions that you use to set the values of `Simulink.Parameter` objects, see “Code Generation of Parameter Objects With Expression Values” (Simulink Coder).

A tunable workspace variable is a `Simulink.Parameter` object or workspace variable that appears tunable in the generated code. For example, an object or variable is tunable if you apply a storage class other than `Auto` or if you set **Default parameter behavior** to `Tunable`.

An expression that contains one or more tunable workspace variables, model arguments, or tunable mask parameters is called a tunable expression. The expression is tunable because the code generator attempts to preserve the expression in the code. Because the code generator preserves the expression, you can change the values of the parameter data during code execution.

The code generator reduces certain expressions to an inlined numeric value in the generated code. The inlining renders workspace variables in the expression nontunable. To avoid loss of tunability due to unsupported expressions, observe these guidelines:

- Expressions involving complex (i) workspace variables or parameter objects are not supported.
- Certain operators and functions cause the code generator to reduce expressions and remove tunability. To determine whether an operator or function causes loss of tunability, use the information in this table.

| Category | Operators or Functions                                                                                                                                              |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1        | + - .* ./ < > <= >= == ~= &                                                                                                                                         |
| 2        | * /                                                                                                                                                                 |
| 3        | abs, acos, asin, atan, atan2, boolean, ceil, cos, cosh, exp, floor, log, log10, sign, sin, sinh, sqrt, tan, tanh, single, int8, int16, int32, uint8, uint16, uint32 |
| 4        | : .^ ^ [] {} . \ .\ ' . ' , ;                                                                                                                                       |

- Use operators from category 1 without loss of tunability.
- Use operators from category 2 in expressions as long as at least one operand is a scalar. For example, scalar/scalar and scalar/matrix operand combinations are supported, but matrix/matrix combinations are not supported.
- You can use tunable workspace variables as arguments for the functions in category 3. If you use other functions, the code generator removes the tunability of the arguments.
- The operators in category 4 are not supported.
- The Fcn and If blocks do not support tunable expressions for code generation or in referenced models.
- You can write mask initialization code that creates and modifies variables. If you use those variables in an expression, the expression is not tunable.
- You can specify a data type for the Simulink.Parameter objects or workspace variables that make up expressions. As long as the data type of these variables and objects and the data type of the corresponding block parameters are the same or double, the code generator can preserve tunability.

If the code generator preserves tunability of a parameter expression that includes at least one element of an integer type, simulation and execution of generated code can produce

results that are numerically inconsistent. Evaluation of the expression in the generated code results in an overflow while the expression saturates during simulation. For more information, see “Numerical Consistency of Model and Generated Code Simulation Results” (Simulink Coder).

## Linear Block Parameter Tunability

These blocks have a `Realization` parameter that affects the tunability of their numeric parameters:

- Transfer Fcn
- State-Space
- Discrete State-Space

To set the `Realization` parameter, you must use the command prompt:

```
set_param(gcb, 'Realization', 'auto')
```

For the `Realization` parameter, you can choose these options:

- `general`: The block's numeric parameters appear tunable in the generated code.
- `sparse`: The generated code represents the block's parameters as transformed values that increase efficiency. The parameters are not tunable.
- `auto`: The default. If one or more of the block's parameters are tunable (for example, because you use a tunable parameter object to set a parameter value), then the block uses the `general` realization. Otherwise, the block uses the `sparse` realization.

To tune the parameter values of one of these blocks during an external mode simulation, the block must use the `general` realization.

## Parameter Structures

As described in “Organize Data into Structures in Generated Code” on page 33-201, you can create structures of parameter data in the generated code.

- If a parameter structure is tunable, the numeric fields of the structure are tunable in the generated code. However, if a field contains a nontunable entity, such as a multidimensional array, the structure fields are not tunable.

- You cannot declare individual substructures or fields within a parameter structure as tunable. You cannot use a `Simulink.Parameter` object as the value of a structure field. Instead, you must store the entire structure in the parameter object.

## Code Generation of Parameter Objects With Expression Values

As described in “Set Variable Value by Using a Mathematical Expression” (Simulink), you can set the value of a `Simulink.Parameter` object to an expression involving other MATLAB variables or parameter objects. When you generate code from a model that uses such a parameter object, to achieve your goal, use the information in the table.

| Goal                                                                                                                                                          | Technique and More Information                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generate code without Embedded Coder.                                                                                                                         | <p>For the parameter object that uses the expression, apply an available storage class (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder)).</p> <p>For the parameter objects used in the expression, apply only the storage class <code>Auto</code>.</p>                                                                                                                      |
| Generate code that defines a global variable and initializes it by using an expression involving system constants and other macros (requires Embedded Coder). | See “Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)” on page 33-148.                                                                                                                                                                                                                                                                                                                             |
| Generate code that defines a macro whose value is an expression involving other macros (requires Embedded Coder).                                             | <p>For the parameter object that uses the expression, apply a storage class that yields a macro in the generated code, such as <code>Define</code> (see “Macro Definitions (#define)” on page 24-70).</p> <p>For the parameter objects used in the expression, apply storage classes that yield imported macros. For example, use the storage class <code>ImportedDefine</code>. Your external code must define these macros.</p> |

### Considerations and Limitations

- To avoid errors that prevent code generation, if you apply a storage class other than `Auto` to the dependent parameter object (which uses the expression as its value), the

parameter objects used in the expression must use either `Auto` or a storage class that yields a macro in the generated code.

- You cannot set the value of a parameter object that represents a symbolic dimension (see “Implement Dimension Variants for Array Sizes in Generated Code” on page 25-2) to an expression.
- With Embedded Coder, you can generate code that preserves the expression, but only for the purpose of statically initializing the value of a global variable or macro that corresponds to the dependent parameter object. Follow the guidelines in “Expression Preservation” (Simulink Coder).

## Expression Preservation

If you want Embedded Coder to preserve expressions in the generated code, adhere to these restrictions and guidelines.

- The dependent parameter object must use a storage class other than `Auto`. For example, to generate a global variable and initialize it by using the expression, use `ExportedGlobal` or `ExportToFile`.
- The parameter objects used in the expression must:
  - Use a storage class that yields a macro in the generated code, such as `Define`.
  - Have scalar, real values if the expression uses operators.
- The expression can use only these operators (in MATLAB syntax):
  - Mathematical: `+`, `-`, `*`
  - Relational: `==`, `~=`, `<`, `>`, `<=`, `>=`
- These data typing guidelines apply:
  - If possible, for a parameter object used in an expression, leave the `DataType` property at the default value, `auto`.

To use a value other than `auto`, you must set the `DataType` property of the object that uses the expression to the same value. Otherwise, the code generator does not preserve the expression.

- If you want to use a parameter object in multiple different expressions, and the dependent parameter objects have different data types, leave the `DataType` property of the independent object at the default value, `auto`. In the generated code, the value of the macro is expressed as a floating-point number (with effective

data type `double`), and the code initializes the dependent parameters by typecasting the result of each expression.

## Specify Instance-Specific Parameter Values for Reusable Referenced Model

When you use model referencing to break a large system into components, each component is a separate model. You can reuse a component by referring to it with multiple Model blocks. Each Model block is an instance of the component. You can then configure a block parameter (such as the **Gain** parameter of a Gain block) to use either the same value or a different value for each instance of the component. To use different values, create and use a model argument to set the value of the block parameter.

When you generate code from a model hierarchy that uses model arguments, the arguments appear in the code as formal parameters of the referenced model entry-point functions, such as the output (`step`) function. The generated code then passes the instance-specific parameter values, which you specify in each Model block, to the corresponding function calls.

Whether you use or do not use model arguments, you can use storage classes to configure block parameters to appear in the generated code as tunable global variables. You can also use storage classes to generate tunable model argument values, which the generated code stores in memory and passes to the function calls. You can then change the values during execution.

### Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments

Configure a referenced model to accept parameter data through formal parameters of the generated model entry-point function. This technique enables you to specify a different parameter value for each instance (Model block) of the referenced model.

#### Configure Referenced Model to Use Model Arguments

Create the model `ex_arg_code_ref`. This model represents a reusable algorithm.

```
open_system('ex_arg_code_ref')
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, in the data table, use the **Data Type** column to set the data type of the Inport block to **single**. Due to data type inheritance, the other signals in the model use the same data type.

Select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to gainArg.

Next to gainArg, click the action button  and select **Create**.

In the Create New Data dialog box, set **Value** to Simulink.Parameter and **Location** to Model Workspace. Click **Create**.

In the property dialog box, set **Value** to a number, for example, 3.17. Click **OK**.

Use the Model Data Editor to set the **Numerator** parameter by using a Simulink.Parameter object named coeffArg whose value is 1.05. As with gainArg, store the parameter object in the model workspace.

In the Model Data Editor, click the **Show/refresh additional information** button.

Use the **Filter contents** box to find each parameter object (gainArg and coeffArg). For each object, select the check box in the **Argument** column.

The screenshot shows the 'Model Data' window with the 'Parameters' tab selected. The 'Design' dropdown is set to 'Design'. The workspace is 'model workspace'. The table below lists the parameters:

| Source          | Name     | Value | Data Type | Min | Max | Dimensions | Unit | Argument                            |
|-----------------|----------|-------|-----------|-----|-----|------------|------|-------------------------------------|
| Model Workspace | coeffArg | 1.05  | auto      | []  | []  | [1 1]      |      | <input checked="" type="checkbox"/> |
| Model Workspace | gainArg  | 3.17  | auto      | []  | []  | [1 1]      |      | <input checked="" type="checkbox"/> |

Save the `ex_arg_code_ref` model.

Alternatively, at the command prompt, you can use these commands to configure the blocks and the parameter objects:

```
set_param('ex_arg_code_ref/In1', 'OutDataTypeStr', 'single')

set_param('ex_arg_code_ref/Gain', 'Gain', 'gainArg')
modelWorkspace = get_param('ex_arg_code_ref', 'ModelWorkspace');
assignin(modelWorkspace, 'gainArg', Simulink.Parameter(3.17));

set_param('ex_arg_code_ref/Discrete Filter', 'Numerator', 'coeffArg')
assignin(modelWorkspace, 'coeffArg', Simulink.Parameter(1.05));

set_param('ex_arg_code_ref', 'ParameterArgumentNames', 'coeffArg,gainArg')

save_system('ex_arg_code_ref')
```

### Specify Instance-Specific Parameter Values in Model Blocks

Create the model `ex_arg_code_ref`. This model uses multiple instances (Model blocks) of the reusable algorithm.

```
open_system('ex_arg_code')
```

In the model, open the Model Data Editor **Parameters** tab (**View > Model Data Editor**). The Model Data Editor shows four rows that correspond to the model arguments, `coeffArg` and `gainArg`, that you can specify for the two Model blocks.

Use the Model Data Editor to set values for the model arguments. For example, use the values in the figure.

| Model Data                                                                                   |                       |       |           |     |     |            |      |          |  |
|----------------------------------------------------------------------------------------------|-----------------------|-------|-----------|-----|-----|------------|------|----------|--|
| Inports/Outports    Signals    Data Stores    States    Parameters                           |                       |       |           |     |     |            |      |          |  |
| Design <input type="button" value="Refresh"/> <input type="button" value="Filter contents"/> |                       |       |           |     |     |            |      |          |  |
| Source                                                                                       | Name                  | Value | Data Type | Min | Max | Dimensions | Unit | Argument |  |
| Model                                                                                        | <code>coeffArg</code> | 0.98  | —         | —   | —   | —          | —    | —        |  |
| Model                                                                                        | <code>gainArg</code>  | 2.98  | —         | —   | —   | —          | —    | —        |  |
| Model1                                                                                       | <code>coeffArg</code> | 1.11  | —         | —   | —   | —          | —    | —        |  |
| Model1                                                                                       | <code>gainArg</code>  | 3.34  | —         | —   | —   | —          | —    | —        |  |

Alternatively, at the command prompt, you can use these commands to set the values:

```
set_param('ex_arg_code/Model', 'ParameterArgumentValues', ...
    struct('coeffArg', '0.98', 'gainArg', '2.98'))
```

```
set_param('ex_arg_code/Model1', 'ParameterArgumentValues', ...
    struct('coeffArg', '1.11', 'gainArg', '3.34'))
```

Generate code from the top model.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code_ref.c` defines the referenced model entry-point function, `ex_arg_code_ref`. The function has two formal parameters, `rtp_coeffArg` and `rtp_gainArg`, that correspond to the model arguments, `coeffArg` and `gainArg`. The formal parameters use the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
/* Output and update for referenced model:
   'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1,
                    real32_T *rty_Out1,
                    DW_ex_arg_code_ref_f_T *localDW,
                    real32_T rtp_coeffArg,
                    real32_T rtp_gainArg)
```

The file `ex_arg_code.c` contains the definition of the top model entry-point function `ex_arg_code`. This function calls the referenced model entry-point function `ex_arg_code_ref` and uses the model argument values that you specified (such as 1.11 and 3.34) as the values of `rtp_coeffArg` and `rtp_gainArg`.

```
/* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
               &(ex_arg_code_DW.Model_InstanceData.rtdw), 0.98F, 2.98F);

/* ModelReference: '<Root>/Model1' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
               &(ex_arg_code_DW.Model1_InstanceData.rtdw), 1.11F, 3.34F);
```

The formal parameters use the data type `real32_T` (`single`).

- The block parameters in `ex_arg_code_ref` determine their data types through internal rules. For example, in the Gain block dialog box, on the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default). In this case, the internal rule chooses the same data type as the input and output signals, `single`.
- The model arguments in the model workspace use context-sensitive data typing because the value of the `DataType` property is set to `auto` (the default). With this setting, the model arguments use the same data type as the block parameters, `single`.
- The formal parameters in the generated code use the same data type as the model arguments, `single`.

## Generate Tunable Argument Values

You can configure the instance-specific values in the Model blocks to appear in the generated code as tunable global variables. This technique enables you to store the parameter values for each instance in memory and tune the values during code execution.

In the top model `ex_arg_code`, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the values of the model arguments according to this figure.

|                                                                                   | Source ^ | Name     | Value         |
|-----------------------------------------------------------------------------------|----------|----------|---------------|
|  | Model    | coeffArg | coeffForInst1 |
|  | Model    | gainArg  | gainForInst1  |
|  | Model1   | coeffArg | coeffForInst2 |
|  | Model1   | gainArg  | gainForInst2  |

```
set_param('ex_arg_code/Model', 'ParameterArgumentValues', ...
    struct('coeffArg', 'coeffForInst1', 'gainArg', 'gainForInst1'))
set_param('ex_arg_code/Model1', 'ParameterArgumentValues', ...
    struct('coeffArg', 'coeffForInst2', 'gainArg', 'gainForInst2'))
```

View the contents of the `ex_arg_code_ref` model workspace in Model Explorer. On the **Modeling** tab, click **Model Explorer**.

Copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace to the base workspace.

Rename `gainArg` as `gainForInst1`. Rename `coeffArg` as `coeffForInst1`.

```
gainForInst1 = getVariable(modelWorkspace, 'gainArg');
gainForInst1 = copy(gainForInst1);
coeffForInst1 = getVariable(modelWorkspace, 'coeffArg');
coeffForInst1 = copy(coeffForInst1);
```

Copy `gainForInst1` and `coeffForInst1` as `gainForInst2` and `coeffForInst2`.

```
gainForInst2 = copy(gainForInst1);
coeffForInst2 = copy(coeffForInst1);
```

Set the instance-specific parameter values by using the `Value` property of the parameter objects in the base workspace.

```
gainForInst1.Value = 2.98;
coeffForInst1.Value = 0.98;
```

```
gainForInst2.Value = 3.34;
coeffForInst2.Value = 1.11;
```

In the Model Data Editor for the top model `ex_arg_code`, click the **Show/refresh additional information** button.

Set the **Change view** drop-down list to Code.

For the new parameter objects, set the value in the **Storage Class** column to `ExportedGlobal`. This setting causes the parameter objects to appear in the generated code as tunable global variables.

```
gainForInst1.StorageClass = 'ExportedGlobal';
coeffForInst1.StorageClass = 'ExportedGlobal';
gainForInst2.StorageClass = 'ExportedGlobal';
coeffForInst2.StorageClass = 'ExportedGlobal';
```

Generate code from the top model.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code.c` defines the global variables that correspond to the parameter objects in the base workspace.

```
/* Exported block parameters */
real32_T coeffForInst1 = 0.98F;          /* Variable: coeffForInst1
                                         * Referenced by: '<Root>/Model'
                                         */
real32_T coeffForInst2 = 1.11F;        /* Variable: coeffForInst2
                                         * Referenced by: '<Root>/Model1'
                                         */
real32_T gainForInst1 = 2.98F;         /* Variable: gainForInst1
                                         * Referenced by: '<Root>/Model'
                                         */
real32_T gainForInst2 = 3.34F;        /* Variable: gainForInst2
                                         * Referenced by: '<Root>/Model1'
                                         */
```

In each call to `ex_arg_code_ref`, the top model algorithm uses the global variables to set the values of the formal parameters.

```

/* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
               &(ex_arg_code_DW.Model_InstanceData.rtdw), coeffForInst1,
               gainForInst1);

/* ModelReference: '<Root>/Model1' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
               &(ex_arg_code_DW.Model1_InstanceData.rtdw), coeffForInst2,
               gainForInst2);

```

The global variables in the generated code use the data type `real32_T` (single).

- The parameter objects in the base workspace use context-sensitive data typing because the `DataType` property is set to `auto` (the default). With this setting, the parameter objects in the base workspace use the same data type as the model arguments, `single`.
- The global variables in the generated code use the same data type as the parameter objects in the base workspace.

### Group Multiple Model Arguments into Single Structure

Use the Model Explorer to copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace into the base workspace.

```

temp = getVariable(modelWorkspace, 'gainArg');
gainArg = copy(temp);
temp = getVariable(modelWorkspace, 'coeffArg');
coeffArg = copy(temp);

```

At the command prompt, combine these two parameter objects into a structure, `structArg`.

```

structArg = Simulink.Parameter(struct('gain', gainArg.Value, ...
    'coeff', coeffArg.Value));

```

Use the Model Explorer to move `structArg` into the model workspace.

```

assignin(modelWorkspace, 'structArg', copy(structArg));
clear structArg gainArg coeffArg

```

In the **Contents** pane, configure `structArg` as the only model argument.

```
set_param('ex_arg_code_ref', 'ParameterArgumentNames', 'structArg')
```

|  | Name      | Value        | Argument                            | DataType | Dimension |
|--|-----------|--------------|-------------------------------------|----------|-----------|
|  | coeffArg  | 1.05         | <input type="checkbox"/>            | auto     | [1 1]     |
|  | gainArg   | 3.17         | <input type="checkbox"/>            | auto     | [1 1]     |
|  | structArg | <1x1 struct> | <input checked="" type="checkbox"/> | struct   | [1 1]     |

In the `ex_arg_code_ref` model, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the value of the **Gain** parameter to `structArg.gain` and the value of the **Numerator** parameter to `structArg.coeff`. Save the model.

```
set_param('ex_arg_code_ref/Gain', 'Gain', 'structArg.gain')
set_param('ex_arg_code_ref/Discrete Filter', ...
    'Numerator', 'structArg.coeff')
```

```
save_system('ex_arg_code_ref')
```

At the command prompt, combine the four parameter objects in the base workspace into two structures. Each structure stores the parameter values for one instance of `ex_arg_code_ref`.

```
structForInst1 = Simulink.Parameter(struct('gain', gainForInst1.Value, ...
    'coeff', coeffForInst1.Value));

structForInst2 = Simulink.Parameter(struct('gain', gainForInst2.Value, ...
    'coeff', coeffForInst2.Value));
```

In the top model `ex_arg_code`, set the **Change view** drop-down list to **Design**. Use the Model Data Editor to set the argument values according to this figure.

| Model Data       |           |                |             |        |            |
|------------------|-----------|----------------|-------------|--------|------------|
| Inports/Outports |           | Signals        | Data Stores | States | Parameters |
| Design           |           |                |             |        |            |
| Source           | Name      | Value          |             |        |            |
| Model            | structArg | structForInst1 |             |        |            |
| Model1           | structArg | structForInst2 |             |        |            |

```
set_param('ex_arg_code/Model', 'ParameterArgumentValues', ...
    struct('structArg', 'structForInst1'))
set_param('ex_arg_code/Model1', 'ParameterArgumentValues', ...
    struct('structArg', 'structForInst2'))
```

Click the **Show/refresh additional information** button.

For the new parameter objects `structForInst1` and `structForInst2`, use the Model Data Editor to apply the storage class `ExportedGlobal`.

```
structForInst1.StorageClass = 'ExportedGlobal';
structForInst2.StorageClass = 'ExportedGlobal';
```

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1.Value);
```

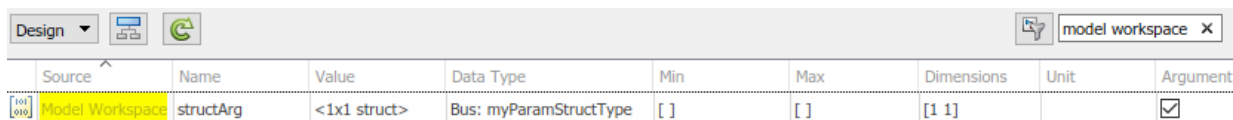

Rename the bus object as `myParamStructType` by copying it.

```
myParamStructType = copy(slBus1);
```

In the Model Data Editor for `ex_arg_code`, set **Change view** to **Design**. Use the **Data Type** column to set the data type of `structForInst1` and `structForInst2` to `Bus: myParamStructType`.

```
structForInst1.DataType = 'Bus: myParamStructType';
structForInst2.DataType = 'Bus: myParamStructType';
```

In the Model Data Editor for `ex_arg_code_ref`, use the Model Data Editor to set the data type of `structArg` to `Bus: myParamStructType`.

| Source          | Name      | Value        | Data Type              | Min | Max | Dimensions | Unit | Argument                            |
|-----------------|-----------|--------------|------------------------|-----|-----|------------|------|-------------------------------------|
| Model Workspace | structArg | <1x1 struct> | Bus: myParamStructType | [ ] | [ ] | [1 1]      |      | <input checked="" type="checkbox"/> |

```
temp = getVariable(modelWorkspace, 'structArg');
temp = copy(temp);
temp.DataType = 'Bus: myParamStructType';
assignin(modelWorkspace, 'structArg', copy(temp));
```

Save the `ex_arg_code_ref` model.

```
save_system('ex_arg_code_ref')
```

When you use structures to group parameter values, you cannot take advantage of context-sensitive data typing to control the data types of the fields of the structures (for example, the fields of `structForInst1`). However, you can use the properties of the bus object to control the field data types.

At the command prompt, set the data type of the elements in the bus object to `single`. The corresponding fields in the structures (such as `structForInst1` and `structArg`) use the same data type.

```
myParamStructType.Elements(1).DataType = 'single';
myParamStructType.Elements(2).DataType = 'single';
```

Generate code from the top model `ex_arg_code`.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code_types.h` defines the structure type `myParamStructType`, which corresponds to the `Simulink.Bus` object.

```
typedef struct {
    real32_T gain;
    real32_T coeff;
} myParamStructType;
```

In the file `ex_arg_code_ref.c`, the referenced model entry-point function has a formal parameter, `rtp_structArg`, that corresponds to the model argument `structArg`.

```
/* Output and update for referenced model:
'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1,
```

```

real32_T *rty_Out1,
DW_ex_arg_code_ref_f_T *localDW,
const myParamStructType *rtp_structArg)

```

The file `ex_arg_code.c` defines the global structure variables that correspond to the parameter objects in the base workspace.

```

/* Exported block parameters */
myParamStructType structForInst1 = {
    2.98F,
    0.98F
} ;
/* Variable: structForInst1
 * Referenced by: '<Root>/Model'
 */

myParamStructType structForInst2 = {
    3.34F,
    1.11F
} ;
/* Variable: structForInst2
 * Referenced by: '<Root>/Model1'
 */

```

The top model algorithm in the file `ex_arg_code.c` passes the addresses of the structure variables to the referenced model entry-point function.

```

/* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1'
 * Output: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
                &(ex_arg_code_DW.Model_InstanceData.rtdw), &structForInst1);

/* ModelReference: '<Root>/Model1' incorporates:
 * Inport: '<Root>/In1'
 * Output: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
                &(ex_arg_code_DW.Model1_InstanceData.rtdw), &structForInst2);

```

## Control Data Types of Model Arguments and Argument Values

When you use model arguments, you can apply a data type to:

- The block parameters that use the arguments (for certain blocks, such as those in the Discrete library).
- The arguments in the referenced model workspace.

- The argument values that you specify in Model blocks.

To generate efficient code by eliminating unnecessary typecasts and C shifts, consider using inherited and context-sensitive data typing to match the data types.

- In the model workspace, use a MATLAB variable whose data type is `double` or a parameter object whose `DataType` property is set to `auto`. In this case, the variable or object uses the same data type as the block parameter.
- When you set the argument values in Model blocks, take advantage of context-sensitive data typing. To set an argument value, use an untyped value.
  - A literal number such as `15.23`. Do not use a typed expression such as `single(15.23)`.
  - A MATLAB variable whose data type is `double`.
  - A `Simulink.Parameter` object whose `DataType` property is set to `auto`.

In these cases, the number, variable, or object uses the same data type as the model argument in the referenced model workspace. If you also configure the model argument to use context-sensitive data typing, you can control the data types of the block parameter, the argument, and the argument value by specifying the type only for the block parameter.

For basic information about controlling parameter data types, see “Parameter Data Types in the Generated Code” on page 33-181.

### **Use Model Argument in Different Data Type Contexts**

If you use a model argument to set multiple block parameter values, and the data types of the block parameters differ, you cannot use context-sensitive data typing (`double` or `auto`) for the argument in the model workspace. You must explicitly specify a data type for the argument. For example, if the argument in the model workspace is a parameter object (such as `Simulink.Parameter`), set the `DataType` property to a value other than `auto`. For more information about this situation, see “Reuse Parameter Data in Different Data Type Contexts” on page 33-197.

In this case, you can continue to take advantage of context-sensitive data typing to control the data type of the argument values that you specify in Model blocks. Each argument value uses the data type that you specify for the corresponding argument in the model workspace.

## Configure Packaging of Parameter Arguments in Generated Code

When you create a reusable component as a referenced model, configure block parameters to use the same value for instances of the component or a different value for each instance.

To customize the implementation of parameter arguments in the generated code, you can configure the packaging of these parameters in the model where they are defined. Configure the default mapping and individual mapping for model parameter arguments by using one of these storage classes:

- **Auto** — The parameter appears as an individual model function argument in the generated code. If a block in the model does not reference the parameter, it can be optimized away by the code generator.
- **Model default** — Each instance of the parameter is allocated a piece of memory in a structure as defined by the code definition of the default storage class. Specify this default storage class through the model default mapping.
- **A structured storage class** — Each instance of the parameter is allocated a piece of memory in a structure as defined by the coder definition of that storage class.

If you use edit-time checking for code generation, you get an error for an invalid storage class.

For a parameter argument with a non-Auto storage class:

- On the Model block, you can specify the per-instance value as either a literal, a numeric MATLAB variable, or a `Simulink.Parameter` object.
- If the per-instance value is a `Simulink.Parameter` object, the object must have storage class `Auto`.
- If the per-instance value is a value expression, the evaluated value of the expression is used to statically initialize the parameter.

If you do not specify a default or individual storage class for a parameter argument, the code generator applies an internal storage class, `InstP`, to the parameter. The `InstP` storage class has these properties:

- Exported scope

- Type naming rule is  $\$R\_InstP\$M$
- Instance name is  $InstP\$R\$M$

## Code Generation Behavior

For single-instance referenced models, the parameter arguments reside in a standalone global structure. The top model defines the structure. The referenced model declares and uses the structure.

For multi-instance referenced models, the parameter arguments are part of a hierarchically nested structure that the top model declares and defines. The referenced model has access to its parameter values through a pointer in its self structure. The self structure points to a substructure of the structure that the top model defines.

For parameter arguments defined in the top model, if the argument does not have a storage class, it is inlined. If it has a storage class, the resulting code depends on the value of the **Code interface packaging** parameter:

- **Nonreusable function** — The parameter is generated in a structure defined in the top model.
- **Reusable function** — The parameter is generated in a structure passed as part of the first argument of the function.

To understand the behavior of instance-specific parameters in the generated code, define two model parameter arguments for a referenced model.

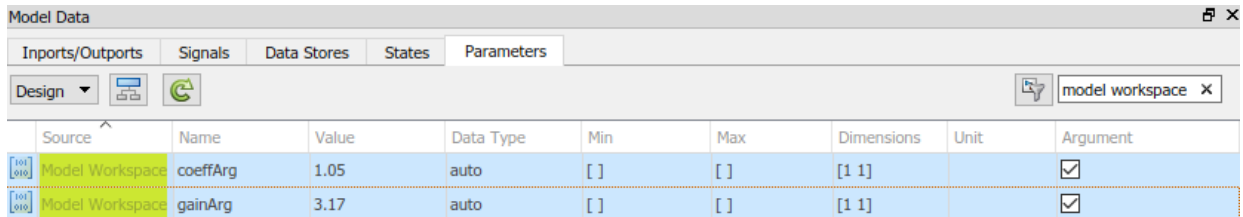

- 1 Open model `ex_arg_code_ref`.

- 2 On the **Modeling** tab, click **Model Data Editor**.

- 3 Select the **Parameters** tab.
- 4 In the model, select the Gain block.
- 5 In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `gainArg`.
- 6 Next to `gainArg`, click the action button  and select **Create**.
- 7 In the Create New Data dialog box, set **Value** to `Simulink.Parameter` and **Location** to `Model Workspace`. Click **Create**.
- 8 In the property dialog box, set **Value** to a number, for example, `3.17`. Click **OK**.
- 9 Use the Model Data Editor to set the **Numerator** parameter by using a `Simulink.Parameter` object named `coeffArg` whose value is `1.05`. As with `gainArg`, store the parameter object in the model workspace.
- 10 In the Model Data Editor, click the **Show/refresh additional information** button.
- 11 Use the **Filter contents** box to find each parameter object (`gainArg` and `coeffArg`). For each object, select the check box in the **Argument** column.

| Source          | Name     | Value | Data Type | Min | Max | Dimensions | Unit | Argument                            |
|-----------------|----------|-------|-----------|-----|-----|------------|------|-------------------------------------|
| Model Workspace | coeffArg | 1.05  | auto      | [ ] | [ ] | [1 1]      |      | <input checked="" type="checkbox"/> |
| Model Workspace | gainArg  | 3.17  | auto      | [ ] | [ ] | [1 1]      |      | <input checked="" type="checkbox"/> |

- 12 Save the `ex_arg_code_ref` model.

First consider the case where this model is configured to support only a single instance and the default mapping for model parameter arguments does not have a storage class. In the `ex_arg_code_ref.h` file, there is a type definition and a declaration for the instance-specific parameters.

```
/* instance parameters */
extern ex_arg_code_ref_InstP ex_arg_code_refrtInstP;
```

```

/* instance parameters, for model 'ex_arg_code_ref' */
typedef struct {
    real32_T coeffArg;          /* Variable: coeffArg
                               * Referenced by: synthesized block
                               */
    real32_T gainArg;          /* Variable: gainArg
                               * Referenced by: synthesized block
                               */
} ex_arg_code_ref_InstP;

```

When the top model references this model and supplies values for the instance-specific parameters, the code for the top model defines the instance-specific parameters by using the values provided by the top model.

```

/* Define buffer for instance parameters, Block: '<Root>/Model' */
ex_arg_code_ref_InstP ex_arg_code_refrtInstP = {
    1.98F,
    3.98F
};

```

Now consider if the referenced model is configured to support multiple instances. `ex_arg_code_ref.h` contains the same type definition as the single-instance, but the self for the model also contains a pointer to an instance of that data structure. There is no pointer declaration to a standalone global variable of that structure.

```

/* instance parameters, for model 'ex_arg_code_ref' */
typedef struct {
    real32_T coeffArg;          /* Variable: coeffArg
                               * Referenced by: synthesized block
                               */
    real32_T gainArg;          /* Variable: gainArg
                               * Referenced by: synthesized block
                               */
} ex_arg_code_ref_InstP;

/* Real-time Model Data Structure */
struct ex_arg_code_ref_tag_RTM {
    ex_arg_code_ref_InstP *ex_arg_code_ref_InstP_ref;
};

```

The top model declares a parent structure, including an instance of this substructure, and initializes the pointer in the self structure for the referenced model.

```

/* Assign pointer for instance parameters, Block: '<Root>/Model' */
ex_arg_code_DW->Model_InstanceData.rtm.ex_arg_code_ref_InstP_ref =
    &ex_arg_code_M->ex_arg_code_InstP_ref->InstP_Model;

/* Assign pointer for instance parameters, Block: '<Root>/Model1' */
ex_arg_code_DW->Model1_InstanceData.rtm.ex_arg_code_ref_InstP_ref =
    &ex_arg_code_M->ex_arg_code_InstP_ref->InstP_Model1;
}

```

## Limitations

When you configure an instance-specific parameter for code generation, these limitations apply:

- The default mapping for model parameter arguments cannot be reused for model parameters or external parameter objects.
- At the time of code generation, you must provide a value for each instance of the parameter within the model reference hierarchy. Failure to supply a value results in a code generation error.
- Instance-specific parameter values must be finite.
- Parameter arguments with a non-`Auto` storage class are not supported for C++ code generation with a C++ class code interface.

## Parameter Data Types in the Generated Code

The data type of a block parameter (such as the **Gain** parameter of a Gain block), numeric MATLAB variable, or `Simulink.Parameter` object determines the data type that the corresponding entity in the generated code uses (for example, a global variable or an argument of a function). To generate more efficient code, you can match parameter data types with signal data types or store parameters in smaller data types.

For basic information about setting block parameter data types in a model, see “Control Block Parameter Data Types” (Simulink).

### Significance of Parameter Data Types

The data type that a block parameter, MATLAB variable, or parameter object uses determines the data type that the generated code uses to store the parameter value in memory. For example:

- If you set the model configuration parameter **Default parameter behavior** (see “Default parameter behavior” (Simulink Coder)) to `Tunable`, the **Gain** parameter of a Gain block appears in the generated code as a field of a global structure that stores parameter data. If you apply the data type `single` to the block parameter in the model, the structure field in the code uses the corresponding data type, `real32_T`.
- If you apply the storage class `ExportedGlobal` to a `Simulink.Parameter` object, the object appears in the generated code as a separate global variable. If you set the `DataType` property of the object to `int8`, the global variable in the code uses the corresponding data type, `int8_T`.
- If you configure a `Simulink.Parameter` object in a model workspace as a model argument, the object appears in the generated code as a formal parameter (argument) of a model entry-point function, such as the `step` function. The `DataType` property of the object determines the data type of the formal parameter.

Other than determining the data type that the generated code uses to store parameter values in memory, the data type of a parameter, variable, or object can also:

- Cause the block to cast the value of the parameter prior to code generation. The cast can result in overflow, underflow, or quantization.
- Cause the generated code to include extra code, for example saturation code.

## Typecasts Due to Parameter Data Type Mismatches

When the data types of block parameters, workspace variables, and signals differ, blocks can use typecasts to reconcile the data type mismatches. These typecasts can cause the generated code algorithm, including the model `step` function, to include explicit casts to reconcile mismatches in storage data type and C bit shifts to reconcile mismatches in fixed-point scaling.

Parameter data type mismatches can occur when:

- The data type that you specify for a MATLAB variable or parameter object (`Simulink.Parameter`) differs from the data type of a block parameter. The block parameter typecasts the value of the variable or object.
- The data type that you specify for an initial value differs from the data type of the initialized signal or state.
- The data type that you specify for a block parameter differs from the data type of the signal or signals that the parameter operates on. Some blocks typecast the parameter to perform the operation. For example, the Gain block performs this typecast.

If you configure a variable or object to use bias or fractional fixed-point slope, the block parameter cannot perform the typecast. In this case, you must match the data type of the variable or parameter object with the data type of the block parameter. Use one of these techniques:

- Use context-sensitive data typing for the variable or parameter object. For a MATLAB variable, use a `double` number to set the value of the variable. For a parameter object, set the `DataType` property to `auto`.
- Use a `Simulink.AliasType` or `Simulink.NumericType` object to set the data type of the block parameter and the data type of a parameter object.

Use this technique when you cannot rely on context-sensitive data typing, for example, when you use the field of a structure to set the value of the block parameter.

- Manually specify the same data type for the block parameter and the variable or parameter object.

Use this technique to reduce the dependence of the model on inherited and context-sensitive data types and on external variables and objects.

For blocks that access parameter data through pointer or reference in the generated code, if you specify different data types for the workspace variable and the block

parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. Note, that an implicit cast requires a data copy which could significantly increase RAM consumption and slow down code execution speed for large data sets. For example, Lookup Table blocks often access large vectors or matrices through pointer or reference in the generated code.

For information about matching parameter data types when you use model arguments, see “Control Data Types of Model Arguments and Argument Values” on page 33-172.

### **Detect Downcast and Loss of Precision due to Data Type Mismatches**

You can configure diagnostic configuration parameters to detect unintentional data type mismatches that result in quantization and loss of parameter precision. See “Model Configuration Parameters: Data Validity Diagnostics” (Simulink).

## **Considerations for Other Modeling Patterns**

When you use specific modeling patterns and constructs such as fixed-point data types, parameter structures, and lookup table objects, use different techniques to control parameter data types.

- “Tunable Parameters and Best-Precision Fixed-Point Scaling” on page 33-183
- “Control Data Types of Structure Fields” on page 33-184
- “Control Data Types of Lookup Table Objects” on page 33-184
- “Data Typing for Expressions in Parameter Objects” on page 33-185

### **Tunable Parameters and Best-Precision Fixed-Point Scaling**

To apply best-precision fixed-point scaling to a tunable block parameter or parameter object, you can use the Fixed-Point Tool to autoscale an entire system or use the Data Type Assistant to configure individual parameters or objects. See “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” (Simulink).

If a tunable parameter uses best-precision fixed-point scaling, Simulink chooses a data type based on the minimum and maximum values that you specify for the parameter (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)). You can specify these values in the block dialog box that uses the parameter or in the properties of a `Simulink.Parameter` object.

If you do not specify a minimum or maximum, Simulink chooses a data type based on the value of the parameter. The chosen scaling might restrict the range of possible tuning

values. Therefore, it is a best practice to specify minimum and maximum values for each tunable parameter.

A tunable parameter can use best-precision scaling even if you do not specify it in the parameter data type. For example, the Gain block can choose a best-precision scaling if the **Parameter data type** in the block dialog box is set to `Inherit: Inherit via internal rule`. This setting is the default for the block.

### **Control Data Types of Structure Fields**

When you use a structure as the value of a block parameter (for example to initialize a bus signal), or when you organize multiple block parameter values into a single structure, you can create a `Simulink.Bus` object to use as the data type of a `Simulink.Parameter` object. You can then control the data types of individual fields in the structure. See “Control Field Data Types and Characteristics by Creating Parameter Object” (Simulink) and “Control Data Types of Initial Condition Structure Fields” (Simulink).

### **Control Data Types of Lookup Table Objects**

When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to store table and breakpoint data for a lookup table block, to control the data types of the table and breakpoint data, use one of these techniques:

- Set the `Value` property of the embedded `Simulink.lookuptable.Table` and `Simulink.lookuptable.Breakpoint` objects by using untyped expressions such as `[1 2 3]`, which returns a `double` vector. To control the data type, set the `DataType` property to a value other than `auto`.

Use this technique to separate the value of the table or breakpoint data from the data type, which can improve readability and understanding of your design. You can then use a `Simulink.NumericType` or `Simulink.AliasType` object to:

- Customize the name of the data type in the generated code.
- Match the data type of the table or breakpoint data with the data type of a signal in the model.
- Set the `Value` property of the embedded objects by using typed expressions such as `single([1 2 3])`. To use a fixed-point data type, set the `Value` property with an `fi` object.

Set the `DataType` property of the embedded objects to the default value, `auto`. The table and breakpoint data then acquire the data type that you use to set the `Value` property.

Use this technique to store the data type information in the `Value` property, which can simplify the way you interact with the `Simulink.LookupTable` and `Simulink.Breakpoint` objects. You can leave the `DataType` property at the default value.

When you later change the breakpoint or table data in the `Value` property, preserve the data type information by using a typed expression. Alternatively, if you use a command at the command prompt or a script to change the data, to avoid using a typed expression, use subscripted assignment, `(:)`.

```
myLUTObject.Table.Value(:) = [4 5 6];
```

When you change the data stored in the `Value` property, if you do not use a typed expression or subscripted assignment, you lose the data type information.

When blocks in a subsystem use `Simulink.LookupTable` or `Simulink.Breakpoint` objects, you cannot set data type override (see “Control Fixed-Point Instrumentation and Data Type Override” (Simulink)) only on the subsystem. Instead, set data type override on the entire model.

## Data Typing for Expressions in Parameter Objects

You can use an expression to set the value of a parameter object (such as `Simulink.Parameter`). The expression encodes mathematical relationships between different objects. When you use this technique, different data typing rules apply. See “Set Variable Value by Using a Mathematical Expression” (Simulink).

- “Control Signal Data Types” (Simulink)
- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-68

## Generate Efficient Code by Specifying Data Types for Block Parameters

To generate more efficient code, match the data types of block parameters (such as the **Gain** parameter of a Gain block) with signal data types. Alternatively, you can store parameters in smaller data types.

### Eliminate Unnecessary Typecasts and Shifts by Matching Data Types

These examples show how to generate efficient code by configuring a block parameter to use the same data type as a signal that the block operates on.

#### Store Data Type Information in Model

Open the example model `rtwdemo_basicsc` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_basicsc')
set_param('rtwdemo_basicsc','HideAutomaticNames','off')
open_system('rtwdemo_basicsc')
```

Identify the Gain block in the model, which uses the base workspace variable `K1` to set the value of the **Gain** parameter. The input signal of this block uses the data type `single`.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block. In the Model Data Editor, the **Data Type** column shows that the data type of the **Gain** parameter of the block is set to **Inherit: Same as input**. With this setting, the **Gain** parameter of this block uses the same data type as the input signal.

In the Model Data Editor, set the **Change view** drop-down list to **Code**.

Update the block diagram. Now, in the Model Data Editor, the data table shows rows that correspond to workspace variables that the model uses, including `K1`.

In the Model Data Editor, find the row that corresponds to K1. For that row, in the **Storage Class** column, select `Convert to parameter object`. Simulink converts K1 to a `Simulink.Parameter` object.

Use the **Storage Class** column to apply the storage class `ExportedGlobal`. With this setting, the object appears in the generated code as a global variable.

In the Model Data Editor, set **Change view** to `Design`.

In the data table, for the row that represents K1, in the **Data Type** column, select `auto`. With this setting, the parameter object acquires its data type from the block parameters that use the object (in this case, the **Gain** block parameter).

Alternatively, to create and configure the object, use these commands at the command prompt:

```
K1 = Simulink.Parameter(2);
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated file `rtwdemo_basicsc.c` defines the global variable K1 by using the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)

/* Exported block parameters */
real32_T K1 = 2.0F;                                /* Variable: K1
```

The generated code algorithm in the model `step` function uses K1 directly without typecasting.

```
rtwdemodbtype(file,' rtwdemo_basicsc_DW.X = K1',...
' rtCP_Table1_bp01Data, rtCP_Table1_tableData,',1,1)

rtwdemo_basicsc_DW.X = K1 * look1_iflf_binlx(rtwdemo_basicsc_U.input2,
rtCP_Table1_bp01Data, rtCP_Table1_tableData, 10U);
```

On the Model Data Editor **Parameters** tab, you can optionally set the data type of the **Gain** block parameter to `Inherit: Inherit via internal rule` (the default). In

this case, the block parameter chooses the same data type as the input signal, `single`. However, when you use `Inherit: Inherit` via internal rule, under other circumstances (for example, when you use fixed-point data types), the block parameter might choose a different data type.

### Store Data Type Information in Parameter Object

When you use a `Simulink.Parameter` object to export or import parameter data from the generated code to your external code, for example by applying the storage class `ImportedExtern`, you can specify data type information in the parameter object. To match the data type of the parameter object with a signal data type, create a `Simulink.NumericType` or `Simulink.AliasType` object. You can strictly control the data type that the parameter object uses in the generated code, eliminating the risk that Simulink chooses a different data type when you make changes to the model.

At the command prompt, create a `Simulink.NumericType` object that represents the data type `single`.

```
myType = Simulink.NumericType;
myType.DataTypeMode = 'Single';
```

Use the Model Data Editor **Data Type** column to set these data types to `myType`:

- The parameter object. Use the **Parameters** tab.
- The Inport block named `In2`. Use the **Inports/Outports** tab. Due to data type propagation, the input signal of the `Gain` block also uses `myType`.

Use the Model Data Editor **Parameters** tab to set the data type of the **Gain** block parameter to `Inherit: Inherit` from `'Gain'`. Use this data type object as the data type of the parameter object.

Alternatively, to configure the object and the blocks, use these commands at the command prompt:

```
K1.DataType = 'myType';
set_param('rtwdemo_basicsc/In2','OutDataTypeStr','myType')
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr','Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The global variable K1 continues to use the data type `real32_T`.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)

/* Exported block parameters */
real32_T K1 = 2.0F;                               /* Variable: K1
```

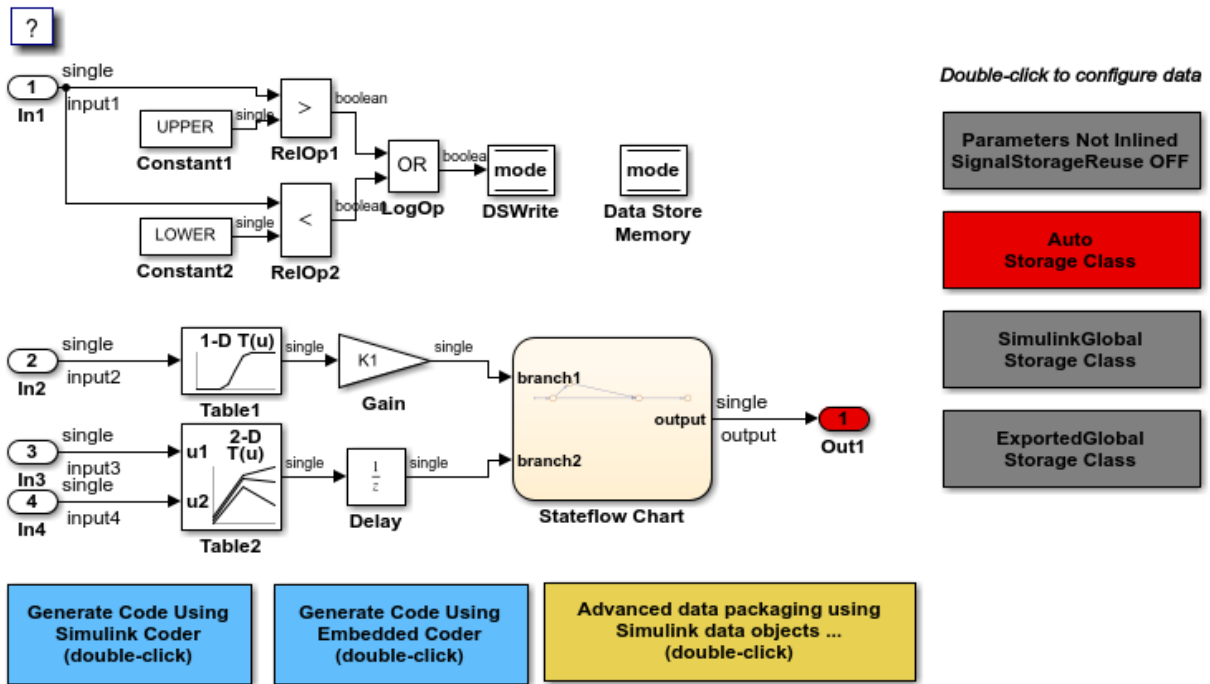

## Reduce Memory Consumption by Storing Parameter Value in Small Data Type

When you use a parameter object (for example, `Simulink.Parameter`) to set block parameter values, you can configure the object to appear in the generated code as a tunable global variable. By default, the parameter object and the corresponding global variable typically uses the same data type as the signal or signals on which the block operates. For example, if the input signal of a Gain block uses the data type `int16`, the parameter object typically use the same data type. To reduce the amount of memory that this variable consumes, specify that the variable use a smaller integer data type such as `int8`.

### Store Parameter Value in Integer Data Type

Run the script `prepare_rtwdemo_basicsc_2`, which prepares the model `rtwdemo_basicsc` for this example.

```
run(fullfile(matlabroot,'examples','simulinkcoder',...
    'main','prepare_rtwdemo_basicsc_2'))
```

Copyright 1994-2019 The MathWorks, Inc.

Many of the signals in the model use the data type `single`.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Click the **Show/refresh additional information** button.

Next to the **Filter contents** box, activate the **Filter using selection** button.

In the model, click the Gain block. The Model Data Editor shows one row that corresponds to the **Gain** parameter of the block and one row that corresponds to the MATLAB variable `K1`, which sets the parameter value to 2. `K1` resides in the base workspace.

In the Model Data Editor, set the **Change view** drop-down list to **Code**.

In the data table, for the row that corresponds to K1, in the **Storage Class** column, from the drop-down list, select **Convert to parameter object**. Simulink converts K1 to a `Simulink.Parameter` object.

```
K1 = Simulink.Parameter(K1);
```

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to K1. With this setting, K1 appears in the generated code as a global variable.

```
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

In the Model Data Editor, set **Change view** to **Design** and use the **Data Type** column to apply the data type `int8` to K1.

```
K1.DataType = 'int8';
```

For the row that represents the **Gain** block parameter, in the **Data Type** column, set the drop-down list to **Inherit: Inherit from 'Gain'**. With this setting, the **Gain** parameter of the block inherits the `int8` data type from the parameter object.

```
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr',...  
          'Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc  
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated file `rtwdemo_basicsc.c` defines the global variable K1 by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');  
rtwdemodbtype(file,'/* Exported block parameters */','int8_T K1 = 2;',1,1)
```

```
/* Exported block parameters */  
int8_T K1 = 2;                               /* Variable: K1
```

The code algorithm in the model step function uses K1 to calculate the output of the Gain block. The algorithm casts K1 to the data type `real32_T` (single) because the signals involved in the calculation use the data type `real32_T`.

```
rtwdemodbtype(file,' rtwdemo_basicsc_DW.X =','10U;',1,1)
```

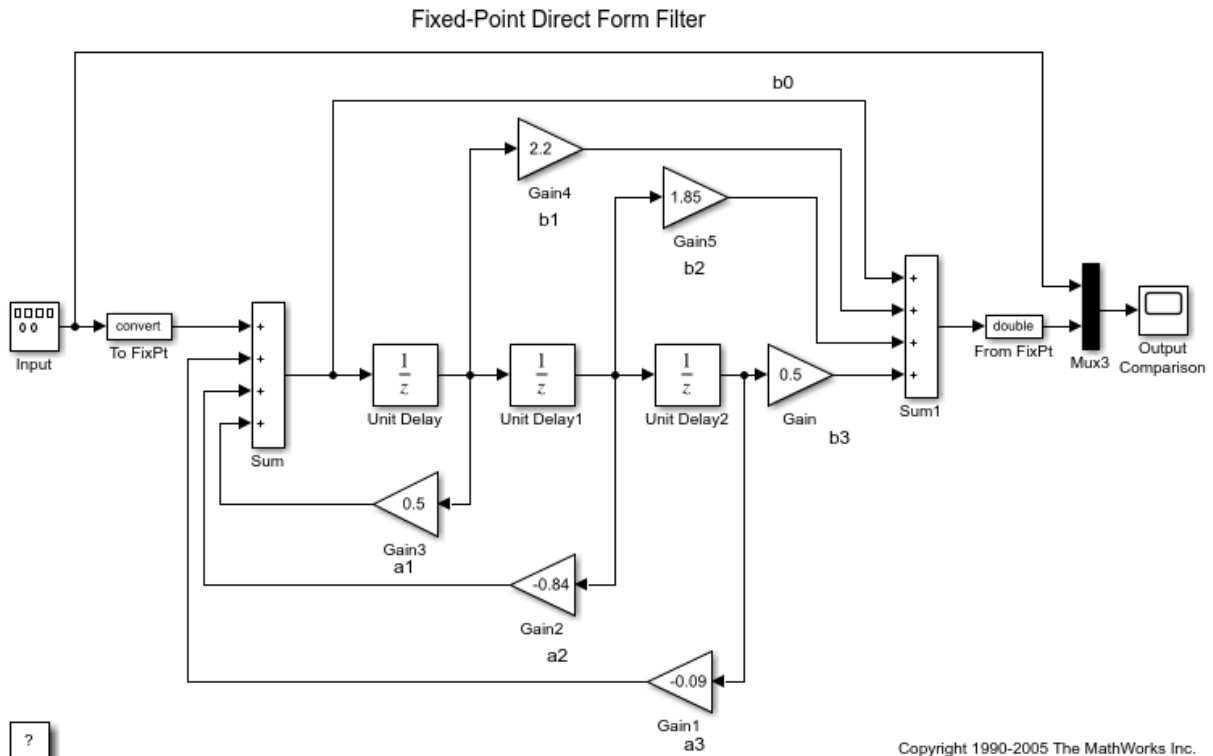

```
rtwdemo_basicsc_DW.X = (real32_T)K1 * look1_iflf_binlx  
    (rtwdemo_basicsc_U.input2, rtCP_Table1_bp01Data, rtCP_Table1_tableData,  
    10U);
```

### Store Fixed-Point Parameter Value in Smaller Integer Data Type

Suppose you configure the signals in your model to use fixed-point data types. You want a gain parameter to appear in the generated code as a tunable global variable. You know the range of real-world values that you expect the parameter to assume (for example, between 0 and 4). If you can meet your application requirements despite reduced precision, you can reduce memory consumption by configuring the parameter to use a different data type than the input and output signals of the block.

Open the example model `fxpdemo_direct_form2` and configure it to show the generated names of blocks.

```
load_system('fxpdemo_direct_form2')  
set_param('fxpdemo_direct_form2','HideAutomaticNames','off')  
open_system('fxpdemo_direct_form2')
```

Update the block diagram. Signals in this model use signed fixed-point data types with a word length of 16 and binary-point-only scaling.

Open the Gain5 block dialog box. The **Gain** parameter is set to 1.85. Suppose you want to configure this parameter.

Set **Gain** to myGainParam and click **Apply**.

Click the action button (with three vertical dots) next to the parameter value. Select **Create**.

In the Create New Data dialog box, set **Value** to Simulink.Parameter(1.85) and click **Create**. The Simulink.Parameter object myGainParam appears in the base workspace.

In the myGainParam property dialog box, set **Storage class** to ExportedGlobal and click **OK**. With this setting, myGainParam appears in the generated code as a global variable.

In the block dialog box, on the **Parameter Attributes** tab, set **Parameter minimum** to 0 and **Parameter maximum** to 4.

Set **Parameter data type** to fixdt(0,8) and click **Apply**.

Click the **Show Data Type Assistant** button. The Data Type Assistant shows that the expression fixdt(0,8) specifies an unsigned fixed-point data type with a word length of 8 and best-precision scaling. When you simulate or generate code, the block parameter chooses a fraction length (scaling) that enables the data type to represent values between the parameter minimum and maximum (0 and 4) with the best possible precision.

In the Data Type Assistant, set **Scaling** to Binary point. Click **Calculate Best-Precision Scaling, Fixed-point details**, and **Refresh Details**. The information under **Fixed-point details** shows that a fraction length of 5 can represent the parameter values with a precision of 0.03125.

Set **Scaling** back to Best precision and click **OK**. In this example, when you simulate or generate code, the block parameter chooses a fraction length of 5.

Alternatively, you can use these commands at the command prompt to create the object and configure the block:

```
myGainParam = Simulink.Parameter(1.85);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
set_param('fxpdemo_direct_form2/Gain5', 'Gain', 'myGainParam')
set_param('fxpdemo_direct_form2/Gain5', 'ParamMin', '0', 'ParamMax', '4')
set_param('fxpdemo_direct_form2/Gain5', 'ParamDataTypeStr', 'fixdt(0,8)')
```

Configure the model to produce a code generation report. To reduce clutter in the Command Window, clear the configuration parameter **Verbose build**.

```
set_param('fxpdemo_direct_form2', 'GenerateReport', 'on', ...
    'LaunchReport', 'on', 'RTWVerbose', 'off')
```

Generate code from the model.

```
evalc('rtwbuild(''fxpdemo_direct_form2'')');
```

The generated file fxpdemo\_direct\_form2.c defines the global variable myGainParam by using the data type uint8\_T, which corresponds to the specified word length, 8. The

code initializes the variable by using an integer value that, given the fraction length of 5, represents the real-world parameter value 1.85.

```
file = fullfile('fxpdemo_direct_form2_grt_rtw','fxpdemo_direct_form2.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T myGainParam = 59U;',1,1)

/* Exported block parameters */
uint8_T myGainParam = 59U;          /* Variable: myGainParam
```

The code algorithm uses `myGainParam` to calculate the output of the Gain5 block. The algorithm uses a C shift to scale the result of the calculation.

```
rtwdemodbtype(file,'/* Gain: '<Root>/Gain5' */',...
'/* Gain: '<Root>/Gain' incorporates:',1,0)

/* Gain: '<Root>/Gain5' */
fxpdemo_direct_form2_B.Gain5 = (int16_T)((myGainParam *
fxpdemo_direct_form2_B.UnitDelay1) >> 5);
```

## Reuse Parameter Data in Different Data Type Contexts

When you use a `Simulink.Parameter` object or a numeric MATLAB variable to set two or more block parameter values, if the block parameters have different data types, you must explicitly specify the data type of the object or variable. For example, you cannot leave the data type of the parameter object at the default value, `auto`.

### Create and Configure Example Model

Create the model `ex_paramdt_contexts`.

`ex_paramdt_contexts`

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, on the **Inports/Outports** tab, use the **Data Type** column to set the data type of the In1 Inport block to `single` and the data type of the In2 block to `int8`.

On the **Signals** tab, set the data types of the Gain block outputs to `Inherit: Same as input`.

On the **Parameters** tab, for the **Gain** parameters of the Gain blocks, set **Data Type** to `Inherit: Same as input`.

For the **Gain** parameters, set **Value** to `myGainParam`.

Alternatively, to configure the blocks, use these commands at the command prompt:

```
set_param('ex_paramdt_contexts/In1', 'OutDataTypeStr', 'single')
set_param('ex_paramdt_contexts/In2', 'OutDataTypeStr', 'int8')
set_param('ex_paramdt_contexts/Gain - single', 'Gain', 'myGainParam', ...
    'OutDataTypeStr', 'Inherit: Same as input', ...
    'ParamDataTypeStr', 'Inherit: Same as input')
set_param('ex_paramdt_contexts/Gain - int8', 'Gain', 'myGainParam', ...
    'OutDataTypeStr', 'Inherit: Same as input', ...
    'ParamDataTypeStr', 'Inherit: Same as input')
```

In the Model Data Editor, for either **Gain** block parameter, click the cell in the **Value** column. Next to myGainParam, click the action button (with three vertical dots) and select **Create**.

In the **Create New Data** dialog box, set **Value** to Simulink.Parameter(3) and click **Create**. A Simulink.Parameter object with value 3 appears in the base workspace.

In the **myGainParam** property dialog box, set **Data type** to int8 and **Storage class** to ExportedGlobal. With the storage class ExportedGlobal, the object appears in the generated code as a global variable.

Alternatively, to create and configure the parameter object, use these commands at the command prompt:

```
myGainParam = Simulink.Parameter(3);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
myGainParam.DataType = 'int8';
```

In this model, you use the parameter object myGainParam to set two block parameter values. The block parameters inherit different data types from the block input signals (single or int8). To use myGainParam in these different data type contexts, you explicitly specify the data type of the parameter object by setting the DataType property to int8.

### Match Parameter Object Data Type with Signal Data Type

Optionally, use a Simulink.NumericType or Simulink.AliasType object to set the parameter object data type and one of the signal data types. This technique eliminates unnecessary typecasts and shifts in the generated code due to a mismatch between the parameter object data type and the signal data type.

At the command prompt, create a Simulink.NumericType object to represent the data type int8.

```
sharedType_int8 = fixdt('int8');
```

In the Model Data Editor, on the **Inports/Outports** tab, set the data type of the In2 Inport block to `sharedType_int8`.

On the **Parameters** tab, update the block diagram. The data table now contains a row that represents the parameter object, `myGainParam`.

Use the **Data Type** column to set the data type of the parameter object to `sharedType_int8`.

Alternatively, to configure the block and the object, use these commands at the command prompt:

```
myGainParam.DataType = 'sharedType_int8';
set_param('ex_paramdt_contexts/In2', 'OutDataTypeStr', 'sharedType_int8')
```

The parameter object and the signal use the data type `int8`. To change this data type, adjust the properties of the data type object `sharedType_int8`.

### Generate and Inspect Code

Generate code from the model.

```
rtwbuild('ex_paramdt_contexts')

### Starting build procedure for model: ex_paramdt_contexts
### Successful completion of build procedure for model: ex_paramdt_contexts
```

The generated file `ex_paramdt_contexts.c` defines the global variable `myGainParam` by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('ex_paramdt_contexts_grt_rtw', 'ex_paramdt_contexts.c');
rtwdemodbtype(file, '/* Exported block parameters */', 'int8_T myGainParam = 3;', 1, 1)

/* Exported block parameters */
int8_T myGainParam = 3;                                /* Variable: myGainParam
```

The generated code algorithm in the model `step` function uses `myGainParam` to calculate the outputs of the two Gain blocks. In the case of the Gain block whose input signal uses the data type `single`, the code algorithm casts `myGainParam` to the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
rtwdemodbtype(file, '/* Model step function */', ...
    '/* Model initialize function */', 1, 0)
```

```
/* Model step function */
void ex_paramdt_contexts_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
     * Gain: '<Root>/Gain - single'
     * Inport: '<Root>/In1'
     */
    ex_paramdt_contexts_Y.Out1 = (real32_T)myGainParam * ex_paramdt_contexts_U.In1;

    /* Outport: '<Root>/Out2' incorporates:
     * Gain: '<Root>/Gain - int8'
     * Inport: '<Root>/In2'
     */
    ex_paramdt_contexts_Y.Out2 = (int8_T)(myGainParam * ex_paramdt_contexts_U.In2);
}
```

## Organize Data into Structures in Generated Code

In C code, you use structures (`struct`) to store data in contiguous locations in memory. You can organize data, such as signals and states, by using meaningful names. Each structure acts as a namespace, so you can reuse a name to designate multiple data items. Like arrays, with structures, you can write code that efficiently transfers and operates on large amounts of data by using pointers.

By default, the code generator aggregates data into standard structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-68). To control the characteristics of these structures or to override this default behavior by creating different structures, use the information in the table.

| Goal                                                                                                                                                      | Technique                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Control the characteristics of the standard data structures. For example, specify the names of the structure types, structure variables, and field names. | With Embedded Coder, see “Control Characteristics of Data Structures (Embedded Coder)” on page 33-45.       |
| Control the placement of the structures in memory, for example, by inserting pragmas or other code decorations.                                           | With Embedded Coder, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 41-2. |

| Goal                                                                                                                                                                                                          | Technique                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Techniques to Create Structures

To create structures in the generated code, you can use these techniques:

- Apply a structured storage class to categories of data by using the Code Mapping Editor. As you add blocks and signals to a model, new data elements acquire this storage class by default.
- Apply a structured storage class, such as the built-in storage class `Struct`, directly to individual data items by using the Model Data Editor.
- Create custom nonvirtual buses and parameter structures.

To decide which techniques to use, use the information in the table.

| Capability                                                                                                   | Default Application of Structured Storage Class | Direct Application of Structured Storage Class | Nonvirtual Buses and Parameter Structures                                                              |
|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------|------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Aggregate new data items into a structure by default                                                         | Yes                                             | No                                             | No                                                                                                     |
| Prevent elimination of the target data by optimizations (specify that the data appear in the generated code) | No                                              | Yes                                            | Only if you directly apply a storage class such as <code>ExportedGlobal</code> to the bus or structure |
| Aggregate data into a structure without changing the appearance of the block diagram                         | Yes                                             | Yes                                            | No                                                                                                     |

| Capability                                                                   | Default Application of Structured Storage Class                                       | Direct Application of Structured Storage Class                           | Nonvirtual Buses and Parameter Structures |

| Control name of structure type                                               | Yes                                                                                   | Yes, but the type name derives from the variable name, which you specify | Yes                                       |
| Create a structure to reduce the number of arguments in a generated function | Yes, but you must create your own storage class by using an Embedded Coder Dictionary | No                                                                       | Yes                                       |
| Requires Embedded Coder                                                      | Yes                                                                                   | Yes                                                                      | No                                        |

## Default Application of Structured Storage Class

You can apply a default storage class to a category of model data. As you add blocks and signals to the model, the associated data acquire the default storage class that you specify. To aggregate new data into structures by default, you can apply structured storage classes. You must use example storage classes `ParamStruct` and `SignalStruct` created by the Quick Start tool or create your own storage class by using an Embedded Coder Dictionary.

You cannot use default application to aggregate global data stores or global parameters (parameter objects that you store in the base workspace or a data dictionary).

To apply default storage classes, use the Code Mapping Editor. In a model window, in the Apps gallery, click **Embedded Coder**. Then, under **Code Mappings > Data Defaults**, apply storage classes by using the **Storage Class** column.

For more information about the Code Mapping Editor, see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 32-7. To create your own storage class by using an Embedded Coder Dictionary, see “Create Code Definitions for Use as Default Code Generation Settings” on page 30-2.

## Direct Application of Structured Storage Class

You can apply a structured storage class to individual data items. The direct application prevents code generation optimizations, such as **Default parameter behavior** and **Signal storage reuse**, from eliminating each data item from the generated code. The direct application also overrides the default storage classes that you specify with **Code Mappings > Data Defaults**.

To directly apply a storage class, use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). Set **Change view** to Code and apply the storage class by using the **Storage Class** column.

For an example that shows how to use `Struct`, see “Organize Parameter Data into a Structure by Using the Struct Storage Class” on page 37-23. For more information about applying storage classes, see “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19.

## Nonvirtual Buses and Parameter Structures

- To create a nonvirtual bus signal, use a Bus Creator block to organize multiple signal lines into a single bus, or configure an Inport block or Outport block as a nonvirtual bus. You must create a `Simulink.Bus` object that represents the structure type. For an example, see “Structures of Signals” on page 33-211. For general information about nonvirtual buses, see “Getting Started with Buses” (Simulink).
- To create a parameter structure, use MATLAB commands or the Variable Editor to organize the values of multiple block parameters into a MATLAB structure. Optionally, create a `Simulink.Bus` object so that you can control the name of the structure type and other characteristics such as the data type and dimensions of each field. For an example, see “Structures of Parameters” on page 33-209. For general information about parameter structures, see “Organize Related Block Parameter Definitions in Structures” (Simulink).

## Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

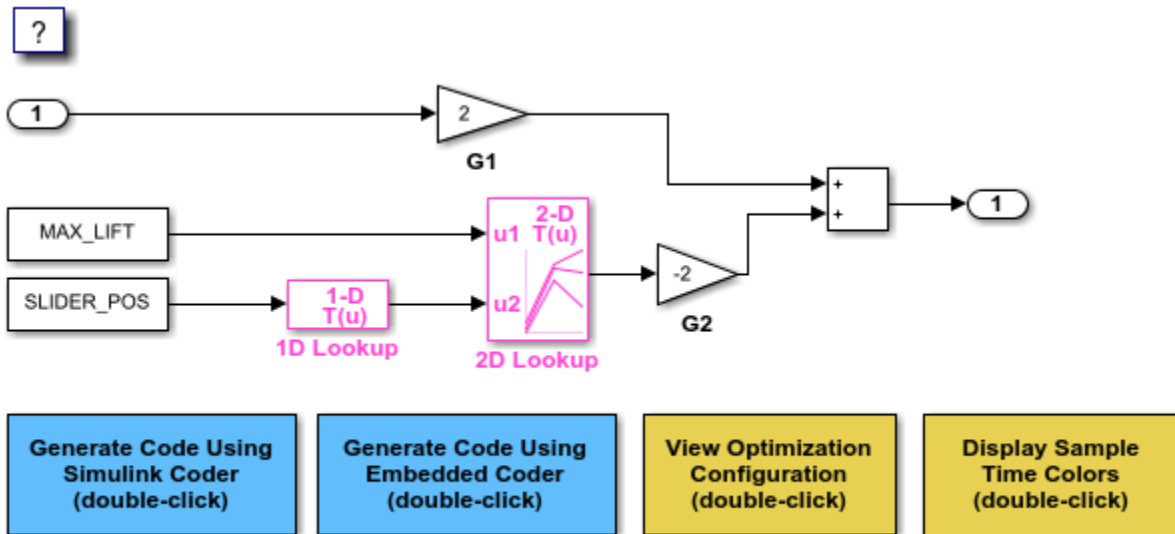

### C Construct

```
typedef struct {
    double G1;
    double G2;
} myStructType;

myStructType myStruct = {
    2.0,
    -2.0
};
```

### Procedure

1. Open the example model `rtwdemo_paraminline`.

2. On the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, select the **Parameters** tab.
3. In the model, click the Gain block labeled G1. In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `myStruct.G1`.
4. Set the value of the **Gain** parameter in the G2 block to `myStruct.G2`.
5. Next to `myStruct.G2`, click the action button (with three vertical dots) and select **Create**.
6. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(struct)` and click **Create**. A `Simulink.Parameter` object named `myStruct` appears in the base workspace.
7. In the `Simulink.Parameter` property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.
8. Right-click the white space under the **Field** column and select **New**. Name the new structure field G1. Use the **Value** column to set the value of the field to 2.
9. Add a field G2 whose value is -2, and then close the Variable Editor.
10. In the `Simulink.Parameter` property dialog box, set **Storage class** to `ExportedGlobal`. The structure `myStruct` appears in the generated code as a global variable.
11. Generate code from the model.

## Results

The generated header file `rtwdemo_paraminline_types.h` defines a structure type that has a random name.

```
typedef struct {  
    real_T G1;  
    real_T G2;  
} struct_6h72eH5WfuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```

/* Exported block parameters */
struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
    2.0,
    -2.0
} ;

/* Variable: myStruct
 * Referenced by:
 *   '<Root>/G1'
 *   '<Root>/G2'
 */

```

### Specify Name of Structure Type

1. Optionally, specify a name to use for the structure type definition (`struct`). At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.
2. The default name of the object is `s1Bus1`. Change the name by copying the object into a new MATLAB variable.
3. In the Model Data Editor, click the **Show/refresh additional information** button.
4. In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.
5. Generate code from the model.

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```

myStructType myStruct = {
    2.0,
    -2.0
} ;

/* Variable: myStruct

```

### Structures of Signals

This example shows how to create a structure of signal data in the generated code.

#### C Construct

```

typedef struct {

```

```

double signal1;
double signal2;
double signal3;
} my_signals_type;

```

### Procedure

1. To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.
2. Create the `ex_signal_struct` model by using Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

3. To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.
4. In the toolstrip, on the **Modeling** tab, under **Design**, click **Bus Editor**.
5. Use the Bus Editor to create a `Simulink.Bus` object named `my_signals_type` that contains three signal elements: `signal1`, `signal2`, and `signal3`. See “Create and Specify Bus Objects” (Simulink).

This bus object represents the structure type that you want the generated code to use.

6. In the Bus Creator block dialog box, set **Output data type** to Bus : my\_signals\_type.

7. Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

8. On the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select Code.

9. In the model, click the output signal of the Bus Creator block.

10. In the Model Data Editor, for the output of the Bus Creator block, set **Name** to sig\_struct\_var.

11. Set **Storage Class** to ExportedGlobal. The output of the Bus Creator block appears in the generated code as a separate global structure variable named sig\_struct\_var.

12. Generate code from the model.

## Results

The generated header file ex\_signal\_struct\_types.h defines the structure type my\_signals\_type.

```
typedef struct {
    real_T signal1;
    real_T signal2;
    real_T signal3;
} my_signals_type;
```

The source file ex\_signal\_struct.c allocates memory for the global variable sig\_struct\_var, which represents the output of the Bus Creator block.

```
/* Exported block signals */  
my_signals_type sig_struct_var;          /* '<Root>/Bus Creator' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

### **Nested Structures of Signals**

You can create nested structures of signal data in the generated code.

#### **C Construct**

```
typedef struct {  
    double signal1;  
    double signal2;  
    double signal3;  
} B_struct_type;  
  
typedef struct {  
    double signal1;  
    double signal2;  
} C_struct_type;  
  
typedef struct {  
    B_struct_type subStruct_B;  
    C_struct_type subStruct_C;  
} A_struct_type;
```

#### **Procedure**

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

To nest a structure inside another structure, use a bus object as the data type of a signal element in another bus object.

1. Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

2. To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

3. In the toolstrip, on the **Modeling** tab, under **Design**, click **Bus Editor**.

Use the Bus Editor to create a `Simulink.Bus` object named `A_struct_type` that contains two signal elements: `subStruct_B` and `subStruct_C`. To create bus objects with the Bus Editor, see “Create and Specify Bus Objects” (Simulink). This bus object represents the top-level structure type that you want the generated code to use.

4. For the `subStruct_B` element, set **Data Type** to `Bus: B_struct_type`. Use a similar type name for `subStruct_C`.

Each signal element in `A_struct_type` uses another bus object as a data type. Now, these elements represent substructures.

5. Use the Bus Editor to create the `Simulink.Bus` objects `B_struct_type` (with three signal elements) and `C_struct_type` (with two signal elements).

6. In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to Bus: `B_struct_type`. Click **Apply**.

7. Select **Output as nonvirtual bus** and click **OK**.

8. In the dialog box of the other subordinate Bus Creator block, set **Output data type** to Bus: `C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

9. In the last Bus Creator block dialog box, set **Output data type** to Bus: `A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

10. On the **Modeling** tab, click **Model Data Editor**.

11. In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select **Code**.

12. In the model, click the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block.

13. In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

14. Set **Storage Class** to `ExportedGlobal`. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

15. Generate code from the model.

## Results

The generated header file `ex_signal_nested_struct_types.h` defines the structure types. Each structure type corresponds to a `Simulink.Bus` object.

```
typedef struct {
    real_T signal1;
    real_T signal2;
    real_T signal3;
} B_struct_type;

typedef struct {
    real_T signal1;
    real_T signal2;
} C_struct_type;

typedef struct {
    B_struct_type subStruct_B;
    C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is `Bus_Creator2`.

```
/* Exported block signals */
A_struct_type sig_struct_var;          /* '<Root>/Bus_Creator2' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

## Combine Techniques to Work Around Limitations

To work around some of the limitations of each technique, you can combine structured storage classes with nonvirtual buses and parameter structures. For example, you can:

- Include a structure of signal data and a structure of parameter data in the same parent structure.
- Nest structures while aggregating new data by default.

In the generated code, a flat parent structure, which corresponds to the structured storage class, contains substructures, which correspond to each bus and parameter structure. Choose one of these combined techniques:

- Apply the structured storage class directly to each bus and parameter structure. For example, set the storage class of two nonvirtual bus signals to `Struct`. Each bus appears in the generated code as a field (substructure) of a single structure.
- Leave the storage class of each bus and parameter structure at the default setting, `Auto`, or at `Model default`, which prevents code generation optimizations from eliminating the bus or parameter structure. Then, configure default storage classes such that signal data and parameter data use the structured storage class by default.

## Arrays of Structures

You can further package multiple consistent bus signals or parameter structures into an array. The array of buses or parameter structures appears in the generated code as an array of structures. To create arrays of buses, see “Combine Buses into an Array of Buses” (Simulink). To create arrays of parameter structures, see “Group Multiple Parameter Structures into an Array” (Simulink).

## Structure Padding

By default, the code generator does not explicitly add padding fields to structure types. Structure types can appear in the generated code through, for example, the standard data structures (see “Standard Data Structures in the Generated Code” (Simulink Coder)), `Simulink.Bus` objects, and parameter structures that you use in a model.

---

However, when you use a code replacement library with Embedded Coder, you can specify data alignment (including structure padding) as part of the replacement library. For more information, see “Provide Data Alignment Specifications for Compilers” on page 65-128.

## Limitations

- With built-in Simulink Coder and Embedded Coder features, you cannot generate or use a custom structure that contains a field whose value is a pointer. You can do so manually by creating an advanced storage class and writing accompanying TLC code (see “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 37-39).
- You cannot use the built-in storage class `Struct`, or a structured storage class that you create with the Custom Storage Class Designer (you set the storage class property **Type** to `FlatStructure`), to set data defaults in the Code Mapping Editor.

## Switch Between Sets of Parameter Values During Simulation and Code Execution

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

### Explore Example Model

Open the example model.

```
open_system('sldemo_fuelsys_dd_controller')
```

### Fuel Rate Controller

Copyright 1990-2017 The MathWorks, Inc.

This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
            'switchable_compensation'])
```

## Loop Compensation and Filtering

This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
            'switchable_compensation/low_mode'])
```

The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the model data badge, then click the **Data Dictionary** link. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane, view the properties of the `Simulink.NumericType` objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

### Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a `Simulink.Parameter` object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```

lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
            'switchable_compensation/low_mode/Discrete Filter'];
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
            'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock, 'Numerator'));
params.richNumerator = eval(get_param(richBlock, 'Numerator'));
params = Simulink.Parameter(params);

```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```

temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp

```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

### Create Variable to Switch Between Parameter Sets

Create a `Simulink.Parameter` object named `Ctrl`.

```

Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';

```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```

set_param(lowBlock, 'Numerator', 'params(Ctrl).lowNumerator');

```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```

set_param(richBlock, 'Numerator', 'params(Ctrl).richNumerator');

```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

### Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

### Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs', {'Weak', 'Aggressive'}, [1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index 2.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

## Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary  
`sldemo_fuelsys_dd_controller.sldd`.

```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.sldd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
addEntry(sectObj,'params',params)
addEntry(sectObj,'paramsType',paramsType)
```

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary” (Simulink).

## Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```

## Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures.  
 The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2017 The MathWorks, Inc.

Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

### Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to **Storage Class**.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj, 'params');  
params = getValue(tempEntryObj);  
params.StorageClass = 'ExportedGlobal';  
setValue(tempEntryObj, params);
```

```
tempEntryObj = getEntry(sectObj, 'Ctrl');  
Ctrl = getValue(tempEntryObj);  
Ctrl.StorageClass = 'ExportedGlobal';  
setValue(tempEntryObj, Ctrl);
```

Generate code from the controller model.

```
rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of code generation for model: sldemo_fuelsys_dd_controller
```

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
    Weak = 1,                               /* Default value */
    Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_paramsType_',...
    '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_

typedef struct {
    real32_T lowNumerator[2];
    real32_T richNumerator[2];
} paramsType;

#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```

file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,'FilterCoeffs Ctrl = Aggressive;',...
    '/* Block signals (default storage) */',1,0)

FilterCoeffs Ctrl = Aggressive;          /* Variable: Ctrl
                                           * Referenced by:
                                           *   '<S12>/Discrete Filter'
                                           *   '<S13>/Discrete Filter'
                                           */

```

The code also defines the array of structures `params`.

```

rtwdemodbtype(file,'/* Exported block parameters */',...
    '/* Variable: params',1,1)

/* Exported block parameters */
paramsType params[2] = { {
    { 8.7696F, -8.5104F },

    { 0.0F, 0.2592F }
}, { { 17.5392F, -17.0208F },

    { 0.0F, 0.5184F }
} } ;                                     /* Variable: params

```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

Close the connections to the data dictionary. This example discards unsaved changes. To save the changes, use the `'-save'` option.

```
Simulink.data.dictionary.closeAll('sldemo_fuelsys_dd_controller.slidd', '-discard')
```

## Design Data Interface by Configuring Inport and Output Blocks

The data interface of a model is the means by which the model exchanges data (for example, signal values) with other, external models or systems. Customize the data interface of a model to:

- Enable integration of the generated code with your own code.
- Improve traceability and readability of the code.

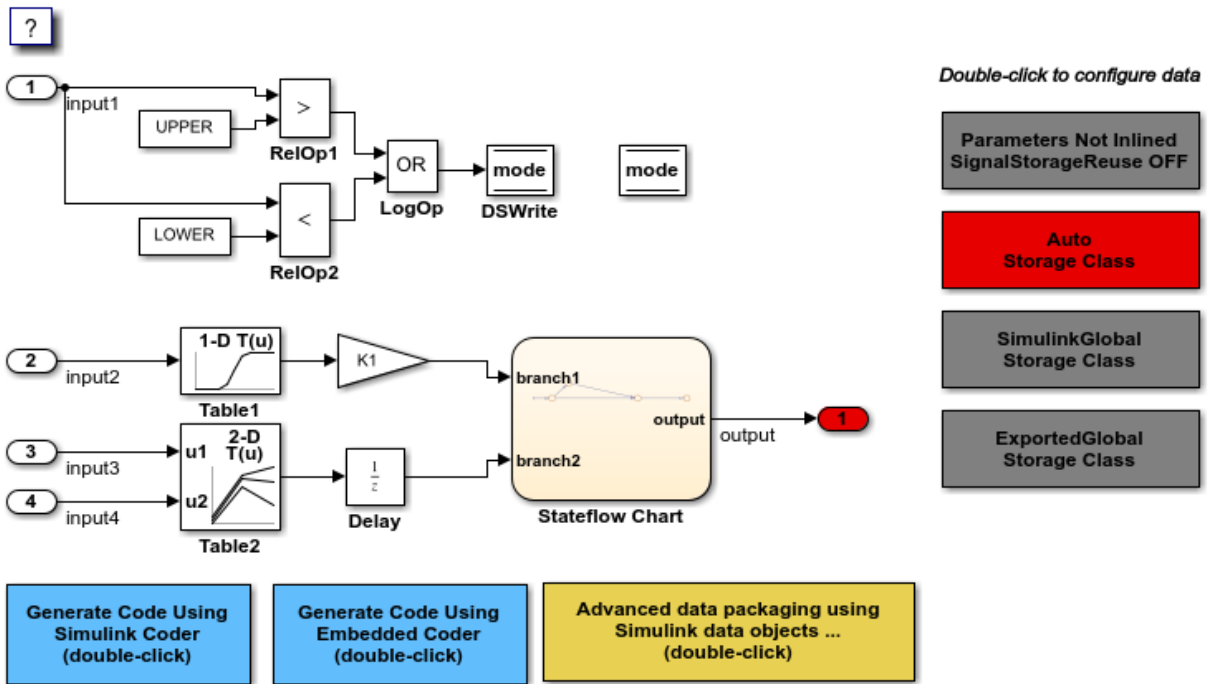

At the top level of a model, Inport and Output blocks represent the input and output signals of the model. To customize the data interface in the generated code, configure these blocks. Early in the design process, when a model can contain unconnected Inport and Output blocks, use this technique to specify the interface before developing the internal algorithm.

When you apply storage classes to Inport and Output blocks, each block appears in the generated code as a field of a global structure or as a separate global variable that the generated algorithm references directly. If you have Embedded Coder, you can use function prototype control instead of storage classes to pass data into and out of the model `step` function as formal parameters. See “Customize Generated C Function Interfaces” on page 40-2.

### Design Data Interface

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Configure the model to show the generated names of blocks.

```
set_param('rtwdemo_basicsc', 'HideAutomaticNames', 'off')
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, select the **Inports/Outports** tab. Each row in the table represents an Output block or a signal that exits an Inport block.

Name the signal data that the Output block Out1 represents. Set **Signal Name** to `output_sig`.

For each of the signals that exit the Inport blocks, set **Data Type** to `single` or to a different data type. Due to the data type inheritance settings that the other blocks in the model use by default, downstream signals in the rest of the model use the same or a similar data type.

Optionally, configure other design attributes such as **Min** and **Max** (minimum and maximum values).

Set the **Change View** drop-down list to Code.

For the Outport block and Inport blocks, set **Storage Class** to ExportedGlobal. To configure the blocks in one step, select the rows in the table.

To configure the blocks and signals, you can use these commands at the command prompt.

```
portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',...
          'StorageClass','ExportedGlobal')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc');

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

View the generated file `rtwdemo_basicsc.c`. Because you applied the storage class `ExportedGlobal` to the Inport and Outport blocks, the code creates separate global variables that represent the inputs and the output.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block signals */','real32_T output_sig;',1,1)

/* Exported block signals */
```

```

real32_T input1;          /* '<Root>/In1' */
real32_T input2;          /* '<Root>/In2' */
real32_T input3;          /* '<Root>/In3' */
real32_T input4;          /* '<Root>/In4' */
real32_T output_sig;      /* '<Root>/Out1' */

```

The generated algorithm in the model `step` function directly references these global variables to calculate and store the output signal value, `output_sig`.

While you use the Model Data Editor to configure the interface of a system, consider using the interface display to view the system inputs and outputs (Inport and Output blocks) at a high level. See “Configure Data Interface for Component” (Simulink).

### Reduce Manual Data Entry by Configuring Default Storage Class (Embedded Coder)

If you have Embedded Coder, you can configure a default storage class for Inport blocks and Output blocks. As you add such blocks to the model, they acquire the storage class that you specify.

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`.

In the Apps gallery, click **Embedded Coder**.

Underneath the block diagram, under **Code Mappings > Data Defaults**, for the **Inports** and **Outports** rows, set **Storage Class** to `ExportedGlobal`.

Underneath the block diagram, open the Model Data Editor by clicking the **Model Data Editor** tab.

Use the Model Data Editor to set the storage class of the Inport and Output blocks to `Auto`. With this setting, the blocks acquire the default storage classes that you specified in **Code Mappings > Data Defaults**.

With `Auto`, the global variables that correspond to the Inport and Output blocks are subject to a naming rule that you specify in the model configuration parameters. By default, the naming rule adds the name of the model to the name of each variable. To remove the model name, change the value of **Configuration Parameters > Code Generation > Symbols > Global variables** from `$R$N$M` to `$N$M`. The token `$R` represents the model name.

Alternatively, to configure the data defaults and the configuration parameter, at the command prompt, use these commands:

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')

coder.mapping.create('rtwdemo_basicsc')
coder.mapping.defaults.set('rtwdemo_basicsc','Inports',...
    'StorageClass','ExportedGlobal')
coder.mapping.defaults.set('rtwdemo_basicsc','Outports',...
    'StorageClass','ExportedGlobal')

portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',...
    'StorageClass','Auto')

set_param('rtwdemo_basicsc','CustomSymbolStrGlobalVar','$$M')
```

### **Route Signal Data to Multiple Outputs**

You can route a single signal to multiple Outport blocks and apply a different storage class to each Outport. For example, use this technique to send signal data to a custom function (such as a device driver) and to a global variable that your custom algorithmic code can use:

- 1 Branch the target signal line to each Outport block.
- 2 For more efficient code, set the storage class of the target signal line to Auto (the default). Optimizations can then eliminate the signal line from the generated code.

- 3 Use the Model Data Editor to apply the storage class `GetSet` to one Output block and `ExportToFile` to the other Output block. Apply a signal name to each block.

```
open_system('ex_route_sig')
```

### Limitations

You cannot apply a storage class to an Output block if the input to the block has a variable size. Instead, apply the storage class to the signal line.

## Generate Efficient Code for Bus Signals

|                                                        |
|--------------------------------------------------------|
| <b>In this section...</b>                              |
| “Code Efficiency for Bus Signals” on page 33-236       |
| “Set Bus Diagnostics” on page 33-237                   |
| “Optimize Virtual and Nonvirtual Buses” on page 33-237 |

In a model, you use bus signals to package multiple signals together into a single signal line. You can create virtual or nonvirtual bus signals. The representation in the generated code depends on:

- For a virtual bus, the generated code appears as if the bus did not exist.
- Generated code for a nonvirtual bus represents the bus data with a structure. When you want to trace the correspondence between the model and the code, the use of a structure in the generated code can be helpful. To generate structures using nonvirtual bus signals, see “Organize Data into Structures in Generated Code” on page 33-201.

For general information about buses, see and “Types of Composite Signals” (Simulink).

To generate efficient code from models that contain bus signals, eliminate unnecessary data copies by following best practices as you construct the model.

### Code Efficiency for Bus Signals

When you use buses in a model for which you intend to generate code:

- Setting bus diagnostic configuration parameters can make model development easier.
- The bus implementation techniques, and the choice of a nonvirtual or virtual bus, can influence the speed, size, and clarity of the generated code.
- Some useful bus implementation techniques are not immediately obvious.

When you work with buses, these guidelines help you to improve the results. The guidelines describe techniques to:

- Simplify the layout of the model.
- Increase the efficiency of generated code.

- Define data structures for function (subsystem) interfaces.
- Define data structures that match existing data structures in external C code.

There are some trade-offs among speed, size, and clarity. For example, the code for nonvirtual buses is easier to read because the buses appear in the code as structures, but the code for virtual buses is faster because virtual buses do not require copying signal data. Apply some of the guidelines based on where you are in the application development process.

## Set Bus Diagnostics

Simulink provides diagnostics that you can use to optimize bus usage. Set the following values on the **Configuration Parameters > Diagnostics > Connectivity** pane.

| Buses                                        |                 |
|----------------------------------------------|-----------------|
| Unspecified bus object at root Output block: | warning         |
| Element name mismatch:                       | warning         |
| Mux blocks used to create bus signals:       | error           |
| Bus signal treated as vector:                | warning         |
| Non-bus signals treated as bus signals:      | none            |
| Repair bus selections:                       | Warn and repair |

## Optimize Virtual and Nonvirtual Buses

Virtual buses are graphical conveniences that do not affect generated code. As a result, the code generation engine is able to fully optimize the signals in the bus. Use virtual buses rather than nonvirtual buses wherever possible. You can convert between virtual and nonvirtual buses by using Signal Conversion blocks. In some cases, Simulink automatically converts a virtual bus to a nonvirtual bus when required. For example, a Stateflow chart converts an input virtual bus to a nonvirtual bus.

To bundle function-call signals, you must use a virtual bus.

You must use nonvirtual buses for:

- Nonauto storage classes

- Generating a specific structure from the bus
- Root-level Inport or Outport blocks when the bus has mixed data types

### Avoid Nonlocal Nested Buses in Nonvirtual Buses

Buses can contain subordinate buses. To generate efficient code, set the storage classes of subordinate buses to **Auto**. Setting the storage class to **Auto** eliminates:

- Allocation of redundant memory for the subordinate bus signal and for the parent bus signal
- Additional copy operations (copying data to the subordinate bus, and then copying from the subordinate bus to the final bus)

This model contains nonvirtual bus signals. The subordinate bus signals `Sub_Bus_1` and `Sub_Bus_2` use the storage class `Auto`.

The generated code algorithm efficiently assigns the input signal data to the bus signals.

```
void ex_nonvirtual_buses_step(void)
{
    Nonvirtual_In_One.SimpleBus_1.A1 = A1;
    Nonvirtual_In_One.SimpleBus_1.A2 = A2;
    Nonvirtual_In_One.SimpleBus_2.A3 = A3;
    Nonvirtual_In_One.SimpleBus_2.A4 = A4;
    Nonvirtual_In_One.A5 = A5;
}
```

## Control Signal and State Initialization in the Generated Code

To initialize signals and discrete states with custom values for simulation and code generation, you can use signal objects and block parameters. Data initialization increases application reliability and is a requirement of safety critical applications. Initializing signals for both simulation and code generation can expedite transitions between phases of Model-Based Design.

For basic information about specifying initial values for signals and discrete states in a model, see “Initialize Signals and Discrete States” (Simulink).

### Signal and State Initialization in the Generated Code

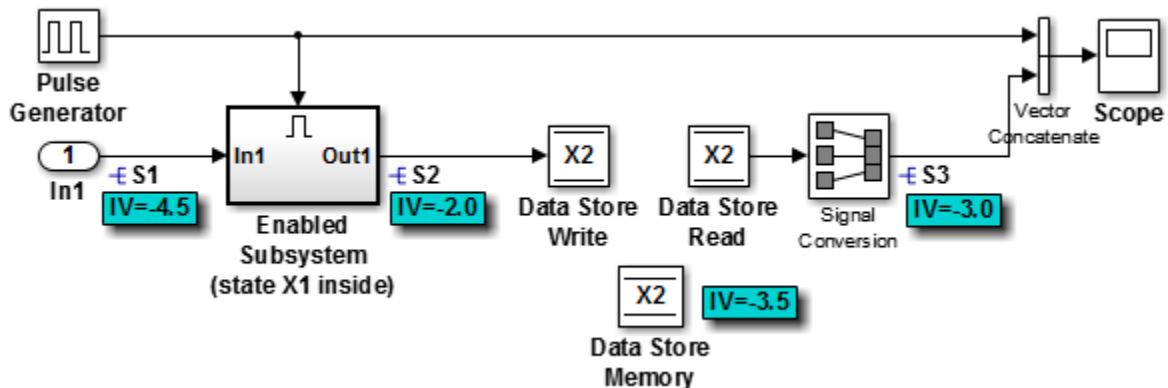

The initialization behavior for code generation is the same as that for model simulation with the following exceptions:

- RSim executables can use the **Data Import/Export** pane of the Configuration Parameters dialog box to load input values from MAT-files. GRT and ERT executables cannot load input values from MAT-files.
- The initial value for a block output signal or root level input or output signal can be overwritten by an external (calling) program.
- Setting the initial value for persistent signals is relevant if the value is used or viewed by an external application.

When you generate code, initialization statements are placed in *model.c* or *model.cpp* in the model's initialize code.

For example, consider the model `rtwdemo_sigobj_iv`.

If you create and initialize signal objects in the base workspace, the code generator places initialization code for the signals in the file `rtwdemo_sigobj_iv.c` under the `rtwdemo_sigobj_iv_initialize` function, as shown below.

```
/* Model initialize function */
void rtwdemo_sigobj_iv_initialize(void)
{
    .
    .
    .
    /* exported global signals */
    S3 = -3.0;
    S2 = -2.0;
    .
    .
    /* exported global states */
    X1 = 0.0;
    X2 = 0.0;
    .
    .
    /* external inputs */
    S1 = -4.5;
    .
    .
}
```

The following code shows the initialization code for the enabled subsystem's Unit Delay block state X1 and output signal S2.

```
void MdlStart(void) {
    .
    .
    .
    /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
    X1 = aal;
}
```

```
/* Start for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */
/* virtual outputs code */
/* (Virtual) Output Block: '<S2>/Out1' */
S2 = aa2;
}
```

For an enabled subsystem, the initial value is also used as a reset value if the subsystem's Output block parameter **Output when disabled** is set to **reset**. The following code from `rtwdemo_sigobj_iv.c` shows the assignment statement for `S3` as it appears in the model output function `rtwdemo_sigobj_iv_output`.

```
/* Model output function */
static void rtwdemo_sigobj_iv_output(void)
{
    .
    .
    .
/* Disable for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */
/* (Virtual) Output Block: '<S2>/Out1' */
S2 = aa2;
```

## Generate Tunable Initial Conditions

You can represent initial conditions for signals and states by creating tunable global variables in the generated code. These variables allow you to restart an application by using initial conditions that are stored in memory.

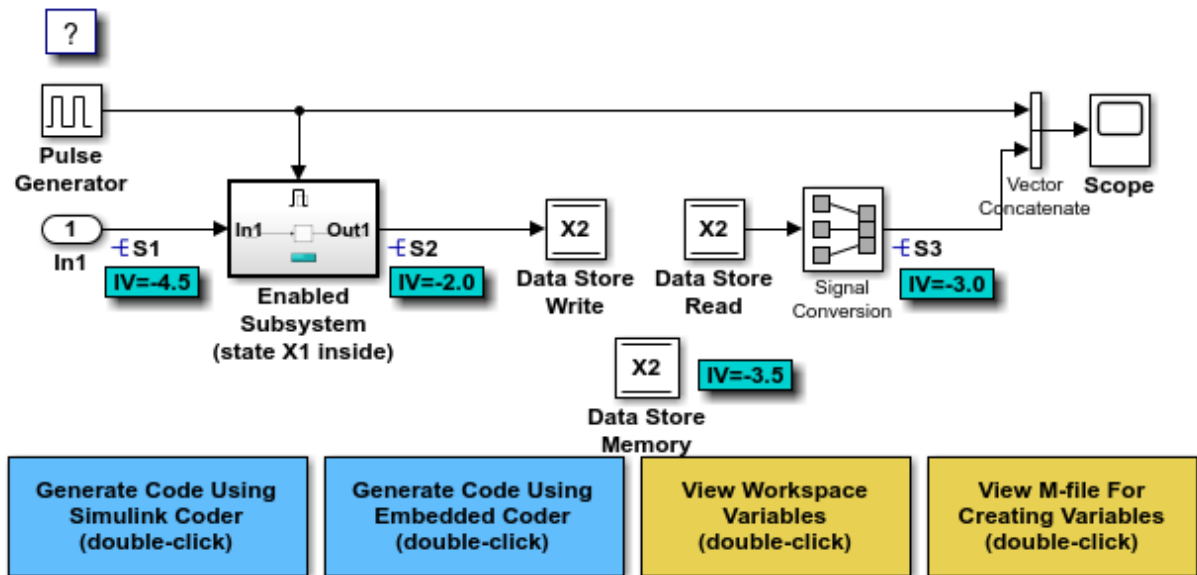

If you set **Configuration Parameters > Optimization > Default parameter behavior** to **Tunable**, initial conditions appear as tunable fields of the global parameters structure.

Whether you set **Default parameter behavior** to **Tunable** or **Inlined**, you can use a tunable parameter to specify the `InitialValue` property of a signal object or the **Initial condition** parameter of a block. For basic information about tunable parameters, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

This example shows how to use tunable parameters to specify initial conditions for signals and states.

### Explore Example Model

Open the example model `rtwdemo_sigobj_iv` and configure it to show the generated names of blocks. The signal `S2` uses a `Simulink.Signal` object in the base workspace.

Copyright 1994-2019 The MathWorks, Inc.

Double-click the `Simulink.Signal` object S2 to view its properties. The **Initial value** property is set to `aa2`. The object uses the variable `aa2` to specify an initial condition for the signal S2. The **Storage class** property is set to `ExportedGlobal`. To use a `Simulink.Signal` object to initialize a signal, the signal object must use a storage class other than `Auto` or, if the corresponding data category in the Code Mapping Editor uses a storage class setting other than `Default`, `Model default`.

On the **Optimization** pane, in the Configuration Parameters dialog box, click **Configure**. The variable `aa2` is a tunable parameter that uses the storage class `ExportedGlobal`.

In the model, open the Enabled Subsystem. In the Outport block dialog box, the parameter **Output when disabled** is set to `reset`. When the subsystem becomes disabled, the output signal S2 resets to the initial value `aa2`.

Open the Unit Delay block dialog box. On the **State Attributes** tab, the **State name** box is set to `X1`.

Open the Enable block dialog box. The parameter **States when enabling** is set to **reset**. When the subsystem transitions from a disabled state to an enabled state, it resets internal block states, such as X1, to their initial values.

In the base workspace, double-click the `Simulink.Signal` object X1 to view its properties. The **Initial value** property is set to `aa1`.

Double-click the `Simulink.Parameter` object `aa1` to view its properties. The **Storage class** property is set to `ExportedGlobal`. You can generate tunable initial conditions for block states by using tunable parameters such as `aa1` and `Simulink.Signal` objects such as X1.

### Generate and Inspect Code

Generate code with the example model.

```
### Starting build procedure for model: rtwdemo_sigobj_iv
### Successful completion of build procedure for model: rtwdemo_sigobj_iv
```

In the code generation report, view the file `rtwdemo_sigobj_iv.c`. The code uses global variables to represent the block state X1 and the signal S2.

```
/* Exported block states */
real_T X1;                               /* '<S1>/Unit Delay' */

/* Exported block signals */
real_T S1;                               /* '<Root>/In1' */
real_T S3;                               /* '<Root>/Signal Conversion' */
real_T S2;                               /* '<S1>/Unit Delay' */
```

The code uses global variable to represent the tunable parameter `aa1`.

```
/* Exported block parameters */
real_T aa1 = -2.5;                       /* Variable: aa1
```

The model initialization function uses the tunable parameter `aa1` to initialize the state X1. The function also uses the tunable parameter `aa2` to initialize the signal S2.

```
/* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem (state X1 inside
/* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
X1 = aa1;
```

```

/* SystemInitialize for Output: '<S1>/Out1' */
S2 = 0.0;

```

In the model step function, when the Enabled Subsystem transitions from a disabled state to an enabled state, the Unit Delay block state X1 resets to its initial value.

```

if (rtb_PulseGenerator > 0) {
    if (!rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
        /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
        X1 = aal;
        rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = true;
    }

    /* UnitDelay: '<S1>/Unit Delay' */
    S2 = X1;

    /* Update for UnitDelay: '<S1>/Unit Delay' incorporates:
     * Inport: '<Root>/In1'
     */
    X1 = S1;
} else {
    if (rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
        /* Disable for Output: '<S1>/Out1' */
        S2 = 0.0;
        rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = false;
    }
}

/* End of Outputs for SubSystem: '<Root>/Enabled Subsystem (state X1 inside)' */

/* DataStoreWrite: '<Root>/Data Store Write' */
X2 = S2;

/* SignalConversion: '<Root>/Signal Conversion' incorporates:
 * DataStoreRead: '<Root>/Data Store Read'
 */
S3 = X2;
}

/* Model initialize function */
void rtwdemo_sigobj_iv_initialize(void)
{

```

```
/* Registration code */

/* initialize error status */
rtmSetErrorStatus(rtwdemo_sigobj_iv_M, (NULL));

/* block I/O */

/* exported global signals */
S3 = -3.0;

/* states (dwork) */
(void) memset((void *)&rtwdemo_sigobj_iv_DW, 0,
              sizeof(DW_rtwdemo_sigobj_iv_T));

/* exported global states */
X1 = 0.0;
X2 = 0.0;

/* external inputs */
S1 = -4.5;

/* Start for DiscretePulseGenerator: '<Root>/Pulse Generator' */
rtwdemo_sigobj_iv_DW.clockTickCounter = -2;

/* Start for DataStoreMemory: '<Root>/Data Store Memory' */
X2 = -3.5;

/* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem (state X1 inside)' */
/* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
X1 = aal;

/* SystemInitialize for Output: '<S1>/Out1' */
S2 = 0.0;

/* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem (state X1 inside)' */
}

/* Model terminate function */
void rtwdemo_sigobj_iv_terminate(void)
{
    /* (no terminate code required) */
}
```

If the Enabled Subsystem becomes disabled during code execution, the algorithm uses the tunable initial condition `aa2` to set the value of the signal `S2`.

```
} else {  
  
    if (rtwdemo_sigobj_iv_DW.EnabledSubsystemstateXlinside_M) {  
        /* Disable for Outport: '<S1>/Out1' */  
        S2 = 0.0;  
        rtwdemo_sigobj_iv_DW.EnabledSubsystemstateXlinside_M = false;  
    }  
}
```

## Generate Tunable Initial Condition Structure for Bus Signal

When you use a MATLAB® structure to specify initialization values for the signal elements in a bus, you can create a tunable global structure in the generated code.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to **Tunable**, the initial condition appears as a tunable substructure of the global parameters structure.

Whether you set **Default parameter behavior** to **Tunable** or **Inlined**, you can specify the initial condition by using a tunable `Simulink.Parameter` object whose value is a structure. If you apply a storage class other than `Auto` to the parameter object, the structure is tunable in the generated code.

To generate efficient code by avoiding data type mismatches between the structure and the bus signal, use either:

- Typed expressions to specify the values of the structure fields. Match the data type of each field with the data type of the corresponding signal element.
- A `Simulink.Bus` object to control the data types of the structure fields and the signal elements.

For basic information about using structures to initialize bus signals, and to decide how to control field data types, see “Specify Initial Conditions for Bus Signals” (Simulink).

## Generate Tunable Initial Condition Structure

This example shows how to use a tunable structure parameter to initialize a virtual bus signal.

Open the example model `rtwdemo_tunable_init_struct` and configure it to show the generated names of blocks.

On the **Modeling** tab, click **Model Data Editor**.

On the **Inports/Outports** tab, the **Data Types** column shows that each Inport block in the model uses a different output data type.

Open the Bus Creator block dialog box. The block output is a virtual bus.

In the Configuration Parameters dialog box, open the **Optimization** pane. The configuration parameter **Default parameter behavior** is set to **Tunable**. By default, block parameters, including initial conditions, appear in the generated code as tunable fields of the global parameters structure.

In the Model Data Editor, inspect the **States** tab.

For the Unit Delay block, set **Initial Value** to a structure that specifies an initial condition for each of the three signal elements. To generate efficient code, match the data types of the structure fields with the data types of the corresponding signal elements. For example, set **Initial Value** to the expression `struct('thermocpl',15.23,'magFlow',uint32(79),'posSwitch',false)`.

```
set_param('rtwdemo_tunable_init_struct/Unit Delay','InitialCondition',...
'struct('thermocpl',15.23,'magFlow',uint32(79),'posSwitch',false)')
```

Generate code from the example model.

```
### Starting build procedure for model: rtwdemo_tunable_init_struct
### Successful completion of build procedure for model: rtwdemo_tunable_init_struct
```

In the code generation report, view the file `rtwdemo_tunable_init_struct_types.h`. The code defines a structure type whose fields use the data types that you specified in the struct expression.

```
#ifndef DEFINED_TYPEDEF_FOR_struct_mqGiljsItE0G7cf1bNqMu_
#define DEFINED_TYPEDEF_FOR_struct_mqGiljsItE0G7cf1bNqMu_

typedef struct {
    real_T thermocpl;
    uint32_T magFlow;
    boolean_T posSwitch;
} struct_mqGiljsItE0G7cf1bNqMu;
```

View the file `rtwdemo_tunable_init_struct.h`. The struct type definition of the global parameters structure contains a substructure, `UnitDelay_InitialCondition`, which represents the **Initial condition** parameter of the Unit Delay block.

```
struct P_rtwdemo_tunable_init_struct_T {
    struct_mqGiljsItE0G7cf1bNqMu UnitDelay_InitialCondition;
```

View the file `rtwdemo_tunable_init_struct_data.c`. This source file allocates memory for the global parameters structure. The substructure `UnitDelay_InitialCondition` appears.

```
/* Block parameters (default storage) */
P_rtwdemo_tunable_init_struct_T rtwdemo_tunable_init_struct_P = {
    /* Mask Parameter: UnitDelay_InitialCondition
     * Referenced by:
     * '<Root>/Unit Delay'
     * '<Root>/Unit Delay'
     * '<Root>/Unit Delay'
     */
    {
        15.23,
```

```
    79U,  
    0  
  },
```

View the file `rtwdemo_tunable_init_struct.c`. The model initialization function uses the fields of the substructure to initialize the block states.

```
/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */  
rtwdemo_tunable_init_struct_DW.UnitDelay_1_DSTATE =  
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.thermocpl;  
  
/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */  
rtwdemo_tunable_init_struct_DW.UnitDelay_2_DSTATE =  
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.magFlow;  
  
/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */  
rtwdemo_tunable_init_struct_DW.UnitDelay_3_DSTATE =  
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.posSwitch;
```

### **Use Bus Object to Specify Data Types**

If you create a bus object, you can use it to specify the data type of the bus signal and the tunable initial condition structure. Before code generation, the `Simulink.Parameter` object casts the values of the structure fields to the data types of the signal elements. For basic information about creating bus objects and using them in models, see “Specify Bus Properties with Bus Objects” (Simulink).

Open the example model `rtwdemo_init_struct_busobj` and configure it to show the generated names of blocks.

In the base workspace, double-click the Simulink.Bus object ComponentData. The object defines three signal elements: thermocpl, magFlow, and posSwitch. The elements each use a different data type.

In the model, open the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). The **Imports/Exports** tab shows that for the Import block DataIn, the output data type (**Data Type** column) is set to Bus: ComponentData.

At the command prompt, create the structure parameter initStruct. You can specify the field values by using untyped expressions. To improve readability, specify the field posSwitch with a Boolean value.

```
initStruct = struct(...
    'thermocpl',15.23,...
    'magFlow',79,...
    'posSwitch',false ...
);
```

```
initStruct = Simulink.Parameter(initStruct);
```

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the Unit Delay block. The Model Data Editor highlights the row that corresponds to the **Initial condition** parameter of the block.

In the Model Data Editor, set the parameter value (**Value** column) to initStruct.

Click the **Show/refresh additional information** button. The parameter object, `initStruct`, appears in the data table as a row.

Use the **Data Type** column to set the data type of `initStruct` to `Bus: ComponentData`.

```
initStruct.DataType = 'Bus: ComponentData';
```

Set the **Change View** drop-down list to `Code`.

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to `initStruct`.

```
initStruct.StorageClass = 'ExportedGlobal';
```

Generate code from the example model.

```
### Starting build procedure for model: rtwdemo_init_struct_busobj  
### Successful completion of build procedure for model: rtwdemo_init_struct_busobj
```

In the code generation report, view the file `rtwdemo_init_struct_busobj_types.h`. The code creates a structure type `ComponentData` whose fields use the data types in the bus object.

```
#ifndef DEFINED_TYPEDEF_FOR_ComponentData_  
#define DEFINED_TYPEDEF_FOR_ComponentData_  
  
typedef struct {  
    real_T thermocpl;  
    uint32_T magFlow;  
    boolean_T posSwitch;  
} ComponentData;
```

View the file `rtwdemo_init_struct_busobj.c`. The code creates a global variable to represent the tunable parameter object `initStruct`.

```
/* Exported block parameters */  
ComponentData initStruct = {  
    15.23,  
    79U,  
    0  
};  
/* Variable: initStruct
```

The model initialization function uses the structure fields to initialize the block states.

```
/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_1_DSTATE = initStruct.thermocpl;

/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_2_DSTATE = initStruct.magFlow;

/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_3_DSTATE = initStruct.posSwitch;
```

To change the data type of a signal element, specify the new type in the bus object. The signal element in the model uses the new type. Before simulation and code generation, the parameter object `initStruct` casts the corresponding structure field to the new type.

## Initialization of Signal, State, and Parameter Data in the Generated Code

Signal lines, block parameters, and block states in a model can appear in the generated code as data, for example, as global variables. By default, the code initializes this data before execution of the primary algorithm. To match the numerics of simulation in Simulink, the code generator chooses the initial values based on specifications that you make in the model.

By understanding how the generated code initializes data, you can:

- Model a system that reinitializes states during execution, which means that the application can restart the entire system.
- Store initial values in memory as variables, which can persist between execution runs. You can then overwrite these values before starting or restarting a system.
- Generate efficient code by eliminating storage for invariant initial values and by preventing the generation of code that unnecessarily or redundantly initializes data.

For basic information about initializing signals and states in a model, see “Initialize Signals and Discrete States” (Simulink) and “Load State Information” (Simulink).

### Static Initialization and Dynamic Initialization

To initialize a data item such as a global variable, an application can use static or dynamic initialization.

- Static initialization occurs in the same statement that defines (allocates memory for) the variable. The initialization does not occur inside a function definition.

The code can be more efficient because none of the generated model functions execute initialization statements.

- Dynamic initialization occurs inside a function. For each model or nonvirtual subsystem, the code generator typically creates one or more functions that are dedicated to initialization.

The generated code or your code can restart a system by calling an initialization function during execution.

## Real-World Ground Initialization Requiring Nonzero Bit Pattern

Each data item has a real-world ground value. This value can depend on the data type of the item. For example, for a signal whose data type is `double` or `int8`, the real-world ground value is zero. For an enumeration, the ground value is the default enumeration member.

For some kinds of data, to represent a real-world ground value, a computer stores zero in memory (all bits zero). However, for some other data, a computer stores a nonzero value in memory. This data includes, for example:

- Fixed-point data with bias. The code initializes such a data item to the stored integer value that, given the scaling and bias, represents real-world zero.
- An enumeration whose default member maps to an integer value other than zero. For example, if the default member is `High` with an underlying integer value of 3, the code initializes such a data item to `High`.

## Initialization of Signal and State Data

In a model, you can control signal and state initial values through block parameters. For example, to set the initial value of a Unit Delay block, you use the **Initial condition** parameter. In some cases, you can also use the `InitialValue` property of a `Simulink.Signal` object. For most of these block parameters, the default value is 0.

You can also initialize states by using State Writer blocks in Initialize Function subsystems and the **Initial states** model configuration parameter.

By default, the generated code dynamically initializes signal and state data (and other data, such as the model error status) in the generated initialization function. The function, named `model_initialize` by default, performs signal and state initialization operations in this order:

- 1 Initializes the signal and state data in the default generated structures, such as the `DWork` structure, to a stored value of zero.
- 2 Initializes additional signal and state data that are not in the default generated structures to the relevant real-world ground value.

This initialization applies only to data that meet both of these criteria:

- The generated code defines (allocates memory for) the data.
- The data use a storage class other than `Auto` (the default storage class) or `Model default` (when the Code Mapping Editor specifies the `Default` storage class, the default setting).

For example, the code applies this operation to data items that use the storage class `ExportedGlobal`.

- 3** Initializes each signal and state to the real-world value that the model specifies, for example, through the **Initial condition** parameter of a Unit Delay block.
- 4** Initializes each state to the real-world value that you assign by using a State Writer block. The function performs this initialization only if you use an Initialize Function subsystem in the model.
- 5** Initializes each state to the real-world value that you specify with the configuration parameter **Initial states**.

After this initialization function executes, each data item has the last real-world value that the function assigned. For example, if you use a State Writer block to initialize a block state to 5 while also using the **Initial states** configuration parameter to initialize the same state to 10, the state ultimately uses 10 as an initial value.

### **memset for Bulk Initialization**

To initialize signal or state data items that have contiguous storage to a stored value of zero, the generated code can call `memset` in an initialization function. Data items that have contiguous storage include the `DWork` structure, arrays, or data items that use a multiword data type.

If your application requires it, you can prevent the generated code from using `memset` for initializing floating-point data to stored zero. See “Use `memset` to initialize floats and doubles to 0.0” (Simulink Coder).

### **Tunable Initial Values**

You can configure the way that tunable block parameters, such as the **Gain** parameter of a Gain block, appear in the generated code. Most block parameters that set initial values (for example, **Initial condition**) are tunable. For example, the configuration parameter **Default parameter behavior** can determine whether the initial values appear in the generated code as inlined constants or as tunable global data. You can also use parameter objects and storage classes to control the representation of these initial values.

For tunable initial values, in the model initialization function, the right-hand side of the assignment statement is a global variable, structure field, or other data whose value you can change in memory.

To make initial values tunable in the generated code, see “Control Signal and State Initialization in the Generated Code” on page 33-240.

## Initialization of Parameter Data

The generated code statically initializes parameter data to the values that you specify in Simulink.

To express the initial value of a tunable parameter (a global variable) as a mathematical expression involving system constants or other macros, which requires Embedded Coder, see “Initialization by Mathematical Expression (Embedded Coder)” (Simulink Coder).

### Kinds of Parameter Data

These model elements appear in the generated code as parameter data:

- Tunable block parameters, such as the **Gain** parameter of a Gain block, when you set **Default parameter behavior** to **Tunable**. Each parameter appears as a field of a dedicated global structure.
- Some tunable block parameters when you set **Default parameter behavior** to **Inlined**. When the code generator cannot inline the value of a parameter as a literal number, the parameter appears as a field of a dedicated global `const` structure.
- `Simulink.Parameter` objects to which you apply a that has an exported data scope. For example, the built-in storage class `ExportedGlobal` has an exported data scope, but the storage class `ImportedExtern` does not.

### Initialization by Mathematical Expression (Embedded Coder)

You can set the value of a parameter object (such as `Simulink.Parameter`) to a mathematical expression involving numbers, MATLAB variables, and other parameter objects. See “Set Variable Value by Using a Mathematical Expression” (Simulink).

If you use this technique with Embedded Coder, you can generate code that initializes the corresponding parameter data (global variable) by using the specified expression. For an example, see “Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)” on page 33-148. For general information, including limitations, see “Code Generation of Parameter Objects With Expression Values” (Simulink Coder).

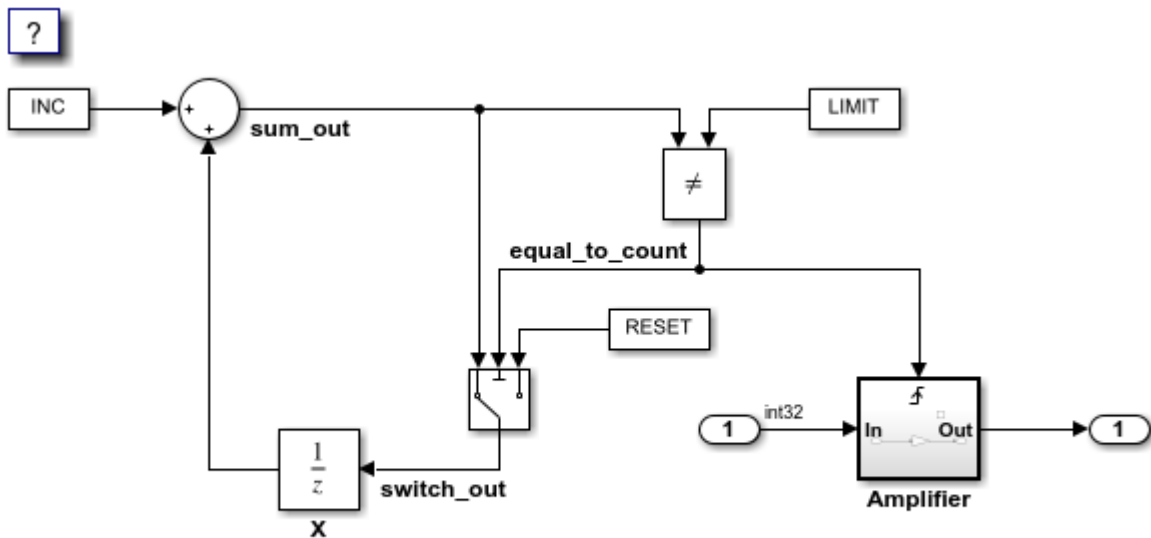

## Data Initialization in the Generated Code

This example shows how the generated code initializes signal, state, and parameter data.

### Explore Example Model

Open the example model, `rtwdemo_rtwintr0`.

```
open_system('rtwdemo_rtwintr0')
```

Copyright 1994-2019 The MathWorks, Inc.

In the Apps gallery, click **Simulink Coder**.

In the Model Data Editor, inspect the **States** tab. For the Unit Delay block state, the **Initial Value** is set to 0, the default, which means the initial value of the state is zero. The state is named X.

Set **Initial Value** to a nonzero number, for example, 5.

```
set_param('rtwdemo_rtwintr0/X', 'InitialCondition', '5')
```

Set the **Change view** drop-down list to Code.

In the data table, set **Storage Class** to `ExportedGlobal`. With this setting, the block state appears in the generated code as a separate global variable.

```
set_param('rtwdemo_rtwinintro/X', 'StateStorageClass', 'ExportedGlobal')
```

In the model, open the `Amplifier` subsystem, which is a triggered subsystem.

In the Model Data Editor, inspect the **Parameters** tab and set the **Change view** drop-down list to **Design**. To set and inspect initial values of signals and states, you can use the **Parameters** tab instead of the **States** tab.

The Model Data Editor shows that for the `Outport` block, the **Initial output** (`InitialOutput`) parameter is set to `0`, the default. This subsystem output requires an initial value because the subsystem executes conditionally. Leave the initial value at the default.

In the model, clear **Configuration Parameters > Signal storage reuse**. When you clear this setting, signal lines appear in the generated code as fields of a generated structure whose purpose is to store signal data. This representation of the signals makes it easier to see how the code generator initializes data.

```
set_param('rtwdemo_rtwinintro', 'OptimizeBlockIOStorage', 'off')
```

In the model, inspect the configuration parameter **Configuration Parameters > Optimization > Default parameter behavior**. The configuration parameter is set to `Inlined`, which means block parameters, including initial values, appear in the generated code as inlined literals or as `const` data.

Navigate to the root level of the model.

In the Model Data Editor, click the **Show/refresh additional information** button.

Near the **Filter contents** box, click the **Filter using selection** button.

In the model, click the Constant block labeled `INC`. The Model Data Editor shows that the **Constant value** (`Value`) parameter of the block is set to `INC`. `INC` is a MATLAB variable in the base workspace.

For `INC`, set the value in the **Value** column to `Simulink.Parameter(uint8(1))`. MATLAB converts `INC` to a `Simulink.Parameter` object.

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to `INC`. With this setting, the generated code defines `INC` as a global variable. Concerning initialization, `INC` is an item of parameter data.

```
INC = Simulink.Parameter(INC);
INC.StorageClass = 'ExportedGlobal';
```

### Generate and Inspect Code

To build the model and generate code, press **Ctrl+B**.

```
rtwbuild('rtwdemo_rtwintr0');
```

```
### Starting build procedure for model: rtwdemo_rtwintr0
### Successful completion of build procedure for model: rtwdemo_rtwintr0
```

In the generated file `rtwdemo_rtwintr0.c`, outside the definition of a function, the code statically initializes the parameter data `INC`. The value of `INC` is 1.

```
file = fullfile('rtwdemo_rtwintr0_grt_rtw','rtwdemo_rtwintr0.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T INC = 1U;',1,1)

/* Exported block parameters */
uint8_T INC = 1U;                                /* Variable: INC
```

In the same file, inspect the definition of the `rtwdemo_rtwintr0_initialize` function. First, the function uses `memset` to initialize the internal signals in the model to a stored value of 0.

```
rtwdemodbtype(file,'/* block I/O */','sizeof(B_rtwdemo_rtwintr0_T)');1,1)

/* block I/O */
(void) memset(((void *) &rtwdemo_rtwintr0_B), 0,
             sizeof(B_rtwdemo_rtwintr0_T));
```

The function then initializes the Unit Delay state, `X`, to a ground value. In this case, the ground value is zero.

```
rtwdemodbtype(file,'/* exported global states */','X = 0U;',1,1)

/* exported global states */
X = 0U;
```

The function also initializes other data, including the root-level inputs and outputs (Inport and Outport blocks), to ground values.

```
rtwdemo_dbtype(file, /* external inputs */, 'Amplifier_Trig_ZCE = POS_ZCSIG;', 1, 1)
```

```
/* external inputs */
rtwdemo_rtwintrou_U.Input = 0;

/* external outputs */
rtwdemo_rtwintrou_Y.Output = 0;
rtwdemo_rtwintrou_PrevZCX.Amplifier_Trig_ZCE = POS_ZCSIG;
```

The function then initializes X to the value that you specified in the **Initial condition** block parameter.

```
rtwdemo_dbtype(file, /* InitializeConditions for UnitDelay: '<Root>/X' */, ...
    'X = 5U;', 1, 1)
```

```
/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 5U;
```

Finally, the function initializes the output of the Amplifier subsystem.

```
rtwdemo_dbtype(file, 'SystemInitialize for Triggered SubSystem', ...
    'End of SystemInitialize for SubSystem', 1, 1)
```

```
/* SystemInitialize for Triggered SubSystem: '<Root>/Amplifier' */
/* SystemInitialize for Outport: '<Root>/Output' incorporates:
 * Outport: '<S1>/Out'
 */
rtwdemo_rtwintrou_Y.Output = 0;
```

### Inspect Difference Between Stored Value and Real-World Value

For some data, even if the real-world initial value is zero, a computer stores a nonzero value in memory. To observe this difference, apply a slope-bias fixed-point data type to the block state, X. To run this example, you must have Fixed-Point Designer™.

In the Model Data Editor, inspect the **Signals** tab.

In the model, click the output signal of the Switch block, switch\_out.

Use the **Data Type** column of the Model Data Editor to set the signal data type to `fixdt(1,16,1,3)`. This expression represents a fixed-point data type with a slope of 1 and a bias of 3.

```
set_param('rtwdemo_rtwinintro/Switch','OutDataTypeStr',...  
         'fixdt(1,16,1,3)')
```

In the model, select the Sum block. In the Property Inspector, under **Signal Attributes**, clear **Require all inputs to have the same data type**.

```
set_param('rtwdemo_rtwinintro/Sum','InputSameDT','off')
```

To prevent compilation errors on different platforms, select the model configuration parameter **Generate code only**. This setting causes the model to generate only code.

```
set_param('rtwdemo_rtwinintro','GenCodeOnly','on')
```

To build the model and generate code, press **Ctrl+B**.

```
rtwbuild('rtwdemo_rtwinintro')
```

```
### Starting build procedure for model: rtwdemo_rtwinintro  
### Successful completion of code generation for model: rtwdemo_rtwinintro
```

The model initialization function first initializes  $X$  to a real-world ground value, 0. Due to the slope-bias data type, which has bias 3, this real-world value corresponds to a stored value of -3.

```
rtwdemodbtype(file,'/* exported global states */','X = -3;',1,1)
```

```
/* exported global states */  
X = -3;
```

The function then initializes  $X$  to the real-world initial value that you specified in the **Initial condition** block parameter, 5. This real-world value corresponds to a stored value of 2.

```
rtwdemodbtype(file,'/* InitializeConditions for UnitDelay: '<Root>/X' */',...  
         'X = 2;',1,1)
```

```
/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 2;
```

## Modeling Goals

| Goal                                                                | More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Explicitly model initialization behavior by using blocks            | <p>You can explicitly model initialization and reset behavior by using Initialize Function and Reset Function subsystems. In the subsystems, use State Writer blocks to calculate and assign an initial value for a state dynamically. The corresponding code appears in the model initialization function.</p> <p>For more information, see “Generate Code That Responds to Initialize, Reset, and Terminate Events” on page 10-2.</p>                                                                                                                                                                                                                                                                                                                                                                                                       |
| Prevent generation of code that explicitly initializes data to zero | <p>If your application environment already initializes global variables to zero, for more efficient code, you can prevent the generation of statements that explicitly initialize global variables to zero. This optimization applies only to signals and states whose initial values are stored in memory as zero. For example, the code generator does not apply the optimization to:</p> <ul style="list-style-type: none"> <li>• Data for which you specify a nonzero initial value by using a block parameter.</li> <li>• Data whose real-world initial value is zero but whose corresponding stored value is not zero.</li> <li>• Enumerated data whose default member maps to a nonzero integer.</li> </ul> <p>The optimization requires Embedded Coder. For more information, see “Remove Zero Initialization Code” on page 70-4.</p> |

| Goal                                                           | More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Generate code that imports data from your external code</p> | <p>You can generate code that reuses (imports) data that your external code defines. For example, you can apply the storage class <code>ImportedExtern</code> to a signal line, block state, or parameter object. For imported data:</p> <ul style="list-style-type: none"> <li>• The generated code does not initialize parameter data. Your code must initialize imported parameter data.</li> <li>• The generated initialization functions dynamically initialize some signal and state data. Unlike data that the generated code allocates, the code does not initialize imported signal or state data to a stored value of zero. Instead, the code immediately initializes the data to the real-world value that you specify in Simulink.</li> </ul> <p>For more information, including how to prevent the generated code from initializing imported data, see “Exchange Data Between External Calling Code and Generated Code” (Simulink Coder).</p> |

## Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box

You can use the Model Parameter Configuration dialog box to declare numeric MATLAB variables in the base workspace as tunable parameters. You can select code generation options, such as storage class, for each tunable parameter.

However, it is a best practice to instead use parameter objects to declare tunable parameters. Do not use the Model Parameter Configuration dialog box to select parameter objects in the base workspace. To use parameter objects, instead of the Model Parameter Configuration dialog box, to declare tunable parameters, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99.

---

**Note** You cannot use the Model Parameter Configuration dialog box to declare tunable parameters for a referenced model. Use `Simulink.Parameter` objects instead.

---

### Declare Existing Workspace Variables as Tunable Parameters

Use the Model Parameter Configuration dialog box to declare existing workspace variables as tunable parameters for a model.

- 1 In the Configuration Parameters dialog box, on the **Optimization** pane, click **Configure**.
- 2 In the Model Parameter Configuration dialog box, under **Source list**, select a method to populate the list of available workspace variables.
  - Select **MATLAB workspace** to view numeric variables that are defined in the base workspace.
  - Select **Referenced workspace variables** to view only the numeric variables in the base workspace that the model uses. Selecting this option begins a diagram update and a search for used variables, which can take time for a large model.
- 3 In the Model Parameter Configuration dialog box, under **Source list**, select one or more workspace variables.
- 4 Click **Add to table**. The variables appear as tunable parameters under **Global (tunable) parameters**, and appear in italic font under **Source list**.
- 5 Optionally, select a parameter under **Global (tunable) parameters**, and adjust the code generation settings for the parameter. For more information about adjusting the

code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 33-268

- 6 Click **OK** to apply your selection of tunable parameters and close the dialog box.

## Declare New Tunable Parameters

Use the Model Parameter Configuration dialog box to declare new tunable parameters. You can use this technique to declare the names of tunable parameters, and to adjust their code generation settings, before you create the corresponding workspace variables.

- 1 In the Configuration Parameters dialog box, on the **Optimization > Signals and Parameters** pane, click **Configure**.
- 2 In the Model Parameter Configuration dialog box, under **Global (tunable) parameters**, click **New**.
- 3 Under the **Name** column, specify a name for the new tunable parameter.
- 4 Optionally, adjust the code generation settings for the new parameter. For more information about adjusting the code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 33-268
- 5 Click **OK** to apply your changes and close the dialog box.

## Set Tunable Parameter Code Generation Options

To set the properties of tunable parameters listed under **Global (tunable) parameters** in the Model Parameter Configuration dialog box, select a parameter and specify a storage class and, optionally, a storage type qualifier.

| Property                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Storage class</b>          | Select one of the following to use for code generation: <ul style="list-style-type: none"> <li>• Model default</li> <li>• ExportedGlobal</li> <li>• ImportedExtern</li> <li>• ImportedExternPointer</li> </ul> For more information about tunable parameter storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99.                                                                        |
| <b>Storage type qualifier</b> | For variables with a storage class other than Auto, you can add a qualifier (such as <code>const</code> or <code>volatile</code> ) to the generated storage declaration. To do so, you can select a predefined qualifier from the list, or add qualifiers not in the list by typing them in. The code generator does not check the storage type qualifier for validity, and includes the qualifier text in the generated code without checking syntax . |

## Programmatically Declare Workspace Variables as Tunable Parameters

### Tune Parameters from the Command Line

When parameters are MATLAB workspace variables, the Model Parameter Configuration dialog box is the recommended way to see or set the properties of tunable parameters. In addition to that dialog box, you can also use MATLAB `get_param` and `set_param` commands.

---

**Note** You can also use `Simulink.Parameter` objects for tunable parameters. See “Create Tunable Calibration Parameter in the Generated Code” on page 33-140 for details.

---

The following commands return the tunable parameters and corresponding properties:

- `get_param(gcs, 'TunableVars')`
- `get_param(gcs, 'TunableVarsStorageClass')`
- `get_param(gcs, 'TunableVarsTypeQualifier')`

The following commands declare tunable parameters or set corresponding properties:

- `set_param(gcs, 'TunableVars', str)`

The argument `str` (character vector) is a comma-separated list of variable names.

- `set_param(gcs, 'TunableVarsStorageClass', str)`

The argument `str` (character vector) is a comma-separated list of storage class settings.

The valid storage class settings are

- `Auto`
- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`
- `set_param(gcs, 'TunableVarsTypeQualifier', str)`

The argument `str` (character vector) is a comma-separated list of storage type qualifiers.

The following example declares the variable `k1` to be tunable, with storage class `ExportedGlobal` and type qualifier `const`. The number of variables and number of specified storage class settings must match. If you specify multiple variables and storage class settings, separate them with a comma.

```
set_param(gcs, 'TunableVars', 'k1')
set_param(gcs, 'TunableVarsStorageClass', 'ExportedGlobal')
set_param(gcs, 'TunableVarsTypeQualifier', 'const')
```

## Share Data Between Code Generated from Simulink, Stateflow, and MATLAB

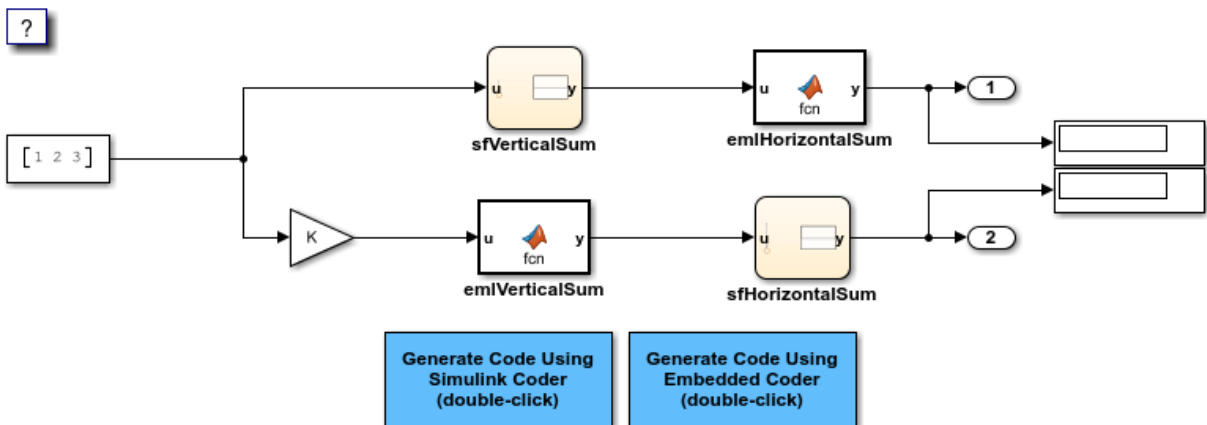

Stateflow and MATLAB Coder can fully define their data definitions, or they can inherit them from Simulink. Data definition capabilities include:

- Inheriting input/output data types and sizes from Simulink.
- Parameterized data types and sizes. That is, data type and size may be specified as a function of another data's type and size, e.g.,  $\text{type}(y)=\text{type}(u)$  and  $\text{size}(y)=\text{size}(u)$ .
- Inferred output size and type from Simulink via signal attribute back propagation.
- Parameter scoped data, which allows referencing Simulink parameters in Stateflow and MATLAB.

### Open Example Model

Open the example model `rtwdemo_dynamicio`.

```
open_system('rtwdemo_dynamicio')
```

Copyright 1994-2019 The MathWorks, Inc.

**Instructions**

- 1** Compile the model (on the **Simulation** tab, under **Prepare**, click **Update Model**) and note the displayed signal types and sizes.
- 2** Change the data type and/or size of the Constant block and recompile the model. Note that the attributes of the signals automatically adapt to the Constant block specification.
- 3** Generate and inspect code using the blue buttons in the model. Note that K is shared by the Gain and sfVerticalSum block.

**Notes**

- The data type and size of Stateflow and MATLAB data is inherited from Simulink.
- The Gain block and the Stateflow chart sfVerticalSum share the Simulink parameter K, which is defined in the MATLAB workspace as a Simulink.Parameter with Model default storage class (i.e., `rtP.K` in the generated code).

- “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2
- “Establish Data Ownership in a System of Components” on page 34-15

## **Control Placement of Global Data Definitions and Declarations in Generated Files**

The generated code can create standard, global structure variables whose fields represent the signal, state, and parameter data in a model. With storage classes, you can configure data to appear in the code as separate global variables or custom global structures. For information about the standard data structures, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-68 and “How Generated Code Exchanges Data with an Environment” on page 33-51. For information about storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-87.

You can control the file placement of the variable definitions and declarations. Use the information in the table.

| Goal                                           | Details and Techniques                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• Reduce the size of a generated file by creating multiple smaller files</li> <li>• Organize data into different files to make generated code easier to understand</li> </ul> | <p>Depending on the setting of <b>Configuration Parameters &gt; File packaging format</b>, generated files such as <i>model.c</i> and <i>model_data.c</i> can contain many definitions of global variables. Corresponding header files can contain many declarations.</p> <ul style="list-style-type: none"> <li>• To make <i>model.c</i> smaller, consider setting <b>File packaging format</b> to <b>Modular</b> or <b>Compact</b> (with <b>separate data file</b>). Then, the generated code defines the standard structures that represent tunable and constant parameter data in <i>model_data.c</i> instead of <i>model.c</i>.</li> <li>• To place different categories of data (for example, external parameters, block states, and internal signals) in specific files by default, use the Code Mapping Editor. For each category of data, use a storage class such as <b>ExportToFile</b> and specify the custom attribute <b>Header file</b>. See “Configure Default Code Generation for Data” on page 32-8.</li> <li>• For precise control over the file placement of data, apply storage classes such as <b>ExportToFile</b> to individual data items. Use the custom attributes of the storage class, such as <b>Definition file</b> and <b>Header file</b>, to specify file placement for each data item. To configure multiple data elements at once, you can use the Model Data Editor. For an example, see “Definition and Declaration of Signal Data” on page 24-9.</li> </ul> |

| Goal                                      | Details and Techniques                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Separate data definitions from function definitions                                             | <p>By default, the generated file that defines the entry-point functions for a model or subsystem also defines the data for that model or subsystem. When you frequently make changes to data, especially initial values for tunable parameters, the changing source code files can impede verification and make change management more difficult. To separate the data from the functions:</p> <ul style="list-style-type: none"> <li>• Consider setting the model configuration parameter <b>File packaging format</b> to a value that results in the generation of the separate data file <i>model_data.c</i>. Then, the definitions of the standard structures that store tunable and constant parameter data appear in this file instead of in <i>model.c</i>.</li> <li>• Apply storage classes such as <code>ExportToFile</code> to data elements by using the Code Mapping Editor and the Model Data Editor. Use the custom attributes of the storage class, such as <b>Definition file</b> and <b>Header file</b>, to specify file placement. For more information, see “Configure Default Code Generation for Data” on page 32-8 and “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19.</li> </ul> |
| Isolate data definitions in separate files for component-based, team-oriented model development | See “Organize Data to Support Component-Based, Team-Oriented Model Development” on page 34-8.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Goal                                                                                                         | Details and Techniques                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aggregate definitions of variant control parameters ( <code>#define</code> macros) into a single header file | <p>As described in “Generate Preprocessor Conditionals for Variant Systems” on page 25-40, a variant control parameter is a parameter object such as <code>Simulink.Parameter</code>. You apply a storage class that makes the object appear in the generated code as a macro. To control the file placement, choose one of these techniques:</p> <ul style="list-style-type: none"> <li>• For each variant control parameter that uses the storage class <code>Define</code>, set the <b>Header file</b> property to the same value. To configure these objects in a list that you can search, sort, and filter, you can use the Model Data Editor <b>Parameters</b> tab. For an example, see “Generate Variant Control Macros in Same Header File” on page 25-42.</li> <li>• Create one or more storage classes that represent variant control parameters. In the Custom Storage Class Designer, you can set <b>Header file</b> to a value that applies to all of the variant control parameters that use the storage class. With this technique, you do not need to manually specify a header file for each variant control parameter. For more information, see “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-26.</li> </ul> |

## Organize Data to Support Component-Based, Team-Oriented Model Development

Depending on your model configuration, data definitions can appear aggregated in large generated files. In a system of components (subsystems or referenced models), you can

separate and organize the data definitions into manageable, meaningful files based on the component hierarchy.

| Goal                                                                                                                      | Technique                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Establish ownership of global data by placing the data definitions with the code generated for specific components</p> | <p>When you divide a system into components by using referenced models and atomic subsystems, by default, global data is typically defined by the code generated for the top component in the hierarchy. Global data includes parameters, signals, and states to which you apply storage classes (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99).</p> <p>Instead, you can place global data definitions with other components in the hierarchy. For an example involving referenced models, see “Establish Data Ownership in a System of Components” on page 34-15.</p> <ul style="list-style-type: none"> <li>To place a data definition with the code generated for a referenced model, use a built-in storage class such as <code>ExportToFile</code>, or a storage class that you create in a package, and set the <b>Owner</b> property to the name of the referenced model.</li> </ul> <p>To use <b>Owner</b> in a model, you must select the model configuration parameter <b>Use owner from data object for data definition placement</b>. The default setting for this parameter, cleared, means the code generator ignores the setting that you specify for <b>Owner</b>.</p> <p>If only one referenced model uses a parameter object, consider storing the object in the model workspace of that model. Then, the code generated for</p> |

## Specify Default Placement

When you create data in a model by adding blocks and signal lines, by default, the data definitions appear in `model.c`. To specify a different default placement, use these tools and parameters:

- The model configuration parameter **File packaging format**. The setting that you choose determines whether the code generator places the standard structures that store tunable and constant parameter data in `model_data.c` instead of `model.c`. See “File packaging format”.

- The Code Mapping Editor. For each category of model data, you can specify a default storage class, which controls file placement. For example, apply the storage class `ExportToFile` to a data category and, in the Property Inspector, use the **DefinitionFile**, **HeaderFile**, and **Owner** custom attributes to control file placement.
- The model configuration parameters **Data definition** and **Data declaration**. These configuration parameters specify the default file placement for data items to which you apply storage classes.
  - These configuration parameters do not affect data items to which you apply the storage classes `ExportedGlobal`, `ImportedExtern`, and `ImportedExternPointer`.
  - If you apply a storage class that explicitly specifies definition and declaration files for a data element, those specifications override the **Data definition** and **Data declaration** configuration parameters.

For more information, see “Data definition” and “Data declaration”.

- The subsystem block parameter **Function with separate data**. When you select this parameter, the standard structures that store the subsystem data, such as the `DWork` structure, appear as separate structure variables. By default, the variable definitions appear in the source file that defines the subsystem execution function. See “Generate Modular Function Code for Nonvirtual Subsystems” on page 40-51.

## Override Default Placement for Individual Data Items

For an individual data item, to override the default file placement, use the Model Data Editor to apply a storage class directly. For example, to make a data item appear in the generated code as a global variable, apply the storage class `ExportToFile`. Then, use the **Definition file**, **Header file** custom attributes to control file placement. To apply storage classes directly, see “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19.

## Prevent Name Clashes by Configuring Data Item as static

To apply the C keyword `static` to a global variable, which can help you avoid name clashes by limiting the scope of the variable name to the file that defines the variable, choose one of these techniques:

- Apply the built-in storage class `FileScope`. For more information, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-87.

- If FileScope does not satisfy your requirements, create your own storage class by using the Custom Storage Class Designer. In the Designer, set **Data scope** to File or Auto.
  - With File, the data element appears in the code as a `static` global variable.
  - With Auto, the code generator first attempts to represent the data element with a local variable in a function. If this attempt fails, the code generator uses a `static` global variable.

For an example that shows how to create your own storage class by using the Designer, see “Create and Apply a Storage Class” on page 37-26.

You cannot apply `static` to the standard data structures such as the DWork structure.

To access `static` data, you can configure the generated code to include an interface such as an `a2l` (ASAP2) file. For more information, see “Export ASAP2 File for Data Measurement and Calibration” on page 58-2. To place the data in a specific memory location by including pragmas or other decorations in the generated code, create your own memory section and storage class. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 41-2.

## Code Generation Impact of Storage Location for Parameter Objects

You can create a parameter object (such as `Simulink.Parameter`) in the base workspace, a model workspace, or a data dictionary. However, when you apply a storage class to the object, the location of the object can impact the file placement of the corresponding data definition in the generated code. See “Code Generation Impact of Storage Location for Parameter Objects” on page 33-149.

## Specify Default `#include` Syntax for Data Header Files

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19). You then use the **Header file** custom attribute to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify **Header file**, you can omit delimiters (“ or <>) and use only the file name. You can then control the default delimiters

that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters > Code Generation > Code Placement > #include file delimiters** to `#include <header.h>`.

## Establish Data Ownership in a System of Components

This example shows how to establish ownership of global data in the code generated from a system of components (referenced models).

When you create a global variable in the generated code by applying a storage class to a data element in a referenced model (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99), under certain conditions, the code generator places the variable definition with the code generated from the top model in the hierarchy. This default placement can make it more difficult to determine which component is responsible for the data and to manage code changes in a team-based development environment.

To establish ownership of a global variable by placing the definition with the code generated from the relevant component, apply a storage class such as `ExportToFile` and specify the **Owner** custom attribute. Alternatively, for parameter objects such as `Simulink.Parameter` that you use in only one component, you can establish ownership by storing the object in a model workspace instead of the base workspace or a data dictionary.

### Explore Example Model

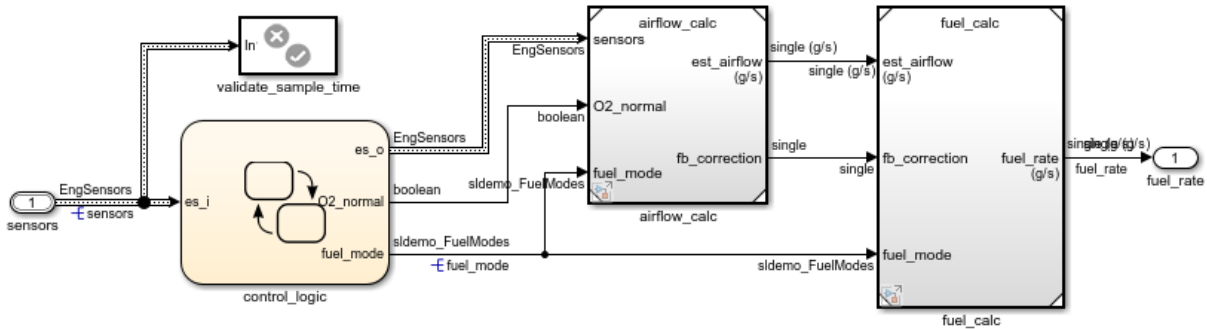

Copy the script file `prepare_sl-demo_fuelsys_dd_ctrl.m` to your current folder.

```
[~, ~] = copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_sl-demo_fuelsys',  
    'prepare_sl-demo_fuelsys_dd_ctrl.m'), 'f');
```

Run the copy of the script in your current folder. The script opens the model `sl-demo_fuelsys_dd_controller` and prepares it for this example.

```
prepare_sl-demo_fuelsys_dd_ctrl  
open_system('sl-demo_fuelsys_dd_controller')
```

## Fuel Rate Controller

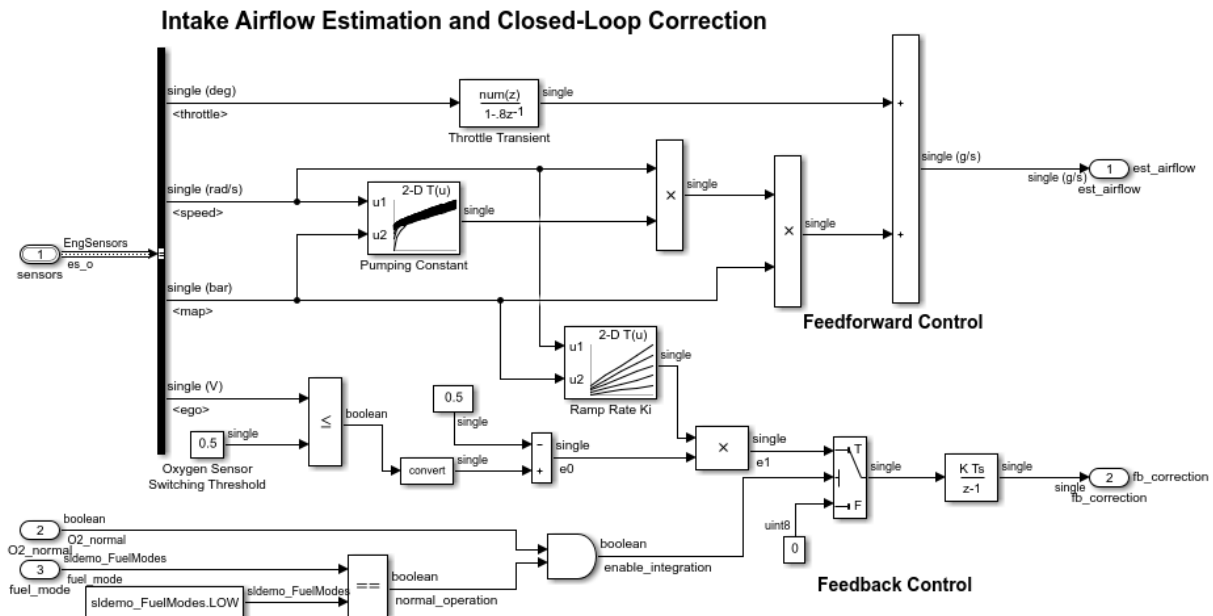

Copyright 1990-2017 The MathWorks, Inc.

This controller model contains two component models, `airflow_calc` and `fuel_calc`. The two outputs of `airflow_calc`, `est_airflow` and `fb_correction`, are inputs of `fuel_calc`.

Open the `airflow_calc` model.

```
open_system('airflow_calc')
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, set the **Change view** drop-down list to Code.

In the model, select the upper Outport block.

In the Model Data Editor, inspect the value in the **Storage Class** column. The signal that this block represents, `est_airflow`, uses the storage class `ExportToFile`. With this setting, the signal appears in the generated code as a global variable. The Outport block labeled `fb_correction` also uses this setting.

In the Model Data Editor, select the **Parameters** tab and click the **Show/refresh additional information** button. The Model Data Editor now shows information about workspace variables and objects, such as `Simulink.Parameter` objects, that the model uses to set block parameter values.

In the **Filter contents** box, enter `numerator`. The `Simulink.Parameter` object `numerator_param`, which is in the base workspace, sets the value of the **Numerator** parameter in the Discrete Filter block labeled `Throttle Transient`. The object uses the storage class `ExportToFile`.

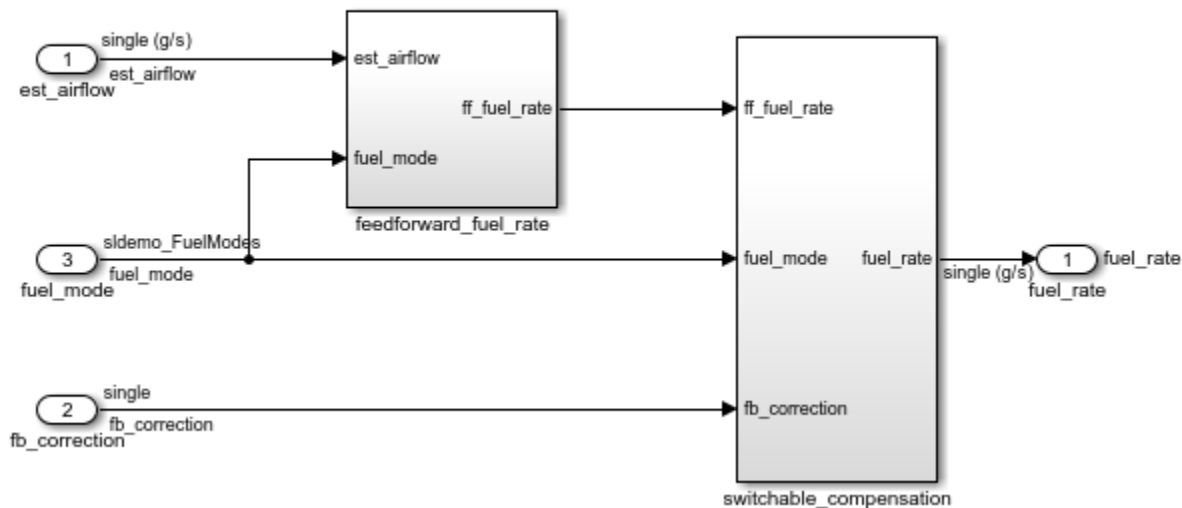

Select the **Signals** tab.

In the **Filter contents** box, enter `e0`. The signal `e0`, which is internal to the `airflow_calc` component, also uses `ExportToFile`. The signal is internal because it is not a root-level input or output of the model.

Open the `fuel_calc` model.

```
open_system('fuel_calc')
```

## Fuel Rate Calculation

In the Model Data Editor for this model, on the **Inports/Outports** tab, set **Change view** to Code. The Inport blocks `est_airflow` and `fb_correction` use the same storage class, `ExportToFile`, as the corresponding Outport blocks in `airflow_calc`. The Outport block labeled `fuel_rate` also uses `ExportToFile`.

### Generate and Inspect Code

Generate code from the controller model, `sldemo_fuelsys_dd_controller`.

```
rtwbuild('sldemo_fuelsys_dd_controller')
```

```

### Starting build procedure for model: airflow_calc
### Successful completion of build procedure for model: airflow_calc
### Starting build procedure for model: fuel_calc
### Successful completion of build procedure for model: fuel_calc
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller

```

In the code generation report, under **Referenced Models**, click the hyperlink to inspect the code generated for `airflow_calc`.

The file `airflow_calc.c` defines the global variable that represents the signal `e0`. Because the blocks that write to and read from `e0` exist only in `airflow_calc`, the code generator assumes that this component owns the signal.

```

file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
    'real32_T e0;',1,1)

/* Definition for custom storage class: ExportToFile */
real32_T e0;                                /* '<Root>/Sum1' */

```

In the code generation report, return to the code generated for `sldemo_fuelsys_dd_controller`.

The file `sldemo_fuelsys_dd_controller.c` defines the other global variables.

```

file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,...
    '/* Definition for custom storage class: ExportToFile */',...
    'real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1);

/* Definition for custom storage class: ExportToFile */
real32_T est_airflow;                        /* '<Root>/airflow_calc' */
real32_T fb_correction;                      /* '<Root>/airflow_calc' */
real32_T fuel_rate;                          /* '<Root>/fuel_calc' */
real32_T numerator_param[2] = { 0.01F, -0.01F } ;

```

Because the signals `est_airflow` and `fb_correction` pass between the two components and through the top-level controller model, the code generator assumes that `sldemo_fuelsys_dd_controller` owns the signals. The code generator makes a similar assumption about `fuel_rate`. Because the parameter object `numerator_param`

exists in the base workspace, any model in the hierarchy can use the object. Therefore, the code generator assumes that `sldemo_fuelsys_dd_controller` owns the parameter.

You can configure each shared signal and the parameter object so that the corresponding variable definition appears in the code generated for the relevant component.

### Configure Data Ownership

In this example, you configure code generation settings so that:

- The code generated for the `airflow_calc` model defines the signals that pass between the two components, `est_airflow` and `fb_correction`.
- The code generated for `airflow_calc` defines the parameter data, `numerator_param`.
- The code generated for `fuel_calc` defines the output signal that it calculates, `fuel_rate`.

In the `airflow_calc` model, on the **Modeling** tab, under **Design**, click **Property Inspector**.

In the Model Data Editor, select the **Inports/Outports** tab.

Find the row that corresponds to the Outport block `est_airflow`.

In the row, click the icon in the left column. The Property Inspector shows the properties of the Outport block.

In the Property Inspector, under **Code**, set **CoderInfo.CustomAttributes.Owner** to `airflow_calc`. The code generator places the definition of the global variable with the code generated for `airflow_calc`.

For `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`.

Select the **Parameters** tab.

Find the row that corresponds to the parameter object, `numerator_param`.

In the row, double-click the icon in the left column. The Model Explorer opens and displays the properties of `numerator_param`.

In the **Model Hierarchy** pane, expand the **airflow\_calc** node so that you can see the subordinate **Model Workspace** node.

Use the Model Explorer to move `numerator_param` from the base workspace to the `airflow_calc` model workspace. For example, in the **Model Hierarchy** pane, select **Base Workspace**. Then, drag `numerator_param` from the **Contents** pane to the **Model Workspace** node in the **Model Hierarchy** pane. With this change, the code generator assumes that `airflow_calc` owns `numerator_param`, and places the variable definition in the code generated for `airflow_calc`.

In the `fuel_calc` model, select **View > Property Inspector**.

For the Inport blocks `est_airflow` and `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`. With this configuration, the `fuel_calc` code does not define the variables.

For the Outport block, use the Model Data Editor and the Property Inspector to set **Owner** to `fuel_calc`.

Alternatively, to configure the data in the models, use these commands at the command prompt:

```
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow', 'SignalName', 'est_airflow')
set_param('airflow_calc/est_airflow', 'SignalObject', copy(temp))

set_param('airflow_calc/fb_correction', 'SignalName', 'fb_correction')
set_param('airflow_calc/fb_correction', 'SignalObject', copy(temp))

mdlwks = get_param('airflow_calc', 'ModelWorkspace');
assignin(mdlwks, 'numerator_param', copy(numerator_param));

portHandles = get_param('fuel_calc/est_airflow', 'portHandles');
outportHandle = portHandles.Output;
set_param(outportHandle, 'Name', 'est_airflow')
set_param(outportHandle, 'SignalObject', copy(temp))

portHandles = get_param('fuel_calc/fb_correction', 'portHandles');
outportHandle = portHandles.Output;
```

```

set_param(outportHandle, 'Name', 'fb_correction')
set_param(outportHandle, 'SignalObject', copy(temp))

temp.CoderInfo.CustomAttributes.Owner = 'fuel_calc';

set_param('fuel_calc/fuel_rate', 'SignalName', 'fuel_rate')
set_param('fuel_calc/fuel_rate', 'SignalObject', copy(temp))

clear temp portHandles outportHandle numerator_param

```

In each of the three models, select **Configuration Parameters > Use owner from data object for data definition placement**. With this setting cleared (the default), the code generator ignores the values that you specify for **Owner**.

```

set_param('fuel_calc', 'EnableDataOwnership', 'on')
set_param('airflow_calc', 'EnableDataOwnership', 'on')
set_param('sldemo_fuelsys_dd_controller', 'EnableDataOwnership', 'on')

```

Save the component models.

```

save_system('fuel_calc')
save_system('airflow_calc')

```

### Generate Improved Code

Generate code from the controller model, `sldemo_fuelsys_dd_controller`.

```

rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: airflow_calc
### Successful completion of build procedure for model: airflow_calc
### Starting build procedure for model: fuel_calc
### Successful completion of build procedure for model: fuel_calc
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller

```

Now, the file `sldemo_fuelsys_dd_controller.c` does not define any of the global variables.

In the code generation report, inspect the code generated for `airflow_calc`.

The file `airflow_calc.c` now defines the global variables that belong to `airflow_calc`.

```

file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
    'real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1)

/* Definition for custom storage class: ExportToFile */
real32_T e0; /* '<Root>/Sum1' */
real32_T est_airflow; /* '<Root>/Sum' */
real32_T fb_correction; /* '<Root>/Discrete Integrator' */
real32_T numerator_param[2] = { 0.01F, -0.01F } ;

```

Inspect the code generated for `fuel_calc`. The file `fuel_calc.c` defines the global variable `fuel_rate`.

```

file = fullfile('slprj','ert','fuel_calc','fuel_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
    'real32_T fuel_rate;',1,1)

/* Definition for custom storage class: ExportToFile */
real32_T fuel_rate; /* '<S2>/Merge' */

```

### Create Single Point of Specification for Signals That Pass Between Components

The signal data elements `est_airflow` and `fb_correction` are represented by `Outport` blocks in `airflow_calc` and by `Inport` blocks in `fuel_calc`. If you want to change the configuration of one of these signals, you must make the change in both models. For example, if you want to change the storage class of `est_airflow` from `ExportToFile` to `Volatile`, you must change the storage class twice: once for the `Outport` block in `airflow_calc` and again for the `Inport` block in `fuel_calc`.

To make maintenance of each signal easier, store the code generation settings in a `Simulink.Signal` object, which can exist in the base workspace or a data dictionary.

In the Model Data Editor for `airflow_calc`, on the **Inports/Outports** tab, find the row that corresponds to `est_airflow`.

For that row, in the **Signal Name** column, click the cell.

In the cell, next to the `est_airflow` text, click the action button (with three vertical dots). Select **Create and Resolve**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Signal` and click **Create**. A `Simulink.Signal` object named `est_airflow` appears in the base workspace. In the

Model Data Editor, for `est_airflow`, the check box in the **Resolve** check box is selected, which means the Outport block acquires code generation settings from the signal object in the base workspace.

In the `est_airflow` property dialog box, set **Storage class** to `ExportToFile`.

Set **Owner** to `airflow_calc`.

Use the Model Data Editor to create a similar signal object for `fb_correction`.

In the Model Data Editor for `fuel_calc`, on the **Inports/Outports** tab, in the **Resolve** column, select the check boxes for `est_airflow` and `fb_correction`. Now, each Inport block acquires code generation settings from the corresponding signal object.

Alternatively, to create the signal object and configure the blocks and lines in the model, at the command prompt, use these commands:

```
est_airflow = Simulink.Signal;
est_airflow.CoderInfo.StorageClass = 'Custom';
est_airflow.CoderInfo.CustomStorageClass = 'ExportToFile';
est_airflow.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

fb_correction = Simulink.Signal;
fb_correction.CoderInfo.StorageClass = 'Custom';
fb_correction.CoderInfo.CustomStorageClass = 'ExportToFile';
fb_correction.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow','MustResolveToSignalObject','on')

set_param('airflow_calc/fb_correction','MustResolveToSignalObject','on')

portHandles = get_param('fuel_calc/est_airflow','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'MustResolveToSignalObject','on')

portHandles = get_param('fuel_calc/fb_correction','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'MustResolveToSignalObject','on')

clear portHandles outportHandle
```

Save the component models and generate code from `sldemo_fuelsys_dd_controller`. The code is the same as it was before you created

the Simulink.Signal objects. Now, you can make changes to the signal objects instead of the corresponding blocks and lines in the models.

```
save_system('airflow_calc')
save_system('fuel_calc')
rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: airflow_calc
### Successful completion of build procedure for model: airflow_calc
### Starting build procedure for model: fuel_calc
### Successful completion of build procedure for model: fuel_calc
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

## Control Data Type Names in Generated Code

By default, the generated code uses Simulink Coder data type aliases to define scalar and array variables. For example, the Simulink Coder type `real32_T` corresponds to the Simulink type `single`. The code defines these types through `typedef` statements that build on C primitive types such as `float` and `short`. You can configure the code to use custom type names instead.

The code also aggregates signal, block parameter, and state data into structures (see “How Generated Code Exchanges Data with an Environment” on page 33-51 and “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-68) by default. You can specify a naming rule for these structure types. You can also place data items into separate custom structures whose type names you can control.

Control these type names to help you to:

- Conform to coding standards. For an example, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-27.
- Integrate the generated code with your external code. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-34.
- Make the generated code more readable and meaningful.

For custom types, you can also specify that the generated code reuse type definitions, for example, `typedef` statements, from your external code.

For information about data type names that you cannot control and about custom data types that the generated code does not support, see “Limitations” on page 35-21.

To inform the code generator about the bit length of generic C types such as `int` and `short` for your target hardware, use **Hardware Implementation** configuration parameters. See “Configure Run-Time Environment Options” on page 8-2.

### Control Names of Primitive Data Types

To rename a Simulink Coder primitive data type such as `int8_T`, create a `Simulink.AliasType` object whose name matches the type name that you want the generated code to use. For example, to create a type named `myType`, at the command prompt, enter:

```
myType = Simulink.AliasType;
```

Set the `BaseType` property to the name of the Simulink data type that corresponds to the target Simulink Coder data type. For example, if the target type is `int8_T`, specify `int8`. To identify the Simulink data type, use the information in the table.

| Simulink Coder Type Name | Corresponding Simulink Type Name                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

\* Replace *n* with the number of bits displayed in **Configuration Parameters > Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to rename.

---

**Note** The `boolean_T` `BaseType` must promote to a signed `int`.

---

For example, to replace the type name `uint8_T` with `myType`, set the `BaseType` property of the `Simulink.AliasType` object to `'int8'`.

```
myType.BaseType = 'int8';
```

Then, use one or both of these techniques to apply the type to data items in a model:

- Configure data type replacements. Throughout the code that you generate from a model, you can replace a Simulink Coder data type name with the name of the `Simulink.AliasType` object. You configure data type replacements through model configuration parameters (**Configuration Parameters > Code Generation > Data Type Replacement**).

For an example that shows how to use data type replacement, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-27.

- Use the name of the `Simulink.AliasType` object to specify the data type of an individual signal, that is, a block output, or block parameter. By default, due to data type propagation and inheritance (see “Data Type Inheritance Rules” (Simulink)), the signals, states, and parameters of other downstream blocks typically inherit the same data type. Optionally, you can configure data items in upstream blocks to inherit the type (**Inherit: Inherit via back propagation**) or stop the propagation at an arbitrary block by specifying a noninherited data type setting.

To specify a data type for an individual data item, use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). You can use the name of the same `Simulink.AliasType` object to specify the data types of multiple data items.

For an example that shows how to use a `Simulink.AliasType` object directly in a model, see “Create Data Type Alias in the Generated Code” on page 35-12.

| <p>Use the same type name for multiple signals and other data items in a data path, which is a series of connected blocks.</p>                                                                                              | <p>In the model, use the name of a <code>Simulink.AliasType</code> object to set the data type of one of the signals in the path, for example, a root-level Inport block or a Constant block. For example, if the path begins with an Inport block at the root level of the model, you can specify the type in that block. By default, due to data type propagation, the data items in the other blocks typically inherit the same type.</p> <p>Usually, no matter where on the data path you specify the type, downstream data items inherit the type. You can configure upstream data items to inherit the type, too. Consider specifying the type in a block that you do not expect to remove or change frequently.</p> |
| <p>Configure the generated code to replace an implementation-dependent type, such as <code>char_T</code> or <code>boolean_T</code>, and another type of equivalent bit length with a single type name that you specify.</p> | <p>Use the name of the <code>Simulink.AliasType</code> object to configure multiple data type replacements simultaneously. See “Replace Implementation-Dependent Types with the Same Type Name” on page 35-8.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### Control Names of 64-Bit Integers

To rename a Simulink Coder data type such as `uint64` and `int64`, create a `Simulink.NumericType` object. The name of the object must match the type name that you want the generated code to use. For example, to create a type named `myType`, at the command prompt, enter:

```
myType = Simulink.NumericType;
```

Set these properties:

- `DataTypeMode - Fixed-point: binary point scaling`
- `WordLength - 64`

- `IsAlias - true`

The value for `Signedness` can be `Signed` or `Unsigned` depending on whether the integer is signed or unsigned respectively.

### Use Simulink Data Type Names Instead of Simulink Coder Data Type Names

For consistency between the data type names that you see in a model and in the generated code, you can configure data type replacements so the code uses Simulink type names instead of Simulink Coder names. For each Simulink Coder type that you want to rename, use the Simulink data type name to specify the replacement name. You do not need to create `Simulink.AliasType` objects.

| Simulink Name | Code Generation Name | Replacement Name |
|---------------|----------------------|------------------|
| double        | real_T               | <empty>          |
| single        | real32_T             | <empty>          |
| int32         | int32_T              | <empty>          |
| int16         | int16_T              | <empty>          |
| int8          | int8_T               | int8             |
| uint32        | uint32_T             | <empty>          |
| uint16        | uint16_T             | <empty>          |
| uint8         | uint8_T              | <empty>          |
| boolean       | boolean_T            | <empty>          |
| int           | int_T                | <empty>          |
| uint          | uint_T               | <empty>          |
| char          | char_T               | <empty>          |
| uint64        | uint64_T             | <empty>          |
| int64         | int64_T              | <empty>          |

To replace `boolean_T`, `int_T`, or `uint_T`, use the information in the table.

| Simulink Coder Type Name | Replacement Names to Use                                                                                                          |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| boolean_T                | One of these names: <ul style="list-style-type: none"> <li>• boolean</li> <li>• uint8</li> <li>• int8</li> <li>• intn*</li> </ul> |
| int_T                    | intn*                                                                                                                             |
| uint_T                   | uintn*                                                                                                                            |
| char_T                   | intn*                                                                                                                             |

\* Replace  $n$  with the number of bits displayed in **Configuration Parameters > Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to replace.

You cannot use this technique to replace `real_T` with `double` or `real32_T` with `single`.

### Replace Implementation-Dependent Types with the Same Type Name

Some Simulink Coder type names map to C primitives that are implementation-dependent. For example, the Simulink Coder type `int_T` maps to the C type `int`, whose bit length depends on the native integer size of your target hardware. Other implementation-dependent types include `boolean_T`, `char_T`, and `uint_T`.

For more readable, simpler code, you can use the same type name to replace multiple Simulink Coder types of the same size. For example, if the native integer size of your hardware is 32 bits, you can replace `int_T` and `int32_T` with the same type name, say, `myInt`.

- 1 Configure your target hardware settings in **Configuration Parameters > Hardware Implementation**.
- 2 Create a `Simulink.AliasType` object named `myInt`. In this case, because `int_T` and `int32_T` represent a 32-bit signed integer, set `BaseType` to `int32`.

```
myInt = Simulink.AliasType('int32')
```

- 3 Configure the same data type replacement for `int32_T` and `int_T`.

## Data type names

| Simulink<br>Name | Code<br>Generation<br>Name | Replacement<br>Name |
|------------------|----------------------------|---------------------|
| double           | real_T                     | <empty>             |
| single           | real32_T                   | <empty>             |
| int32            | int32_T                    | myInt               |
| int16            | int16_T                    | <empty>             |
| int8             | int8_T                     | <empty>             |
| uint32           | uint32_T                   | <empty>             |
| uint16           | uint16_T                   | <empty>             |
| uint8            | uint8_T                    | <empty>             |
| boolean          | boolean_T                  | <empty>             |
| int              | int_T                      | myInt               |
| uint             | uint_T                     | <empty>             |
| char             | char_T                     | <empty>             |
| uint64           | uint64_T                   | <empty>             |
| int64            | int64_T                    | <empty>             |

---

**Note** Many-to-one data type replacement does not support the char (char\_T) built-in data type. Use char only in one-to-one data type replacements.

---

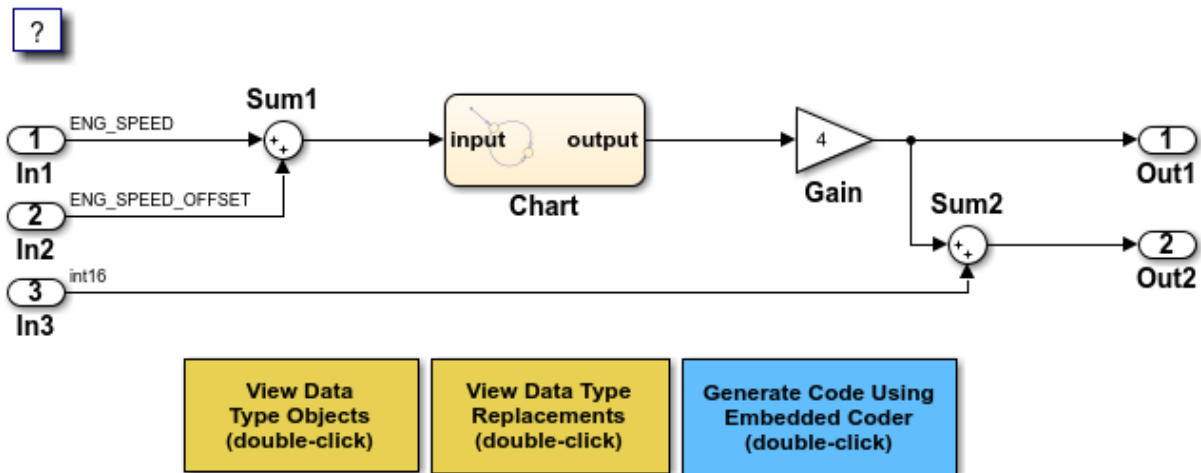

### Define Abstract Numeric Types and Rename Types

This model shows user-defined types, consisting of numeric and alias types. Numeric types allow you to define abstract numeric types, which is particularly useful for fixed-point types. Alias types allow you to rename types, which allows you create a relationship for types.

## Explore Example Model

Open the example model and configure it to show the generated names of blocks.

```
load_system('rtwdemo_udt')
set_param('rtwdemo_udt','HideAutomaticNames','off')
open_system('rtwdemo_udt')
```

Copyright 1994-2019 The MathWorks, Inc.

## Key Features of User-Defined Types

- Displayed and propagated on signal lines
- Used to parameterize a model by type (e.g., In1 specifies its **Output data type** as ENG\_SPEED)
- Types with a common ancestor can be mixed, whereby the common ancestor is propagated (e.g., output of Sum1)
- Intrinsically supported by the Simulink Model Explorer
- Include an optional header file attribute that is ideal for importing legacy types (ignored for GRT targets)
- Types used in the generated code (ignored for GRT targets)

## Instructions

- 1 Inspect the user-defined types in the Model Explorer by double-clicking the first yellow button below.
- 2 Inspect the replacement data type mapping by double-clicking the second yellow button below.
- 3 Compile the diagram to display the types in this model (Simulation > Update Diagram or **Ctrl+D**).
- 4 Generate code with the blue button below and inspect model files to see how user-defined types appear in the generated code.
- 5 Modify the attributes of `ENG_SPEED` and `ENG_SPEED_OFFSET` and repeat steps 1-4.

## Notes

- User-defined types are a feature of Simulink that facilitate parameterization of the data types in a model. Embedded Coder preserves alias data type names (e.g., `ENG_SPEED`) in the generated code, whereas Simulink Coder implements user-defined types as their base type (e.g., `real32_T`).
- Embedded Coder also enables you to replace the built-in data types with user-defined data types in the generated code.

## Control Names of Structure Types

To control the names of the standard structures that Simulink Coder creates by default to store data (*model\_P* for parameter data, for example), use **Configuration Parameters > Code Generation > Identifiers > Global types** to specify a naming rule. For more information, see “Customize Generated Identifiers” on page 88-21.

When you use nonvirtual buses and parameter structures to aggregate signals and block parameters into a custom structure in the generated code, control the name of the structure type by creating a `Simulink.Bus` object. For more information, see “Organize Data into Structures in Generated Code” on page 33-201.

## Generate Code That Reuses Data Types From External Code

To generate code that reuses a data type definition from your external C code, specify the data scope of the corresponding data type object or enumeration in Simulink as `Imported`. With this setting, the generated code includes (`#include`) the definition from

your code. For more information about controlling the file placement of a custom data type, see “Control File Placement of Custom Data Types” on page 35-23.

Instead of creating individual data type objects and enumerated types, and then configuring them, consider creating the objects and types by using the `Simulink.importExternalCTypes` function. By default, the function configures the new objects and types so that the generated code imports (reuses) the type definitions from your code. You can then use the objects and types to set data types in a model and to configure data type replacements. For more information, see `Simulink.importExternalCTypes` and “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-34.

## Create Data Type Alias in the Generated Code

This example shows how to configure the generated code to use a data type name (`typedef`) that you specify.

### Export Type Definition

When you integrate code generated from a model with code from other sources, your model code can create an exported `typedef` statement. Therefore, all of the integrated code can use the type. This example shows how to export the definition of a data type to a generated header file.

Create a `Simulink.AliasType` object named `mySingleAlias` that acts as an alias for the built-in data type `single`.

```
mySingleAlias = Simulink.AliasType('single')
```

```
mySingleAlias =
```

```
  AliasType with properties:
```

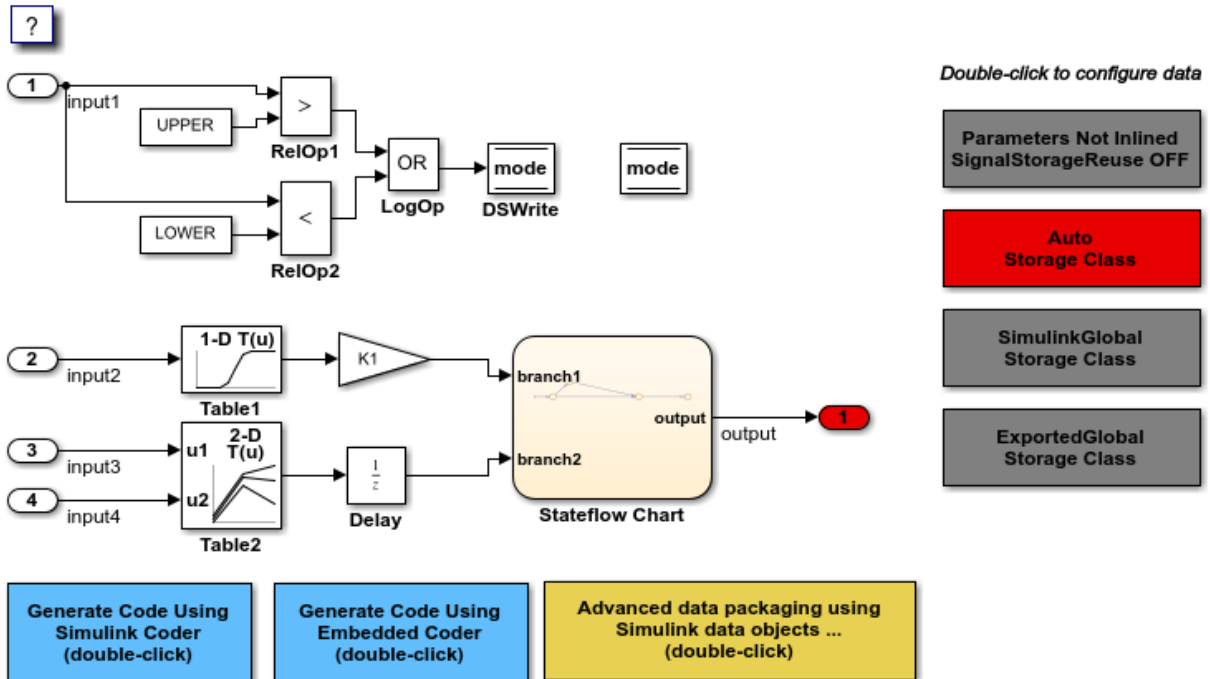

```
  Description: ''
  DataScope: 'Auto'
  HeaderFile: ''
  BaseType: 'single'
```

Configure the object to export its definition to a header file called `myHdrFile.h`.

```
mySingleAlias.DataScope = 'Exported';
mySingleAlias.HeaderFile = 'myHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Copyright 1994-2019 The MathWorks, Inc.

Configure the model to show the generated names of blocks.

```
set_param('rtwdemo_basicsc', 'HideAutomaticNames', 'off')
```

On the **Modeling** tab, click **Model Data Editor**.

In the model, select the Inport block labeled In1.

Use the **Data Type** column to set the data type to `mySingleAlias`.

```
set_param('rtwdemo_basicsc/In1', 'OutDataTypeStr', 'mySingleAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. The code generator honors data type aliases such as `mySingleAlias` only if you select an ERT-based system target file.

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for the generated file `myHdrFile.h`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwdemodbtype(file,'#include "myHdrFile.h"',...
    '#include "myHdrFile.h"',1,1)
```

```
#include "myHdrFile.h"
```

View the file `myHdrFile.h`. The code uses the identifier `mySingleAlias` as an alias for the data type `real32_T`. By default, generated code represents the Simulink data type `single` by using the identifier `real32_T`.

The code also provides a macro guard of the form `RTW_HEADER_filename_h_`. When you export a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','myHdrFile.h');
rtwdemodbtype(file,'#ifndef RTW_HEADER_myHdrFile_h_',...
    ' * File trailer for generated code.',1,0)
```

```
#ifndef RTW_HEADER_myHdrFile_h_
#define RTW_HEADER_myHdrFile_h_
#include "rtwtypes.h"
```

```
typedef real32_T mySingleAlias;
typedef creal32_T cmySingleAlias;
```

```
#endif /* RTW_HEADER_myHdrFile_h_ */
```

```
/*
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `mySingleAlias` to define the structure field `input1`, which corresponds to the Inport block labeled In1.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,...
    /* External inputs (root inport signals with default storage) */,...
    '} ExtU_rtwdemo_basicsc_T;',1,1)
```

```
/* External inputs (root inport signals with default storage) */
typedef struct {
    mySingleAlias input1;          /* '<Root>/In1' */
    real32_T input2;              /* '<Root>/In2' */
    real32_T input3;              /* '<Root>/In3' */
    real32_T input4;              /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;
```

### Import Type Definition

When you integrate code generated from a model with code from other sources, to avoid redundant `typedef` statements, you can import a data type definition from the external code. This example shows how to import your own definition of a data type from a header file that you create.

Use a text editor to create a header file to import. Name the file `ex_myImportedHdrFile.h`. Place it in your working folder. Copy the following code into the file.

```
#ifndef HEADER_myImportedHdrFile_h_
#define HEADER_myImportedHdrFile_h_

typedef float myTypeAlias;

#endif
```

The code uses the identifier `myTypeAlias` to create an alias for the data type `float`. The code also uses a macro guard of the form `HEADER_filename_h`. When you import a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

At the command prompt, create a `Simulink.AliasType` object named `myTypeAlias` that creates an alias for the built-in type `single`. The Simulink data type `single` corresponds to the C data type `float`.

```
myTypeAlias = Simulink.AliasType('single')
```

```
myTypeAlias =
```

```
AliasType with properties:
```

```
Description: ''  
DataScope: 'Auto'  
HeaderFile: ''  
BaseType: 'single'
```

Configure the object so that generated code imports the type definition from the header file `ex_myImportedHdrFile.h`.

```
myTypeAlias.DataScope = 'Imported';  
myTypeAlias.HeaderFile = 'ex_myImportedHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

On the **Modeling** tab, click **Model Data Editor**.

In the model, select the Inport block labeled `In1`.

Use the **Data Type** column to set the data type to `myTypeAlias`.

```
set_param('rtwdemo_basicsc/In1', 'OutDataTypeStr', 'myTypeAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. The code generator honors data type aliases such as `mySingleAlias` only if you select an ERT-based system target file.

```
set_param('rtwdemo_basicsc', 'SystemTargetFile', 'ert.tlc')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for your header file `ex_myImportedHdrFile.h`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwdemodbtype(file,'#include "ex_myImportedHdrFile.h',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#include "ex_myImportedHdrFile.h"
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `myTypeAlias` to define the structure field `input1`, which corresponds to the Inport block labeled In1.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,...
    '/* External inputs (root inport signals with default storage) */',...
    '} ExtU_rtwdemo_basicsc_T;',1,1)
```

```
/* External inputs (root inport signals with default storage) */
typedef struct {
    myTypeAlias input1;          /* '<Root>/In1' */
    real32_T input2;           /* '<Root>/In2' */
    real32_T input3;           /* '<Root>/In3' */
    real32_T input4;           /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;
```

## Display Base Data Types and Aliases on Model Diagram

When you display signal data types on the model diagram, you can choose to display aliases (such as `myTypeAlias`) and base data types (such as `int16`). To display aliases, on the **Debug** tab, select **Information Overlays > Alias Data Types**. To display the base types, select **Information Overlays > Alias Data Types**. For more information, see “Port Data Types” (Simulink).

## Create a Named Fixed-Point Data Type in the Generated Code

This example shows how to create and name a fixed-point data type in generated code. You can use the name of the type to specify parameter and signal data types throughout a model and in generated code.

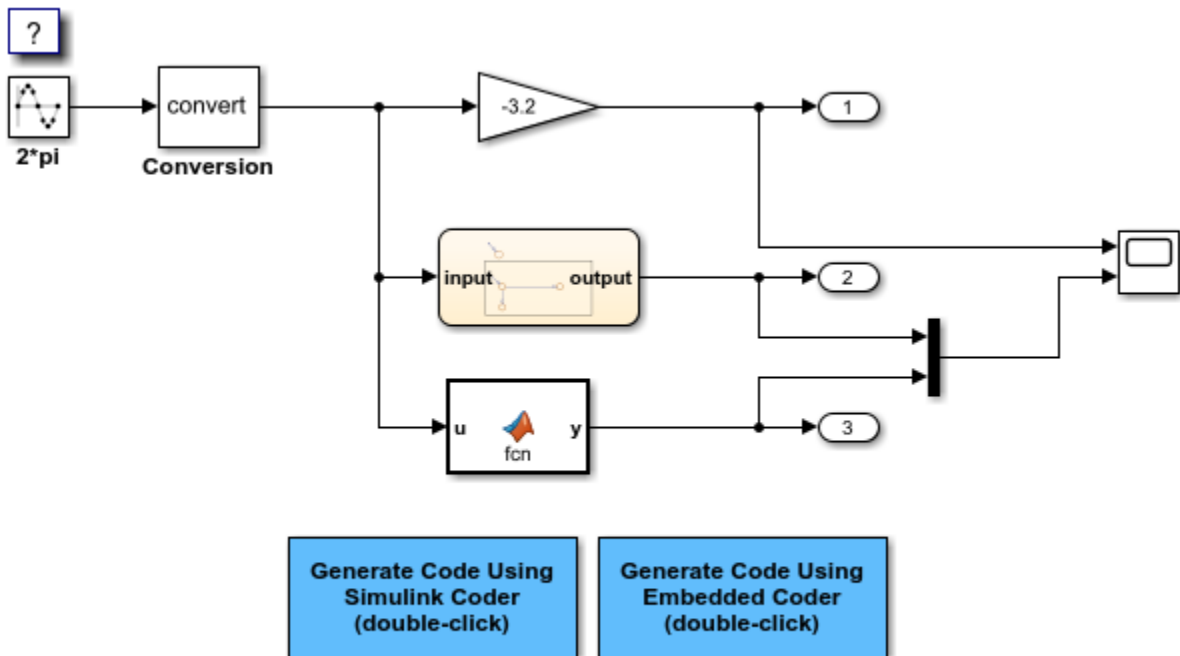

The example model `rtwdemo_fixpt1` uses fixed-point data types. So that you can more easily see the fixed-point data type in the generated code, in this example, you create a `Simulink.Parameter` object that appears in the code as a global variable.

Create a `Simulink.AliasType` object that defines a fixed-point data type. Name the object `myFixType`. The generated code uses the name of the object as a data type.

```
myFixType = Simulink.AliasType('fixdt(1,16,4)');
```

Open the model `rtwdemo_fixpt1`.

```
open_system('rtwdemo_fixpt1')
```

Copyright 1994-2019 The MathWorks, Inc.

Configure the model to show the generated names of the blocks.

```
set_param('rtwdemo_fixpt1', 'HideAutomaticNames', 'off')
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, for the row that represents the **Gain** parameter of the Gain block, in the **Value** column, specify myParam.

Click the action button (with three vertical dots) next to the parameter value. Select **Create**.

In the **Create New Data** dialog box, set Value to Simulink.Parameter(8). In this example, for more easily readable code, you set the parameter value to 8 instead of -3.2. Click **Create**. A Simulink.Parameter object named myParam appears in the base workspace. The object stores the real-world value 8, which the Gain block uses for the value of the **Gain** parameter.

In the **Simulink.Parameter** property dialog box, set **Storage class** to ExportedGlobal. Click **OK**. With this setting, myParam appears in the generated code as a separate global variable.

In the Model Data Editor, use the **Data Type** column to set the data type of the **Gain** parameter of the Gain block to myFixType.

On the **Signals** tab, use the **Data Type** column to set the data type of the Gain block output to myFixType.

Use the **Data Type** column to set the data type of the Conversion block output to myFixType.

Alternatively, you can use these commands at the command prompt to configure the blocks and create the object:

```
set_param('rtwdemo_fixpt1/Gain', 'Gain', 'myParam', 'OutDataTypeStr', 'myFixType', ...
          'ParamDataTypeStr', 'myFixType')
myParam = Simulink.Parameter(8);
myParam.StorageClass = 'ExportedGlobal';
set_param('rtwdemo_fixpt1/Conversion', 'OutDataTypeStr', 'myFixType')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to ert.tlc. With this setting, the code generator honors data type aliases such as myFixType.

```
set_param('rtwdemo_fixpt1', 'SystemTargetFile', 'ert.tlc')
```

Select the configuration parameter **Generate code only**.

```
set_param('rtwdemo_fixpt1','GenCodeOnly','on')
```

Generate code from the model.

```
rtwbuild('rtwdemo_fixpt1')
```

```
### Starting build procedure for model: rtwdemo_fixpt1
### Successful completion of code generation for model: rtwdemo_fixpt1
```

In the code generation report, view the file `rtwdemo_fixpt1_types.h`. The code defines the type `myFixType` based on an integer type of the specified word length (16).

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_myFixType_','...
    /* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_myFixType_
#define DEFINED_TYPEDEF_FOR_myFixType_

typedef int16_T myFixType;
typedef cint16_T cmyFixType;

#endif
```

View the file `rtwdemo_fixpt1.c`. The code uses the type `myFixType`, which is an alias of the integer type `int16`, to define the variable `myParam`.

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1.c');
rtwdemodbtype(file,'myFixType myParam = 128;', 'myFixType myParam = 128;',1,1)
```

```
myFixType myParam = 128;          /* Variable: myParam
```

The stored integer value 128 of `myParam` is not the same as the real-world value 8 because of the scaling that the fixed-point data type `myFixType` specifies. For more information, see “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

The line of code that represents the Gain block applies a right bit shift corresponding to the fraction length specified by `myFixType`.

```

rtwdemodbtype(file,...
    'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',...
    'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',1,1)

rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);

```

## Rename Data Type Object

To rename a data type object such as `Simulink.AliasType` or `Simulink.Bus` after you create it (for example, to rename an alias when coding standards change or when you encounter a naming conflict), you can allow Simulink to rename the object and correct all of the references to the object that appear in a model or models. In the Model Explorer, right-click the variable and select **Rename All**. For more information, see “Rename Variables” (Simulink).

## Display Signal Data Types on Block Diagram

For readability, you can display signal data types directly on a block diagram. When you use custom names for primitive data types, you can choose to display the custom name (the alias), the underlying primitive, or both. See “Port Data Types” (Simulink).

## Limitations

- You cannot configure the generated code to use these custom C data types:
  - Array types
  - Pointer types
  - `const` or `volatile` types
- You cannot configure the generated code to use generic C primitive types such as `int` and `short`.

### Data Type Replacement Limitations

When you select the model configuration parameter **Replace data type names in the generated code** on the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box, these limitations apply:

- Data type replacement does not support multiple levels of mapping. Each replacement data type name maps directly to one or more built-in data types.

- Data type replacement is not supported for simulation target code generation for referenced models.
- If you select the **Classic call interface** configuration parameter for your model, data type replacement is not supported.
- Code generation performs data type replacements while generating `.c`, `.cpp`, and `.h` files. Code generation places these files in build folders (including top and referenced model build folders) and in the `_sharedutils` folder. *Exceptions* are as follows:
  - `rtwtypes.h`
  - `multiword_types.h`
  - `model_reference_types.h`
  - `builtin_typeid_types.h`
  - `model_sf.c` or `.cpp` (ERT S-function wrapper)
  - `model_dt.h` (C header file supporting external mode)
  - `model_capi.c` or `.cpp`
  - `model_capi.h`
- Data type replacement is not supported for complex data types.
- Many-to-one data type replacement is not supported for the `char` data type. Attempting to use `char` as part of a many-to-one mapping to a custom data type represents a violation of the MISRA C specification. For example, if you map `char` (`char_T`) and either `int8` (`int8_T`) or `uint8` (`uint8_T`) to the same replacement type, the result is a MISRA C violation. If you try to generate C++ code, the code generator makes invalid implicit type casts, resulting in compile-time errors. Use `char` only in one-to-one data type replacements.
- For ERT S-functions, replace the `boolean` data type with only an 8-bit integer, `int8`, or `uint8`.
- Set the `DataScope` property of a `Simulink.AliasType` object to `Auto` (default) or `Imported`.

## Control File Placement of Custom Data Types

By default, when you use data type objects, such as `Simulink.AliasType` and `Simulink.Bus`, and custom enumerations to specify data types for signals and block parameters, the code generated from the model defines the types (for example, with `typedef` statements). To ease integration of the generated code with other existing code and to modularize the generated code, you can control the file placement of the type definitions by adjusting the properties of the objects and the enumerations.

### Data Scope and Header File

To control the file placement of a custom type definition in generated code, set the `DataScope` and `HeaderFile` properties of the data type object according to the table. Similarly, for an enumeration that you define in a MATLAB file, set the return arguments of the `getDataScope` and `getHeaderFile` methods.

- *typename* is the name of the custom data type.
- *filename* is the name of a header file.
- *model* is the name of the model.

| Goal                                                                       | Specify DataScope as | Specify HeaderFile as                                  |
|----------------------------------------------------------------------------|----------------------|--------------------------------------------------------|
| Export type definition to <i>model_types.h</i>                             | Auto                 | Empty                                                  |
| Import type definition from a header file that you create, <i>filename</i> | Auto or Imported     | <i>filename</i> (if necessary, include a .h extension) |
| Export type definition to a generated header file, <i>filename.h</i>       | Exported             | <i>filename</i> or <i>filename.h</i>                   |
| Export type definition to a generated header file, <i>typename.h</i>       | Exported             | Empty                                                  |

When you import a data type definition (for example, by setting `DataScope` to `Imported`), the generated model code creates an `#include` directive for your header file in place of a type definition. You supply the header file that contains the definition.

### Considerations for Data Type Replacement

- If you use data type replacement to replace a built-in Simulink data type with your own data type in generated code (see “Model Configuration Parameters: Code Generation Data Type Replacement”), `typedef` statements and `#include` directives appear in `rtwtypes.h` instead of `model_types.h`.
- When a `Simulink.AliasType` or `Simulink.NumericType` object participates in data type replacements, you cannot set the `DataScope` property of the object to `Exported`. Therefore, if you want the code generator to generate the corresponding `typedef` statement, you cannot control the file placement of the statement. However, you can set `DataScope` to `Imported`, which means that you can configure the code to reuse the `typedef` statement that your external code provides.

As a workaround, instead of using the data type object as a data type replacement, use the object to set the data types of individual data items in a model. To configure many data items, you can use the Model Data Editor and take advantage of data type propagation and inheritance. For more information, see “Control Names of Primitive Data Types” on page 35-2.

### Import Definition of Numerically Complex Data Type

You can use a `Simulink.AliasType` object with numerically complex data (i). In this case, if you configure the generated code to import the type definition from your external code (for example, by setting the `DataScope` property to `Imported`), your code must provide two complementary `typedef` statements.

Suppose your external header file `myAliasTypes.h` defines the data type `IAT_int32` as an alias of a 32-bit integer. The file must define two types: `IAT_int32` and `cIAT_int32`:

```
#ifndef myAliasTypes_H_
#define myAliasTypes_H_

#include "rtwtypes.h"

typedef int32_T IAT_int32;
typedef cint32_T cIAT_int32;

#endif
```

You do not need to create two `Simulink.AliasType` objects. In this example, you create one object, `IAT_int32`. The generated code then creates complex data (variables) by using both `IAT_int32` and `cIAT_int32`.

## Macro Guards

When you export one or more data type definitions to a generated header file, the file contains a file-level macro guard of the form `RTW_HEADER_<filename>.h`.

Suppose that you use several `Simulink.AliasType` objects: `mySingleAlias`, `myDoubleAlias`, and `myIntAlias` with these properties:

- `DataScope` set to `Exported`
- `HeaderFile` set to `myTypes.h`

When you generate code, the guarded file `myTypes.h` contains the `typedef` statements:

```
#ifndef RTW_HEADER_myTypes_h_
#define RTW_HEADER_myTypes_h_
#include "rtwtypes.h"

typedef real_T myDoubleAlias;
typedef real32_T mySingleAlias;
typedef int16_T myIntAlias;

#endif
```

When you export data type definitions to `model_types.h`, the file contains a macro guard of the form `_DEFINED_TYPEDEF_FOR_<typename>` for each `typedef` statement. Suppose that you use a `Simulink.AliasType` object `mySingleAlias` with these properties:

- `DataScope` set to `Auto`
- `HeaderFile` not specified

When you generate code, the file `model_types.h` contains the guarded `typedef` statement:

```
#ifndef _DEFINED_TYPEDEF_FOR_mySingleAlias_
#define _DEFINED_TYPEDEF_FOR_mySingleAlias_

typedef real32_T mySingleAlias;

#endif
```

`Simulink.AliasType` | `Simulink.Bus` | `Simulink.NumericType`

## **Related Examples**

- “Control Data Type Names in Generated Code” on page 35-2

## Replace and Rename Data Types to Conform to Coding Standards

By default, the generated code uses data type aliases such as `real_T` and `int32_T`. The code uses these aliases to define global and local variables. If your coding standards require that you use other data type aliases, including aliases that your existing code defines, you can:

- Configure data type replacement for the entire model.
- Configure individual data items (such as signals, parameters, and states) to use specific data type aliases.

For information about controlling data types in a model, see “Control Signal Data Types” (Simulink).

### Inspect External C Code

Save this C code into a file named `my_types.h` in your current folder. This file represents a header file in your existing code that defines custom data type aliases by using `typedef` statements.

```
#include <stdbool.h>

typedef double my_dblPrecision;
typedef short my_int16;
typedef bool my_bool;
```

### Explore Example Model and Default Generated Code

- 1 Open the example model `ex_data_type_replacement`.
 

```
open_system(fullfile(docroot, 'toolbox', 'ecoder', 'examples', ...
    'ex_data_type_replacement'))
```
- 2 On the **Modeling** tab, click **Model Data Editor**.
- 3 In the Model Data Editor, inspect the **Signals** tab.
- 4 Set the **Change view** drop-down list to **Code**. In the data table, the **Storage Class** column shows that named signal lines such as `temp` use the storage class `ExportedGlobal`. With this setting, the signal lines appear in the generated code as separate global variables.

- 5 Set the **Change view** drop-down list to **Design**.
- 6 Update the block diagram.

Simulink assigns a specific data type to each signal that uses an inherited data type setting such as `Inherit: Inherit via internal rule`.

- 7 In the data table, expand the width of the **Data Type** column. The column shows that the signals in the model use a mix of the data types `int16`, `double`, and `boolean`. You can also see these data types in the model.
- 8 Generate code from the model.
- 9 In the code generation report, inspect the shared utility file `rtwtypes.h`. The code uses `typedef` statements to rename the primitive C data types by using standard Simulink Coder aliases. For example, the code renames the primitive type `double` by using the alias `real_T`.

```
typedef double real_T;
```

- 10 Inspect the file `ex_data_type_replacement.c`. The code uses the default data type aliases to declare and define variables. For example, the code uses the data types `real_T`, `int16_T`, and `boolean_T` to define the global variables `flowIn`, `temp`, and `intlk`.

```
real_T flowIn;                /* '<Root>/In3' */
int16_T temp;                /* '<Root>/Add2' */
boolean_T intlk;            /* '<S1>/Compare' */
```

The model `step` function defines local variables by using the same data type aliases.

```
real_T rtb_Add;
real_T rtb_FilterCoefficient;
```

## Reuse External Data Type Definitions

Configure the generated code to define variables by using the custom data types defined in `my_types.h` instead of the default type names.

- 1 At the command prompt, create a `Simulink.AliasType` object for each data type alias that your external code defines.

```
Simulink.importExternalCTypes('my_types.h');
```

In the base workspace, the `Simulink.importExternalCTypes` function creates the objects `my_dblPrecision`, `my_int16`, and `my_bool`.

For each object, the function sets the `DataScope` property to 'Imported' and the `HeaderFile` property to 'my\_types.h'. With these settings, the code generator does not create a `typedef` statement for each object, but instead the generated code reuses the statements from `my_types.h` by including (`#include`) the file.

- 2 In the model, in the Configuration Parameters dialog box, on the **Code Generation > Data Type Replacement** pane, select **Replace data type names in the generated code**.
- 3 Specify the options in the **Replacement Name** column according to the table.

| Simulink Name | Replacement Name |
|---------------|------------------|
| double        | my_dblPrecision  |
| int16         | my_int16         |
| boolean       | my_bool          |

- 4 Generate code from the model.
- 5 In the code generation report, inspect the file `rtwtypes.h`. Now, the code uses an `#include` directive to import the contents of the external header file `my_types.h`, which contains the custom data type aliases.

```
#include "my_types.h"      /* User defined replacement datatype for int16_T real_T boolean_T */
```

- 6 Inspect the file `ex_data_type_replacement.c`. The code uses the custom data type aliases `my_dblPrecision`, `my_int16`, and `my_bool` to define the global variables such as `flowIn`, `temp`, and `intlk`.

```
my_dblPrecision flowIn;          /* '<Root>/In3' */
my_int16 temp;                  /* '<Root>/Add2' */
my_bool intlk;                  /* '<S1>/Compare' */
```

The model `step` function defines local variables by using the custom data type aliases.

```
my_dblPrecision rtb_Add;
my_dblPrecision rtb_FilterCoefficient;
```

## Create Meaningful Data Type Aliases for Individual Data Items

Suppose that your coding standards require that important data items use a data type whose name indicates the real-world significance. You can create more `Simulink.AliasType` objects to represent these custom data type aliases. Use the objects to set the data types of data items in the model.

- 1 In the Model Data Editor **Data Type** column, use the `Simulink.AliasType` objects to set the data types of these block outputs. You can select a signal line in the model, which highlights the corresponding row in the Model Data Editor, or search for the signals in the Model Data Editor by using the **Filter contents** box.

| Block                                | Output Data Type |
|--------------------------------------|------------------|
| Flow Setpoint                        | flow_T           |
| Add2 (which feeds the Compare block) | diffTemp_T       |

- 2 Use the Model Data Editor **Inports/Outports** tab to set the data type of the third Inport block to `flow_T`.
- 3 On the **Modeling** tab, under **Design**, click **Property Inspector**.
- 4 Select the block labeled Flow Controller. In the Property Inspector, click **Open** to open the block dialog box.
- 5 On the **Data Types** tab, set **Sum output** to `ctrl_T`. Click **OK**.

With these data type settings, some of the named signals, such as `temp` and `flowIn`, use data types that evoke real-world quantities, such as liquid flow rate and temperature.

- 6 At the command prompt, create `Simulink.AliasType` objects to represent these new custom data type aliases.

```
flow_T = Simulink.AliasType('double');
diffTemp_T = Simulink.AliasType('int16');
ctrl_T = Simulink.AliasType('double');
```

In the model, the signals `flowIn` and `flowSetPt` use the primitive data type `double`, so the data type alias `flow_T` maps to `double`.

- 7 Update the block diagram.

Due to data type inheritance, other signals also use the custom data type aliases. For example, the output data type of the Add block fed by the third Inport block is set to `Inherit: Inherit via internal rule`. The internal rule chooses the same data type that the block inputs use, `flow_T`.

- 8 Generate code from the model.
- 9 The file `ex_data_type_replacement_types.h` defines the new data types `flow_T`, `diffTemp_T`, and `ctrl_T` as aliases of `my_dblPrecision` and `my_int16`.

```
typedef my_dblPrecision flow_T;
typedef my_int16 diffTemp_T;
typedef my_dblPrecision ctrl_T;
```

- 10** In the file `ex_data_type_replacement.c`, the code defines global variables by using the new type names.

```
flow_T flowIn; /* '<Root>/In3' */
flow_T flowSetPt; /* '<Root>/Flow Setpoint' */
ctrl_T flowCtrl; /* '<Root>/Interlock' */
diffTemp_T temp; /* '<Root>/Add2' */
```

- 11** For blocks that do not use the new data types, the corresponding generated code continues to use the replacement types that you specified earlier. For example, in the file `ex_data_type_replacement.h`, the outputs of the blocks `In1` and `In2` appear as structure fields that use the replacement type `my_int16`.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
    my_int16 In1; /* '<Root>/In1' */
    my_int16 In2; /* '<Root>/In2' */
} ExtU_ex_data_type_replacement_T;
```

## Create Single Point of Definition for Primitive Types

The custom data type aliases `flow_T` and `ctrl_T` map to the primitive data type `double`. If you want to change this underlying data type from `double` to `single` (`float`), you must remember to modify the `BaseType` property of both `Simulink.AliasType` objects.

To more easily make this change, you can create a `Simulink.NumericType` object and configure both `Simulink.AliasType` objects to refer to it. Then, you need to modify only the `Simulink.NumericType` object. A `Simulink.NumericType` object enables you to share a data type without creating a data type alias.

- 1** At the command prompt, create a `Simulink.NumericType` object to represent the primitive data type `single`.

```
sharedType = Simulink.NumericType;
sharedType.DataTypeMode = 'Single';
```

- 2** Configure the `Simulink.AliasType` objects `flow_T` and `ctrl_T` to acquire an underlying data type from this new object.

```
flow_T.BaseType = 'sharedType';  
ctrl_T.BaseType = 'sharedType';
```

- 3 On the **Debug** tab, select **Information Overlays > Base Data Types Information Overlays > Alias Data Types** and (see “Port Data Types” (Simulink)). Update the block diagram.

The data type indicators in the model show that the aliases `flow_T` and `ctrl_T` map to the primitive type `single`. To change this underlying primitive type, you can modify the `DataTypeMode` property of the `Simulink.NumericType` object, `sharedType`.

By default, the `Simulink.NumericType` object does not cause another `typedef` statement to appear in the generated code.

If you generate code from the model while the `Simulink.NumericType` object represents the data type `single`, the generated code maps `flow_T` and `ctrl_T` to the default Simulink Coder data type alias `real32_T`, which maps to the C data type `float`. You can replace `real32_T` in the same way that you replaced `real_T`, `int16_T`, and `boolean_T` (**Configuration Parameters > Code Generation > Data Type Replacement**).

## Permanently Store Data Type Objects

The `Simulink.NumericType` and `Simulink.AliasType` objects in the base workspace do not persist if you end your current MATLAB session. To permanently store these objects, consider migrating your model to a data dictionary. See “Migrate Models to Use Simulink Data Dictionary” (Simulink).

## Create and Maintain Objects Corresponding to Multiple C typedef Statements

To create `Simulink.AliasType` objects for a large number of `typedef` statements in your external C code, consider using the `Simulink.importExternalCTypes` function.

## Exchange Structured and Enumerated Data Between Generated and External Code

This example shows how to generate code that exchanges data with external, existing code. Construct and configure a model to match data types with the external code and to avoid duplicating type definitions and memory allocation (definition of global variables). Then, compile the generated code together with the external code into a single application.

### Inspect External Code

Create the file `ex_cc_algorithm.c` in your current folder.

```
#include "ex_cc_algorithm.h"

inSigs_T inSigs;

float_32 my_alg(void)
{
    if (inSigs.err == TMP_HI) {
        return 27.5;
    }
    else if (inSigs.err == TMP_LO) {
        return inSigs.sig1 * calPrms.cal3;
    }
    else {
        return inSigs.sig2 * calPrms.cal3;
    }
}
```

The C code defines a global structure variable named `inSigs`. The code also defines a function, `my_alg`, that uses `inSigs` and another structure variable named `calPrms`.

Create the file `ex_cc_algorithm.h` in your current folder.

```
#ifndef ex_cc_algorithm_h
#define ex_cc_algorithm_h

typedef float float_32;

typedef enum {
```

```
    TMP_HI = 0,  
    TMP_LO,  
    NORM,  
} err_T;  
  
typedef struct inSigs_tag {  
    err_T err;  
    float_32 sig1;  
    float_32 sig2;  
} inSigs_T;  
  
typedef struct calPrms_tag {  
    float_32 cal1;  
    float_32 cal2;  
    float_32 cal3;  
} calPrms_T;  
  
extern calPrms_T calPrms;  
extern inSigs_T inSigs;  
  
float_32 my_alg(void);  
  
#endif
```

The file defines `float_32` as an alias of the C data type `float`. The file also defines an enumerated data type, `err_T`, and two structure types, `inSigs_T` and `calPrms_T`.

The function `my_alg` is designed to calculate a return value by using the fields of `inSigs` and `calPrms`, which are global structure variables of the types `inSigs_T` and `calPrms_T`. The function requires another algorithm to supply the signal data that `inSigs` stores.

This code allocates memory for `inSigs`, but not for `calPrms`. Create a model whose generated code:

- Defines and initializes `calPrms`.
- Calculates values for the fields of `inSigs`.
- Reuses the type definitions (such as `err_T` and `float_32`) that the external code defines.

## Create Simulink Model

- 1 So that you can create enumerated and structured data in the Simulink model, first create Simulink representations of the data types that the external code defines. Store the Simulink types in a new data dictionary named `ex_cc_integ.sldd`.

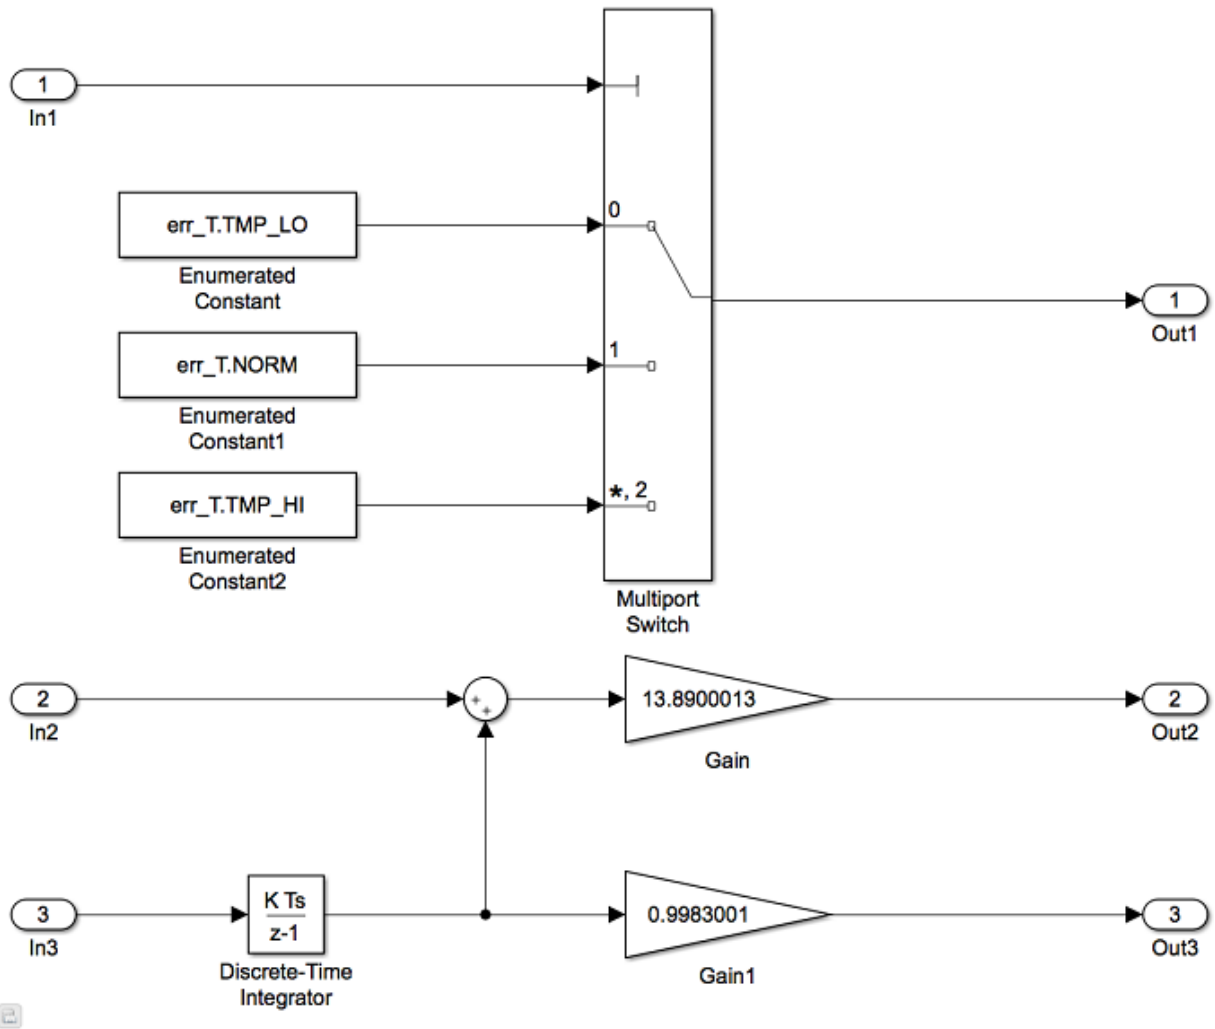

```
Simulink.importExternalCTypes('ex_cc_algorithm.h', ...  
    'DataDictionary', 'ex_cc_integ.sldd');
```

The data dictionary appears in your current folder.

- 2 To inspect the dictionary contents in the Model Explorer, in your current folder, double-click the file, `ex_cc_integ.sldd`.

The `Simulink.importExternalCTypes` function creates `Simulink.Bus`, `Simulink.AliasType`, and `Simulink.data.dictionary.EnumTypeDefinition` objects that correspond to the custom C data types from `ex_cc_algorithm.h`.

- 3 Create a new model and save it in your current folder as `ex_struct_enum_integ`.
- 4 Link the model to the data dictionary. On the **Modeling** tab, under **Design**, click **Data Dictionary**.
- 5 Add algorithmic blocks that calculate the fields of `inSigs`.

Now that you have the algorithm model, you must:

- Organize the output signals into a structure variable named `inSigs`.
- Create the structure variable `calPrms`.
- Include `ex_cc_algorithm.c` in the build process that compiles the code after code generation.

## Configure Generated Code to Write Output Data to Existing Structure Variable

- 1 Add a Bus Creator block near the existing Output blocks. The output of a Bus Creator block is a bus signal, which you can configure to appear in the generated code as a structure.
- 2 In the Bus Creator block, set these parameters:
  - **Number of inputs** to 3
  - **Output data type** to Bus: `inSigs_T`
  - **Output as nonvirtual bus** to selected
- 3 Delete the three existing Output blocks (but not the signals that enter the blocks).
- 4 Connect the three remaining signal lines to the inputs of the Bus Creator block.
- 5 Add an Output block after the Bus Creator block. Connect the output of the Bus Creator to the Output.
- 6 In the Output block, set the **Data type** parameter to Bus: `inSigs_T`.
- 7 On the **Modeling** tab, click **Model Data Editor**.
- 8 On the **Inports/Outports** tab, for the Inport blocks labeled In2 and In3, change **Data Type** from Inherit: auto to `float_32`.
- 9 Change the **Change View** drop-down list from Design to Code.
- 10 For the Output block, set **Signal Name** to `inSigs`.
- 11 Set **Storage Class** to `ImportFromFile`.
- 12 Set **Header File** to `ex_cc_algorithm.h`.
- 13 Inspect the **Signals** tab.
- 14 In the model, select the output signal of the Multiport Switch block.
- 15 In the Model Data Editor, for the selected signal, set **Name** to `err`.
- 16 Set the name of the output signal of the Gain block to `sig1`.
- 17 Set the name of the output signal of the Gain1 block to `sig2`.

When you finish, the model stores output signal data (such as the signals `err` and `sig1`) in the fields of a structure variable named `inSigs`.

Because you set **Storage Class** to `ImportFromFile`, the generated code does not allocate memory for `inSigs`.

## Configure Generated Code to Define Parameter Data

Configure the generated code to define the global structure variable, `calPrms`, that the external code needs.

- 1 In the Model Explorer **Model Hierarchy** pane, under the dictionary node **ex\_cc\_integ**, select the **Design Data** node.
- 2 In the **Contents** pane, select the `Simulink.Bus` object `calPrms_T`.
- 3 In the Dialog pane (the right pane), click **Launch Bus Editor**.
- 4 In the Bus Editor, in the left pane, select `calPrms_T`.

- 5 On the Bus Editor toolbar, click the **Create/Edit a Simulink.Parameter Object from a Bus Object** button.
- 6 In the MATLAB Editor, copy the generated MATLAB code and run the code at the command prompt. The code creates a `Simulink.Parameter` object in the base workspace.
- 7 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- 8 Use the Model Explorer to move the parameter object, `calPrms_T_Param`, from the base workspace to the Design Data section of the data dictionary.
- 9 With the data dictionary selected, in the **Contents** pane, rename the parameter object as `calPrms`.
- 10 In the Model Data Editor, select the **Parameters** tab.
- 11 Set the **Change view** drop-down list to **Design**.
- 12 For the Gain block, replace the value `13.8900013` with `calPrms.cal1`.
- 13 In the other Gain block, use `calPrms.cal2`.
- 14 While editing the value of the other Gain block, next to `calPrms.cal2`, click the action button  and select **calPrms > Open**.
- 15 In the `calPrms` property dialog box, next to the **Value** box, click the action button  and select **Open Variable Editor**.
- 16 Use the Variable Editor to set the field values in the parameter object.
  - For the fields `cal1` and `cal2`, use the numeric values that the Gain blocks in the model previously used.
  - For `cal3`, use a nonzero number such as `15.2299995`.

When you finish, close the Variable Editor.

- 17 In the property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**.
- 18 Use the Model Explorer to save the changes that you made to the dictionary.

## Generate, Compile, and Inspect Code

- 1 Configure the model to include `ex_cc_algorithm.c` in the build process. Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_cc_algorithm.c`.
- 2 Generate code from the model.

- 3 Inspect the generated file `ex_struct_enum_integ.c`. The file defines and initializes `calPrms`.

```
/* Exported block parameters */
calPrms_T calPrms = {
    13.8900013F,
    0.998300076F,
    15.23F
}; /* Variable: calPrms
```

The generated algorithm in the model `step` function defines a local variable for buffering the value of the signal `err`.

```
err_T rtb_err;
```

The algorithm then calculates and stores data in the fields of `inSig`.

```
inSigs.err = rtb_err;
inSigs.sig1 = (rtU.In2 + rtDW.DiscreteTimeIntegrator_DSTATE) * calPrms.cal1;
inSigs.sig2 = (real32_T)(calPrms.cal2 * rtDW.DiscreteTimeIntegrator_DSTATE);
```

## Replace Data Type Names Throughout Model

To generate code that uses `float_32` instead of the default, `real32_T`, instead of manually specifying the data types of block output signals and bus elements, you can use data type replacement (**Configuration Parameters > Code Generation > Data Type Replacement**). For more information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-27.

## See Also

`Simulink.importExternalCTypes`

## Related Examples

## Specify Boolean and Data Type Limit Identifiers

You can use command-line parameters to replace the default Boolean and data type limit identifiers. If you want to associate the data type limit identifiers with the data type names, consider replacing the default identifiers. You can also use command-line parameters to import a header file with the Boolean and data type limit identifier definitions.

### Data Type Limit Identifiers

You can control the data type limit identifiers in the generated code by using the command-line parameters in this table.

| Data Type Limit                   | Default Identifier | Command-Line Parameter |
|-----------------------------------|--------------------|------------------------|
| 64-bit integer maximum            | MAX_int64_T        | MaxIdInt64             |
| 16-bit integer maximum            | MAX_int16_T        | MaxIdInt16             |
| 32-bit integer maximum            | MAX_int32_T        | MaxIdInt32             |
| 8-bit integer maximum             | MAX_int8_T         | MaxIdInt8              |
| 64-bit unsigned integer maximum   | MAX_uint64_T       | MaxIdUInt64            |
| 16-bit unsigned integer maximum   | MAX_uint16_T       | MaxIdUInt16            |
| 32-bit unsigned integer maximum   | MAX_uint32_T       | MaxIdUInt32            |
| 8-bit unsigned integer maximum    | MAX_uint8_T        | MaxIdUInt8             |
| 64-bit integer minimum identifier | MIN_int64_T        | MinIdInt64             |
| 16-bit integer minimum            | MIN_int16_T        | MinIdInt16             |
| 32-bit integer minimum            | MIN_int32_T        | MinIdInt32             |
| 8-bit integer minimum             | MIN_int8_T         | MinIdInt8              |

For example, to change the default identifiers for the 8-bit integer data limit minimum and maximum to `s4g_S4MIN` and `s4g_S4MAX`, respectively:

```
set_param(gcs, 'MinIdInt8', 's4g_S4MIN');
set_param(gcs, 'MaxIdInt8', 's4g_S4MAX')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the 8-bit integer data minimum and maximum identifiers:

```
#define s4g_S4MAX          ((int8_T)(127))
#define s4g_S4MIN        ((int8_T)(-128))
```

If you do import a header file defining the data type limit identifiers, the header file is included in `rtwtypes.h`.

## Boolean Identifiers

You can control the Boolean identifiers in the generated code by using the command-line parameters in this table. When changing boolean identifiers, you must define `false` to be numerically equivalent to 0, and `true` to be numerically equivalent to 1.

| Boolean | Default Identifier | Command-Line Parameter      |
|---------|--------------------|-----------------------------|
| True    | <code>true</code>  | <code>BooleanTrueId</code>  |
| False   | <code>false</code> | <code>BooleanFalseId</code> |

For example, to change the default Boolean true and false identifiers:

```
set_param(gcs, 'BooleanTrueId', 'bTrue');
set_param(gcs, 'BooleanFalseId', 'bFalse')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the Boolean identifiers:

```
#define bFalse          (0U)
#define bTrue          (1U)
```

If you do import a header file defining the Boolean identifiers, the header file is included in `rtwtypes.h`.

---

**Note** When changing boolean identifiers, you must define `false` to be numerically equivalent to 0, and `true` to be numerically equivalent to 1.

---

## Boolean and Data Type Limit Identifier Header Files

You can import a header file that defines Boolean and data type limit identifiers by using the configuration parameter **Type limit identifier replacement header file** or command-line parameter `TypeLimitIdReplacementHeaderFile`. The header file is included in `rtwtypes.h`. You must use the command-line parameters to specify the Boolean and data type limit identifiers that are included in the imported header file.

For example, if you have a header file `myfile.h` with data type limit definitions, use `TypeLimitIdReplacementHeaderFile` to include the definitions in the generated code:

```
set_param(gcs, 'TypeLimitIdReplacementHeaderFile', 'myfile.h');
```

The generated file `rtwtypes.h` includes `myfile.h`.

```
/* Import type limit identifier replacement definitions. */  
#include "myfile.h"
```

## Air-Fuel Ratio Control System with Fixed-Point Data

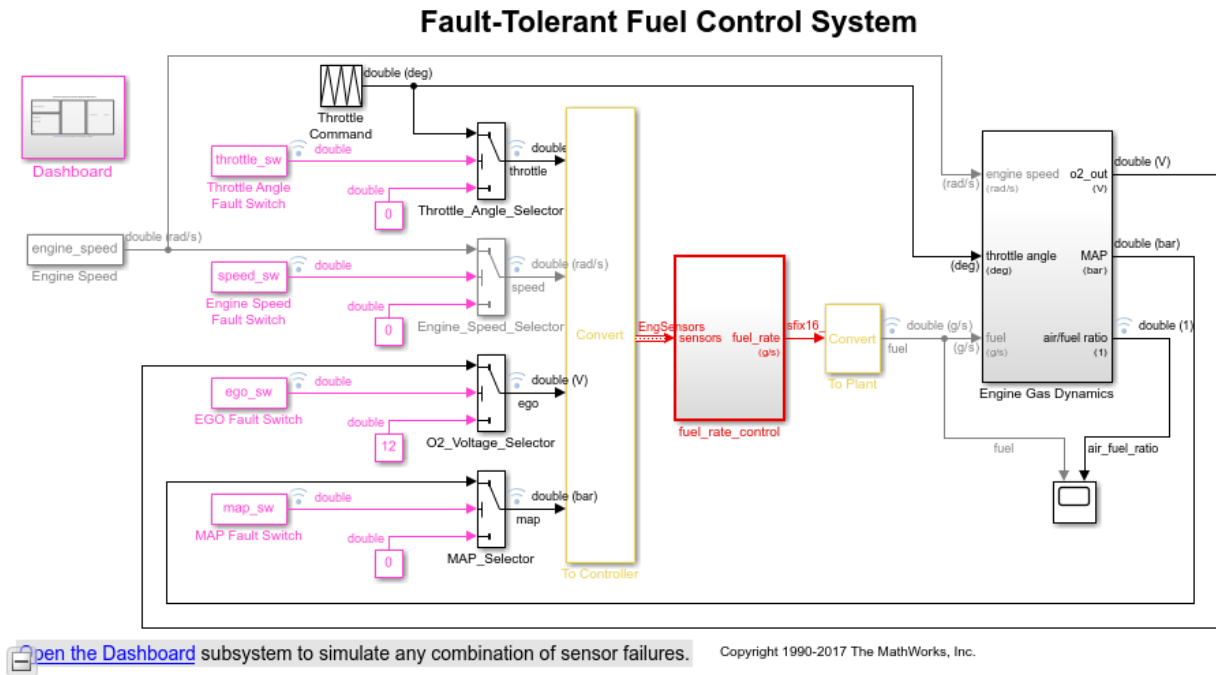

This example shows how to generate and optimize the code for a fixed-point air-fuel ratio control system designed with Simulink® and Stateflow®. For a detailed explanation of the model, see `sldemo_fuelsys` and `fxpdemo_fuelsys`. The example uses the Embedded Coder® (ERT target). The concepts also apply for Simulink® Coder™.

### Relevant Portions of the Model

Figures 1-4 show relevant portions of the `sldemo_fuelsys` model, which is a closed-loop system containing a plant subsystem and a controller subsystem. The plant allows engineers to validate the controller through simulation early in the design cycle. In this example, generate code for the relevant controller subsystem, `fuel_rate_control`. Figure 1 shows the top-level simulation model.

```
% Open |sldemo_fuelsys| via |rtwdemo_fuelsys_fxp| and update the model diagram  
% to view the signal data types.  
rtwdemo_fuelsys_fxp;
```

```
sldemo_fuelsys([],[],[],'compile');  
sldemo_fuelsys([],[],[],'term');
```

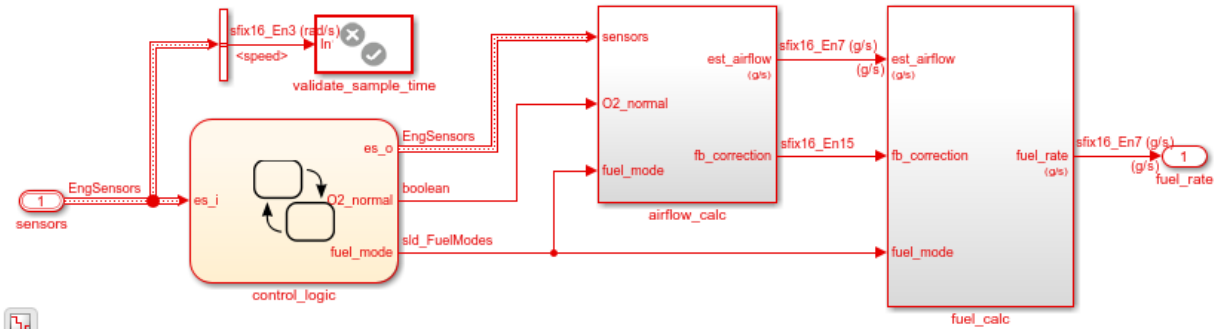

**Figure 1: Top-level model of the plant and controller**

The air-fuel ratio control system is composed of Simulink® and Stateflow® blocks. It is the portion of the model for which to generate code.

```
open_system('sldemo_fuelsys/fuel_rate_control');
```

## Fuel Rate Control Subsystem

**Figure 2: The air-fuel ratio controller subsystem**

The intake airflow estimation and closed loop correction system contains two lookup tables, Pumping Constant and Ramp Rate  $K_i$ .

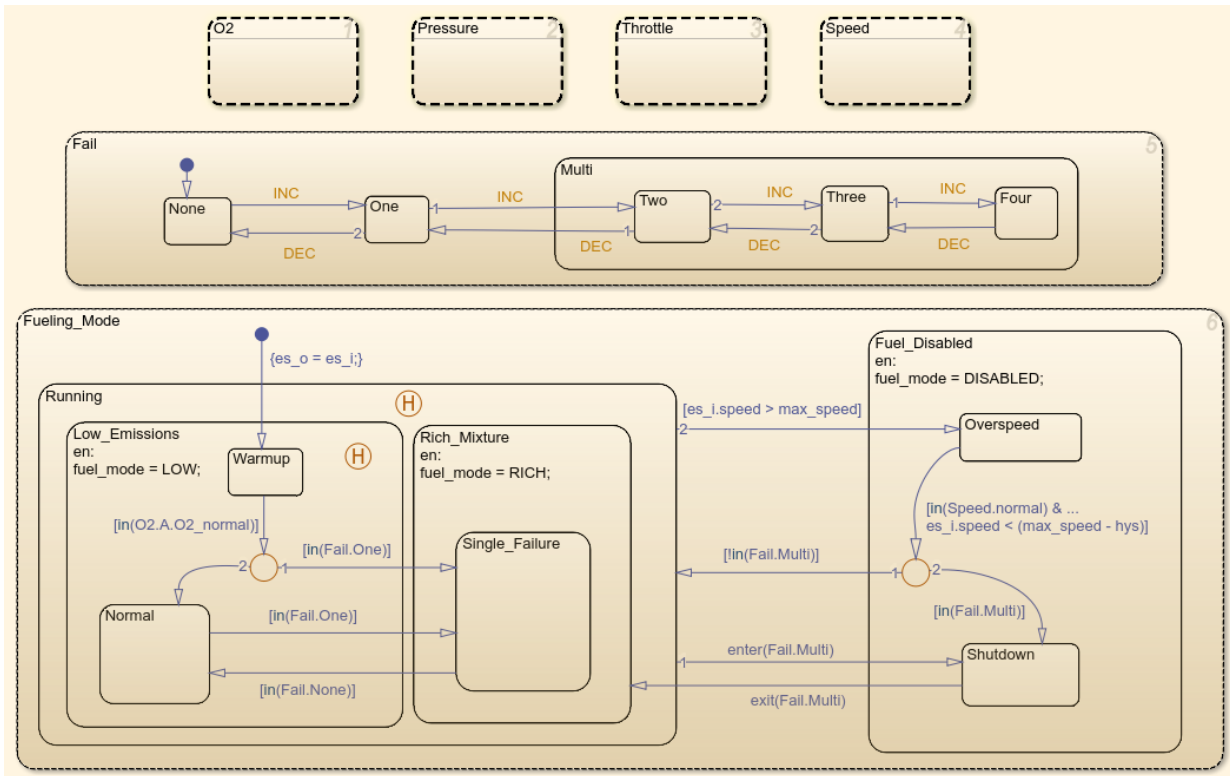

```
open_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
```

**Figure 3: The airflow\_calc subsystem**

The control logic is a Stateflow® chart that specifies the different modes of operation.

```
open_system('sldemo_fuelsys/fuel_rate_control/control_logic');
```

**Figure 4: Fuel ratio controller logic**

Remove the window clutter.

```
close_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
close_system('sldemo_fuelsys/fuel_rate_control/fuel_calc');
close_system('sldemo_fuelsys/fuel_rate_control/control_logic');
hDemo.rt=sfroot;hDemo.m=hDemo.rt.find('-isa','Simulink.BlockDiagram');
hDemo.c=hDemo.m.find('-isa','Stateflow.Chart','-and','Name','control_logic');
hDemo.c.visible=false;
close_system('sldemo_fuelsys/fuel_rate_control');
```

Build the air-fuel ratio control system only. Once the code generation process is complete, an HTML report detailing the generated code is displayed. The main body of the code is located in `fuel_rate_control.c`.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
```

```
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

Figure 5 shows snippets of the generated code for the lookup table Pumping Constant.

To see the code for Pumping Constant, right-click the block and select **Code Generation > Navigate to code**.

```
rtwtrace('sldemo_fuelsys/fuel_rate_control/airflow_calc/Pumping Constant');
```

The code for the pumping constant contains two breakpoint searches and a 2D interpolation. The SpeedVect breakpoint is unevenly spaced, and while the PressVect breakpoint is evenly spaced, neither have power of two spacing. The current spacing leads to extra code (ROM), including a division, and requires all breakpoints to be in memory (RAM).

```
/* Lookup_n-D: '<S2>/Pumping Constant' */
bpIdx = plook_u32s16u32n31_linca_s(rtB.es_o.speed, &rtConstP.pooled2[0], 17U, &frac);
fractions[0U] = frac;
bpIndices[0U] = bpIdx;
bpIdx = plook_u32u8u32n31_linca_s(rtb_map, &rtConstP.pooled8[0], 18U, &frac);

**Figure 5: Generated code for Pumping Constant lookup (contains unevenly spaced breakpoints)**

### **Optimize Code with Evenly Spaced Power of Two Breakpoints**

You can optimize the generated code performance by using evenly spaced power of two breakpoints. In this example, remap the lookup table data in the air-fuel ratio control system based on the existing measured data.

When you loaded the model, the model `PostLoadFcn` created the lookup table data in the model workspace. Retrieve the original table data via `sldemo_fuelsys_data`, modify it for evenly spaced power of two, and reassign it in the model workspace.

```
td = sldemo_fuelsys_data('sldemo_fuelsys', 'get_table_data');
```

Compute new table data for evenly spaced power of two breakpoints.

```
ntd.SpeedVect = 64 : 2^5 : 640;           % 32 rad/sec  
ntd.PressVect = 2*2^-5 : 2^-5 : 1-(2*2^-5); % 0.03 bar  
ntd.ThrotVect = 0:2^1:88;                 % 2 deg  
ntd.RampRateKiX = 128:2^7:640;           % 128 rad/sec  
ntd.RampRateKiY = 0:2^-2:1;              % 0.25 bar
```

Remap table data.

```
ntd.PumpCon = interp2(td.PressVect,td.SpeedVect,td.PumpCon, ntd.PressVect',ntd.SpeedVect');  
ntd.PressEst = interp2(td.ThrotVect,td.SpeedVect,td.PressEst,ntd.ThrotVect',ntd.SpeedVect');  
ntd.SpeedEst = interp2(td.PressVect,td.ThrotVect,td.SpeedEst,ntd.PressVect',ntd.ThrotVect');  
ntd.ThrotEst = interp2(td.PressVect,td.SpeedVect,td.ThrotEst,ntd.PressVect',ntd.SpeedVect');
```

Recompute Ramp Rate table data.

```
ntd.RampRateKiZ = (1:length(ntd.RampRateKiX))' * (1:length(ntd.RampRateKiY)) * td.Ki;
```

### **Pumping Constant Power Of Two Spacing**

title(sprintf('Ramp Rate Ki\nOriginal Spacing (%dx%d) vs. Power of Two Spacing (%dx%d)
              size(td.RampRateKiZ,1),size(td.RampRateKiZ,2),size(ntd.RampRateKiZ,1),size(ntd.Ramp

```

The default configuration causes the model to log simulation data for the top-level signals. These simulation results are stored in the workspace variable `sldemo_fuelsys_output`. Before updating the model workspace with the new data, save the result of the simulation in `hDemo.orig_data` for later comparison with the evenly spaced power of two table simulation.

```
set_param('sldemo_fuelsys','StopTime','8')
sim('sldemo_fuelsys')
hDemo.orig_data = sldemo_fuelsys_output;
```

Reassign the new table data in the model workspace.

```
hDemo.hWS = get_param('sldemo_fuelsys', 'ModelWorkspace');
hDemo.hWS.assignin('PressEst', ntd.PressEst);
```

```

hDemo.hWS.assignin('PressVect', ntd.PressVect);
hDemo.hWS.assignin('PumpCon', ntd.PumpCon);
hDemo.hWS.assignin('SpeedEst', ntd.SpeedEst);
hDemo.hWS.assignin('SpeedVect', ntd.SpeedVect);
hDemo.hWS.assignin('ThrotEst', ntd.ThrotEst);
hDemo.hWS.assignin('ThrotVect', ntd.ThrotVect);
hDemo.hWS.assignin('RampRateKiX', ntd.RampRateKiX);
hDemo.hWS.assignin('RampRateKiY', ntd.RampRateKiY);
hDemo.hWS.assignin('RampRateKiZ', ntd.RampRateKiZ);

```

Reconfigure lookup tables for evenly spaced data.

```

hDemo.lookupTables = find_system(get_param('sldemo_fuelsys','Handle'),...
    'BlockType','Lookup_n-D');

for hDemo_blkIdx = 1 : length(hDemo.lookupTables)
    hDemo.blkH = hDemo.lookupTables(hDemo_blkIdx);
    set_param(hDemo.blkH,'IndexSearchMethod','Evenly spaced points')
    set_param(hDemo.blkH,'InterpMethod','None - Flat')
    set_param(hDemo.blkH,'ProcessOutOfRangeInput','None')
end

```

Rerun the simulation for the evenly spaced power of two implementation, and store the result of the simulation in `hDemo.pow2_data`.

```

sim('sldemo_fuelsys')
hDemo.pow2_data = sldemo_fuelsys_output;

```

Compare the result of the simulation for the fuel flow rate and the air fuel ratio. The simulation exercised the Pumping Constant and Ramp Rate Ki lookup tables, and shows an excellent match for the evenly spaced power of two breakpoints relative to the original table data.

```

Rebuild the air-fuel ratio control system and compare the difference in the generated lookup table code.

```
rtwbuild('sldemo_fuelSYS/fuel_rate_control');

### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

Figure 6 shows the same snippets of the generated code for the 'Pumping Constant' lookup table. The generated code for evenly spaced power of two breakpoints is significantly more efficient than the unevenly spaced breakpoint case. The code consists of two simple breakpoint calculations and a direct index into the 2D lookup table data. The expensive division is avoided and the breakpoint data is not required in memory.

```
rtwtrace('sldemo_fuelSYS/fuel_rate_control/airflow_calc/Pumping Constant');
```

```
/* Lookup_n-D: '<S2>/Pumping Constant' */
bpIdx = plook_u32s16_even8cka(rtB.es_o.speed, 512, 18U);
bpIndices_idx = bpIdx;
bpIdx = plook_u32u8_even2cka(rtb_map, 8U, 28U);

/* DiscreteFilter: '<S2>/Throttle Transient' */
rtDWork.ThrottleTransient_tmp = (int16_T) (((rtb_throttle << 14) - -13107 *
    rtDWork.ThrottleTransient_DSTATE) >> 14);

/* Sum: '<S2>/Sum' incorporates:
 * Product: '<S2>/Product'
 * Product: '<S2>/Product2'
 */
rtb_Product2 = (int16_T) (((rtConstP.PumpingConstant_tab[bpIdx * 19U + bpIndices_idx] *
    rtb_speed >> 11) * rtb_map >> 7) + ((20972 *
    rtDWork.ThrottleTransient_tmp + -20972 * rtDWork.ThrottleTransient_DSTATE) >>
    17));
```

**Simple index calculation**

**Direct index into table data**

```

uint32_T plook_u32s16_even8cka(int16_T u, int16_T bp0, uint32_T maxIndex)
{
    uint32_T bpIndex;
    uint16_T fbpIndex;

    /* Prelookup - Index only
       Index Search method: 'even'
       Process out of range input: 'Clip to range'
       Use previous index: 'off'
       Use last breakpoint for index at or above upper limit: 'on'
    */
    if (u < bp0) {
        bpIndex = 0U;
    } else {
        fbpIndex = (uint16_T)((uint32_T)u - (uint32_T)bp0) >> 8U;
        if ((uint32_T)fbpIndex >= maxIndex) {
            bpIndex = maxIndex;
        } else {
            bpIndex = (uint32_T)fbpIndex;
        }
    }

    return bpIndex;
}

```

**Figure 6: Generated code for Pumping Constant lookup (evenly spaced power of two breakpoints)**

Close the example.

```

close(findobj(0, 'Tag', 'CloseMe'));
clear hDemo* td ntd
close_system('sldemo_fuelsys',0);

```

### Model Advisor for Code Efficiency

Improving code efficiency by using evenly spaced power of two breakpoints is one of several important optimizations for fixed-point code generation. The Simulink® Model Advisor is a great tool for identifying other methods of improving code efficiency for a

Simulink® and Stateflow® model. Make sure to run the checks under the Embedded Coder® folder.

The following table describes the properties and property values for `mpt.Parameter` and `mpt.Signal` data objects that appear in the Model Explorer.

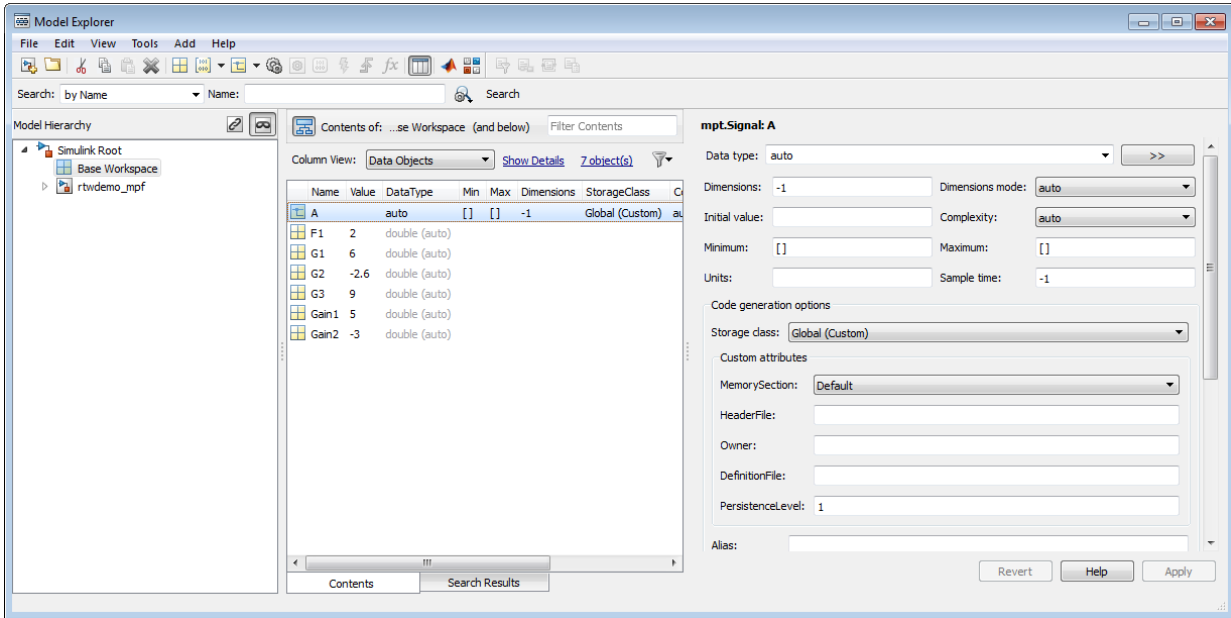

---

**Note** You can create `mpt.Signal` and `mpt.Parameter` objects in the base MATLAB or model workspace. However, if you create a signal object in a model workspace, the object's storage class must be set to `Auto`.

---

The figure below shows an example of the Model Explorer. When you select an `mpt.Parameter` or `mpt.Signal` data object in the middle pane, its properties and property values display in the rightmost pane.

In the Properties column, the table lists the properties in the order in which they appear on the Model Explorer.

**Parameter and Signal Property Values**

| <b>Class:<br/>Parameter,<br/>Signal, or<br/>Both</b> | <b>Property</b>  | <b>Available Property<br/>Values<br/>(* Indicates<br/>Default)</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------|------------------|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Both                                                 | User object type | *auto                                                              | <p>Prenamed and predefined property sets that are registered in the <code>sl_customization.m</code> file. (See “Register mpt User Object Types” on page 36-18.) This field is active when a user object type is registered.</p> <p>Select <code>auto</code> if this field is available but you do not want to apply the properties of a user object type to a selected data object. The fields on the Model Explorer are populated with default values.</p> |
|                                                      |                  | Listed user object type name                                       | Select a user object type name to apply the properties and values that you associated with this name in the <code>sl_customization.m</code> file. The fields on the Model Explorer are automatically populated with those values.                                                                                                                                                                                                                           |
| Parameter                                            | Value            | *0                                                                 | The data type and numeric value of the data object. For example, <code>int8(5)</code> . The numeric value is used as an initial parameter value in the generated code.                                                                                                                                                                                                                                                                                      |
| Both                                                 | Data type        |                                                                    | Used to specify the data type for an <code>mpt.Signal</code> data object, but not for an <code>mpt.Parameter</code> data object. The data type for an <code>mpt.Parameter</code> data object is specified in the <b>Value</b> field above. See “About Data Types in Simulink” (Simulink).                                                                                                                                                                   |
| Both                                                 | Unit             | *null                                                              | Units of measurement of the signal or parameter. (Enter text in this field.)                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Class:<br/>Parameter,<br/>Signal, or<br/>Both</b> | <b>Property</b>         | <b>Available Property<br/>Values<br/>(* Indicates<br/>Default)</b>                                                              | <b>Description</b>                                                                                                                                                                         |
|------------------------------------------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Both                                                 | Dimensions              | * - 1                                                                                                                           | The dimension of the signal or parameter. For a parameter, the dimension is derived from its value.                                                                                        |
| Both                                                 | Complexity              | *auto<br>real<br>complex                                                                                                        | Complexity specifies whether the signal or parameter is a real or complex number. Select auto for the code generator to decide. For a parameter, the complexity is derived from its value. |
| Signal                                               | Sample time             | * - 1                                                                                                                           | Model or block execution rate.                                                                                                                                                             |
| Signal                                               | Sample mode             | *auto                                                                                                                           | Determines how the signal propagates through the model. Select auto for the code generator to decide.                                                                                      |
|                                                      |                         | Sample based                                                                                                                    | The signal propagates through the model one sample at a time.                                                                                                                              |
|                                                      |                         | Frame based                                                                                                                     | The signal propagates through the model in batches of samples.                                                                                                                             |
| Both                                                 | Minimum                 | *0.0                                                                                                                            | The minimum value to which the parameter or signal is expected to be bound.                                                                                                                |
|                                                      |                         | Number within the minimum range of the parameter or signal. (Based on the data type and resolution of the parameter or signal.) |                                                                                                                                                                                            |
| Both                                                 | Maximum                 | *0.0                                                                                                                            | Maximum value to which the parameter or signal is expected to be bound. (Enter information using a dialog box.)                                                                            |
|                                                      | Code generation options |                                                                                                                                 |                                                                                                                                                                                            |

| <b>Class:<br/>Parameter,<br/>Signal, or<br/>Both</b> | <b>Property</b> | <b>Available Property<br/>Values<br/>(* Indicates<br/>Default)</b>                  | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                                            |             | Valid ANSI <sup>a</sup> C/C++<br>variable name           |                                                                                                                                                                                                                                                                                                                                        |
| Both                                       | Description | *null                                                    | Text description of the parameter or signal. Appears as a comment beside the signal or parameter's identifier in the generated code.                                                                                                                                                                                                   |
|                                            |             | Character vector                                         |                                                                                                                                                                                                                                                                                                                                        |
| Signal                                     | Reusable    |                                                          | Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same storage class for both. The storage class is either <b>Reusable</b> or derived from <b>Reusable</b> .                                                                                                                        |
| Signal                                     | Data Scope  | *Auto                                                    | You can specify the scope of symbols code generation generates for a data object of this class by selecting a value for <b>DataScope</b> . When you take the default of <b>Auto</b> , code generation determines the symbol scope internally. If possible, symbols have <b>File</b> scope. Otherwise, they have <b>Exported</b> scope. |
|                                            |             | <b>File</b>                                              | Code generation defines the scope of each symbol as the file that defines it. <b>File</b> scope requires each symbol to be used in a single file. If the same symbol is referenced in multiple files, code generation reports an error.                                                                                                |
|                                            |             | <b>Exported</b>                                          | Code generation exports symbols to external code in the header file specified by the <b>HeaderFile</b> field. If a <b>HeaderFile</b> is not specified, symbols are exported to external code in <i>model.h</i> .                                                                                                                       |

| Class:<br>Parameter,<br>Signal, or<br>Both | Property        | Available Property<br>Values<br>(* Indicates<br>Default) | Description                                                                                                                                                                                                                                       |
|--------------------------------------------|-----------------|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                            |                 | Imported                                                 | Code generation imports symbols from external code in the header file specified by the <b>HeaderFile</b> field. If you do not specify a header file, code generation generates an <code>extern</code> directive in <code>model_private.h</code> . |
| Signal                                     | Header file     |                                                          | See above.                                                                                                                                                                                                                                        |
| Signal                                     | Owner           |                                                          | See above.                                                                                                                                                                                                                                        |
| Signal                                     | Definition file |                                                          | See above.                                                                                                                                                                                                                                        |

**mpt Package Storage Classes**

| <b>CSC Name</b> | <b>Purpose</b>                                                                                                                                                                           | <b>Signals?</b> | <b>Parameters?</b> |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------|
| BitField        | Generate a struct declaration that embeds Boolean data in named bit fields.                                                                                                              | Y               | Y                  |
| CompilerFlag    | Supports preprocessor conditionals defined via compiler flag. See “Generate Preprocessor Conditionals for Variant Systems” on page 25-40.                                                | N               | Y                  |
| Const           | Generate a constant declaration with the <code>const</code> type qualifier.                                                                                                              | N               | Y                  |
| ConstVolatile   | Generate declaration of volatile constant with the <code>const volatile</code> type qualifier.                                                                                           | N               | Y                  |
| Define          | Generate <code>#define</code> directive.                                                                                                                                                 | Y               | Y                  |
| ExportToFile    | Generate header (.h) file, with user-specified name, containing global variable declarations.                                                                                            | Y               | Y                  |
| FileScope       | Generate a static qualifier suffix for a variable declaration so that the scope of the variable is limited to the current file.                                                          | Y               | Y                  |
| GetSet          | Supports specialized function calls to read and write the memory associated with a Data Store Memory block. See “Access Data Through Functions with Storage Class GetSet” on page 37-42. | Y               | Y                  |
| Global          | The default storage class for the mpt package. Generate the declaration and definition of a data object in specified files, and use the specified memory section.                        | Y               | Y                  |

| <b>CSC Name</b> | <b>Purpose</b>                                                                                                                                                                                   | <b>Signals?</b> | <b>Parameters?</b> |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------|
| ImportedDefine  | Supports preprocessor conditionals defined via legacy header file. See “Generate Preprocessor Conditionals for Variant Systems” on page 25-40.                                                   | N               | Y                  |
| ImportFromFile  | Generate directives to include predefined header files containing global variable declarations.                                                                                                  | Y               | Y                  |
| Reusable        | Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same storage class for both. The storage class is either Reusable or derived from Reusable. | Y               | N                  |
| Struct          | Generate a struct declaration encapsulating parameter or signal object data.                                                                                                                     | Y               | Y                  |
| StructConst     | Generate a struct declaration, with a const type qualifier, encapsulating parameter object data.                                                                                                 | N               | Y                  |
| StructVolatile  | Generate a struct declaration, with a volatile type qualifier, encapsulating parameter or signal object data.                                                                                    | Y               | Y                  |
| Volatile        | Use volatile type qualifier in declaration.                                                                                                                                                      | Y               | Y                  |

## Examples of Property Value Changes on Generated Code

| What I noticed when inspecting the .c/.cpp file                                                                                                                                                                                                                                                                                                                                  | Change I made to property value settings                                                                                                                                                                                                                                                                                                                                                                                                 | What I noticed after regenerating and reinspecting the file                                                                                                                                                                                                  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Example 1:<br/>Parameter data objects can be declared or defined as constants. I know that the data object GAIN is a parameter. I want this to be declared or defined in the .c file as a variable. But I notice that GAIN is declared as a constant by the statement <code>const real_T GAIN = 5.0;</code>. Also, this statement is in the constant section of the file.</p> | <p>In the Model Explorer, I clicked the data object GAIN. I noticed that the property value for its <b>Memory section</b> property is set at MemConst. I changed this to Default.</p>                                                                                                                                                                                                                                                    | <p>I notice two differences. One is that now GAIN is declared as a variable with the statement <code>real_T GAIN = 5.0;</code>. The second difference is that the declaration now is located in the MemConst memory section in the .c or .cpp file.</p>      |
| <p>Example 2:<br/>I notice again the declaration of GAIN in the .c file mentioned in Example 1. It appears as <code>real_T GAIN = 5.0;</code>. But I have changed my mind. I want data object GAIN to be <code>#define</code>.</p>                                                                                                                                               | <p>I changed the <b>Storage class</b> selection to Define.</p>                                                                                                                                                                                                                                                                                                                                                                           | <p>GAIN is not declared in the .c file as a MemConst parameter. Rather, it is defined as a <code>#define</code> macro by the code <code>#define GAIN 5.0</code>, and this is located near the top of the .c file with the other preprocessor directives.</p> |
| <p>Example 3:<br/>I changed my mind again after doing Example 2. I do want GAIN defined using the <code>#define</code> preprocessor directive. But I do not want to include the <code>#define</code> in this file. I know it exists in another file and I want to reference that file.</p>                                                                                       | <p>On the Model Explorer, I notice that the property value for the <b>Header file</b> property is blank. I changed this to <code>filename.h</code>. (I chose the ANSI C/C++ double quote mechanism for the <code>#include</code>, but could have chosen the angle bracket mechanism.) Also, I must make the user-defined <code>filename.h</code> available to the compiler, placing it either in the system path or local directory.</p> | <p><code>#define GAIN 5.0</code> is not present in this .c file. Instead, the <code>#include filename.h</code> code appears as a preprocessor directive at the top of the file.</p>                                                                          |

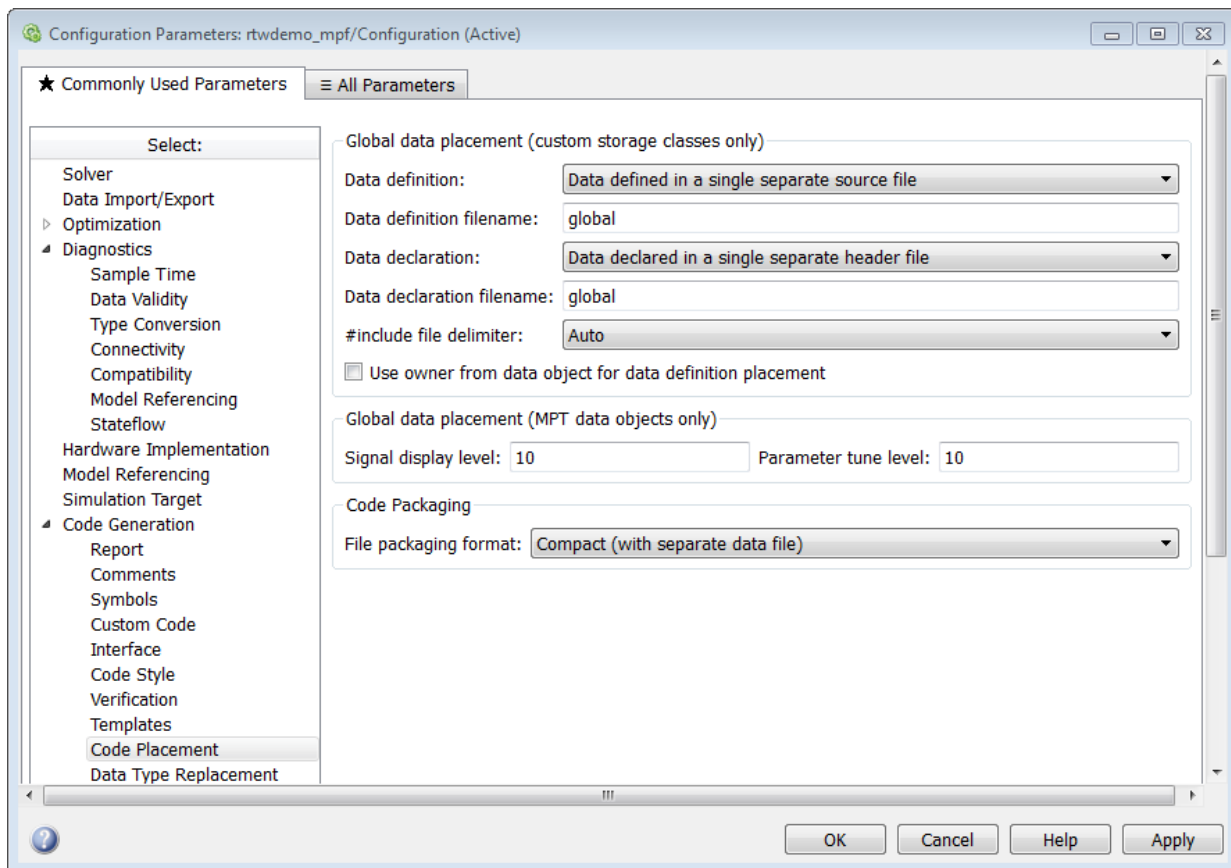

| What I noticed when inspecting the .c/.cpp file                                                                                                                                                                                                                                                                              | Change I made to property value settings                                                                                                                                                                                       | What I noticed after regenerating and reinspecting the file                                                                        |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <p>Example 4:<br/>I have one more change I want to make. Let us say that we have declared the data object <code>data_in</code>, and that its declaration statement in the <code>.c</code> file reads<br/><code>real_T data_in = 0.0;</code>. I want to replace this statement with an alias in the <code>.c</code> file.</p> | <p>In the Model Explorer, I selected the data object <code>data_in</code>. I noticed that the <b>Alias</b> field is blank. I changed this to <code>data_in_alias</code>, which I know is a valid ANSI C/C++ variable name.</p> | <p>The identifier <code>data_in_alias</code> now appears in the <code>.c</code> file everywhere <code>data_in</code> appeared.</p> |

## Specify Persistence Level for Signals and Parameters

With this procedure, you can control the persistence level of signal and parameter objects associated with a model. Persistence level allows you to make intermediate variables or parameters global during initial development. At the later stages of development, you can use this procedure to remove these signals and parameters for efficiency. Use the **Persistence Level** property of `mpt.Signal` and `mpt.Parameter` data objects. For descriptions of the properties on the Model Explorer, see “MPT Data Object Properties” on page 36-2.

Notice also the **Signal display level** and **Parameter tune level** fields on the **Code Placement** pane of the Configuration Parameters dialog box, as illustrated in the next figure.

The **Signal display level** field allows you to specify whether or not the code generator defines a signal data object as global data in the generated code. The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Signal display level** number is for mpt (module packaging tool) signal data objects in the model. The **Persistence level** number is for a *particular* mpt signal data object. If the data object's **Persistence level** is equal to or less than the **Signal display level**, the signal appears in the generated code as global data with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Signal display level** is 5.

Otherwise, the code generator automatically determines how the particular signal data object appears in the generated code. Depending on the settings on the **Optimization**

pane of the Configuration Parameters dialog box, the signal data object could appear in the code as local data without the custom attributes you specified for that data object. Or, based on expression folding, the code generator could remove the data object so that it does not appear in the code.

The **Parameter tune level** field allows you to specify whether or not the code generator declares a parameter data object as tunable global data in the generated code.

The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Parameter tune level** number is for `mpt` parameter data objects in the model. The **Persistence level** number is for a *particular* `mpt` parameter data object. If the data object's **Persistence level** is equal to or less than the **Parameter tune level**, the parameter appears tunable in the generated code with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Parameter tune level** is 5.

Otherwise, the parameter is inlined in the generated code, and the code generation settings determine its exact form.

Note that, in the initial stages of development, you might be more concerned about debugging than code size. Or, you might want one or more particular data objects to appear in the code so that you can analyze intermediate calculations of an equation. In this case, you might want to specify the **Parameter tune level (Signal display level for signals)** to be higher than **Persistence level** for some `mpt` parameter (or signal) data objects. This results in larger code size, because the code generator defines the parameter (or signal) data objects as global data, which have the custom properties you specified. As you approach production code generation, however, you might have more concern about reducing the size of the code and less need for debugging or intermediate analyses. In this stage of the tradeoff, you could make the **Parameter tune level (Signal display level for signals)** greater than **Persistence level** for one or more data objects, generate code and observe the results. Repeat until satisfied.

- 1 With the model open, in the Configuration Parameters dialog box, select **Code Generation > Code Placement**.
- 2 Type the desired number in the **Signal display level** or **Parameter tune level** field, and click **Apply**.
- 3 In the Model Explorer, type the desired number in the **Persistence** field for the selected signal or parameter, and click **Apply**.
- 4 Save the model and generate code.

## Register mpt User Object Types

- “Introduction” on page 36-18
- “Register mpt User Object Types Using `sl_customization.m`” on page 36-18
- “mpt User Object Type Customization Using `sl_customization.m`” on page 36-19

### Introduction

Embedded Coder allows you to create custom `mpt` object types and specify properties and property values to be associated with them. Once created, a user object type can be applied to data objects displayed in Model Explorer. When you apply a user object type to a data object, by selecting a type name in the **User object type** pull-down list in Model Explorer, the data object is automatically populated with the properties and property values that you specified for the user object type.

To register `mpt` user object type customizations, use the Simulink customization file `sl_customization.m`. This file is a mechanism that allows you to use MATLAB code to perform customizations of the standard Simulink user interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see “Registering Customizations” (Simulink).

### Register mpt User Object Types Using `sl_customization.m`

To register `mpt` user object type customizations, you create an instance of `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.slDataObjectCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following methods for registering `mpt` user object type customizations:

- `addMPTObjectType(hObj, objectTypeName, classtype, propName1, propValue1, propName2, propValue2, ...)`

```
addMPTObjectType(hObj, objectTypeName, classtype, {propName1,
propName2, ...}, {propValue1, propValue2, ...})
```

Registers the specified user object type, along with specified values for object properties, and adds the object type to the top of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `objectTypeName` — Name of the user object type
- `classType` — Class to which the user object type applies: 'Signal', 'Parameter', or 'Both'
- `propName` — Name of a property of an mpt or mpt-derived data object to be populated with a corresponding `propValue` when the registered user object type is selected
- `propValue` — Specifies the value for a corresponding `propName`
- `moveMPTObjectTypeToTop(hObj, objectTypeName)`

Moves the specified user object type to the top of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `moveMPTObjectTypeToEnd(hObj, objectTypeName)`

Moves the specified user object type to the end of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `removeMPTObjectType(hObj, objectTypeName)`

Removes the specified user object type from the user object type list.

Your instance of the `sl_customization` function should use these methods to register mpt object type customizations for your Simulink installation.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, to use the changes, you must restart your MATLAB session.

### **mpt User Object Type Customization Using `sl_customization.m`**

The `sl_customization.m` file shown in “mpt User Object Type Customization Using `sl_customization.m`” on page 36-19 uses the `addMPTObjectType` method to register the user signal types `EngineType` and `FuelType` for mpt objects.

#### **Example 36.1. `sl_customization.m` for mpt Object Type Customizations**

```
function sl_customization(cm)
% Register user customizations
```

```
% Get default (factory) customizations
hObj = cm.slDataObjectCustomizer;

% Add commonly used signal types
hObj.addMPTObjectType(...
    'EngineType','Signal',...
    'DataType', 'uint8',...
    'Min', 0,...
    'Max', 255,...
    'Unit','m/s');

hObj.addMPTObjectType(...
    'FuelType','Signal',...
    'DataType', 'int16',...
    'Min', -12,...
    'Max', 3000,...
    'Unit','mg/hr');

end
```

If you include the above file on the MATLAB path of the Simulink installation that you want to customize, the specified customizations will appear in Model Explorer. For example, you could view the customizations as follows:

- 1 Start a MATLAB session.
- 2 Open Model Explorer, for example, by entering the MATLAB command `daexplr`.
- 3 Select **Base Workspace**.
- 4 Add an `mpt` signal, for example, by selecting **Add > Add Custom**.
- 5 In the right-hand pane display for the added `mpt` signal, examine the **User object type** drop-down list, noting the impact of the changes specified in “`mpt User Object Type Customization Using sl_customization.m”` on page 36-19.
- 6 From the **User object type** drop-down list, select one of the registered user signal types, for example, `FuelType`, and verify that the displayed settings are consistent with the arguments specified to the `addMPTObjectType` method in `sl_customization.m`.

## Reuse Parameter Data from External Code in the Generated Code

This example shows how to generate code that imports a parameter value from your external code.

### Create External Code Files

Suppose your external code defines a vector parameter `myGains` with three elements. Save the definition in your current folder in a file called `ex_vector_import_src.c`.

```
#include "ex_vector_import_decs.h"

my_int8 myGains[3] = {
    2,
    4,
    6
};
```

Save the declaration in your current folder in a file called `ex_vector_import_decs.h`.

```
#include "ex_vector_import_cust_types.h"

extern my_int8 myGains[3];
```

Save the data type definition `my_int8` in your current folder in a file called `ex_vector_import_cust_types.h`.

```
typedef signed char my_int8;
```

### Import Parameter Value for Simulation

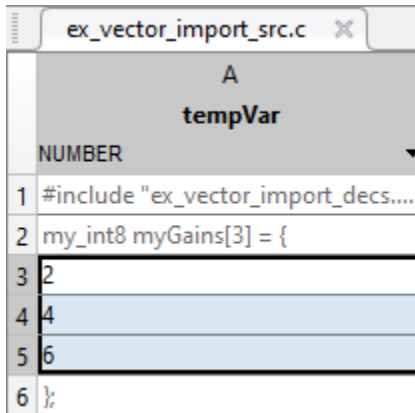

In your current folder, right-click the file `ex_vector_import_src.c` and select **Import Data**.

In the Import dialog box, set **Output Type** to `Numeric Matrix`.

Set the name of the generated MATLAB variable to `tempVar`.

Select only the parameter values (2, 4, and 6) to import.

Import the data by clicking the green check mark. The MATLAB variable `tempVar` appears in the base workspace.

Alternatively, use the command prompt to manually create `tempVar`.

```
tempVar = [2;4;6];
```

At the command prompt, create a `Simulink.Parameter` object that represents `myGains`.

```
myGains = Simulink.Parameter(tempVar);
```

### Create and Configure Model

Create the model `ex_vector_import`.

```
open_system('ex_vector_import')
```

Open the **Embedded Coder** app.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Use the **Value** column to set the value of the **Gain** parameter in the Gain block to myGains.

Click the **Show/refresh additional information** button. The data table now contains a row that represents the parameter object, myGains.

Use the **Data Type** column to set the data type of myGains to my\_int8.

For the other row (which represents the **Gain** parameter of the Gain block), set **Data Type** to **Inherit: Inherit from 'Gain'**. With this setting, the **Gain** parameter inherits the data type my\_int8 from myGains.

Set the **Change view** drop-down list to Code.

Set these properties for myGains:

- **Storage Class** to ImportFromFile
- **Header File** to ex\_vector\_import\_decs.h

Alternatively, use these commands at the command prompt to configure the object and the block:

```
set_param('ex_vector_import/Gain','Gain','myGains',...  
         'ParamDataTypeStr','Inherit: Inherit from ''Gain''')  
myGains.DataType = 'my_int8';  
myGains.CoderInfo.StorageClass = 'Custom';  
myGains.CoderInfo.CustomStorageClass = 'ImportFromFile';  
myGains.CoderInfo.CustomAttributes.HeaderFile = 'ex_vector_import_decs.h';
```

At the command prompt, create a Simulink.AliasType object to represent your custom data type my\_int8. Set the DataScope and HeaderFile properties to import the type definition from your external code.

```
my_int8 = Simulink.AliasType('int8');  
my_int8.DataScope = 'Imported';  
my_int8.HeaderFile = 'ex_vector_import_cust_types.h';
```

Set model configuration parameter **Source files** to ex\_vector\_import\_src.c.

```
set_param('ex_vector_import','CustomSource','ex_vector_import_src.c')
```

### Generate and Inspect Code

Generate code.

```

rtwbuild('ex_vector_import')

### Starting build procedure for model: ex_vector_import
### Successful completion of build procedure for model: ex_vector_import

The generated file ex_vector_import.h includes the external header files
ex_vector_import_decs.h and ex_vector_import_cust_types.h, which contain
the parameter variable declaration (myGains) and custom type definition (my_int8).

file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.h');
rtwdemodbtype(file,'#include "ex_vector_import_cust_types.h"',...
    '#include "ex_vector_import_cust_types.h"',1,1)
rtwdemodbtype(file,'/* Includes for objects with custom storage classes. */',...
    '#include "ex_vector_import_decs.h"',1,1)

#include "ex_vector_import_cust_types.h"

/* Includes for objects with custom storage classes. */
#include "ex_vector_import_decs.h"

```

The generated code algorithm in the model step function in the generated file `ex_vector_import.c` uses `myGains` for calculations.

```

file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function */',1,0)

/* Model step function */
void ex_vector_import_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
     * Gain: '<Root>/Gain'
     * Inport: '<Root>/In1'
     */
    rtY.Out1[0] = (real_T)myGains[0] * rtU.In1;
    rtY.Out1[1] = (real_T)myGains[1] * rtU.In1;
    rtY.Out1[2] = (real_T)myGains[2] * rtU.In1;
}

```

The generated code does not define (allocate memory for) or initialize the global variable `myGains` because the data scope of the corresponding parameter object is imported.

When you simulate the model in Simulink, the model uses the value stored in the `Value` property of the parameter object. However, if you use external mode simulation, the

external executable begins the simulation by using the value from your code. See “Considerations for Other Modeling Goals” on page 53-105.

- “Import Parameter Data with Conditionally Compiled Dimension Length” on page 37-7

## Import Parameter Data with Conditionally Compiled Dimension Length

Suppose your external code conditionally allocates memory for and initializes lookup table and breakpoint set data based on a dimension length that you specify as a `#define` macro. This example shows how to generate code that imports this external global data.

### Create External Code Files

Save the definition of the breakpoint set data `T1Break` and lookup table data `T1Data` in your current folder in a file called `ex_vec_syndim_src.c`. These global variables have either 9 or 11 elements depending on the value of the macro `bpLen`.

```
#include "ex_vec_syndim_decs.h"
```

```
#if bpLen == 11
double T1Break[bpLen] = {
    -5.0,
    -4.0,
    -3.0,
    -2.0,
    -1.0,
    0.0,
    1.0,
    2.0,
    3.0,
    4.0,
    5.0
};
```

```
double T1Data[bpLen] = {
    -1.0,
    -0.99,
    -0.98,
    -0.96,
    -0.76,
    0.0,
    0.76,
    0.96,
    0.98,
    0.99,
    1.0
};
```

```
};  
#endif  
  
#if bpLen == 9  
double T1Break[bpLen] = {  
    -4.0,  
    -3.0,  
    -2.0,  
    -1.0,  
    0.0,  
    1.0,  
    2.0,  
    3.0,  
    4.0  
};  
  
double T1Data[bpLen] = {  
    -0.99,  
    -0.98,  
    -0.96,  
    -0.76,  
    0.0,  
    0.76,  
    0.96,  
    0.98,  
    0.99  
};  
#endif
```

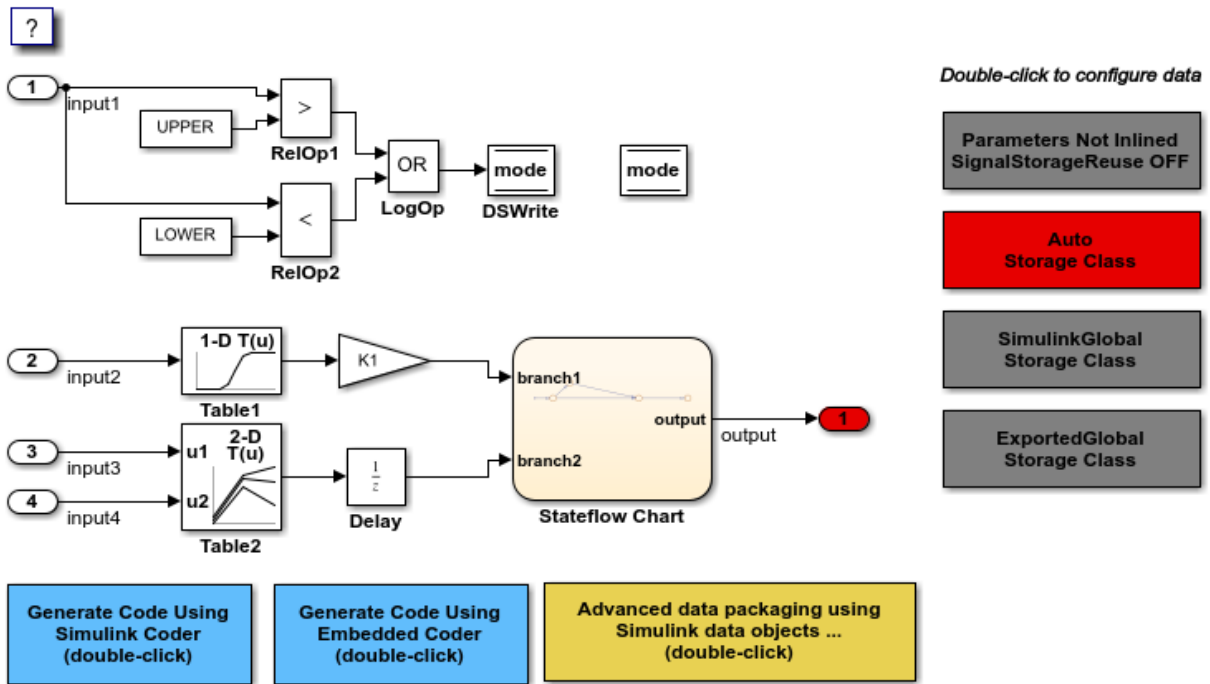

Save the declarations of the variables and the definition of the macro in your current folder in a file called `ex_vec_syndim_decs.h`.

```
#define bpLen 11  
  
extern double T1Break[bpLen];  
extern double T1Data[bpLen];
```

### **Explore and Configure Example Model**

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Copyright 1994-2019 The MathWorks, Inc.

Open the Table1 block dialog box. The block refers to variables, T1Data and T1Break, in the base workspace. These variables store the lookup table and breakpoint set data with 11 elements.

At the command prompt, convert the variables to Simulink.Parameter objects.

```
T1Data = Simulink.Parameter(T1Data);
T1Break = Simulink.Parameter(T1Break);
```

Configure the objects to import the data definitions from your external code.

```
T1Data.CoderInfo.StorageClass = 'Custom';
T1Data.CoderInfo.CustomStorageClass = 'ImportFromFile';
T1Data.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_syndim_decs.h';
```

```
T1Break.CoderInfo.StorageClass = 'Custom';
```

```
T1Break.CoderInfo.CustomStorageClass = 'ImportFromFile';  
T1Break.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_syndim_decs.h';
```

At the command prompt, create a `Simulink.Parameter` object to represent the custom macro `bpLen`.

```
bpLen = Simulink.Parameter(11);  
bpLen.Min = 9;  
bpLen.Max = 11;  
bpLen.DataType = 'int32';  
bpLen.CoderInfo.StorageClass = 'Custom';  
bpLen.CoderInfo.CustomStorageClass = 'ImportedDefine';  
bpLen.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_syndim_decs.h';
```

Use `bpLen` to set the dimensions of the lookup table and breakpoint set data. Configure the model to enable symbolic dimensions by selecting the configuration parameter **Allow symbolic dimension specification**.

```
T1Data.Dimensions = '[1 bpLen]';  
T1Break.Dimensions = '[1 bpLen]';  
set_param('rtwdemo_basicsc', 'AllowSymbolicDim', 'on')
```

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_vec_syndim_src.c`.

```
set_param('rtwdemo_basicsc', 'CustomSource', 'ex_vec_syndim_src.c')
```

To generate code with custom storage classes such as `ImportFromFile`, you must use an ERT-based system target file. Set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`.

```
set_param('rtwdemo_basicsc', 'SystemTargetFile', 'ert.tlc')
```

### Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')  
  
### Starting build procedure for model: rtwdemo_basicsc  
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated code algorithm is in the model `step` function in the generated file `rtwdemo_basicsc.c`. The algorithm passes `T1Break`, `T1Data`, and `bpLen` as argument

values to the function that performs the table lookup. In this case, `bpLen` controls the upper bound of the binary search that the function uses.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.c');  
rtwdemodbtype(file, '.X = look1_iflf_binlx', 'bpLen - 1U', 1, 1)
```

```
rtwdemo_basicsc_DW.X = look1_iflf_binlx(rtwdemo_basicsc_U.input2,  
    (&(T1Break[0])), (&(T1Data[0])), bpLen - 1U) * 2.0F;
```

For more information about symbolic dimensions, see “Implement Dimension Variants for Array Sizes in Generated Code” on page 25-2.

## Access Structured Data Through a Pointer That External Code Defines

This example shows how to generate code that uses global data that some handwritten code defines. In the handwritten code, a pointer variable points to one of three structure variables that contain parameter data. A handwritten function switches the pointer between the structures. The generated code accesses the parameter data by dereferencing the pointer variable.

### Explore External Code

Open the example source file `rtwdemo_importstruct_user.c`. The code defines a default data structure variable `ReferenceStruct` as constant (`const`) data and statically initializes each field. This structure represents the reference data set.

```
/* Constant default data structure (reference data set) */
const DataStruct_type ReferenceStruct =
{
    11,    /* OFFSET */
    2     /* GAIN */
};
```

The code defines two other structure variables, `WorkingStruct1` and `WorkingStruct2`, as volatile (`volatile`) data.

```
/* Volatile data structures (working data sets) */
volatile DataStruct_type WorkingStruct1;
volatile DataStruct_type WorkingStruct2;
```

The code defines a function that can initialize:

- An inactive working structure from the active working structure.
- Both working structures from the reference structure.

```
/* Function to initialize inactive working structures from active structure */
void InitInactiveWorkingStructs(void)
{
    if (StructPointer == &WorkingStruct1) {
        /* Copy values from WorkingStruct1 to WorkingStruct2 */
    }
}
```

```

        memcpy((void*)&WorkingStruct2, (void*)&WorkingStruct1, sizeof(ReferenceStruct))
    } else if (StructPointer == &WorkingStruct2) {
        /* Copy values from WorkingStruct2 to WorkingStruct1 */
        memcpy((void*)&WorkingStruct1, (void*)&WorkingStruct2, sizeof(ReferenceStruct))
    } else {
        /* Initialize both working structures from ReferenceStruct */
        memcpy((void*)&WorkingStruct1, &ReferenceStruct, sizeof(ReferenceStruct));
        memcpy((void*)&WorkingStruct2, &ReferenceStruct, sizeof(ReferenceStruct));
    }
}

```

The code defines `StructPointer`, which is a `const volatile` pointer to a structure. The code initializes the pointer to the address of `ReferenceStruct`.

```

/* Define structure pointer. Point to reference structure by default */
const volatile DataStruct_type *StructPointer = &ReferenceStruct;

```

Finally, the code defines a function that can dynamically set `StructPointer` to point to either `ReferenceStruct`, `WorkingStruct1`, or `WorkingStruct2`.

```

/* Function to switch between structures */
void SwitchStructPointer(Dataset_T Dataset)
{
    switch (Dataset) {
        case Working1:
            StructPointer = &WorkingStruct1;
            break;
        case Working2:
            StructPointer = &WorkingStruct2;
            break;
        default:
            StructPointer = &ReferenceStruct;
    }
}

```

The example header file `rtwdemo_importstruct_user.h` defines the enumeration `Dataset_T` and the structure type `Datastruct_type`. The file includes (`#include`) the built-in Simulink® Coder™ header file `rtwtypes.h`, which defines (typedef) Simulink Coder data types such as `int16_T`.

```
#include "rtwtypes.h"

typedef enum {
    Reference = 0,
    Working1,
    Working2
} Dataset_T;

typedef struct DataStruct_tag {
    int16_T  OFFSET; /* OFFSET */
    int16_T  GAIN;   /* GAIN */
} DataStruct_type;
```

The file also declares the global variables and the functions.

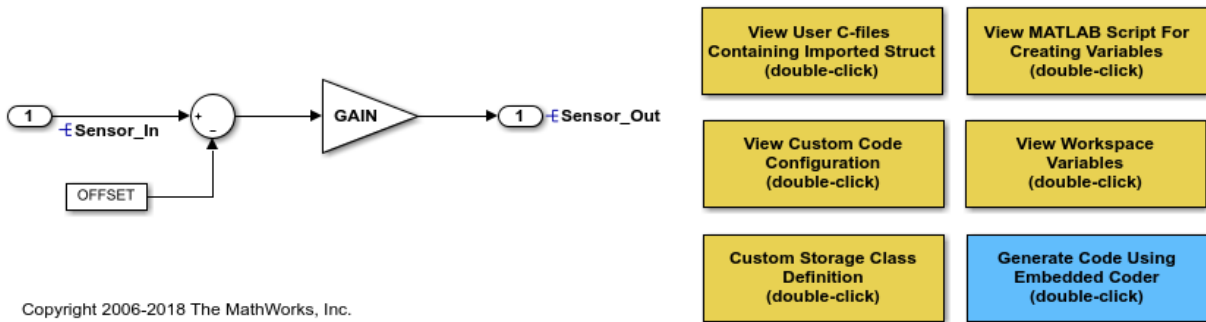

### **Purpose of External Code**

The code is designed so that the source code of a control algorithm (whether generated or handwritten) can read data from `ReferenceStruct`, `WorkingStruct1`, or `WorkingStruct2` by dereferencing (`->`) `StructPointer`. The two working structures (`WorkingStruct1` and `WorkingStruct2`) are located in volatile memory and are intended to be changed during runtime by an external calibration tool. The calibration engineer does not change the active working structure. Instead, the engineer changes the parameter values in the inactive working structure and then activates it by switching working structures.

If necessary for safety or in preparation for shutting down the application, the calibration tool can point `StructPointer` to `ReferenceStruct` instead. `ReferenceStruct` stores default parameter values that do not change during execution.

### **Explore Example Model**

Open the example model, `rtwdemo_importstruct`.

The model creates variables and objects in the base workspace. The Constant block and the Gain block use the `ECoderDemos.Parameter` objects `GAIN` and `OFFSET` to set the **Constant value** and **Gain** block parameters. `ECoderDemos` is an example custom package that defines two classes, `Parameter` and `Signal`, and some custom storage classes.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Set the **Change view** drop-down list to Code.

Click the **Show/refresh additional information** button.

The Model Data Editor shows rows that correspond to the **Constant value** and **Gain** parameters of the blocks and rows that corresponds to `OFFSET` and `GAIN`, which set the parameter values. In the **Storage Class** column, `OFFSET` and `GAIN` use the custom storage class `StructPointer`, which the `ECoderDemos` package defines.

Open the Custom Storage Class Designer and inspect the custom storage classes in the `ECoderDemos` package. At the command prompt, use this command:

```
cscdesigner('ECoderDemos')
```

This example package defines multiple custom storage classes, including `StructPointer`. You cannot edit the definitions. However, you can create your own packages and custom storage classes later. For an example that shows how to create a package and a custom storage class, see “Create and Apply a Storage Class” on page 37-26.

Under **Custom storage class definitions**, click **StructPointer**. The settings for this custom storage class enable the generated code to interact with the pointer variable, **StructPointer**, from the external code. For example, the custom storage class uses these settings:

- **Data scope** is set to **Imported** because the example external code defines (allocates memory for) **StructPointer**. With this setting, the code generator avoids generating unnecessary, duplicate definitions for the data items, such as the `ECoderDemos.Parameter` objects, that use the custom storage class.
- **Data access** is set to **Pointer** because in the example external code, **StructPointer** is a pointer.
- **Memory section** is set to **ConstVolatile** because the example external code defines **StructPointer** as constant, volatile data (`const volatile`).
- **Type** is set to **FlatStructure** because in the example external code, **StructPointer** points to a structure. With this setting, the generated code treats each data item (`ECoderDemos.Parameter` object) as a field of a flat structure whose variable name and type name you can specify.
- On the **Structure Attributes** tab, **Struct name** is set to **StructPointer**. For a **FlatStructure** custom storage class, **Struct name** specifies the name of the structure variable in the generated code. In this example, **StructPointer** is the name of the variable that the external code defines.
- **Type name** is set to `DataStruct_type`, which is the name of the structure type that the example external code defines.

In the model, in the **Configuration Parameters** dialog box, inspect the **Code Generation > Custom Code** pane.

Under **Insert custom C code in generated**, select **Initialize function**. This parameter value specifies the code to include in the generated model initialize function. In this model, the configuration parameter is set so that the generated code calls the `InitInactiveWorkingStructs` function. `InitInactiveWorkingStructs` initializes the working structures with the values from `ReferenceStruct`. The initialization code then sets the pointer to the first working structure.

Under **Additional build information**, select **Source files**. This configuration parameter identifies the example external code file `rtwdemo_importstruct_user.c` for inclusion in the build process after code generation.

## Generate and Inspect Code

Generate code from the model.

In the generated file `rtwdemo_importstruct.c`, the model initialization function calls `InitInactiveWorkingStructs`.

```
/* Model initialize function */
void rtwdemo_importstruct_initialize(void)
{
    /* user code (Initialize function Body) */

    /* Initialize the working structures to reference values */
    InitInactiveWorkingStructs();

    /* Switch to first working structure */
    SwitchStructPointer(Working1);
}

/*
```

The algorithm in the model execution (`step`) function dereferences the pointer variable `StructPointer`.

```
/* Model step function */
void rtwdemo_importstruct_step(void)
{
    /* Outport: '<Root>/Out' incorporates:
     * Constant: '<Root>/Offset'
     * Gain: '<Root>/Gain'
     * Inport: '<Root>/In'
     * Sum: '<Root>/Sum'
     */
    Sensor_Out = (int16_T)((int16_T)(Sensor_In - StructPointer->OFFSET) *
```

```
    StructPointer->GAIN);  
}
```

## Apply Built-In and Customized Storage Classes to Data Elements

In “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99, you control the declaration and definition of global variables in the generated code by applying storage classes directly to individual data elements. With Embedded Coder and an ERT-based system target file, you can have more precise control over the way that data appear in the generated code.

To achieve C code patterns such as grouping variables into flat structures and to control declaration and definition file placement, you can use the storage classes, available with Embedded Coder, from the built-in package `Simulink`.

For information about applying storage classes to categories of data by default, by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 32-8.

### Built-In Storage Classes

For a list of built-in storage classes that you can choose, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-87.

### Create Your Own Storage Class

If the storage classes from the `Simulink` package do not satisfy your requirements, you can define your own storage classes. For information about defining your own storage class, see “Create Code Definitions to Override Default Settings” on page 30-2.

### Techniques to Apply Storage Classes Interactively

To directly apply a storage class from the built-in package `Simulink` interactively, use the techniques described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99.

To apply a storage class from a package other than `Simulink` (such as a package that you create):

- To apply the storage class to a signal, state, or Data Store Memory block (without creating a data object), configure the data item to use storage classes from the target

package instead of the Simulink package. For example, if the name of the target package is `myPackage`, in a Signal Properties dialog box or the Property Inspector, set **Signal object class** to `myPackage.Signal`. If the target class does not appear in the list, see “Target Class Does Not Appear in List of Signal Object Classes” on page 37-20.

If you use the Model Data Editor, to identify the target package, you must use a different technique. See “Apply Storage Class from Specific Package to Signal, State, or Data Store Memory Block Using the Model Data Editor” on page 37-20.

- To apply the storage class by using a data object (required for block parameters), instead of creating a `Simulink.Signal` or `Simulink.Parameter` object, create a `myPackage.Signal` or `myPackage.Parameter` object. To create data objects from your package, see “Create Data Objects from Another Data Class Package” (Simulink). For an example that shows how to create and apply your own storage class, see “Create and Apply a Storage Class” on page 37-26.

### **Target Class Does Not Appear in List of Signal Object Classes**

When you use the **Signal object class** drop-down list in a dialog box or in the Property Inspector, if the class that you want does not appear in the list:

- 1 From the list, select `Customize class lists`.
- 2 In the dialog box, under **Signal classes**, select the check box next to the class that you want. For example, to use storage classes from the built-in package `mpt`, select the check box next to `mpt.Signal`. Click **OK**.

If you created your own package, the classes that the package defines appear in the dialog box only if you put the package folder in your current folder or put the parent folder of the package folder on the MATLAB path.

- 3 From the drop-down list, select the option that corresponds to what you selected. For example, select `mpt.Signal`.

### **Apply Storage Class from Specific Package to Signal, State, or Data Store Memory Block Using the Model Data Editor**

When you use the Model Data Editor, to apply storage classes from a specific package, use the Model Explorer to create a signal object from the target package. Then, when you open the Model Data Editor, the **Storage class** column displays storage classes from the target package.

- 1 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- 2 In the toolbar, click the arrow next to the **Add Signal**  button.
- 3 In the drop-down list, select `Customize class lists`.
- 4 In the **Customize class lists** dialog box, select a signal class from the target package. Click **OK**.
- 5 In the Model Explorer toolbar, click the arrow next to the **Add Signal** button.
- 6 In the drop-down list, select the target signal class.

An object of the target signal class appears in the base workspace. Optionally, delete this unnecessary object.

- 7 Use the Model Data Editor to apply storage classes from the target package to other data items. In the Model Data Editor, in the **Storage class** column, the drop-down list allows you to select storage classes from the target package.

To learn how to use the Model Data Editor to configure a data interface, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder).

## Techniques to Apply Storage Classes Programmatically

To apply a storage class to an individual data item programmatically:

- 1 Create a signal or parameter data object from the target package. For example, create a `Simulink.Signal` object or a `myPackage.Parameter` object.

```
myParam = Simulink.Parameter(5.2);
```

- 2 In the nested `Simulink.CoderInfo` object, set the `StorageClass` property to `'Custom'`. Then, use the `CustomStorageClass` property to specify the storage class.

```
myParam.CoderInfo.StorageClass = 'Custom';
myParam.CoderInfo.CustomStorageClass = 'ExportToFile';
```

- 3 If the storage class allows you to specify additional settings such as **Header file** (see “Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)” on page 33-94), in the nested `Simulink.CoderInfo` object, use the `CustomAttributes` property to specify values for the additional settings.

```
myParam.CoderInfo.CustomAttributes.HeaderFile = 'myHeader.h';
```

- 4 Choose one of these techniques to apply the storage class to a data item in a model:
  - To apply the storage class directly to a signal, state, or Data Store Memory block, name the signal or state. Then, use the data object you created to set the `SignalObject` signal property, the `SignalObject` block parameter (for an Output block), or the `StateSignalObject` block parameter. Clear the data object you created. For an example, see “Apply Storage Class Directly to Signal Line Programmatically” on page 37-22.
  - To apply the storage class by keeping the data object you created (required for parameters), associate the data object with the data item in the model. To make this association, see “Use Data Objects in Simulink Models” (Simulink).

### Apply Storage Class Directly to Signal Line Programmatically

This example shows how to apply a storage class directly to a signal line in a model, without an external data object.

- 1 Open the example model `rtwdemo_secondOrderSystem`.

```
rtwdemo_secondOrderSystem
```

- 2 Create a handle to the output of the block named Force: `f(t)`.

```
portHandles = get_param('rtwdemo_secondOrderSystem/Force: f(t)', 'PortHandles');  
outputHandle = portHandles.Output;
```

- 3 Set the name of the corresponding signal to `ForceSignal`.

```
set_param(outputHandle, 'Name', 'ForceSignal');
```

- 4 In the base workspace, create a signal object and specify a storage class and relevant additional settings such as `HeaderFile`.

```
tempObj = Simulink.Signal;  
tempObj.CoderInfo.StorageClass = 'Custom';  
tempObj.CoderInfo.CustomStorageClass = 'ExportToFile';  
tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myHdrFile.h';
```

You can create the object from the data class package `Simulink`, or from any other package, such as a package that you create.

- 5 Embed the signal object in the target signal line by attaching a copy of the temporary workspace object.

```
set_param(outputHandle, 'SignalObject', tempObj);
```

- 6 Clear the object from the base workspace. The signal now uses an embedded copy of the object.

```
clear tempObj
```

### Modify Storage Class Applied Directly to Signal Line

To modify an existing embedded signal object, copy the object into the base workspace, modify the copy, and reattach the copy to the signal or state. For example, to change the storage class of the embedded signal object that you attached to the signal `ForceSignal` in “Apply Storage Class Directly to Signal Line Programmatically” on page 37-22:

- 1 Copy the existing embedded signal object into the base workspace.

```
tempObj = get_param(outportHandle, 'SignalObject');
```

- 2 Modify the properties of the object in the workspace.

```
tempObj.CoderInfo.CustomStorageClass='ImportFromFile';
tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myOtherHdrFile.h';
```

- 3 Reattach a copy of the signal object.

```
set_param(outportHandle, 'SignalObject', tempObj);
clear tempObj
```

### Organize Parameter Data into a Structure by Using the Struct Storage Class

This example shows how to use the `Struct` storage class to organize block parameter values into a structure in the generated code. You apply the storage class directly to individual data items in a model.

To create a custom structure of parameter data in the generated code, consider creating a corresponding structure in Simulink. See “Organize Data into Structures in Generated Code” on page 33-201.

- 1 Create the `ex_struct_param` model with three Constant blocks and three Output blocks.

- 2 On the **Modeling** tab, click **Model Data Editor**.
- 3 In the Model Data Editor, select the **Parameters** tab.
- 4 In the model, select the upper Constant block.
- 5 In the Model Data Editor, use the **Value** column to set the constant value to p1.
- 6 Next to p1, click the action button  and select **Create**.
- 7 In the Create New Data dialog box, set **Value** to `Simulink.Parameter(1.0)` and click **Create**.

A `Simulink.Parameter` object named p1 appears in the base workspace.

- 8 In the property dialog box for p1, click **OK**.
- 9 Use the Model Data Editor to set the other constant values by using parameter objects named p2 (value 2.0) and p3 (value 3.0).
- 10 In the Model Data Editor, set the **Change view** drop-down list to Code.
- 11 Click the **Show/refresh additional information** button.

The data table now contains rows that correspond to the new parameter objects.

- 12 Use the **Storage Class** column to apply the storage class `Struct` to all three parameter objects.
- 13 Use the **Struct Name** column to set the structure name to `my_struct`.
- 14 Press **Ctrl+B** to generate code.

The file `ex_struct_param.h` defines a structure type, `my_struct_type`.

```
/* Type definition for custom storage class: Struct */
typedef struct my_struct_tag {
    real_T p1;
    real_T p2;
```

```
    real_T p3;  
} my_struct_type;
```

The file `ex_struct_param.c` defines the global variable `my_struct`.

```
/* Definition for custom storage class: Struct */  
my_struct_type my_struct = {  
    /* p1 */  
    1.0,  
  
    /* p2 */  
    2.0,  
  
    /* p3 */  
    3.0  
};
```

## Storage Class Limitations

For information about limitations, see “Storage Class Limitations” on page 33-95.

## Create Storage Classes by Using the Custom Storage Class Designer

You can use built-in storage classes such as `ExportToFile` to control the appearance of data in the generated code (see “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19). If the built-in storage classes do not satisfy your requirements, you can create your own storage classes. As described in “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2, to create a storage class that you can apply to individual data elements (for example, in the Model Data Editor), you must create the storage class in a package by using the Custom Storage Class Designer.

To define a storage class that you can apply as the default storage class for a category of data elements, use the **Embedded Coder Dictionary**. See “Configure Default C Code Generation for Categories of Model Data and Functions” on page 32-7.

A package also defines `Signal` and `Parameter` data classes (see “Data Objects” (Simulink)). A data object from a package such as `Simulink` can use storage classes defined in that package but not storage classes that are defined in other packages.

For information about using the Custom Storage Class Designer to create memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 41-2.

### Create and Apply a Storage Class

This example shows how to control code generated from a model by creating and applying your own storage class.

#### Explore Example Model

Open the model `rtwdemo_cscpredef`. You can control code generated from this model by defining your own data classes and creating your own storage classes.

In this example, you export the declarations and definitions of multiple signals and parameters in the model to one declaration header file and one definition file.

## Create Data Class Package

To create storage classes, you first create a data class package to contain the storage class definitions. Data objects that you create from your package can use the storage classes that the package defines.

- 1 Create your own data class package by copying the example package folder +SimulinkDemos. Navigate to the example package folder.

```
% Remember the current folder path
currentPath = pwd;

% Navigate to the example package folder
demoPath = '\toolbox\simulink\simdemos\dataclasses';
cd([matlabroot,demoPath])
```

- 2 Copy the +SimulinkDemos folder to your clipboard.

- 3 Return to your working folder.

```
cd(currentPath)
```

- 4 Paste the +SimulinkDemos folder from your clipboard into your working folder. Rename the copied folder to +myPackage.

- 5 Navigate inside the +myPackage folder to the file Signal.m to edit the definition of the Signal class.

- 6 Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section appears as follows:

```
methods
    function setupCoderInfo(h)
        % Use custom storage classes from this package
        useLocalCustomStorageClasses(h, 'myPackage');
    end
end % methods
```

The function useLocalCustomStorageClasses allows you to apply the storage classes that myPackage defines to data objects that you create from myPackage.

- 7 Save and close the file.

- 8 Navigate inside the +myPackage folder to the file Parameter.m to edit the definition of the Parameter class. Uncomment the methods section that defines the method setupCoderInfo and replace 'packageName' with 'myPackage'.

- 9 Save and close the file.

### Create Storage Class

You can use the Custom Storage Class Designer to create or to edit the storage classes that a data class package defines.

- 1 Set your current folder to the folder that contains the package `myPackage`.
- 2 Open the Custom Storage Class Designer.  

```
cscdesigner('myPackage')
```
- 3 Select the storage class `ExportToFile`.
- 4 In the **Name** field, rename the storage class to `ExportToGlobal`.
- 5 In the **Header file** drop-down list, change the selection from `Instance specific` to `Specify`. In the new field, provide the header file name `global.h`.
- 6 In the **Definition file** drop-down list, change the selection from `Instance specific` to `Specify`. In the new field, provide the definition file name `global.c`.
- 7 Click **OK**. Click **Yes** to save changes to the data class package `myPackage`.

### Apply Storage Class

To apply your own storage class, you create data objects from your package and configure the objects to use your storage class.

- 1 Create data objects to represent some of the parameters and signals in the example model. Create the objects using the data class package `myPackage`.

```
% Parameters
templimit = myPackage.Parameter(202);
pressurelimit = myPackage.Parameter(45.2);
O2limit = myPackage.Parameter(0.96);
rpmlimit = myPackage.Parameter(7400);
```

```
% Signals
tempalarm = myPackage.Signal;
pressurealarm = myPackage.Signal;
O2alarm = myPackage.Signal;
rpmalarm = myPackage.Signal;
```

- 2 Set the storage class of each object to `ExportToGlobal`.

```
% Parameters
templimit.CoderInfo.StorageClass = 'Custom';
```

```

templimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurelimit.CoderInfo.StorageClass = 'Custom';
pressurelimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2limit.CoderInfo.StorageClass = 'Custom';
O2limit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmlimit.CoderInfo.StorageClass = 'Custom';
rpmlimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';

```

#### % Signals

```

tempalarm.CoderInfo.StorageClass = 'Custom';
tempalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurealarm.CoderInfo.StorageClass = 'Custom';
pressurealarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2alarm.CoderInfo.StorageClass = 'Custom';
O2alarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmalarm.CoderInfo.StorageClass = 'Custom';
rpmalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';

```

- 3 Select the **Signal name must resolve to Simulink signal object** option for each of the target signals in the model. You can select the option by using the Signal Properties dialog box, the **Resolve** column in the Model Data Editor, or by using the command prompt.

#### % Signal tempalarm

```

portHandles = get_param('rtwdemo_cscpredef/Rel0p1', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')

```

#### % Signal pressurealarm

```

portHandles = get_param('rtwdemo_cscpredef/Rel0p2', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')

```

#### % Signal O2alarm

```

portHandles = get_param('rtwdemo_cscpredef/Rel0p3', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')

```

#### % Signal rpmalarm

```

portHandles = get_param('rtwdemo_cscpredef/Rel0p4', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')

```

## Generate Code

- 1 Generate code for the example model.

```
rtwbuild('rtwdemo_cscpredef')
```

- 2 In the code generation report, view the generated header file `global.h`. The file contains the extern declarations of the model signals and parameters that use the storage class `ExportToGlobal`.

```
/* Declaration for custom storage class: ExportToGlobal */  
extern boolean_T O2alarm;  
extern real_T O2limit;  
extern boolean_T pressurealarm;  
extern real_T pressurelimit;  
extern boolean_T rpmalarm;  
extern real_T rpmlimit;  
extern boolean_T tempalarm;  
extern real_T templimit;
```

- 3 View the generated file `global.c`. The file contains the definitions of the model signals and parameters that use the storage class `ExportToGlobal`.

```
/* Definition for custom storage class: ExportToGlobal */  
boolean_T O2alarm;  
real_T O2limit = 0.96;  
boolean_T pressurealarm;  
real_T pressurelimit = 45.2;  
boolean_T rpmalarm;  
real_T rpmlimit = 7400.0;  
boolean_T tempalarm;  
real_T templimit = 202.0;
```

## Modify a Built-In Storage Class

You cannot directly modify a built-in storage class, such as `ExportToFile` from the Simulink package, but you can create a copy, and then modify the copy. When you create a new package with no `csc_registration.m` file, and then open the Custom Storage Class Designer for the first time in that package, Simulink copies the definitions of the built-in storage classes into the package. Then, in the Custom Storage Class Designer, you can modify the copied definitions. Alternatively, to keep the built-in storage classes available in your package, copy one of them by clicking **Copy**, then modify the resulting copy.

## Control Data Representation by Configuring Storage Class Properties

The Custom Storage Class Designer is a tool for creating and managing storage classes and memory sections. To open the Custom Storage Class Designer for a specific package, for example, `+mypkg`, at the command prompt, use the `cscdesigner` function:

```
cscdesigner('mypkg')
```

The name of the folder that represents a package begins with a `+`. When you use `cscdesigner`, omit the `+` from the name of the target package.

To control the effect that a storage class has on data in a model, you specify properties of the storage class in the Custom Storage Class Designer. To determine how to generate a particular kind of code, use the information in the table.

| Kind of Data in Generated Code                   | Technique                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Structure                                        | Set <b>Type</b> to <code>FlatStructure</code> . See “Generate Structured Data” on page 37-33.                                                                                                                                                                                                                                                                                            |
| Macro                                            | Set <b>Data initialization</b> to <code>Macro</code> and clear <b>For signals</b> . See “Generate a Macro” on page 37-32.                                                                                                                                                                                                                                                                |
| Pointer                                          | Set <b>Data access</b> to <code>Pointer</code> and <b>Data scope</b> to <code>Auto</code> , <code>Imported</code> , or <code>Instance specific</code> . Your external code must define the pointer variable.                                                                                                                                                                             |
| <code>static</code> data (file-scoped data)      | Set <b>Data scope</b> to <code>File</code> .                                                                                                                                                                                                                                                                                                                                             |
| <code>const</code> or <code>volatile</code> data | Set <b>Memory section</b> to a memory section that specifies <code>const</code> , <code>volatile</code> , or both. For example, use one of the built-in memory sections <code>MemConst</code> , <code>MemVolatile</code> , and <code>MemConstVolatile</code> . To create your own memory section, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 41-2. |

| Kind of Data in Generated Code                        | Technique                                                                                                 |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Calls to external functions to read and write to data | See “Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables” on page 37-34. |

### Allow Users of Storage Class to Specify Property Value

For some properties of a storage class, such as **Data scope**, instead of specifying a value in the Custom Storage Class Designer, you can allow users of the storage class to specify the value. You can create a single, flexible storage class instead of multiple storage classes that vary only by a few property values.

For example, suppose you create a storage class that yields a global variable in the generated code. You can configure the storage class so that a user can set the **Data scope** property to **Exported** for a signal in a model and set the property to **Imported** for a different signal.

In the Custom Storage Class Designer, for each property that you want to configure in this way, set the property value to **Instance specific**. Then, when a user applies the storage class to a data item, the property appears to the user as a custom attribute for that data item. For information about instance-specific custom attributes, see “Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)” on page 33-94.

### Generate a Macro

To create a storage class that yields a macro in the generate code, set **Data initialization** to **Macro** and clear **For signals**.

When you set **Data initialization** to **Macro**, **Definition file** has no meaning. To prevent users of the storage class from specifying a meaningless definition file, in the Custom Storage Class Designer, set **Definition file** to **Specify** and leave the text box empty.

- To define the macro in a header file (**#define**), specify the name of the header file with the **Header file** property.
- To provide the macro definition as a compiler option or compiler flag, set **Data access** to **Imported** and **Header file** to **Specify**. Leave the **Header file** text box empty. Then, the generated code does not define the macro and does not include (**#include**) a header file.

To specify the compiler option or flag, use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Additional**

**build information > Defines.** See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

### Generate Structured Data

To create a storage class that aggregates data items into a flat structure (similar to the built-in storage class `Struct`), set **Type** to `FlatStructure`. The **Structure Attributes** tab appears.

- To control the name of the global structure variable that appears in the generated code, use the **Struct name** property and text box.
- If you set **Struct name** to `Instance specific`, users of the storage class specify the name of the structure variable. In this case, the code generator derives the name of the structure type from the name of the variable.

To more precisely control the name and other characteristics of the structure type, set **Struct name** to `Specify`. Control the type characteristics by using the additional properties that appear.

- To generate a structure with bit fields (similar to the built-in storage class `BitField`), select **Bit-pack booleans**. Data items that use the data type `boolean` appear in the generated code as bit fields of the structure.

### Control Assignment of Initial Value in Generated Code

- To use the default Simulink Coder initialization strategy, set **Data initialization** to the default value, `Auto`.
  - The generated code statically initializes parameter data with an assignment statement at the top of a `.c` or `.cpp` source file, outside of any function.
  - The generated code dynamically initializes signal and state data as part of the initialization function of the model (named `model_initialize` by default).
- To statically initialize the data, set **Data initialization** to `Static`.
- To dynamically initialize the data, set **Data initialization** to `Dynamic`.
- To prevent the generated code from initializing the data, set **Data initialization** to `None`. When your external code initializes the data, use this setting to prevent the generated code from overwriting your initialization.

### Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables

Using the built-in storage class `GetSet`, you can generate code that calls your external, custom functions instead of directly interacting with variables. For general information about `GetSet`, see “Access Data Through Functions with Storage Class `GetSet`” on page 37-42.

To create a similar storage class, set **Type** to `AccessFunction`.

- Specify the names of the external functions.
  - To apply the same `get` or `set` function naming scheme to data items that use the storage class, set **Get function** and **Set function** to `Specify`. Then, in the text boxes, specify the function naming scheme, for example, `get_myData_$N`. Use the token `$N` in a naming scheme to represent the name of each data item. If you do not use the token, each data item uses the same specified `get` or `set` function name, so the model generates an error when you generate code.
  - To specify a different `get` or `set` function name for each data item, set **Get function** or **Set function** to `Instance specific`. Later, when you create a data item and apply the storage class, specify the function name by configuring the custom attributes of the data item.
- Specify the name of the header file that declares the `get` and `set` functions with the **Header file** property. In this case, **Definition file** has no meaning. To prevent users of the storage class from specifying a meaningless definition file, set **Definition file** to `Specify` and leave the text box empty.
- If you implement the `get` mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data. On the **Access Function Attributes** tab, select **Get data through macro (omit parentheses)**.

### Generate Code That Uses Data From External Code

When your external code defines data, to avoid generating a duplicate definition, you must configure the generated code to read and write to the existing data. In the Custom Storage Class Designer, set **Data scope** to `Imported`. The code generator does not generate a definition for the global variable or macro.

- If your code defines a pointer variable, to generate code that interacts with the pointer, set **Data access** to `Pointer`.

- If you generate structured data by setting **Type** to `FlatStructure`, your code must define the structure type and the global structure variable.
- If your code initializes state or signal data, you can prevent the generated code from overwriting your initialization by setting **Data initialization** to `None`. See “Prevent Duplicate Initialization Code for Global Variables” on page 53-108

### **Generate Code Comments with Data Definitions and Declarations**

To customize the comments that appear in the generated code, on the **Comments** tab, set **Comment rules** to `Specify`. To specify a comment that appears with the declaration of each data item, use the **Declaration comment** box. To specify a comment that appears with the definition, use the **Definition comment** box.

For structured data (you set **Type** to `FlatStructure`), to specify a comment that appears with the structure type definition, use the **Type comment** box.

### **Avoid Errors During Code Generation by Validating Storage Class Configuration**

As you configure a storage class in the Custom Storage Class Designer, to check for possible errors in the configuration, click **Validate**.

For example, validating the storage class warns you if you accidentally set **Data initialization** to `Macro` with **For signals** selected. A signal cannot appear in the generated code as a macro.

### **Make Storage Classes Available Outside the Current Folder**

To use a storage class that you create, you must make the defining package available. Either set your current folder to the folder that contains the package or add the folder containing the package folder to the MATLAB path (see “What Is the MATLAB Search Path?” (MATLAB)). Adding the package to the MATLAB path enables you to use the storage classes no matter where you set your current folder.

### **Share Storage Class Between Packages**

When you create a package, you can refer to a storage class defined in another package such as the built-in package `Simulink` or a different package that you created. Then, the defining package and any referencing packages can use the storage class. When you want

to make a change to the storage class, you make the change only once, in the defining package.

To configure a package to refer to a storage class that another package defines:

- 1 In the Custom Storage Class Designer, select the **Custom Storage Class** tab.
- 2 Use **Select Package** to select the referencing package. The package must be writable.
- 3 In the **Custom storage class definitions** pane, select the existing definition below which you want to insert the reference.
- 4 Click **New Reference**.

A new reference with a default name and properties appears below the previously selected definition. The new reference is selected and a **Reference** tab appears that shows the initial properties.

- 5 Use **Name** to specify a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package. The name cannot be a TLC keyword.
- 6 Set **Refer to custom storage class in package** to specify the package that contains the storage class that you want to reference.
- 7 Set **Custom storage class to reference** to specify the storage class to be referenced.
- 8 Click **OK** or **Apply**. To save the changes permanently, click **Save**.

## Control Appearance of Storage Class Drop-Down List

When you apply a storage class to a data item, you select the storage class from a drop-down list.

- To control the order of the custom storage classes in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of the storage classes in drop-down lists matches the order that you specify in the Custom Storage Class Designer.
- To prevent a user of a storage class from applying the storage class to parameter data or to signal and state data, use the **For parameters** and **For signals** check boxes. When you clear one of these properties, for the corresponding kind of data, the storage class does not appear in the drop-down list.

For example, if your storage class yields a macro in the generated code because you set **Data initialization** to `Macro`, to prevent users from applying the storage class to signal data, clear **For signals**.

## Protect Custom Storage Class Definitions

When you click **Save** in the Custom Storage Class Designer, the Designer saves memory section and storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of **Filename**.

You can prevent changes to the storage class definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep both `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you need to modify the storage classes by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, when both files exist in the package, the storage classes are protected and cannot be modified in the Custom Storage Class Designer.

## Further Customize Generated Code by Writing TLC Code

If creating your own storage class by manipulating the properties in the Custom Storage Class Designer does not satisfy your requirements, you can finely control the generated code by writing TLC code for your storage class. Use an advanced mode of the Custom Storage Class Designer and, for the storage class, set **Type** to `Other`. See “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 37-39.

- “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 37-39
- “Access Structured Data Through a Pointer That External Code Defines” on page 37-12

## Finely Control Data Representation by Writing TLC Code for a Storage Class

If creating your own storage class by using the properties in an Embedded Coder Dictionary or the Custom Storage Class Designer does not meet your requirements for controlling data representation in the generated code, you can write TLC code that explicitly controls the effect that a storage class has on the code. For example, to create a storage class that yields arbitrarily nested structures, you must write TLC code. In the Custom Storage Class Designer, these advanced storage classes have **Type** set to **Other**. You cannot create such a storage class in an Embedded Coder Dictionary, so you cannot use the storage class as a default code generation setting in the Code Mapping Editor.

For an example, see “Generate Code That Dereferences Data from a Literal Memory Address” on page 63-21. For general information about TLC code, see “Why Use the Target Language Compiler?” (Simulink Coder).

### Create Custom Attributes Class for Storage Class

As described in “Allow Users of Storage Class to Specify Property Value” on page 37-32, instance-specific properties enable users of a storage class to control the effect that the storage class has on each data item. For example, the built-in storage class `ExportToFile` has several instance-specific properties such as **Header file** and **Definition file**.

When you create a storage class with **Type** set to **Other**, to add your own instance-specific properties that are not built into the Custom Storage Class Designer, create a custom attributes class for your package. A custom attributes class is a MATLAB class that you create as a subclass of `Simulink.CustomStorageClassAttributes`. Each property that you add to your custom attributes class appears to the user of the storage class as an instance-specific property.

To create your custom attributes class, see “Define Data Classes” (Simulink).

### Write TLC Code for Storage Class

To control the effect of your storage class, write TLC code that specifies the code to generate for each data item.

- 1 In your package folder (for example, `+myPackage`), create a `tlc` folder.

- 2 Copy a TLC template such as `TEMPLATE_v1.tlc` from the folder `matlabroot/toolbox/rtw/targets/ecoder/csc_templates` (open) into your `tlc` folder.
- 3 Write your TLC code, following the comments in the template file. The comments describe how to specify, for example, how the generated code declares, defines, and accesses (by value or by reference) each data item.

## Create Storage Class by Using Custom Storage Class Designer

To create your storage class in your package, you open the Custom Storage Class Designer in an advanced mode.

- 1 At the command prompt, enter:  

```
cscdesigner -advanced
```
- 2 Select your package and create a storage class.
- 3 For the storage class, set **Type** to **Other**. In the **Other Attributes** pane, specify the name of your TLC file and the name of your custom attributes class.
- 4 Set the properties on the **Other Attributes** pane.
  - **Is grouped:** Select this option if you intend to combine multiple data items into a single entity in the generated code. For example, the built-in storage classes `BitField` and `Struct` are grouped because they can aggregate multiple data items into a single structure variable.
  - **TLC file name:** Enter the name of your TLC file. The Custom Storage Class Designer assumes that the file exists in the package `tlc` folder, so specify only the name of the file, not the file path.
  - **CSC attributes class name:** (optional) If you created a custom attributes class, enter the full name of the class, including the package name. For example, specify `myPackage.myCustomAttsClass`. For more information, see “Create Custom Attributes Class for Storage Class” on page 37-39.
- 5 On the **General** and **Comments** panes, specify values for the remaining properties.

## Access Data Through Functions with Storage Class GetSet

To integrate the generated code with legacy code that uses specialized functions to read from and write to data, you can use the storage class `GetSet`. Signals, block parameters, and states that use `GetSet` appear in the generated code as calls to accessor functions. You provide the function definitions.

You can also create your own storage class in Embedded Coder Dictionary to access data through functions. Creating your own storage class in Embedded Coder Dictionary gives you the flexibility of customizing function names and return types. For more information, see “Access Data Through Functions by Using Storage Classes in Embedded Coder Dictionary” on page 37-63.

To generate code that conforms to the AUTOSAR standard by accessing data through `Rte` function calls, use the AUTOSAR code perspective. See “AUTOSAR Component Configuration” (AUTOSAR Blockset).

### Access Legacy Data Using Get and Set Functions

This example shows how to generate code that interfaces with legacy code by using specialized `get` and `set` functions to access data.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h', /* ComponentData */,'} ComponentData;',1,1)

/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `scalars` is a substructure that uses the structure type `ScalarData`. The structure type `ScalarData` defines three scalar fields: `inSig`, `scalarParam`, and `outSig`.

```
rtwdemodbtype('ComponentDataHdr.h', /* ScalarData */,'} ScalarData;',1,1)
```

```
/* ScalarData */
typedef struct {
    double inSig;
    double scalarParam;
    double outSig;
} ScalarData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `scalars`.

```
rtwdemodbtype('getsetSrc.c', /* Field "scalars" */,'/* End of "scalars" */',1,1)
```

```
/* Field "scalars" */
{
    3.9,

    12.3,

    0.0
},
/* End of "scalars" */
```

The file also defines functions that read from and write to the fields of the substructure `scalars`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`.

```
rtwdemodbtype('getsetSrc.c',...
    /* Scalar get() and set() functions */,'/* End of scalar functions */',1,1)
```

```
/* Scalar get() and set() functions */
double get_inSig(void)
{
    return ex_getset_data.scalars.inSig;
}
void set_inSig(double value)
{
```

```

    ex_getset_data.scalars.inSig = value;
}

double get_scalarParam(void)
{
    return ex_getset_data.scalars.scalarParam;
}

void set_scalarParam(double value)
{
    ex_getset_data.scalars.scalarParam = value;
}

double get_outSig(void)
{
    return ex_getset_data.scalars.outSig;
}

void set_outSig(double value)
{
    ex_getset_data.scalars.outSig = value;
}

```

View the example legacy header file `getsetHdrScalar.h`. The file contains the extern prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_scalar`. The model creates the data objects `inSig`, `outSig`, and `scalarParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_scalar')
```

Copyright 2015 The Mathworks, Inc.

In the base workspace, double-click the object `inSig` to view its properties. The object uses the storage class `GetSet`. The `GetFunction` and `SetFunction` properties are set

to the defaults, `get_$N` and `set_$N`. The generated code uses the function names that you specify in `GetFunction` and `SetFunction` to read from and write to the data. The code replaces the token `$N` with the name of the data object. For example, for the data object `inSig`, the generated code uses calls to the legacy functions `get_inSig` and `set_inSig`.

For the data object `inSig`, the `HeaderFile` property is set to `getsetHdrScalar.h`. This legacy header file contains the `get` and `set` function prototypes. The data objects `outSig` and `scalarParam` also use the storage class `GetSet` and the header file `getsetHdrScalar.h`.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, under **Additional build information**, select **Source files**. The **Source files** box identifies the source file `getsetSrc.c` for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_scalar');

### Starting build procedure for model: rtwdemo_getset_scalar
### Successful completion of build procedure for model: rtwdemo_getset_scalar
```

In the code generation report, view the file `rtwdemo_getset_scalar.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm. The generated code accesses the legacy signal and parameter data by calling the custom, handwritten `get` and `set` functions.

```
rtwdemodbtype(fullfile('rtwdemo_getset_scalar_ert_rtw','rtwdemo_getset_scalar.c'),...
    /* Model step function */,'}',1,1)

/* Model step function */
void rtwdemo_getset_scalar_step(void)
{
    /* Gain: '<Root>/Gain' incorporates:
     * Inport: '<Root>/In1'
     */
    set_outSig(get_scalarParam() * get_inSig());
}
```

You can generate code that calls your custom `get` and `set` functions as long as the functions that you write accept and return the expected values. For scalar data, the functions must have these characteristics:

- The `get` function must return a single scalar numeric value of the appropriate data type, and must not accept any arguments (`void`).
- The `set` function must not return anything (`void`), and must accept a single scalar numeric value of the appropriate data type.

## Use GetSet with Vector Data

This example shows how to apply the storage class `GetSet` to signals and parameters that are vectors.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h', '/* ComponentData */', '} ComponentData;', 1, 1)

/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `vectors` is a substructure that uses the structure type `VectorData`. The structure type `VectorData` defines three vector fields: `inVector`, `vectorParam`, and `outVector`. The vectors each have five elements.

```
rtwdemodbtype('ComponentDataHdr.h', '/* VectorData */', '} VectorData;', 1, 1)

/* VectorData */

typedef struct {
    double inVector[5];
    double vectorParam[5];
    double outVector[5];
} VectorData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure vectors.

```
rtwdemodbtype('getsetSrc.c', /* Field "vectors" */, /* End of "vectors" */, 1, 1)

/* Field "vectors" */
{
    {5.7, 6.8, 1.2, 3.5, 10.1},
    {12.3, 18.7, 21.2, 28, 32.9},
    {0.0, 0.0, 0.0, 0.0, 0.0}
},
/* End of "vectors" */
```

The file also defines functions that read from and write to the fields of the substructure vectors. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`. To access the vector data, the functions accept an integer index argument. The `get` function returns the vector value at the input index. The `set` function assigns the input value to the input index.

```
rtwdemodbtype('getsetSrc.c', ...
    /* Vector get() and set() functions */, /* End of vector functions */, 1, 1)

/* Vector get() and set() functions */

double get_inVector(int index)
{
    return ex_getset_data.vectors.inVector[index];
}

void set_inVector(int index, double value)
{
    ex_getset_data.vectors.inVector[index] = value;
}

double get_vectorParam(int index)
{
    return ex_getset_data.vectors.vectorParam[index];
}

void set_vectorParam(int index, double value)
```

```

{
    ex_getset_data.vectors.vectorParam[index] = value;
}

double get_outVector(int index)
{
    return ex_getset_data.vectors.outVector[index];
}

void set_outVector(int index, double value)
{
    ex_getset_data.vectors.outVector[index] = value;
}

```

View the example legacy header file `getsetHdrVector.h`. The file contains the extern prototypes for the get and set functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_vector`. The model creates the data objects `inVector`, `outVector`, and `vectorParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_vector')
```

Copyright 2015 The Mathworks, Inc.

In the base workspace, double-click the object `inVector` to view its properties. The object uses the storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrVector.h`. This legacy header file contains the get and set function prototypes.

In the Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the get and set function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_vector');

### Starting build procedure for model: rtwdemo_getset_vector
### Successful completion of build procedure for model: rtwdemo_getset_vector
```

In the code generation report, view the file `rtwdemo_getset_vector.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_vector_ert_rtw', 'rtwdemo_getset_vector.c'), ...
    /* Model step function */,'}',1,1)

/* Model step function */
void rtwdemo_getset_vector_step(void)
{
    int32_T i;

    /* Gain: '<Root>/Gain' incorporates:
     * Inport: '<Root>/In1'
     */
    for (i = 0; i < 5; i++) {
        set_outVector(i, get_vectorParam(i) * get_inVector(i));
    }
}
```

When you use the storage class `GetSet` with vector data, the `get` and `set` functions that you provide must accept an index input. The `get` function must return a single element of the vector. The `set` function must write to a single element of the vector.

## Use GetSet with Structured Data

This example shows how to apply the storage class `GetSet` to nonvirtual bus signals and structure parameters in a model.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h', ...
    /* ComponentData */,'}' ComponentData;',1,1)

/* ComponentData */
typedef struct {
    ScalarData scalars;
```

```
    VectorData vectors;  
    StructData structs;  
    MatricesData matrices;  
} ComponentData;
```

The field `structs` is a substructure that uses the structure type `StructData`. The structure type `StructData` defines three fields: `inStruct`, `structParam`, and `outStruct`.

```
rtwdemodbtype('ComponentDataHdr.h', '/* StructData */', '}' StructData;', 1, 1)  
  
/* StructData */  
  
typedef struct {  
    SigBus inStruct;  
    ParamBus structParam;  
    SigBus outStruct;  
} StructData;
```

The fields `inStruct`, `structParam`, and `outStruct` are also substructures that use the structure types `SigBus` and `ParamBus`. Each of these two structure types define three scalar fields.

```
rtwdemodbtype('ComponentDataHdr.h', '/* SigBus */', '}' ParamBus', 1, 1)  
  
/* SigBus */  
  
typedef struct {  
    double cmd;  
    double sensor1;  
    double sensor2;  
} SigBus;  
  
/* ParamBus */  
  
typedef struct {  
    double offset;  
    double gain1;  
    double gain2;  
} ParamBus;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `structs`.

```
rtwdemodbtype('getsetSrc.c',...
  /* Field "structs" */,'/* End of "structs" */',1,1)

  /* Field "structs" */
  {
    {1.3, 5.7, 9.2},
    {12.3, 9.6, 1.76},
    {0.0, 0.0, 0.0}
  },
  /* End of "structs" */
```

The file also defines functions that read from and write to the fields of the substructure `structs`. The functions simplify data access by dereferencing the fields of the global structure variable `ex_getset_data`. The functions access the data in the fields `inStruct`, `structParam`, and `outStruct` by accepting and returning complete structures of the types `SigBus` and `ParamBus`.

```
rtwdemodbtype('getsetSrc.c',...
  /* Structure get() and set() functions */',...
  /* End of structure functions */',1,1)

/* Structure get() and set() functions */

SigBus get_inStruct(void)
{
  return ex_getset_data.structs.inStruct;
}

void set_inStruct(SigBus value)
{
  ex_getset_data.structs.inStruct = value;
}

ParamBus get_structParam(void)
{
  return ex_getset_data.structs.structParam;
}
```

```
void set_structParam(ParamBus value)
{
    ex_getset_data.structs.structParam = value;
}

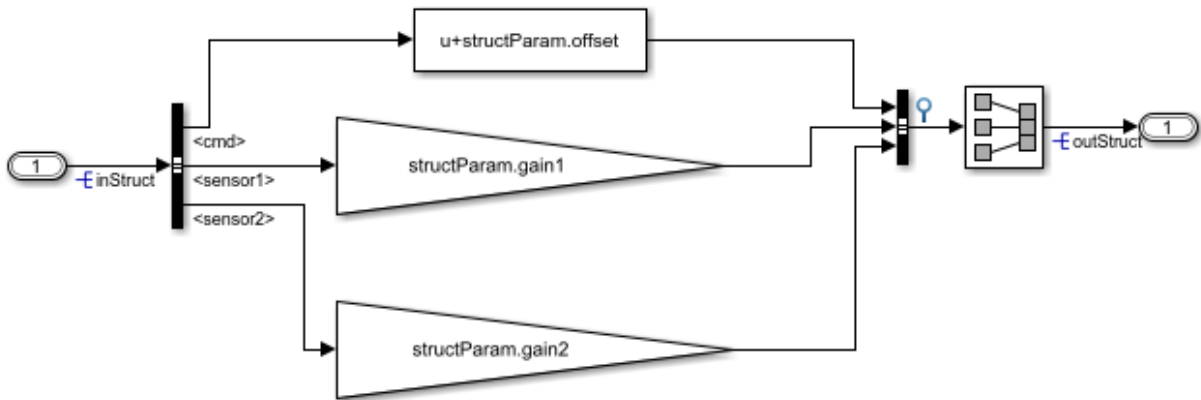

SigBus get_outStruct(void)
{
    return ex_getset_data.structs.outStruct;
}

void set_outStruct(SigBus value)
{
    ex_getset_data.structs.outStruct = value;
}
```

View the example legacy header file `getsetHdrStruct.h`. The file contains the extern prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_struct`. The model creates the data objects `inStruct`, `structParam`, and `outStruct` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_struct')
```

Copyright 2015 The Mathworks, Inc.

In the base workspace, double-click the object `inStruct` to view its properties. The object uses the storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrStruct.h`. This legacy header file contains the `get` and `set` function prototypes.

The model also creates the bus objects `ParamBus` and `SigBus` in the base workspace. The signals and parameter in the model use the bus types that these objects define. The property `DataScope` of each bus object is set to `Imported`. The property `HeaderFile` is set to `ComponentDataHdr.h`. The generated code imports these structure types from the legacy header file `ComponentDataHdr.h`.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_struct');
```

```
### Starting build procedure for model: rtwdemo_getset_struct
### Successful completion of build procedure for model: rtwdemo_getset_struct
```

In the code generation report, view the file `rtwdemo_getset_struct.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_struct_ert_rtw',...
    'rtwdemo_getset_struct.c'),...
    /* Model step function */,'}',1,1)

/* Model step function */
void rtwdemo_getset_struct_step(void)
{
    /* Bias: '<Root>/Bias' incorporates:
     * Inport: '<Root>/In1'
     */
    rtDW.BusCreator.cmd = (get_inStruct()).cmd + (get_structParam()).offset;

    /* Gain: '<Root>/Gain' incorporates:
     * Inport: '<Root>/In1'
     */
    rtDW.BusCreator.sensor1 = (get_structParam()).gain1 * (get_inStruct()).sensor1;

    /* Gain: '<Root>/Gain1' incorporates:
     * Inport: '<Root>/In1'
     */
    rtDW.BusCreator.sensor2 = (get_structParam()).gain2 * (get_inStruct()).sensor2;

    /* SignalConversion: '<Root>/Signal Conversion' */
    set_outStruct(rtDW.BusCreator);
}
```

When you use the storage class `GetSet` with structured data, the `get` and `set` functions that you provide must return and accept complete structures. The generated code dereferences individual fields of the structure that the `get` function returns.

The output signal of the Bus Creator block is a test point. This signal is the input for a Signal Conversion block. The test point and the Signal Conversion block exist so that the generated code defines a variable for the output of the Bus Creator block. To provide a complete structure argument for the function `set_outStruct`, you must configure the model to create this variable.

## Use GetSet with Matrix Data

This example shows how to apply the storage class `GetSet` to signals and parameters that are matrices.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h',...
    /* ComponentData */,'} ComponentData;',1,1)

/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `matrices` is a substructure that uses the structure type `MatricesData`. The structure type `MatricesData` defines three fields: `matrixInput`, `matrixParam`, and `matrixOutput`. The fields store matrix data as serial arrays. In this case, the input and parameter fields each have 15 elements. The output field has nine elements.

```
rtwdemodbtype('ComponentDataHdr.h'...
    /* MatricesData */,'} MatricesData;',1,1)

/* MatricesData */

typedef struct {
    double matrixInput[15];
    double matrixParam[15];
    double matrixOutput[9];
} MatricesData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `matrices`.

```
rtwdemodbtype('getsetSrc.c',...
    /* Field "matrices" */,'/* End of "matrices" */',1,1)

/* Field "matrices" */
{
    {12.0, 13.9, 7.4,
     0.5, 11.8, 6.4,
```

```
        4.7, 5.3, 13.0,  
        0.7, 16.1, 13.5,  
        1.6, 0.5, 3.1},  
  
        {8.3, 12.0, 11.5, 2.0, 5.7,  
        7.5, 12.8, 11.1, 8.4, 9.9,  
        10.9, 4.6, 2.7, 16.3, 3.8},  
  
        {0.0, 0.0, 0.0,  
        0.0, 0.0, 0.0,  
        0.0, 0.0, 0.0}  
    }  
    /* End of "matrices" */
```

The input matrix has five rows and three columns. The matrix parameter has three rows and five columns. The matrix output has three rows and three columns. The file defines macros that indicate these dimensions.

```
rtwdemodbtype('getsetSrc.c',...  
    /* Matrix dimensions */,'/* End of matrix dimensions */',1,1)
```

```
/* Matrix dimensions */
```

```
#define MATRIXINPUT_NROWS 5  
#define MATRIXINPUT_NCOLS 3
```

```
#define MATRIXPARAM_NROWS 3  
#define MATRIXPARAM_NCOLS 5
```

```
#define MATRIXOUTPUT_NROWS MATRIXPARAM_NROWS  
#define MATRIXOUTPUT_NCOLS MATRIXINPUT_NCOLS
```

The file also defines functions that read from and write to the fields of the substructure matrices.

```
rtwdemodbtype('getsetSrc.c',...  
    /* Matrix get() and set() functions */,'/* End of matrix functions */',1,1)
```

```
/* Matrix get() and set() functions */
```

```
double get_matrixInput(int colIndex)  
{
```

```

    int rowIndexGetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colIndex;
    return ex_getset_data.matrices.matrixInput[rowIndexGetInput];
}

void set_matrixInput(int colIndex, double value)
{
    int rowIndexSetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colIndex;
    ex_getset_data.matrices.matrixInput[rowIndexSetInput] = value;
}

double get_matrixParam(int colIndex)
{
    int rowIndexGetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colIndex;
    return ex_getset_data.matrices.matrixParam[rowIndexGetParam];
}

void set_matrixParam(int colIndex, double value)
{
    int rowIndexSetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colIndex;
    ex_getset_data.matrices.matrixParam[rowIndexSetParam] = value;
}

double get_matrixOutput(int colIndex)
{
    int rowIndexGetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colIndex;
    return ex_getset_data.matrices.matrixOutput[rowIndexGetOut];
}

void set_matrixOutput(int colIndex, double value)
{
    int rowIndexSetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colIndex;
    ex_getset_data.matrices.matrixOutput[rowIndexSetOut] = value;
}

```

The code that you generate from a model represents matrices as serial arrays. Therefore, each of the `get` and `set` functions accept a single scalar index argument.

The generated code uses column-major format to store and to access matrix data. However, many C applications use row-major indexing. To integrate the generated code with the example legacy code, which stores the matrices `matrixInput` and `matrixParam` using row-major format, the custom `get` functions use the column-major index input to calculate an equivalent row-major index. The generated code algorithm, which interprets matrix data using column-major format by default, performs the correct

matrix math because the `get` functions effectively convert the legacy matrices to column-major format. The `set` function for the output, `matrixOutput`, also calculates a row-major index so the code writes the algorithm output to `matrixOutput` using row-major format. Alternatively, to integrate the column-major generated code with your row-major legacy code, you can manually convert the legacy code to column-major format by transposing your matrix data and algorithms.

View the example legacy header file `getsetHdrMatrix.h`. The file contains the extern prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_matrix`. The model creates the data objects `matrixInput`, `matrixParam`, and `matrixOutput` in the base workspace. The objects correspond to the signals and parameter in the model.

```
load_system('rtwdemo_getset_matrix')
set_param('rtwdemo_getset_matrix','SimulationCommand','Update')
open_system('rtwdemo_getset_matrix')
```

Copyright 2015 The Mathworks, Inc.

In the base workspace, double-click the object `matrixInput` to view its properties. The object uses the storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrMatrix.h`. This legacy header file contains the `get` and `set` function prototypes.

In the Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_matrix');

### Starting build procedure for model: rtwdemo_getset_matrix
### Successful completion of build procedure for model: rtwdemo_getset_matrix
```

In the code generation report, view the file `rtwdemo_getset_matrix.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_matrix_ert_rtw',...
    'rtwdemo_getset_matrix.c'), '/* Model step function */', '}', 1, 1)

/* Model step function */
void rtwdemo_getset_matrix_step(void)
{
    int32_T i;
    int32_T i_0;
    int32_T i_1;
    int32_T matrixOutput_tmp;

    /* Product: '<Root>/Product' incorporates:
     * Constant: '<Root>/Constant'
     * Inport: '<Root>/In1'
     */
    for (i_0 = 0; i_0 < 3; i_0++) {
        for (i = 0; i < 3; i++) {
            matrixOutput_tmp = i + 3 * i_0;
            set_matrixOutput(matrixOutput_tmp, 0.0);
            for (i_1 = 0; i_1 < 5; i_1++) {
                set_matrixOutput(matrixOutput_tmp, get_matrixParam(3 * i_1 + i) *
                    get_matrixInput(5 * i_0 + i_1) + get_matrixOutput
                    (matrixOutput_tmp));
            }
        }
    }
}
```

## Specify Header File or Function Naming Scheme for Data Items

By default, you specify a header file name, `get` function name, and `set` function name for each data item, such as a signal or parameter, that uses the storage class `GetSet`.

To configure a single header file, `get` function naming scheme, or `set` function naming scheme to use for every data item, you can use the Custom Storage Class Designer to create your own copy of `GetSet`. You can specify the header file or function names in a single location.

Follow these steps to create your own storage class by creating your own data class package, creating a copy of GetSet, and applying the new storage class to data items in your model.

- 1 Create your own data class package, `myPackage`, by copying the example package folder `+SimulinkDemos` and renaming the copied folder as `+myPackage`. Modify the `Parameter` and `Signal` class definitions so that they use the storage class definitions from `myPackage`. For an example, see “Create Data Class Package” on page 37-27.
- 2 Set your current folder to the folder that contains the package folder. Alternatively, add the folder containing the package folder to your MATLAB path.
- 3 Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

- 4 Select the storage class `GetSet`. Click **Copy** to create a copy called `GetSet_1`.
- 5 Select the new storage class `GetSet_1`. In the **General** tab, set **Name** to `myGetSet`.
- 6 Set the drop-down list **Header file** to `Specify`. In the new text box, set **Header file** to `myFcnHdr.h`. Click **Apply**.
- 7 On the **Access Function Attributes** tab, set the drop-down lists **Get function** and **Set function** to `Specify`.
- 8 In the new boxes, set **Get function** to `myGetFcn_$$N` and **Set function** to `mySetFcn_$$N`. Click **OK**. Click **Yes** in response to the message about saving changes.

When you generate code, the token `$$N` expands into the name of the data item that uses this storage class.

- 9 Apply the storage class `myGetSet` from your package to a data item. For example, create a `myPackage.Parameter` object in the base workspace.

```
myParam = myPackage.Parameter(15.23);  
myParam.CoderInfo.StorageClass = 'Custom';  
myParam.CoderInfo.CustomStorageClass = 'myGetSet';
```

- 10 Use the object to set a parameter value in your model. When you generate code, the code algorithm accesses the parameter through the functions that you specified. The code uses an `#include` directive to include the header file that you specified.

## Access Scalar and Array Data Through Macro Instead of Function Call

If you implement the `get` mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data.

- For scalar data, your macro must yield the scalar value.
- For array data, your macro must yield the starting memory address.

Create your own `AccessFunction` storage class by using the Custom Storage Class Designer, as described in “Specify Header File or Function Naming Scheme for Data Items” on page 37-59. In the Designer, on the **Access Function Attributes** tab, select **Get data through macro (omit parentheses)**.

## GetSet Storage Class Restrictions

- `GetSet` does not support complex signals.
- Multiple data in the same model cannot use the same `GetFunction` or `SetFunction`.
- Some blocks do not directly support `GetSet`.
- Custom S-functions do not directly support `GetSet`.

To use `GetSet` with an unsupported block or a custom S-function:

- 1 Insert a Signal Conversion block at the output of the block or function.
- 2 In the Signal Conversion block dialog box, select **Exclude this block from 'Block reduction' optimization**.
- 3 Assign the storage class `GetSet` to the output of the Signal Conversion block.

## Access Data Through Functions by Using Storage Classes in Embedded Coder Dictionary

To replace the direct access to data in the generated code with your own or legacy functions that read and write data in a customized way, you can enable function access on your storage classes. You create these storage classes in the Embedded Coder Dictionary. Root-level inports, root-level outports, and model parameters that use your storage class appear in the generated code as calls to specified functions. You provide the function declarations and definitions in separate header and source files pointed to by the storage class.

### Access Legacy Data by Value

You can define and apply a storage class to root-level inports, root-level outports, and model parameters so they can be accessed by customizable `get` and `set` functions. Such customization can be useful, for example, to abstract layers of software, gain access to data from an external file or to control access to critical sections of code.

This example shows how to set up a storage class in the Embedded Coder Dictionary and map the storage class to root-level inports/outports and model parameters in the Code Mappings editor.

- 1 Open example model `rtwdemo_roll`. In the MATLAB command window, run this command:

```
addpath(fullfile(docroot,'toolbox','ecoder','examples'))
```

Running the preceding command gives you these supporting files required for the example that define the `get` and `set` functions:

- `rtwdemo_roll_Value.h`
- `rtwdemo_roll_Value.c`
- `rtwdemo_roll_Pointer.h`
- `rtwdemo_roll_Pointer.c`

Save these files to your local path.

- 2 In the Apps gallery, click **Embedded Coder**.
- 3 Open the Embedded Coder Dictionary.
- 4 The `rtwdemo_roll` model has two storage classes: `SignalStruct` and `ParamStruct`. They are already created by using the **Add** button. This example uses

these storage classes. You can perform the following steps for a storage class that you create as well.

- For the `SignalStruct` storage class, in the **Property Inspector** pane, update these property values:

- **Data Access** to `Function`
- **Header File** to `$R_Value.h`

Make sure that **Access Mode** is set to `Value`. **Data Scope** is set to `Imported` by default and cannot be changed.

The screenshot shows the Embedded Coder software interface. The Dictionary pane on the left displays a table of storage classes. The Property Inspector pane on the right shows the configuration for the `SignalStruct` storage class.

| Name                  | Data Access | Data Scope          | Header File         | Storage Type   | Data Initializ... | Memory Section   | Source           |

| Struct                | Direct      | Exported            | ---                 | FlatStructure  | Auto              | None             | Simulink package |
| GetSet                | Direct      | Imported            | <Instance specific> | AccessFunction | Auto              | ---              | Simulink package |
| CompilerFlag          | Direct      | Imported            | ---                 | Unstructured   | Macro             | ---              | Simulink package |
| Reusable              | Direct      | <Instance specific> | <Instance specific> | Unstructured   | Dynamic           | None             | Simulink package |
| SignalStruct          | Function    | Imported            | SR_Value.h          | Structured     | Dynamic           | ---              | rtwdemo_rol      |
| ParamStruct           | Function    | Imported            | SR_Value.h          | Structured     | Static            | ---              | rtwdemo_rol      |

The Property Inspector pane for `SignalStruct` shows the following configuration:

- Name: `SignalStruct`
- Description: A multi-instance storage class for signals. This is an example storage class. Please modify this storage class or a copy of it to suit your application needs.
- Source: `rtwdemo_rol`
- Data Access: `Function`
- File Placement: (empty)
- Data Scope: `Imported`
- Header File: `SR_Value.h`
- Access Function: (empty)
- Access Mode: `Value`
- Allowed Access: `Read/Write`
- Name of Getter: `get_SNSM`
- Name of Setter: `set_SNSM`
- Storage: (empty)
- Use different property settings for single-instance and multi-instance data:
- Storage Type: `Structured`
- Structure Properties: (empty)
- Data Initialization: `Dynamic`
- Qualifiers: (empty)
- Allowed Usage:  Parameters,  Signals

The Pseudocode Preview pane shows the following code:

```

PSEUDOCODE PREVIEW
For single-instance data | For multi-instance data
Type definition
typedef struct {
    ...
    FIELDTYPE FIELDNAME;
    ...
} rtwdemo_rol_Signals_T;
Declaration: imported from file: "rtwdemo_rol_Value.h"
extern rtwdemo_rol_Signals_T rtwdemo_rol_Signals;
Get Function
DATATYPE get_DATATYPE();
Set Function
void set_DATATYPE(const DATATYPE DATATYPE);

```

For the `ParamStruct` storage class, in the **Property Inspector** pane, update these property values:

- **Data Access** to Function
- **Header File** to \$R\_Value.h

These properties are already set:

- **Access Mode** to Value
- **Data Initialization** to Static

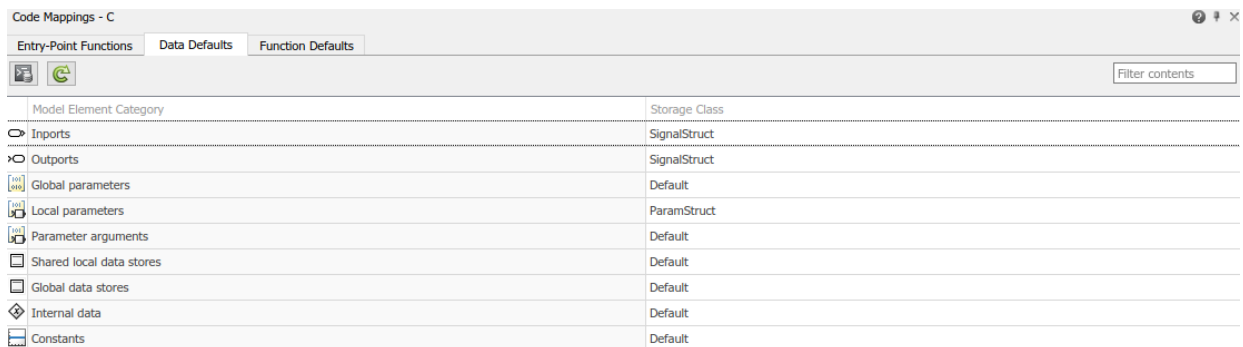

Storage classes used for parameters can have only **Data Initialization** set to **Static**.

- 6 Open the Configuration Parameters dialog box. Select **Code Generation > Custom Code > Additional build information > Source files** and specify:

rtwdemo\_roll\_Value.c

- 7 In the Code perspective, open the **Code Mappings > Data Defaults** tab. Map these model element categories:

- **Inports** to SignalStruct
- **Outports** to SignalStruct
- **Model parameters** to ParamStruct

| Model Element Category   | Storage Class |
|--------------------------|---------------|
| Inports                  | SignalStruct  |
| Outports                 | SignalStruct  |
| Global parameters        | Default       |
| Local parameters         | ParamStruct   |
| Parameter arguments      | Default       |
| Shared local data stores | Default       |
| Global data stores       | Default       |
| Internal data            | Default       |
| Constants                | Default       |

- 8 Build the model and generate code.

In the generated code, view the file `rtwdemo_roll.c`. The model `step` function uses the specified `get` and `set` functions to execute the algorithm. The generated code accesses the legacy data by calling the custom, handwritten `get` and `set` functions. For example, here is the code snippet for the `HDG_Ref` inport:

```
if (get_HDG_Mode()) {
    /* Outputs for Atomic SubSystem: '<Root>/HeadingMode' */
```

```

    rtb_Sum1 = (get_HDG_Ref() - get_Psi()) * 0.015F * get_TAS();

    /* End of Outputs for SubSystem: '<Root>/HeadingMode' */
} else {
    /* Outputs for Atomic SubSystem: '<Root>/RollAngleReference' */
    if ((real32_T)fabs(get_Turn_Knob()) >= 3.0F) {
        rtb_Sum1 = get_Turn_Knob();
    }
}

```

You can generate code that calls your custom `get` and `set` functions if the functions that you write accept and return the expected values.

## Access Legacy Data by Pointer

To access data using a pointer, follow all the preceding steps but make these changes:

- In the Embedded Coder Dictionary, for storage classes `SignalStruct` and `ParamStruct`, specify:
  - **Access Mode** to `Pointer`
  - **Header File** to `$R_Pointer.h`
- Select **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** and replace `rtwdemo_roll_Value.c` with:

```
rtwdemo_roll_Pointer.c
```

With the pointer access, a `get` function now returns a pointer whose value must be dereferenced with the `*` before use. For example, the generated code for the `HDG_Ref` inport now looks like this code:

```

if (*get_HDG_Mode()) {
    /* Outputs for Atomic SubSystem: '<Root>/HeadingMode' */
    rtb_Sum1 = (*get_HDG_Ref() - *get_Psi()) * 0.015F * *get_TAS();

    /* End of Outputs for SubSystem: '<Root>/HeadingMode' */
} else {
    /* Outputs for Atomic SubSystem: '<Root>/RollAngleReference' */
    if ((real32_T)fabs(tmp_1) >= 3.0F) {
        rtb_Sum1 = tmp_1;
    }
}

```

Creating your own storage class in Embedded Coder Dictionary gives you the flexibility of customizing function names and return types. You can also use the storage class `GetSet`

to access data through `get` and `set` functions. For more information, see “Access Data Through Functions with Storage Class `GetSet`” on page 37-42.

## Integrate External Application Code with Code Generated from PID Controller

This example shows how to generate C code from a control algorithm model and integrate that code with existing, external application code. In the complete application, which consists of three modules, the algorithm module must exchange data with other modules through global variables. In the example, you configure the generated code to interact with existing external variables, resemble the external code in appearance and organization, and conform to specific coding requirements.

### Inspect External Code

Set your current folder to a writable location.

Copy the script `prepare_ext_code` to your current folder and run the script. The script copies external code files into several folders.

```
try
copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_ext_code.m'), ...
    'prepare_ext_code.m', 'f');
catch
end
run('prepare_ext_code.m');
```

In your current folder, open `ext_code_main.c`. This application code represents an embedded system with a trivial scheduling algorithm (a while loop) and three modules whose algorithms run in every execution cycle: `ex_ext_inputs_proc`, `ex_ext_ctrl_alg`, and `ex_ext_outputs_proc`.

```
type('ext_code_main.c')
```

In the `shared` folder, inspect `ex_ext_projTypes.h`. The file defines two custom data types (typedef) that the data in the modules use.

```
type(fullfile('shared', 'ex_ext_projTypes.h'))
```

In the `io_drivers` folder, inspect `ex_sensor_accessors.c`. This file defines functions, `get_fromSensor_flow` and `get_fromSensor_temp`, that return raw data recorded by a flow sensor and a temperature sensor. For this example, the functions return trivial sinusoidal stimuli for the control algorithm.

```
type(fullfile('io_drivers', 'ex_sensor_accessors.c'))
```

In the `ex_ext_inputs_proc` folder, inspect `ex_ext_inputs_proc.c`. The `ex_ext_inputs_proc` module reads the sensor data (by calling the accessor functions), filters the data, and stores it in two global variables, `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. These global variables are defined in the file `ex_ext_proc_inputs.c` and declared in `ex_ext_proc_inputs.h`.

```
type(fullfile('ex_ext_inputs_proc', 'ex_ext_inputs_proc.c'))
```

The filter algorithm in this module and the algorithms in the other two modules require state data, which must persist between execution cycles of the application. Each module stores relevant state data as global variables. For example, in the `ex_ext_inputs_proc` module, `ex_ext_inputs_proc.c` defines these variables:

- `flowFilterIn_state_data`
- `tempFilterIn_state_data`
- `flowFilterIn_tmp_data`
- `tempFilterIn_tmp_data`

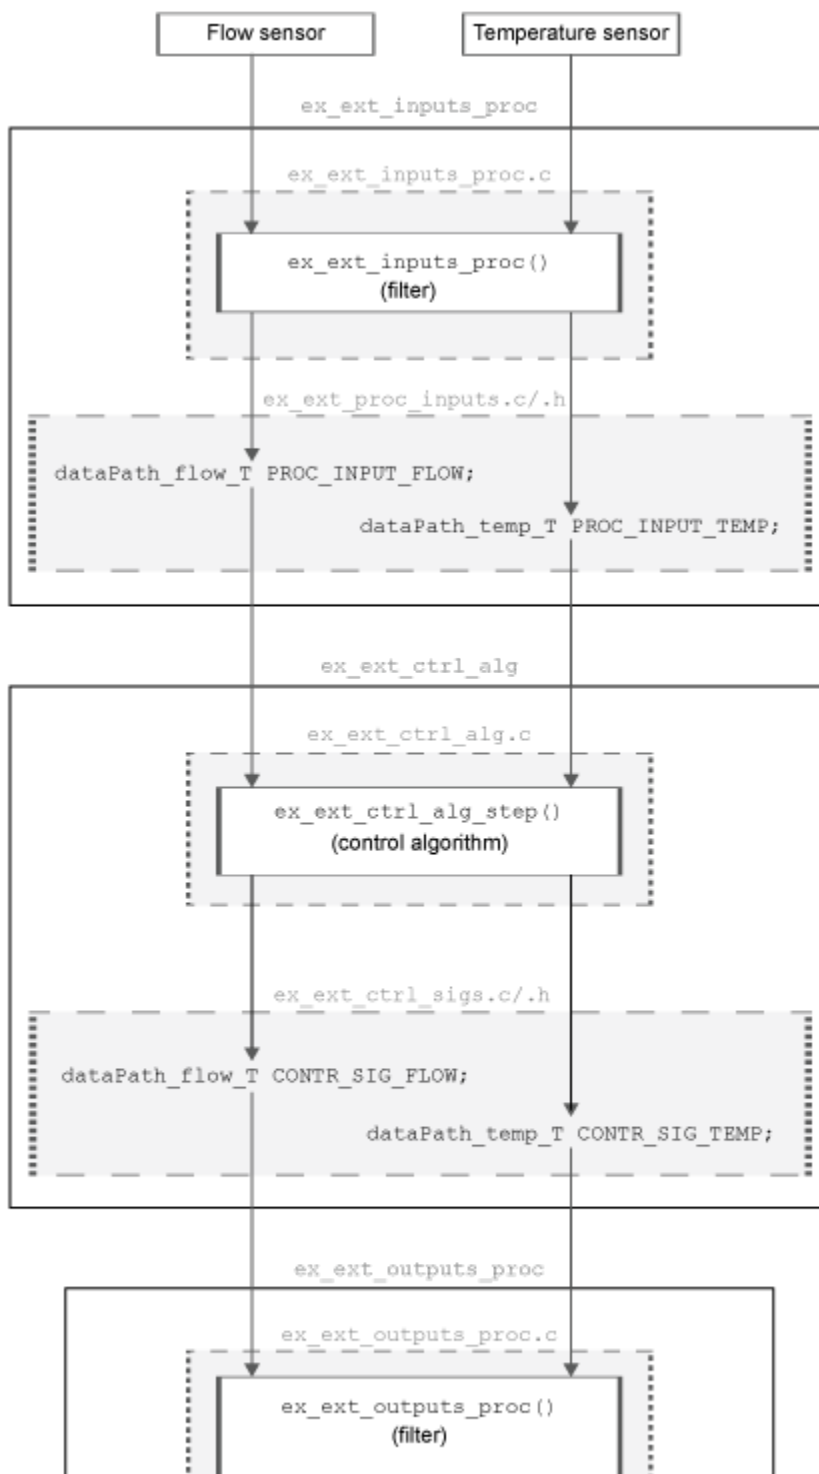

The empty `ex_ext_ctrl_alg` folder is a placeholder for the generated code. The `ex_ext_ctrl_alg` module must perform PID control on the filtered flow and temperature measurements. Later, you examine the requirements for this code, which are based on the code in the other modules.

In the `ex_ext_outputs_proc` folder, inspect `ex_ext_outputs_proc.c`. This module reads the PID output signals from global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The `ex_ext_ctrl_alg` module (the generated code) must define these variables. The `ex_ext_outputs_proc` module then filters these signals and passes the filtered values to functions that represent device drivers for actuators (for example, a valve and a heater filament).

```
type(fullfile('ex_ext_outputs_proc', 'ex_ext_outputs_proc.c'))
```

The actuator functions are defined in the `io_drivers` folder in the file `ex_actuator_accessors.c`.

The figure shows the intended flow of data through the system. The figure also shows the code files that define and declare the data (global variables) that cross the module boundaries.

## Inspect Simulink Model and Determine Requirements for Generated Code

Open the example model `ex_ext_ctrl_alg`.

```
open_system('ex_ext_ctrl_alg')
```

The blocks in the model implement the required PID control algorithm. The model uses default code generation settings for an ERT-based system target file (`ert.tlc`).

To complete the application by performing the function of the `ex_ext_ctrl_alg` module, the code generated from this model must:

- Use the custom data types `dataPath_flow_T` and `dataPath_temp_T` from the external file `ex_ext_projTypes.h`.
- Read filtered sensor data from the global variables `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. The generated code must not define these variables because the module `ex_ext_inputs_proc` defines them, declaring them in `ex_ext_proc_inputs.h`.
- Write PID control signals to global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The generated code must define these variables and declare them in a file named `ex_ext_ctrl_sigs.h`. Then, the `ex_ext_outputs_proc` module can read the raw control signals from them.
- Conform to variable naming standards that govern the external application. For example, the generated code must store state data in global variables whose names end in `_data`. In addition, for this example, the names of local function variables must end in `_local`.
- Conform to standards that govern the organization of the code in each of the external files. For example, each file contains sections, delimited by comments, that aggregate similar code constructs such as type definitions, variable declarations, and function definitions.

So that you and others can interact with the control algorithm during execution, for this example, you also configure the generated code to define and declare `const` global variables named `PARAM_setpoint_flow` and `PARAM_setpoint_temp`, which represent the PID controller setpoints. The definitions must appear in a file named `ex_ext_ctrl_params.c` and the declarations must appear in a file named `ex_ext_ctrl_params.h`.

## Configure Model to Use Custom Data Types

Set your current folder to the shared folder.

Use the function `Simulink.importExternalCTypes` to generate `Simulink.AliasType` objects that represent the custom data types `dataPath_flow_T` and `dataPath_temp_T`.

```
cd('shared')
Simulink.importExternalCTypes('ex_ext_projTypes.h');
```

The objects appear in the base workspace.

In the `ex_ext_ctrl_alg` model, on the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, for the Inport block that represents `PROC_INPUT_FLOW`, set **Data Type** to `dataPath_flow_T`.

For the Inport block that represents `PROC_INPUT_TEMP`, set **Data Type** to `dataPath_temp_T`.

Select the **Signals** tab.

In the model, select the output signal of each Constant block. In the Model Data Editor, set **Data Type** to **Inherit: Inherit via back propagation**. With this setting, each Constant block inherits its output data type from the block immediately downstream, in this case, a Sum block.

Alternatively, to configure the data types, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg/In1', 'OutDataTypeStr', 'dataPath_flow_T')
set_param('ex_ext_ctrl_alg/In2', 'OutDataTypeStr', 'dataPath_temp_T')
set_param('ex_ext_ctrl_alg/Flow Setpt', 'OutDataTypeStr', ...
    'Inherit: Inherit via back propagation')
set_param('ex_ext_ctrl_alg/Temp Setpt', 'OutDataTypeStr', ...
    'Inherit: Inherit via back propagation')
```

Update the block diagram. The diagram shows that, due to data type inheritance and propagation, signals in the model use a custom data type.

### **Configure Interface Data**

Configure the model to generate code that accesses and defines the correct global variables such as `PROC_INPUT_FLOW` and `CONTR_SIG_TEMP`.

In the Model Data Editor, select the **Inports/Outputs** tab and set the **Change view** drop-down list to **Code**.

Select the rows that correspond to the two Inport blocks.

For either row, set **Storage Class** to `ImportFromFile` and **Header File** to `ex_ext_proc_inputs.h`. With the storage class `ImportFromFile`, each Inport block appears in the generated code as a global variable. However, the generated code does not define the variable, instead including (`#include`) the variable declaration from `ex_ext_proc_inputs.h`.

For the rows that correspond to the Outport blocks, set:

- **Storage Class** to `ExportToFile`
- **Header file** to `ex_ext_ctrl_sigs.h`
- **Definition File** to `ex_ext_ctrl_sigs.c`

With `ExportToFile`, the generated code defines the global variable.

Alternatively, to configure the signals, at the command prompt, use these commands.

```
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ImportFromFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_proc_inputs.h';

portHandles = get_param('ex_ext_ctrl_alg/In1', 'portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'SignalObject', copy(temp))

portHandles = get_param('ex_ext_ctrl_alg/In2', 'portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'SignalObject', copy(temp))

temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_sigs.h';
temp.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_sigs.c';

set_param('ex_ext_ctrl_alg/Out1', 'SignalObject', copy(temp))
set_param('ex_ext_ctrl_alg/Out2', 'SignalObject', copy(temp))
```

To apply a storage class to a block parameter, such as the **Constant value** parameter of a Constant block, you must create a parameter object such as `Simulink.Parameter`. You can use the Model Data Editor to create parameter objects.

Select the **Parameters** tab and set **Change view** to `Design`.

In the model, select the Constant block labeled Flow Setpt.

In the Model Data Editor, set **Value** to PARAM\_setpoint\_flow.

Next to PARAM\_setpoint\_flow, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to Simulink.Parameter(3).

Set **Location** to Model Workspace and click **Create**.

In the PARAM\_setpoint\_flow property dialog box, set **Storage class** to Const.

Set **HeaderFile** to ex\_ext\_ctrl\_params.h and **DefinitionFile** to ex\_ext\_ctrl\_params.c.

For the other Constant block, use the Model Data Editor to create a Simulink.Parameter object named PARAM\_setpoint\_temp with value 2.

Alternatively, to configure the blocks, at the command prompt, use these commands.

```
PARAM_setpoint_flow = Simulink.Parameter(3);  
PARAM_setpoint_flow.CoderInfo.StorageClass = 'Custom';  
PARAM_setpoint_flow.CoderInfo.CustomStorageClass = 'Const';  
PARAM_setpoint_flow.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_params.h';  
PARAM_setpoint_flow.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_params.c';
```

```
PARAM_setpoint_temp = copy(PARAM_setpoint_flow);  
PARAM_setpoint_temp.Value = 2;
```

```
mdlwks = get_param('ex_ext_ctrl_alg', 'ModelWorkspace');  
assignin(mdlwks, 'PARAM_setpoint_flow', copy(PARAM_setpoint_flow))  
assignin(mdlwks, 'PARAM_setpoint_temp', copy(PARAM_setpoint_temp))
```

```
set_param('ex_ext_ctrl_alg/Flow Setpt', 'Value', 'PARAM_setpoint_flow')  
set_param('ex_ext_ctrl_alg/Temp Setpt', 'Value', 'PARAM_setpoint_temp')
```

```
clear temp PARAM_setpoint_flow PARAM_setpoint_temp mdlwks portHandles outportHandle
```

### Configure Internal Data

In the external code, internal data that does not participate in the module interfaces, such as state data and local variables in functions, conform to naming schemes. In the model,

configure internal data that appears in the generated code to mimic these naming schemes.

In the model Configuration Parameters dialog box, inspect the **Code Generation > Identifiers** pane. When you specify values for the naming schemes under **Identifier format control**:

- $\$R$  represents the name of the model, `ex_ext_ctrl_alg`.
- $\$N$  represents the name of each model element to which the scheme applies, such as a signal, block state, or standard data structure.
- $\$M$  represents name-mangling text that the code generator inserts, if necessary, to avoid name clashes. For most naming rules, this token is required.

Set **Global variables** to  $\$R\$N\_data\$M$ . This setting controls the names of global variables, such as those that represent state data. The naming scheme  $\$R\$N\_data\_\$M$  most closely approximates the scheme that the state variables in the external code use.

Set **Local temporary variables** and **Local block output variables** to  $\$N\_local\$M$ .

Alternatively, to set the configuration parameters, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg','CustomSymbolStrGlobalVar','$R$N_data$M')
set_param('ex_ext_ctrl_alg','CustomSymbolStrTmpVar','$N_local$M')
set_param('ex_ext_ctrl_alg','CustomSymbolStrBlkIO','$N_local$M')
```

Configure the state data in the model to appear in the generated code as separate global variables instead of fields of the standard DWork structure. Enable the Code perspective. In the Apps gallery, click **Embedded Coder**.

Underneath the block diagram, under **Code Mappings > Data Defaults**, for the **Internal data** row, in the **Storage Class** column select `ExportedGlobal`.

Alternatively, to configure this default storage class, use these commands at the command prompt:

```
coder.mapping.create('ex_ext_ctrl_alg');
coder.mapping.defaults.set('ex_ext_ctrl_alg','InternalData',...
    'StorageClass','ExportedGlobal');
```

### Configure Organization of Code in Each Generated File

Set your current folder to the `ex_ext_ctrl_alg` folder.

```
cd(fullfile('.', 'ex_ext_ctrl_alg'))
```

At the command prompt, navigate to the folder that contains the built-in code generation template `ert_code_template.cgt`. By default, when you generate code with the system target file `ert.tlc`, this template governs the organization and, in part, the appearance of the code in each generated file.

```
currentFolder = pwd;  
cd(fullfile(matlabroot, 'toolbox', 'rtw', 'targets', 'ecoder'))
```

Copy the `ert_code_template.cgt` file to your clipboard.

Return to the `ex_ext_ctrl_alg` folder. To avoid overwriting your clipboard, instead of using the command prompt to navigate to the folder, you can use the **Back** button in MATLAB.

```
cd(currentFolder)  
clear currentFolder
```

Paste the file into the `ex_ext_ctrl_alg` folder. Rename the file as `ex_my_code_template.cgt`.

Open the file and replace the contents with this code.

```
type(fullfile(matlabroot, 'examples', 'ecoder', 'ex_my_code_template.cgt'))
```

This new template conforms more closely to the organization of the external files. For example, the template organizes similar code constructs into named sections (delimited by comments) and, at the top of the template, specifies only minimal information about each generated file.

In the model, select **Configuration Parameters > Code Generation > Templates**.

Under **Code templates** and **Data templates**, set the four configuration parameters to `ex_my_code_template.cgt`.

Alternatively, to copy the file and set the parameters, at the command prompt, use these commands.

```
copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'ex_my_code_template.cgt'), ...  
         'ex_my_code_template.cgt', 'f')  
set_param('ex_ext_ctrl_alg', 'ERTSrcFileBannerTemplate', 'ex_my_code_template.cgt')  
set_param('ex_ext_ctrl_alg', 'ERTHdrFileBannerTemplate', 'ex_my_code_template.cgt')
```

```
set_param('ex_ext_ctrl_alg', 'ERTDataSrcFileTemplate', 'ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg', 'ERTDataHdrFileTemplate', 'ex_my_code_template.cgt')
```

### Generate and Inspect Code

Because the external code already defines a `main` function, select **Configuration Parameters > Generate code only** and clear **Configuration Parameters > Generate an example main program**.

```
set_param('ex_ext_ctrl_alg', 'GenCodeOnly', 'on')
set_param('ex_ext_ctrl_alg', 'GenerateSampleERTMain', 'off')
```

Generate code from the model.

```
rtwbuild('ex_ext_ctrl_alg')
```

In the code generation report, inspect the generated files. The code meets the requirements. For example, `ex_ext_ctrl_sigs.c` defines the control output signals, `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw', 'ex_ext_ctrl_sigs.c');
rtwdemodbtype(file, 'dataPath_flow_T CONTR_SIG_FLOW;', ...
    'dataPath_temp_T CONTR_SIG_TEMP;', 1, 1)
```

The setpoint parameters appear in `ex_ext_ctrl_params.c`.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw', 'ex_ext_ctrl_params.c');
rtwdemodbtype(file, 'const dataPath_flow_T PARAM_setpoint_flow = 3.0;', ...
    'const dataPath_temp_T PARAM_setpoint_temp = 2.0;', 1, 1)
```

The file `ex_ext_ctrl_alg.c` defines global variables to store state data. The variables follow the naming scheme that you specified. Code is similar to the following:

```
dataPath_temp_T ex_ext__Integrator_DSTATE_datag;
dataPath_flow_T ex_ext_c_Integrator_DSTATE_data;
dataPath_temp_T ex_ext_ctrl_Filter_DSTATE_datad;
dataPath_flow_T ex_ext_ctrl__Filter_DSTATE_data;
```

In the same file, the model execution function, `ex_ext_ctrl_alg_step`, creates local function variables to store temporary calculations. The variables follow the naming scheme that you specified. Code is similar to the following:

```
dataPath_flow_T Diff_local;
dataPath_flow_T FilterCoefficient_local;
```

```
dataPath_temp_T Diff1_local;  
dataPath_temp_T FilterCoefficient_locali;
```

Some of the global and local variable names contain extra mangling characters that prevent name clashes. These extra characters correspond to the  $\$M$  token that you specified in the naming schemes.

The generated code files are in the generated folders `ex_ext_ctrl_alg_ert_rtw` and `s1prj`. You must configure file management systems and build tools to use these folders and files.

## Configure Generated Code According to Interface Control Document Interactively

This example shows how to configure code generation settings for a model according to specifications in an interface control document (ICD). Store necessary Simulink variables and objects, such as `Simulink.Parameter` objects, in a data dictionary.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

### Explore Interface Control Document

Navigate to the folder `matlabroot/examples/ecoder` (open). Copy this file to a writable, working folder:

- `ex_ICD_PCG_inter.xls`

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG_inter.xls` workbook and view the first worksheet, `Signals`. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The `Owner` column indicates the name of the component that allocates memory for each signal. The `DataType` column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus:EngSensors` to indicate a structure type named `EngSensors`.

In the `Parameters` worksheet, the `Value` column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the `Numeric Types` worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The `IsAlias` column indicates whether the C code uses the name of the data type (for example, `s16En3`) or uses the name of the primitive integer data type that corresponds to the word length (such as `short`). The `DataScope` column indicates whether the generated code exports or imports the definition of the type.

In the **Structure Types** worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the **Data Type** column is `struct`. Subsequent rows that do not use `struct` represent fields of the preceding structure type. This ICD defines a structure type, `EngSensors`, with four fields: `throttle`, `speed`, `ego`, and `map`.

In the **Enumerated Types** worksheet, similar to the **Structure Types** worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type `sldemo_FuelModes`.

### **Write External Code**

Some data items in the ICD belong to `other_component`, which is a component that exists outside of MATLAB. Create the code files that define and declare this external data.

Create the header file `ex_inter_types.h` in your current folder. This file defines the structure type `EngSensors` and numeric data types such as `u8En7`.

```
#ifndef INTER_TYPES_H__
#define INTER_TYPES_H__

typedef short s16En3;

typedef short s16En7;

typedef unsigned char u8En7;

typedef short s16En15;

/* Structure type for instrument measurements. */
typedef struct {
    /* Throttle angle. */
    s16En3 throttle;

    /* Engine speed. */
    s16En3 speed;

    /* EGO sensors. */
    s16En7 ego;

    /* Manifold pressure. */
    u8En7 map;
} EngSensors;
```

```
#endif
```

Create the source file `ex_inter_sigs.c` in your current folder. This file defines the imported signal sensors.

```
#include "ex_inter_sigs.h"
```

```
EngSensors sensors;          /* Instrument measurements. */
```

Create the header file `ex_inter_sigs.h` in your current folder.

```
#include "ex_inter_types.h"
```

```
extern EngSensors sensors; /* Instrument measurements. */
```

### Explore Example Model

Run the script `prepare_sldemo_fuelsys_dd_inter`. For this example, the script prepares a system model, `sldemo_fuelsys_dd`.

```
run(fullfile(matlabroot,'examples','ecoder','main','prepare_sldemo_fuelsys_dd_inter'))
```

Open the system model `sldemo_fuelsys_dd`.

```
sldemo_fuelsys_dd
```

This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model `sldemo_fuelsys_dd_controller`.

```
sldemo_fuelsys_dd_controller
```

Some of the signals in the controller model have names, for example, the input signal `sensors`. Some block parameters in the model refer to Simulink.Parameter objects in a data dictionary. For example, in the `airflow_calc` subsystem, the `Pumping Constant` block uses the parameter objects `PumpCon`, `SpeedVect`, and `PressVect`. These parameter objects set the values of the corresponding block parameters. You can apply code generation settings to the signals and parameter objects.

The controller model is linked to a data dictionary, `sldemo_fuelsys_dd_controller.sldd`. In the lower-left corner of the model, click

the model data badge, then click the **Data Dictionary** link. In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

The dictionary already stores:

- The parameter objects
- `Simulink.NumericType` objects such as `u8En7`
- A `Simulink.Bus` object, `EngSensors`
- The definition of an enumerated data type, `sldemo_FuelModes`

### **Configure Model According to ICD**

Navigate to the root level of the controller model then, on the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, activate the **Change scope** button. The Model Data Editor now shows information about data items in the subsystems.

Click the **Show/refresh additional information** button. The Model Data Editor now shows information about data objects (the `Simulink.Parameter` objects in the data dictionary) that the model uses.

Select the **Inports/Outports** tab (which is selected by default).

In the model, select the Inport block labeled sensors. The Model Data Editor highlights the corresponding row.

In the ICD, select the **Signals** tab.

Use the Model Data Editor to configure the signal according to the information in the ICD:

- Set the value in the **Data Type** column to `Bus: EngSensors`. In this case, the value is already set.
- Set the **Change view** drop-down list to `Code` and, for sensors, set **Storage Class** to `ImportFromFile`. Use this storage class because the **Owner** column in the ICD implies that a different component, not `sldemo_fuelsys_dd_controller`, provides the C-code definition of the sensors variable. With this storage class, the generated code does not define the variable.
- Set **Header File** to `ex_inter_sigs.h`. When you use a storage class that represents imported data, such as `ImportFromFile`, you cannot specify **Definition File** in the

Model Data Editor. Instead, include the definition file (in this case, `ex_inter_sigs.c`) in the code generation and build process by using model configuration parameter **Source files**.

In the model, select the Outport block labeled `fuel_rate`.

Use the Model Data Editor to configure `fuel_rate` according to the ICD. To access design properties such as minimum value (**Min**) and physical unit (**Unit**), set **Change view** to **Design**. For code generation settings, because the ICD specifies `sldemo_fuelsys_dd_controller` as the owner of the other signals, set **Storage Class** to `ExportToFile`.

Inspect the **Signals** tab.

Set **Change view** to **Code** and configure code generation settings for the signal `fuel_mode`.

You cannot use the Model Data Editor to configure design properties for `fuel_mode` (such as data type) because `fuel_mode` is an output of a Stateflow chart. In the model, navigate into the chart.

On the **Modeling** tab, click **Model Explorer**.

In the Model Explorer **Contents** pane (the middle pane), select the `fuel_mode` data item.

In the Dialog pane (the right pane), configure `fuel_mode` according to the ICD. In this case, the signal data type is already set, so you can specify only the description.

Navigate to the root level of the model.

In the ICD and the Model Data Editor, select the **Parameters** tab. In the Model Data Editor, set **Change view** to **Design**.

In the Model Data Editor, use the **Filter contents** box to search for the first parameter, `PressEst`. The Model Data Editor shows two rows: One row that corresponds to the parameter object `PressEst` and one row that corresponds to the block parameter that uses `PressEst`.

Use the Model Data Editor to configure `PressEst` according to the ICD. The parameter value (the **Value** column) is already set. Because the ICD specifies `sldemo_fuelsys_dd_controller` as the owner of `PressEst`, set **Storage Class** to `ExportToFile`.

Use the Model Data Editor to configure the other parameters. Optionally, to apply a change to multiple parameters at once, select multiple rows in the data table.

In the lower-left corner of the model, click the model data badge, then click the **Data Dictionary** link to open the data dictionary in the Model Explorer.

In the **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane (the middle pane), select the `Simulink.NumericType` object `u8En7`. This object represents one of the primitive typedef statements in `ex_inter_types.h`.

In the ICD, select the **Numeric Types** tab.

Use the Model Explorer Dialog pane (the right pane) to configure the object according to the ICD.

Use the Model Explorer to configure the other `Simulink.NumericType` objects. You can use the **Contents** pane to perform batch operations.

In the **Contents** pane, click the `Simulink.Bus` object `EngSensors`. This object represents the structure type that `ex_inter_types.h` defines.

In the Dialog pane (the right pane), click **Launch Bus Editor**.

In the ICD, select the **Structure Types** tab.

Use the Bus Editor to configure the bus object and the signal elements in the bus (such as `throttle`) according to the ICD.

In the ICD, select the **Enumerated Types** tab.

In the Model Explorer **Contents** pane, click the enumerated type definition `sldemo_FuelModes`.

Use the Dialog pane to configure the type according to the ICD. Set **Storage Type** to `Native Integer` and **Data Scope** to `Exported`.

### **Generate and Inspect Code**

Configure the controller model to compile the generated code into an executable program by clearing the model configuration parameter **Generate code only**.

Generate code from the controller model.

The generated header file `sldemo_FuelModes.h` defines the enumeration `sldemo_FuelModes`.

The file `sldemo_fuelsys_dd_controller_types.h` includes (`#include`) the external header file `ex_inter_types.h`, which defines data types such as `u8En7` and the structure type `EngSensors`.

The file `sldemo_fuelsys_dd_controller_private.h` includes the header file `ex_inter_sigs.h`. This external header file contains the `extern` declaration of the signal sensors, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

The data definitions (memory allocation) appear in the source files that the ICD specifies: `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

The algorithm is in the model `step` function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a `switch` block to control the flow of execution.

## Configure Generated Code According to Interface Control Document

Import specifications from an interface control document (ICD), configure code generation settings for a model according to the specifications, and store the settings in data dictionaries.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

### Explore Interface Control Document

Navigate to the folder `matlabroot/examples/ecoder` (open). Copy this file to a writable, working folder:

- `ex_ICD_PCG.xls`

Navigate to the folder `matlabroot/examples/ecoder/main` (open). Copy this file to the same writable, working folder:

- `ex_importICD_PCG.m`

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG.xls` workbook and view the first worksheet, `Signals`. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The `Owner` column indicates the name of the component that allocates memory for each signal. The `DataType` column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus : EngSensors` to represent a structure type named `EngSensors`.

In the `Parameters` worksheet, the `Value` column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the `Numeric Types` worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The `IsAlias` column

indicates whether the C code uses the name of the data type (for example, `u8En7`) or uses the name of the primitive integer data type that corresponds to the word length. The `DataScope` column indicates whether the generated code exports or imports the definition of the type.

In the `Structure Types` worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the `DataType` column is `struct`. Subsequent rows that do not use `struct` represent fields of the preceding structure type. This ICD defines a structure type, `EngSensors`, with four fields: `throttle`, `speed`, `ego`, and `map`.

In the `Enumerated Types` worksheet, similar to the `Structure Types` worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type `sldemo_FuelModes`.

### **Write External Code**

Some data items in the ICD belong to `other` component, which is a component that exists outside of MATLAB. Create the code files that define and declare this external data.

Create the source file `ex_inter_sigs.c` in your current folder. This file defines the imported signal sensors.

```
#include "ex_inter_sigs.h"

EngSensors sensors;          /* Instrument measurements. */
```

Create the header file `ex_inter_sigs.h` in your current folder.

```
#include "ex_inter_types.h"

extern EngSensors sensors;  /* Instrument measurements. */
```

Create the header file `ex_inter_types.h` in your current folder. This file defines the structure type `EngSensors` and numeric data types such as `u8En7`.

```
#ifndef INTER_TYPES_H__
#define INTER_TYPES_H__

typedef short s16En3;
```

```
typedef short s16En7;  
  
typedef unsigned char u8En7;  
  
typedef short s16En15;  
  
/* Structure type for instrument measurements. */  
typedef struct {  
    /* Throttle angle. */  
    s16En3 throttle;  
  
    /* Engine speed. */  
    s16En3 speed;  
  
    /* EGO sensors. */  
    s16En7 ego;  
  
    /* Manifold pressure. */  
    u8En7 map;  
} EngSensors;  
  
#endif
```

### **Explore Example Model**

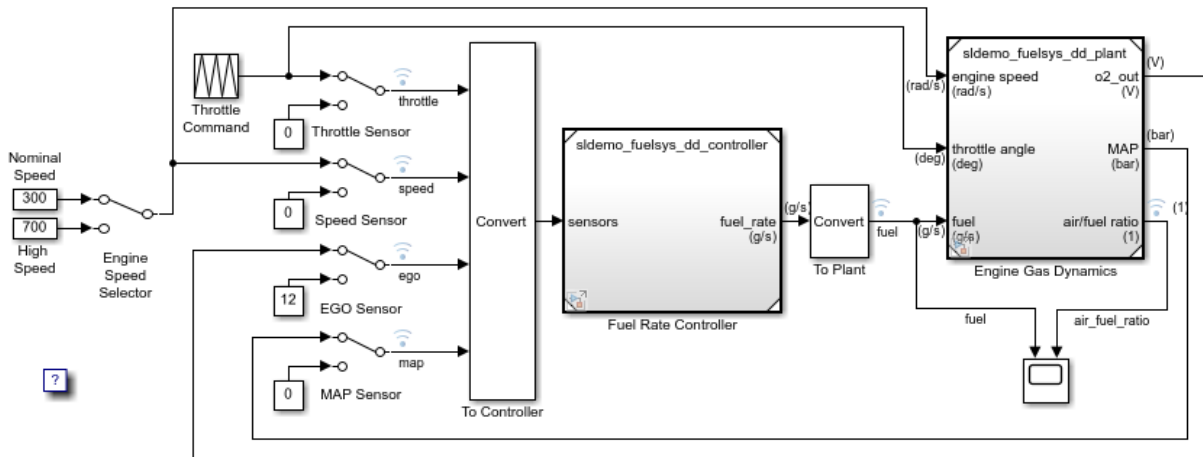

Run the script `prepare_slldemo_fuelsys_dd`. The script prepares a system model, `slldemo_fuelsys_dd`, for this example.

```
run(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_slldemo_fuelsys_dd'))
```

Open the system model, `slldemo_fuelsys_dd`.

```
slldemo_fuelsys_dd
```

### Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures.  
 The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2017 The MathWorks, Inc.

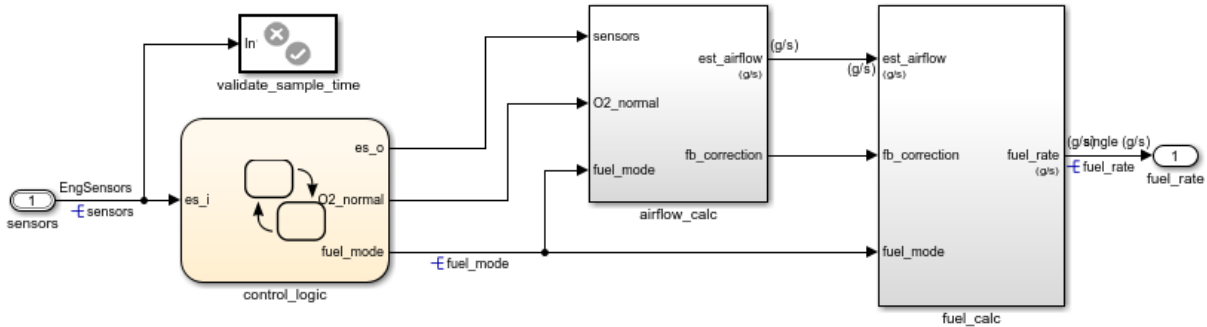

This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model, `sldemo_fuelsys_dd_controller`.

`sldemo_fuelsys_dd_controller`

## Fuel Rate Controller

Copyright 1990-2017 The MathWorks, Inc.

Data items in the controller model refer to `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace. For example, the input signal `sensors` refers to a `Simulink.Signal` object that has the same name. These objects store settings such as data types, block parameter values, and physical units. The names of these data items and objects match the names of the signals and parameters in the ICD.

### Import ICD Specifications into Simulink

To configure code generation settings for the data items, import the settings from the ICD.

Open the example script `ex_importICD_PCG`. The script imports the data from each worksheet of the ICD into variables in the base workspace. It then configures the properties of the `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace by using the imported data.

```
edit('ex_importICD_PCG')
```

If the base workspace already contains a data object that corresponds to a target data item in the ICD, the script configures the properties of the existing object. If the object does not exist, the script creates the object.

Run the `ex_importICD_PCG` script.

```
run('ex_importICD_PCG')
```

The script configures the data objects in the base workspace for code generation according to the specifications in the ICD. The `Simulink.Bus` object `EngSensors` represents the structure type from the ICD. The `Simulink.NumericType` objects, such as `u8En7`, represent the fixed-point data types.

### Generate and Inspect Code

Configure the controller model to compile the generated code into an executable by clearing the model configuration parameter **Generate code only**.

Generate code from the controller model.

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
### Simulink cache artifacts for 'sldemo_fuelsys_dd_controller' were created in 'H:\Do
```

The generated header file `sldemo_FuelModes.h` defines the enumeration `sldemo_FuelModes`.

```
typedef enum {
    LOW = 1,                /* Default value */
    RICH,
    DISABLED
} sldemo_FuelModes;
```

The file `sldemo_fuelsys_dd_controller_types.h` includes (`#include`) the external header file `ex_inter_types.h`, which defines data types such as `u8En7` and the structure type `EngSensors`.

```
#include "ex_inter_types.h"
```

The file `sldemo_fuelsys_dd_controller_private.h` includes the header file `ex_inter_sigs.h`. This external header file contains the extern declaration of the signal sensors, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

```
/* Exported data declaration */
```

```

/* Declaration for custom storage class: ExportToFile */
extern u8En7 PressEst[855];
        /* Lookup table to estimate pressure on sensor failure. */
extern s16En15 PumpCon[551];
/* Lookup table to determine pumping constant based on measured engine speed and manifold pressure. */
extern s16En15 RampRateKiZ[25]; /* Lookup table to determine throttle rate. */
extern s16En3 SpeedEst[1305];
        /* Lookup table to estimate engine speed on sensor failure. */
extern s16En7 ThrotEst[551];
        /* Lookup table to estimate throttle angle on sensor failure. */
extern sldemo_FuelModes fuel_mode;
        /* Fueling mode of engine. Enrich air/fuel mixture on sensor failure. */
extern int16_T fuel_rate; /* Fuel rate setpoint. */

```

The data definitions (memory allocation) appear in the source files that the ICD specifies, `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

```

s16En15 RampRateKiZ[25] = { 393, 786, 1180, 1573, 1966, 786, 1573, 2359, 3146,
    3932, 1180, 2359, 3539, 4719, 5898, 1573, 3146, 4719, 6291, 7864, 1966, 3932,
    5898, 7864, 9830 } ; /* Lookup table to determine throttle rate. */

```

The algorithm is in the model `step` function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a switch block to control the flow of execution.

```

/* SwitchCase: '<S10>/Switch Case' incorporates:
 * Constant: '<S11>/shutoff'
 */
switch (fuel_mode) {
case LOW:
    /* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates:
     * ActionPort: '<S12>/Action Port'
     */
    /* DiscreteFilter: '<S12>/Discrete Filter' incorporates:
     * DiscreteIntegrator: '<S1>/Discrete Integrator'
     */
    DiscreteFilter_tmp = (int16_T)(int32_T)((int32_T)((int32_T)((int32_T)
    rtDWork.DiscreteIntegrator_DSTATE << 14) - (int32_T)(-12137 * (int32_T)
    rtDWork.DiscreteFilter_states_g) >> 14);

```

### Change Ownership of Data in ICD

When you make changes to the ICD, you can reuse the `ex_importICD_PCG` script to reconfigure the model. Change the ownership of the signal sensors, the structure type, and the fixed-point data types from `other_component` to `sldemo_fuelsys_dd_controller`.

In the ICD, on the signals worksheet, for the signal sensors, set these cell values:

- Owner to `sldemo_fuelsys_dd_controller`
- HeaderFile to `global_data.h`
- DefinitionFile to `signals.c`

On the Numeric Types worksheet, for the fixed-point data types, set:

- DataScope to Exported
- HeaderFile to `exported_types.h`.

On the Structure Types worksheet, for the structure type `EngSensors`, set:

- DataScope to Exported
- HeaderFile to `exported_types.h`.

Rerun the `ex_importICD_PCG` script.

Generate code from the model.

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
### Simulink cache artifacts for 'sldemo_fuelsys_dd_controller' were created in 'H:\Do
```

The generated file `exported_types.h` defines the structure type `EngSensors` and the fixed-point data types.

```
typedef int16_T s16En3;
typedef int16_T s16En7;
typedef uint8_T u8En7;

/* Structure type for instrument measurements. */
typedef struct {
    /* Throttle angle. */
```

```

s16En3 throttle;

/* Engine speed. */
s16En3 speed;

/* EGO sensors. */
s16En7 ego;

/* Manifold pressure. */
u8En7 map;
} EngSensors;

typedef int16_T s16En15;

```

The file `signals.c` now includes the definition of the signal sensors.

```

/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
sldemo_FuelModes fuel_mode;
/* Fueling mode of engine. Enrich air/fuel mixture on sensor failure. */
int16_T fuel_rate; /* Fuel rate setpoint. */
EngSensors sensors; /* Instrument measurements. */

```

## Migrate Base Workspace Data to Data Dictionary

Objects and variables that you create in the base workspace (for example, `Simulink.Parameter` objects) are not saved with the model. When you end your MATLAB session, the objects and variables do not persist. To permanently store the objects and variables, link one or more models to one or more data dictionaries.

Data dictionaries also enable you to track changes made to the objects and variables, which helps you to:

- Reconcile the data stored in MATLAB with the data stored in the ICD.
  - Export data from MATLAB to the ICD.
- 1 In the top model, `sldemo_fuel_sys_dd`, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
  - 2 In the Model Properties dialog box, click **New**.
  - 3 In the Create a new Data Dictionary dialog box, set **File name** to `sysDict` and click **Save**.

- 4 Click **Migrate data**.
- 5 Click **Change all models** in response to the message about using the dictionary for referenced models.
- 6 Click **Migrate** in response to the message about copying referenced variables.

The variables and objects that the models use exist in the new data dictionary `sysDict.slidd`, which is in your current folder. The three models in the model reference hierarchy are linked to this dictionary.

### **Store Enumerated Type Definition in Data Dictionary**

You can import the definition of the enumerated type `sldemo_FuelModes` into the controller dictionary. See “Enumerations in Data Dictionary” (Simulink).

### **Store Signal and State Design Attributes Inside or Outside of Model File**

In this example, you use `Simulink.Signal` objects to specify design attributes such as data types, minimum and maximum values, and physical units. The signal objects store these specifications outside of the model file.

Alternatively, you can store these specifications in the model file by using block and port parameters, which you can access through the Model Data Editor, the Property Inspector, and other dialog boxes.

To decide where to store the specifications, see “Store Design Attributes of Signals and States” (Simulink).

## Generate Local Variables with Localizable Storage Class

For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove these variables from the generated code. Local variables improve observability, readability, and are helpful in debugging the generated code.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation” (Simulink Coder).

### Example Model

The model `rtwdemo_localizable_csc` contains two signals that have a `Localizable` storage class. In the `Latching` subsystem, the signal with the label `Latch` has a `Localizable` storage class. In the `Debug` subsystem, the signal with the label `Debug` has a `Localizable` storage class.

Copyright 2017 The MathWorks, Inc.

## Generate Code with Localizable Storage Class

- 1 Open the model.

```
model='rtwdemo_localizable_csc';
open_system(model);
```

- 2 To observe the specification, for each signal, open the Signal Properties dialog box and select the **Code Generation** tab. The **Signal object class** parameter is set to

Simulink.Signal. The **Storage class** parameter is set to Localizable (Custom).

- 3 Build the model. The Debug\_b function contains this code:

```
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
                  rtd_A[6])
{
    real_T Debug;
    int32_T i;
    for (i = 0; i < 6; i++) {
        Debug = rtu_In1[i] * rtu_In2[i];
        rtd_A[i] += Debug;
    }
}
```

The Latching function contains this code:

```
static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
                   rty_Out2[6], real_T rtd_A[6])
{
    real_T Latch[6];
    int32_T i;
    int32_T i_0;
    for (i = 0; i < 6; i++) {
        Latch[i] = rtd_A[i];
        rty_Out2[i] = -Latch[i];
    }

    for (i = 0; i < 6; i++) {
        rty_Out1[i] = 0.0;
        for (i_0 = 0; i_0 < 6; i_0++) {
            rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
        }
    }
}
```

Both functions contain variables for holding intermediate values. The Debug\_b function contains the variable Debug. The Latching function contains the variable Latch.

## Generate Code Without Localizable Storage Class

- 1 Change the signal storage class from Localizable to ExportToFile. For each signal, open the **Signal Properties** dialog box. On the **Code Generation** tab, for the **Storage class** parameter, select ExportToFile. The rtwdemo\_localizable\_csc.c file contains these two global variable declarations:

```
real_T Debug[6];
real_T Latch[6];
```

The Debug\_b function contains this code:

```

static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
                  rtd_A[6])
{
    int32_T i;
    for (i = 0; i < 6; i++) {
        Debug[i] = rtu_In1[i] * rtu_In2[i];
        rtd_A[i] += Debug[i];
    }
}

```

The Latching function contains this code:

```

static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
                   rty_Out2[6], real_T rtd_A[6])
{
    int32_T i;
    int32_T i_0;
    for (i = 0; i < 6; i++) {
        Latch[i] = rtd_A[i];
        rty_Out2[i] = -Latch[i];
    }

    for (i = 0; i < 6; i++) {
        rty_Out1[i] = 0.0;
        for (i_0 = 0; i_0 < 6; i_0++) {
            rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
        }
    }
}

```

The code readability and observability is the same as with the Localizable storage class specification except the labeled signals are global variables.

- 2 Remove the Debug and Latch labels. Build the model. The Debug\_b function contains this code:

```

static void Debug(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
                 rtd_A[6])
{
    int32_T i;
    for (i = 0; i < 6; i++) {
        rtd_A[i] += rtu_In1[i] * rtu_In2[i];
    }
}

```

The Latching function contains this code:

```

static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
                   rty_Out2[6], real_T rtd_A[6])
{
    int32_T i;
    int32_T i_0;
    for (i = 0; i < 6; i++) {
        rty_Out2[i] = -rtd_A[i];
        rty_Out1[i] = 0.0;
        for (i_0 = 0; i_0 < 6; i_0++) {
            rty_Out1[i] += rtu_In1[6 * i_0 + i] * rtd_A[i_0];
        }
    }
}

```

Without the `Localizable` or `ExportToFile` storage classes, the code generator removes the `Debug` and `Latch` variables. Without these variables, the readability and observability of the generated code decreases.

## Additional Information

- For the code generator to localize signals with the `Localizable` storage class specification, in the Configuration Parameters dialog box, you must select the **Enable Local Block Outputs** parameter. This parameter is on by default.
- You can specify the same `Localizable` storage class on two signals that are in different reusable subsystems. Therefore, you can create a library block from a reusable subsystem with a `Localizable` storage class specification.
- The code generator does not create a local variable for a signal that must stay global. A few cases in which the code generator can not localize a signal are:
  - Input and output signals of a Nonreusable subsystem even when the **Function interface** parameter is set to `Allow arguments`.
  - Signal is holding a state because its receiver and drive blocks execute at different rates.
  - `Localizable` specification is on a signal that crosses the boundary of a conditionally executed subsystem.

# Data Object Wizard in Embedded Coder

---

## Create Data Objects for Code Generation with Data Object Wizard

To specify code generation options for signal lines, block parameters, and states in a model, you can use data objects that you store in a workspace or data dictionary. For basic information about data objects, see “Data Objects” (Simulink).

You can use the Data Object Wizard to create data objects for:

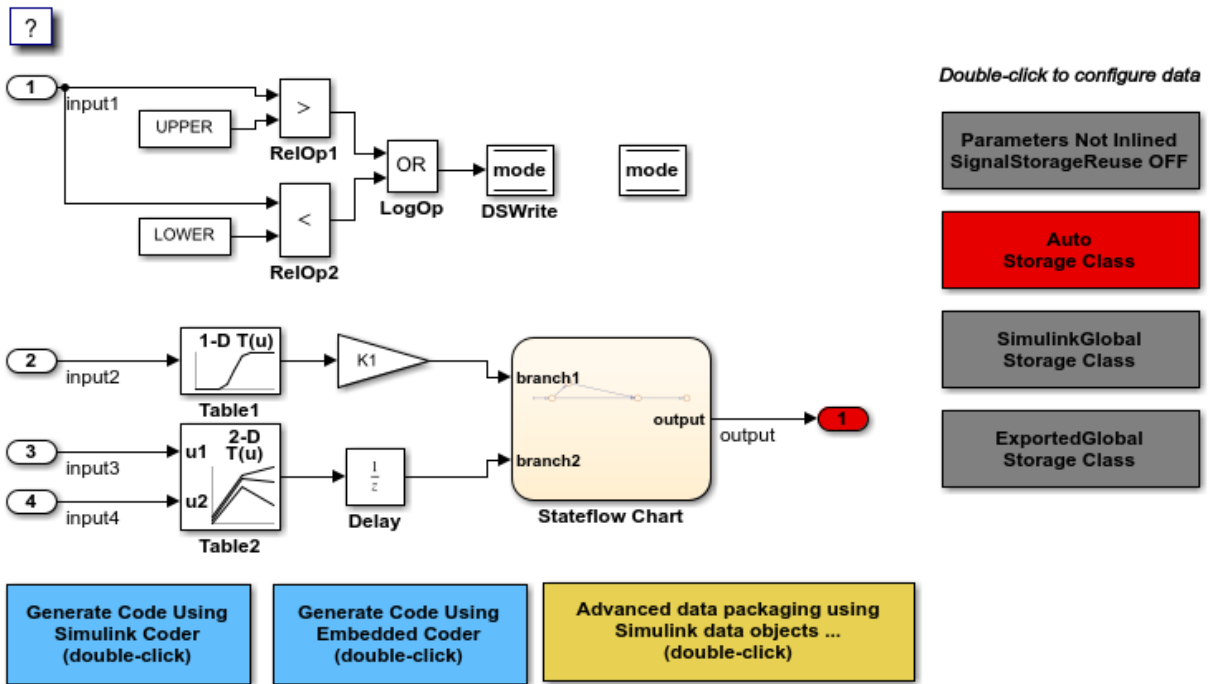

- New or existing models that do not use data objects.
- Existing models to which you have added signal lines or blocks.

This example shows how to use the Data Object Wizard to create and configure data objects for code generation from the built-in package `Simulink`.

### Create Data Objects

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Copyright 1994-2019 The MathWorks, Inc.

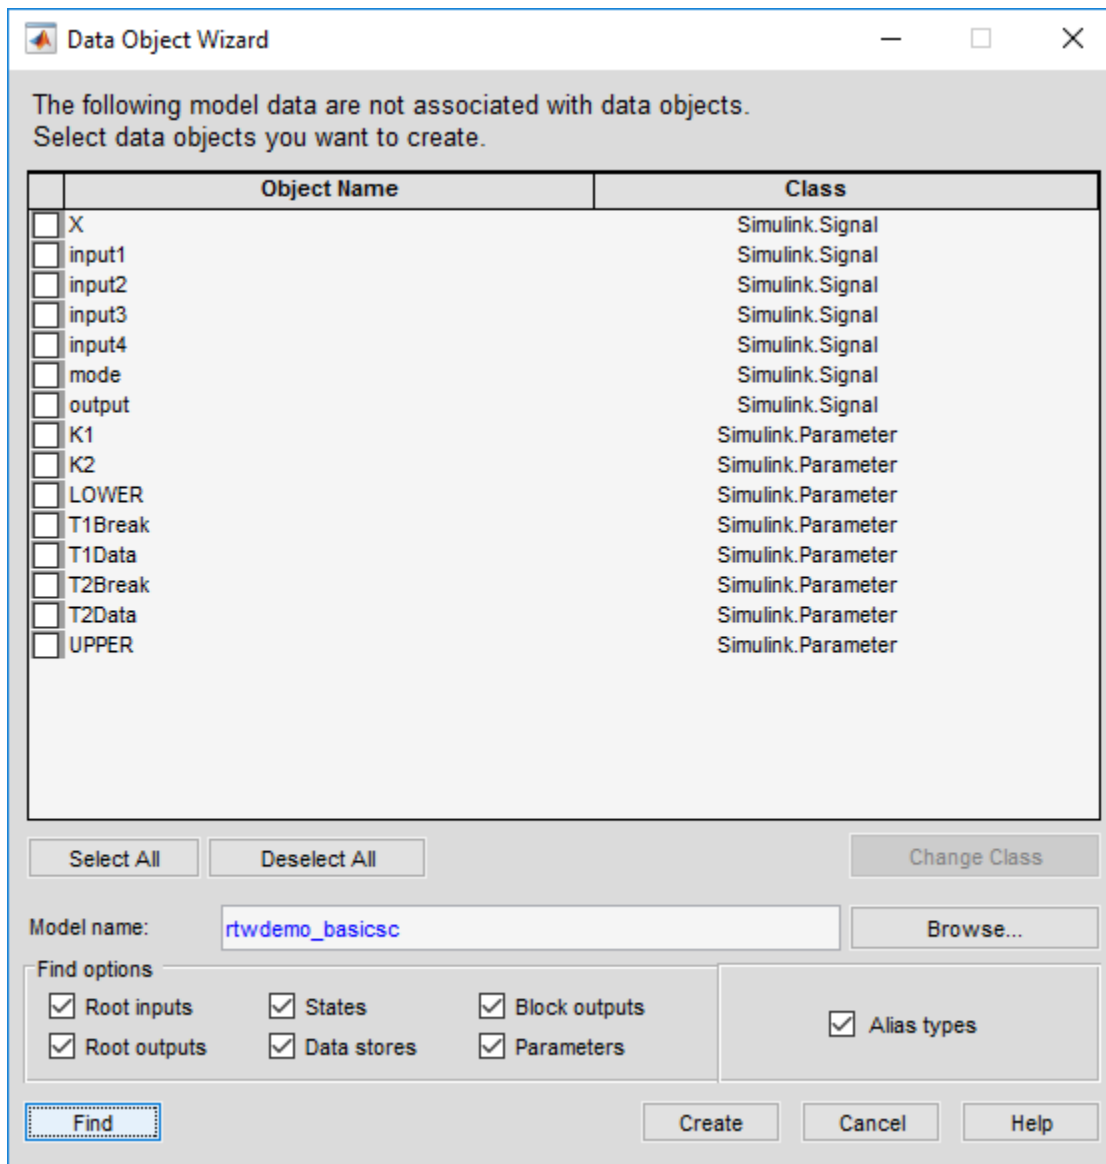

The model creates numeric variables in the base workspace. Blocks in the model use these variables to set parameter values (such as the **Gain** parameter of a Gain block). Some of the signals and block states in the model have explicit names, such as input1.

On the **Modeling** tab, under **Design**, click **Data Object Wizard**.

In the Data Object Wizard, click **Find**. The wizard proposes the creation of Simulink.Parameter objects to replace the variables and the creation of Simulink.Signal objects to represent the signals and states.

The wizard finds only signals, parameters, data stores, and states whose storage class is set to Auto. For example, if you use the Signal Properties dialog box to specify a storage class other than Auto for a signal line, the wizard does not propose a data object.

Click **Select All**.

Click **Create**. The data objects appear in the base workspace.

For detailed information about the options that you can choose in the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” (Simulink).

### **Set Storage Class for Data Objects**

Storage classes determine how the generated code uses variables to represent signals, parameters, and states. For data objects from the built-in package Simulink, the default storage class is Auto. To specify storage classes for the new data objects, use the Model Explorer.

Open the Model Explorer.

In the **Model Hierarchy** pane, select **Base Workspace**.

In the **Contents** pane, from the drop-down list **Column View**, select **Storage Class**.

Select all of the new data objects. For example, select the object `input1`, hold **Shift**, and select the object `X`.

Set the property `StorageClass` for all of the data objects to `ExportToFile`. To change the storage class for all of the selected objects, in the **StorageClass** column, click any of the objects. In the drop-down list, select `ExportToFile`. The change that you make propagates to all of the selected objects.

Specify the `HeaderFile` property for all of the objects as `myExportedHdrFile.h`.

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors storage classes such as `ExportToFile`.

### Generate and Inspect Code

Generate code from the model.

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the generated file `myExportedHdrFile.h`. The file contains `extern` declarations for the global variables that correspond to the data objects.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern int8_T K1; /* Referenced by: '<Root>/Gain' */
extern real_T K2; /* Referenced by: '<Root>/Stateflow Chart' */
extern real32_T LOWER; /* Referenced by: '<Root>/Constant2' */
extern real32_T T1Break[11]; /* Referenced by: '<Root>/Table1' */
extern real32_T T1Data[11]; /* Referenced by: '<Root>/Table1' */
extern real32_T T2Break[3]; /* Referenced by: '<Root>/Table2' */
extern real32_T T2Data[9]; /* Referenced by: '<Root>/Table2' */
extern real32_T UPPER; /* Referenced by: '<Root>/Constant1' */
extern real32_T X; /* '<Root>/Delay' */
extern real32_T input1; /* '<Root>/In1' */
extern real32_T input2; /* '<Root>/In2' */
extern real32_T input3; /* '<Root>/In3' */
extern real32_T input4; /* '<Root>/In4' */
extern boolean_T mode; /* '<Root>/Data Store Memory' */
extern real32_T output; /* '<Root>/Stateflow Chart' */
```

View the file `rtwdemo_basicsc.c`. The file contains the definitions for the global variables. The code assigns numeric values for the variables that correspond to parameter objects.

```
/* Exported data definition */

/* Definition for custom storage class: ExportToFile */

## Configure Code Generation for Model Entry-Point Functions

### What Is an Entry-Point Function?

An entry point is a location in code where a transfer of program control (execution) occurs. The main function (`main()`) is the entry point to a C/C++ program and is called when the application starts executing. Calls to other functions, for example from the `main` function, provide entry points to function code. Program control is transferred to the called function. The function code executes, and when finished, returns control to the `main` or other calling function.

When producing code for a model, the code generator defines a set of entry-point functions that you can call to execute the generated code. You can call the generated functions from external code or from a version of the generated main function that you modify.

The Code Interface Report section of the code generation report lists the entry-point functions that the code generator produces for a model. For more information, see “Analyze the Generated Code Interface” on page 49-18.

### Categories and Types of Generated Entry-Point Functions

The type of entry-point functions that the code generator produces for a model and the calling interface for the functions depend on whether the model is:

- Rate-based or is an export-function model
- Configured for reusable, multi-instance code generation

Depending on the style and configuration of a model, the code generator produces one or more of these entry-point functions.

| Function Category        | Function                      | Description                                                                                                                                                                                       |
|--------------------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initialize/<br>Terminate | <code>model_initialize</code> | Initialization code for a model. At the start of the application code, call the function <i>once</i> . Do not use this function to reset the real-time model data structure ( <code>rtM</code> ). |

| Function Category | Function                                                  | Description                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <i>model_terminate</i>                                    | Code for turning off a system. For ERT-based models, you can suppress generation of this function by clearing the model configuration parameter "Terminate function required" (Simulink Coder) (set by default).                                                                                                        |
| Execution         | <i>model_step</i>                                         | For blocks in a rate-based model, output and update code. If you clear the model configuration parameter "Single output/update function" (Simulink Coder) (selected by default), instead of producing a <i>model_step</i> function, the code generator produces functions <i>model_output</i> and <i>model_update</i> . |
|                   | <i>model_function-name</i>                                | For an exported-function model, the exported function for a subsystem.                                                                                                                                                                                                                                                  |
|                   | <i>function-name</i>                                      | For an exported-function model, the exported function for a Simulink Function block.                                                                                                                                                                                                                                    |
|                   | <i>model_reset</i>                                        | If the model includes a Reset Function block, reset code generated. To reset conditions or state, call the function from the application code.                                                                                                                                                                          |
|                   | <i>ref-model</i>                                          | For a reference model, output and update code.                                                                                                                                                                                                                                                                          |
|                   | <i>isr_numinterrupt-number_vecinterrupt-vector-offset</i> | For an Async Interrupt block, interrupt service routine (ISR) code.                                                                                                                                                                                                                                                     |
| Shared utility    | <i>function-name</i>                                      | For shared utility functions, output code.                                                                                                                                                                                                                                                                              |

## Configure Whether Entry-Point Functions Are Reusable

By default, for top models, the code generator produces code that is not reusable or reentrant. Entry-point functions have a `void-void` interface. Code communicates with other code by directly accessing global data structures that reside in shared memory.

If your application requires reusable, multi-instance entry-point function code, you can configure the code generator to call each function (instance) with unique data. In this case, the code is reentrant.

You configure whether entry-point functions are reusable with the model configuration parameter “Code interface packaging” (Simulink Coder) and related parameters. The parameter settings that you choose depend on factors such as configuration selections for the system target file, programming language, and argument interface.

### **Default Configurations for Single-Instance C Entry-Point Functions**

By default, for GRT- and ERT-based system target files, the code generator produces single-instance C entry-point functions. The generated code:

- Creates an execution function without arguments (`void-void`).
- Allocates memory statically (at compile time) for model data structures.

The default model configuration parameter settings for configuring single-instance entry-point function code are:

- “Language” (Simulink Coder) set to `C`.
- “Code interface packaging” (Simulink Coder) set to `Nonreusable function`.

### **Generate Reusable, Multi-Instance C Entry-Point Functions**

You can configure the code generator to produce reusable entry-point functions in C for either a GRT- or ERT-based system target file. However, the function interfaces that the code generator produces by default varies. Assuming that model configuration parameter “Language” (Simulink Coder) is set to `C` and “Code interface packaging” (Simulink Coder) is set to `Reusable function`, the code generator produces this entry-point function code for each system target file scenario.

| System Target File | Interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GRT-based          | <ul style="list-style-type: none"> <li>• Reusable, multi-instance C entry-point functions that are reentrant.</li> <li>• Packs values of model root-level Inport blocks and Output blocks into the real-time model data structure. Passes that structure to the execution function as an argument by reference.</li> <li>• Allocates memory dynamically at runtime for the data of a model instance. Allocates the memory by calling a function, such as <code>malloc</code>.</li> </ul> |
| ERT-based          | <ul style="list-style-type: none"> <li>• Reusable, multi-instance C entry-point functions that are reentrant.</li> <li>• Passes the value of each model root-level Inport block and Output block to the execution function as a separate argument.</li> <li>• Allocates memory statically for model data structures.</li> </ul>                                                                                                                                                          |

If you are using an ERT-based system target file and want to generate reusable, multi-instance C entry-point functions that are reentrant, consider:

- Using dynamic memory allocation to initialize model data structures. Select “Use dynamic memory allocation for model initialization” (Simulink Coder).
- Packing values of model root-level Inport blocks into a structure, packing values of root-level Outport blocks into a second structure, and passing the structures to the execution function as arguments by reference. Set “Pass root-level I/O as” (Simulink Coder) to `Structure reference`.
- Packing values of model root-level Inport blocks and Output blocks into the real-time model data structure and passing that structure to the execution function as an argument by reference. Set “Pass root-level I/O as” (Simulink Coder) to `Part of model data structure`.

### Generate Reusable, Multi-Instance C++ Entry-Point Functions

The C++ class interface encapsulates model data as class properties and entry-point functions as class methods. That interface is available for use with ERT-based system target files. To use the interface, set “Language” (Simulink Coder) to C++ and set “Code interface packaging” (Simulink Coder) to `C++ class`. You can:

- Preview and customize the C++ class interface by clicking “Configure C++ Class Interface” (Simulink Coder). Customization means that you can generate code for integration with external code and verify that the code complies with coding standards.
- Configure the visibility of class inheritance by specifying whether to generate the block parameter structure as a public, private, or protected data member. Set “Parameter visibility” (Simulink Coder) to `public`, `private`, or `protected`.
- Generate C++ interface code for model block parameters that meet code execution speed or tunability requirements. The code can be noninlined or inlined access methods. Set “Parameter access” (Simulink Coder) to `Method` or `Inlined method`.
- Generate C++ interface code for model root-level Inport and Outport blockset that meets code execution speed, data tunability, or data packaging requirements. The code can be one of these types of access methods.

| For Access Method Type     | Set “External I/O access” (Simulink Coder) To |
|----------------------------|-----------------------------------------------|
| Noninlined                 | Method                                        |
| Inlined                    | Inlined method                                |
| Noninlined structure-based | Structure-based method                        |
| Inlined structured-based   | Inlined structure-based method                |

## Configure Generated Entry-Point Function Declarations

Depending on application requirements, such as integration or compliance with code standards, you might need to configure how the code generator produces declarations for entry-point functions. Embedded Coder provides multiple configuration options.

- Apply a default function naming rule to a category of functions across a model. For example, a default naming rule can produce a `model_step` function for each rate in the multi-rate model. In the Code Mappings editor, on the **Function Defaults** tab, map a function category to a function customization template that is defined to use the function naming rule (see Code Mappings Editor). You can override the default naming of a function by changing the name on the **Functions** tab (see “Override Default Naming for Individual C Entry-Point Functions” on page 40-5 or “Override Default C Step Function Interface” on page 40-7).
- Configure interfaces for individual entry-point functions. In the Code Mappings editor, on the **Functions** tab, specify the names of individual functions (see “Override Default

Naming for Individual C Entry-Point Functions” on page 40-5). For a *model\_step* (execution) function, you can customize the entire entry-point function interface (see “Override Default C Step Function Interface” on page 40-7).

## Configure Placement of Entry-Point Functions in Memory

If your application requires that you configure the placement of entry-point functions in memory, for example, to optimize the generated code for specific hardware, you can apply a default memory section to a category of functions across a model. In the Code Mappings editor, map a function category to a function customization template that is defined to use a specific memory section. See Code Mappings Editor.

## How to Interface with Generated Entry-Point Functions

- 1 After generating code for a model, use the **Code** view to review the generated entry-point functions and, if applicable, variables representing external input and output ports.
- 2 Add `#include` statements to your external code that include the generated header files that declare the model entry-point functions.
- 3 Add an `#include` statement that includes the generated file `rtwtypes.h`. This file provides type definitions, `#define` statements, and enumerations.
- 4 Initialize target-specific data structures and hardware, such as ADCs or DACs.
- 5 If applicable, initialize data for each instance of a reusable model.
- 6 If applicable, write input data to generated variables that represent model Inport blocks.
- 7 Call the generated entry-point functions or set up use of the `rt_OneStep` function.
- 8 If applicable, read data from generated variables that represent model Outport blocks.

For more information, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 63-2.

## Generate C++ Class Interface to Model or Subsystem Code

To generate a C++ class interface to model code, set model configuration parameter “Code interface packaging” (Simulink Coder) to C++ class. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to create multiple instances of model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Generate C++ Class Interface to Nonvirtual Subsystem Code” on page 39-10.)

### Generate C++ Class Interface to Model Code

To generate encapsulated C++ class code from a GRT-based model:

- 1 Set model configuration parameter **Language** to C++. This selection also enables C++ class code interface packaging for the model.
- 2 Verify that model configuration parameter **Code interface packaging** (Simulink Coder) is set to C++ class.
- 3 Examine the setting of **Multi-instance code error diagnostic** (Simulink Coder). Leave the parameter at its default value Error unless you need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

- 4 Generate code for the model.
- 5 Examine the C++ model class code in the generated files *model.h* and *model.cpp*. For example, the following code excerpt from the H file generated for the example model *rtwdemo\_secondOrderSystem* shows the C++ class declaration for the model.

```
/* Class declaration for model rtwdemo_secondOrderSystem */
class rtwdemo_secondOrderSystemModelClass {
    /* public data and function members */
public:
    /* External outputs */
    ExtY_rtwdemo_secondOrderSystem_T rtwdemo_secondOrderSystem_Y;

    /* Model entry point functions */

    /* model initialize function */
    void initialize();

    /* model step function */
    void step();

    /* model terminate function */
    void terminate();

    /* Constructor */
    rtwdemo_secondOrderSystemModelClass();

    /* Destructor */
    ~rtwdemo_secondOrderSystemModelClass();

    /* Real-Time Model get method */
    RT_MODEL_rtwdemo_secondOrderS_T * getRTM();
    ...
};
```

For more information about generating and calling model entry-point functions, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

---

**Note** If you have an Embedded Coder license and you have selected an ERT-based system target file for your model, use additional **Code Generation > Interface** pane parameters to customize the generated C++ class interface.

---

## Generate C++ Class Interface to Nonvirtual Subsystem Code

You can generate C++ class interfaces for right-click builds of nonvirtual subsystems, if the following requirements are met:

- The model is configured for the C++ language and C++ class code interface packaging.
- The subsystem is convertible to a Model block using the function `Simulink.SubSystem.convertToModelReference`. For referenced model conversion requirements, see the Simulink reference page `Simulink.SubSystem.convertToModelReference`.

To configure C++ class interfaces for a subsystem that meets the requirements:

- 1 Open the containing model and select the subsystem block.
- 2 Right-click the subsystem and select **C/C++ Code > Build This Subsystem**.
- 3 When the subsystem build completes, examine the C++ class interfaces in the generated files and the HTML code generation report. For more information about generating and calling model entry-point methods, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

If you have an Embedded Coder license and you have selected an ERT-based system target file for your model, you can use the MATLAB command `RTW.configSubsystemBuild` to customize the generated C++ class interface to subsystem code.

## C++ Class Interface Limitations

- Among the data exchange interfaces available on the **Interface** pane of the Configuration Parameters dialog box, only the C API interface is supported for C++ class code generation. If you select **External mode** or **ASAP2 interface**, code generation fails with a validation error.
- If a model root inport value connects to a Simscape conversion block, you must insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. On the Simulink Signal Conversion block parameter dialog box, select **Exclude this block from 'Block reduction' optimization**.
- You cannot use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that
  - Has a continuous sample time
  - Saves states

## Execution of Code Generated from a Model

The code generator produces algorithmic code as defined by your model. You can include external (for example, custom or legacy) code in a model by using techniques explained in “Choose an External Code Integration Workflow” (Simulink Coder).

The code generator also provides an interface that executes the generated model code. The interface and model code are compiled together to create an executable program. The next figure shows a high-level object-oriented view of the executable.

### The Object-Oriented View of a Real-Time Program

In general, the conceptual design of the model execution driver does not change between the rapid prototyping and embedded style of generated code. The following sections describe model execution for single-tasking and multitasking environments both for simulation (non-real-time) and for real time. For most model code, the multitasking environment provides the most efficient model execution (that is, fastest sample rate).

The following concepts are useful in describing how model code executes.

- **Initialization:** `model_initialize` initializes the interface code and the model code.
- **ModelOutputs:** Calls blocks in your model that have a sample hit at the current time and has them produce their output. `model_output` can be done in major or minor time steps. In major time steps, the output is a given simulation time step. In minor time steps, the interface integrates the derivatives to update the continuous states.
- **ModelUpdate:** `model_update` calls blocks that have a sample hit at the current point in time and has them update their discrete states or similar type objects.

- **ModelDerivatives:** Calls blocks in your model that have continuous states and has them update their derivatives. *model\_derivatives* is only called in minor time steps.
- **ModelTerminate:** *model\_terminate* terminates the program if it is designed to run for a finite time. It destroys the real-time model data structure, deallocates memory, and can write data to a file.

## Program Execution

A real-time program cannot require 100% of the CPU time. This requirement provides an opportunity to run background tasks during the free time.

Background tasks include operations such as writing data to a buffer or file, allowing access to program data by third-party data monitoring tools, or updating program parameters.

It is important, however, that the program be able to preempt the background task so the model code can execute in real time.

The way the program manages tasks depends on capabilities of the environment in which it operates.

## Program Timing

Real-time programs require careful timing of the task invocations (either by using an interrupt or a real-time operating system tasking primitive) so that the model code executes to completion before another task invocation occurs. The timing includes time to read and write data to and from external hardware.

The next figure illustrates interrupt timing.

## Task Timing

The sample interval must be long enough to allow model code execution between task invocations.

In the figure above, the time between two adjacent vertical arrows is the sample interval. The empty boxes in the upper diagram show an example of a program that can complete one step within the interval and still allow time for the background task. The gray box in the lower diagram indicates what happens if the sample interval is too short. Another task invocation occurs before the task is complete. Such timing results in an execution error.

If the real-time program is designed to run forever (that is, the final time is 0 or infinite so that the `while` loop never exits), then the shutdown code does not execute.

For more information on how the timing engine works, see “Absolute and Elapsed Time Computation” (Simulink Coder).

## External Mode Communication

External mode allows communication between the Simulink block diagram and the standalone program that is built from the generated code. In this mode, the real-time program functions as an interprocess communication server, responding to requests from the Simulink engine.

## Data Logging in Single-Tasking and Multitasking Model Execution

“Debug” on page 43-42 explains how you can save system states, outputs, and time to a MAT-file at the completion of the model execution. The LogTXY function, which performs data logging, operates differently in single-tasking and multitasking environments.

If you examine how LogTXY is called in the single-tasking and multitasking environments, notice that for single-tasking LogTXY is called after ModelOutputs. During this ModelOutputs call, blocks that have a hit at time  $t$  execute, whereas in multitasking, LogTXY is called after ModelOutputs(tid=0), which executes only the blocks that have a hit at time  $t$  and that have a task identifier of 0. This results in differences in the logged values between single-tasking and multitasking logging. Specifically, consider a model with two sample times, the faster sample time having a period of 1.0 second and the slower sample time having a period of 10.0 seconds. At time  $t = k*10$ ,  $k=0,1,2\dots$  both the fast (tid=0) and slow (tid=1) blocks execute. When executing in multitasking mode, when LogTXY is called, the slow blocks execute, but the previous value is logged, whereas in single-tasking the current value is logged.

Another difference occurs when logging data in an enabled subsystem. Consider an enabled subsystem that has a slow signal driving the enable port and fast blocks within the enabled subsystem. In this case, the evaluation of the enable signal occurs in a slow task, and the fast blocks see a delay of one sample period; thus the logged values will show these differences.

To summarize differences in logged data between single-tasking and multitasking, differences will be seen when

- A root output block has a sample time that is slower than the fastest sample time
- A block with states has a sample time that is slower than the fastest sample time
- A block in an enabled subsystem where the signal driving the enable port is slower than the rate of the blocks in the enabled subsystem

For the first two cases, even though the logged values are different between single-tasking and multitasking, the model results are not different. The only real difference is where (at what point in time) the logging is done. The third (enabled subsystem) case results in a delay that can be seen in a real-time environment.

## Non-Real-Time Single-Tasking Systems

This pseudocode shows the execution of a model for a non-real-time single-tasking system.

```
main()
{
  Initialization
  While (time < final time)
    ModelOutputs      -- Major time step.
    LogTXY            -- Log time, states and root outputs.
    ModelUpdate       -- Major time step.
    Integrate         -- Integration in minor time step for
                      -- models with continuous states.
    ModelDerivatives
    Do 0 or more
      ModelOutputs
      ModelDerivatives
    EndDo -- Number of iterations depends upon the solver
    Integrate derivatives to update continuous states.
  EndIntegrate
EndWhile
Termination
}
```

The initialization phase begins first. This consists of initializing model states and setting up the execution engine. The model then executes, one step at a time. First `ModelOutputs` executes at time  $t$ , then the workspace I/O data is logged, and then `ModelUpdate` updates the discrete states. Next, if your model has continuous states, `ModelDerivatives` integrates the continuous states' derivatives to generate the states for time  $t_{new} = t + h$ , where  $h$  is the step size. Time then moves forward to  $t_{new}$  and the process repeats.

During the `ModelOutputs` and `ModelUpdate` phases of model execution, only blocks that reach the current point in time execute.

## Non-Real-Time Multitasking Systems

This pseudocode shows the execution of a model for a non-real-time multitasking system.

```
main()
{
```

```
Initialization
While (time < final time)
  ModelOutputs(tid=0) -- Major time step.
  LogTXY           -- Log time, states, and root
                  -- outports.
  ModelUpdate(tid=0) -- Major time step.
  Integrate       -- Integration in minor time step for
                  -- models with continuous states.
  ModelDerivatives
  Do 0 or more
    ModelOutputs(tid=0)
    ModelDerivatives
  EndDo (Number of iterations depends upon the solver.)
  Integrate derivatives to update continuous states.
EndIntegrate
For i=1:NumTids
  ModelOutputs(tid=i) -- Major time step.
  ModelUpdate(tid=i) -- Major time step.
EndFor
EndWhile
Termination
}
```

Multitasking operation is more complex than single-tasking execution because the output and update functions are subdivided by the *task identifier* (`tid`) that is passed into these functions. This allows for multiple invocations of these functions with different task identifiers using overlapped interrupts, or for multiple tasks when using a real-time operating system. In simulation, multiple tasks are emulated by executing the code in the order that would occur if preemption did not exist in a real-time system.

Multitasking execution assumes that task rates are multiples of the base rate. The Simulink product enforces this when you create a fixed-step multitasking model. The multitasking execution loop is very similar to that of single-tasking, except for the use of the task identifier (`tid`) argument to `ModelOutputs` and `ModelUpdate`.

You cannot use `tid` values from code generated by a target file and not by Simulink Coder. Simulink Coder tracks the use of `tid` when generating code for a specific subsystem or function type. When you generate code in a target file, this argument cannot be tracked because the scope does not have subsystem or function type. Therefore, `tid` becomes an undefined variable and your target file fails to compile.

## Real-Time Single-Tasking Systems

This pseudocode shows the execution of a model in a real-time single-tasking system where the model is run at interrupt level.

```

rtOneStep()
{
    Check for interrupt overflow
    Enable "rtOneStep" interrupt
    ModelOutputs      -- Major time step.
    LogTXY           -- Log time, states and root outputs.
    ModelUpdate      -- Major time step.
    Integrate        -- Integration in minor time step for models
                   -- with continuous states.
        ModelDerivatives
        Do 0 or more
            ModelOutputs
            ModelDerivatives
        EndDo (Number of iterations depends upon the solver.)
    Integrate derivatives to update continuous states.
EndIntegrate
}

main()
{
    Initialization (including installation of rtOneStep as an
    interrupt service routine, ISR, for a real-time clock).
    While(time < final time)
        Background task.
    EndWhile
    Mask interrupts (Disable rtOneStep from executing.)
    Complete any background tasks.
    Shutdown
}

```

Real-time single-tasking execution is very similar to non-real-time single-tasking execution, except that instead of free-running the code, the `rt_OneStep` function is driven by a periodic timer interrupt.

At the interval specified by the program's base sample rate, the interrupt service routine (ISR) preempts the background task to execute the model code. The base sample rate is the fastest in the model. If the model has continuous blocks, then the integration step size determines the base sample rate.

For example, if the model code is a controller operating at 100 Hz, then every 0.01 seconds the background task is interrupted. During this interrupt, the controller reads its inputs from the analog-to-digital converter (ADC), calculates its outputs, writes these outputs to the digital-to-analog converter (DAC), and updates its states. Program control then returns to the background task. These steps must occur before the next interrupt.

## Real-Time Multitasking Systems

This pseudocode shows how a model executes in a real-time multitasking system where the model is run at interrupt level.

```
rtOneStep()
{
    Check for interrupt overflow
    Enable "rtOneStep" interrupt
    ModelOutputs(tid=0)    -- Major time step.
    LogTXY                 -- Log time, states and root outputs.
    ModelUpdate(tid=0)    -- Major time step.
    Integrate              -- Integration in minor time step for
                          -- models with continuous states.

    ModelDerivatives
    Do 0 or more
        ModelOutputs(tid=0)
        ModelDerivatives
    EndDo (Number of iterations depends upon the solver.)
    Integrate derivatives and update continuous states.
EndIntegrate
For i=1:NumTasks
    If (hit in task i)
        ModelOutputs(tid=i)
        ModelUpdate(tid=i)
    EndIf
EndFor
}

main()
{
    Initialization (including installation of rtOneStep as an
        interrupt service routine, ISR, for a real-time clock).
    While(time < final time)
        Background task.
    EndWhile
    Mask interrupts (Disable rtOneStep from executing.)
}
```

```

    Complete any background tasks.
    Shutdown
}

```

Running models at interrupt level in a real-time multitasking environment is very similar to the previous single-tasking environment, except that overlapped interrupts are employed for concurrent execution of the tasks.

The execution of a model in a single-tasking or multitasking environment when using real-time operating system tasking primitives is very similar to the interrupt-level examples discussed above. The pseudocode below is for a single-tasking model using real-time tasking primitives.

```

tSingleRate()
{
    MainLoop:
        If clockSem already "given", then error out due to overflow.
        Wait on clockSem
        ModelOutputs           -- Major time step.
        LogTXY                 -- Log time, states and root
                               -- outputs
        ModelUpdate            -- Major time step
        Integrate               -- Integration in minor time step
                               -- for models with continuous
                               -- states.

        ModelDerivatives
        Do 0 or more
            ModelOutputs
            ModelDerivatives
        EndDo (Number of iterations depends upon the solver.)
        Integrate derivatives to update continuous states.
    EndIntegrate
EndMainLoop
}

main()
{
    Initialization
    Start/spawn task "tSingleRate".
    Start clock that does a "semGive" on a clockSem semaphore.
    Wait on "model-running" semaphore.
    Shutdown
}

```

In this single-tasking environment, the model executes as real-time operating system tasking primitives. In this environment, create a single task (tSingleRate) to run the model code. This task is invoked when a clock tick occurs. The clock tick gives a clockSem (clock semaphore) to the model task (tSingleRate). The model task waits for the semaphore before executing. The clock ticks occur at the fundamental step size (base rate) for your model.

## Multitasking Systems Using Real-Time Tasking Primitives

This pseudocode is for a multitasking model using real-time tasking primitives.

```
tSubRate(subTaskSem,i)
{
  Loop:
    Wait on semaphore subTaskSem.
    ModelOutputs(tid=i)
    ModelUpdate(tid=i)
  EndLoop
}
tBaseRate()
{
  MainLoop:
    If clockSem already "given", then error out due to overflow.
    Wait on clockSem
    For i=1:NumTasks
      If (hit in task i)
        If task i is currently executing, then error out due to
        overflow.
        Do a "semGive" on subTaskSem for task i.
      EndIf
    EndFor
    ModelOutputs(tid=0)    -- major time step.
    LogTXY                 -- Log time, states and root outputs.
    ModelUpdate(tid=0)    -- major time step.
    Loop:                 -- Integration in minor time step for
                        -- models with continuous states.
      ModelDerivatives
      Do 0 or more
        ModelOutputs(tid=0)
        ModelDerivatives
      EndDo (number of iterations depends upon the solver).
      Integrate derivatives to update continuous states.
    EndLoop
}
```

```

    EndMainLoop
}
main()
{
    Initialization
    Start/spawn task "tSubRate".
    Start/spawn task "tBaseRate".

    Start clock that does a "semGive" on a clockSem semaphore.
    Wait on "model-running" semaphore.
    Shutdown
}

```

In this multitasking environment, the model is executed using real-time operating system tasking primitives. Such environments require several model tasks (`tBaseRate` and several `tSubRate` tasks) to run the model code. The base rate task (`tBaseRate`) has a higher priority than the subrate tasks. The subrate task for `tid=1` has a higher priority than the subrate task for `tid=2`, and so on. The base rate task is invoked when a clock tick occurs. The clock tick gives a `clockSem` to `tBaseRate`. The first thing `tBaseRate` does is give semaphores to the subtasks that have a hit at the current point in time. Because the base rate task has a higher priority, it continues to execute. Next it executes the fastest task (`tid=0`), consisting of blocks in your model that have the fastest sample time. After this execution, it resumes waiting for the clock semaphore. The clock ticks are configured to occur at the fundamental step size for your model.

## Rapid Prototyping and Embedded Model Execution Differences

The rapid prototyping program framework provides a common application programming interface (API) that does not change between model definitions.

The Embedded Coder product provides a different framework called the embedded program framework. The embedded program framework provides an optimized API that is tailored to your model. When you use the embedded style of generated code, you are modeling how you would like your code to execute in your embedded system. Therefore, the definitions defined in your model should be specific to your embedded targets. Items such as the model name, parameter, and signal storage class are included as part of the API for the embedded style of code.

One major difference between the rapid prototyping and embedded style of generated code is that the latter contains fewer entry-point functions. The embedded style of code can be configured to have only one function, `model_step`.

Thus, model execution code eliminates `Loop...EndLoop` statements and groups `ModelOutputs`, `LogTXY`, and `ModelUpdate` into a single statement, *model\_step*.

For more information about how generated embedded code executes, see “Configure Code Generation for Model Entry-Point Functions” on page 39-2.

## Rapid Prototyping Model Functions

Rapid prototyping code defines the following functions that interface with the main program (`main.c` or `main.cpp`):

- `Model()`: The model registration function. This function initializes the work areas (for example, allocating and setting pointers to various data structures) used by the model. The model registration function calls the `MdlInitializeSizes` and `MdlInitializeSampleTimes` functions. These two functions are very similar to the S-function `mdlInitializeSizes` and `mdlInitializeSampleTimes` methods.
- `MdlStart(void)`: After the model registration functions `MdlInitializeSizes` and `MdlInitializeSampleTimes` execute, the main program starts execution by calling `MdlStart`. This routine is called once at startup.

The function `MdlStart` has four basic sections:

- Code to initialize the states for each block in the root model that has states. A subroutine call is made to the “initialize states” routines of conditionally executed subsystems.
- Code generated by the one-time initialization (start) function for each block in the model.
- Code to enable the blocks in the root model that have enable methods, and the blocks inside triggered or function-call subsystems residing in the root model. Simulink blocks can have enable and disable methods. An enable method is called just before a block starts executing, and the disable method is called just after the block stops executing.
- Code for each block in the model whose output value is constant. The block code appears in the `MdlStart` function only if the block parameters are not tunable in the generated code and if the code generator cannot eliminate the block code through constant folding.
- `MdlOutputs(int_T tid)`: `MdlOutputs` updates the output of blocks. The `tid` (task identifier) parameter identifies the task that in turn maps when to execute blocks based upon their sample time. This routine is invoked by the main program during major and minor time steps. The major time steps are when the main program is taking an actual time step (that is, it is time to execute a specific task). If your model contains continuous states, the minor time steps will be taken. The minor time steps are when the solver is generating integration stages, which are points between major outputs. These integration stages are used to compute the derivatives used in advancing the continuous states.

- `MdlUpdate(int_T tid)`: `MdlUpdate` updates the states and work vector state information (that is, states that are neither continuous nor discrete) saved in work vectors. The `tid` (task identifier) parameter identifies the task that in turn indicates which sample times are active, allowing you to conditionally update only states of active blocks. This routine is invoked by the interface after the major `MdlOutputs` has been executed. The solver is also called, and `model_Derivatives` is called in minor steps by the solver during its integration stages. All blocks that have continuous states have an identical number of derivatives. These blocks are required to compute the derivatives so that the solvers can integrate the states.
- `MdlTerminate(void)`: `MdlTerminate` contains any block shutdown code. `MdlTerminate` is called by the interface, as part of the termination of the real-time program.

The contents of the above functions are directly related to the blocks in your model. A Simulink block can be generalized to the following set of equations.

$$y = f_0(t, x_c, x_d, u)$$

Output  $y$  is a function of continuous state  $x_c$ , discrete state  $x_d$ , and input  $u$ . Each block writes its specific equation in a section of `MdlOutputs`.

$$x_{d+1} = f_u(t, x_d, u)$$

The discrete states  $x_d$  are a function of the current state and input. Each block that has a discrete state updates its state in `MdlUpdate`.

$$\dot{x} = f_d(t, x_c, u)$$

The derivatives  $x$  are a function of the current input. Each block that has continuous states provides its derivatives to the solver (for example, `ode5`) in `model_Derivatives`. The derivatives are used by the solver to integrate the continuous state to produce the next value.

The output,  $y$ , is generally written to the block I/O structure. Root-level Output blocks write to the external outputs structure. The continuous and discrete states are stored in the states structure. The input,  $u$ , can originate from another block's output, which is located in the block I/O structure, an external input (located in the external inputs structure), or a state. These structures are defined in the `model.h` file that the Simulink Coder software generates.

The next example shows the general contents of the rapid prototyping style of C code written to the `model.c` file.

```
/*
 * Version, Model options, TLC options,
 * and code generation information are placed here.
 */
<includes>
void MdlStart(void)
{
    /*
     * State initialization code.
     * Model start-up code - one time initialization code.
     * Execute any block enable methods.
     * Initialize output of any blocks with constant sample times.
     */
}

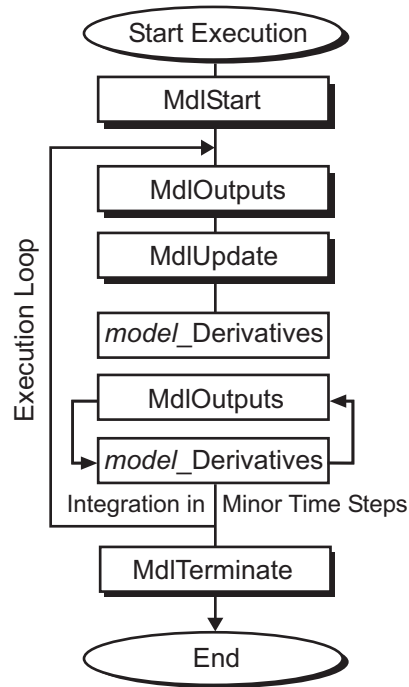

void MdlOutputs(int_T tid)
{
    /* Compute:  $y = f_0(t, x_c, x_d, u)$  for each block as needed. */
}

void MdlUpdate(int_T tid)
{
    /* Compute:  $x_{d+1} = f_u(t, x_d, u)$  for each block as needed. */

    /* Compute:  $dx_c = f_d(t, x_c, u)$  for each block in model_derivatives
        as needed. */
}

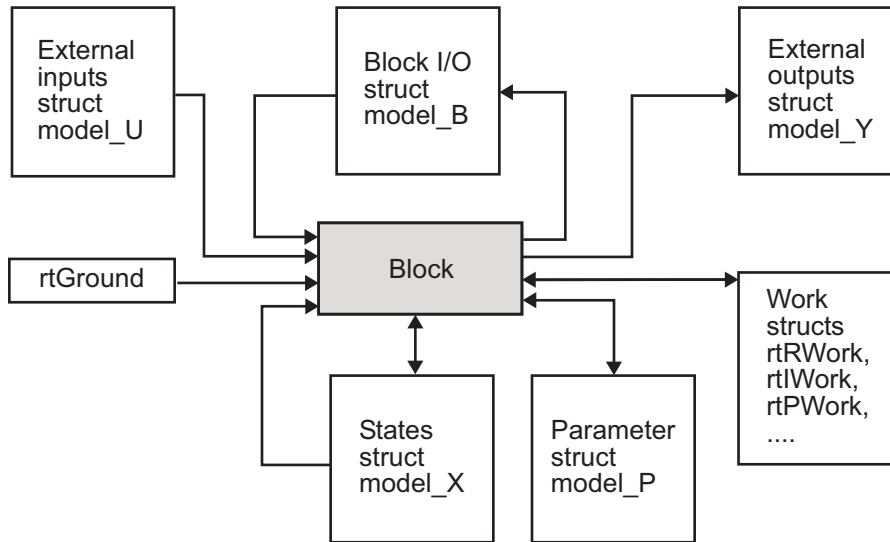

void MdlTerminate(void)
{
    /* Perform shutdown code for any blocks that
        have a termination action */
}
}
```

This figure shows a flow chart describing the execution of the rapid prototyping generated code.

### Rapid Prototyping Execution Flow Chart

Each block places code in specific Mdl routines according to the algorithm that it is implementing. Blocks have input, output, parameters, and states, as well as other general items. For example, in general, block inputs and outputs are written to a block I/O structure (*mdl\_B*). Block inputs can also come from the external input structure (*mdl\_U*) or the state structure when connected to a state port of an integrator (*mdl\_X*), or ground (*rtGround*) if unconnected or grounded. Block outputs can also go to the external output structure (*mdl\_Y*). This figure shows the general mapping between these items.

### Data View of the Generated Code

The following list defines the structures shown in the preceding figure:

- Block I/O structure (*model\_B*): This structure consists of persistent block output signals. The number of block output signals is the sum of the widths of the data output ports of the nonvirtual blocks in your model. If you activate block I/O optimizations, the Simulink and Simulink Coder products reduce the size of the *model\_B* structure by
  - Reusing the entries in the *model\_B* structure
  - Making other entries local variables

See “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder) for more information on these optimizations.

Structure field names are determined either by the block's output signal name (when present) or by the block name and port number when the output signal is left unlabeled.

- Block states structures: The continuous states structure (*model\_X*) contains the continuous state information for blocks in your model that have continuous states. Discrete states are stored in a data structure called the *DWork vector* (*model\_DWork*).

- Block parameters structure (*model\_P*): The parameters structure contains block parameters that can be changed during execution (for example, the parameter of a Gain block).
- External inputs structure (*model\_U*): The external inputs structure consists of the root-level Inport block signals. Field names are determined by either the block's output signal name, when present, or by the Inport block's name when the output signal is left unlabeled.
- External outputs structure (*model\_Y*): The external outputs structure consists of the root-level Outport blocks. Field names are determined by the root-level Outport block names in your model.
- Real work, integer work, and pointer work structures (*model\_RWork*, *model\_IWork*, *model\_PWork*): Blocks might have a need for real, integer, or pointer work areas. For example, the Memory block uses a real work element for each signal. These areas are used to save internal states or similar information.

## Customize Generated C Function Interfaces

### Choose an Approach for Customizing Generated C Function Interfaces

To facilitate integration of external and generated code and achieve compliance with code standards and guidelines, you can configure how the code generator produces function interfaces from a model or subsystem. For this level of customization, you must configure the model with an ERT-based system target file.

| Configuration                                                                                                                                                      | More Information                                                                                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Default naming rules for categories of functions (initialize/terminate, execution, and shared utility) across a model                                              | “Configure Default Code Generation for Functions” on page 32-15                                            |
| Name for individual entry-point functions (override the default naming rule)                                                                                       | “Override Default Naming for Individual C Entry-Point Functions” on page 40-5                              |
| Step function interface (function name, return value, and argument C type qualifiers, names, and order) for the base rate step entry-point function interactively  | “Override Default C Step Function Interface” on page 40-7                                                  |
| Function interfaces (function name, return value, and argument C type qualifiers, names, and order) for Simulink Function and Function Caller blocks interactively | “Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 40-18 |

You can use software-in-the-loop (SIL) testing to verify code generated for customized entry-point functions. Create a SIL block by using your generated code. Then, integrate the SIL block into a model to verify that the generated code provides the same result as the original model or nonvirtual subsystem. For more information, see “Choose a SIL or PIL Approach” on page 78-14.

### Function Interface Customization Limitations

These limitations apply to customizations for generated function interfaces:

- You must select the model configuration parameter **Single output/update function**.

- Multirate models are supported, but you must configure the models for single tasking.
- You must configure root-level inports and outports to use the `Default` storage class.
- If you choose to customize a function interface, you must provide your own custom main program. You cannot configure the function interface with the static `rt_main.c` that MathWorks provides. Specifying a function interface configuration other than the default creates a mismatch between the generated code and the default static `rt_main.c`.
- The code generator removes the data structure for the root inports of the model unless a subsystem implemented by a nonreusable function uses the value of one or more of the inports.
- The code generator removes the data structure for the root outports of the model except when you enable MAT-file logging or if the sample time of one or more of the outports is not the fundamental base rate (including a constant rate).
- If you copy a subsystem block to create a block in a new model or the same model, the function interface information from the original subsystem block is not copied to the new subsystem block.
- If you have Stateflow, for a Stateflow chart that uses a model root inport value or that calls a subsystem that uses a model root inport value, do one of the following to generate code:
  - Clear the **Execute (enter) Chart At Initialization** check box in the Stateflow chart.
  - Make the Stateflow function a nonreusable function.
  - Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- If a model root inport value connects to a Simscape conversion block, insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- When building a referenced model that is configured with a function interface, do not use virtual buses as inputs or outputs to the referenced model. Use nonvirtual buses instead.
- If the C function interface is not the default, the value is ignored for the model configuration parameter **Pass fixed-size scalar root inputs by value for code generation**. For more information, see “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

## Override Default Naming for Individual C Entry-Point Functions

For your generated C code to adhere to code standards and guidelines or to more easily integrate that code with Simulink functions, you can customize the name of an entry-point function, for example, initialize, execution, terminate.

This example shows how to change the name of the `initialize` function for model `rtwdemo_fcnprotoctrl`.

- 1 Open and save a copy of model `rtwdemo_fcnprotoctrl` in a writable location.
- 2 Open the **Embedded Coder** app.
- 3 Click the **Code Mappings - C** tab.
- 4 In the Code Mappings editor, click the **Functions** tab.
- 5 Change the function name by using one of these methods:
  - In the **Function Name** column, enter a name for the function.
  - In the **Function Preview** column, click the function prototype hyperlink to open a configuration dialog box. In the **C Initialize Function Name** field, enter the function name. Click **Apply** to verify the change in the **C function prototype** field or click **OK** to exit the dialog box and view the function name in the **Function Preview** column of the Code Mappings editor.

For this example, change the name of the `initialize` function to `fcnprotoctrl_init`.

- 6 Save the model.
- 7 Generate code.
- 8 Verify the changes in the generated code. In the **Code** view, find instances of function name `fcnprotoctrl_init`. The function name appears in generated files `rtwdemo_fcnprotoctrl.h` and `rtwdemo_fcnprotoctrl.c`.
  - In `rtwdemo_fcnprotoctrl.h`:

```
extern void fcnprotoctrl_init(void);
```
  - In `rtwdemo_fcnprotoctrl.c`:

```
void fcnprotoctrl_init(void)
{
    ...
}
```

## Override Default C Step Function Interface

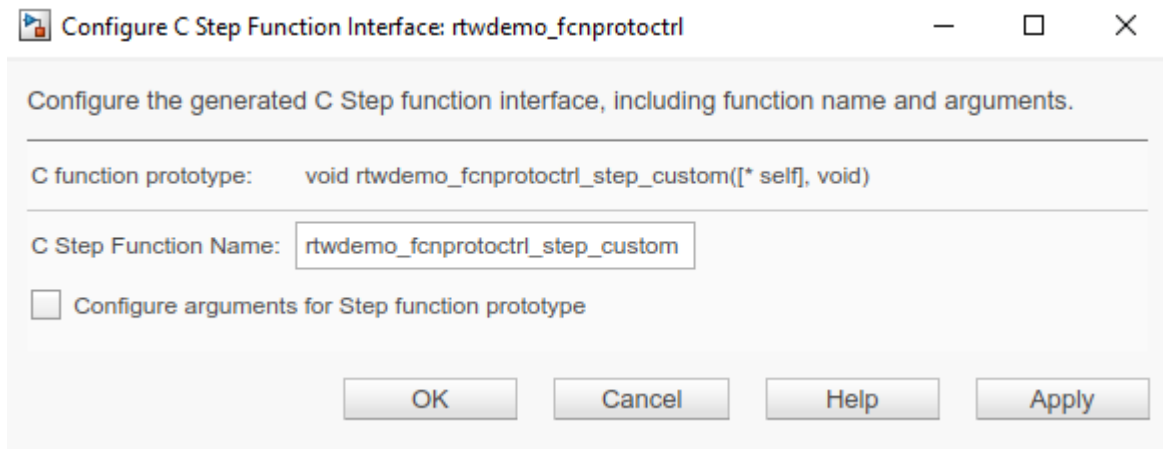

This example shows how to customize the step function name and arguments for a rate-based model. To adhere to code guidelines and standards or easily integrate generated code with external code, you can customize these aspects of a step function:

- Function name
- Argument names
- Order of the arguments
- Return value and argument data qualifiers
- Buffering optimizations for arguments

You can make step function customizations by using a model-specific configuration dialog box that you open from the Code Mappings editor.

### Open the Configuration Dialog Box

1. Open and save a copy of model `rtwdemo_fcncnprotoctrl` to a writable location.
2. Open the **Embedded Coder** app.
3. Click the **Code Mappings - C** tab.
4. In the Code Mappings editor, click the **Functions** tab. To refresh the view, click the **Update code mappings** button.
5. For the step function row, in the **Function Preview** column, click the prototype hyperlink to open the Configure C Step Function Interface dialog box.

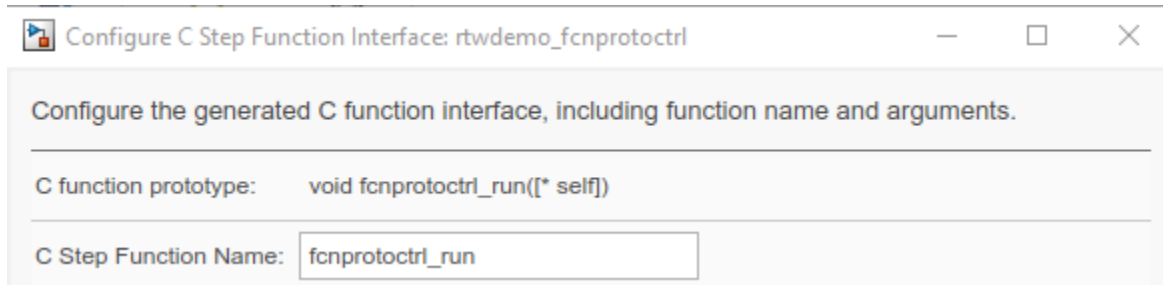

In the Configure C Step Function Interface dialog box, the **C function prototype** field displays a preview of changes that you make to the function prototype.

For models configured to generate multi-instance code, see “Generate Reentrant Code from Top Models” on page 6-25.

### Customize the Function Name

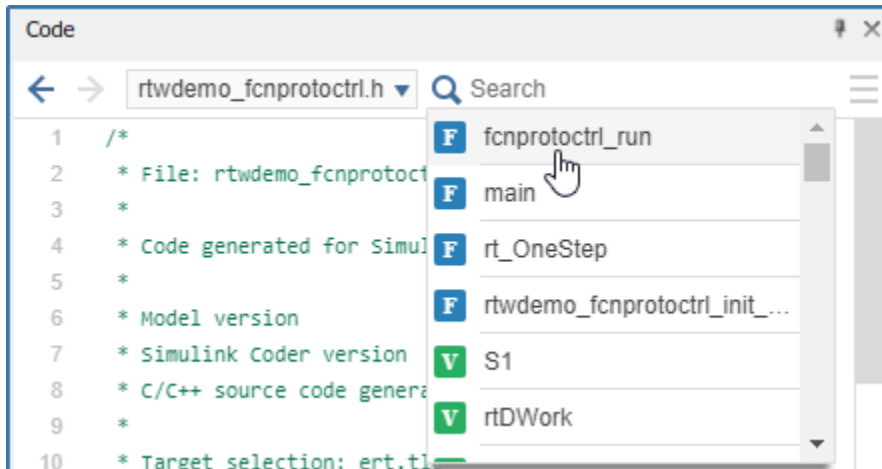

1. In the Configure C Step Function Interface dialog box, set **C Step Function Name** to `fcnprotoctrl_run`. The function preview is updated to reflect the new function name.

2. Click **Apply**, close the dialog box, and save the model.

3. Generate code and verify the name change.

- Click the **Code** tab. In the **Code** view file list, select file `rtwdemo_fcnprotoctrl.h`. In the **Search** field, verify that the list of code elements includes function name `fcnprotoctrl_run`. To view the declaration, select the function name.

The declaration is highlighted in the code:

```
/* Model entry point functions */
extern void rtwdemo_fcnprotoctrl_init_custom(void);
extern void fcnprotoctrl_run(void);
```

- Verify the name change in file `rtwdemo_fcnprotoctrl.c`. To view the source code (definition), in the **Search** field, select `fcnprotoctrl_run`.

```
/* Model step function */
void fcnprotoctrl_run(void)
{
```

For more examples, see “Override Default Naming for Individual C Entry-Point Functions” on page 40-5.

### Customize Function Arguments

### Configure Global Data Structures

By default, a top or referenced model uses a `void-void` step function to pass data. This type of function enables generated code to communicate with external code by accessing global data stored as data structures that reside in shared memory.

To configure a model to have a `void-void` step function, open the Configure C Step Function Interface dialog box and clear the **Configure arguments for Step function prototype** check box. Verify the change in the **C function prototype** preview.

### **Configure Arguments**

Rate-based model step functions can use arguments to pass data. You can customize these argument settings:

- Return value
- Type qualifiers
- Names
- Order

### **Example**

1. Open the Configure C Step Function Interface dialog box. Click the **Code Mappings - C** tab. In the **Functions** tab, click the function preview for the step function.
2. In the Configure C Step Function Interface dialog box, select **Configure arguments for Step function prototype**.
3. Click **Get default**. The dialog box expands to show a field for configuring the function return value and a table that lists input and output arguments with default settings.

Configure C Step Function Interface: rtwdemo\_fcncntrl

Configure the generated C function interface, including function name and arguments.

C function prototype: void fcncntrl\_run([\* self], arg\_In1, \* arg\_In2, \* arg\_In3, arg\_In4, \* arg\_Ou...

C Step Function Name: fcncntrl\_run

Configure arguments for Step function prototype

Get default (\* invokes update diagram)

C return argument: void

| Port Name | Port Type | C Type Qualifier | C Identifier Name |
|-----------|-----------|------------------|-------------------|
| In1       | Inport    | Value            | arg_In1           |
| In2       | Inport    | Pointer          | arg_In2           |
| In3       | Inport    | Pointer          | arg_In3           |
| In4       | Inport    | Value            | arg_In4           |
| Out1      | Output    | Pointer          | arg_Out1          |
| Out2      | Output    | Pointer          | arg_Out2          |

Drag and drop rows to specify argument order

Validate (\* invokes update diagram)

Press Validate button to get validation results.

OK Cancel Help Apply

4. Customize the return value of the step function. Set **C return argument** to either void or one of the output arguments. For this example, select void.

5. For each argument, specify a **C Type Qualifier**.

**Type Qualifiers:**

- Value: Value, for example, arg
- Const: Value with the const qualifier, for example, const arg
- Pointer to const: Value with const qualifier and referenced by pointer, for example, const \*arg
- Pointer: Reference by pointer, for example, \*arg
- Const pointer to const: Value with const qualifier, reference by pointer, and the pointer itself, for example, const \*const arg

**Models that include a referenced model**

- For a referenced model, the type qualifier for a root input argument in the step function interface is set to Auto. The code generator uses the interface specification by generating a type cast that discards the const qualifier from the source signal.
- For the parent of the reference model, the type qualifier for the source signal is set to a value other than Auto. To override this behavior, add a const type qualifier to the referenced model.

For this example, make no changes to the C type qualifier.

6. Customize the argument names by editing values in the **C Identifier Name** column.

For this example, change the names of the arguments by removing the underscores, for example, change arg\_In1 to argIn1.

7. Customize the argument order by dragging table rows to new positions.

For this example, move Out1 to the first position. Move Out 2 to the third position.

8. Validate, apply your changes, close the dialog box, and save the model.

9. Generate code and verify the changes in the **Code** view.

- Verify your changes in file `rtwdemo_fcnprotoctrl.h` by checking that the **Search** field includes function `fcnprotoctrl_run`. To view the function declaration, select the function name.

```
/* Customized model step function */
extern void fcnprotoctrl_run(boolean_T *argOut1, real_T argIn1, BusObject
    *argOut2, BusObject *argIn2, BusObject *argIn3, uint8_T argIn4);
```

- Verify your changes file `rtwdemo_fcnprotoctrl.c`. To view the definition for the function, select function name `fcnprotoctrl_run`.

```
/* Model step function */
void fcnprotoctrl_run(boolean_T *argOut1, real_T argIn1, BusObject *argOut2,
    BusObject *argIn2, BusObject *argIn3, uint8_T argIn4)
{
```

### Prototype Different From Preview

In the Configure C Step Function Interface dialog box, the function prototype preview for a referenced model can show fewer arguments than the function prototype in the generated code.

For example, consider a model named `mdlref_counter` with an inport (`arg_input`), an outport (`arg_output`), and a saturation block with limits that have workspace parameter argument names `lower_saturation_limit` and `upper_saturation_limit`. The Configure C Step Function Interface dialog box shows a function prototype preview as:

```
mdlref_counter_custom(arg_input, arg_output)
```

In the generated code, the prototype includes the parameter arguments:

```
mdlref_counter_custom(real_T arg_input, real_T arg_output, real_T
    rtp_lower_saturation_limit, real_T rtp_upper_saturation_limit)
```

### Optimize Buffering for Arguments

You can optimize the buffering required for I/O arguments in the step function for a model. If you adhere to these requirements when configuring an inport and outport pair, the code generator merges the corresponding arguments and reuses the associated buffer.

- The Inport and Outport blocks must have the same properties, including data type, dimension, and sample rate.
- The sample rate of the Inport and Outport blocks must be the same as the base rate of the model.
- A conditionally executed subsystem cannot drive the Outport block.
- A single, nonvirtual block output must drive the Outport block. For example, a Mux block, which merges multiple buffers, cannot drive the Outport block.
- In the Configure C Step Function Interface dialog box, you must configure the Inport and Outport with the same C type qualifier and identifier name.

This example shows how to merge arguments for ports In3 and Out2 for example model [rtwdemo\\_fcnprotoctrl](#).

1. Open the Configure C Step Function Interface dialog box for the model `rtwdemo_fcnprotoctrl`.
2. Open the display for the arguments by selecting **Configure arguments for Step function prototype**.
3. For ports In3 and Out2, set **C Type Qualifier** to `Pointer` and **C Identifier Name** to `sharedArg`.

| Port Name | Port Type | C Type Qualifier | C Identifier Name |
|-----------|-----------|------------------|-------------------|
| Out1      | Output    | Pointer          | argOut1           |
| In1       | Inport    | Value            | argIn1            |
| In3       | Inport    | Pointer          | sharedArg         |
| Out2      | Output    | Pointer          | sharedArg         |
| In2       | Inport    | Pointer          | argIn2            |
| In4       | Inport    | Value            | argIn4            |

4. Verify that the preview shows the merged argument for `argIn3` and `argOut2`.

5. Validate, apply your changes, close the dialog box, and save the model.
6. Generate and view the code. In the **Code** view, search for the `fcncnprotoctrl_run` function and check the function interface. For this example, the shared argument appears in read code for the Inport block and write code for the Outport block.

```

/* Model step function */
void fcnprotoctrl_run(boolean_T *argOut1, real_T argIn1, BusObject *sharedArg,
                    BusObject *argIn2, uint8_T argIn4)
{
    /* Output: '<Root>/Out1' incorporates:
     * Constant: '<Root>/Constant1'
     * Constant: '<Root>/Constant2'
     * Inport: '<Root>/In1'
     * Logic: '<Root>/LogOp'
     * RelationalOperator: '<Root>/RelOp1'
     * RelationalOperator: '<Root>/RelOp2'
     * UnitDelay: '<Root>/Unit Delay'
     */
    *argOut1 = ((rtDWork.UnitDelay_DSTATE > 10.0) || (argIn1 < 2.0));

    /* Switch: '<Root>/Switch' incorporates:
     * Inport: '<Root>/In2'
     * Inport: '<Root>/In4'
     */
    if (argIn4 != 0) {
        S1 = *argIn2;
    } else {
        S1 = *sharedArg;
    }

    /* End of Switch: '<Root>/Switch' */

    /* BusCreator: '<Root>/BusConversion_InsertedFor_Out2_at_inport_0' */
    *sharedArg = S1;

    /* Update for UnitDelay: '<Root>/Unit Delay' incorporates:
     * Inport: '<Root>/In1'
     */
    rtDWork.UnitDelay_DSTATE = argIn1;
}

```

- “Override Default Naming for Individual C Entry-Point Functions” on page 40-5
- “Customize C Step and Initialize Function Interfaces Programmatically”

## Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks

With Embedded Coder, you can customize the generated C and C++ function interfaces for Simulink Function and Function Caller blocks. Function code interface configuration supports easier integration of generated code with functions or function calls in external code and customizations for coding standards or design requirements.

You can customize generated C and C++ function interfaces for:

- Global Simulink functions
- Exported scoped Simulink functions

You cannot customize the generated function interface for a scoped Simulink Function block that is not located at the root level of a model. For more information, see “Scoped and Global Simulink Function Blocks Overview” (Simulink).

By opening a dialog box from a selected Simulink Function or Function Caller block, you can customize the function prototype generated for that block. Your changes for the selected block also update other corresponding Simulink Function and Function Caller blocks in the model. The function visibility, global or scoped, set in the function Trigger Port block determines which function attributes you can modify:

- For a global function, you can change the function name, and the names, type qualifiers, and order of function arguments.
- For an exported scoped function, you can change the argument type qualifiers and the order of arguments. You cannot change the function and argument names.

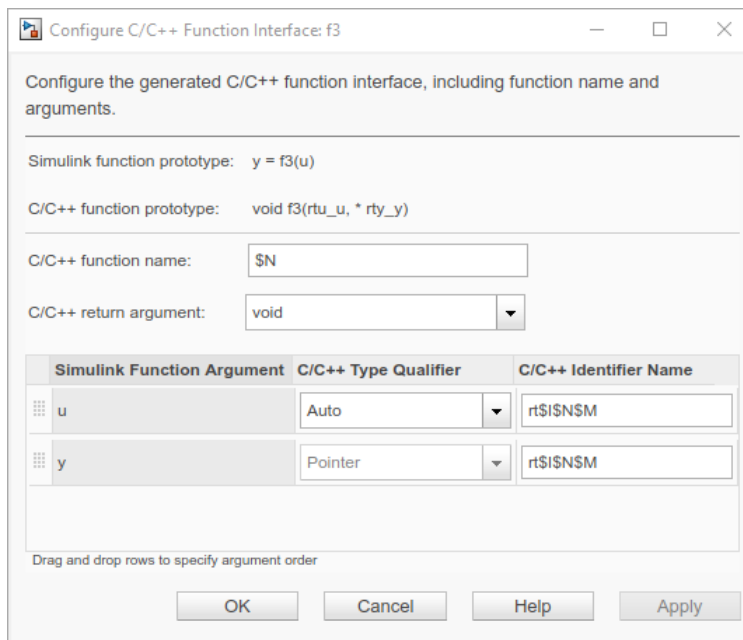

Your changes do not graphically alter the model and do not affect the Simulink function prototype defined in the block.

Embedded Coder supports Simulink function code interface configuration for models configured with ERT-based system target files, except for AUTOSAR system target files.

### Configure Generated C Function Interface for Global Simulink Function Block

This example shows how to customize the C function interface that the code generator produces for a global Simulink Function block.

- 1 Open example model `rtwdemo_functions`. Save a copy of the model to a writable location.
- 2 In the apps gallery, open the **Embedded Coder** app.
- 3 In the **C Code** tab, click the **Code Mappings - C** tab.
- 4 In the Code Mappings editor, click the **Functions** tab.
- 5 In the row for function `f3`, click the function preview hyperlink. The C/C++ Function Interface dialog box shows **Simulink function prototype** as `y = f3(u)` and **C/C++ function prototype** as `void f3(rtu_u, * rty_y)`. The preview for **C/C++ function prototype** is updated as you make changes.

- 6 Configure the function name and arguments.
  - Modify the function and argument identifier names. Model configuration parameter **Subsystem method arguments** defines the default naming rule for Simulink Function arguments. Changes that you make in the C/C++ Function Interface dialog box override the default naming rule.

In the **C/C++ function name** field, and in the **C/C++ Identifier Name** column for each Simulink function argument, enter a custom name or naming rule.

Specify valid C-identifier characters, identifier format macros, or a combination of characters and macros. For this example, name the function `function3` and, for the arguments, enter naming rule `$N$M`.

To see tips about available macros, place your cursor over **C/C++ function name** and **C/C++ Identifier Name**. For more information about identifier naming rules, see “Identifier Format Control” on page 50-22.

- For argument `u`, set **C/C++ Type Qualifier** to `Pointer to const`.
- Reorder the arguments. Drag the `y` argument row above the `u` argument row.

Configure the generated C/C++ function interface, including function name and arguments.

Simulink function prototype: `y = f3(u)`

C/C++ function prototype: `void function3(* y, const * u)`

C/C++ function name:

C/C++ return argument:

| Simulink Function Argument | C/C++ Type Qualifier | C/C++ Identifier Name |
|----------------------------|----------------------|-----------------------|
| y                          | Pointer              | \$N\$M                |
| u                          | Pointer to const     | \$N\$M                |

Drag and drop rows to specify argument order

OK Cancel Help Apply

- 7 Verify your changes by checking the function prototype preview.
- 8 Click **Apply**. Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.

Optionally, you can change **C/C++ return argument** from `void` to `y`. In that case, the C function prototype is `y = function3(const * u)`.

- 9 Save your changes by clicking **OK**.

- 10 Save the model.
- 11 Make sure that the Simulink Function block is no longer selected. Then, generate code for the model.
- 12 In the **Code** view, open the generated file `rtwdemo_functions.c` and search for `function3`. The generated function code reflects the changes to the generated C function prototype.

```
void function3(real_T *y, const real_T *u)
{
    rtY.TicToc10 = rtDWork.Delay_DSTATE;

    rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

    adder(rtB.Subtract, rtU.U2, *u, &rtB.FunctionCaller);

    *y = rtB.FunctionCaller;
}
```

## Configure Generated C Function Interface for Exported Scoped Simulink Function Block

This example shows how to customize the C function interface that the code generator produces for an exported, scoped Simulink Function block.

For an exported, scoped function, you can modify the generated return argument, the argument type qualifiers, and the order of arguments. You cannot change the generated function name and argument names.

- 1 Open the model `rtwdemo_functions`. Save it to a writable location.
- 2 Change the visibility of the global function `f3` from global to scoped. Open the Simulink Function block `f3`. Inside the function block, double-click the Trigger Port block `f3`. In the block parameters dialog box, set **Function visibility** to `scoped`. Click **Apply** and **OK**.
- 3 In the apps gallery, open the **Embedded Coder** app.
- 4 In the **C Code** tab, click the **Code Mappings - C** tab.
- 5 In the Code Mappings editor, click the **Functions** tab.
- 6 In the row for function `f3`, click the function preview hyperlink. The C/C++ Function Interface dialog box shows **Simulink function prototype** as `y = f3(u)` and **C/C++ function prototype** as `y = rtwdemo_functions_f3(rtu_u)`. The preview for **C/C++ function prototype** is updated as you make changes.

For models that you configure for C multi-instantiable code, the interface preview for scoped Simulink functions includes a `self` argument. The `self` argument is a pointer to a version of the real-time model (RT\_MODEL) data structure that stores multi-instance data associated with reusable functions.

If model configuration parameter **Code interface packaging** is set to Reusable function and **Total number of instances allowed per top model** is set to Multiple, the argument appears as `self`, indicating that the code generator produces a self structure.

If model configuration parameter **Code interface packaging** is set to Reusable function or **Total number of instances allowed per top model** is set to Multiple, the argument appears as `[self]`, indicating that the argument is optional. The code generator produces a `self` structure only if you use the model as a top model and **Code interface packaging** is set to Reusable function or if you use the model as a referenced model and **Total number of instances allowed per top model** is set to Multiple.

For more information about configuring a model for multi-instantiable code generation, see “Generate Reentrant Code from Simulink Function Blocks” on page 6-31.

- 7 Configure the arguments. For this example, configure the `u` argument. Set **C/C++ type Qualifier** to `Pointer to const`.
- 8 Verify your change by checking the function prototype preview.
- 9 Click **Apply**. Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.

Optionally, you can change **C/C++ return argument** from `y` to `void`. In that case, the C function prototype is `void = rtwdemo_functions_f3(* rty_y, const * rtu_u)`.

- 10 Save your change by clicking **OK**.
- 11 Save the model.
- 12 Make sure that the Simulink Function block is no longer selected. Then, generate code for the model.
- 13 In the **Code** view, open the generated file `rtwdemo_functions.c` and search for `rtwdemo_functions_f3`. The generated function code reflects the changes to the generated C function prototype.

```
real_T rtwdemo_functions_f3(const real_T *rtu_u)
{
    real_T rty_y_0;

    rtY.TicToc10 = rtDWork.Delay_DSTATE;

    rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

    adder(rtB.Subtract, rtU.U2, *rtu_u, &rtB.FunctionCaller);

    rty_y_0 = rtB.FunctionCaller;

    return rty_y_0;
}
```

## Configure Generated C++ Function Interface for Exported Scoped Simulink Function Block

This example shows how to customize the C++ function interface that the code generator produces for an exported scoped Simulink Function block.

For an exported scoped function, you can modify the generated return argument, the argument type qualifiers, and the order of arguments. You cannot change the generated function name and argument names.

- 1 Open the model `rtwdemo_functions`. Save it to a writable work area.
- 2 Change the visibility of the global function `f3` from global to scoped. Open the Simulink Function block `f3`. Inside the function block, double-click the Trigger Port block `f3`. In the block parameters dialog box, set **Function visibility** to `scoped`. Click **Apply** and **OK**.
- 3 In the apps gallery, open the **Embedded Coder** app.
- 4 Set the model configuration parameter **Language** to C++.
- 5 Open the Configure C/C++ Function Interface dialog box. Right-click the Simulink Function block `f3`. In the context menu, select **C/C++ Code > Configure C/C++ Function Interface**. The dialog box shows **Simulink function prototype** as `y = f3(u)` and **C/C++ function prototype** as `y = rtwdemo_functions_f3(rtu_u)`. The preview for **C/C++ function prototype** is updated as you make changes.

- 6 Configure the arguments. For this example, configure the `u` argument. Set **C/C++ type Qualifier** to `Pointer to const`.
- 7 Click **Apply**. Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.

Optionally, you can change **C/C++ return argument** from `y` to `void`. In that case, the C++ function prototype is `void = rtwdemo_functions_f3(* rty_y, const * rtu_u)`.

- 8** Save your change by clicking **OK**.
- 9** Save the model.
- 10** Make sure that the Simulink Function block is no longer selected. Then, generate code for the model.
- 11** In the **Code** view, open the generated file `rtwdemo_functions.cpp` and search for function `f3`. The generated function code reflects the changes to the generated C++ function prototype.

```
real_T rtwdemo_functionsModelClass::f3(const real_T *rtu_u)
{
    real_T rty_y_0;

    rtY.TicToc10 = rtDWork.Delay_DSTATE;

    rtDWork.Delay_DSTATE = static_cast<int8_T>(static_cast<int32_T>
        (-static_cast<int32_T>(rtY.TicToc10)));

    adder(rtB.Subtract, rtU.U2, *rtu_u, &rtB.FunctionCaller);

    rty_y_0 = rtB.FunctionCaller;

    return rty_y_0;
}
```

## Simulink Function Code Interface Limitations

- For C++ code generation, global Simulink functions are incompatible with C++ class interfaces for model entry-point functions.
- Simulink function code interface configuration does not support Simulink functions and function callers in Stateflow.

## Customize Generated C++ Class Interfaces

By setting the model configuration parameter **Code interface packaging** (Simulink Coder) to `C++ class`, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry-point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 40-38.)

To generate C++ class interfaces in model code:

- 1 Configure your model to use an ERT-based system target file provided by MathWorks.
- 2 In the Configuration Parameters dialog box, set these parameters:
  - Set **Language** to `C++`.
  - Set **Code interface packaging** to `C++ class`.
- 3 Optionally, configure related C++ class interface settings for your model code, using a graphical user interface (GUI) or application programming interface (API).
- 4 Generate model code and examine the results.

To get started with an example, see “Simple Use of C++ Class Control” on page 40-28. For more details about configuring C++ class interfaces for model code, see “Customize C++ Class Interfaces Using Graphical Interfaces” on page 40-30 and “Customize C++ Class Interfaces Programmatically”. For limitations that apply, see “C++ Class Interface Control Limitations” on page 40-42.

For an example of C++ class code generation, see “Customize Interface to Generated C++ Code That Is Called By C Code” on page 40-44.

“Customize Interface to Generated C++ Code That Is Called By C Code” on page 40-44

## Simple Use of C++ Class Control

This example illustrates a simple use of C++ class code interface packaging. It generates C++ class code interfaces from an example model, without extensive modifications to default settings.

For details about setting C++ class parameters, see the sections that follow this example, beginning with “Customize C++ Class Interfaces Using Graphical Interfaces” on page 40-30.

To generate C++ class interfaces for a Simulink model:

- 1 Open a model for which you would like to generate C++ class code interfaces. This example uses the model `rtwdemo_counter`. Save a copy of the model to a writable location.
- 2 Configure the model to use an ERT-based system target file provided by MathWorks.
- 3 Set model configuration parameter **Language** to C++. The setting for model configuration parameter **Code interface packaging** changes to C++ class. Save the model configuration changes by clicking **Apply**.

---

**Note** To immediately generate the default style of C++ class code, without exploring related model configuration options, skip steps 4 to 8.

---

- 4 Open the **Interface** pane of the Configuration Parameters dialog box and examine the **Code interface** section. When you select C++ class code interface packaging for your model, additional C++ class interface controls appear in the **Code interface** section. See “Configure C++ Code Interface Parameters” on page 40-30 for descriptions of these controls. Modify the parameter settings according to your application requirements.

- 5 Open the Configure C++ class interface dialog box by clicking the **Configure C++ Class Interface** button. Use the dialog box to configure the step method for your generated model class. The dialog box initially displays a view for configuring a **Default step method** for the model class. In this view, you can specify the model class name, step method name, and namespace for your model.

See “Configure Step Method for Your Model Class” on page 40-33 for descriptions of these controls.

If the default interface style meets your needs, skip steps 6 to 8.

- 6 If you want root-level model input and output to be arguments on the step method, set **Function specification** to I/O arguments step method. The dialog box displays a view for configuring an I/O arguments style step method for the model class. See “Configure Step Method for Your Model Class” on page 40-33 for descriptions of the controls.
- 7 Click the **Get Default Configuration** button. A **Configure C++ class interface** subpane appears. The subpane displays the initial interface configuration for your model. See “Passing I/O Arguments” on page 40-35 for descriptions of the controls.
- 8 If you want to configure I/O arguments generated for your model step method, continue modifying and validating the interface until you are satisfied with the step method configuration. Use the dialog box controls to configure I/O argument attributes. For example, in the **Configure C++ class interface** subpane, in the row for the Input argument, you can change the value of **Category** from Value to Pointer and change the value of **Qualifier** from none to const \*. The preview updates to reflect your changes. Click the **Validate** button to validate the modified interface configuration. To save your changes, click **Apply** and **OK**.

If you choose not to configure I/O arguments, click **Cancel** to exit the dialog box.

- 9 Generate code for the model In the **Code** view, review the generated code. Observe that required model data is encapsulated into C++ class attributes and model entry-point functions are encapsulated into C++ class methods. For example, select file `rtwdemo_counter.h` to see the class declaration for the model.

If you configured custom I/O arguments for the model step method (optional step 8), examine the generated code for the step method in `rtwdemo_counter.h` and `rtwdemo_counter.cpp`. The arguments should reflect your changes. For example, if you made the suggested changes for the Input argument, the input argument should appear as `const int32_T *arg_Input`.

## Customize C++ Class Interfaces Using Graphical Interfaces

- “Select C++ Class Code Interface Packaging” on page 40-30
- “Configure C++ Code Interface Parameters” on page 40-30
- “Configure Step Method for Your Model Class” on page 40-33
- “Use Namespaces to Scope C++ Model Classes” on page 40-37
- “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 40-38

### Select C++ Class Code Interface Packaging

To configure a model for C++ class code packaging:

- 1 Set model configuration parameter **Language** to C++.
- 2 Set parameter **Code interface packing** to C++ class.

These parameter settings:

- Disable model configuration parameters that C++ class does not support. For details, see “C++ Class Interface Control Limitations” on page 40-42.
- Adds additional C++ class interface parameters, which the next section describes.

### Configure C++ Code Interface Parameters

When you configure a model for select C++ class code interface packaging, the **Interface** pane shows parameters that apply to a C++ interface:

Code interface

Code interface packaging: C++ class Multi-instance code error diagnostic: Error

Remove error status field in real-time model data structure

Data Member Visibility/Access Control

Parameter visibility: private Parameter access: None

External I/O access: None

Configure C++ Class Interface

- **Multi-instance code error diagnostic**

Specifies the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

- **None** — Proceed with build without displaying a diagnostic message.
- **Warning** — Proceed with build after displaying a warning message.
- **Error (default)** — Abort build after displaying an error message.
- **Remove error status field in real-time model data structure**

Specifies whether to omit the error status field from the generated real-time model data structure `rtModel` (off by default). Selecting this option reduces memory usage.

Be aware that selecting this option can cause the code generator to omit the `rtModel` data structure from generated code.

- **Parameter visibility**

Specifies whether to generate the block parameter structure as a `public`, `private`, or `protected` data member of the C++ model class (`private` by default).

- **Parameter access**

Specifies whether to generate access methods for block parameters for the C++ model class (`None` by default). You can select noninlined access methods (`Method`) or inlined access methods (`Inlined method`).

- **External I/O access**

Specifies whether to generate access methods for root-level I/O signals for the C++ model class (`None` by default). If you want to generate access methods, you have the following options:

- Generate noninlined or inlined access methods.
- Generate per-signal or structure-based access methods. You can generate a series of set and get methods on a per-signal basis, or generate just one set method that takes the address of an external input structure as an argument and, for external outputs (if applicable), just one get method that returns a reference to an external output structure. The generated code for structure-based access methods has the following general form:

```
class ModelClass {
...
    // Root inports set method
    void setExternalInputs(const ExternalInputs* pExternalInputs);

    // Root outputs get method
    const ExternalOutputs & getExternalOutputs() const;
}
```

This parameter affects generated code only if you are using the default style step method for your model class; *not* if you are explicitly passing arguments for root-level I/O signals using an I/O arguments style step method. For more information, see “Passing Default Arguments” on page 40-34 and “Passing I/O Arguments” on page 40-35.

- **Configure C++ Class Interface**

Opens the Configure C++ class interface dialog box, which allows you to configure the step method for your model class. For more information, see “Configure Step Method for Your Model Class” on page 40-33.

Interface parameters that are related, but are less commonly used, appear under **Advanced parameters**:

- **Terminate function required**

Specifies whether to generate the `model_terminate` method (on by default). This function contains model termination code and should be called as part of system shutdown.

- **Combine signal/state structures**

Specifies whether to combine global block signals and global state data into one data structure in the generated code (cleared by default). Selecting this parameter reduces RAM and improves readability of the generated code.

- **Internal data visibility**

Specifies whether to generate internal data structures, such as Block I/O, DWork vectors, Runtime model, Zero-crossings, and continuous states, as `public`, `private`, or protected data members of the C++ model class (`private` by default).

- **Internal data access**

Specifies whether to generate access methods for internal data structures, such as Block I/O, DWork vectors, Runtime model, Zero-crossings, and continuous states, for the C++ model class (`None` by default). You can select noninlined access methods (`Method`) or inlined access methods (`Inlined method`).

- **Generate destructor**

Specifies whether to generate a destructor for the C++ model class (selected by default).

- **Use dynamic memory allocation for model block instantiation** (Simulink Coder)

For a model containing Model blocks, specifies whether generated code should use dynamic memory allocation, during model object registration, to instantiate objects for referenced models configured with a C++ class interface (cleared by default). If you select this parameter, during instantiation of an object for the top model in a model reference hierarchy, the generated code uses the operator `new` to instantiate objects for referenced models.

Selecting this parameter frees a parent model from having to maintain information about referenced models beyond its direct children. Clearing this parameter means that a parent model maintains information about its referenced models, including its direct and indirect children.

- If you select this parameter, a `bad_alloc` exception might be thrown, per the C++ standard, if an out-of-memory error occurs during the use of `new`. Provide code to catch and process the `bad_alloc` exception in case an out-of-memory error occurs for a `new` call during construction of a top model object.
- If you select **Use dynamic memory allocation for model block instantiation** and the base model contains a Model block, the build process might generate copy constructor and assignment operator functions in the private section of the model class. The purpose of the functions is to prevent pointer members within the model class from being copied by other code. For more information, see “Model Class Copy Constructor and Assignment Operator” on page 40-41.

### Configure Step Method for Your Model Class

To configure the step method for your model class, on the **Code Generation > Interface** pane, click the **Configure C++ Class Interface** button, which is available when you select C++ class code interface packaging for a model. In the Configure C++ class interface dialog box that appears, configure the step method for your model class in either of two styles:

- “Passing Default Arguments” on page 40-34
- “Passing I/O Arguments” on page 40-35

The `Default` step method supports single-rate models and multirate models. You can configure the model for single-tasking operation or multi-tasking operation. This method also supports virtual bus crossing boundaries.

The `I/O arguments` step method supports single-rate models and multirate models. You can configure the model for single-tasking operation.

### Passing Default Arguments

The Configure C++ class interface dialog box initially displays a view for configuring a **Default step method** for the model class.

- **Step method name**

Allows you to specify a step method name other than the default, `step`.

- **Class name**

Allows you to specify a model class name other than the default, `mdlModelClass`.

- **Namespace**

Allows you to specify a namespace for the model class. If specified, the namespace is emitted in the generated code for the model class. The **Namespace** parameter provides a means of scoping C++ model classes. In a model reference hierarchy, you can specify a different namespace for each referenced model.

- **Step function preview**

Displays a preview of the model step function prototype as currently configured. The preview display is dynamically updated after you validate your current configuration.

The list of step function arguments has an entry for each of the model's root-level I/O ports. This list does not include model parameter arguments that can appear in the generated code when the model is used as a referenced model. For example, a model `sldemo_mdhref_counter_paramargs` has an inport with argument name `arg_input`, an outport with argument name `arg_output`, and a saturation block whose limits have workspace parameter argument names `lower_saturation_limit` and `upper_saturation_limit`.

The step function preview for this model is:

```
sldemo_mdhref_counter_paramargsModelClass :: step ( arg_input, * arg_output )
```

The function prototype in the generated code differs from the preview. The prototype in the generated code (with the additional model parameter arguments) is:

```
sldemo_mdhref_counter_paramargsModelClass::step (  
    real_T arg_input,  
    real_T *arg_output,  
    real_T rtp_lower_saturation_limit,  
    real_T rtp_upper_saturation_limit)
```

- **Validate**

Validates your current model step function configuration. The **Validation** pane displays the status and an explanation of a failure.

### Passing I/O Arguments

If you select `I/O arguments` step method from the **Function specification** menu, the dialog box displays a view for configuring an I/O arguments style step method for the model class.

- **Get Default Configuration**

Click this button to get the initial interface configuration that provides a starting point for further customization.

- **Step function preview**

Displays a preview of the model step function prototype as currently configured. The preview dynamically updates as you make configuration changes.

- **Validate**

Validates your current model step function configuration. The **Validation** pane displays the status and an explanation of a failure.

When you click **Get Default Configuration**, the **Configure C++ class interface** subpane appears in the dialog box, displaying the initial interface configuration. For example:

Configure C++ class interface

Step method name:  Class name:  Namespace:

| Order | Port Name | Port Type | Category | Argument Name | Qualifier |
|-------|-----------|-----------|----------|---------------|-----------|
| 1     | In1       | Inport    | Value    | arg_In1       | none      |
| 2     | In2       | Inport    | Value    | arg_In2       | none      |
| 3     | In3       | Inport    | Value    | arg_In3       | none      |
| 4     | Out1      | Outport   | Pointer  | arg_Out1      | none      |
| 5     | Out2      | Outport   | Pointer  | arg_Out2      | none      |

Up  
Down

- **Step method name**

Allows you to specify a step method name other than the default, `step`.

- **Class name**

Allows you to specify a model class name other than the default, *modelModelClass*.

- **Namespace**

Allows you to specify a namespace for the model class. If specified, the namespace is emitted in the generated code for the model class. The **Namespace** parameter provides a means of scoping C++ model classes. In a model reference hierarchy, you can specify a different namespace for each referenced model.

- **Order**

Displays the numerical position of each argument. Use the **Up** and **Down** buttons to change argument order.

- **Port Name**

Displays the port name of each argument (not configurable using this dialog box).

- **Port Type**

Displays the port type, **Inport** or **Outport**, of each argument (not configurable using this dialog box).

- **Category**

Displays the passing mechanism for each argument. To change the passing mechanism for an argument, select **Value**, **Pointer**, or **Reference** from the argument's **Category** menu.

- **Argument Name**

Displays the name of each argument. To change an argument name, click in the argument's **Argument name** field, position the cursor for text entry, and enter the new name.

- **Qualifier**

Displays the `const` type qualifier for each argument. To change the qualifier for an argument, select an available value from the argument's **Qualifier** menu. The possible values are:

- none
- `const` (value)

- `const*` (value referenced by the pointer)
- `const*const` (value referenced by the pointer and the pointer itself)
- `const &` (value referenced by the reference)

---

**Tip** When a model includes a referenced model, the `const` type qualifier for the root input argument of the referenced model's specified step function interface is set to `none` and the qualifier for the source signal in the referenced model's parent is set to a value other than `none`, code generation honors the referenced model's interface specification by generating a type cast that discards the `const` type qualifier from the source signal. To override this behavior, add a `const` type qualifier to the referenced model.

---

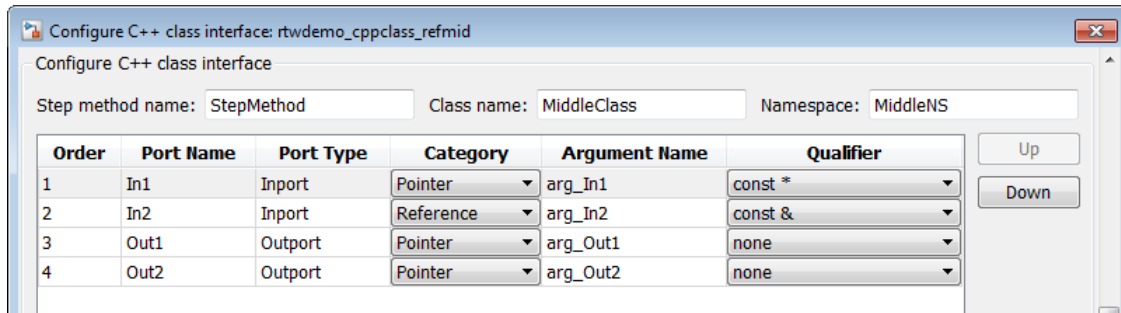

### Use Namespaces to Scope C++ Model Classes

Embedded Coder provides namespace control for scoping model classes generated using C++ class code interface packaging. In the Configure C++ class interface dialog box, use the **Namespace** parameter to specify a namespace for a model class. If specified, the namespace is emitted in the generated code for the model class. To scope the C++ model classes in a model reference hierarchy, you can specify a different namespace for each referenced model.

For an example of namespace control, see the example model `rtwdemo_cppclass`. This model assigns namespaces as follows:

- `TopNS` for top-level model `rtwdemo_cppclass`
- `MiddleNS` for referenced model `rtwdemo_cppclass_refmid`
- `BottomNS` for referenced model `rtwdemo_cppclass_refbot`

If you build the model with its default settings, you can examine the generated header and source files for each model to see where the namespace is emitted. For example, the **Namespace** setting for the model `rtwdemo_cppclass_refmid` is shown below, followed by excerpts of the emitted namespace code in the model header and source files.

```

42 // Class declaration for model rtwdemo_cppclass_refmid
43 namespace MiddleNS {
44     class MiddleClass {
45         // public data and function members
46     public:
47         // Model entry point functions
48     ...
49         // model step function
50     void StepMethod(const real_T *arg_In1, const real_T &arg_In2, real_T
51         *arg_Out1, real_T *arg_Out2);
52     ...
53     };
54 }

15 #include "rtwdemo_cppclass_refmid.h"
16 #include "rtwdemo_cppclass_refmid_private.h"
17
18 namespace MiddleNS
19 {
20     // Model step function
21     void MiddleClass::StepMethod(const real_T *arg_In1, const real_T &arg_In2,
22         real_T *arg_Out1, real_T *arg_Out2)
23     {
24     ...
25     }
26     ...
27 }

```

### Configure C++ Class Interfaces for Nonvirtual Subsystems

You can configure C++ class interfaces for right-click builds of nonvirtual subsystems in Simulink models, if the following requirements are met:

- The model is configured for the C++ language and C++ class code interface packaging.
- The subsystem is convertible to a Model block using the function `Simulink.SubSystem.convertToModelReference`. For referenced model

conversion requirements, see the Simulink reference page `Simulink.SubSystem.convertToModelReference`.

To configure C++ class interfaces for a subsystem that meets the requirements:

- 1 Open the containing model and select the subsystem block.
- 2 Enter the following MATLAB command:

```
RTW.configSubsystemBuild(gcb)
```

where `gcb` is the Simulink function `gcb`, returning the full block path name of the current block.

This command opens a subsystem equivalent of the Configure C++ class interface dialog sequence that is described in detail in the preceding section, “Configure Step Method for Your Model Class” on page 40-33. (For more information about using the MATLAB command, see `RTW.configSubsystemBuild`.)

- 3 Use the Configure C++ class interface dialog boxes to configure C++ class settings for the subsystem.
- 4 Right-click the subsystem and select **C/C++ Code > Build This Subsystem**.
- 5 When the subsystem build completes, you can examine the C++ class interfaces in the generated files and the HTML code generation report.

## Configure Step Method for Model Class

The following sample MATLAB script configures the step method for the `rtwdemo_counter` model class, using the C++ Class Interface Control Functions.

```
%% Open the rtwdemo_counter model
rtwdemo_counter

%% Select ert.tlc as the System Target File for the model
set_param(gcs,'SystemTargetFile','ert.tlc')

%% Select C++ as the target language for the model
set_param(gcs,'TargetLang','C++')

%% Select C++ class as the code interface packaging for the model
set_param(gcs,'CodeInterfacePackaging','C++ class')

%% Set required option for I/O arguments style step method (cmd off = GUI on)
set_param(gcs,'ZeroExternalMemoryAtStartup','off')

%% Create a C++ class interface using an I/O arguments style step method
a=RTW.ModelCPPArgsClass
```

```
%% Attach the C++ class interface to the model
attachToModel(a,gcs)

%% Get the default C++ class interface configuration from the model
getDefaultConf(a)

%% Move the Output port argument from position 2 to position 1
setArgPosition(a,'Output',1)

%% Reset the model step method name from step to StepMethod
setStepMethodName(a,'StepMethod')

%% Change the Input port argument name, category, and qualifier
setArgName(a,'Input','inputArg')
setArgCategory(a,'Input','Pointer')
setArgQualifier(a,'Input','const *')

%% Validate the function prototype against the model
[status,message]=runValidation(a)

%% if validation succeeded, generate code and build
if status
    rtwbuild(gcs)
end
```

## Specify Custom Storage Class for C++ Class Code Generation

To configure a Simulink parameter, signal, or state to use a custom storage class (CSC) with C++ class code generation:

- 1 Open an ERT-based model for which **Language** is set to C++ and **Code interface packaging** is set to C++ class.
- 2 Open the Configuration Parameters dialog box.
- 3 On the **Code Generation > Interface** pane, set parameter **Multi-instance code error diagnostic** (Simulink Coder) to a value other than Error.
- 4 If the parameter **Ignore custom storage classes** is selected, clear it.

Apply the changes.

- 5 In the model, select a custom storage class for a parameter, signal, or state. For example, select a signal, open its Properties dialog box, and view its code generation options. In the **Storage class** drop-down list, select a custom storage class, and then configure its attributes. Apply the changes.

C++ class code generation does not support the following storage classes:

- Storage classes with `Volatile` specifications.
  - Storage classes of type `Other`, except `GetSet`.
- 6 Generate code.
  - 7 Examine the files `model.h` and `model.cpp` to observe the use of storage classes in the generated C++ code.

## Model Class Copy Constructor and Assignment Operator

Code generation automatically adds a copy constructor and an assignment operator to C++ class declarations when required to securely handle pointer members. The constructor and operator are added as private member functions when both of the following conditions exist:

- Model configuration parameter **Use dynamic memory allocation for model block instantiation** (Simulink Coder) is set.
- The base model contains a Model block. The Model block is not directly or indirectly within a subsystem for which block parameter **Function packaging** is set to `Reusable function`.

Under these conditions, the software generates a private copy constructor and assignment operator to prevent pointer members within the model class from being copied by other code.

To prevent generation of these functions, consider clearing the parameter **Use dynamic memory allocation for model block instantiation**.

The code excerpt below shows generated `model.h` code for a model class that has a pointer member. (Look for instances of `MiddleClass_ptr`). The copy constructor and assignment operator declarations are shown in **bold**.

```
class MiddleClass;    // class forward declaration for <S1>/Bottom model instance
typedef MiddleClass* MiddleClass_ptr;
...

// Class declaration for model cppclass_top
class Top {
...
// private data and function members
private:
// Block signals
BlockIO_cppclass_top cppclass_top_B;

// Block states
```

```
D_Work_cppclass_top cppclass_top_DWork;

// Real-Time Model
RT_MODEL_cppclass_top cppclass_top_M;

// private member function(s) for subsystem '<Root>/Subsystem'
void cppclass_top_Subsystem_Init();
void cppclass_top_Subsystem_Start();
void cppclass_top_Subsystem();

//Copy Constructor
Top(const Top &rhs);

//Assignment Operator
Top& operator= (const Top &rhs);

// model instance variable for '<S1>/Bottom model instance'
MiddleClass_ptr Bottom_model_instanceMDLOBJ1;
};
```

## C++ Class Interface Control Limitations

- If a model has a custom model step function for which a scalar output is passed by value and is updated in a conditionally executed context, configure the output to be passed by pointer. In the model Configure C++ class interface dialog box, set **Category** to **Pointer**. Examples of a conditionally executed context include:
  - Output has a slower sample time than the fundamental rate of the model when the model is used as a referenced model.
  - Output is written to in a conditionally executed subsystem.
  - Output is written to by an S-function that might conditionally update the output.
  - Output is written to by a Hit Crossing block.
  - Output is written to by a Rate Transition block.
- The C++ class value for model configuration parameter **Code interface packaging** does not support some Simulink model configuration parameters. Selecting C++ class disables these parameters:
  - **Identifier format control** subpane on the **Identifiers** pane
  - **File customization template** parameter on the **Templates** pane

The code and data templates on the **Templates** pane are supported for C++ class code generation. However, the following template file features that are supported for other language selections are not supported for C++ class generated code:

- Free-form text outside template sections
- Custom tokens
- TLC commands (<! > tokens)
- **Global data placement (custom storage classes only)** subpane on the **Code Placement** pane

Selecting C++ `class` also disables the Code Mappings editor (see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 32-7). You cannot apply default storage classes, memory sections, or function templates to the model.

- Among the data exchange interfaces available on the **Interface** pane of the Configuration Parameters dialog box, only the C API interface is supported for C++ `class` code generation. If you select **External mode** or **ASAP2 interface**, code generation fails with a validation error.
- The I/O arguments style of step method specification supports single-rate models and multirate single-tasking models, but not multirate multitasking models.
- If you have a Stateflow license, for a Stateflow chart that resides in a root model configured to use the I/O arguments step method function specification, and that uses a model root inport value or calls a subsystem that uses a model root inport value, do one of the following to generate code:
  - In the Stateflow chart, clear the **Execute (enter) Chart At Initialization** check box.
  - Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- If a model root inport value connects to a Simscape conversion block, insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- When building a referenced model that is configured to generate a C++ class interface:
  - Do not use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that has a continuous sample time or saves states.
  - Do not use virtual buses as inputs or outputs to the referenced model when the referenced model uses the I/O arguments step method. When bus signals cross

referenced model boundaries, either use nonvirtual buses or use the Default step method.

- If the C++ encapsulation interface is not the default, the value is ignored for the **Pass fixed-size scalar root inputs by value for code generation** parameter. For more information, see “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

## Customize Interface to Generated C++ Code That Is Called By C Code

Customize the interface of C++ code that you generate from a model and want to call from C or C++ code. To call the C++ code from C code, you encapsulate the C++ class interface in the generated code.

### Configure a Model with Custom C++ Encapsulation Interface

If starting with a new model:

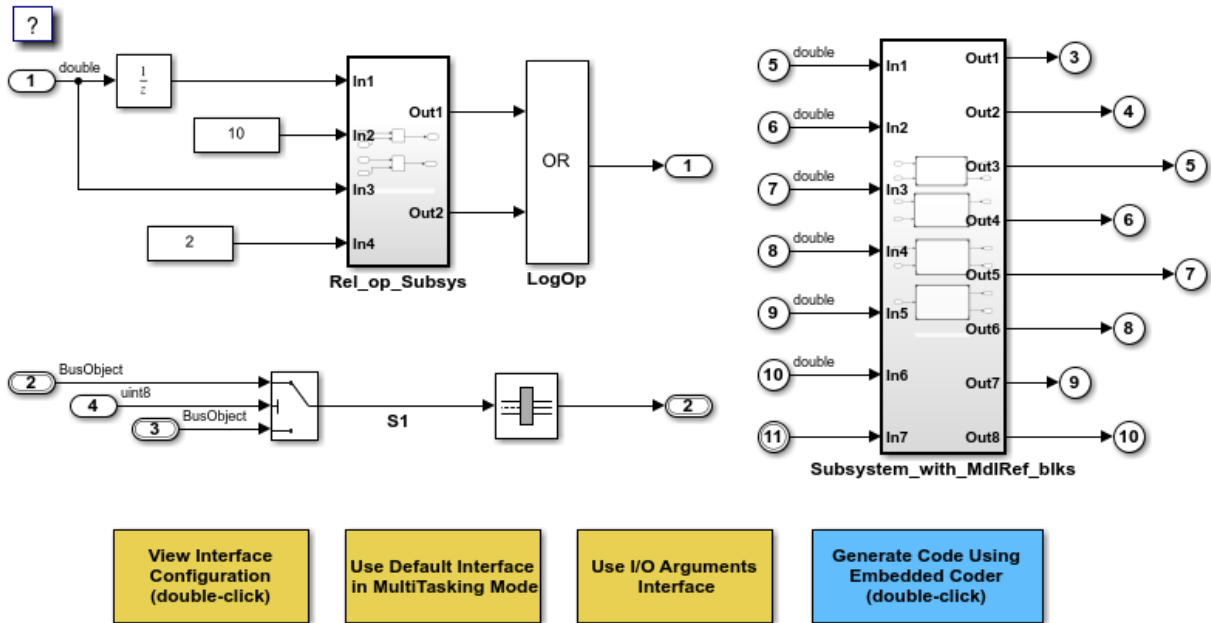

- 1 Create a model with at least one inport and at least one outport.
- 2 Open the **Embedded Coder** app.
- 3 Set model configuration parameter **Language** to C++.
- 4 Set model configuration parameter **Code interface packaging** to C++ class.
- 5 In the Model Configuration Parameters dialog box, on the **Code Generation > Interface** pane, click **Configure C++ Class Interface**. Customize the interface as needed. See “Customize Generated C++ Class Interfaces” on page 40-27.

### About C++ Encapsulation Interfaces

A generated C++ class encapsulates model data and methods. Using Embedded Coder®, the encapsulation interface is configurable through model-neutral configuration parameters and model-specific configurations. The interface supports two styles of model step method interfaces: default step method and I/O arguments step method. Use the I/O arguments style interface to customize the step method prototype. Use the and default step method style interface to achieve the maximized supported feature set including virtual buses across model boundaries and a multitasking interface.

```
open_system('rtwdemo_cppclass');
```

Copyright 2008-2019 The MathWorks, Inc.

## Generate Code

- 1 Open the example model `rtwdemo_cppclass`.
- 2 Save a copy of the model to a writable location.
- 3 Open the **Embedded Coder** app.
- 4 Generate code.
- 5 Examine the generated source code. Minimally, review the customized model step and initialization classes `ModelClass::step_method` and `ModelClass::initialize` in file `rtwdemo_cppclass.cpp`.
- 6 View the interface configuration. In the model, double-click the yellow button labeled **View Interface Configuration**. Alternatively, in the Model Configuration Parameters dialog box on the **Code Generation > Interface** pane, click **Configure C++ Class Interface**. Observe the customized arguments for the step function and how they relate to the generated code.

| Order  | Port Name | Port Type | Category    | Argument Name | Qualifier |
|--------|-----------|-----------|-------------|---------------|-----------|
| Return | Out1      | Outport   | Value ▼     | arg_Out1      | none ▼    |
| 1      | In1       | Inport    | Reference ▼ | arg_In1       | const & ▼ |
| 2      | In2       | Inport    | Pointer ▼   | arg_In2       | const * ▼ |
| 3      | In4       | Inport    | Value ▼     | arg_In4       | const ▼   |
| 4      | In3       | Inport    | Pointer ▼   | arg_In3       | none ▼    |
| 5      | In5       | Inport    | Pointer ▼   | arg_In5       | const * ▼ |
| 6      | In10      | Inport    | Pointer ▼   | arg_In10      | none ▼    |

| 12     | Out2      | Outport   | Pointer ▼   | arg_Out2      | none ▼    |
| 13     | Out3      | Outport   | Pointer ▼   | arg_Out3      | none ▼    |
| 14     | Out4      | Outport   | Pointer ▼   | arg_Out4      | none ▼    |
| 15     | Out5      | Outport   | Pointer ▼   | arg_Out5      | none ▼    |
| 16     | Out6      | Outport   | Pointer ▼   | arg_Out6      | none ▼    |
| 17     | Out7      | Outport   | Pointer ▼   | arg_Out7      | none ▼    |
| 18     | Out8      | Outport   | Pointer ▼   | arg_Out8      | none ▼    |
| 19     | Out9      | Outport   | Pointer ▼   | arg_Out9      | none ▼    |
| 20     | Out10     | Outport   | Pointer ▼   | arg_Out10     | none ▼    |

### Change to Default Arguments and Rebuild Model

If starting with a new model, populate the initial configuration for the C++ class interface.

- 1 In the Model Interface dialog box, click **Get Default Configuration**.
- 2 Close the Model Interface dialog box.
- 3 Close the Model Configuration Parameters dialog box.

- 4 Generate code.
- 5 Use the code generation report to inspect the customized model step and initialization classes `ModelClass::step_method` and `ModelClass::initialize` inside the file `rtwdemo_cppclass.cpp`. Observe the default arguments for the step function and how these relate to the generated code.

| Order | Port Name | Port Type | Category | Argument Name | Qualifier |
|-------|-----------|-----------|----------|---------------|-----------|
| 1     | In1       | Inport    | Value    | arg_In1       | none      |
| 2     | In2       | Inport    | Pointer  | arg_In2       | const *   |
| 3     | In4       | Inport    | Pointer  | arg_In4       | const *   |
| 4     | In3       | Inport    | Value    | arg_In3       | none      |
| 5     | In5       | Inport    | Value    | arg_In5       | none      |
| 6     | In10      | Inport    | Value    | arg_In10      | none      |
| 7     | In6       | Inport    | Value    | arg_In6       | none      |
| 8     | In7       | Inport    | Value    | arg_In7       | none      |
| 9     | In8       | Inport    | Value    | arg_In8       | none      |
| 10    | In9       | Inport    | Value    | arg_In9       | none      |
| 11    | In11      | Inport    | Pointer  | arg_In11      | const *   |
| 12    | Out1      | Outport   | Pointer  | arg_Out1      | none      |
| 13    | Out2      | Outport   | Pointer  | arg_Out2      | none      |
| 14    | Out3      | Outport   | Pointer  | arg_Out3      | none      |
| 15    | Out4      | Outport   | Pointer  | arg_Out4      | none      |
| 16    | Out5      | Outport   | Pointer  | arg_Out5      | none      |
| 17    | Out6      | Outport   | Pointer  | arg_Out6      | none      |
| 18    | Out7      | Outport   | Pointer  | arg_Out7      | none      |
| 19    | Out8      | Outport   | Pointer  | arg_Out8      | none      |
| 20    | Out9      | Outport   | Pointer  | arg_Out9      | none      |
| 21    | Out10     | Outport   | Pointer  | arg_Out10     | none      |

### Apply Custom Arguments and Rebuild Model

- 1 In the model, double-click the yellow button labeled **View Interface Configuration**. Alternatively, Model Configuration Parameters dialog box, in the **Code Generation > Interface** pane, click **Configure C++ Class Interface**.
- 2 In the Configure C++ class interface dialog box, move Port Name Out1 to the top of the order and set its **Category** to Value.
- 3 Close the Configure C++ class interface dialog box.
- 4 Close the Model Configuration Parameters dialog box.
- 5 Generate code.
- 6 In the generated file `rtwdemo_cppclass.cpp`, inspect the customized model step and initialization classes `ModelClass::step_method` and `ModelClass::initialize`. Observe that the custom arguments appear in the generated code.

### Compare Default Interface (Maximum Support) with I/O Arguments Interface

The `rtwdemo_cppclass` model provides buttons to toggle the function specification for the C++ class interface between the default step method (in multitasking mode) and the I/O arguments step method.

- 1 Configure the function specification for the default step method by double-clicking the yellow button labeled **Use Default Interface in MultiTasking Mode**.
- 2 Generate code.
- 3 In the generated code, inspect the model step and initialization classes.
- 4 Configure the function specification for the I/O arguments step method by double-clicking the yellow button labeled **Use I/O Arguments Interface**.
- 5 Generate code.
- 6 In the generated code, inspect the model step and initialization classes.

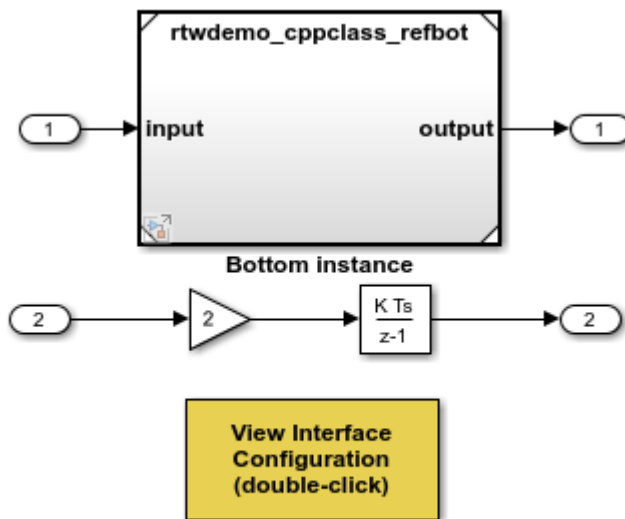

### Apply C++ Class Interface with Referenced Models

The `rtwdemo_cppclass_refmid` model is a referenced model in example model `rtwdemo_cppclass`. That referenced model shows how to generate a customizable C++ class interface to generated code for a referenced model in a model reference hierarchy.

- 1 Open model `rtwdemo_cppclass_refmid`.
- 2 Open the **Embedded Coder** app.

- 3 Double-click the `Subsystem_with_MdlRef_blks` block. Then, double-click the `middle_instance_1` block.
- 4 View the interface configuration in the `rtwdemo_cppclass_refmid` model. Double-click the yellow button labeled **View Interface Configuration**. Alternatively, in the Model Configuration Parameters dialog box, on the **Code Generation > Interface** pane, click **Configure C++ Class Interface**. Observe that the configuration for the class interface for the referenced model differs from the class interface for the top model (for example, the namespace differs).

```
open_system('rtwdemo_cppclass_refmid');
```

Copyright 2008-2019 The MathWorks, Inc.

### Apply Mixed C/C++ Interface Styles in Model Reference Hierarchy

The `rtwdemo_cppclass_refc` model is a referenced model in the example model `rtwdemo_cppclass`. That referenced model shows how to use mixed interface styles within a model reference hierarchy. The model uses the C code interface style (compiled with a C++ compiler), while the other models in the same model hierarchy use C++ class interfaces.

- 1 Open model `rtwdemo_cppclass`.

- 2 Double-click the `Subsystem_with_MdlRef_blks` block. Then, double-click the `ref_c_instance` block.
- 3 Open the **Embedded Coder** app. A dialog box appears asking whether you want to generate code for the top model `rtwdemo_cppclass` or for the active model `rtwdemo_cppclass_refc`.
- 4 Click the **Open active model as top** button.
- 5 In the Simulink Editor window that opens for model `rtwdemo_cppclass_refc`, open the **Embedded Coder** app.
- 6 Check the setting of model configuration parameter **Code interface packaging**. It is set to **Nonreusable function** (for a C function prototype). Then, close the Model Configuration Parameters dialog box.
- 7 Click the **Code Mappings - C** tab.
- 8 In the Code Mappings editor, click the **Functions** tab.
- 9 Click the **Update Code Mappings** button.
- 10 In the table, view the function prototype preview for the step function.
- 11 Close the model.

```
open_system('rtwdemo_cppclass_refc');
```

## More About

For more detail and limitations, see “Customize Generated C++ Class Interfaces” on page 40-27 in the Embedded Coder® documentation.

# Generate Modular Function Code for Nonvirtual Subsystems

## About Nonvirtual Subsystem Code Generation

By default, when producing code for a nonvirtual subsystem, the code generator places internal data associated with a nonvirtual subsystem in the same data structure as internal data for the parent model. This can make it difficult to trace and test code, particularly for nonreusable subsystems. Also, in large models containing nonvirtual subsystems, data structures can become large and potentially difficult to compile.

To generate modular function code for nonvirtual subsystems, including atomic subsystems and conditionally executed subsystems, use the subsystem block parameter **Function with separate data**. This block parameter instructs the code generator to produce a block I/O and DWork data structure for the nonvirtual subsystem function that is independent from the parent model data structures. As a result, generated code for the subsystem:

- Is easier to trace.
- Is easier to test.
- Reduces the size of a model's global data structures.

To use the **Function with separate data** parameter,

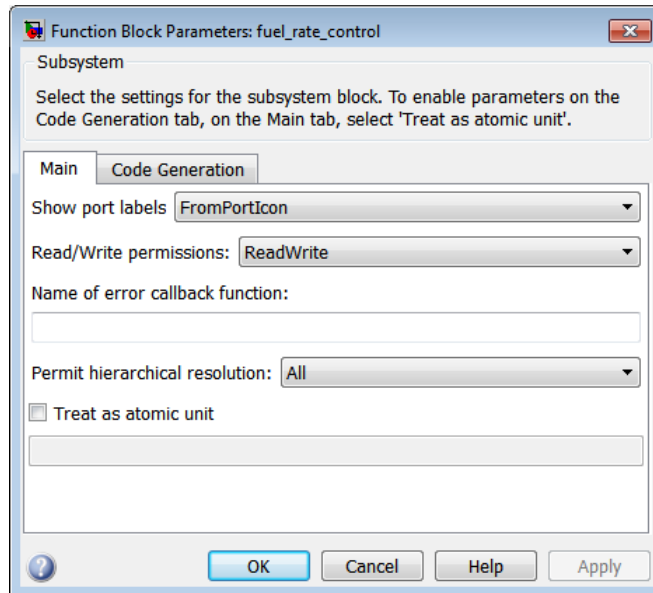

- Configure the model with an ERT-based system target file.
- Configure the subsystem to be atomic or conditionally executed.
- Set the subsystem block parameter **Function packaging** to Nonreusable function.

To configure your subsystem for generating modular function code, invoke the Subsystem Parameters dialog box and make a series of selections to display and enable the **Function with separate data** option. See “Configure Subsystem for Generating Modular Function Code” on page 40-52 and “Modular Function Code for Nonvirtual Subsystems” on page 40-55 for details. For limitations that apply, see “Nonvirtual Subsystem Modular Function Code Limitations” on page 40-71.

For more information about generating code for atomic subsystems, see the sections “Control Generation of Functions for Subsystems” (Simulink Coder) and “Generate Code and Executables for Individual Subsystems” (Simulink Coder).

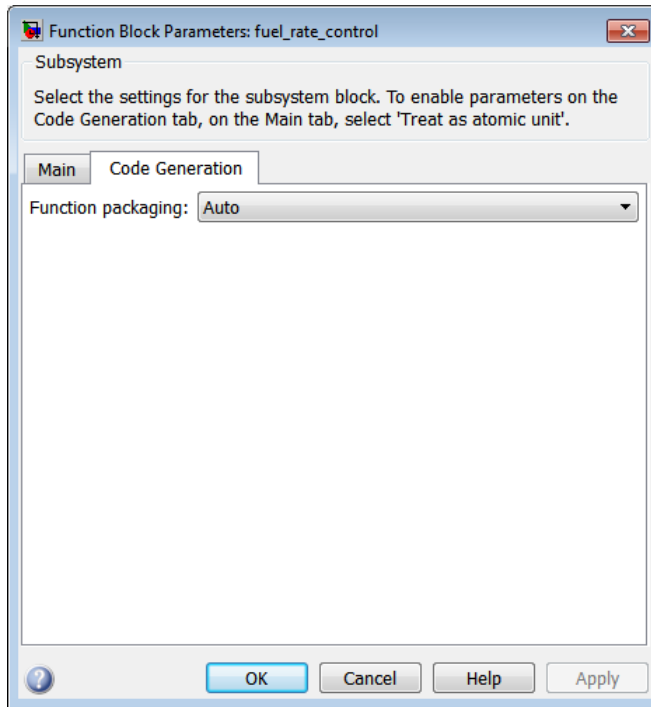

## Configure Subsystem for Generating Modular Function Code

- 1 Verify that the model containing the subsystem uses an ERT-based system target file.
- 2 Select the subsystem for which you want to generate modular function code and open the Subsystem Parameters dialog box. The dialog box for an atomic subsystem is shown below. (In the dialog box for a conditionally executed subsystem, the dialog box option **Treat as atomic unit** is greyed out, and you can skip Step 3.)

- 3 If the block parameter **Treat as atomic unit** is available for selection but not selected, the subsystem is neither atomic nor conditionally executed. Select the parameter **Treat as atomic unit**, which enables the **Function packaging** parameter on the **Code Generation** tab. Select the **Code Generation** tab.

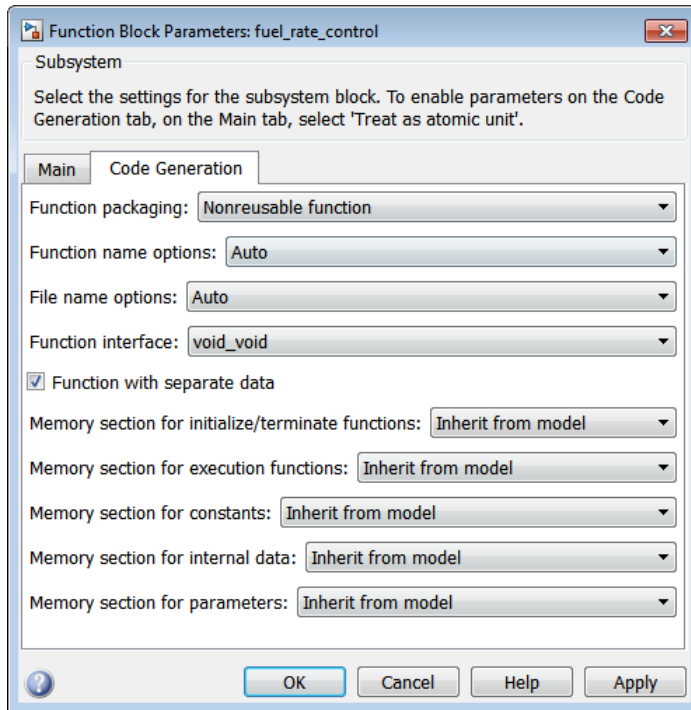

- 4 For the **Function packaging** parameter, select **Nonreusable function**. After you make this selection, the **Function with separate data** parameter is displayed.

Before you generate code for the nonvirtual subsystem with the **Function with separate data** parameter selected, consider generating function code with the parameter cleared and save the generated function .c and .h files in a separate directory for later comparison.

- 5 Select the **Function with separate data** parameter. Additional parameters appear.

To control the naming of the generated subsystem function and the subsystem files, modify subsystem parameters **Function name options** and **File name options**.

- 6 Save your subsystem parameter changes and exit the dialog box by clicking **OK**.
- 7 Generate code for the subsystem and examine the generated files, including the function .c and .h files named according to your subsystem parameter specifications.

For more information on generating code for nonvirtual subsystems, see “Control Generation of Functions for Subsystems” (Simulink Coder). For examples of generated subsystem function code, see “Modular Function Code for Nonvirtual Subsystems” on page 40-55.

## Modular Function Code for Nonvirtual Subsystems

This example shows how to generate nonvirtual subsystem function code with the **Function with separate data** parameter cleared and selected and compares the results.

- 1 Open example model `rtwdemo_atomic`. Then, open the **Embedded Coder** app. Change the system target file to `ert.tlc`.

This model shows how to preserve the boundary of a virtual subsystem. When you select subsystem block parameter **Treat as atomic unit**, the code that the code generator produces for the subsystem executes as an atomic unit. When configured as atomic, you can specify how the code generator represents the subsystem by setting the **Function Packaging** parameter on the **Code Generation** tab. You can specify that the subsystem is translated to one of these types of implementation:

- **Inline:** Inlined subsystem code at call sites.
  - **Function:** `void/void` function with I/O and internal data in the model global data structure.
  - **Reusable Function:** Reentrant function with data passed in as function arguments.
  - **Auto:** Code generator optimizes the implementation based on context.
- 2 Double-click the SS1 subsystem and examine the contents.

Then, close the subsystem window.

- 3 Right-click the SS1 subsystem, select **Block Parameters (Subsystem)** from the context menu, and examine the settings. Simulink and the code generator can avoid "artificial" algebraic loops when you make the subsystem atomic with subsystem parameter **Minimize algebraic loop occurrences**.

- 4 Create a variant of `rtwdemo_atomic` that shows function code *without* data separation.
  - a In the Subsystem Parameters dialog box,
    - In the **Main** tab, select **Treat as atomic unit**.
    - In the **Code Generation** tab:
      - Set **Function packaging** to Nonreusable function.
      - Set **Function name options** to User specified.
      - Set **Function name** to `myfun`.
      - Set **File name options** to Use function name. This setting is optional but simplifies the later task of code comparison by causing the atomic subsystem function code to be generated into files `myfun.c` and `myfun.h`.
  - Do not select the **Function with separate data** parameter.
  - b Click **Apply** to apply the changes and click **OK** to exit the dialog box.
  - c Save the model variant with a unique file name (for example, `rtwdemo_atomic1`) to a writable location.
- 5 Create a variant of `rtwdemo_atomic` that shows function code *with* data separation.
  - a Open model `rtwdemo_atomic`.
  - b Open the **Embedded Coder** app. Change the system target file to `ert.tlc`.
  - c In the model canvas, right-click the SS1 subsystem and select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box,
    - In the **Main** tab, select **Treat as atomic unit**.
    - In the **Code Generation** tab:
      - Set **Function packaging** to Nonreusable function.
      - Set **Function name options** to User specified.
      - Set **Function name** to `myfun`.
      - Set **File name options** to Use function name.
      - Select **Function with separate data**.
  - d Click **Apply** to apply the change and click **OK** to exit the dialog box.
  - e Save the model variant with a unique file name (for example, `rtwdemo_atomic2`) to a writable location.

- 6 Generate code for each model (for example, `rtwdemo_atomic1` and `rtwdemo_atomic2`).
- 7 Compare the `model.c/.h` and `myfun.c/.h` files generated for the two models. For code comparison discussion, see “H File Differences for Nonvirtual Subsystem Function Data Separation” on page 40-58 and “C File Differences for Nonvirtual Subsystem Function Data Separation” on page 40-59.

In this example, there are not significant differences in the generated variants of `ert_main.c`, `model_private.h`, `model_types.h`, or `rtwtypes.h`.

## H File Differences for Nonvirtual Subsystem Function Data Separation

- Selecting **Function with separate data** causes the code generator to place type definitions for subsystem data in the `myfun.h` file for `rtwdemo_atomic2`:

```
/* Block signals for system '<Root>/SS1' */
typedef struct {
    real_T Integrator;           /* '<S1>/Integrator' */
} rtB_myfun;

/* Block states (auto storage) for system '<Root>/SS1' */
typedef struct {
    real_T Integrator_DSTATE;   /* '<S1>/Integrator' */
} rtDW_myfun;
```

For `rtwdemo_atomic1`, type definitions for subsystem data belong to the model and appear in `rtwdemo_atomic1.h`:

```
/* Block signals (auto storage) */
typedef struct {
    ...
    real_T Integrator;           /* '<S1>/Integrator' */
} BlockIO_rtwdemo_atomic1;

/* Block states (auto storage) for system '<Root>' */
typedef struct {
    real_T Integrator_DSTATE;   /* '<S1>/Integrator' */
} D_Work_rtwdemo_atomic1;
```

- Selecting **Function with separate data** generates the following external declarations in the `myfun.h` file for `rtwdemo_atomic2`:

```
/* Extern declarations of internal data for 'system '<Root>/SS1'' */
extern rtB_myfun rtwdemo_atomic2_myfunB;
```

```
extern rtDW_myfun rtwdemo_atomic2_myfunDW;
extern void myfun_initialize(void);
```

By contrast, the generated code for `rtwdemo_atomic1` contains model-level external declarations for the subsystem `BlockIO` and `D_Work` data, in `rtwdemo_atomic1.h`:

```
/* Block signals (auto storage) */
extern BlockIO_rtwdemo_atomic1 rtwdemo_atomic1_B;

/* Block states (auto storage) */
extern D_Work_rtwdemo_atomic1 rtwdemo_atomic1_DWork;
```

### C File Differences for Nonvirtual Subsystem Function Data Separation

- Selecting **Function with separate data** causes a separate subsystem initialize function, `myfun_initialize`, to be generated in the `myfun.c` file for `rtwdemo_atomic2`:

```
void myfun_initialize(void) {
    {
        ((real_T*)&rtwdemo_atomic2_myfunB.Integrator)[0] = 0.0;
    }
    rtwdemo_atomic2_myfunDW.Integrator_DSTATE = 0.0;
}
```

The subsystem initialize function in `myfun.c` is invoked by the model initialize function in `rtwdemo_atomic2.c`:

```
/* Model initialize function */

void rtwdemo_atomic2_initialize(void)
{
    ...

    /* Initialize subsystem data */
    myfun_initialize();
}
```

By contrast, for `rtwdemo_atomic1`, subsystem data is initialized by the model initialize function in `rtwdemo_atomic1.c`:

```
/* Model initialize function */

void rtwdemo_atomic1_initialize(void)
```

```
{
...
  /* block I/O */
  {
    ...
    ((real_T*)&rtwdemo_atomic1_B.Integrator)[0] = 0.0;
  }

  /* states (dwork) */

  rtwdemo_atomic1_DWork.Integrator_DSTATE = 0.0;
  ...
}
```

- Selecting **Function with separate data** generates the following declarations in the myfun.c file for rtwdemo\_atomic2:

```
/* Declare variables for internal data of system '<Root>/SS1' */
rtB_myfun rtwdemo_atomic2_myfunB;

rtDW_myfun rtwdemo_atomic2_myfunDW;
```

By contrast, the generated code for rtwdemo\_atomic1 contains model-level declarations for the subsystems BlockIO and D\_Work data, in rtwdemo\_atomic1.c:

```
/* Block signals (auto storage) */
BlockIO_rtwdemo_atomic1 rtwdemo_atomic1_B;

/* Block states (auto storage) */
D_Work_rtwdemo_atomic1 rtwdemo_atomic1_DWork;
```

- Selecting **Function with separate data** generates identifier naming that reflects the subsystem orientation of data items. The references to subsystem data in subsystem functions, such as myfun and myfun\_update, are in the model *model\_step* function. For example, compare this code from myfun for rtwdemo\_atomic2

```
/* DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_atomic2_myfunB.Integrator = rtwdemo_atomic2_myfunDW.Integrator_DSTATE;
```

to the corresponding code from myfun for rtwdemo\_atomic1.

```
/* DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_atomic1_B.Integrator = rtwdemo_atomic1_DWork.Integrator_DSTATE;
```

## Partition Functions in Generated Code

This example shows how to associate subsystems in a model with function names and files.

Learn how to:

- Specify function and file names in the generated code.
- Identify the parts of the generated code that are required for integration.
- Generate code for atomic subsystems.
- Identify data that are required to execute a generated function.

For information about the example model and other examples in this series, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Atomic and Virtual Subsystems

The example models in “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20 and “Configure Data Interface in the Generated Code” on page 48-35 use *virtual subsystems*. Virtual subsystems visually organize blocks but do not affect the model functionality. *Atomic subsystems* evaluate the blocks included in a model as a unit. With atomic subsystems, you can specify additional function partitioning information. In a model, atomic subsystems appear with a bold border.

### View Changes in Model Architecture

Open the example model `rtwdemo_PCG_Eval_P3`.

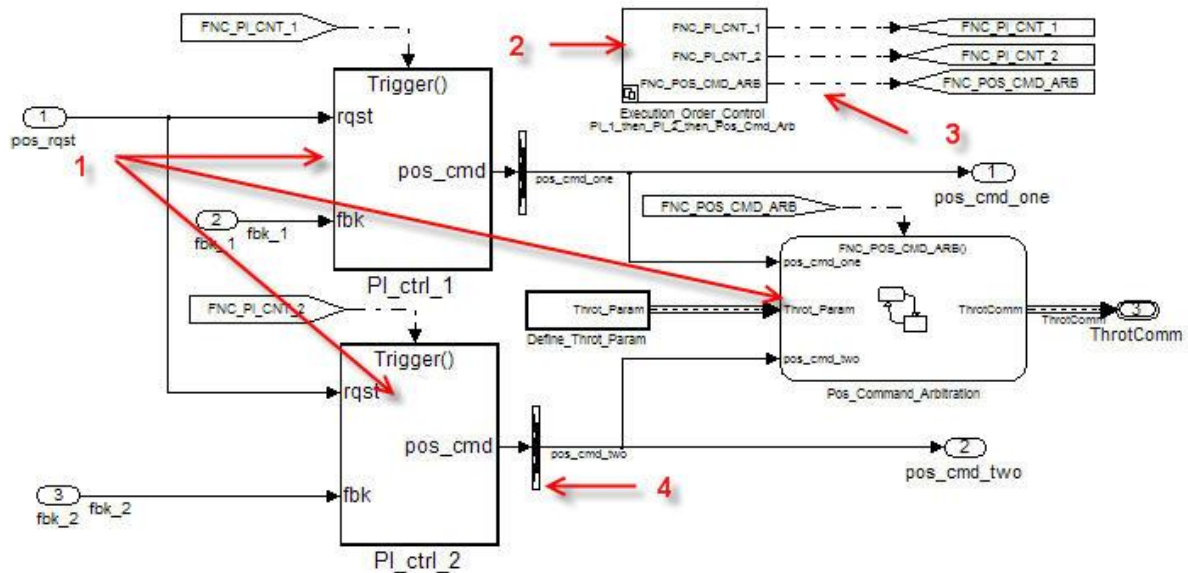

Save a copy of the model to a writable folder.

This example shows how to replace the virtual subsystems with *function-call subsystems*. Function-call subsystems:

- Are atomic subsystems
- Enable you to control subsystem execution order
- Execute when a *function call signal* triggers

By controlling the execution order of the subsystems, you can match the model with an existing system that has a specific execution order.

The figure identifies the function call subsystems (1) PI\_ctrl\_1, PI\_ctrl\_2, and Pos\_Command\_Arbitration.

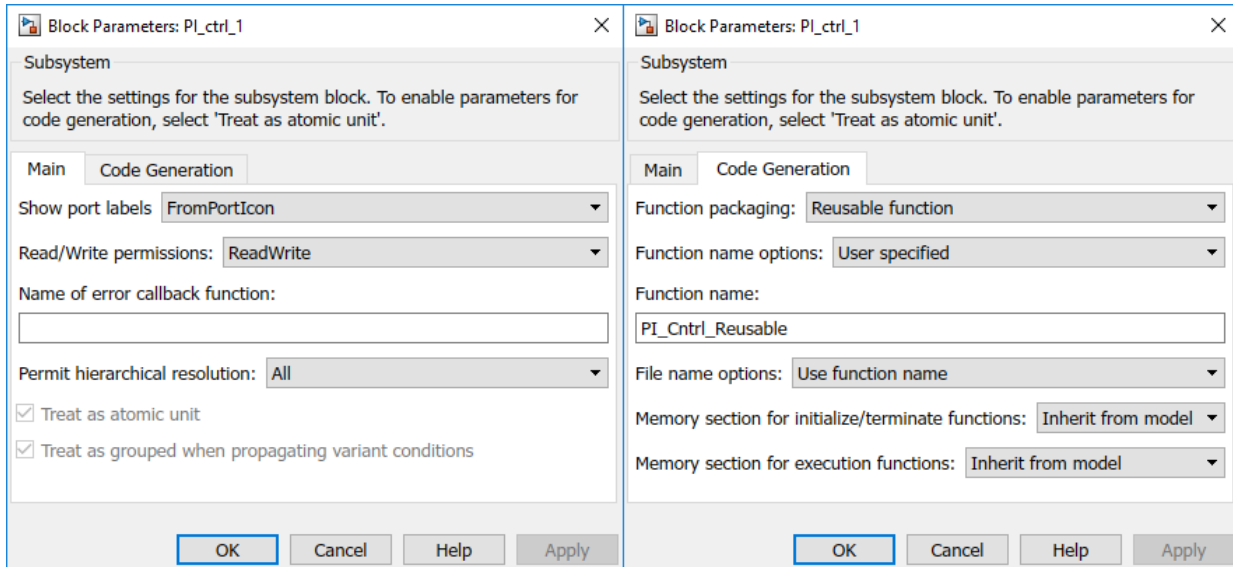

This version of the model contains the new subsystem Execution\_Order\_Control (2), which contains a Stateflow® chart that models the calling functionality of a scheduler. The subsystem controls the execution order of the function call subsystems through function call signals (3). Later in this example, you examine how changing the execution order can change the simulation results.

This version of the model contains new Signal Conversion blocks (4) at the outputs of the PI controllers. With these additional blocks in place, the code generator can generate a single reentrant function for the PI controllers.

### Control Function Location and File Placement in the Generated Code

In “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20 and “Configure Data Interface in the Generated Code” on page 48-35, the code generator creates a single *model\_step* function that contains the control algorithm code. However, many applications require a greater level of control over the file placement of functions. By modifying the parameters of atomic subsystems, you can specify multiple functions within a single model.

The figure shows the subsystem parameters for `PI_ctrl_1`.

### Treat as atomic unit

- Enables other submenus. For atomic subsystems, this parameter is automatically selected and disabled.

### Sample time

- Specifies a sample time for execution. Not available for function-call subsystems.

### Function packaging options

- `Auto` -- Determines how the subsystem appears in the generated code. This value is the default.
- `Inline` -- Places the subsystem code inline with the rest of the model code.
- `Function` -- Generates the code for the subsystem as a function.
- `Reusable function` -- Generates a reusable (reentrant) function from the subsystem. The function passes all input and output data through formal parameters. The function does not directly access global variables.

### Function name options

- Selecting `Function` or `Reusable` function for **Function packaging** enables function name options.
- `Auto` -- Determines the function.
- `Use subsystem name` -- Bases the function on the subsystem name.
- `User specified` -- Applies the specified file name.

### **File name options**

- Selecting `Function` or `Reusable` function for **Function packaging** enables file name options.
- `Auto` -- Places the function definition in the module generated for the parent system, or, if the model root is the parent, in `model.c`.
- `Use subsystem name` -- Generates a separate file. The name of the file is the name of the subsystem or library block.
- `Use function name` -- Generates a separate file. The name of the file is the name that you specify with **Function name options**.
- `User specified` -- Applies the specified, unique file name.

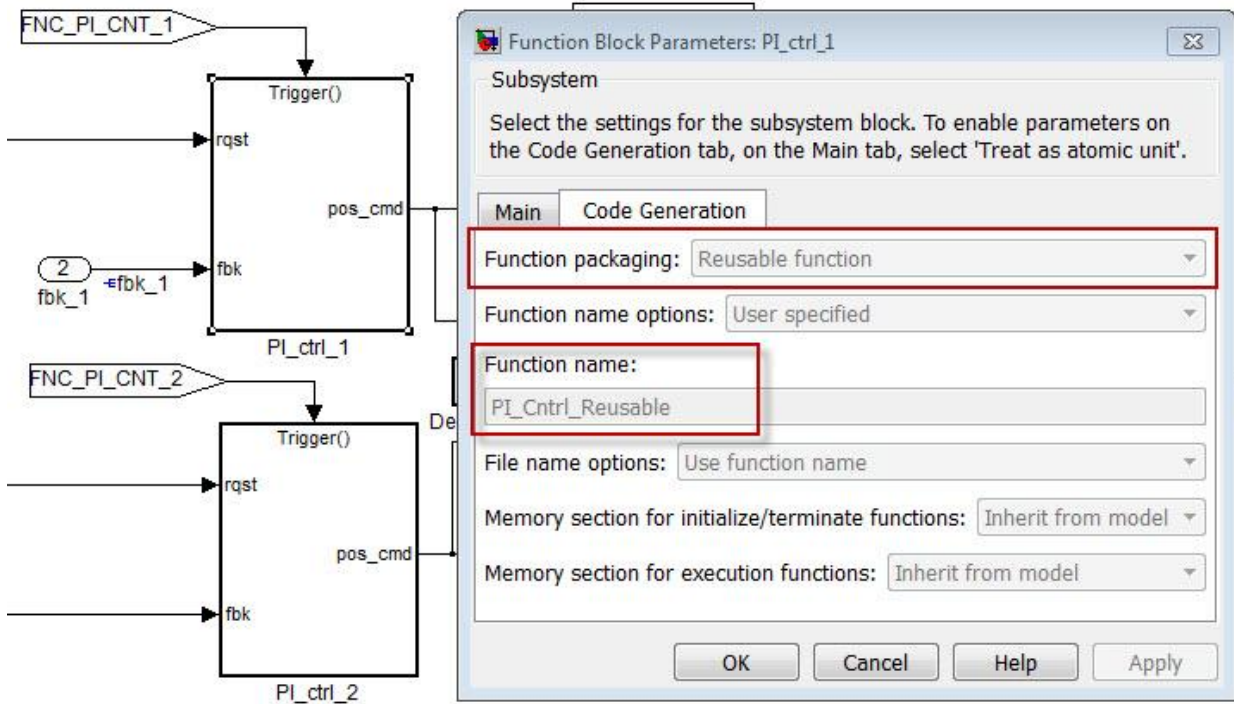

### **Function with separate data**

- Enabled when you set **Function packaging** to `Function`. When selected, the code generator separates the internal data of the subsystem (for example, signals) from the data of the parent model. The subsystem owns this separate data.

### **Generate Reentrant Code**

Embedded Coder® supports *reentrant code*. Reentrant code is a reusable programming routine that multiple programs can use simultaneously. Reentrant code is used in operating systems and other system software that uses multithreading to handle concurrent events. Reentrant code does not maintain state data, so there are no persistent variables in the function. Calling programs maintain state variables and must pass the state data into the function. Multiple users or processes can share one copy of a reentrant function.

To generate reentrant code, you must first specify the subsystem as reusable by configuring the subsystem parameter **Function packaging**.

In some cases, the configuration of the model prevents reusable code. The table lists common issues.

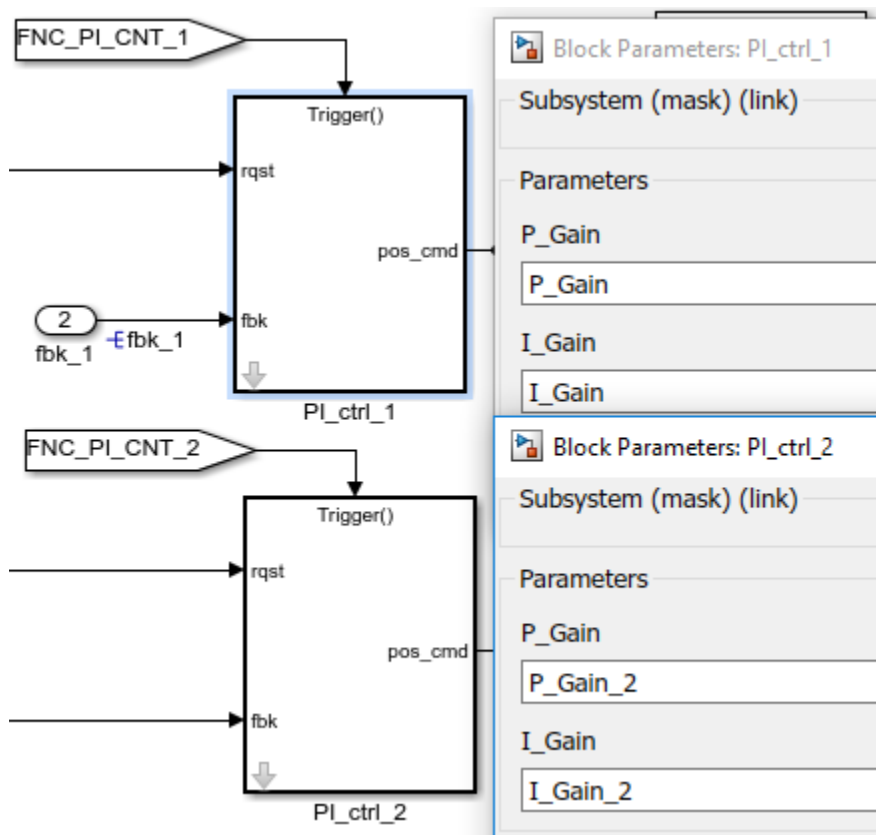

| Cause                                                                 | Solution                                                                                                          |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Subsystem output feeds global signal data                             | Add a Signal Conversion block between the subsystem and the global signal.                                        |
| Generated function receives data (formal parameters) through pointers | Select Configuration Parameters > Model Referencing > Pass fixed-size scalar inputs by value for code generation. |
| Subsystem uses global signal data in internal algorithm               | Use a port to pass the global data in and out of the subsystem.                                                   |

### Use a Mask to Pass Parameter Values into Library Subsystem

To define algorithmic parameter data (such as a gain or coefficient) outside the scope of a reusable library block or subsystem, you can apply a *mask* to the block or subsystem and

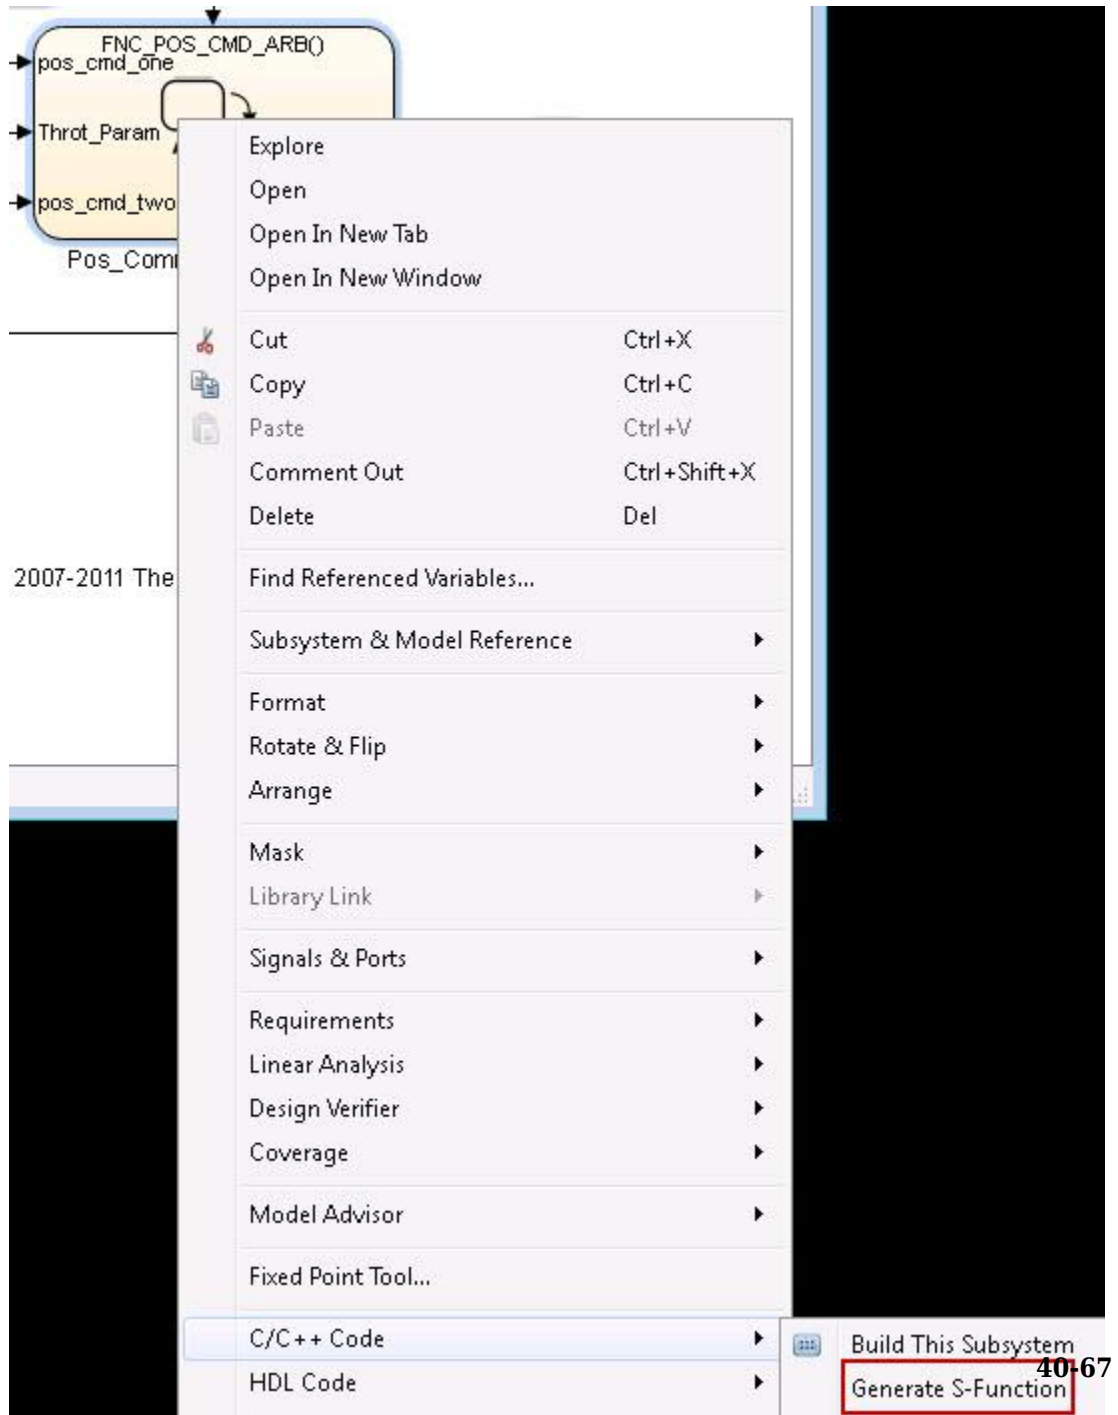

create a mask parameter. You can then specify a different parameter value for each instance of the block or subsystem. Each mask parameter appears in the generated code as a formal parameter of the reentrant function.

In this version of the model, the subsystems `PI_ctrl_1` and `PI_ctrl_2` are masked. In each mask, the values of the P and I gains are set by data objects such as `I_Gain_2` and `P_Gain_2`.

### Generate Code for Atomic Subsystem

In “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20 and “Configure Data Interface in the Generated Code” on page 48-35, you generate code at the root level of the model. Alternatively, you can build a specific subsystem.

To initiate a subsystem build, use the context menu. You can choose from these options:

- 1 Build This Subsystem:** Treats the subsystem as a separate mode and creates the full set of source C files and header files. This option does not support function-call subsystems.
- 2 Generate S-Function:** Generates C code for the subsystem and creates an S-Function wrapper. You can then simulate the code in the original model. This option does not support function-call subsystems.
- 3 Export Functions:** Generates C code without the scheduling code that comes with the **Build This Subsystem** option. Use this option to build subsystems that use triggers, such as function-call subsystems.

Alternatively, select the subsystem and on the **C Code** tab, click **Build**.

### **Examine Generated Code**

This example compares the files that are generated for the full system build with the files that are generated for exported functions. You also examine how the masked data appears in the code.

Run the build script for the three options. Then, examine the generated files by clicking the hyperlinks.

- 1** Generate code from the entire model.
- 2** Export the function `PI_ctrl_1`.
- 3** Export the function `Pos_Command_Arbitration`.

#### **rtwdemo\_PCG\_Eval\_P3.c**

- Full Build: Yes, Step function
- `PI_ctrl_1`: No
- `Pos_Command_Arbitration`: No

#### **PI\_ctrl\_1.c**

- Full Build: No
- `PI_ctrl_1`: Yes, Trigger function
- `Pos_Command_Arbitration`: No

#### **Pos\_Command\_Arbitration.c**

- Full Build: No
- PI\_ctrl\_1: No
- Pos\_Command\_Arbitration: Yes, Init and Function

### **PI\_Ctrl\_Reusable.c**

- Full Build: Yes
- PI\_ctrl\_1: Yes
- Pos\_Command\_Arbitration: No

### **ert\_main.c**

- Full Build: Yes
- PI\_ctrl\_1: Yes
- Pos\_Command\_Arbitration: Yes

### **eval\_data.c**

- Full Build: Yes(1)
- PI\_ctrl\_1: Yes(1)
- Pos\_Command\_Arbitration: No, Eval data not used in diagram

(1) `eval_data.c` has different content in the full and export function builds. The full build includes all of the parameters that the model uses. The export function contains only the variables that the subsystem uses.

### **Masked Data in the Generated Code**

In the file `rtwdemo_PCG_Eval_P3.c`, the call sites of the reentrant function use the data objects `P_Gain`, `I_Gain`, `P_Gain_2`, and `I_Gain_2` as arguments.

```
PI_Cntrl_Reusable(*pos_rqst, fbk_1, &rtwdemo_PCG_Eval_P3_B->PI_ctrl_1,
                 &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_1, I_Gain, P_Gain);
PI_Cntrl_Reusable(*pos_rqst, fbk_2, &rtwdemo_PCG_Eval_P3_B->PI_ctrl_2,
                 &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_2, I_Gain_2, P_Gain_2);
```

### **Effect of Execution Order on Simulation Results**

By default, Simulink® executes the subsystems in this order:

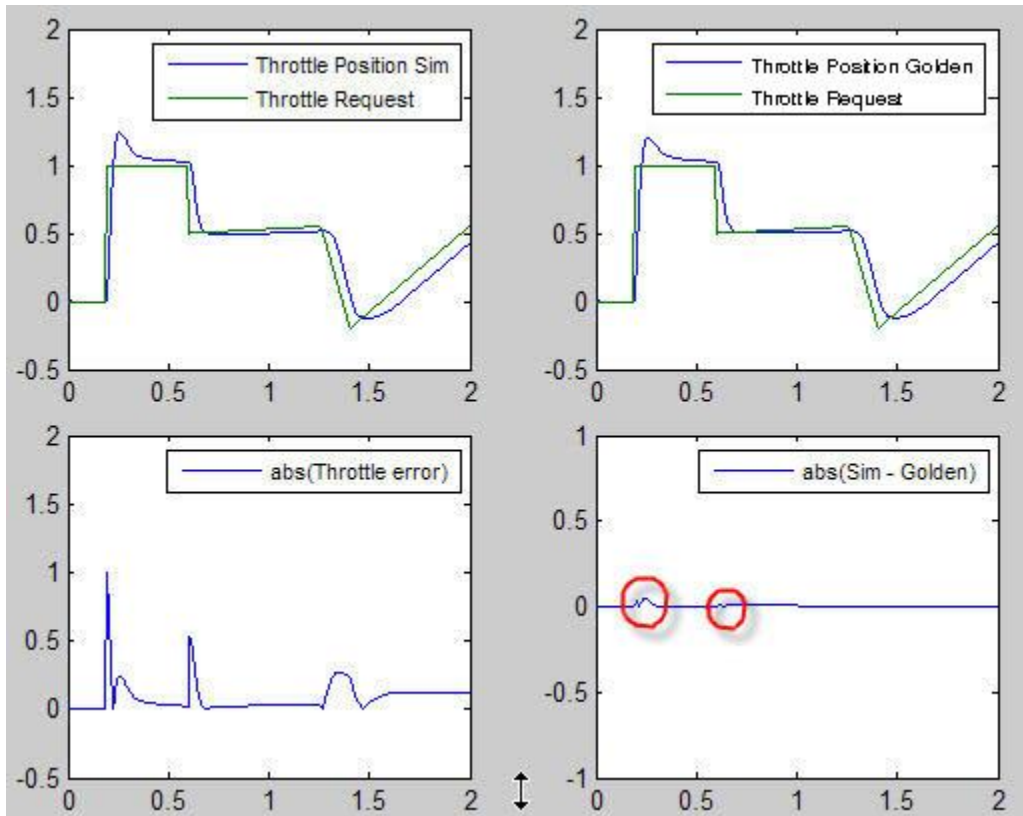

- 1** PI\_ctrl\_1
- 2** PI\_ctrl\_2
- 3** Pos\_Command\_Arbitration

For this example, you can specify one of two alternative orders of execution. You can then use the test harness to observe the effect of the execution order on the simulation results. The subsystem `Execution_Order_Control` has two configurations that control the execution order. To choose a configuration, use the subsystem context menu.

Change the execution order and observe the results.

- 1** Set the execution order to `PI_ctrl_1`, `PI_ctrl_2`, `Pos_Command_Arbitration`.
- 2** Open the test harness.
- 3** Run the test harness.
- 4** Change the execution order to `Pos_Command_Arbitration`, `PI_ctrl_1`, `PI_ctrl_2`.
- 5** Run the test harness.

The simulation results (throttle position over time) vary slightly depending on the order of execution. You can see the difference most clearly when the throttle request changes.

For the next example in this series, see “Call External C Code from Model and Generated Code” on page 48-60.

## Nonvirtual Subsystem Modular Function Code Limitations

Nonvirtual subsystem block parameter **Function with separate data** has the following limitations:

- The parameter is available for models configured with an ERT-based system target file.
- The nonvirtual subsystem to which the parameter is applied cannot have multiple sample times or continuous sample times; that is, the subsystem must be single-rate with a discrete sample time.

- The nonvirtual subsystem cannot contain continuous states.
- The nonvirtual subsystem cannot output function call signals.
- The nonvirtual subsystem cannot contain noninlined S-functions.
- The generated files for the nonvirtual subsystem will reference model-wide header files, such as *model.h* and *model\_private.h*.
- The parameter is incompatible with the **Classic call interface** parameter. Selecting both parameters generates an error.
- The parameter is incompatible with the `Reusable function` setting for model configuration parameter **Code interface packaging**. Selecting both parameters generates an error.
- When you select the parameter for a subsystem, the model that contains the subsystem cannot contain a Data Store Memory block with **Share across model instances** selected. See Data Store Memory.

- “Design Models for Generated Embedded Code Deployment” on page 1-2

## Generate Reentrant, Multi-Instance Code

This example shows you how to configure a model for reentrant, multi-instance code generation. Multiple programs can use reentrant code simultaneously. When you configure a model for reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures. After examining the configuration settings, generate and review the generated code.

### Open the Model

Open the model `rtwdemo_reusable`. The model contains two root Inport blocks and a root Outputport block.

```
model='rtwdemo_reusable';
open_system(model);
```

Copyright 1994-2016 The MathWorks, Inc.

Save a copy of the model to a writable location.

```
currentDir=pwd;
[~,cgDir] = rtwdemodir();
```

### Examine Relevant Model Configuration Parameter Settings

1. Open the **Embedded Coder** app.
2. Open the Model Configuration Parameters dialog box.
3. Model configuration parameter **System target file** is set to `ert.tlc`. Although you can generate reentrant code for a model configured with **System target file** set to `grt.tlc`, ERT and ERT-based system target files provide more control over how the code passes root-level I/O.

4. Open the **Code Generation > Interface** pane and explore relevant model configuration parameter settings.
  - **Code interface packaging** is set to `Reusable` function. This parameter setting instructs the code generator to produce reusable, multi-instance code.
  - Setting of `Reusable` function displays parameter **Multi-instance code error diagnostic**. That parameter is set to `Error`, indicating that the code generator abort if the model violates requirements for generating multi-instance code.
  - **Pass root-level I/O as** is set to `Part of model data structure`. This setting packages root-level model input and output into the real-time model data structure (`rtModel`), which is an optimized data structure that replaces `SimStruct` as the top-level data structure for a model.
  - **Remove error status field in real-time model data structure** is selected. This parameter setting reduces memory usage by omitting the error status field from the generated real-time model data structure.

### Generate and Review Code

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_reusable  
### Successful completion of build procedure for model: rtwdemo_reusable
```

### Review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_reusable_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_reusable.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_reusable.h` declare model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

### Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework.

1. Include the generated header file by adding directive `#include rtwdemo_reusable.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for the model Outport block.

Input ports:

- `<Root>/In1` of data `real_T` with dimension of 1
- `<Root>/In2` of data `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_reusable_initialize(RT_MODEL *const rtM)`. At startup, call this function once.
- Output and update (step) entry-point function, `void rtwdemo_reusable_step(RT_MODEL *const rtM)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output port:

- `<Root>/Out1` of data type `real_T` with dimension of 1

### Examine the Step Function

Examine the `|rtwdemo_reusable_step|` function code in `|rtwdemo_reusable.c|`.

```
cfile = fullfile(cgDir, 'rtwdemo_reusable_ert_rtw', 'rtwdemo_reusable.c');
rtwdemodbtype(cfile, '/* Model step function', '/* Model initialize function ', 1, 0);
```

```
/* Model step function */
void rtwdemo_reusable_step(RT_MODEL *const rtM)
{
    D_Work *rtDWork = ((D_Work *) rtM->dwork);
    ExternalInputs *rtU = (ExternalInputs *) rtM->inputs;
    ExternalOutputs *rtY = (ExternalOutputs *) rtM->outputs;
```

```
/* Outport: '<Root>/Out1' incorporates:  
 * UnitDelay: '<Root>/Delay'  
 */  
rtY->Out1 = rtDWork->Delay_DSTATE;  
  
/* Gain: '<Root>/Gain' incorporates:  
 * Inport: '<Root>/In1'  
 * Inport: '<Root>/In2'  
 * Sum: '<Root>/Sum'  
 * UnitDelay: '<Root>/Delay'  
 */  
rtDWork->Delay_DSTATE = (rtU->In1 + rtU->In2) * rtP.k1;  
}
```

The code generator passes model data to the `rtwdemo_reusable_step` function as part of the real-time model data structure. Try different settings for model configuration parameters **Code interface packaging** and **Pass root-level I/O** and regenerate code. Observe how the function prototype changes.

### Close the Model and Report

Close the model and the code generation report.

```
bdclose(model)  
rtwdemoclean;  
cd(currentDir)
```

## Generate Code for String Blocks by using the Standard C++ String Library

Optimize generated code for Simulink string blocks by using standard C++ library string functions and string objects. The C++ string library provides consistent C++ code and improves functionality, such as string length retrieval, concatenation, string copy, string swapping, string comparison, and substring computations.

### Example Model

In the model `matlab:mStrfindSubStr`, a string constant block that has the value "Hello!" connects to the `str` port of a String Find block. An inport connects to the `sub` port of the same String Find block.

```
model = 'mStrfindSubStr';
open_system(model);
```

In your system's temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

### Generate Code by using C++ String Libraries

In the Configuration Parameters dialog box, set the **Language** parameter to C++.

```
set_param(model, 'TargetLang', 'C++');
```

In the Configuration Parameters dialog box, set the **Code interface packaging** parameter to C++ class.

```
set_param(model, 'CodeInterfacePackaging', 'C++ class');
```

In the Configuration Parameters dialog box, set the **Standard math library** parameter to C++03 (ISO).

```
set_param(model, 'TargetLangStandard', 'C++03 (ISO)');
```

Through the UI or at the command line, set these parameters:

- Turn off **Use dynamic memory allocation for model block instantiation**.
- Turn off **Use dynamic memory allocation for model initialization**.
- Turn on **Remove root level I/O zero initialization**.
- Turn on **Remove internal data zero initialization**.

```
set_param(model, 'UseOperatorNewForModelRefRegistration', 'off');  
set_param(model, 'GenerateAllocFcn', 'off');  
set_param(model, 'ZeroExternalMemoryAtStartup', 'off');  
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
```

Build the model.

```
evalc('rtwbuild(model)');
```

View the generated code with C++ string library objects. Here is a portion of `mStrfindSubStr.h`. The code instantiates a `std:string` object `In1`.

```
cfile = fullfile(cgDir, 'mStrfindSubStr_ert_rtw', 'mStrfindSubStr.h');  
rtwdemodbtype(cfile, 'External inputs', 'External outputs', 0, 0);
```

```
typedef struct {  
    std::string In1; // '<Root>/In1'  
} ExtU_mStrfindSubStr_T;
```

View the generated code with C++ string library functions. Here is a portion of `mStrfindSubStr.cpp`. The code uses the `find` function to look for the first character match, which is present in the C++ string library.

```
cfile = fullfile(cgDir, 'mStrfindSubStr_ert_rtw', 'mStrfindSubStr.cpp');  
rtwdemodbtype(cfile, 'Model step function', 'Model initialize function', 0, 0);
```

```
void untitled1ModelClass::step()  
{
```

```

uint32_T tmpOut;

// StringFind: '<Root>/String Find' incorporates:
//   Inport: '<Root>/In1'
//   StringConstant: '<Root>/String Constant'

tmpOut = mStrfindSubStr_P.StringConstant_String.find(mStrfindSubStr_U.In1);
if (tmpOut == (uint32_T)std::string::npos) {
    // Outport: '<Root>/Out1'
    mStrfindSubStr_Y.Out1 = -1;
} else {
    // Outport: '<Root>/Out1'
    mStrfindSubStr_Y.Out1 = static_cast<int32_T>(tmpOut) + 1;
}

// End of StringFind: '<Root>/String Find'
}

```

This code executes faster and is easier to read. Close the model and the code generation report.

```

bdclose(model);
rtwdemoclean;
cd(currentDir);

```

**Note:** Before selecting the **Remove root level I/O zero initialization** and **Remove internal data initialization** parameters, confirm that your model meets the following conditions:

- If your compiler is not standards-compliant, confirm that it initializes global data to zero.
- Confirm that data is either statically allocated or that dynamically allocated data is initialized to zero.

### Limitations:

1. An array of a bus that contains std:string is not supported in software-in-loop (SIL) and processor-in-loop (PIL) simulations.
2. Code generation that uses the std:string library does not work and the generated code uses C char\_T arrays if:
  - The **Use dynamic memory allocation for model initialization** parameter is enabled.

- The **Use dynamic memory allocation for model block instantiation** parameter is enabled.
- The **Remove root level I/O zero initialization** parameter is disabled in the configuration parameters dialog box.
- The **Remove internal data zero initialization** parameter is disabled in the configuration parameters dialog box.

3. All the aforementioned parameters should match in between a model and any referenced model that may be present.

# Memory Sections in Embedded Coder

---

- “Control Data and Function Placement in Memory by Inserting Pragmas” on page 41-2
- “Protect Global Data with const and volatile Type Qualifiers” on page 41-17

## Control Data and Function Placement in Memory by Inserting Pragmas

For some applications, you can use pragmas and other code decorations to control the placement of data (global variables) and function definitions in memory. For example, a linker configuration file can define named sections in a `SECTIONS` directive and map each section to a range of memory addresses. In the C code, you include pragmas that assign global variables and functions to these named sections and, by extension, to the memory ranges. By controlling memory placement, you can:

- Generate code that is more efficient for your hardware.
- Modularize your application code for easier maintenance and modification later in the development process and after deployment.

With Embedded Coder and memory sections, you can:

- Apply default pragmas or other decorations to categories of model data and entry-point functions. To configure these defaults, use the Code Mapping Editor. For example, you can:
  - Apply a default pragma to internal data, which includes block states that the code generator cannot eliminate through optimizations. You can apply a different default pragma to constant parameters, such as nonscalar parameters that the generated code must store in memory.
  - Apply a default pragma to categories of generated functions, including entry-point functions such as `model_step`.
- Override the default pragmas for individual data items such as block parameters, states, and signals. To do so, create your own storage class.
- Override the default pragmas for individual functions that correspond to atomic subsystems, which you can configure to appear in the generated code as separate functions with separate data. Use the subsystem parameters dialog box.

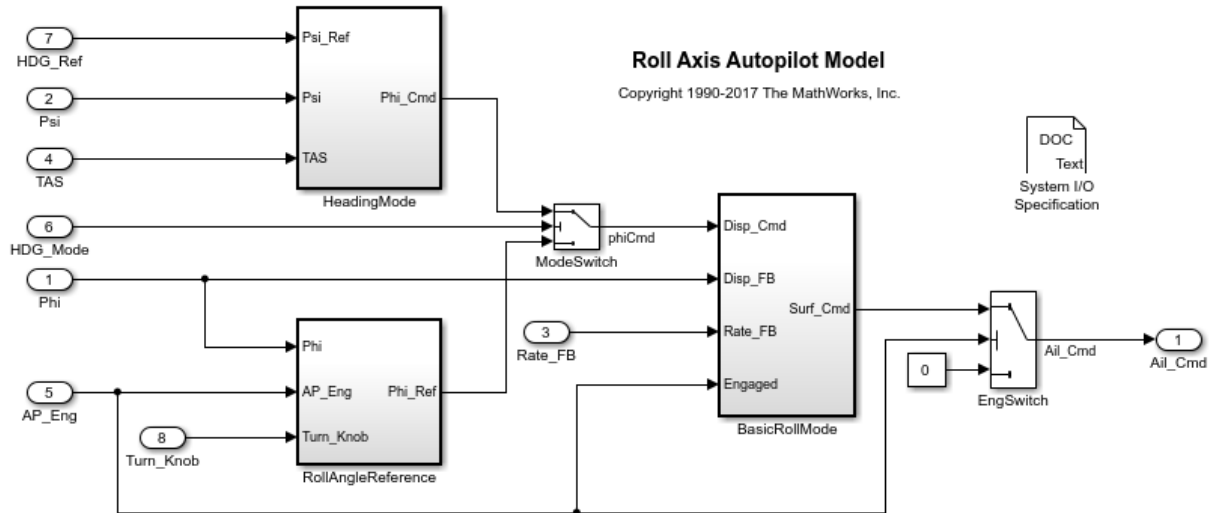

### Insert Pragmas by Using Memory Sections

In this example, you configure the default memory placement for all of the data and functions of the algorithm represented by the example model `rtwdemo_roll`. Then, for some signal data, you override the default placement.

## Explore Example Model and Inspect Default Generated Code

- 1 Open the example model.

```
open_system('rtwdemo_roll')
```

The model is configured to generate efficient production code. For example, the configuration parameter **Default parameter behavior** is set to **Inlined**.

- 2 In the **Apps** gallery, under **Code generation**, click **Embedded Coder**. The **C Code** tab opens. Generate code from the model.
- 3 In the code generation report, inspect the file `rtwdemo_roll.h`. The file defines structure types that represent data that the algorithm needs. For example, the file defines a structure type that represents block states such as the states of Discrete-Time Integrator blocks.

```
/* Block states (default storage) for system '<Root>' */
typedef struct {
    real32_T FixPtUnitDelay1_DSTATE; /* '<S7>/FixPt Unit Delay1' */
    real32_T Integrator_DSTATE; /* '<S1>/Integrator' */
    int8_T Integrator_PrevResetState; /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;
```

The file also declares entry-point functions for the model.

- ```
/* Model entry point functions */
extern void rtwdemo_roll_initialize(void);
extern void rtwdemo_roll_step(void);
```
- 4 Inspect `rtwdemo_roll.c`. This file defines global structure variables to store the data. The file also defines the functions.

In this example, assume your linker configuration file defines named sections `MYALGORITHM_DATA` and `MYALGORITHM_CODE` in a `SECTIONS` directive. You can configure the model so that the generated code includes pragmas, placing the memory allocated for the data and functions in these named sections.

- For a global variable named `myVar`, the pragma syntax is:

```
#pragma SEC_MYALGORITHM_DATA("myVar")

double myVar;
```

- For a function named `myFunction`, the pragma syntax is the same except for the section name:

```
#pragma SEC_MYALGORITHM_CODE("myFunction")

void myFunction(void)
```

### Create Memory Sections

In this example, you use two pragmas with different syntaxes, so you must create two memory sections.

- 1 Underneath the block diagram, under **Code Mappings > Data Defaults**, click the **Embedded Coder Dictionary** icon.
- 2 In the **Embedded Coder Dictionary** dialog box, select the **Memory Sections** tab.
- 3 Click the **Add** button.
- 4 For the new memory section, set these options:
  - **Name** to `MYALGORITHM_DATA`.
  - **Statements Surround** to `Each variable`.
  - **Pre Statement** to `#pragma SEC_MYALGORITHM_DATA("$N")`. The token `$N` stands for the name of each variable that uses the memory section.
- 5 Create another, similar memory section that corresponds to `MYALGORITHM_CODE`.

## Configure Default Pragmas for Data and Functions

- 1 In the model, inspect the **Code Mappings > Data Defaults** tab.
- 2 In the table, select the **Inports** row.
- 3 In the Property Inspector, set **Memory Section** to MYALGORITHM\_DATA.
- 4 For the other rows in the table, set **Memory Section** to MYALGORITHM\_DATA.
- 5 Under **Function Defaults**, for each row in the table, set **Memory Section** to MYALGORITHM\_CODE.
- 6 In your current folder, delete the existing slprj folder.
- 7 Configure the model to generate only code. Select the configuration parameter **Configuration Parameters > Generate code only**.
- 8 Generate code from the model.

Now, the `rtwdemo_roll.c` file applies the pragmas to the definitions of the structure variables and the functions. For each category of data and functions that you configured in the Code Mapping Editor, the code applies a pragma. For example, the code applies the MYALGORITHM\_DATA pragma to each of the structures that store block states, root-level inputs, and root-level outputs.

```
/* Block states (default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_DW")

DW_rtwdemo_roll_T rtwdemo_roll_DW;

/* External inputs (root inport signals with default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_U")

ExtU_rtwdemo_roll_T rtwdemo_roll_U;

/* External outputs (root outports fed by signals with default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_Y")

ExtY_rtwdemo_roll_T rtwdemo_roll_Y;
```

## Retain Default Memory Section After Applying a Default Storage Class or Function Template

In the Code Mapping Editor, you can use the **Storage Class** and **Function Customization Template** columns to control the default appearance of data and functions in the generated code. When you use these columns to apply a setting other than **Default**, the Code Mapping Editor discards the memory section that you applied in the Property Inspector. To retain the memory section, use the Embedded Coder Dictionary to create a storage class or function template, then apply the memory section to that storage class or function template.

In this example, you configure the nonparameter data of the model, such as signals and states, to appear in the same structure by creating a storage class. To retain the MYALGORITHM\_DATA memory section, you apply the memory section to the storage class.

- 1 In the Embedded Coder Dictionary for the model, select the **Storage Classes** tab and click the **Add** button.
- 2 For the new storage class, set:
  - **Name** to STRUCT\_DATA.
  - **Storage Type** to Structured.
  - **Memory Section** to MYALGORITHM\_DATA.
- 3 In the Code Mapping Editor, under **Data Defaults**, in the **Storage Class** column, select STRUCT\_DATA for all of the rows except:
  - **External parameter objects**
  - **Model parameters**
  - **Global data stores**
  - **Constants**
- 4 Generate code from the model.
- 5 Inspect rtwdemo\_roll.c. Now, the file defines a single structure variable that contains the nonparameter data, applying the pragma to that variable.

```
/* Storage class 'STRUCT_DATA' */  
#pragma SEC_MYALGORITHM_DATA("STRUCT_DATA_rtwdemo_roll")  
  
rtwdemo_roll_STRUCT_DATA STRUCT_DATA_rtwdemo_roll;
```

### **Retain Default Memory Section After Directly Applying a Storage Class**

To override the default storage classes that you specify in **Code Mappings > Data Defaults**, you can apply a storage class directly to a data item by using the Model Data Editor. Directly applying any storage class other than Auto or Model default bypasses the default memory section that you specify in **Data Defaults**. To retain the memory section, you must migrate the memory section definition out of the Embedded Coder Dictionary and into a package, which is a folder that can contain storage class and memory section definitions. Then, you can create a storage class in the package, apply the memory section to the storage class, and apply the storage class directly to individual data items in the Model Data Editor.

In rtwdemo\_roll, in the BasicRollMode subsystem, the three Gain blocks represent the parameters of a PID control algorithm. In this example, you configure the output

signals of these blocks so that the generated code allocates memory for them and places the memory in the MYALGORITHM\_DATA section. You also configure the signals so that the code defines them in mySigs.c and declares them in mySigs.h.

To create the memory section and the storage class:

- 1 In your current folder, create a folder named +myPackage. The folder defines a package named myPackage.

To make the package available outside of your current folder, optionally, you can add the folder containing the +myPackage folder to the MATLAB path.

- 2 Open the Custom Storage Class designer.

```
cscdesigner('myPackage');
```

- 3 In the Custom Storage Class Designer, select the **Memory Section** tab.

- 4 Click **New**.

- 5 For the new memory section, set these options, which match the options that you set for MYALGORITHM\_DATA in the Embedded Coder Dictionary:

- **Name** to MYALGORITHM\_DATA.
- **Statements surround** to Each variable.
- **Pre statement** to #pragma SEC\_MYALGORITHM\_DATA("\$N").

- 6 Click **Apply** and **Save**.

- 7 In the myPackage package folder, create a folder named @Signal.

- 8 In the @Signal folder, create a file named Signal.m.

```
classdef Signal < Simulink.Signal

    methods

        function setupCoderInfo(h)
            useLocalCustomStorageClasses(h, 'myPackage');
        end

        function h = Signal()
            % SIGNAL Class constructor.
        end % End of constructor

    end % methods
end % classdef
```

The file defines a class named myPackage.Signal, which is derived from the built-in class Simulink.Signal. The class definition overrides the setupCoderInfo

method, which the `Simulink.Signal` class already implements. The new implementation specifies that objects of the `myPackage.Signal` class use custom storage classes from the `myPackage` package instead of custom storage classes from the built-in `Simulink` package.

- 9 Set your current folder to the folder that contains the `+myPackage` folder.
- 10 In the Custom Storage Class Designer for `myPackage`, select the **Custom Storage Class** tab.
- 11 Click **New**.
- 12 For the new custom storage class, set these properties:
  - **Name** to `myCSC`.
  - Clear **For parameters**.
  - **Memory section** to `MYALGORITHM_DATA`.
  - **Data scope** to `Exported`.
  - **Header file** to `mySigs.h`.
  - **Definition file** to `mySigs.c`.
- 13 Click **Apply** and **Save**.

To apply the storage class in the model:

- 1 In the model, on the **Modeling** tab, select **Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- 3 In the Model Explorer toolbar, click the arrow next to the **Add Signal** button and select **Customize class lists**.
- 4 In the **Customize class lists** dialog box, under **Signal classes**, select the check box next to `myPackage.Signal` and click **OK**.
- 5 In the Model Explorer, click the arrow next to **Add Signal** again and select **myPackage Signal**. A `myPackage.Signal` object appears in the base workspace.
- 6 Delete the `myPackage.Signal` object from the base workspace. Now, when you use the Model Data Editor to apply storage classes to signals, you can choose storage classes from the `myPackage` package.
- 7 In the model, navigate into the `BasicRollMode` subsystem.
- 8 Underneath the block diagram, select the **Model Data Editor > Signals** tab.
- 9 In the model, select the three Gain blocks.
- 10 In the Model Data Editor, in the data table, for any of the highlighted rows, set **Storage Class** to `myCSC`.
- 11 Generate code from the model.

- 12** Inspect the generated file `mySigs.c`. The file defines the global variables that correspond to the Gain block outputs in the model. The pragma applies to the definitions.

```
/* Definition for custom storage class: myCSC */
#pragma SEC_MYALGORITHM_DATA("DispGain")

real32_T DispGain;

#pragma SEC_MYALGORITHM_DATA("IntGain")

real32_T IntGain;

#pragma SEC_MYALGORITHM_DATA("RateGain")

real32_T RateGain;
```

Now, two definitions of the `MYALGORITHM_DATA` memory section exist: One in the Embedded Coder Dictionary and one in `myPackage`. When you make changes to the memory section, make the same changes for each definition.

## Configure Pragma to Surround Groups of Definitions

If your build toolchain requires that a pragma or other decoration surround multiple definitions of variables or functions at once, in an Embedded Coder Dictionary or the Custom Storage Class Designer, set **Statements surround** to `Group of variables` (the default in the Custom Storage Class Designer).

## Override Default Memory Placement for Individual Data Elements

After you configure memory section defaults in the Code Mapping Editor (see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 32-7), to override these default settings for individual data elements (signals, parameters, and states), create a storage class and any required memory sections by using the Custom Storage Class Designer. In the Designer, when you create the storage class, set the **Memory section** property to the appropriate memory section. Then, use the Model Data Editor to apply the storage class to individual data elements.

## Choose Where to Create and Store Memory Section Definition

To define a memory section, you must choose where to create it: in an Embedded Coder Dictionary or in a package (by using the Custom Storage Class Designer).

- If you need to use the memory section only in the Code Mapping Editor, define the memory section in an Embedded Coder Dictionary.
- If you need to use the memory section outside of the Code Mapping Editor, for example, in the Model Data Editor, define the memory section in a package.

Optionally, you can enable use of the package memory section in the Code Mapping Editor by loading the package into an Embedded Coder Dictionary (see “Refer to Code Generation Definitions in a Package”). However, if you create storage classes in the dictionary, you cannot apply the package memory section to them. To associate a memory section with storage classes that you define in an Embedded Coder Dictionary and with other storage classes that you define in a package, maintain two definitions of the memory section: one in the dictionary and one in the package.

## Share Memory Section Definition Between Models

- If you define the memory section in the Embedded Coder Dictionary of a model, you cannot use the memory section in other models. To share the memory section, migrate the definition to a Simulink data dictionary (sldd). Then, share the dictionary between the target models. For more information, see “Share Embedded Coder Dictionary Definition Between Models” on page 30-17.
- If you define the memory section in a package, any model can use the memory section. Add the folder containing the package folder to the MATLAB path (see “What Is the MATLAB Search Path?” (MATLAB)).

## Share Memory Section Between Packages (Package Memory Sections Only)

Packages can access and use memory sections that are defined in other packages, including custom packages and built-in packages such as Simulink. Only one copy of the memory section exists, in the package that defines it. Other packages refer to the memory section by pointing to it in its original location. Changes to the memory section, including changes to a built-in memory section in later MathWorks product releases, are immediately available in every referencing package.

To configure a package to refer to a memory section that is defined in another package:

- 1 Open the Custom Storage Class Designer. At the command prompt, enter `cscdesigner`.
- 2 Select the **Memory Section** tab.
- 3 Use **Select Package** to select the package in which you want to reference a class or section defined in some other package.
- 4 In the **Memory section definitions** pane, select the existing definition below which you want to insert the reference.
- 5 Click **New Reference**.

A new reference with a default name and properties appears below the previously selected definition. The new reference is selected, and a **Reference** tab appears that shows the reference's initial properties.

- 6 Use the **Name** field to enter a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package.
- 7 Set **Refer to memory section in package** to specify the package that contains the memory section that you want to reference.
- 8 Set **Memory section to reference** to specify the memory section to be referenced.
- 9 Click **OK** or **Apply** to save the changes to memory. To save the changes permanently, click **Save**.

## Control Appearance of Memory Section Drop-Down List (Package Memory Sections Only)

When you apply a package memory section, you select the memory section from a drop-down list. To control the order of the memory sections in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of memory sections in drop-down lists matches the order in the Custom Storage Class Designer.

## Protect Definitions of Package Memory Sections (Package Memory Sections Only)

When you click **Save** in the Custom Storage Class Designer, the Designer saves memory section and custom storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of **Filename**.

You can prevent changes to the memory section definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you need to modify the memory sections by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, while both files exist in the package, the memory sections are protected.

### Override Default Memory Placement for Subsystem Functions and Data

When you use atomic subsystems to partition the generated code into functions (see “Generate Subsystem Code as Separate Function and Files” on page 3-12), you can apply different memory sections to the functions and data of each subsystem. You can also specify that a subsystem not use a memory section.

- To use different memory sections to override the model-level defaults that you set in the Code Mapping Editor, see “Override Memory Section for Atomic Subsystem” on page 41-12.
- To specify that a subsystem not use a memory section (in other words, to prevent the subsystem from inheriting the model-level defaults), see “Specify That Atomic Subsystem Not Use a Memory Section” on page 41-13.

### Override Memory Section for Atomic Subsystem

The memory sections that you specify for a subsystem override the model-level defaults that you set in the Code Mapping Editor. Use this technique to aggregate the data and instruction code for subroutines or subcomponents (represented by subsystems) into different regions of memory. To apply a memory section directly to an atomic subsystem:

- 1 Define the memory sections in a package. You cannot use a memory section that you define in an Embedded Coder Dictionary.
- 2 In the target model, set **Configuration Parameters > Code Generation > Advanced parameters > Memory Sections > Package** to the name of the package. If the package does not appear in the list, click **Refresh package list**.

- 3 Configure the Embedded Coder Dictionary of the model to load the target package as described in “Refer to Code Generation Definitions in a Package”.
- 4 Configure the target subsystem to use the memory section. In the subsystem parameters dialog box, on the **Code Generation** tab:
  - Set **Function packaging** to Nonreusable function or Reusable function (for reentrant code).
  - If you set **Function packaging** to Nonreusable function, to enable configuration of memory sections for the subsystem data, select **Function with separate data**. If you do not select **Function with separate data**, the subsystem data inherit memory sections from the model or, if applicable, a parent subsystem.
  - Use parameters such as **Memory section for initialize/terminate functions** to apply default memory sections to the subsystem functions and data.

### Specify That Atomic Subsystem Not Use a Memory Section

By default, subsystem functions and data inherit the model-level memory sections that you specify for relevant function and data categories in the Code Mapping Editor. For example, if you specify a function customization template for the **Execution** category, and that template carries a memory section, the memory section applies to subsystem execution functions as well as model entry-point execution functions.

To specify that a subsystem not use a memory section:

- 1 In the target model, set **Configuration Parameters > Code Generation > Advanced parameters > Memory Sections > Package** to one of these values:
  - If the Embedded Coder Dictionary of the model does not refer to code generation definitions in a package (see “Refer to Code Generation Definitions in a Package”), set **Package** to **Simulink**.
  - If the Embedded Coder Dictionary of the model refers to a package, set **Package** to that package.
- 2 In the target subsystem, on the **Code Generation** tab, set parameters such as **Memory section for initialize/terminate functions** to **Default**. With this setting, the subsystem does not use a memory section for the data or functions that each parameter represents.

### Limitations and Other Considerations

- The settings that you specify for an atomic, nonreusable subsystem with separate data apply only to the data and functions of that subsystem, not to data in similarly configured child subsystems. Atomic, nonreusable child subsystems with separate data can inherit memory sections from the containing model, not from the parent subsystem.
- If you use **Build This Subsystem** or **Build Selected Subsystem** to generate code for an atomic subsystem that specifies memory sections, the code generator ignores the subsystem-level specifications and uses the model-level specifications instead. For information about building subsystems, see “Generate Code and Executables for Individual Subsystems” (Simulink Coder).

### Create Fewer Custom Storage Classes (Package Memory Sections Only)

In the example “Insert Pragmas by Using Memory Sections” on page 41-2, to apply a memory section to individual signal data items, you create a custom storage class by using the Custom Storage Class Designer. Suppose you want to apply a different memory section to each of the signals. Instead of copying the custom storage class (myCSC) and associating a different memory section with the copy, which results in two very similar custom storage classes, in the Custom Storage Class Designer, for myCSC, set **Memory section** to **Instance specific**. Then, when you apply the custom storage class to a data item, you can choose a memory section for that data item.

### Limitations

- The code generator does not apply memory sections to data that uses these built-in storage classes:
  - ExportedGlobal
  - ImportedExtern
  - ImportedExternPointer
- In the Custom Storage Class Designer, the storage type qualifier that you specify for a memory section by using the **Qualifier** text box affects only data items that use a storage class setting other than these built-in storage classes:
  - ExportedGlobal

- ImportedExtern
- ImportedExternPointer

The code generator omits the qualifier from other data categories.

- When you create a subsystem in a custom block library, you cannot specify memory sections for the subsystem definition in the library. Instead, specify memory sections for the subsystem instances that you place in your models.

## Insert Pragmas for Functions and Data in Generated Code

This model shows how to insert pragmas for functions and data in generated code.

### Explore Example Model

Open the example model.

```
open_system('rtwdemo_memsec')
```

Copyright 1994-2015 The MathWorks, Inc.

### Instructions

- 1 Learn about memory sections by clicking the documentation link in the model.
- 2 View the memory sections in the ECoderDemos package by clicking the button in the model and then selecting the **Memory Sections** tab.

- 3 View the memory sections selected for this model by clicking the button in the model. The model-level settings are also the default settings for atomic subsystems.
- 4 Open the SubSystem Parameters dialog for the subsystems to see the memory section settings for each of the atomic subsystems in the model.
- 5 Generate code by clicking the button in the model. A code generation report is displayed automatically. Inspect the data and function definitions in the .c files and observe how the generated pragmas correspond to the specified memory sections.

- “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-26
- “Protect Global Data with const and volatile Type Qualifiers” on page 41-17
- “Standard Data Structures in the Generated Code” (Simulink Coder)

## Protect Global Data with const and volatile Type Qualifiers

In C, you use the type qualifier `const` to prevent code in an application from assigning a new value to a variable. In an application where an external actor (for example, a hardware device) can manipulate the value of a variable, you use the keyword `volatile` to prevent a compiler from optimizing the assembly code in a way that compromises the integrity of the variable value. You can also use `volatile` to prevent a compiler from eliminating storage for `const` data, such as a parameter that has a value that you want to tune during execution.

- To apply the qualifiers to an individual data item in a model, including a custom structure that you create by using a nonvirtual bus or a parameter structure, apply the appropriate built-in custom storage class directly to the data item. The custom storage class prevents optimizations such as **Default parameter behavior** from eliminating storage for the data item. For an example, see “Type Qualifiers” on page 24-15. For information about optimizations that a directly applied storage class prevents, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-68.

If the built-in custom storage classes do not meet your requirements, you can create your own custom storage class. To make your custom storage class apply the qualifiers, in the Custom Storage Class Designer, set **Memory section** to the appropriate built-in memory section or to a memory section that you create. For more information, see “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-26.

- You can apply the qualifiers to a category of model data by default, such as parameters or states. As you add blocks to a model, new data items in these categories carry the qualifiers that you specify. For more information, see “Configure Default Code Generation for Data” on page 32-8.

If the built-in storage classes do not meet your requirements, you can create your own by using an Embedded Coder Dictionary. In the Dictionary, for your new storage class, select the appropriate check boxes under **Qualifiers**. For more information, see “Create Code Definitions for Use as Default Code Generation Settings” on page 30-2.

## Maintain `const` Correctness for Arguments of Entry-Point Functions

When your external code calls a generated entry-point function and passes `const` data through an argument (formal parameter) of the function, to make the corresponding argument in the function definition `const`, customize the execution (step) entry-point function interface.

- To configure the step entry-point function interface for a model, see “Override Default C Step Function Interface” on page 40-7.
- To configure the step entry-point function interface for a Simulink Function block, see “Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 40-18.

## Incorrect Results or Undefined Behavior When Passing Volatile Data to a Generated Function

The generated code can define and call functions other than model entry-point functions. For example, you can configure an atomic subsystem to appear in the code as a separate function. Also, lookup table blocks, such as n-D Lookup Table, typically yield separate utility functions.

When the generated code defines a function that has an argument (formal parameter), the function definition does not apply `volatile` to the argument. Therefore, when other generated code or your external code calls the function and passes a volatile variable as the value of the argument, the called function implicitly casts away the volatility.

If your application executes the called function while the value of the volatile data changes, the function can yield incorrect results or undefined behavior. In particular, for lookup table data that you prepare for calibration, by applying `const` and `volatile`, make sure that you do not calibrate the data while your application executes the lookup utilities.

# Array Layout

---

## Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks

Simulink® Coder™ supports row-major array layout for code generation. You can integrate existing applications that use row-major array layout with the generated code in row-major array layout. When you switch an existing model with lookup table (LUT) blocks from the column-major array layout to the row-major array layout, it is recommended to convert the LUT blocks from the column-major algorithm to the row-major algorithm. The code generated by using row-major algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

This example shows the workflow of converting a model with LUT blocks from column-major layout to row-major layout to achieve the best performance on a row-major array layout.

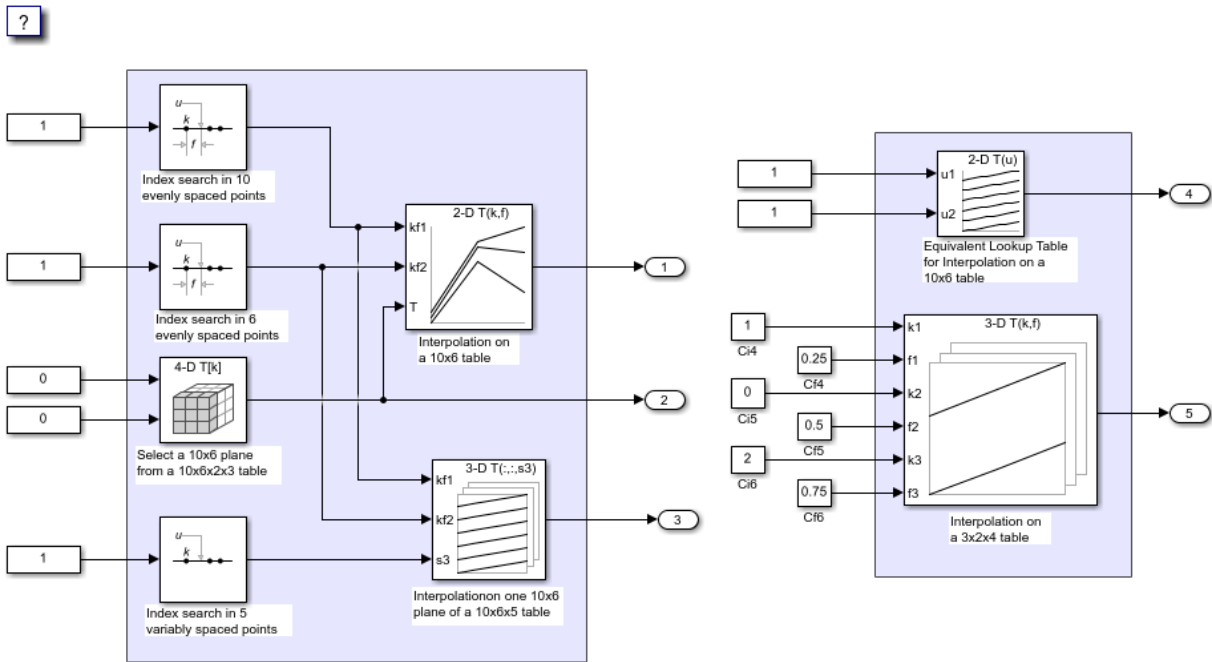

In this example, you:

- Identify the array layout and select the optimized algorithm.
- Preserve semantics through table permutation.
- Generate code by using a row-major algorithm and an array layout.

### Simulate and Generate Code by Using Column-Major Algorithms

1. Open the example model `rtwdemo_row_lutcol2row_workflow`.

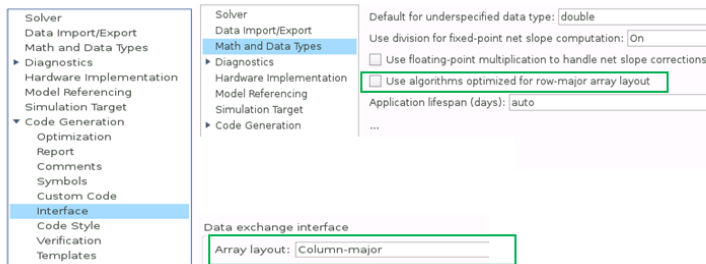

```
open_system('rtwdemo_row_lutcol2row_workflow');
```

Copyright 2018-2019 The MathWorks, Inc.

By default, Simulink configures a model to use column-major algorithms and a column-major array layout. These parameters are the configuration parameters in the Configuration Parameters dialog box.

- Math and Data Types > “Use algorithms optimized for row-major array layout” (Simulink) — This parameter affects simulation and code generation.
- Code Generation > Interface > “Array layout” (Simulink Coder) — This parameter affects only code generation.

2. On the **Modeling** tab, click **Run** to simulate the model and observe the output logged in workspace variable `yout`.

3. Change your current folder in MATLAB® to a writable folder. On the **C Code** tab, click **Build** to generate C code.

### Select Optimized Algorithms for Row-Major Array Layout

Table data with row-major array layout is frequently used in the field of calibration. To interface the row-major table data with the existing model, update the column-major model to operate efficiently on row-major table data.

Use the algorithm that is optimized for the specified array layout to achieve the best performance. For example, use row-major algorithms when **Array layout** is set as Row-major during code generation.

Array Layout	Algorithm	Cache-Friendly Algorithm
Column-major	Column-major	✓ (Recommended)
Row-major	Row-major	✓ (Recommended)
Row-major	Column-major	⚠ (Not recommended)
Column-major	Row-major	⚠ (Not recommended)

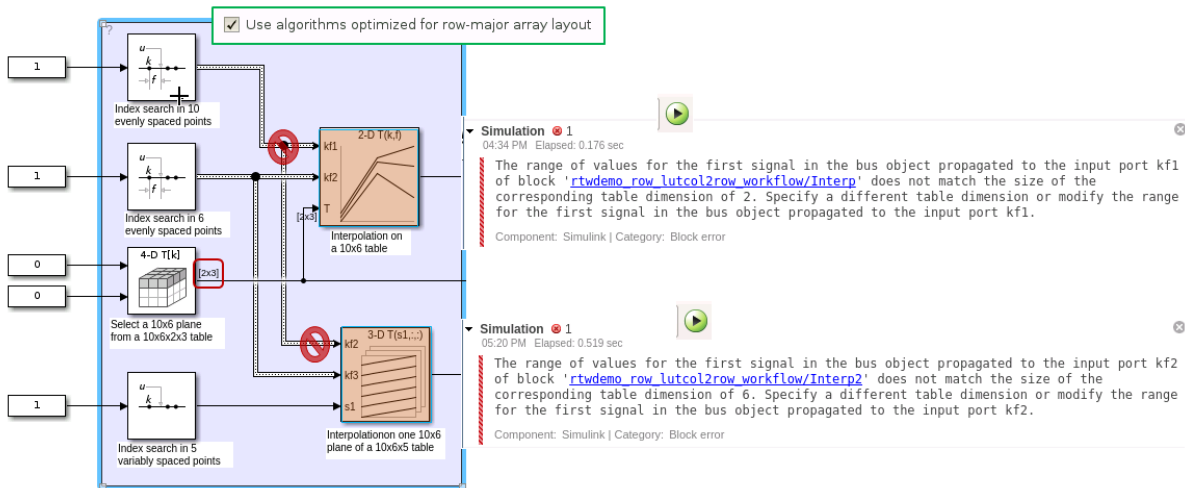

1. To enable row-major algorithms, open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter **Use algorithms**

**optimized for row-major array layout.** Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_row_lutcol2row_workflow', 'UseRowMajorAlgorithm', 'on');
```

2. Click **Run** to simulate the model. Simulink reports errors because it encounters inconsistent breakpoint and table data between prelookup and interpolation blocks. The causes of this error are the two semantic changes that occur when you switch from column-major algorithms to row-major algorithms, that is, when you:

- Select a plane from a 3-D table in interpolation block.
- Select a plane from a 4-D table through a direct lookup table block.

Dimension of the Selected Plane (Semantic Changes)

	Column-major algorithm	Row-major algorithm
Select a plane from a 4-D table (10x6x2x3)	10x6	2x3
Select a plane from a 3-D table (10x6x5)	10x6	6x5

### Preserve Semantics by Using Table Permutation

1. For subtable selection before interpolation, or direct lookup that outputs a vector or 2-D matrix, the model semantics change when you switch from a column-major algorithm to a row-major algorithm by selecting the configuration parameter **Use algorithms optimized for row-major array layout**. To preserve the semantics and fix the previous errors, permute the table data by using these commands:

```
T4d_str = get_param('rtwdemo_row_lutcol2row_workflow/Direct LUT','Table');  
set_param('rtwdemo_row_lutcol2row_workflow/Direct LUT','Table',...  
['permute(' ,T4d_str, ',' ,[3,4,1,2] )']]);
```

```
T3d_str = get_param('rtwdemo_row_lutcol2row_workflow/Interp2','Table');  
set_param('rtwdemo_row_lutcol2row_workflow/Interp2','Table',...  
['permute(' ,T3d_str, ',' ,[3,1,2] )']]);
```

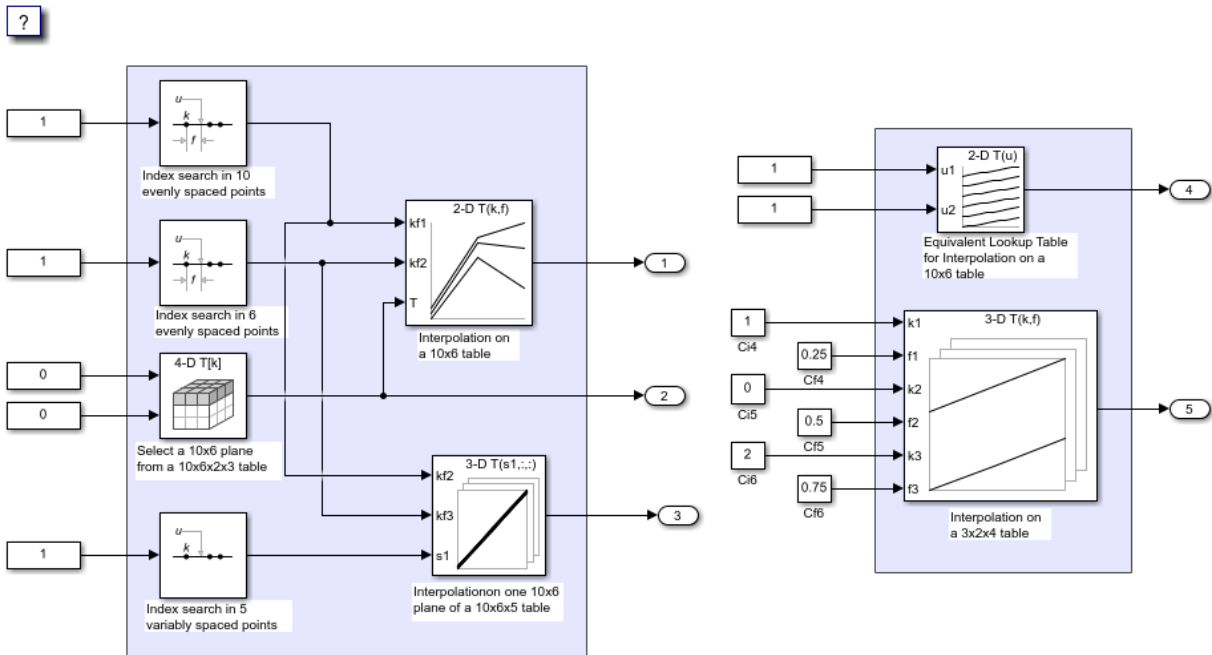

2. Before you import table data from a file, you must permute the table data in the file. This permutation keeps the table tunable throughout the simulation and code generation workflow.

### Code Generation by Using Row-Major Algorithm and Array Layout

After permuting the table data, Simulink configures the model `rtwdemo_row_lutcol2row_workflow` for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_lutcol2row_workflow_rowrow` that has permuted table data and uses a row-major algorithm.

1. Open the example model `rtwdemo_row_lutcol2row_workflow_rowrow`.

```
open_system('rtwdemo_row_lutcol2row_workflow_rowrow');
```

Copyright 2018-2019 The MathWorks, Inc.

2. To set up these models for row-major code generation, open the Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter **Array Layout** to Row-Major option. The **Array Layout** parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
% For model 'rtwdemo_row_lutcol2row_workflow_rowrow'
set_param('rtwdemo_row_lutcol2row_workflow_rowrow', 'ArrayLayout', 'Row-major');
% For model 'rtwdemo_row_lutcol2row_workflow'
set_param('rtwdemo_row_lutcol2row_workflow', 'ArrayLayout', 'Row-major');
```

3. In the block dialog boxes, examine the permuted 3-D table.

Block Parameters: Interp2 ×

**Interpolation\_n-D**

Perform interpolation (or extrapolation) on an n-dimensional table using pre-calculated indices and fraction values.

Use 'Number of table dimensions' and 'Table data' to specify an n-dimensional table that represents a function of 'n' variables.

'Number of subtable selection dimensions' lets you specify that the block interpolates only a subset of table data. If you specify 'k' as its value, the block displays 'n-k' pairs of index and fraction inputs and 'k' subtable selection inputs. Its default value is 0, i.e., interpolate the entire table. Use the selection inputs to specify the indices of the subtable to be interpolated.

You may use Prelookup blocks to compute the index, fraction, and selection inputs.

Main Data Types

**Table data**

Number of dimensions:   Require index and fraction as bus

Specification	Source	Value
<input type="text" value="Explicit values"/>	<input type="text" value="Dialog"/>	<input type="text" value="permute(reshape([1:300], [10,6,5]),[3,1,2])"/> <input type="button" value="Edit..."/>

4. Change your current folder in MATLAB to a writable folder. On the **C Code** tab, click **Build** to generate C code. In the generated code, observe the table data with row-major array layout

```
21 /* Block parameters (default storage) */
22 P rtP = {
23   /* Variable: Tbl_1
24     * Referenced by: '<Root>/2-D Lookup Table'
25     */
26   { 1.0, 11.0, 21.0, 31.0, 41.0, 51.0, 2.0, 12.0, 22.0, 32.0, 42.0, 52.0, 3.0,
27     13.0, 23.0, 33.0, 43.0, 53.0, 4.0, 14.0, 24.0, 34.0, 44.0, 54.0, 5.0, 15.0,
28     25.0, 35.0, 45.0, 55.0, 6.0, 16.0, 26.0, 36.0, 46.0, 56.0, 7.0, 17.0, 27.0,
29     37.0, 47.0, 57.0, 8.0, 18.0, 28.0, 38.0, 48.0, 58.0, 9.0, 19.0, 29.0, 39.0,
30     49.0, 59.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0 }
31 };
```

In the generated code, the memcpy function replaces the for loops. Using memcpy reduces the amount of memory for storing data. This optimization improves execution speed.

```

83 /* Model step function */
84 void rtwdemo_row_lutcol2row_workflow_rowrow_step(void)
85 {
86     uint32_T rtb_Prelookup_Index;
87     real_T rtb_Prelookup_Fraction;
88     uint32_T rtb_Prelookup1_Index;
89     real_T rtb_Prelookup1_Fraction;
90     uint32_T rtb_Prelookup2;
91     real_T frac[2];
92     uint32_T bpIndex[2];
93     real_T frac_0[2];
94     uint32_T bpIndex_0[3];
95     real_T frac_1[3];
96     uint32_T bpIndex_1[3];
97
98     /* LookupNDDirect: '<Root>/Direct LUT'
99      *
100     * About '<Root>/Direct LUT':
101     * 4-dimensional Direct Look-Up returning a 2-D Matrix,
102     * which is contiguous for row-major array
103     */
104    memcpy(&rtY.Out2[0], &rtCP_DirectLUT_table[0], 60U * sizeof(real_T));
105
106    /* PreLookup: '<Root>/PreLookup' incorporates:
107     * Constant: '<Root>/Constant1'
108     */
109    rtb_Prelookup_Index = plook_evenca(1.0, rtCP_Prelookup_BreakpointsData[0],
110    rtCP_Prelookup_BreakpointsData[1] - rtCP_Prelookup_BreakpointsData[0], 9U,
111    &rtb_Prelookup_Fraction);

```

Observe the algorithms optimized for row-major data.

```
17 real_T intrp2d_la(const uint32_T bpIndex[], const real_T frac[], const real_T
18                  table[], const uint32_T stride, const uint32_T maxIndex[])
19 {
20     real_T y;
21     real_T yR_1d;
22     uint32_T offset_1d;
23
24     /* Row-major Interpolation 2-D
25     Interpolation method: 'Linear point-slope'
26     Use last breakpoint for index at or above upper limit: 'on'
27     Overflow mode: 'wrapping'
28     */
29     offset_1d = bpIndex[1U] * stride + bpIndex[0U];
30     if (bpIndex[0U] == maxIndex[0U]) {
31         y = table[offset_1d];
32     } else {
33         y = (table[offset_1d + 1U] - table[offset_1d]) * frac[0U] + table[offset_1d];
34     }
35
36     if (bpIndex[1U] == maxIndex[1U]) {
37     } else {
38         offset_1d += stride;
39         if (bpIndex[0U] == maxIndex[0U]) {
40             yR_1d = table[offset_1d];
41
42         close_system('rtwdemo_row_lutcol2row_workflow',0);
43         close_system('rtwdemo_row_lutcol2row_workflow_rowrow',0);
```

## Interpolation Algorithm for Row-Major Array Layout

This example illustrates the interpolation algorithm in 2-D and 3-D Lookup Table that is optimized for row-major array layout. The interpolation algorithm that is optimized for column-major array layout is also presented as a reference. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major interpolation algorithm performs best with column-major array layout.

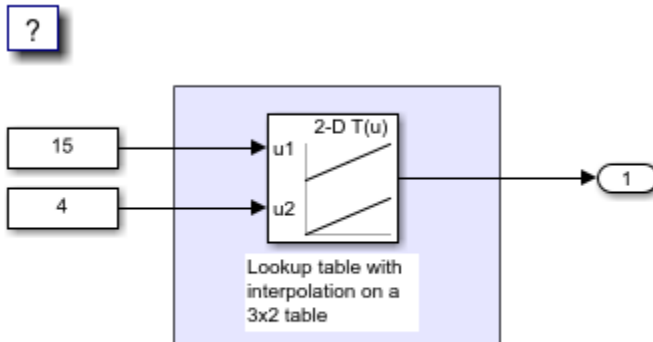

In this example, you:

- Interpolate on a 2-D Lookup Table with column-major and row-major algorithm.
- Generate code with a row-major algorithm and an array layout.
- Identify the array layout and select the optimized algorithm.
- Interpolate on a 3-D Lookup Table with column-major and row-major algorithm.

### Simulate with 2-D Row-Major Algorithm

1. Open the example model `rtwdemo_row_lut2d`.

```
model = 'rtwdemo_row_lut2d';
open_system(model);
```

Copyright 2018-2019 The MathWorks, Inc.

2. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_row_lut2d` is configured to use column-major

algorithm. Simulate the model. To observe the output, open the Data Inspector from the **Simulation** tab. The output value is 4.

3. To enable row-major algorithms, open the Configuration Parameters dialog box. On the **Math and Data Types** pane, enable the configuration parameter “Use algorithms optimized for row-major array layout” (Simulink). Alternatively, in the MATLAB Command Window, enter:

```
set_param(model, 'UseRowMajorAlgorithm', 'on');
```

4. Simulate the model and observe those results in the Data Inspector. The output value is 4.

The column-major and row-major algorithms differ only in the interpolation order. In some cases, due to different operation order on the same data set, you might experience minor numeric differences in the outputs of column-major and row-major algorithms. For the 2-D Lookup Table used in the example model, the interpolation algorithm is illustrated here.

## Generate Code by Using Row-Major Algorithm and Array Layout

The 2-D table data used in model `rtwdemo_row_lut2d` is:

`Table_3by2.Value`

`ans =`

```

     1     4
     2     5
     3     6

```

1. Open the Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter “Array layout” (Simulink Coder) to Row-Major option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
set_param(model, 'ArrayLayout', 'Row-major');
```

2. Change your current folder in MATLAB® to a writable folder. On the **C Code** tab, click **Build** to generate C code.

3. In the generated code, observe the table data with row-major array layout. For comparison, here is the table data in the generated code for column-major array layout.

### 2-D Table with row-major array layout

```

/* Block parameters (default storage) */
P_rtwdemo_row_lut2d_T rtwdemo_row_lut2d_P = {
  /* Variable: Table_3by2
   * Referenced by: '<Root>/2-D Lookup Table'
   */
  { 1.0, 4.0, 2.0, 5.0, 3.0, 6.0 }
};

```

### 2-D Table with column-major array layout

```

/* Block parameters (default storage) */
P_rtwdemo_row_lut2d_T rtwdemo_row_lut2d_P = {
  /* Variable: Table_3by2
   * Referenced by: '<Root>/2-D Lookup Table'
   */
  { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0 }
};

```

In the generated code, the table data is in row-major order and the interpolation algorithm is optimized for row-major array layout. The row-major algorithm operates on table data that is contiguous in memory. This leads to faster cache access, making these algorithms cache-friendly.

This table summarizes the relationship between array layout and cache-friendly algorithms. It is recommended to use the algorithm that is optimized for the specified

array layout to achieve good performance. For example, use row-major interpolation algorithm when the array layout is set to Row-Maj or for code generation.

Array Layout	Algorithm	Cache-Friendly Algorithm
Column-major	Column-major	✓ (Recommended)
Row-major	Row-major	✓ (Recommended)
Row-major	Column-major	⚠ (Not recommended)
Column-major	Row-major	⚠ (Not recommended)

### Interpolation on a 3-D Table

1. Open the example model `rtwdemo_row_interpalg`.

```
open_system('rtwdemo_row_interpalg');
```

Copyright 2018 The MathWorks, Inc.

2. Generate code for the model by using the preceding procedure. Simulate and generate code from the model by repeating the steps performed on `rtwdemo_row_lut2d` model.

The row-major and column-major interpolations on the 3-D table used in the example model are illustrated here.

```
close_system('rtwdemo_row_lut2d',0);
close_system('rtwdemo_row_interpalg', 0);
```

## Interpolation with Subtable Selection Algorithm for Row-Major Array Layout

This example illustrates the algorithm for interpolating a subtable that the interpolation block selects from a higher dimension table. The interpolation algorithm with subtable selection is optimized for row-major array layout. As a reference, see the interpolation algorithm with subtable selection that is optimized for column-major array layout. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

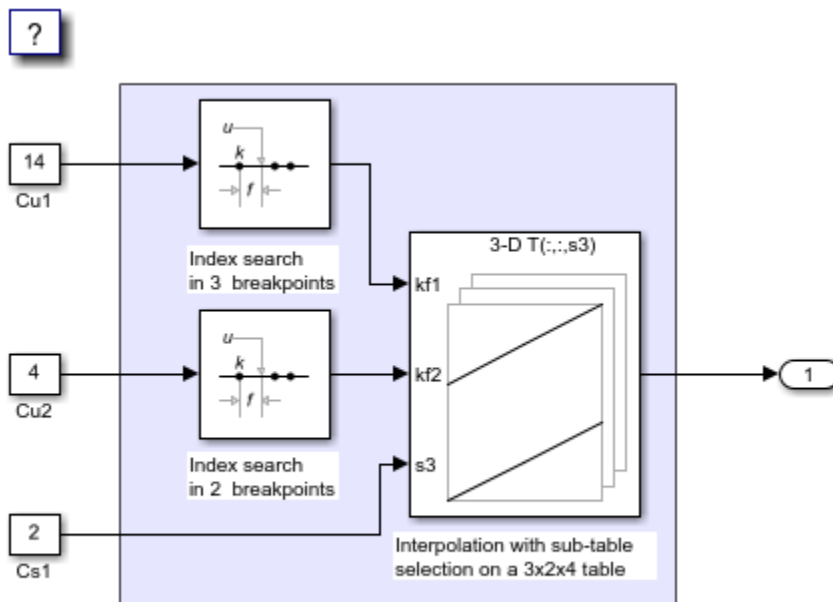

In this example, you:

- Interpolate on a selected subtable with column-major and row-major algorithm.
- Preserve block semantics through table permutation.
- Generate code with row-major algorithm and array layout.

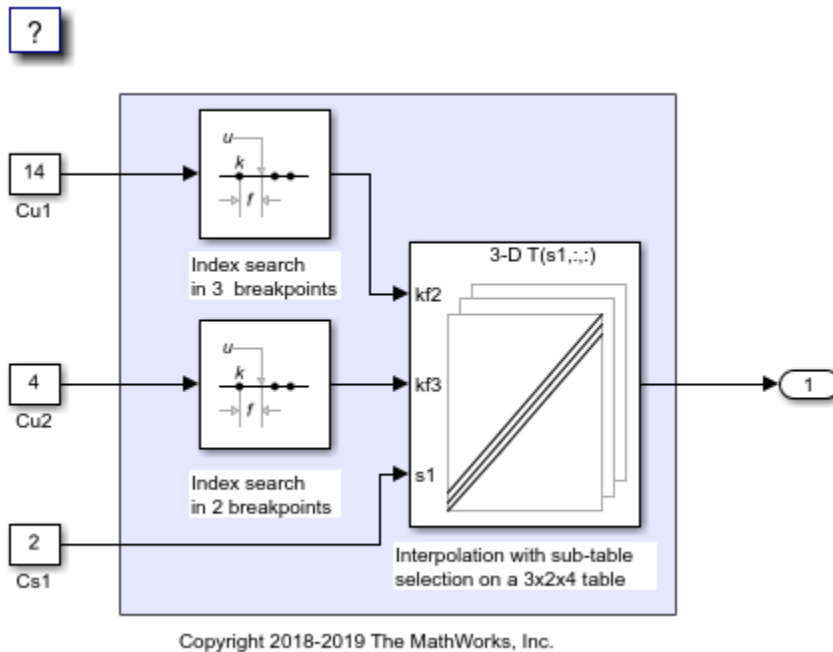

### Simulate by Using Row-Major Algorithm

1. Open example model `rtwdemo_col_interpselsubtable` and `rtwdemo_row_interpselsubtable`.

```
open_system('rtwdemo_col_interpselsubtable');  
open_system('rtwdemo_row_interpselsubtable');
```

Copyright 2018-2019 The MathWorks, Inc.

2. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_col_interpselsubtable` is configured to use a column-major algorithm. Run the model and observe the output stored in workspace variable `yout`.

3. To enable row-major algorithms, open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter “Use algorithms optimized for row-major array layout” (Simulink) Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_col_interpselsubtable', 'UseRowMajorAlgorithm', 'on');
```

4. Simulate the model and observe the error.

The range of values for the first signal in the bus object propagated to the input port kf2 of block '[rtwdemo\\_col\\_interpselsubtable/Interp](#)' does not match the size of the corresponding table dimension of 2. Specify a different table dimension or modify the range for the first signal in the bus object propagated to the input port kf2.

Component: Simulink | Category: Block error

The column-major and row-major algorithms differ in terms of subtable selection and interpolation order. The subtable selection is performed inside the original table. No extra memory is allocated for the subtable. The selected subtable is contiguous in memory. The interpolation order is cache-friendly for column-major algorithms with column-major array layouts and row-major algorithms with row-major array layouts. This illustration compares the row-major and column-major interpolations with subtable selection.

Due to a change in semantics, column-major and row-major interpolations are performed on different subtables or data sets. This interpolation leads to different numeric outputs or an error.

### Preserve Semantics Through Table Permutation

With subtable selection, the model semantics change when switching from a column-major algorithm to a row-major algorithm. To preserve the semantics or ensure that the same subtable is selected for interpolation, you need to permute the table data. Otherwise, Simulink might report error if it encounters inconsistent breakpoint and table data between prelookup and interpolation blocks.

1. The block `rtwdemo_col_interpselectsubtable/Interp` has 3-D table data given as **T3d = reshape([1:24], 3,2,4)** and one selection port with input **2** (0-based index). The selected subtable is **T3d(:, :, 3)** (1-based index in MATLAB) for the column-major algorithm. To preserve the semantics for the row-major algorithm on the same model, that is, select the same subtable with same index and selection port inputs, permute the table as **T3d\_p = permute(T3d, [3,1,2])**. The selected subtable is **T3d\_p(3, :, :)** (1-based index) for the row-major algorithm.

```
T3d_str = get_param('rtwdemo_col_interpselsubtable/Interp','Table');  
set_param('rtwdemo_col_interpselsubtable/Interp','Table', ...  
    ['permute(' ,T3d_str, ', [3,1,2]]')]);
```

2. When you import table data from a file, you must permute the table data in the file before importing it. This permutation keeps the table tunable throughout the simulation and code generation workflow.

### Generate Code by Using Row-Major Algorithm and Array Layout

After permuting the table data, model `rtwdemo_col_interpselsubtable` is configured for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_interpselsubtable` that uses a row-major algorithm.

1. To set up the model for row-major code generation, open the Configuration Parameters dialog box. In addition to selecting the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter “Array layout” (Simulink Coder) to Row-Major option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_col_interpselsubtable', 'ArrayLayout', 'Row-major');
```

2. In the dialog box, examine the permuted 3-D table data and the selected 2-D subtable.

Block Parameters: Interp ×

**Interpolation\_n-D**

Perform interpolation (or extrapolation) on an n-dimensional table using pre-calculated indices and fraction values.

Use 'Number of table dimensions' and 'Table data' to specify an n-dimensional table that represents a function of 'n' variables.

'Number of subtable selection dimensions' lets you specify that the block interpolates only a subset of table data. If you specify 'k' as its value, the block displays 'n-k' pairs of index and fraction inputs and 'k' subtable selection inputs. Its default value is 0, i.e., interpolate the entire table. Use the selection inputs to specify the indices of the subtable to be interpolated.

You may use Prelookup blocks to compute the index, fraction, and selection inputs.

102     Use last breakpoint for index at or above upper limit: 'on'
103     Overflow mode: 'wrapping'
104  */
105  offset_1d = bpIndex[1U] * stride + bpIndex[0U];
106  if (bpIndex[0U] == maxIndex[0U]) {
107    y = table[offset_1d];
108  } else {
109    y = (table[offset_1d + 1U] - table[offset_1d]) * frac[0U] + table[offset_1d];
110  }
111
112  if (bpIndex[1U] == maxIndex[1U]) {
113  } else {
114    offset_1d += stride;
115    if (bpIndex[0U] == maxIndex[0U]) {
116      yR_1d = table[offset_1d];
117    } else {
118      yR_1d = (table[offset_1d + 1U] - table[offset_1d]) * frac[0U] +
119        table[offset_1d];
120    }
121
122    y += (yR_1d - y) * frac[1U];
123  }
124
125  return y;
126 }
```

```
close_system('rtwdemo_col_interpselsubtable',0);
```

## Direct Lookup Table Algorithm for Row-Major Array Layout

This example shows how Simulink selects a vector or a 2-D matrix from table data. In a 2-D table, the output vector can be a column or a row depending on the model configuration setting **Use algorithms optimized for row-major array layout**. In this example, the Direct Lookup Table algorithm is optimized for row-major array layout. The Direct Lookup Table algorithm that is optimized for column-major array layout is also presented as a reference. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

In this example, you:

- Output a vector or a plane by using direct lookup with a column-major or a row-major algorithm.
- Preserve semantics when switching from a column-major algorithm to a row-major algorithm.
- Generate code by using a row-major algorithm and an array layout.

### Simulate by Using Row-Major Algorithm — Output a Vector from 3-D Table

Open example models `rtwdemo_row_dlut3d_selvector` and `rtwdemo_col_dlut3d_selvector`.

```
open_system('rtwdemo_row_dlut3d_selvector');  
open_system('rtwdemo_col_dlut3d_selvector');
```

Copyright 2018-2019 The MathWorks, Inc.

Copyright 2018-2019 The MathWorks, Inc.

1. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_col_dlut3d_selvector` is preconfigured to use column-major algorithms. Simulate the model and observe the output stored in workspace variable `yout`.

2. To enable row-major algorithms, open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter “Use algorithms optimized for row-major array layout” (Simulink) Alternatively, in the MATLAB Command Window, enter:

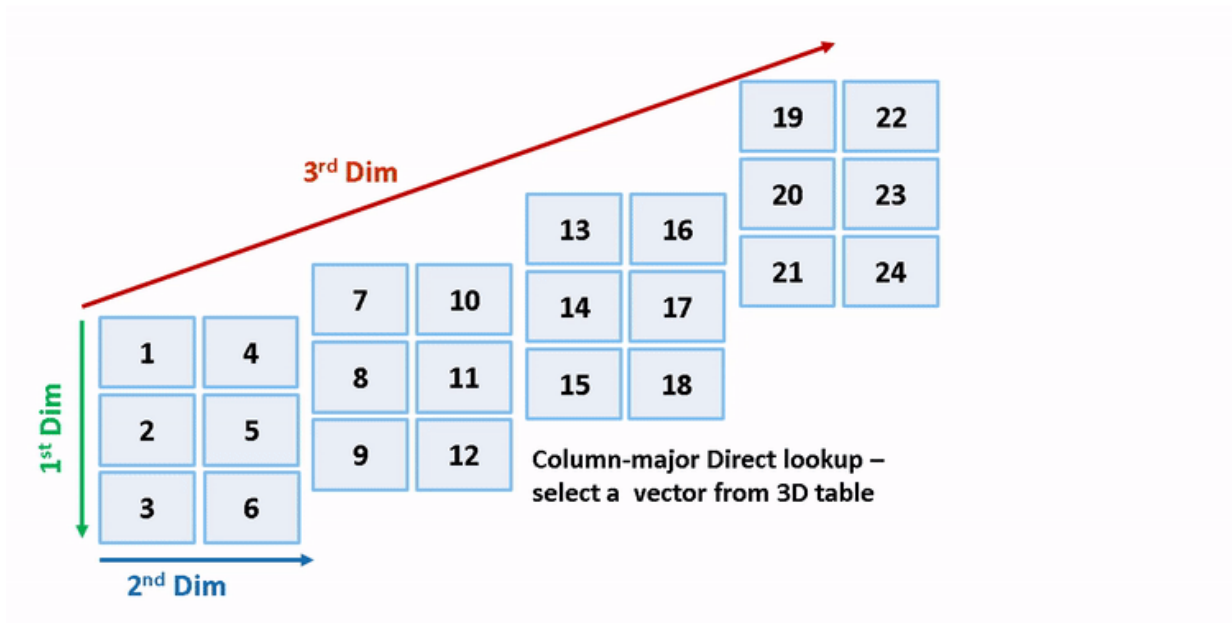

```
set_param('rtwdemo_col_dlut3d_selvector', 'UseRowMajorAlgorithm', 'on');
```

3. On the **Simulation** tab, click **Run** to simulate the model. Observe the change in output dimension and numeric values logged in workspace variable `yout`.

The column-major and row-major algorithms differ semantically in the selection of output vector. For example, in a 2-D table, Simulink selects a column vector as output for column-major algorithm and a row vector for row-major algorithm. In a table with a 3-D or higher dimension, Simulink selects the output vector from the first dimension of the table for a column-major algorithm and from the last dimension of the table for a row-major algorithm. The elements of the selected vector are contiguous in the table storage memory. In this example, the last dimension is the third dimension of the 3-D table. Due to semantic change, column-major and row-major direct lookup table algorithms output different vector size and numeric values.

These illustrations compare the vector output of row-major and column-major direct lookup table algorithms in a 3-D table.

### Preserve Semantics by Using Table Permutation

For a direct lookup table that outputs a vector or 2-D matrix, the model semantics change when you switch from a column-major algorithm to a row-major algorithm. To preserve the semantics or ensure the same output given the same block I/O connections, you must permute the table data. Otherwise, Simulink propagates incorrect dimensions to downstream blocks.

1. The block `rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)` has 3-D table data  $\mathbf{T3d} = \text{reshape}([1:24], 3,2,4)$  and two input ports with value  $\mathbf{0}$  and  $\mathbf{1}$  (both are 0-based indices). The selected output vector is  $\mathbf{T3d}(:,\mathbf{1},\mathbf{2})$  (1-based index) for a column-major algorithm. To preserve the semantics for a row-major algorithm on the same model, that is, select the same vector with same index port inputs, permute the table as  $\mathbf{T3d}_p = \text{permute}(\mathbf{T3d}, [2,3,1])$ . For a row-major algorithm, the selected vector is  $\mathbf{T3d}_p(\mathbf{1},\mathbf{2},:)$ .

```
T3d_str = get_param('rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)', 'Table');
set_param('rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)', 'Table', ...
['permute(' ,T3d_str, ', [2,3,1]')]);
```

2. When you import table data from a file, you must permute the table data in the file before importing it. This permutation keeps the table tunable throughout the simulation and code generation workflow.

### Code Generation by Using Row-Major Algorithm and Array Layout

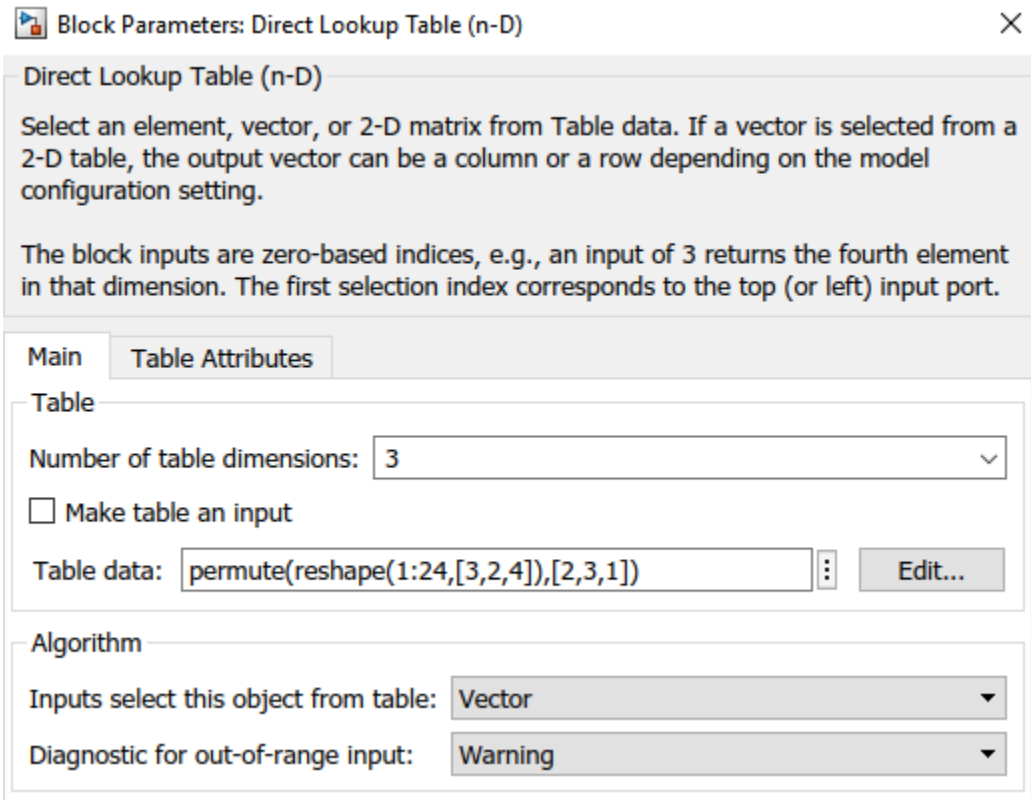

After permuting the table data, Simulink configures the model `rtwdemo_col_dlut3d_selvector` for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_dlut3d_selvector` that has permuted table data and uses a row-major algorithm.

1. To set up these models for row-major code generation, open the Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter “Array layout” (Simulink Coder) to the Row-Major option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
% For model 'rtwdemo_col_dlut3d_selvector'  
set_param('rtwdemo_col_dlut3d_selvector', 'ArrayLayout', 'Row-major');  
% For model 'rtwdemo_row_dlut3d_selvector'  
set_param('rtwdemo_row_dlut3d_selvector', 'ArrayLayout', 'Row-major');
```

2. In the Direct Lookup Table (n-D) block dialog box, examine the permuted 3-D table data.

3. Change your current folder in MATLAB® to a writable folder. On the **C Code** tab, click **Build** to generate C code. In the generated code, the `memcpy` function replaces the `for` loops. Using `memcpy` reduces the amount of memory for storing data. This optimization improves execution speed.

```

34 void rtwdemo_row_dlut3d_selvector_step(void)
35 {
36     /* Outport: '<Root>/Out2' incorporates:
37      * LookupNDDirect: '<Root>/Direct Lookup Table (n-D)'
38      *
39      * About '<Root>/Direct Lookup Table (n-D)':
40      * 3-dimensional Direct Look-Up returning a Vector,
41      * which is contiguous for row-major array
42      */
43     memcpy(&rtY.Out2[0], &rtCP_DirectLookupTablenD_table[3], 3U * sizeof(real_T));
44 }

```

### Simulate by Using Row-Major Algorithm — Output a Plane from 3-D Table

```

open_system('rtwdemo_row_dlut3d_selplane');
open_system('rtwdemo_col_dlut3d_selplane');

```

### Column-Major Algorithm

Copyright 2018 The MathWorks, Inc.

1. Open the example model `rtwdemo_row_dlut3d_selplane` that outputs a plane or 2-D matrix from a 3-D table.
2. Simulate and generate code from the model by repeating the steps performed on `rtwdemo_col_dlut3d_selvector`. The row-major and column-major direct lookup algorithms that output a 2-D matrix from a 3-D table are illustrated here.

```
close_system('rtwdemo_row_dlut3d_selvector',0);
close_system('rtwdemo_col_dlut3d_selvector',0);
close_system('rtwdemo_row_dlut3d_selplane',0);
close_system('rtwdemo_col_dlut3d_selplane',0);
```

## Generate Row-Major Code for S-Functions

You can generate row-major code for models that contain S-functions. By default, the code generator generates column-major code. To learn more about row-major code generation, see “Code Generation of Matrices and Arrays” (Simulink Coder).

For an existing model that contains S-functions, when you set the configuration parameter “Array layout” (Simulink Coder) as Row-major, the configuration parameter “External functions compatibility for row-major code generation” (Simulink Coder) is enabled and set to error by default. When you try to build the existing model, you get an error because the S-functions are not enabled for row-major code generation by default. You can test the compatibility of your S-function for row-major code generation by using the **External functions compatibility for row-major code generation** configuration parameter.

This workflow is also applicable to C Caller blocks in a model.

### Example

1. Open example model `ex_sfcn_rowmajor_unset`. The model needs these additional files:

- S-function: `ex_sfcn_rowmajor.c`
- TLC: `ex_sfcn_rowmajor.tlc`

Save these files to your local folder.

```
open_system('ex_sfcn_rowmajor_unset');
```

2. The model is configured with **Array layout** set to Column-major. To enable row-major code generation, set **Array layout** to Row-major.

3. When you build the model, the code generator terminates the build and you see this error message:

```
### Build procedure for model: 'ex_sfcn_rowmajor_unset' aborted due to an error.
```

```
S-function "ex_sfcn_rowmajor" with SSArrayLayout set to 'SS_UNSET' does not support row major code generation. To test this S-function, set the configuration parameter 'External functions compatibility for row-major code generation' to 'warning' or 'none'.
```

```
Component: Simulink | Category: Block diagram error
```

4. To proceed, do one of the following:

- If you want to test your existing S-functions with the row-major code for the model, change the setting of the configuration parameter **External functions compatibility for row-major code generation** to warning or none. The code generator completes the build without generating row-major code for the S-functions.
- If you want to update your S-functions so that they are compatible with row-major array layout, use the S-function API to enable the S-function for row-major code generation.

To test your model for S-functions with unspecified array layout, you can also run the Model Advisor checks on the model. Select the **Identify TLC S-functions with unset array layout** check and click the **Run This Check** button. If the model includes S-functions with unspecified array layout, you see a warning such as:

**Identify TLC S-Functions with unset array layout**

Analysis (^Triggers Update Diagram)

Identify all TLC S-Functions which have SSArrayLayout set to SS\_UNSET.

Result:  Warning View by

List all S-Functions which have SSArrayLayout set to SS\_UNSET. These S-Functions can have numerical implications in the generated code.

**Warning**

The following TLC S-Functions have SSArrayLayout set to SS\_UNSET whose algorithms need evaluation.

- [ex\\_sfcn\\_rowmajor\\_unset/S-Function](#)

To specify the array layout of the user-defined S-function, use the `ssSetArrayLayoutForCodeGen` function of the SimStruct API. You can set the enumerated type `SSArrayLayout` to:

- `SS_UNSET` - This setting is the default setting that disables the block for row-major code generation.
- `SS_COLUMN_MAJOR` - Specify the block for column-major code generation only.
- `SS_ROW_MAJOR` - Specify the block for row-major code generation only.
- `SS_ALL` - Specify the block as allowed for code generation regardless of the array layout.

5. Update the `ex_sfcn_rowmajor.c` file by adding the `ssSetArrayLayoutForCodeGen` in the `mdlInitializeSizes` method:

```
static void mdlInitializeSizes(SimStruct *S)
{
    /* Specify array layout of the S-function */
    ssSetArrayLayoutForCodeGen(S, SS_ROW_MAJOR);
    .
    .
    .
}
```

If your S-function is not affected by an array layout, set `SSArrayLayout` to `SS_ALL`.

6. Compile the S-function by using this command in the MATLAB Command Window:

```
mex ex_sfcn_rowmajor.c
```

```
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
```

7. To build the model and generate code, press **Ctrl+B**.

If you generate S-functions by using S-Function Builder, use the parameter **Array layout** to specify the majority of the S-function. For more information, see “S-Function Builder Dialog Box” (Simulink). If you use the Legacy Code Tool to integrate C functions, use the `convertNDArrayToRowMajor` option in `legacy_code`. The S-Function Builder and

Legacy Code Tool apply preceding transposes when the S-function is set to row-major array layout during simulation in normal mode.

## Generate Row-Major Code for Model That Contains a MATLAB Function Block

Programming languages and environments assume a single array layout for all data. MATLAB and Fortran use column-major layout by default, whereas C and C++ use row-major layout. With Simulink Coder, you can generate C/C++ code that uses row-major layout or column-major layout.

To learn more about row-major code generation, see “Code Generation of Matrices and Arrays” on page 47-79.

MATLAB Function blocks enable you to define custom functionality in Simulink models by using the MATLAB language. You can generate row-major code for models that contain a MATLAB Function block by using row-major or column-major data. For more information on MATLAB Function blocks, see “Implementing MATLAB Functions Using Blocks” (Simulink).

By default, the code generator generates column-major code. For C/C++ code generation, you can specify the array layout at the model level by using the **Array layout** (Simulink Coder) model configuration parameter. Setting this parameter to `Row-major` enables the model for row-major code generation. To enable the MATLAB Function block in your model for row-major code generation, use the `coder.rowMajor` function at the function level inside the block.

### Row-Major Code Generation

For certain algorithms, row-major layout provides more efficient memory access. You get efficient code when you generate code for a model that uses row-major array layout and the model contains a MATLAB Function block that uses an algorithm for row-major data.

- 1 Consider an example model `ex_row_major_MLFB`.

This model contains a Constant block that has a [5 4] matrix. To specify the matrix, set **Constant value** to:

```
reshape(1:20,5,4)
```

The Inport block also specifies a [5 4] matrix. To specify the matrix, set the **Port dimensions** to [5 4].

- 2 In the Configuration Parameters dialog box, set **Array layout** to Row-major.
- 3 Write a function for matrix addition called `addMatrix`. The MATLAB Function block inherits the array layout setting from the model configuration parameter **Array layout** unless specified otherwise.

Optionally, you can use `coder.rowMajor` to explicitly set the array layout of the MATLAB Function block to row-major layout.

```
function S = addMatrix(A,B)
S = zeros(size(A));
for row = 1:size(A,1)
    for col = 1:size(A,2)
        S(row,col) = A(row,col) + B(row,col);
    end
end
```

- 4 Generate code for the model. From the **C Code** tab, click **Build**.

The code generator produces this C code:

```
for (b_row = 0; b_row < 5; b_row++) {
    for (b_col = 0; b_col < 4; b_col++) {
        rtb_S_tmp = (b_row << 2) + b_col;
        rtb_S[rtb_S_tmp] = ex_row_major_MLFB_P.Constant_Value[rtb_S_tmp] +
            ex_row_major_MLFB_U.Inport1[rtb_S_tmp];
    }
}
```

```
    }
}
```

The generated code has two `for` loops. The first `for` loop accesses the rows and the second `for` loop accesses the columns. When the array layout of the MATLAB Function block and the model is the same, the generated code is efficient because no transposes or conversion are required.

## Mixed-Majority Code Generation

You can generate mixed-majority code when you have a model that operates on row-major data and a MATLAB Function block that operates on column-major data. When you generate code for a model that uses column-major layout, and the model contains a MATLAB Function block that uses row-major layout, then the code generator converts the block input data to row-major and the block output data back to column-major data, as needed. You can also generate mixed majority code when you have a model that operates on column-major data and a MATLAB Function block that operates on row-major data.

Array layout conversions can affect performance.

- 1 Consider the example model `ex_row_major_MLFB`. For more information on the example model, see “Row-Major Code Generation” on page 42-41.

In the Configuration Parameters dialog box, set **Array layout** to `Row-major`.

- 2 Update the `addMatrix` function in the MATLAB Function block for column-major data by using the `coder.columnMajor` function.

```
function S = addMatrix(A,B)
coder.columnMajor;
S = zeros(size(A));
for row = 1:size(A,1)
    for col = 1:size(A,2)
        S(row,col) = A(row,col) + B(row,col);
    end
end
```

You can generate mixed-majority code by using the MATLAB Function block. In this case, you configure the model for row-major array layout and the MATLAB Function block for column-major array layout.

- 3 Generate code for the model. From the **C Code** tab, click **Build**.

The code generator produces this C code:

```
for (b_row = 0; b_row < 4; b_row++) {
    for (b_col = 0; b_col < 5; b_col++) {
        B_tmp = (b_col << 2) + b_row;
        B_tmp_0 = b_col + 5 * b_row;
        B[B_tmp_0] = ex_row_major_MLFB_19b_U.Inport1[B_tmp];
        A[B_tmp_0] = ex_row_major_MLFB_19b_P.Constant_Value[B_tmp];
    }
}

for (b_row = 0; b_row < 5; b_row++) {
    /* Outport: '<Root>/Outport' */
    for (b_col = 0; b_col < 4; b_col++) {
        B_tmp = 5 * b_col + b_row;
        ex_row_major_MLFB_19b_Y.Outport[b_col + (b_row << 2)] = A[B_tmp] + B[B_tmp];
    }
}
```

The inputs to the MATLAB Function block exist in a row-major environment. The code generator performs a conversion operation on inputs before they are fed to the MATLAB Function block because the block is column-major layout. After processing the algorithm in the MATLAB Function block, the code generator converts the data back to row-major data before passing the data to an Outport.

## Code Generation Configuration

When you are ready to generate code for a model, you can modify the model configuration parameters specific to code generation. The code generation parameters determine how the code generator produces code and builds an executable program from your model.

The model configuration parameters for code generation are in the **Code Generation** pane in the Configuration Parameters dialog box. The content of the **Code Generation** pane and its subpanes can change depending on the target that you specify. Some configuration options are available only with the Embedded Coder product.

Your application objectives can include a combination of these code generation objectives: debugging, traceability, execution efficiency, and safety precaution. There are tradeoffs associated with these configuration choices, such as execution speed and memory usage. To help configure a model to achieve your application objectives, use the Model Advisor and the Code Generation Advisor.

### Open the Model Configuration for Code Generation

To modify the model configuration parameters for code generation, open the **Code Generation** pane. There are several different ways to open the **Code Generation** pane from the Simulink editor:

- To open the Configuration Parameters dialog box, click the model configuration parameters icon.

Then, click **Code Generation** in the left pane.

- On the **C Code** tab, select **Settings > Code Generation Settings**.
- On the **Modeling** tab, click **Model Explorer**, or from the MATLAB command line, type `daexplr` and press **Enter**. In the left pane of the Model Explorer, expand the node for the current model and click the Configurations node. In the **Contents** pane, right-click the configuration and select **Open** from the context menu. Then click **Code Generation** in the left pane.

---

**Note** In the Configuration Parameters dialog box, when you change the value of a check box, menu selection, or edit field, the white background of the element changes color to

indicate that you made an unsaved change. When you click **OK**, **Cancel**, or **Apply**, the background resets to white.

## Configuration Tools

To help you configure your model for code generation and to check your configuration against your code generation objectives, Simulink Coder and Embedded Coder provide several tools.

## Configure Code Generation Parameters for Model Programmatically

You can modify code generation parameters for the active configuration set in the Configuration Parameters dialog box or from the MATLAB command line. Use the command-line approach for creating a script that automates setting parameters for an established model configuration.

### Modify Parameters to Support Execution efficiency

In this example, you modify the configuration parameters to support the Code Generation Advisor application objective, Execution efficiency.

#### Step 1. Open a model.

```
slexAircraftExample
```

#### Step 2. Get the active configuration set.

```
cs = getActiveConfigSet(model);
```

#### Step 3. Select the Generic Real-Time (GRT) target.

```
switchTarget(cs, 'grt.tlc', []);
```

#### Step 4. To optimize execution speed, modify parameters.

If your application objective is Execution efficiency, use `set_param` to modify these parameters:

```
set_param(cs, 'MatFileLogging', 'off');  
set_param(cs, 'SupportNonFinite', 'off');  
set_param(cs, 'RTWCompilerOptimization', 'on');  
set_param(cs, 'OptimizeBlockIOStorage', 'on');  
set_param(cs, 'EnhancedBackFolding', 'on');  
set_param(cs, 'ConditionallyExecuteInputs', 'on');  
set_param(cs, 'DefaultParameterBehavior', 'Inlined');  
set_param(cs, 'BooleanDataType', 'on');  
set_param(cs, 'BlockReduction', 'on');  
set_param(cs, 'ExpressionFolding', 'on');  
set_param(cs, 'LocalBlockOutputs', 'on');  
set_param(cs, 'EfficientFloat2IntCast', 'on');  
set_param(cs, 'BufferReuse', 'on');
```

### **Step 5. Save the model configuration to a file.**

Save the model configuration to a file, 'Exec\_efficiency\_cs.m', and view the parameter settings.

```
saveAs(cs, 'Exec_Efficiency_cs');  
dbtype Exec_Efficiency_cs 1:50
```

- “Code Generation Configuration” on page 43-2
- “Application Objectives Using Code Generation Advisor” on page 43-21

## Configure Model from Command Line

The code generator provides model configuration parameters for customizing generated code. Depending on how you use and interact with the generated code, you make configuration decisions. You choose a configuration that best matches your needs for debugging, traceability, code efficiency, and safety precaution.

It is common to automate the model configuration process by using a MATLAB® script once you have decided upon a desired configuration.

The example describes:

- Concepts of working with configuration parameters
- Documentation to understand the code generation options
- Tools and scripts to automate the configuration of a model

### Configuration Parameter Workflows

There are many workflows for Configuration Parameters that include persistence within a single model or persistence across multiple models. Depending on your needs, you can work with configuration sets as copies or references. This example shows the basics steps for working directly with the active configuration set of a model. For a comprehensive description of configuration set features and workflows, see Configuration Sets in the Simulink® documentation.

### Configuration Set Basics

Load a model into memory.

```
model='rtwdemo_configwizard';  
load_system(model)
```

Obtain the model's active configuration set.

```
cs = getActiveConfigSet(model);
```

Simulink® Coder™ exposes a subset of the code generation options. If you are using Simulink® Coder™, select the Generic Real-Time (GRT) target.

```
switchTarget(cs, 'grt.tlc', []);
```

Embedded Coder® exposes the complete set of code generation options. If you are using Embedded Coder®, select the Embedded Real-Time (ERT) target.

```
switchTarget(cs, 'ert.tlc', []);
```

To automate configuration of models built for GRT- and ERT-based targets, the configuration set **IsERTTarget** attribute is useful.

```
isERT = strcmp(get_param(cs, 'IsERTTarget'), 'on');
```

You can interact with code generation options via the model or the configuration set. This example gets and sets options indirectly via the model.

```
deftParamBehvr = get_param(model, 'DefaultParameterBehavior'); % Get
set_param(model, 'DefaultParameterBehavior', deftParamBehvr) % Set
```

This example gets and sets options directly via the configuration set.

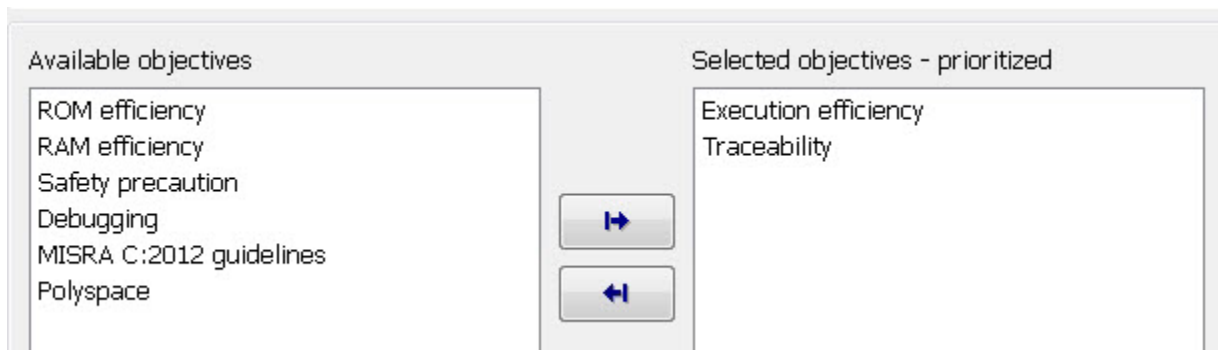

```
if isERT
    lifespan = get_param(cs, 'LifeSpan'); % Get LifeSpan
    set_param(cs, 'LifeSpan', lifespan) % Set LifeSpan
end
```

### Configuration Option Summary

The full list of code generation options are documented with tradeoffs for debugging, traceability, code efficiency, and safety precaution.

- Simulink® Coder™ options
- Embedded Coder® options

Use Code Generation Advisor to obtain a model configuration optimized for your goals. In the Set Objectives dialog box, you can set and prioritize objectives.

You can find documentation about the Code Generation Advisor in the Simulink Coder documentation and additional documentation specific to Embedded Coder®.

### Parameter Configuration Scripts

Simulink® Coder™ provides an example configuration script that you can use as a starting point for your application. A list of the most relevant GRT and ERT code generation options are contained in `rtwconfiguremodel.m`.

Alternatively, you can generate a MATLAB function that contains the complete list of model configuration parameters by using the configuration set `saveAs` function.

`% Go to a temporary writable directory.`

```
currentDir = pwd;
rtwdemodir();
```

`% Save the model's configuration parameters to file 'MyConfig.m'.`

```
saveAs(cs, 'MyConfig')
```

`% Display the first 50 lines of MyConfig.m.`

```
dbtype MyConfig 1:50
```

```
1 function cs = MyConfig()
2 % MATLAB function for configuration set generated on 27-Aug-2019 14:01:16
3 % MATLAB version: 9.7.0.1190202 (R2019b)
4
5 cs = Simulink.ConfigSet;
6
7 % Original configuration set version: 19.1.1
8 if cs.versionCompare('19.1.1') < 0
9     error('Simulink:MFileVersionViolation', 'The version of the target configuration set is older than the current version.')
10 end
11
12 % Original environment character encoding: windows-1252
13 if ~strcmpi(get_param(0, 'CharacterEncoding'), 'windows-1252')
14     warning('Simulink:EncodingUnMatched', 'The target character encoding (%s) is not supported by the current environment.')
15 end
16
17 % Do not change the order of the following commands. There are dependencies between them.
18 cs.set_param('Name', 'Configuration'); % Name
19 cs.set_param('Description', ''); % Description
20
21 % Original configuration set target is ert.tlc
```

```

22     cs.switchTarget('ert.tlc','');
23
24     cs.set_param('HardwareBoard', 'None');    % Hardware board
25
26     cs.set_param('TargetLang', 'C');    % Language
27
28     cs.set_param('CodeInterfacePackaging', 'Nonreusable function');    % Code interface
29
30     cs.set_param('Solver', 'FixedStepDiscrete');    % Solver
31
32     % Solver
33     cs.set_param('StartTime', '0.0');    % Start time
34     cs.set_param('StopTime', '48');    % Stop time
35     cs.set_param('SampleTimeConstraint', 'STIndependent');    % Periodic sample time constraint
36     cs.set_param('SolverType', 'Fixed-step');    % Type
37
38     % Data Import/Export
39     cs.set_param('Decimation', '1');    % Decimation
40     cs.set_param('LoadExternalInput', 'off');    % Load external input
41     cs.set_param('SaveFinalState', 'off');    % Save final state
42     cs.set_param('LoadInitialState', 'off');    % Load initial state
43     cs.set_param('LimitDataPoints', 'off');    % Limit data points
44     cs.set_param('SaveFormat', 'StructureWithTime');    % Format
45     cs.set_param('SaveOutput', 'off');    % Save output
46     cs.set_param('SaveState', 'off');    % Save states
47     cs.set_param('SignalLogging', 'on');    % Signal logging
48     cs.set_param('DSMLogging', 'on');    % Data stores
49     cs.set_param('InspectSignalLogs', 'off');    % Record logged workspace data in Simulink
50     cs.set_param('SaveTime', 'off');    % Save time

```

Each parameter setting in the generated file includes a comment for the corresponding parameter string in the Configuration Parameters dialog box.

```

% Return to previous working directory.
cd(currentDir)

```

### Configuration Wizard Blocks

Embedded Coder® provides a set of Configuration Wizard blocks to obtain an initial configuration of a model for a specific goal. The predefined blocks provide configuration for:

- ERT optimized for fixed point
- ERT optimized for floating point

- GRT optimized for fixed and floating point
- GRT debug settings for fixed and floating point
- Custom (you provide the script)

Put the block into a model and double-click it to configure the model. Open model `rtwdemo_configwizard` and click **Open Configuration Wizard Library** to interact with the blocks.

```
open_system(model)
```

[Open Configuration Parameters](#)

[Open Configuration Wizard Library](#)

Copyright 1994-2019 The MathWorks, Inc.

To use configuration wizard blocks in the `rtwdemo_configwizard` model follow these steps:

- Open the Configuration Wizard Library by clicking the link provided in the model.
- Open the Model's Configuration Parameters by clicking the link provided in the model.
- Drag and drop a Configuration Wizard Block, for example ERT (optimized for fixed point), from the wizard library into the model.
- Double-click the wizard block.

The Configuration Parameter options are modified automatically.

```
% cleanup
rtwdemoclean;
close_system(model,0)
```

### Summary

Simulink provides a rich set of MATLAB functions to automate the configuring a model for simulation and code generation. Simulink Coder and Embedded Coder® provide additional functionality specific for code generation. The Code Generation Advisor optimizes the model configuration based on a set of prioritized goals. You can save the optimal configuration to a MATLAB file by using the configuration set `saveAs` function, and reuse it across models and projects.

- “Application Objectives Using Code Generation Advisor” on page 43-21

## Use Configuration Reference to Select Code Generation Target

This example shows how to use a configuration reference to select a code generation target for a model reference hierarchy without modifying individual models.

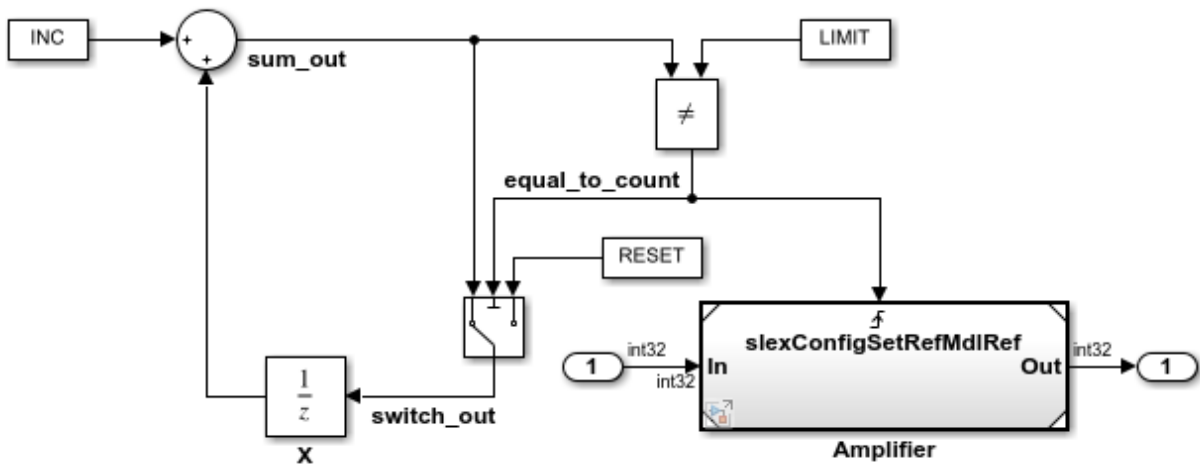

### Open Example Model

Open the example model `slexConfigSetRefExample`.

```
open_system('slexConfigSetRefExample');
```

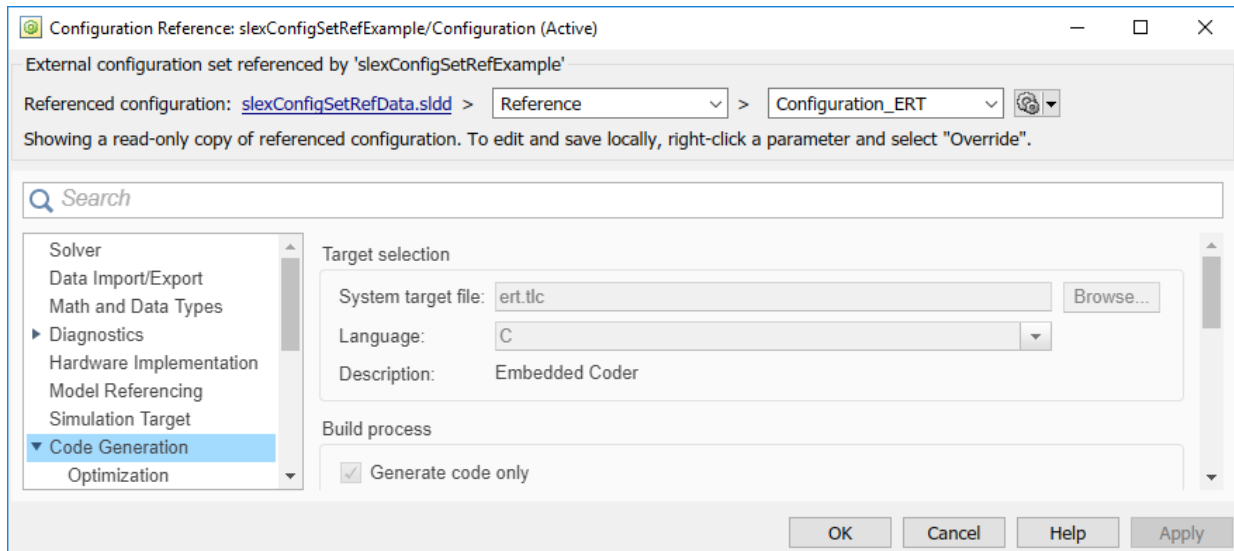

### Sharing and Switching Configurations with Configuration Reference

This model and its referenced model use the same configuration set stored in data dictionary.

Copyright 2017 The MathWorks, Inc.

To open the active configuration set for the model `slexConfigSetRefExample`, on the **Modeling** tab, click the **Model Configuration Parameters** button.

Because the model is using a referenced configuration, the Configuration Reference dialog box opens and displays a read-only view of the referenced configuration set. Information at the top of the dialog box indicates that the model is using the configuration set, `Reference`, located in the data dictionary, `slexConfigSetRefData.sldd`. In this example, `Reference` is another configuration reference, `Configuration_ERT`.

In the model editor, right-click the Model block, `Amplifier`, and select **Open As Top Model**.

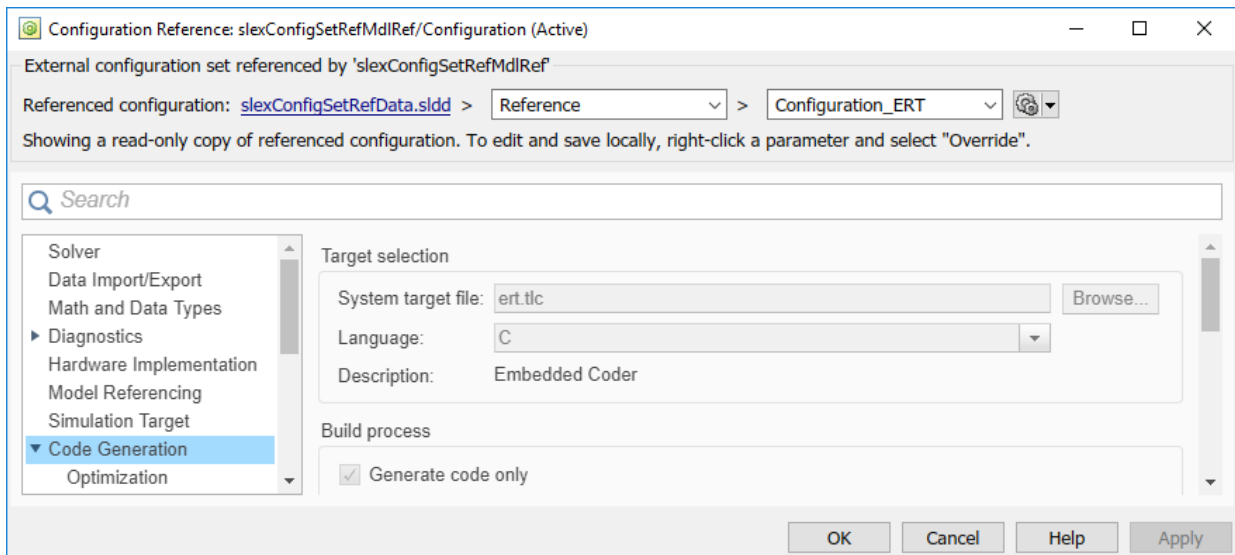

```
open_system('slexConfigSetRefExample/Amplifier');
```

## Sharing and Switching Configurations with Configuration Reference

This model and its parent model use the same configuration set stored in data dictionary.

Open the active configuration set for this model. The name and location for the referenced configuration is the same as in `slexConfigSetRefExample`.

### Open the Referenced Configuration Set

If you need to change and apply parameter values in the configuration set, open `Configuration_ERT` for edit in the Configuration Parameters dialog box by clicking the

Model Configuration Parameters icon at the top of either of the Configuration Reference dialog boxes.

### Generate Code for ERT Target

The referenced configuration set is customized for ERT code generation. To generate code, press **Ctrl+B**.

```
rtwbuild('slexConfigSetRefExample');
```

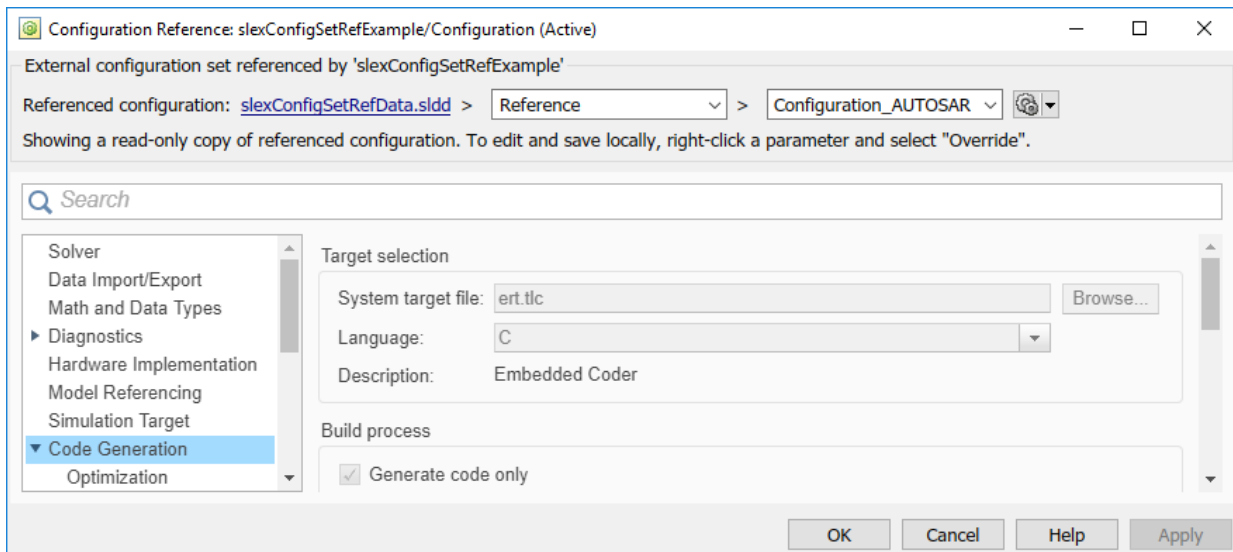

```
### Starting build procedure for model: slexConfigSetRefMdlRef
### Successful completion of code generation for model: slexConfigSetRefMdlRef
```

```
### Starting build procedure for model: slxConfigSetRefExample
### Successful completion of code generation for model: slxConfigSetRefExample
```

The code generation report displays once code generation is complete.

### Switch Targets and Generate Code for AUTOSAR Target

For this model there is another configuration set, `Configuration_AUTOSAR`, that is customized for AUTOSAR code generation. At the top of the Configuration Reference dialog box, in the rightmost drop-down list, select `Configuration_AUTOSAR`. `slxConfigSetREFExample` and its referenced model, `slxConfigSetMdlRef`, now both use the configuration set, `Configuration_AUTOSAR`.

Because you edited the configuration reference, the data dictionary has unsaved changes. The configurations are stored outside of the models so the models do not have unsaved changes.

If you have downloaded the AUTOSAR package, you can now generate code for an AUTOSAR target. In the model editor window, press **Ctrl+B**.

## Check Model and Configuration for Code Generation

You can use the Model Advisor checks to assess model readiness to generate code. To check and configure your model for code generation application objectives such as traceability or debugging, use the Code Generation Advisor.

For information about	See
Model Advisor	“Run Model Advisor Checks” (Simulink)
Code Generation Advisor	“Application Objectives Using Code Generation Advisor” (Simulink Coder)
Checks available with Simulink Coder	“Simulink Coder Checks” (Simulink Coder)
Checks available with Embedded Coder	“Embedded Coder Checks”

### Check Mode for Code Efficiency with Model Advisor

To check model `rtwdemo_throttlecntl` for code efficiency, use the Model Advisor.

- 1 Open `rtwdemo_throttlecntl`. Save a copy as `throttlecntl` in a writable location on your MATLAB path.
- 2 To start the Model Advisor, on the **Modeling** tab, click **Model Advisor**. A dialog box opens showing the model system hierarchy.
- 3 Click `throttlecntl` and then click **OK**. The Model Advisor window opens.
- 4 Expand **By Task > Code Generation Efficiency**. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
- 5 In the left pane, select the remaining checks, and then select **Code Generation Efficiency**.
- 6 In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
- 7 Review the report. The warnings highlight issues that impact code efficiency. For more information about the report, see “View Model Advisor Check Reports” (Simulink).

## Check Model During Code Generation with Code Generation Advisor

To review a model as part of the code generation process, use the Code Generation Advisor.

- 1 To specify your code generation objectives, on the **Configuration Parameters > Code Generation** pane, choose a value for the **Select objective** parameter.
- 2 Select one of the following values for the parameter **Check model before generating code**:
  - On (proceed with warnings)
  - On (stop for warnings)
- 3 If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.
- 4 Apply your changes, and press **Ctrl+B** to generate code. The Code Generation Advisor starts and reviews the top model and subsystems.

If the Code Generation Advisor issues failures or warnings, and you specified:

- On (proceed with warnings) — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
  - On (stop for warnings) — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.
- 5 In the Code Generation Advisor dialog box, review the results by selecting a check from the left pane. The results for that check display in the right pane.
  - 6 After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Advisor Check Warning or Failure” (Simulink).

---

**Note** When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

---

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)

## **See Also**

### **Related Examples**

- “Check Your Model Using the Model Advisor” (Simulink)
- “Application Objectives Using Code Generation Advisor” on page 43-21

## Application Objectives Using Code Generation Advisor

### In this section...

“High-Level Code Generation Objectives” on page 43-22

“Configure Model for Code Generation Objectives Using Code Generation Advisor” on page 43-22

“Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box” on page 43-24

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation options in a model configuration set. Parameters that you set in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in “Recommended Settings Summary for Model Configuration Parameters” (Simulink Coder) to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference (Simulink), you can run the Code Generation Advisor to review your configuration parameter settings. However, the Code Generation Advisor cannot modify the configuration parameter settings.

## High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability might be more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- Execution efficiency (all targets) — Configure code generation settings to achieve fast execution time.
- ROM efficiency (ERT-based targets) — Configure code generation settings to reduce ROM usage.
- RAM efficiency (ERT-based targets) — Configure code generation settings to reduce RAM usage.
- Traceability (ERT-based targets) — Configure code generation settings to provide mapping between model elements and code.
- Safety precaution (ERT-based targets) — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- Debugging (all targets) — Configure code generation settings to debug the code generation build process.
- MISRA C:2012 guidelines (ERT-based targets) — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- Polyspace (ERT-based targets) — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

## Configure Model for Code Generation Objectives Using Code Generation Advisor

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

- 1 On the **C Code** tab, click **C/C++ Code Advisor**.
- 2 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
- 3 In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives from the drop-down list (GRT-based targets). As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it will run on your model. If your model is configured with an ERT-based target, more objectives are available.
- 4 Click **Run Selected Checks** to run the checks listed in the left pane of the Code Generation Advisor.
- 5 In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

#### **Check model configuration settings against code generation objectives**

triggers a warning for these issues:

- Parameters are set to values other than the value recommended for the specified code generation objectives.
- Selected code generation objectives differ from the objectives set in the model.

Click **Modify Parameters** to set:

- Parameters to the value recommended for the specified code generation objectives.
  - Code generation objectives in the model to the objectives specified in the Code Generation Advisor.
- 6 In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.
  - 7 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Advisor Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

## Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

This example shows how to check and configure the code generation objectives in the Configuration Parameters dialog box:

- 1 Open the Configuration Parameters dialog box and select **Code Generation**.
- 2 Select or confirm selection of a System target file.
- 3 Specify the objectives using the **Select objectives** drop-down list (GRT-based targets) or clicking **Set Objectives** button (ERT-based targets). Clicking **Set Objectives** opens the “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder) dialog box.
- 4 Click **Check Model** to run the model checks. The Code Generation Advisor dialog box opens. The Code Generation Advisor uses the code generation objectives to determine which model checks to run.
- 5 On the left pane, the Code Generation Advisor lists the checks run on the model and the results. Click each warning to see the suggestions for changes that you can make to your model to pass the check.
- 6 Determine which changes to make to your model. On the right pane of the Code Generation Advisor, follow the instructions listed for each check to modify the model.

# Simulink Coder Model Advisor Checks for Standards and Code Efficiency

To check that your model meets standards and is ready to generate code, you can use the Model Advisor checks available with Simulink Coder.

- On the **Modeling** tab, click **Model Advisor**.
- In the Model Advisor window, expand the **By Task** folder. The folder contains Model Advisor checks that you can run to help accomplish the task.

For more information about the Model Advisor, see “Run Model Advisor Checks” (Simulink).

The table summarizes the Simulink Coder Model Advisor checks that are available in the **By Task** folders.

By Task folder	Model Advisor checks
<b>Code Generation Efficiency</b>	“Identify blocks using one-based indexing” (Simulink Coder)
<b>Modeling Standards for DO-178C/DO-331</b>	“Check solver for code generation” (Simulink Coder) “Check for blocks that have constraints on tunable parameters” (Simulink Coder) “Check sample times and tasking mode” (Simulink Coder)
<b>Model Referencing</b>	“Check for model reference configuration mismatch” (Simulink Coder) “Check for code generation identifier formats used for model reference” (Simulink Coder)

## Configure Code Comments

Configure how the code generator inserts comments into generated code by modifying parameters on the **Code Generation > Comments** pane.

Goal	Action
Include comments in generated code	<b>Include comments</b> (Simulink Coder). Selecting this parameter allows you to select one or more autogenerated comment types to be placed in the code.
Include comments that describe a Simulink block's code	<b>Simulink block comments</b> (Simulink Coder). Selecting this parameter includes the comments before the Simulink block's code in the generated code. In Embedded Coder, use <b>Trace to model using</b> (Simulink Coder) to select <code>Block path</code> or <code>Simulink identifier</code> as the comment format.
Include comments that describe Stateflow objects	<b>Stateflow object comments</b> (Simulink Coder). Selecting this parameter includes the comments describing Stateflow objects in the generated code. In Embedded Coder, use <b>Trace to model using</b> (Simulink Coder) to select <code>Block path</code> or <code>Simulink identifier</code> as the comment format.
Include MATLAB source code as comments	<b>MATLAB source code as comments</b> (Simulink Coder). Selecting this parameter inserts these comments preceding the associated generated code. The function signature is included in the function banner.
Include comments for eliminated blocks	<b>Show eliminated blocks</b> (Simulink Coder). Selecting this parameter includes comments for blocks that were eliminated as the result of optimizations, such as inlining parameters.
Include parameter comments regardless of the number of parameters	<b>Verbose comments for 'Model default' storage class</b> (Simulink Coder). Selecting this parameter includes comments for parameter variable names and names of source blocks in the model parameter structure declaration in <code>model_prm.h</code> .  If you do not select this parameter, parameter comments are generated if less than 1000 parameters are declared. This reduces the size of the generated file for models with a large number of parameters.
Include MATLAB user comments	<b>MATLAB user comments</b> (Simulink Coder). Selecting this parameter includes function description comments and other user comments from MATLAB code as comments in the generated code.
Specify comment style	<b>Comment style</b> (Simulink Coder). Select <code>Auto</code> , <code>Multi-line</code> or <code>Single-line</code> as the style of comments in the generated code.

**Note** When you configure the code generator to produce code that includes comments, the code generator includes text for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter `ア` with the escape sequence `&#x30A2`. For more information, see “Internationalization and Code Generation” (Simulink Coder).

### More About

- “Model Configuration Parameters: Comments”

## Include MATLAB Code as Comments in Generated Code

If you have Simulink Coder, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select the **MATLAB source code as comments** parameter, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires Embedded Coder), the traceability tags are hyperlinks to the source code. For more information, see “Use Traceability in MATLAB Function Blocks” on page 75-45.

For examples and information on the location of the comments in the generated code, see “Location of Comments in Generated Code” on page 43-30.

- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

---

**Note** With Embedded Coder, you can also include the function help text in the generated code function banner. For more information, see “Include MATLAB User Comments in Generated Code” on page 43-32.

---

## Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

- 1 On the **C Code** tab, click **Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

## Location of Comments in Generated Code

The comments containing the source code appear after the traceability tag in the generated code as follows.

```
/* '<S2>:1:18' for y = 1 : 2 : (HEIGHT-4) */
```

Selecting the **Stateflow object comments** parameter generates the traceability comment '<S2>:1:18'. Selecting the **MATLAB source code as comments** parameter generates the for y = 1 : 2 : (HEIGHT-4) comment.

### Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after comments that you add, which precede the generated code. The comments are separated from the generated code because the statements are assigned to function outputs.

#### MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

#### Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
/* Convert polar to Cartesian */
/* '<S1>:1:4' x = r * cos(theta); */
/* '<S1>:1:5' y = r * sin(theta); */
straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

/* Output: '<Root>/y' incorporates:
 * Inport: '<Root>/r'
 * Inport: '<Root>/theta'
 * MATLAB Function Block: '<Root>/straightline'
 */
straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

### If Statements

The comment for the if statement immediately precedes the code that implements the statement. This comment appears after comments that you add, which precede the

generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause and before the code generated for statements in the clause.

### MATLAB Code

```
function y = ifstmt(u,v)
%#codegen
if u > v
    y = v + 10;
elseif u == v
    y = u * 2;
else
    y = v - 10;
end
```

### Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' if u > v */
if (MLFcn_U.u > MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:4' y = v + 10; */
    MLFcn_Y.y = MLFcn_U.v + 10.0;
} else if (MLFcn_U.u == MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:5' elseif u == v */
    /* '<S1>:1:6' y = u * 2; */
    MLFcn_Y.y = MLFcn_U.u * 2.0;
} else {
    /* Output: '<Root>/y' */
    /* '<S1>:1:7' else */
    /* '<S1>:1:8' y = v - 10; */
    MLFcn_Y.y = MLFcn_U.v - 10.0;
```

### For Statements

The comment for the `for` statement header immediately precedes the generated code, which implements the header. This comment appears after comments that you add, which precede the generated code.

### MATLAB Code

```
function y = forstmt(u)
%#codegen
```

```
y = 0;
for i=1:u
    y = y + 1;
end
```

### Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' y = 0; */
rtb_y = 0.0;

/* '<S1>:1:5' for i=1:u */
for (i = 1.0; i <= MLFcn_U.u; i++) {
/* '<S1>:1:6' y = y + 1; */
    rtb_y++;
}
```

### While Statements

The comment for the `while` statement header immediately precedes the generated code, which implements the statement header. This comment appears after comments that you add, which precede the generated code.

### Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

## Include MATLAB User Comments in Generated Code

MATLAB user comments include the function help text and other comments. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it. You can include the MATLAB user comments in the code generated for a MATLAB Function block.

- 1 On the **C Code** tab, click **Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select “MATLAB user comments” (Simulink Coder) and click **Apply**.

## Limitations of MATLAB Source Code as Comments

For including MATLAB source code as comments, the MATLAB Function block has these limitations :

- You cannot include MATLAB source code as comments for:
  - MathWorks toolbox functions
  - P-code
  - Simulation targets
  - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on these conditions:
  - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
  - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
  - For certain optimizations, the comments might be separated from the generated code.
  - The generated code includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

## Construction of Generated Identifiers

For GRT and RSim targets, the code generator automatically constructs identifiers for variables and functions in the generated code. These identifiers represent:

- Signals and parameters that have `Auto` storage class
- Subsystem function names that are not user-defined
- Stateflow names

The components of a generated identifier include

- The root model name, followed by
- The name of the generating object (signal, parameter, state, and so on), followed by
- Unique *name-mangling* text

The code generator conditionally generates the name-mangling text to resolve potential conflicts with other generated identifiers.

To configure how the code generator names identifiers and objects, see:

- “Specify Identifier Length to Avoid Naming Collisions” on page 43-36
- “Specify Reserved Names for Generated Identifiers” on page 43-37

The code generator reserves certain words for its own use as keywords of the generated code language. For more information, see “Reserved Keywords” on page 43-38.

With an Embedded Coder license, you can specify parameters to control identifier formats, mangle length, scalar inlined parameters, and Simulink data object naming rules. For more information, see “Customize Generated Identifier Naming Rules” on page 50-15.

## Identifier Name Collisions and Mangling

In identifier generation, a circumstance that would cause generation of two or more identical identifiers is called a *name collision*. When a potential name collision exists, unique *name-mangling* text is generated and inserted into each of the potentially conflicting identifiers. Each set of name-mangling characters is unique for each generated identifier.

### Identifier Name Collisions with Referenced Models

Referenced models can introduce additional naming constraints. Within a model that uses referenced models, collisions between the names of the models cannot exist. When you generate code from a model that includes referenced models, the **Maximum identifier length** parameter must be large enough to accommodate the root model name and name-mangling text. A code generation error occurs if **Maximum identifier length** is too small.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

For more information on referenced models, see “Parameterize Instances of a Reusable Referenced Model” (Simulink).

## Specify Identifier Length to Avoid Naming Collisions

The length of a generated identifier is limited by the **Maximum identifier length** parameter specified on the **Identifiers** pane of the Configuration Parameters dialog box. The **Maximum identifier length** field allows you to limit the number of characters in function, type definition, and variable names. The default is 31 characters. This is also the minimum length you can specify. The maximum is 256 characters.

When there is a potential name collision between two identifiers, name-mangling text is generated. The text has the minimum number of characters required to avoid the collision. The other symbol components are then inserted. If **Maximum identifier length** is not large enough to accommodate full expansions of the other components, they are truncated. To avoid this outcome, it is good practice to:

- Avoid name collisions by not using default block names (for example, Gain1, Gain2 . . .) when the model includes multiple blocks of the same type.
- For subsystems, make them atomic and reusable.
- Increase the **Maximum identifier length** parameter to accommodate the length of the identifier you expect to generate.

## Specify Reserved Names for Generated Identifiers

You can specify a set of reserved keywords that the code generation process should not use, facilitating code integration where functions and variables from external environments are unknown in the Simulink model. To create a list of reserved names, open the Configuration Parameters dialog box. On the **Code Generation > Identifiers** pane, enter the keywords in the “Reserved names” (Simulink Coder) field.

If your model contains MATLAB Function or Stateflow blocks, the code generation process can use the reserved names specified for those blocks if you select **Use the same reserved names as Simulation Target** (Simulink Coder) on the **Code Generation > Identifiers** pane.

## Reserved Keywords

### In this section...

“C Reserved Keywords” on page 43-38

“C++ Reserved Keywords” on page 43-39

“Reserved Keywords for Code Generation” on page 43-39

“Code Generation Code Replacement Library Keywords” on page 43-40

Generator keywords are reserved for internal use. Do not use them in models as identifiers or function names. Also avoid using C reserved keywords in models as identifiers or function names. If your model contains reserved keywords, code generation does not complete and an error message appears. To address the error, modify your model to use identifiers or names that are not reserved.

If you use the code generator to produce C++ code, your model must not contain the “Reserved Keywords for Code Generation” on page 43-39 nor the “C++ Reserved Keywords” on page 43-39.

**Note** You can register additional reserved identifiers in the Simulink environment. For more information, see “Specify Reserved Names for Generated Identifiers” on page 43-37.

## C Reserved Keywords

auto	double	int	struct
break	else	long	switch
case	enum	register	typedef
char	extern	return	union
const	float	short	unsigned
continue	for	signed	void
default	goto	sizeof	volatile
do	if	static	while

## C++ Reserved Keywords

catch	friend	protected	try
class	inline	public	typeid
const_cast	mutable	reinterpret_cast	typename
delete	namespace	static_cast	using
dynamic_cast	new	template	virtual
explicit	operator	this	wchar_t
export	private	throw	

## Reserved Keywords for Code Generation

abs	int8_T	MAX_uint8_T*	rtInf
asm	int16_T	MAX_uint16_T*	rtMinusInf
bool	int32_T	MAX_uint32_T*	rtNaN
boolean_T	int64_T	MAX_uint64_T	SeedFileBuffer
byte_T	INTEGER_CODE	MIN_int8_T*	SeedFileBufferLen
char_T	LINK_DATA_BUFFER_SIZE	MIN_int16_T*	single
cint8_T	LINK_DATA_STREAM	MIN_int32_T*	TID01EQ
cint16_T	localB	MIN_int64_T	time_T
cint32_T	localC	MODEL	true
creal_T	localDWork	MT	uint_T
creal32_T	localP	NCSTATES	uint8_T
creal64_T	localX	NULL	uint16_T
cuint8_T	localXdis	NUMST	uint32_T
cuint16_T	localXdot	pointer_T	uint64_T
cuint32_T	localZCE	PROFILING_ENABLED	UNUSED_PARAMETER
ERT	localZCSV	PROFILING_NUM_SAMPLES	USE_RTMODEL
false	matrix	real_T	VCAST_FLUSH_DATA

fortran	MAX_int8_T*	real32_T	vector
HAVESTDIO	MAX_int16_T*	real64_T	
id_t	MAX_int32_T*	RT	
int_T	MAX_int64_T	RT_MALLOCC	
*Not reserved if you specify a replacement identifier.			

## Code Generation Code Replacement Library Keywords

The list of code replacement library reserved keywords for your development environment varies depending on which libraries are registered. The list of available code replacement libraries varies depending on other installed products (for example, a target product), or if you used Embedded Coder to create and register custom code replacement libraries.

To generate a list of reserved keywords for libraries currently registered in your environment, use the following MATLAB function:

```
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers()
```

This function returns an array of library keywords. Specifying the input argument is optional.

---

**Note** To list the libraries currently registered in your environment, use the MATLAB command `crviewer`.

---

To generate a list of reserved keywords for a specific library that you are using to generate code, call the function passing the name of the library as displayed in the **Code replacement library** menu on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. For example,

```
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 Extensions')
```

Here is a partial example of the function output:

```
>> lib_ids = ...
    RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 Extensions')

lib_ids =

    'exp10'
    'exp10f'
```

```
'acosf'  
'acoshf'  
'asinf'  
'asinhf'  
'atanf'  
'atanhf'  
...  
'rt_lu_cplx'  
'rt_lu_cplx_sgl'  
'rt_lu_real'  
'rt_lu_real_sgl'  
'rt_mod_boolean'  
'rt_rem_boolean'  
'strcpy'  
'utAssert'
```

---

**Note** Some of the returned keywords appear with the suffix \$N, for example, 'rt\_atan2\$N'. \$N expands into the suffix \_snf only if nonfinite numbers are supported. For example, 'rt\_atan2\$N' represents 'rt\_atan2\_snf' if nonfinite numbers are supported and 'rt\_atan2' if nonfinite numbers are not supported. As a precaution, you should treat both forms of the keyword as reserved.

---

## Debug

In the Configuration Parameters dialog box, use parameters on the **Diagnostics** pane and debugging parameters to configure a model such that the generated code and the build process are set for debugging. You can set parameters that apply to the model compilation phase, the target language code generation phase, or both.

Parameters in the following table will be helpful if you are writing TLC code for customizing targets, integrating legacy code, or developing new blocks.

To...	Select...
Display progress information during code generation in the MATLAB Command Window	"Verbose build" (Simulink Coder). Compiler output also displays.
Prevent the build process from deleting the <i>model.rtw</i> file from the build folder at the end of the build	"Retain .rtw file" (Simulink Coder). This parameter is useful if you are modifying the target files, in which case you need to look at the <i>model.rtw</i> file.
Instruct the TLC profiler to analyze the performance of TLC code executed during code generation and generate a report	"Profile TLC" (Simulink Coder). The report is in HTML format and can be read in your web browser.
Start the TLC debugger during code generation	"Start TLC debugger when generating code" (Simulink Coder). Alternatively, enter the argument <code>-dc</code> for the "System target file" (Simulink Coder) parameter on the <b>Code Generation</b> pane. To start the debugger and run a debugger script, enter <code>-df filename</code> for <b>System target file</b> .

To...	Select...
Generate a report containing statistics indicating how many times the code generator reads each line of TLC code during code generation	“Start TLC coverage when generating code” (Simulink Coder). Alternatively, enter the argument <code>-dg</code> for the <b>System Target File</b> parameter on the <b>Code Generation</b> pane.
Halt a build if a user-supplied TLC file contains an <code>%assert</code> directive that evaluates to <code>FALSE</code>	<p>“Enable TLC assertion” (Simulink Coder). Alternatively, you can use MATLAB commands to control TLC assertion handling.</p> <p>To set the flag on or off, use the <code>set_param</code> command. The default is off.</p> <pre>set_param(model, 'TLCAssertion', 'on off')</pre> <p>To check the current setting, use <code>get_param</code>.</p> <pre>get_param(model, 'TLCAssertion')</pre>
Detect loss of tunability	<p>“Detect loss of tunability” (Simulink) on the <b>Diagnostics &gt; Data Validity</b> pane. You can use this parameter to report loss of tunability when an expression is reduced to a numeric expression. This can occur if a tunable workspace variable is modified by Mask Initialization code, or is used in an arithmetic expression with unsupported operators or functions. Possible values are:</p> <ul style="list-style-type: none"> <li>• <code>none</code> — Loss of tunability can occur without notification.</li> <li>• <code>warning</code> — Loss of tunability generates a warning (default).</li> <li>• <code>error</code> — Loss of tunability generates an error.</li> </ul> <p>For a list of supported operators and functions, see “Tunable Expression Limitations” (Simulink Coder)</p>

To...	Select...
<p>Enable model verification (assertion) blocks</p>	<p>“Model Verification block enabling” (Simulink). Use this parameter to enable or disable model verification blocks such as Assert, Check Static Gap, and related range check blocks. The diagnostic applies to generated code and simulation behavior. For example, simulation and code generation ignore this parameter when model verification blocks are inside an S-function. Possible values are:</p> <ul style="list-style-type: none"> <li>• User local settings</li> <li>• Enable All</li> <li>• Disable All</li> </ul> <p>For Assertion blocks not disabled, generated code for a model includes one of the following statements, depending on the blocks input signal type (Boolean, real, or integer, respectively).</p> <pre>utAssert(input_signal); utAssert(input_signal != 0.0); utAssert(input_signal != 0);</pre> <p>By default, <code>utAssert</code> does not change generated code. For assertions to abort execution, you must enable them by specifying the following <code>make_rtw</code> command for <b>Code Generation</b> &gt; “Make command” (Simulink Coder) parameter:</p> <pre>make_rtw OPTS="-DDOASSERTS"</pre> <p>Use the following variant if you want triggered assertions to print the assertion statement instead of aborting execution:</p> <pre>make_rtw OPTS="-DDOASSERTS -DPRINT_ASSERTS"</pre> <p><code>utAssert</code> is defined as <code>#define utAssert(exp) assert(exp)</code>.</p> <p>To customize assertion behavior, provide your own definition of <code>utAssert</code> in a handwritten header file that overrides the default <code>utAssert.h</code>. For details on how to include a customized header file in generated code, see “Integrate</p>

To...	Select...
	<p data-bbox="552 298 1261 357">External Code by Using Model Configuration Parameters” (Simulink Coder).</p> <p data-bbox="552 388 1332 512">When running a model in accelerator mode, the Simulink engine calls back to itself to execute assertion blocks instead of using generated code. Thus, user-defined callbacks are still called when assertions fail.</p>

For more information about the TLC debugging options, see Debugging on “Target Language Compiler” (Simulink Coder). Also, consider using the Model Advisor as a tool for troubleshooting model builds.

## Configure Model for Code Generation Objectives by Using Code Generation Advisor

<b>In this section...</b>
---------------------------

“High-Level Code Generation Objectives” on page 44-3
------------------------------------------------------

“Specify Objectives in Referenced Models” on page 44-3
--------------------------------------------------------

“Configure Model Using Code Generation Advisor” on page 44-4
--------------------------------------------------------------

“Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box” on page 44-6
------------------------------------------------------------------------------------------------------------

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation parameters in a model configuration set. Parameters that you set in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in “Recommended Settings Summary for Model Configuration Parameters” to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks that the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference (Simulink), you can run the Code Generation Advisor to review your configuration parameter settings. However, the Code Generation Advisor cannot modify the configuration parameter settings.

## High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability are more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- Execution efficiency (all targets) — Configure code generation settings to achieve fast execution time.
- ROM efficiency (ERT-based targets) — Configure code generation settings to reduce ROM usage.
- RAM efficiency (ERT-based targets) — Configure code generation settings to reduce RAM usage.
- Traceability (ERT-based targets) — Configure code generation settings to provide mapping between model elements and code.
- Safety precaution (ERT-based targets) — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- Debugging (all targets) — Configure code generation settings to debug the code generation build process.
- MISRA C:2012 guidelines (ERT-based targets) — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- Polyspace (ERT-based targets) — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

## Specify Objectives in Referenced Models

When you check a model during the code generation process, you must specify the same objectives in the top model and referenced models. If you specify different objectives for the top model and referenced model, the build process generates an error.

To specify different objectives for the top model and each referenced model, review the models separately without generating code.

## Configure Model Using Code Generation Advisor

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

- 1 On the **C Code** tab, click **C/C++ Code Advisor**.
- 2 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
- 3 In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. If your model is configured with an ERT-based target, more objectives are available. For this example, the model is configured with an ERT-based target. If your objectives are execution efficiency and traceability, in that priority, do the following:
  - a In **Available objectives**, double-click Execution efficiency. Execution efficiency is added to **Selected objectives - prioritized**.
  - b In **Available objectives**, double-click Traceability. Traceability is added to **Selected objectives - prioritized** under Execution efficiency.

- 4 To run the checks listed in the left pane of the Code Generation Advisor, click **Run Selected Checks**.
- 5 In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

### Check model configuration settings against code generation objectives

triggers a warning for these issues:

- Parameters are set to values other than the value recommended for the specified code generation objectives.
- Selected code generation objectives differ from the objectives set in the model.

Click **Modify Parameters** to set:

- Parameters to the value recommended for the specified code generation objectives.
- Code generation objectives in the model to the objectives specified in the Code Generation Advisor.

**Check model configuration settings against code generation objectives**

Analysis

Check model configuration settings against the code generation objectives. Successfully passing this check may take multiple iterations since a change to one option can impact other options.

Result:  Warning

**Current Objectives:** [Execution efficiency](#), [Traceability](#)

The code generation objectives differ from the objectives set in the model (Unspecified). Click the 'Modify Parameters' button to store the current objectives in the model.

The following parameter values are not optimized for the selected objectives.

To automatically fix the warning, click the 'Modify Parameters' button and then rerun the check. To manually fix the warning, click the parameter hyperlink to open the Configuration Parameters dialog box, and manually apply the recommended value.

Parameter	Current Value	Recommended Value
<a href="#">Suppress error status in real-time model data structure</a>	off	on
<a href="#">non-finite numbers</a>	on	off
<a href="#">Remove root level I/O zero initialization</a>	off	on

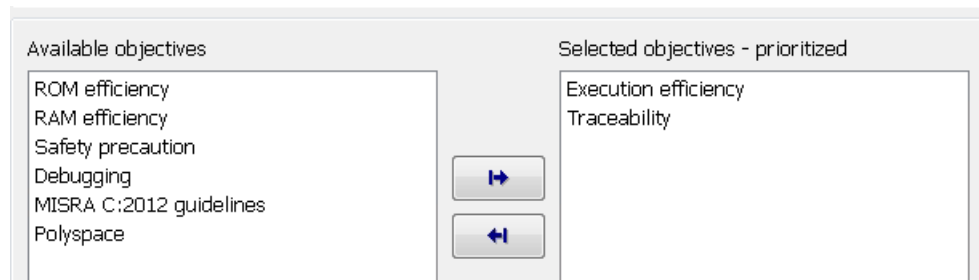

- 6 In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.
- 7 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Advisor Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

## Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

This example shows how to configure and check your model to meet code generation objectives via the Configuration Parameters dialog box:

- 1 Open the Configuration Parameters dialog box. Select **Code Generation**.
- 2 Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, choose an ERT-based target such as `ert.tlc`.
- 3 Click **Set Objectives**.
- 4 In the “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder), specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, do the following:
  - a In **Available objectives**, double-click Execution efficiency. Execution efficiency is added to **Selected objectives - prioritized**.
  - b In **Available objectives**, double-click Traceability. Traceability is added to **Selected objectives - prioritized** under Execution efficiency.

- c To accept the objectives, click **OK**. In the Configuration Parameters dialog box, **Code Generation > Prioritized objectives** is updated.
- 5 On the **Code Generation** pane, click **Check Model**.
- 6 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**. The Code Generation Advisor opens and reviews the model or subsystem that you specified.

- 7 In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.

**Check model configuration settings against code generation objectives**

Analysis

Check model configuration settings against the code generation objectives. Successfully passing this check may take multiple iterations since a change to one option can impact other options.

Result:  Warning

**Current Objectives:** [Execution efficiency](#), [Traceability](#)

The code generation objectives differ from the objectives set in the model (Unspecified). Click the 'Modify Parameters' button to store the current objectives in the model.

The following parameter values are not optimized for the selected objectives.

To automatically fix the warning, click the 'Modify Parameters' button and then rerun the check. To manually fix the warning, click the parameter hyperlink to open the Configuration Parameters dialog box, and manually apply the recommended value.

Parameter	Current Value	Recommended Value
<a href="#">Suppress error status in real-time model data structure</a>	off	on
<a href="#">non-finite numbers</a>	on	off
<a href="#">Remove root level I/O zero initialization</a>	off	on

- 8 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Advisor Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)

- “Recommended Settings Summary for Model Configuration Parameters”
- “Recommended Model Configuration Parameters for Polyspace Analysis” (Polyspace Bug Finder)
- “Code Generation Advisor Checks” (Simulink Coder)

## Configure Code Generation Objectives Programmatically

This example shows how to configure code generation objectives by writing a MATLAB script or entering commands at the command line.

- 1 Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, specify `ert.tlc`. *model\_name* is the name or handle to the model.

```
set_param(model_name, 'SystemTargetFile', 'ert.tlc');
```

- 2 Specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, enter:

```
set_param(model_name, 'ObjectivePriorities', ...  
{'Execution efficiency', 'Traceability'});
```

- 3 Execute the Code Generation Advisor, by using either the Code Generation Advisor or in the Configuration Parameters dialog box. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 44-2.

When you specify a GRT-based system target file, you can specify an objective at the command line. If you specify ROM efficiency, RAM efficiency, Traceability, MISRA C:2012 guidelines, Polyspace, or Safety precaution, the build process changes the objective to Unspecified because you have specified a value that is invalid when using a GRT-based target.

## Check Model and Configuration for Code Generation

You can use the Model Advisor checks to assess model readiness to generate code. To check and configure your model for code generation application objectives such as traceability or debugging, use the Code Generation Advisor.

For information about	See
Model Advisor	"Run Model Advisor Checks" (Simulink)
Code Generation Advisor	"Configure Model for Code Generation Objectives by Using Code Generation Advisor" on page 44-2
Checks available with Simulink Coder	"Simulink Coder Checks" (Simulink Coder)
Checks available with Embedded Coder	"Embedded Coder Checks"

To check model `rtwdemo_throttlecntl` for code efficiency, use the Model Advisor.

- 1 Open `rtwdemo_throttlecntl`. Save a copy as `throttlecntl` in a writable location on your MATLAB path.
- 2 On the **Modeling** tab, click **Model Advisor**. A dialog box opens showing the model system hierarchy.
- 3 Click `throttlecntl` and then click **OK**. The Model Advisor window opens.
- 4 Expand **By Task > Code Generation Efficiency**. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
- 5 In the left pane, select the remaining checks, and then select **Code Generation Efficiency**.
- 6 In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
- 7 Review the report. The warnings highlight issues that impact code efficiency. For more information about the report, see "View Model Advisor Check Reports" (Simulink).

### Check Model During Code Generation

To review a model as part of the code generation process, use the Code Generation Advisor .

- 1 To select and prioritize your code generation objectives, on the **Configuration Parameters > Code Generation** pane, click **Set Objectives**.
- 2 On the **Configuration Parameters > Code Generation > General** pane, select one of the following from **Check model before generating code**:
  - On (proceed with warnings)
  - On (stop for warnings)
- 3 If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.
- 4 Apply your changes. Press **Ctrl+B** to generate code or build the model.

If the Code Generation Advisor issues failures or warnings, and you specified:

- On (proceed with warnings) — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
  - On (stop for warnings) — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.
- 5 In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.
  - 6 After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Advisor Check Warning or Failure” (Simulink).

---

**Note** When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

---

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)

## Embedded Coder Model Advisor Checks for Standards, Guidelines, and Code Efficiency

To check that your model meets guidelines, standards, and is ready to generate code, you can use the Model Advisor checks available with Embedded Coder.

- On the **Modeling** tab, select **Model Advisor**.
- In the Model Advisor window, expand the **By Task** folder. The folder contains Model Advisor checks that you can run to help accomplish the task.

For more information about the Model Advisor, see “Run Model Advisor Checks” (Simulink).

The table summarizes the Embedded Coder Model Advisor checks that are available in the **By Task** folders.

By Task folder	Model Advisor checks
<b>Modeling Standards for MAAB</b>	Check for blocks not recommended for C/C++ production code deployment
<b>Code Generation Efficiency</b>	Identify lookup table blocks that generate expensive out-of-range checking code  Check output types of logic blocks  Identify questionable software environment specifications  Identify questionable code instrumentation (data I/O)  Identify blocks that generate expensive fixed-point and saturation code  Identify blocks that generate expensive rounding code  Identify questionable fixed-point operations  Check configuration parameters for generation of inefficient saturation code

<b>By Task folder</b>	<b>Model Advisor checks</b>
<b>Modeling Standards for</b>  <ul style="list-style-type: none"> <li>• <b>IEC 61508, IEC 62304, ISO 26262, and EN 50128</b></li> </ul>	Check for blocks not recommended for C/C++ production code deployment
<b>Modeling Standards for DO-178C/DO-331</b>	Check for blocks not recommended for C/C++ production code deployment  Check the hardware implementation  Identify questionable subsystem settings
<b>Modeling Guidelines for MISRA C:2012</b>	Check configuration parameters for MISRA C:2012  Check for blocks not recommended for C/C++ production code deployment  Check for blocks not recommended for MISRA C:2012  Check for unsupported block names  Check usage of Assignment blocks  Check for switch case expressions without a default case  Check for missing error ports for AUTOSAR receiver interfaces  Check for bitwise operations on signed integers  Check for recursive function calls  Check for equality and inequality operations on floating-point values  Check for missing const qualifiers in model functions  Check bus object names that are used as element names

By Task folder	Model Advisor checks
<p><b>Modeling Guidelines for secure coding standards (CERT C, CWE, ISO/IEC TS 17961)</b></p>	<p>Check configuration parameters for secure coding standards</p> <p>Check for blocks not recommended for C/C++ production code deployment</p> <p>Check for blocks not recommended for secure coding standards</p> <p>Check usage of Assignment blocks</p> <p>Check for switch case expressions without a default case</p> <p>Check for bitwise operations on signed integers</p> <p>Check for equality and inequality operations on floating-point values</p> <p>Check integer word length</p> <p>If you have a Simulink Design Verifier™ license, the following checks are also available.</p> <p>Detect Dead Logic</p> <p>Detect Integer Overflow</p> <p>Detect Division by Zero</p> <p>Detect Out Of Bound Array Access</p> <p>Detect Violation of Specified Minimum and Maximum Values</p>

## Create Custom Code Generation Objectives

In this section...
“Specify Parameters in Custom Objectives” on page 44-16
“Specify Checks in Custom Objectives” on page 44-17
“Determine Checks and Parameters in Existing Objectives” on page 44-17
“Steps to Create Custom Objectives” on page 44-18

The Code Generation Advisor reviews your model based on objectives that you specify. If the predefined efficiency, traceability, Safety precaution, and debugging objectives do not meet your requirements, you can create custom objectives.

To create custom objectives:

- Create an objective and add parameters and checks to this new objective.
- Create an objective based on an existing objective, then add, modify, and remove the parameters and checks within that new objective.

### Specify Parameters in Custom Objectives

When you create a custom objective, you specify the values of configuration parameters that the Code Generation Advisor reviews. You can use the following methods:

- `addParam` — Add parameters and specify the values that the Code Generation Advisor reviews in **Check model configuration settings against code generation objectives**.
- `modifyInheritedParam` — Modify inherited parameter values that the Code Generation Advisor reviews in **Check model configuration settings against code generation objectives**.
- `removeInheritedParam` — Remove inherited parameters from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this parameter, the Code Generation Advisor reviews the parameter value in **Check model configuration settings against code generation objectives**.

## Specify Checks in Custom Objectives

Objectives include the **Check model configuration settings against code generation objectives** check by default. When you create a custom objective, you specify the list of additional checks that are associated with the custom objective. You can use the following methods:

- **addCheck** — Add checks to the Code Generation Advisor. When you select the custom objective, the Code Generation Advisor displays the check, unless you specify an additional objective with a higher priority that excludes the check.

For example, add a check to the Code Generation Advisor to include a custom check in the automatic model checking process.

- **excludeCheck** — Exclude checks from the Code Generation Advisor. When you select multiple objectives, if you specify an additional objective that includes this check as a higher priority objective, the Code Generation Advisor displays this check.

For example, exclude a check from the Code Generation Advisor when a check takes a long time to process.

- **removeInheritedCheck** — Remove inherited checks from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this check, the Code Generation Advisor displays the check.

For example, remove an inherited check, rather than exclude the check, when the check takes a long time to process, but the check is important for another objective.

## Determine Checks and Parameters in Existing Objectives

When you base a new objective on an existing objective, you can determine what checks and parameters the existing objective contains. The Code Generation Advisor contains the list of checks in each objective.

For example, the Efficiency objective includes checks that you can see in the Code Generation Advisor.

- 1 Open the `rtwdemo_rtwecintro` model.
- 2 Specify an ERT-based target.
- 3 On **C Code** tab, click **C/C++ Code Advisor**.
- 4 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.

- 5 In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. For this example, select Execution efficiency. In **Available objectives**, double-click Execution efficiency. Execution efficiency is added to **Selected objectives - prioritized**.

In the left pane, the Code Generation Advisor lists the checks for the Execution efficiency objective. The first check, **Check model configuration settings against code generation objectives**, lists parameters and values specified by the objective. For example, the Code Generation Advisor displays the list of parameters and the recommended values in the Execution efficiency objective. To see the list of parameters and values:

- 1 Run **Check model configuration settings against code generation objectives**.
- 2 Click **Modify Parameters**.
- 3 Rerun the check.

In the check results, the Code Generation Advisor displays the list of parameters and recommended values for the Execution efficiency objective.

Passed  
Current Objectives: Execution efficiency

The following parameters have been checked and confirmed with the recommended value

Parameter	Value
<a href="#">non-inlined S-functions</a>	off
<a href="#">Suppress error status in real-time model data structure</a>	on
<a href="#">MAT-file logging</a>	off
<a href="#">Classic call interface</a>	off
<a href="#">continuous time</a>	off
<a href="#">non-finite numbers</a>	off
<a href="#">Single output/update function</a>	on
<a href="#">Minimize algebraic loop occurrences</a>	off

## Steps to Create Custom Objectives

To create a custom objective:

- 1 Create an `sl_customization.m` file.
  - Specify custom objectives in a single `sl_customization.m` file only or the software generates an error. This issue is true even if you have more than one `sl_customization.m` file on your MATLAB path.

- Except for the *matlabroot*/work folder, do not place an `sl_customization.m` file in your root MATLAB folder or its subfolders. Otherwise, the software ignores the customizations that the file specifies.
- 2** Create an `sl_customization` function that takes a single argument. When the software invokes the function, the value of this argument is the Simulink customization manager. In the function:
- To create a handle to the code generation objective, use the `ObjectiveCustomizer` constructor.
  - To register a callback function for the custom objectives, use the `ObjectiveCustomizer.addCallbackObjFcn` method.
  - To add a call to execute the callback function, use the `ObjectiveCustomizer.callbackFcn` method.

For example:

```
function sl_customization(cm)
%SL_CUSTOMIZATION objective customization callback

objCustomizer = cm.ObjectiveCustomizer;
index = objCustomizer.addCallbackObjFcn(@addObjectives);
objCustomizer.callbackFcn{index}();

end
```

- 3** Create a MATLAB callback function that:
- Creates code generation objective objects by using the `rtw.codegenObjectives.Objective` constructor.
  - Adds, modifies, and removes configuration parameters for each objective by using the `addParam`, `modifyInheritedParam`, and `removeInheritedParam` methods.
  - Includes and excludes checks for each objective by using the `addCheck`, `excludeCheck`, and `removeInheritedCheck` methods.
  - Registers objectives by using the `register` method.

The following example shows how to create an objective `Reduce RAM Example`. `Reduce RAM Example` includes five parameters and three checks that the Code Generation Advisor reviews.

```
function addObjectives

% Create the custom objective
obj = rtw.codegenObjectives.Objective('ex_ram_1');
```

```
setObjectiveName(obj, 'Reduce RAM Example');

% Add parameters to the objective
addParam(obj, 'DefaultParameterBehavior', 'Inlined');
addParam(obj, 'BooleanDataType', 'on');
addParam(obj, 'OptimizeBlockIOStorage', 'on');
addParam(obj, 'EnhancedBackFolding', 'on');
addParam(obj, 'BooleansAsBitFields', 'on');

% Add additional checks to the objective
% The Code Generation Advisor automatically includes 'Check model
% configuration settings against code generation objectives' in every
% objective.
addCheck(obj, 'mathworks.design.UnconnectedLinesPorts');
addCheck(obj, 'mathworks.design.Update');

%Register the objective
register(obj);

end
```

The following example shows you how to create an objective `My Traceability Example` based on the existing `Traceability` objective. The custom objective modifies, removes, and adds parameters that the Code Generation Advisor reviews. It also adds and removes checks from the Code Generation Advisor.

```
function addObjectives

% Create the custom objective from an existing objective
obj = rtw.codegenObjectives.Objective('ex_my_trace_1', 'Traceability');
setObjectiveName(obj, 'My Traceability Example');

% Modify parameters in the objective
modifyInheritedParam(obj, 'GenerateTraceReportSf', 'Off');
removeInheritedParam(obj, 'ConditionallyExecuteInputs');
addParam(obj, 'MatFileLogging', 'On');

% Modify checks in the objective
addCheck(obj, 'mathworks.codegen.SWEnvironmentSpec');
removeInheritedCheck(obj, 'mathworks.codegen.CodeInstrumentation');

%Register the objective
register(obj);

end
```

- 4 If you previously opened the Code Generation Advisor, close the model from which you opened the Code Generation Advisor.
- 5 Refresh the customization manager. At the MATLAB command line, enter `sl_refresh_customizations`.
- 6 Open your model and review the new objectives.

## Configuration Variations

Every model contains one or more named configuration sets that specify model parameters such as solver options, code generation options, and other choices. A model can contain multiple configuration sets, but only one configuration set is active at a time. For more information on configuration sets and how to view and edit them in the Configuration Parameters dialog box, see “About Model Configurations” (Simulink).

A configuration set includes parameters that specify code generation in general. For more information, see “Configure Model and Generate Code” on page 47-13. With Embedded Coder and an ERT system target file, more parameters are available for fine-tuning to optimize and customize the appearance of the generated code.

Multiple configuration sets can be useful in embedded systems development. By defining multiple configuration sets in a model, you can easily retarget code generation from that model. For example, one configuration set can specify the default ERT target with external mode support enabled for rapid prototyping. Another configuration set can specify the ERT-based target for Visual C++ to generate production code for deployment of the application. Activation of either configuration set fully reconfigures the model for that type of code generation.

## Configure and Optimize Model with Configuration Wizard Blocks

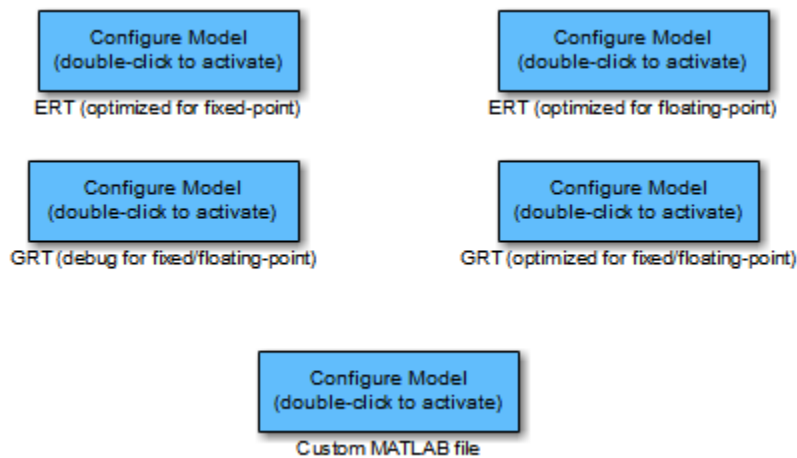

The Embedded Coder software provides a library of Configuration Wizard blocks and scripts to help you configure and optimize code generation from your models.

In this section...
“Configuration Wizard Block Library” on page 44-23
“Add a Configuration Wizard Block” on page 44-24
“Use Configuration Wizard Blocks to Configure Your Model” on page 44-25
“Create a Custom Configuration Wizard Block” on page 44-26

### Configuration Wizard Block Library

The library provides a Configuration Wizard block that you can customize. It also provides four preset Configuration Wizard blocks that update the active configuration parameters for a specified goal.

Block	Description
Custom MATLAB file	Update active configuration parameters of parent model by using a custom file
ERT (optimized for fixed-point)	Update active configuration parameters of parent model for ERT fixed-point code generation
ERT (optimized for floating-point)	Update active configuration parameters of parent model for ERT floating-point code generation
GRT (debug for fixed/floating-point)	Update active configuration parameters of parent model for GRT fixed- or floating-point code generation with debugging enabled
GRT (optimized for fixed/floating-point)	Update active configuration parameters of parent model for GRT fixed- or floating-point code generation

When you add one of the preset Configuration Wizard blocks to your model and double-click it, a predefined MATLAB file script configures parameters of the active configuration set without manual intervention. The preset blocks optimally configure the parameters for one of the following cases:

- Fixed-point code generation with the ERT target
- Floating-point code generation with the ERT target
- Fixed-point or floating-point code generation with TLC debugging parameters enabled, with the GRT target.
- Fixed-point or floating-point code generation with the GRT target

The Custom block provides an example MATLAB file script that you can adapt to your requirements.

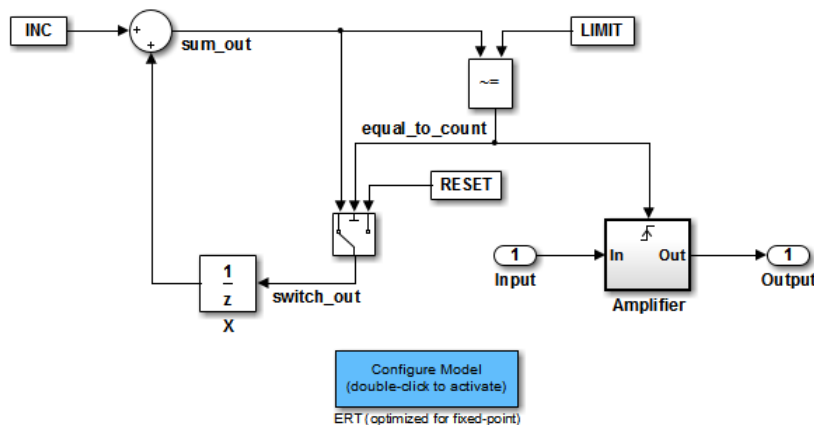

You can also set up the Configuration Wizard blocks to invoke the build process after configuring the model.

## Add a Configuration Wizard Block

The Configuration Wizard blocks are available in the Embedded Coder block library. To use a Configuration Wizard block:

- 1 Open the model that you want to configure.

- 2 Open the Embedded Coder block library by typing the command `rtweclib`.
- 3 Double-click the Configuration Wizards icon. The Configuration Wizards sublibrary opens.
- 4 Select the Configuration Wizard block that you want to use and drag it into your model. This model contains the ERT (optimized for fixed-point) Configuration Wizard block.

- 5 If you want the Configuration Wizard block to invoke the build process after configuration, right-click the Configuration Wizard block in your model, and select **Mask > Mask Parameters** from the context menu. Then, select the **Invoke build process after configuration** parameter. Do not change the **Configure the model for** block parameter, unless you want to create a custom block and script. In that case, see “Create a Custom Configuration Wizard Block” on page 44-26.
- 6 Click **Apply** and close the Mask Parameters dialog box.
- 7 Save the model.

## Use Configuration Wizard Blocks to Configure Your Model

After you add a Configuration Wizard block to your model, to configure your model, double-click the block. The script associated with the block sets parameters of the active configuration set that are relevant to code generation (including selection of the target). You can see that the parameters have changed by opening the Configuration Parameters dialog box and examining the parameter settings.

If you selected the **Invoke build process after configuration** block parameter, the script also initiates the code generation and build process.

---

**Note** To provide a quick way to switch between configurations, you can add more than one Configuration Wizard block to your model.

---

## Create a Custom Configuration Wizard Block

The Custom Configuration Wizard block and the associated MATLAB file script, *matlabroot/toolbox/rtw/rtw/rtwsampleconfig.m*, provide a starting point for customization.

### Set Up a Configuration Wizard Block

Set up a custom Configuration Wizard block and link it to a script. If you want to use the block in more than one mode, it is advisable to create a Simulink library to contain the block.

To begin, make a copy of the example script for later customization:

- 1 To store your custom script, create a folder. This folder must not be anywhere inside the MATLAB folder structure (that is, it must not be under *matlabroot*).

The example refers to this folder as */my\_wizards*.

- 2 Add the folder to the MATLAB path. Save the path for future sessions.
- 3 Copy the example script *rtwsampleconfig.m* in the folder *matlabroot/toolbox/rtw/rtw* (open) to the */my\_wizards* folder that you created. Then, rename the script. This example uses the name *my\_configscript.m*.
- 4 Open the example script into the MATLAB editor. Scroll to the end of the file and enter the following line of code:

```
disp('Custom Configuration Wizard Script completed.');
```

This statement is used later as a test to see that your custom block has executed the script.

- 5 Save your script and close the MATLAB editor.

The next task is to create a Simulink library and add a custom block to it.

- 1 Open the Embedded Coder block library and the Configuration Wizards sublibrary, as described in “Add a Configuration Wizard Block” on page 44-24.
- 2 Select **New > Library** from the **File** menu of the Configuration Wizards sublibrary window. An empty library window opens.
- 3 Select the Custom MATLAB file block from the Configuration Wizards sublibrary and drag it into the empty library window.
- 4 To distinguish your custom block from the original, edit the Custom MATLAB file label under the block.
- 5 Select **Save as** from the **File** menu of the new library window. Save the library to the /my\_wizards folder, under your library name of choice. In this figure, the library is saved as ex\_custom\_button and the block is labeled my\_wizard MATLAB-file.

The next task is to link the custom block to the custom script:

- 1 Right-click the block in your model and select **Mask > Mask Parameters** from the context menu. The **Configure the model for** menu is set to Custom. When Custom is selected, the **Configuration function** edit field is enabled so that you can enter the name of a custom script.
- 2 In the **Configuration function** field, enter the name of your custom script . (Do not enter the .m file name extension, which is implicit.)

- 3 By default, the **Invoke build process after configuration** parameter is cleared. You can change the default for your custom block by selecting this option. For now, leave this parameter cleared.
- 4 Click **Apply** and close the Mask Parameters dialog box.
- 5 Save the library.
- 6 Close the Embedded Coder block library and the Configuration Wizards sublibrary. Leave your custom library open for use in the next task.

Test your block and script in a model.

- 1 Open the vdp model by typing the command:

```
vdp
```

- 2 Open the Configuration Parameters dialog box and view the parameters by clicking **Code Generation** in the list in the left pane of the dialog box.
- 3 Observe that vdp is configured, by default, for the GRT target. Close the Configuration Parameters dialog box.
- 4 Select your custom block from your custom library. Drag the block into the vdp model.
- 5 In the vdp model, double-click your custom block.
- 6 In the MATLAB window, you see the test message that you previously added to your script:

```
Custom Configuration Wizard Script completed.
```

The test message indicates that the custom block executed the script.

- 7 Reopen the Configuration Parameters dialog box and view the **Code Generation** pane again. The model is now configured for the ERT target.

Before applying further edits to your custom script, proceed to the next section to learn about the operation and conventions of Configuration Wizard scripts.

### **Create a Configuration Wizard Script**

Create your custom Configuration Wizard script by copying and modifying the example script, `rtwsampleconfig.m`.

## The Configuration Function

The example script implements a single function without a return value. The function takes a single argument `cs`:

```
function rtwsampleconfig(cs)
```

The argument `cs` is a handle to a proprietary object that contains information about the active configuration set. The Simulink software obtains this handle and passes it in to the configuration function when you double-click a Configuration Wizard block.

Your custom script must conform to this prototype. Your code must use `cs` as a “black-box” object that transmits information to and from the active configuration set.

## Access Configuration Set Parameters

To set parameters or obtain parameter values, use the Simulink `set_param` and `get_param` functions.

Option names are passed in to `set_param` and `get_param` as character vectors specifying an *internal option name*. The internal option name can be different from the option label on the UI (for example, the Configuration Parameters dialog box). The example configuration accompanies each `set_param` and `get_param` call with a comment that correlates internal option names to UI option labels. For example:

```
set_param(cs, 'LifeSpan', '1'); % Application lifespan (days)
```

To obtain the current setting of an option in the active configuration set, call `get_param`. Pass in the `cs` object as the first argument, followed by the internal option name. For example, the following code excerpt tests the setting of the **Create code generation report** option:

```
if strcmp(get_param(cs, 'GenerateReport'), 'on')
    ...
end
```

To set an option in the active configuration set, call `set_param`. Pass in the `cs` object as the first argument, followed by one or more parameter/value pairs that specify the internal option name and its value. For example, the following code excerpt turns off the **Support absolute time** option:

```
set_param(cs, 'SupportAbsoluteTime', 'off');
```

### Select a Target

A Configuration Wizard script must select a target configuration. The example script uses the ERT target as a default. The script first stores character vector variables that correspond to the required **System target file**, **Template makefile**, and **Make command** settings:

```
stf = 'ert.tlc';  
tmf = 'ert_default_tmf';  
mc = 'make_rtw';
```

You select the system target file by passing the `cs` object and the `stf` character vector to the `switchTarget` function:

```
switchTarget(cs,stf,[]);
```

Set the template makefile and make command options by using `set_param` calls:

```
set_param(cs,'TemplateMakefile',tmf);  
set_param(cs,'MakeCommand',mc);
```

To select a target, your custom script must set up the character vector variables `stf`, `tmf`, and `mc` and pass them to the calls.

### Obtain Target and Configuration Set Information

The following utility functions and properties are provided so that your code can obtain information about the current target and configuration set with the `cs` object:

- `isValidParam(cs, 'option')`: The `option` argument is an internal option name. `isValidParam` returns true if `option` is a valid option in the context of the active configuration set.
- `getPropEnabled(cs, 'option')`: The `option` argument is an internal option name. Returns true if this `option` is enabled (that is, writable).
- `IsERTTarget` property: Your code can detect whether the currently selected target is derived from the ERT target by checking the `IsERTTarget` property, as follows:

```
isERT = strcmp(get_param(cs,'IsERTTarget'),'on');
```

You can use this information to determine whether the script must configure ERT-specific parameters, for example:

```
if isERT  
    set_param(cs,'ZeroExternalMemoryAtStartup','off');
```

```
set_param(cs, 'ZeroInternalMemoryAtStartup', 'off');  
set_param(cs, 'InitFltsAndDblsToZero', 'off');  
set_param(cs, 'NoFixptDivByZeroProtection', 'on')  
end
```

### Invoke a Configuration Wizard Script from the Command Line

Configuration Wizard scripts can be run from the MATLAB command line.

Before invoking the script, you must open a model and instantiate a `cs` object to pass in as an argument to the script. After running the script, you can invoke the build process with the `rtwbuild` command. The following example opens, configures, and builds a model.

```
open my_model;  
cs = getActiveConfigSet ('my_model');  
rtwsampleconfig(cs);  
rtwbuild('my_model');
```

## Aircraft Position Radar Model

This model shows the code generated for a Simulink model containing a MATLAB script.

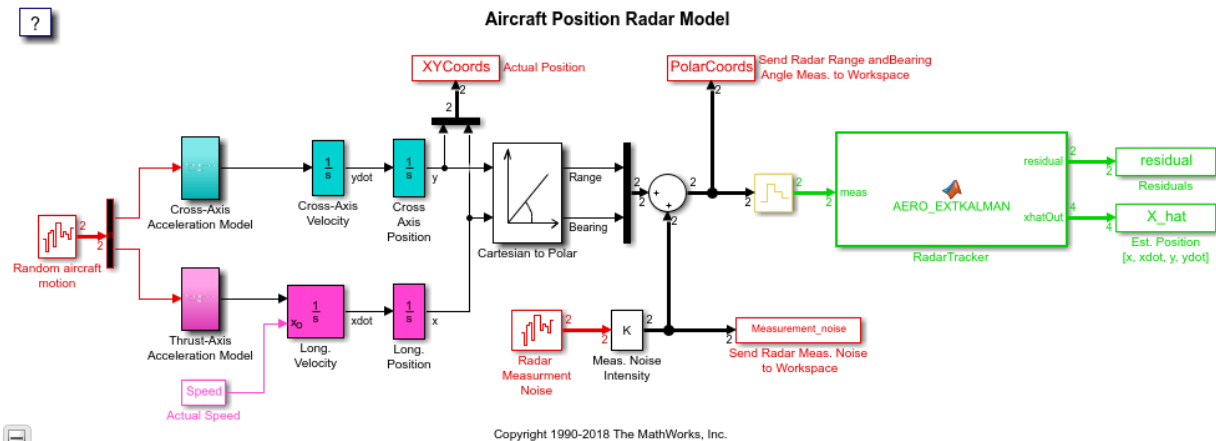

The model contains an Extended Kalman Filter that estimates aircraft position from radar measurements. The MATLAB script `rtwdemo_eml_aero_radar.m` contains data for running the model. The estimated and actual positions are saved to the workspace and are plotted at the end of the simulation by the program `rtwdemo_aero_radplot` (called from the simulation automatically).

### Review and Simulate the Model

In this section you should review the model and perform a simulation.

Open the Simulink model.

```
model='rtwdemo_eml_aero_radar';
open_system(model)
rtwdemo_eml_aero_radar([],[],[],'compile');
rtwdemo_eml_aero_radar([],[],[],'term');
```

Open the MATLAB Function block `RadarTracker` in the MATLAB Editor.

```
open_system([model, '/RadarTracker'])
```

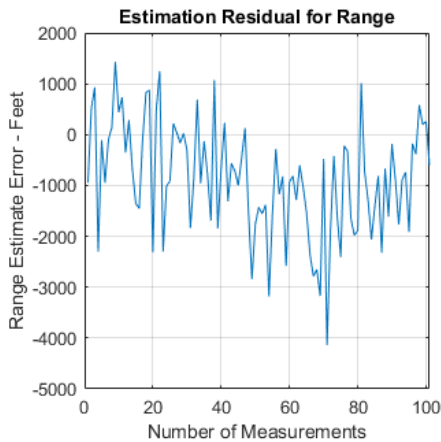

```

### Generate Code for the Model

In this section you will generate code for the Kalman Filter portion of the model using the subsystem build functionality provided by Simulink Coder. In the first build, the model is configured to generate code using Simulink Coder. In the second build, the model is configured to generate code using Embedded Coder.

```
% Create a temporary folder (in your system's temporary folder) for the  
% build and inspection process.
```

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Configure and build the model using Simulink Coder.

```
rtwconfiguredemo(model,'GRT')
rtwbuild([model,'/RadarTracker'])

### Starting build procedure for model: RadarTracker
### Successful completion of build procedure for model: RadarTracker
```

Configure and build the model using Embedded Coder.

```
rtwconfiguredemo(model,'ERT')
rtwbuild([model,'/RadarTracker'])

### Starting build procedure for model: RadarTracker
### Successful completion of build procedure for model: RadarTracker
```

A portion of RadarTracker.c is listed below.

```
cfile = fullfile(cgDir,'RadarTracker_ert_rtw','RadarTracker.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

# System Target File Configuration

---

- “Configure a System Target File” on page 45-2
- “Configure STF-Related Code Generation Parameters” on page 45-6
- “Configure a Code Replacement Library” on page 45-16
- “Configure Standard Math Library for Target System” on page 45-17
- “Compare System Target File Support Across Products” on page 45-20

## Configure a System Target File

To configure a model for code generation, follow the steps in “Select a Solver That Supports Code Generation” (Simulink Coder) and “Select a System Target File from STF Browser” (Simulink Coder). When you select a system target file, other model configuration parameters change to serve requirements of the execution environment. For example:

- Code interface parameters
- Build process parameters, such as the toolchain or template makefile
- Target hardware parameters, such as word size and byte ordering

After selecting a system target file, you can modify model configuration parameter settings.

You can switch between different system target files in a single workflow for different code generation purposes (for example, rapid prototyping versus production code deployment). To switch, set up different configuration sets for the same model and switch the active configuration set for the current operation. For more information on how to set up configuration sets and change the active configuration set, see “Manage a Configuration Set” (Simulink).

### Select a Solver That Supports Code Generation

To build a model, the model configuration must specify a solver that is compatible with code generation for the system target file. Few system target files support code generation with variable-step solvers or for models with a nonzero start time.

- For GRT, ERT, and ERT-based system target files, set the **Type** configuration parameter to **Fixed-step**.
- For Rapid Simulation (Rsim) or S-Function (rtwsfcn) system target files, set the **Type** configuration parameter to **Fixed-step** or **Variable-step**.

For more information about the requirement that you use a fixed-step solver to generate code for a realtime system target file, see “Time-Based Scheduling and Code Generation” on page 27-2.

The Rapid Simulation (RSim) system target file supports a nonzero start time when the **Solver selection** configuration parameter is set to `Use Simulink solver module`.

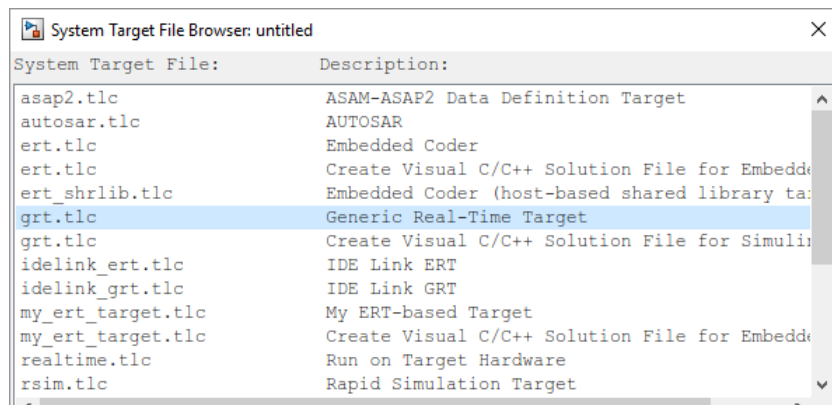

Other system target files do not support a nonzero start time -- the code generator does not produce code and the build process produces an error.

## Select a System Target File from STF Browser

After you select a solver (see “Select a Solver That Supports Code Generation” (Simulink Coder)), specify a value for the **System target file** configuration parameter. Enter the name of your system target file directly in the field or use the System Target File Browser to select a file.

To use the System Target File Browser:

- 1 In the configuration parameters dialog box, next to the **System target file** field, click the **Browse** button. The browser displays a list of available system target files, including customizations.
- 2 From the list, select your file, for example, the GRT system target file (`grt.tlc`). The background of the list box turns yellow to indicate that the choice is not applied. Click **Apply** or **OK**.

### System Target File Browser

You also can select a system target file programmatically from MATLAB code, as described in “Select a System Target File Programmatically” on page 45-4.

After selecting a system target file, you can modify model configuration parameter settings. Selecting a system target file for your model selects either the toolchain approach or template makefile approach for build process control. For more information

about these approaches, see “Choose Build Approach and Configure Build Process” on page 54-14.

If you want to switch between different system target files in a single workflow for different code generation purposes, set up different configuration sets for the same model. Switch the active configuration set for the current operation. This approach is useful for switching between rapid prototyping and production code deployment. For more information on how to set up configuration sets and change the active configuration set, see “Manage a Configuration Set” (Simulink).

## Select a System Target File Programmatically

Simulink models store model-wide parameters and system target file-specific data in *configuration sets*. Every configuration set contains a component that defines the structure of a particular system target file and the current values of relevant options. Simulink loads some of this information from the system target file that you specify. You can configure models to generate alternative code by copying and modifying old or adding new configuration sets and browsing to select a new system target file. Then, you can interactively select an active configuration from among these sets (only one configuration set can be active at a given time).

Scripts that automate system target file selection must emulate this process.

To program system target file selection:

- 1 Obtain a handle to the active configuration set with a call to the `getActiveConfigSet` function.
- 2 Define character vector variables that correspond to the required system target file, toolchain or template makefile, and/or make command settings. For example, for the ERT system target file, you would define variables for the character vectors `'ert.tlc'`, `'ert_default_tmf'`, and `'make_rtw'`.
- 3 Select the system target file with a call to the `switchTarget` function. In the function call, specify the handle for the active configuration set and the system target file.
- 4 Set the `TemplateMakefile` and `MakeCommand` configuration parameters to the corresponding variables created in step 2.

For example:

```
cs = getActiveConfigSet(model);  
stf = 'ert.tlc';
```

```
tmf = 'ert_default_tmf';  
mc = 'make_rtw';  
switchTarget(cs,stf,[]);  
set_param(cs,'TemplateMakefile',tmf);  
set_param(cs,'MakeCommand',mc);
```

For more information about selecting system target files programmatically, see `switchTarget`.

## Develop Custom System Target Files

You can create your own system target files that interface with external code or operating environments.

For more information on how to make custom system target files appear in the System Target File Browser and display relevant controls, see “About Embedded Target Development” (Simulink Coder) and the topics it references.

## Configure STF-Related Code Generation Parameters

Many model configuration parameters for code generation are specific to GRT, ERT, or ERT-based system target files.

### Specify Generated Code Interfaces

Use interface model configuration parameters to control which libraries to use when generating code, whether to include support for an API in generated code, and other interface options.

To...	Select or Enter...
Specify the standard math library that the code generator uses when generating code.	<p>Select C89/C90 (ANSI), C99 (ISO), or C++03 (ISO) for the <b>Standard math library</b> parameter.</p> <p>Selecting C89/C90 (ANSI) provides the ANSI<sup>a</sup> C set of library functions. For example, selecting C89/C90 (ANSI) results in generated code that calls <code>sin()</code> whether the input argument is double precision or single precision. However, if you select C99 (ISO), the generated code calls the function <code>sinf()</code> when the input argument is single precision. If your compiler supports the ISO<sup>b</sup> C math extensions, selecting the ISO C library can result in more efficient code.</p> <p>For more information, see “Standard math library” (Simulink Coder).</p> <p>The options for this parameter have dependencies. See Interface Dependencies.</p>
Specify an application-specific library that the code generator uses when generating code.	<p>If you generate application-specific C or C++ code for math functions or operations, select a value for <b>Code replacement library</b>. Otherwise, specify None.</p> <p>For more information about code replacement libraries, see “Choose a Code Replacement Library” on page 51-8 and “Code replacement library” (Simulink Coder).</p> <p>The options for this parameter have dependencies. See Interface Dependencies.</p>

To...	Select or Enter...
<p>Direct where the code generator places fixed-point and other utility code.</p>	<p>Select Auto or Shared location for <b>Shared code placement</b>. The shared location directs code for utilities to be placed within the <code>slprj</code> folder in your working folder, which is used for building referenced models. If you select Auto,</p> <ul style="list-style-type: none"> <li>• When the model contains Model blocks, places utility code within the <code>slprj/target/_sharedutils</code> folder.</li> <li>• When the model does not contain Model blocks, places utility code in the build folder (generally, in <code>model.c</code> or <code>model.cpp</code>).</li> </ul>
<p>Specify text to be added to the variable names used when logging data to MAT-files and to distinguish logging data from code generation and simulation applications.</p>	<p>Enter a prefix or suffix, such as <code>rt_</code> or <code>_rt</code>, for the <b>MAT-file variable name modifier</b> parameter. The code generator prefixes or appends the text to the variable names for system outputs, states, and simulation time specified in the <b>Data Import/Export</b> pane. See “Log Program Execution Results” on page 56-2 for information on MAT-file data logging.</p>
<p>Specify data exchange APIs to be included in generated code.</p>	<p>Select one or more <b>C API</b> options, the <b>ASAP2 interface</b> option, or the <b>External mode</b> option. When you select <b>External mode</b>, other options appear. The data exchange APIs are independent, and you can select combinations of these APIs. For example, you could choose C API and external mode.</p> <p>For more information on working with these interfaces, see “Exchange Data Between Generated and External Code Using C API” on page 57-2, “Export ASAP2 File for Data Measurement and Calibration” on page 58-2, and “Host-Target Communication with External Mode Simulation” (Simulink Coder).</p> <p>The options for this parameter have dependencies. See Interface Dependencies.</p>

- a. ANSI is a registered trademark of the American National Standards Institute, Inc.
- b. ISO is a registered trademark of the International Organization for Standardization.

**Note** Before setting **Standard math library** or **Code replacement library**, verify that your compiler supports the library you want to use. If you select a parameter value that your toolchain does not support, compiler errors can occur. For example, if you select

standard math library C99 (ISO) and your compiler does not support the ISO C math extensions, compile-time errors could occur.

---

When the Embedded Coder product is installed on your system, the **Code Generation > Interface** pane expands to include several additional options. For descriptions of **Code Generation > Interface** pane parameters, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Several interface parameters have dependencies on settings of other parameters. The following table summarizes the dependencies.

## Interface Dependencies

Parameter	Dependencies?	Dependency Details
<b>Standard math library</b>	Yes	Available values depend on <b>Language</b> selection.
<b>Code replacement library</b>	Yes	Available values depend on product licensing and other parameters. For more information, see “Code replacement library” (Simulink Coder).
<b>Shared code placement</b>	No	
<b>Support: floating-point numbers</b> (ERT system target files only)	No	
<b>Support: non-finite numbers</b>	Yes (ERT) No (GRT)	For ERT system target files, enabled by <b>Support floating-point numbers</b>
<b>Support: complex numbers</b> (ERT system target files only)	No	
<b>Support: absolute time</b> (ERT system target files only)	No	
<b>Support: continuous time</b> (ERT system target files only)	Yes	Requires that you disable <b>Remove error status field in real-time model data structure</b> .
<b>Support: non-inlined S-functions</b> (ERT system target files only)	Yes	Requires that you enable <b>Support floating-point numbers</b> and <b>Support non-finite numbers</b>
<b>Classic call interface</b>	Yes	Requires that you disable <b>Single output/update function</b> . For ERT system target files, requires that you enable <b>Support floating-point numbers</b> .
<b>Single output/update function</b>	Yes	Disable for <b>Classic call interface</b>
<b>Terminate function required</b> (ERT system target files only)	Yes	
<b>Code interface packaging</b>	Yes	Available values depend on <b>Language</b> selection.

Parameter	Dependencies?	Dependency Details
<b>Multi-instance code error diagnostic</b>	Yes	Set <b>Code interface packaging</b> to Reusable function or C++ class
<b>Pass root-level I/O as</b> (ERT system target files only)	Yes	Set <b>Code interface packaging</b> to Reusable function
<b>Use dynamic memory allocation for model initialization</b> (ERT system target files only)	Yes	Set <b>Code interface packaging</b> to Reusable function
<b>MAT-file logging</b>	Yes	For GRT system target files, requires that you enable <b>Support non-finite numbers</b> ; for ERT system target files, requires that you enable <b>Support floating-point numbers</b> , <b>Support non-finite numbers</b> , and <b>Terminate function required</b>
<b>MAT-file file variable name modifier</b>	Yes	Enabled by <b>MAT-file logging</b>
<b>Remove error status field in real-time model data structure</b> (ERT system target files only)	Yes	Requires that you disable <b>Support: continuous time</b> .
<b>Generate C API for: signals</b>	No	
<b>Generate C API for: parameters</b>	No	
<b>Generate C API for: states</b>	No	
<b>Generate C API for: root-level I/O</b>	No	
<b>ASAP2 interface</b>	No	
<b>External mode</b>	No	
<b>Transport layer</b>	Yes	Enable <b>External mode</b>
<b>MEX-file arguments</b>	Yes	Enable <b>External mode</b>
<b>Static memory allocation</b>	Yes	Enable <b>External mode</b>
<b>Static memory buffer size</b>	Yes	Enable <b>Static memory allocation</b>

## Configure Numeric Data Support

By default, ERT system target files support code generation for integer, floating-point, nonfinite, and complex numbers.

To Generate Code That Supports...	Do...
Integer data only	Clear <b>Support floating-point numbers</b> . If noninteger data or expressions are encountered during code generation, an error message reports the offending blocks and parameters.
Floating-point data	Select <b>Support floating-point numbers</b> .
Nonfinite values (for example, NaN, Inf)	Select <b>Support floating-point numbers</b> and <b>Support non-finite numbers</b> .
Complex data	Select <b>Support complex numbers</b> .

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

## Configure Time Value Support

Certain blocks require the value of absolute time, elapsed time, or continuous time. Absolute time is the time from the start of program execution to the present time. Elapsed time is the time elapsed between two trigger events. Depending on the blocks used, your model could require adjustment of the configuration settings for supported time values.

To...	Select...
Generate code that creates and maintains integer counters for blocks that use absolute or elapsed time values (default).	<b>Support absolute time</b> . For further information on the allocation and operation of absolute and elapsed timers, see “Absolute and Elapsed Time Computation” (Simulink Coder). If you do not select this parameter and the model includes a block that uses absolute or elapsed time values, the build process generates an error.
Generate code for blocks that rely on continuous time.	<b>Support continuous time</b> . If you do not select this parameter and the model includes continuous-time blocks, the build process generates an error.

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

## Configure Noninlined S-Function Support

To generate code for noninlined S-Functions in a model, select **Support noninlined S-functions**. The generation of noninlined S-functions requires floating-point and nonfinite numbers. Thus, when you select **Support non-inlined S-functions**, the ERT system target file selects **Support floating-point numbers** and **Support non-finite numbers**.

When you select **Support non-finite numbers** and the model includes a C MEX S-function that does not have a corresponding TLC implementation (for inlining code generation), the build process generates an error.

Inlining S-functions is highly advantageous in production code generation, for example in implementing device drivers. To enforce the use of inlined S-functions for code generation, clear **Support non-inlined S-functions**.

When generating code for a model that contains noninlined S-functions with an ERT system target file, there can be a mismatch between the simulation and code generation results when either of the following is true:

- Model configuration parameter `GenCodeOnly` is set to `off`.
- Model configuration parameter `ProdEqTarget` is set to `off`.

To avoid such a mismatch, set `ProdEqTarget` to `on` or set `GenCodeOnly` to `on`.

## Configure Model Function Generation and Argument Passing

For ERT system target files, you can configure model for how functions are generated and how arguments are passed to the functions.

To...	Do...
Generate model function calls that are compatible with the main program module of the pre-R2012a GRT system target file ( <code>grt_main.c</code> or <code>.cpp</code> ).	Select <b>Classic call interface</b> and <b>MAT-file logging</b> . In addition, clearing <b>Remove error status field in real-time model data structure</b> . <b>Classic call interface</b> provides a quick way to use code generated in R2012a or higher with a pre-R2012a GRT-based custom system target file by generating wrapper function calls that interface to the generated code.

To...	Do...
Reduce overhead and use more local variables by combining the output and update functions in a single <i>model_step</i> function.	Select <b>Single output/update function</b>  Errors or unexpected behavior can occur if a Model block is part of a cycle and the model configuration enables “Single output/update function” (Simulink Coder) (the default). For more information about direct feed through, see “Algebraic Loop Concepts” (Simulink).
Generate a <i>model_terminate</i> function for a model not designed to run indefinitely.	Select <b>Terminate function required</b> (Simulink Coder). For more information, see the description of <i>model_terminate</i> .
Generate reusable, reentrant code from a model or subsystem.	Select <b>Generate reusable code</b> . See “Configure Code Reuse Support” on page 45-14 for details.
Statically allocate model data structures and access them directly in the model code.	Clear <b>Generate reusable code</b> . The generated code is not reusable or reentrant. See “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder) for information on the calling interface generated for model functions in this case.
Suppress the generation of an error status field in the real-time model data structure, <i>rtModel</i> , for example, if you do not require to log or monitor error messages.	Select <b>Remove error status field in real-time model data structure</b> . Selecting this parameter can also cause the code generator to omit the <i>rtModel</i> structure from the generated code.  When generating code for multiple integrated models, set this parameter the same for all of the models. Otherwise, the integrated application could exhibit unexpected behavior. For example, if you select the option in one model but not in another, it is possible that the integrated application could not register the error status.  Do not select this parameter if you select the <b>MAT-file logging</b> option. The two options are incompatible.

To...	Do...
Open the Configure C Step Function Interface dialog box and modify the <i>model_step</i> function prototype.	In the Code Mapping Editor, on the <b>Entry-Point Functions</b> tab, click in the Function Name column for the base-rate step function. Click the three vertical dots that appear. Then click <b>Configure Prototype</b> . Unless a function prototype was previously configured, the dialog box opens showing a preview of the step function interface without arguments ( <b>void-void</b> ). The dialog box also shows the current function name. If arguments have previously been configured for the model, the dialog box displays the current settings. You can change the name and argument settings for the step function. For more information, see “Override Default C Step Function Interface” on page 40-7.

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

## Configure Code Reuse Support

For GRT, ERT, GRT-based, and ERT-based system target files, you can configure how a model reuses code by setting the **Code interface packaging** configuration parameter value to **Reusable function**.

The **Pass root-level I/O as** configuration parameter provides options that control how model inputs and outputs at the root level of the model are passed to the *model\_step* function.

To...	Select...
Pass each root-level model input and output argument to the <i>model_step</i> function individually (the default)	<b>Code interface packaging</b> > <b>Reusable function</b> and <b>Pass root-level I/O as</b> > <b>Individual arguments</b> .
Pack root-level input arguments and root-level output arguments into separate structures that are then passed to the <i>model_step</i> function	<b>Code interface packaging</b> > <b>Reusable function</b> and <b>Pass root-level I/O as</b> > <b>Structure reference</b> .
Pack root-level input arguments and root-level output arguments into the model data structure to support reentrant multi-instance code from a model for ERT system target file	<b>Code interface packaging</b> > <b>Reusable function</b> and <b>Pass root-level I/O as</b> > <b>Part of model data structure</b> .

If using the **Code interface packaging** > Reusable function selection, consider using the **Use dynamic memory allocation for model initialization** option to control whether an allocation function is generated. This option applies for ERT system target files.

Sometimes, selecting **Code interface packaging** as Reusable function can generate code that compiles but is not reentrant. For example, if a signal, DWork structure, or parameter data has a storage class other than Auto, global data structures are generated. To handle such cases, use the **Multi-instance code error diagnostic** parameter to choose the severity levels for diagnostics.

Sometimes, the code generator is unable to generate valid and compilable code. For example, if the model contains one of the following, the generated code is invalid.

- An S-function that is not code-reuse compliant
- A subsystem triggered by a wide function-call trigger

In these cases, the build terminates after reporting the problem.

For more information, see “Generate Reentrant Code from Top Models” on page 6-25 and “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

## Configure a Code Replacement Library

You can configure the code generator to change the code that it generates for functions and operators such that the code meets application requirements. Configure the code generator to apply a code replacement library (CRL) during code generation. If you have Embedded Coder, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 52-2 and “Code Replacement Libraries” (Simulink Coder). For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 65-3.

- “Compare System Target File Support Across Products” on page 45-20
- “Specify Generated Code Interfaces” on page 45-6

## Configure Standard Math Library for Target System

Specify standard library extensions that the code generator uses for math operations. When you generate code for a new model or with a new configuration set object, the code generator uses the ISO@/IEC 9899:1999 C (C99 (ISO)) library by default. For preexisting models and configuration set objects, the code generator uses the library specified by the **Standard math library** parameter.

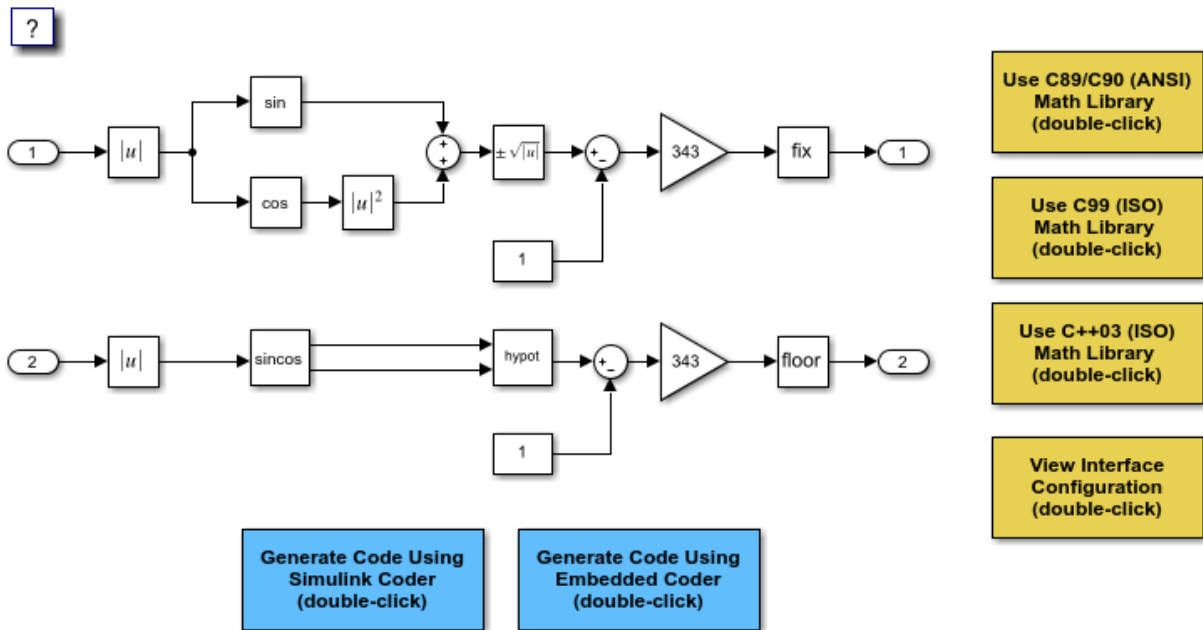

If your compiler supports the ISO@/IEC 9899:1990 (C89/C90 (ANSI)) or ISO/IEC 14882:2003(C++03 (ISO)) math library extensions, you can change the standard math library setting. The C++03 (ISO) library is an option when you select C++ for the programming language.

The C99 library leverages the performance that a compiler offers over standard ANSI C. When using the C99 library, the code generator produces calls to ISO C functions when possible. For example, the generated code calls the function `sqrtf()`, which operates on single-precision data, instead of `sqrt()`.

To change the library setting, use the **Configuration Parameters>Standard math library** parameter. The command-line equivalent is `TargetLangStandard`.

### Generate and Inspect ANSI C Code

1. Open the example model `rtwdemo_clibsup`.

Copyright 1994–2019 The MathWorks, Inc.

## 2. Generate code.

```
### Starting build procedure for model: rtwdemo_clibsup
### Successful completion of code generation for model: rtwdemo_clibsup
```

## 3. Examine the code in the generated file rtwdemo\_clibsup.c. Note that the code calls the sqrt function.

```
if (rtb_Abs2 < 0.0F) {
    rtb_Abs2 = -(real32_T)sqrt((real32_T)fabs(rtb_Abs2));
} else {
    rtb_Abs2 = (real32_T)sqrt(rtb_Abs2);
}
```

## Generate and Inspect ISO C Code

1. Change the setting of **Standard math library** to C99 (ISO). Alternatively, at the command line, set TargetLangStandard to C99 (ISO).

## 2. Regenerate the code.

```
### Starting build procedure for model: rtwdemo_clibsup  
### Successful completion of code generation for model: rtwdemo_clibsup
```

## 3. Reexamine the code in the generated file `rtwdemo_clibsup.c`. Now the generated code calls the function `sqrtf` instead of `sqrt`.

```
if (rtb_Abs2 < 0.0F) {  
    rtb_Abs2 = -sqrtf(fabsf(rtb_Abs2));  
} else {  
    rtb_Abs2 = sqrtf(rtb_Abs2);  
}
```

## Compare System Target File Support Across Products

When you select a system target file (such as `grt.tlc`), the selection defines the run-time environment and the code generation features. Identify the system target file features that match your code generation workflow goals.

The code generator uses the system target file to produce code intended for execution on certain target hardware or on a certain operating system. The system target file invokes other run-time environment-specific files. For more information on configuring model code generation parameters for target hardware, see “Configure Run-Time Environment Options” (Simulink Coder).

Different types of system target files support a selection of generated code features. In the system target file, the value of the `CodeFormat` TLC variable and corresponding `rtwgensettings.DerivedFrom` field value identify the system target file type and generated code features. These selections apply your code generation control decisions at several points in the code generation process. Your selections include whether and how the model build generates:

- Certain data structures (for example, `SimStruct` or `rtModel`)
- Static or dynamic memory allocation code
- Calling interface for generated model functions

For custom system target file development, the `CodeFormat` value differs among code generation targets:

- If the system target file does not include a value for the `CodeFormat` TLC variable, the default value is `RealTime` for generic real-time target (GRT). The corresponding `rtwgensettings.DerivedFrom` field value is `grt.tlc` (default value).
- If you are developing a custom system target file and you have Embedded Coder software, consider setting the `CodeFormat` TLC variable value to `Embedded-C` for embedded real-time target (ERT). The corresponding `rtwgensettings.DerivedFrom` field value is `ert.tlc`. The ERT system target file supports more generated code features than the GRT system target file.

This example shows how the value for the `CodeFormat` TLC variable and corresponding `rtwgensettings.DerivedFrom` field value are set in `ert.tlc`.

```
%assign CodeFormat = "Embedded-C"
```

```
/%  
  BEGIN_RTW_OPTIONS  
    rtwgensettings.DerivedFrom = 'ert.tlc';  
  END_RTW_OPTIONS  
%/
```

---

**Note** Use the value for the CodeFormat TLC variable with its corresponding `rtwgensettings.DerivedFrom` field value to generate code for the model. If you do not select a value explicitly, the default values correspond. For more information, see “System Target File Structure” (Simulink Coder).

---

For a description of the optimized call interface generated by default for the GRT and ERT system target files, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

Code generation with the GRT and ERT system target files uses the real-time model data structure (`rtModel`). This structure encapsulates model-specific information in a much more compact form than the simulation structure, `SimStruct`. Many efficient features of generated code depend on generation of `rtModel` rather than `SimStruct`, including:

- Integer absolute and elapsed timing services
- Independent timers for asynchronous tasks
- Generation of improved C API code for signal, state, and parameter monitoring
- Pruning the data structure to minimize its size (ERT-derived system target files only)

For a description of the `rtModel` data structure, see “Use the Real-Time Model Data Structure” (Simulink Coder).

## Compare Product System Target Files

You can select from a range of system target files by using the System Target File Browser. This selection lets you experiment with configuration options and save your model with different configurations.

You cannot build or generate code for non-GRT system target files, unless you have the required software on your system. For example, you require Embedded Coder for ERT system target files, Simulink Desktop Real-Time for SLDRT system target files, and so on.

Selecting a system target file for your model selects either the toolchain approach or the template makefile approach for build process control. For more information about these approaches, see “Choose Build Approach and Configure Build Process” on page 54-14.

## Compare Code Styles and STF Support

The code generator produces two styles of code. One code style is suitable for rapid prototyping (and simulation by using code generation). The other style is suitable for embedded applications. This table maps system target files to corresponding code styles.

### Code Styles Listed by System Target File

System Target File	Code Style	Purpose
Embedded Coder embedded real-time (ERT)	Embedded	A starting point for embedded application development of C/C++ generated code.
Simulink Coder generic real-time (GRT)	Rapid prototyping	A starting point for creating a rapid prototyping target hardware that does not use real-time operating system tasking primitives and for verifying the generated C/C++ code on your desktop computer.
Rapid simulation (RSim)	Rapid prototyping	Provides non-real-time simulation on your desktop computer and a high-speed or batch simulation tool.
S-function	Rapid prototyping	Creates a C MEX S-function for simulation within another Simulink model.
Simulink Desktop Real-Time	Rapid prototyping	Runs a model in real time at interrupt level while your desktop computer runs Microsoft Windows in the background.
Simulink Real-Time	Rapid prototyping	Runs a model in real time on a desktop computer running the Simulink Real-Time kernel.

Third-party vendors supply additional system target files to support code generation for their products. For more information about third-party products, see the vendor website or the MathWorks Connections program web page: <https://www.mathworks.com/products/connections>.

### Compare Generated Code Features by Product

The code generation process for real-time system target files (such as GRT) provides many embedded code optimizations. Selecting an ERT-based system target file offers more extensive features than GRT. The system target file selection determines the available features for the code generation product. As you select the code generation target that matches your development process, use this table to compare code generation features available with Simulink Coder and features available with Embedded Coder.

**Compare Code Generation Features for Simulink Coder Versus Embedded Coder**

Feature	Simulink Coder	Embedded Coder
rtModel data structure	<ul style="list-style-type: none"> <li>• Full rtModel structure generated</li> <li>• GRT variable declaration: rtModel_model model_M_;</li> </ul>	<ul style="list-style-type: none"> <li>• rtModel is optimized for the model</li> <li>• Optional suppression of error status field and data logging fields</li> <li>• ERT variable declaration: RT_MODEL_model model_M_;</li> </ul>
Custom storage classes (CSCs)	Code generation ignores CSCs. Objects are assigned a CSC default to Auto storage class.	Code generation with CSCs is supported
HTML code generation report	Basic HTML code generation report	Enhanced report with additional detail and hyperlinks to the model
Symbol formatting	Symbols (for signals, parameters, and so on) are generated in accordance with hard-coded default	Detailed control over generated symbols
User-defined maximum identifier length for generated symbols	Supported	Supported
Generation of terminate function	Generated	Option to suppress the terminate function
Combined output/update function	Separate output/update functions are generated	Option to generate combined output/update function
Optimized data initialization	Not available	Options to suppress generation of unnecessary initialization code for zero-valued memory, I/O ports, and so on
Comments generation	Basic options to include or suppress comment generation	Options to include Simulink block descriptions, Stateflow object descriptions, and Simulink data object descriptions in comments

<b>Feature</b>	<b>Simulink Coder</b>	<b>Embedded Coder</b>
Module Packaging Features (MPF)	Not supported	Extensive code customization features See “Control Data Type Names in Generated Code” on page 35-2 and “MPT Data Object Properties” on page 36-2.
System target file-optimized data types header file	Requires full <code>tmwtypes.h</code> header file	Generates optimized <code>rtwtypes.h</code> header file, including definitions required by the system target file
User-defined types	User-defined types default to base types in code generation	User-defined data type aliases are supported in code generation
Rate grouping	Not supported	Supported
Auto-generation of main program module	Not supported. Static main program module is provided.	Automated and customizable generation of main program module is supported (static main program also available)
Reusable (multi-instance) code generation	Option to generate reusable code with dynamic memory allocation	Option to generate reusable code with static or dynamic memory allocation
Software constraint options	Support for floating-point, complex, and nonfinite numbers is enabled	Options to enable or disable support for floating-point, complex, and nonfinite numbers
Application life span	Defaults to <code>inf</code>	User-specified. Determines most efficient word size for integer timers
Software-in-the-loop (SIL) testing	Model reference simulation target can be used for SIL testing	Additional SIL testing support by using auto-generation of SIL block
ANSI-C/C++ code generation	Supported	Supported
ISO-C/C++ code generation	Supported	Supported
GNU <sup>®</sup> -C/C++ code generation	Supported	Supported

Feature	Simulink Coder	Embedded Coder
Generate scalar inlined parameters as #DEFINE statements	Not supported	Supported
MAT-file variable name modifier	Supported	Supported
Data exchange: C API, ASAP2, external mode	Supported	Supported

## Compare Generated Code Features by STF

The code generator supports a selection of generated code features for different types of system target files. In each system target file, the value of the CodeFormat TLC variable identifies the set of features.

This table summarizes how different system target files support applications.

Application	System Target File (STF)
Fixed- or variable-step acceleration	RSIM, S-Function, Model Reference
Fixed-step real-time deployment	GRT, ERT, Simulink Real-Time, Simulink Desktop Real-Time, ...

This table summarizes the various options available for each **System target file** selection, with the exceptions noted.

**Features Supported in Code Generated for System Target Files (STF)**

Feature	System Target Files (STF)							
	grt.tlc (See note 1.)	ert.tlc (See note 1.)	ert_shrlib.tlc (See note 1.)	rtwshfcn.tlc (See note 1.)	rsim.tlc (See note 1.)	sldrt.tlc (See note 1.)	slrt.tlc (See note 1.)	Other (See note 1.)
Static memory allocation	X	X				X	X	X
Dynamic memory allocation	X (See notes 4, 5.)	X (See notes 4, 5.)		X	X		X	
Continuous time	X	X		X	X	X	X	
C/C++ MEX S-functions (noninlined)	X	X		X	X	X	X	
S-function (inlined)	X	X		X	X	X	X	X
Minimize RAM/ROM usage		X					X <sup>2</sup>	X
Supports external mode	X	X			X	X	X	
Rapid prototyping	X					X	X	X
Production code		X					X <sup>2</sup>	X (See note 3.)

Feature	System Target Files (STF)							
	grt.tlc (See note 1.)	ert.tlc (See note 1.)	ert_shrllib.tlc (See note 1.)	rtwsfcn.tlc (See note 1.)	rsim.tlc (See note 1.)	sldrt.tlc (See note 1.)	slrt.tlc (See note 1.)	Other (See note 1.)

Non-real-time executable included	X	X			X			
Multiple instances of model	X (See notes 4, 5.)	X (See notes 4, 5.)		X <sup>4</sup>			X (See notes 4, 5.)	X (See notes 4, 5.)
Supports variable-step solvers				X	X			
Supports SIL/PIL		X						X

**Notes**

- 1 System Target Files:

- **grt.tlc** - generic real-time target
  - **ert.tlc** - embedded real-time target
  - **ert\_shrlib.tlc** - embedded real-time target shared library)
  - **rtwsfcn.tlc** - S-Function
  - **rsim.tlc** - rapid simulation
  - **sldrt.tlc** - Simulink Desktop Real-Time
  - **slrt.tlc** - Simulink Real-Time
  - **Other** - The embedded real-time capabilities in Simulink Coder support other system target files
- 2 Does not apply to GRT-based system target files. Applies to only ERT-based system target files.
  - 3 The default GRT and ERT `rt_main` files emulate execution of hard real time. When explicitly connected to a real-time clock, they execute in hard real time.
  - 4 You can generate code for multiple instances of a Stateflow chart or subsystem containing a chart, except when the chart contains exported graphical functions or the Stateflow model contains machine-parented events.
  - 5 In the Configuration Parameters dialog box, for the **Code interface packaging** (Simulink Coder) field, select `Reusable` function.

# Internationalization Support in Embedded Coder

---

## Internationalization and Code Generation

Internationalization support in software development tooling is vital to enabling efficient globalization. If there is a remote possibility that you could collaborate in the future with others across locales, consider internationalization from project inception. Internationalization can prevent rework or having to develop a new model design. The relevant requirement concerns locale settings.

In this section...
“Locale Settings” on page 46-2
“Prepare to Generate Code for Mixed Languages and Locales” on page 46-3
“Character Set Limitations” on page 46-3
“XML Escape Sequence Replacements” on page 46-3
“CGT Files and XML Escape Sequence Replacements” on page 46-3
“Generate and Review Code with Mixed Languages and Mixed Locales” on page 46-4

### Locale Settings

On a computer, a locale setting defines the language (character set encoding) for the user interface and the display formats for information such as time, date, and currency. The encoding dictates the number of characters that a locale can render. For example, the US-ASCII coded character set (codeset) defines 128 characters. A Unicode® codeset, such as UTF-8, defines more than 1,100,000 characters.

For code generation, the locale setting determines the character set encoding of generated file content. To avoid garbled text or incorrectly displayed characters, the locale setting for your MATLAB session must be compatible with the setting for your compiler and operating system. For information on finding and changing the operating system setting, see “Internationalization” (MATLAB) or see the operating system documentation.

To check a model for characters that cannot be represented in the locale setting of your current MATLAB session, use the Simulink Model Advisor check “Check model for foreign characters” (Simulink).

## Prepare to Generate Code for Mixed Languages and Locales

To prepare to generate code for a model, identify:

- The operating system locale.
- The locale of the MATLAB session.
- Code generation requirements for:
  - Target Language Compiler files
  - Code generation template files that include comments (requires Embedded Coder)

## Character Set Limitations

Target language compiler files support user default encoding only. To produce international, custom generated code that is portable, use the 7-bit ASCII character set.

## XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding of a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in:

- Generated code comments
- Code generation reports
- Block paths logged to MAT-files
- Block paths logged to C API files *model\_capi.c* (or *.cpp*) and *model\_capi.h*

## CGT Files and XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding for a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in Comments in code generation template (CGT) files.

By default, code generation template files do not contain character set encoding information. The operating system reads the files, using its current encoding, regardless of the encoding that you use to write the file. You can enable escape sequence replacements by adding the following token at the top of the template file:

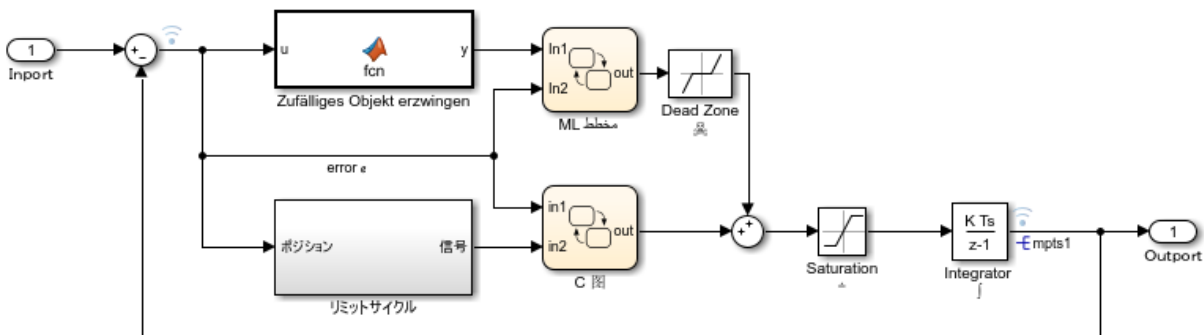

- C and C++ API interfaces
- Code generation template (CGT) files (requires Embedded Coder®)
- Target Language Compiler (TLC) files that apply code customizations (requires Embedded Coder®)

### Open the example model `rtwdemo_unicode`.

Open example model `rtwdemo_unicode`. Labels in the model appear in multiple languages (Arabic, Chinese, English, German, and Japanese) and various Unicode symbols.

```
model = 'rtwdemo_unicode';
open_system(model);
%
```

Copyright 2015-2019 The MathWorks, Inc.

### Open the Embedded Coder App

In the Apps tab, select **Embedded Coder**.

### Verify Locale Settings

Verify that the locale setting for your MATLAB® software is compatible with your compiler. See the documentation for your operating system or the following MATLAB documentation:

- “Set Locale on Windows Platforms” (MATLAB)
- “Set Locale on Linux Platforms” (MATLAB)

- “Set Locale on macOS Platforms” (MATLAB)

### Verify Model for Use of Foreign Characters

To verify the model for characters that the code generator cannot represent in the model's current character set encoding, use the Simulink® Model Advisor check **Check model for foreign characters**.

1. Open the Model Advisor. In the **Modeling** tab, click **Model Advisor**. Select **Model Advisor**. Or, in the Command Window, type:

```
modeladvisor('rtwdemo_unicode')
```

```
Updating Model Advisor cache...
```

```
Model Advisor cache updated. For new customizations, to update the cache, use the Adv...
```

2. Expand **By Product**.
3. Expand **Simulink**.
4. Select **Check model for foreign characters**
5. Click **Run This Check**.
6. Review the results. Several warnings appear. Verify that the characters in the model can be represented in the current character set encoding.
7. Close the Model Advisor.

### Code Generation Template Files

To use a code generation template file with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

1. Open the Configuration Parameters dialog box.
2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code generation template file `rtwdemo_unicode.cgt`. That file adds comments to the top of generated code files. For the code generator to apply escape sequence replacements for the `.cgt` file, enable replacements by specifying:

```
<encodingIn = "encoding-name">
```

3. Open the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

```
edit rtwdemo_unicode.cgt
```

4. Find the line of code that enables escape sequence replacements for the character set encoding UTF-8.

```
<encodingIn = "UTF-8">
```

5. Close the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

### Generated File Customization Template

To use file customization templates with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

You can specify customizations to generated code files by using TLC code. TLC files support user default encoding only. To produce international custom generated code that is portable, use the 7-bit ASCII character set.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code customization file `example_file_process.tlc`. That file customizes the generated code just before the code generator writes the code files. For example, the file adds a C source file, corresponding include file, and `#define` and `#include` statements.

3. Open the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

```
edit example_file_process.tlc
```

4. Before generating code, uncomment the following line of code:

```
%% %assign ERTCustomFileTest = TLC_TRUE%
```

5. Close the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

### Generate C Code and a Report

Generate C code and a code generation report.

```
evalc('rtwbuild(''rtwdemo_unicode'')');
```

## Review the Generated Code

For characters that are not in the current MATLAB® character set encoding, the code generator uses escape sequence replacements to render characters correctly in the code generation report.

1. If the code generation report for model `rtwdemo_unicode` is not open, in the Command Window, type:

```
coder.report.open('rtwdemo_unicode')
```

2. Review the generated code in `rtwdemo_unicode.c` and `rtwdemo_unicode.h`. Names of model elements appear in code comments as replacement names in the local language.

3. Open the Traceability Report. The report maintains traceability information, even when the name contains characters that are not represented in the current encoding. Names of model elements appear in the report as replacement names in the local language.

4. Scroll down to and click the code location link for the first Chart (State 'Selection' <S2>:23). The report view changes to show the corresponding code in `rtwdemo_unicode.c`.

5. In the code comment, click the <S2>:23 link. The model window shows the chart in a new tab.

6. In the model window, right-click that chart. From the context menu, select **C/C++ Code > Navigate to C/C++ Code**. The report view changes to show the named constant section of code for that chart.

7. Close the code generation report, Model Advisor, and model. In the Command Window, type:

```
coder.report.close();  
bdclose('all');
```

## Generate C++ Code

Generate C++ code and a code generation report.

1. Open the model.

```
model = 'rtwdemo_unicode';  
open_system(model);
```

Copyright 2015-2019 The MathWorks, Inc.

2. Set model configuration parameter **Language** to C++. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','TargetLang','C++');
```

3. Set model configuration parameter **Code interface packaging** to C++ class. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','CodeInterfacePackaging','C++ class');
```

4. Generate C++ code and a code generation report.

```
evalc('rtwrebuild(''rtwdemo_unicode'')');
```

5. To see internationalization and localization support, review the generated code. See **Review the Generated Code**.

6. Close the code generation report and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

- “Run Simulation Tests” on page 47-10
- “Key Points” on page 47-11
- “Learn More” on page 47-12

### About This Example

#### Learning Objectives

- Learn about the functional behavior of the example model.
- Learn about the role of the example test harness and its components.
- Run simulation tests on a model.

#### Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Understand subsystems and how to view subsystem details.
- Understand referenced models and how to view referenced model details.
- Ability to set model configuration parameters.

#### Required Files

Before you use each example model file, place a copy in a writable location and add it to your MATLAB path.

- `rtwdemo_throttlecntrl` model file
- `rtwdemo_throttlecntrl_testharness` model file

## Functional Design of the Model

This example uses a simple, but functionally complete, example model of a throttle controller. The model features redundant control algorithms. The model highlights a standard model structure and a set of basic blocks in algorithm design.

## View the Top Model

Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

---

**Note** This model uses Stateflow software.

---

The top level of the model consists of the following elements:

Subsystems	<code>PI_ctrl_1</code> <code>PI_ctrl_2</code> <code>Define_Throt_Param</code> <code>Pos_Command_Arbitration</code>
Top-level input	<code>pos_rqst</code> <code>fbk_1</code> <code>fbk_2</code>

Top-level output	pos_cmd_one pos_cmd_two ThrotComm1
Signal routing	
Omit blocks that change the value of a signal, such as Sum and Integrator	

The layout uses a basic architectural style for models:

- Separation of calculations from signal routing (lines and buses)
- Partitioning into subsystems

You can apply this style to a wide range of models.

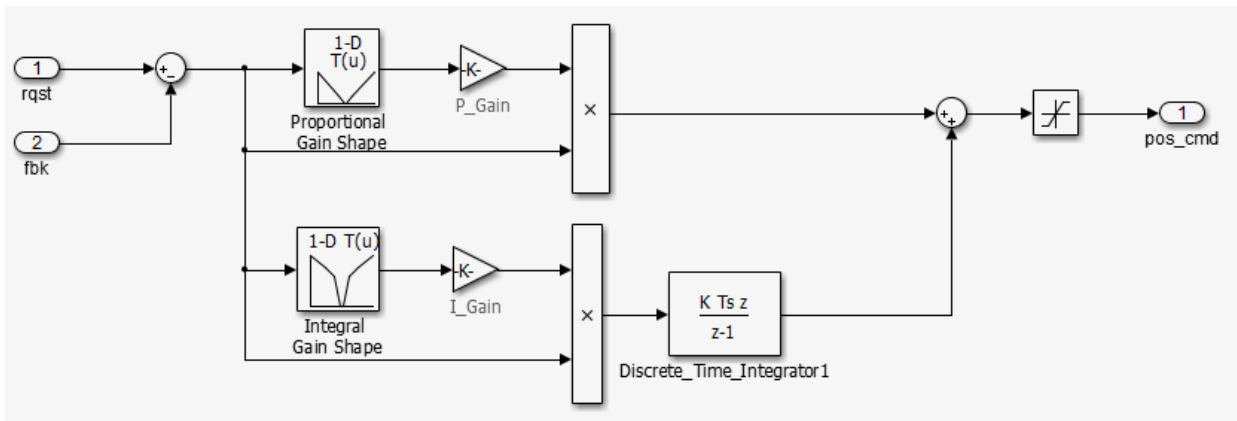

## View the Subsystems

Explore two of the subsystems in the top model.

- 1 If not already open, open `throttlectrl`.

Two subsystems in the top model represent proportional-integral (PI) controllers, `PI_ctrl_1` and `PI_ctrl_2`. At this stage, these identical subsystems, use identical data.

- 2 Open the `PI_ctrl_1` subsystem.

The PI controllers in the model are from a *library*, a group of related blocks or models for reuse. Libraries provide one of two methods for including and reusing models. The second method, model referencing, is described in “Simulation Test Environment” on page 47-5. You cannot edit a block that you add to a model from a library. Edit the block in the library so that instances of the block in different models remain consistent.

- 3 Open the Pos\_Command\_Arbitration subsystem. This Stateflow chart performs basic error checking on the two command signals. If the command signals are too far apart, the Stateflow diagram sets the output to a fail\_safe position.

- 4 Close throttlecntrl.

## Simulation Test Environment

To test the throttle controller algorithm, incorporate it into a test harness. A test harness is a model that evaluates the control algorithm and offers the following benefits:

- Separates test data from the control algorithm.
- Separates the plant or feedback model from the control algorithm.
- Provides a reusable environment for multiple versions of the control algorithm.

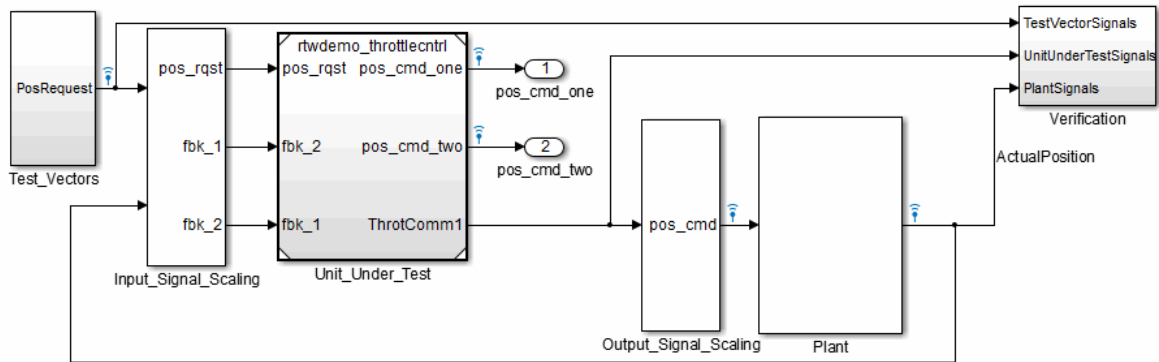

The test harness model for this example implements a common simulation testing environment consisting of the following parts:

- Unit under test

- Test vector source
- Evaluation and logging
- Plant or feedback system
- Input and output scaling

Explore the simulation testing environment.

- 1 Open the test harness model `rtwdemo_throttlecntrl_testharness` and save a copy as `throttlecntrl_testharness` in a writable location on your MATLAB path.

Copyright 2007-2011 The MathWorks, Inc.

- 2 Set up your `throttlecntrl` model as the control algorithm of the test harness.
  - a Open the `Unit_Under_Test` block and view the control algorithm.
  - b View the model reference parameters by right-clicking the `Unit_Under_Test` block and selecting **Block Parameters (ModelReference)**.

rtwdemo\_throttlecctrl appears as the name of the referenced model.

- c Change the value of **Model name** to throttlecctrl.
- d Update the test harness model diagram by clicking **Simulation > Update Diagram**.

The control algorithm is the unit under test, as indicated by the name of the Model block, Unit\_Under\_Test.

The Model block provides a method for reusing components. From the top model, it allows you to reference other models (directly or indirectly) as compiled functions. By default, Simulink software recompiles the model when the referenced models change. Compiled functions have the following advantages over libraries:

- Simulation time is faster for large models.

- You can directly simulate compiled functions.
  - Simulation requires less memory. Only one copy of the compiled model is in memory, even when the model is referenced multiple times.
- 3 Open the test vector source, implemented in this test harness as the `Test_Vectors` subsystem.

The subsystem uses a Signal Builder block for the test vector source. The block has data that drives the simulation (`PosRequest`) and provides the expected results used by the `Verification` subsystem. This example test harness uses only one set of test data. Typically, create a test suite that fully exercises the system.

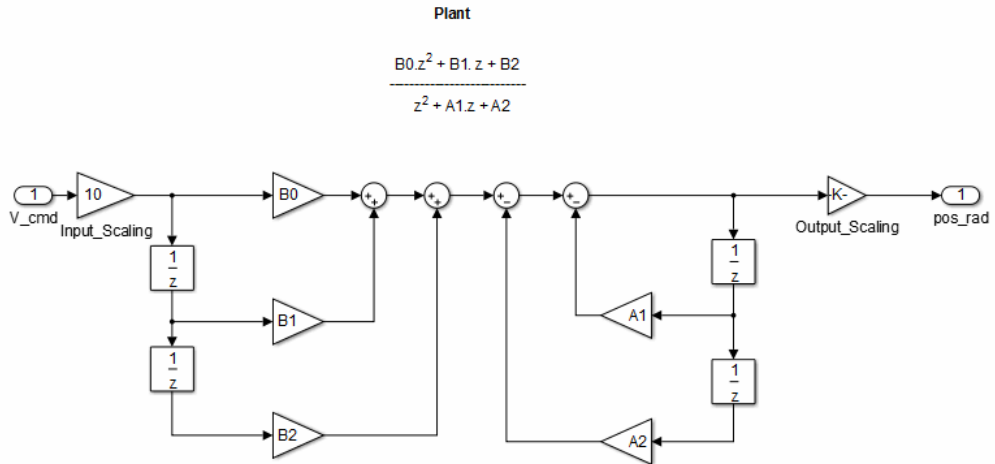

- 4 Open the evaluation and logging subsystem, implemented in this test harness as subsystem `Verification`.

A test harness compares control algorithm simulation results against golden data — test results that exhibit the desired behavior for the control algorithm as certified by an expert. In the `Verification` subsystem, an Assertion block compares the simulated throttle value position from the plant against the golden value from the test harness. If the difference between the two signals is greater than 5%, the test fails and the Assertion block stops the simulation.

Alternatively, you can evaluate the simulation data after the simulation completes execution. Perform the evaluation with either MATLAB scripts or third-party tools. Post-execution evaluation provides greater flexibility in the analysis of data. However, it requires waiting until execution is complete. Combining the two methods can provide a highly flexible and efficient test environment.

- Open the plant or feedback system, implemented in this test harness as the `Plant` subsystem.

The `Plant` subsystem models the throttle dynamics with a transfer function in canonical form. You can create plant models to varying levels of fidelity. It is common to use different plant models at different stages of testing.

- Open the input and output scaling subsystems, implemented in this test harness as `Input_Signal_Scaling` and `Output_Signal_Scaling`.

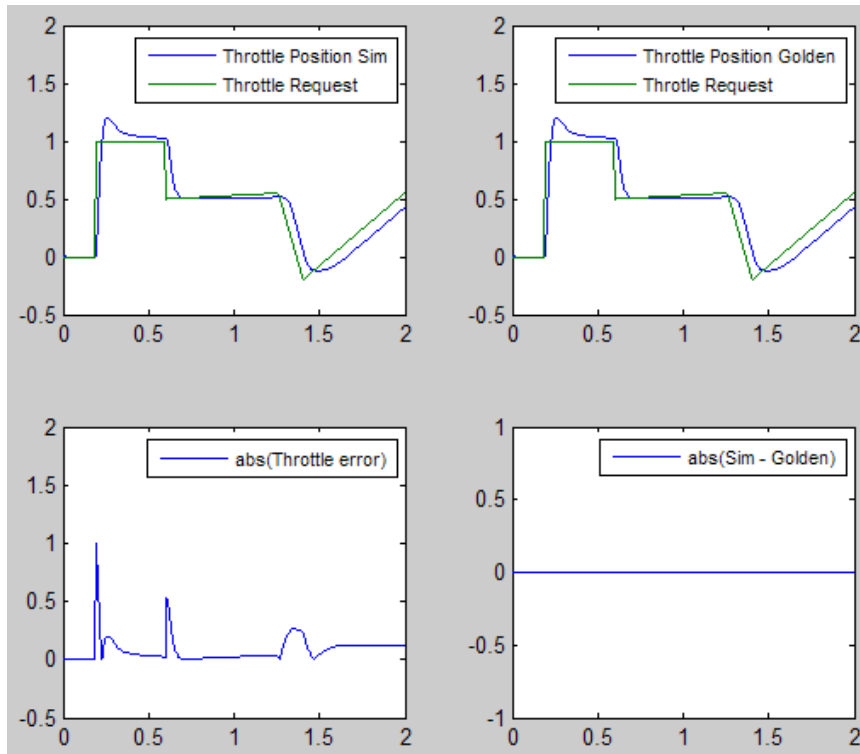

The subsystems that scale input and output perform the following primary functions:

- Select input signals to route to the unit under test.
  - Select output signals to route to the plant.
  - Rescale signals between engineering units and units that are writable for the unit under test.
  - Handle rate transitions between the plant and the unit under test.
- 7 Save and close `throttlecntrl_testharness`.

## Run Simulation Tests

- 1 Check that your working folder is set to a writable folder, such as the folder into which you placed copies of the example model files.
- 2 Open your copy of the test harness model, `throttlecntrl_testharness`.
- 3 Start a test harness model simulation. When the simulation is complete, the following results appear.

The lower-right hand plot shows the difference between the expected (golden) throttle position and the throttle position that the plant calculates. If the difference between the two values is greater than  $\pm 0.05$ , the simulation stops.

- 4 Save and close throttle controller and test harness models.

## Key Points

- A basic model architecture separates calculations from signal routing and partitions the model into subsystems
- Two options for model reuse include block libraries and model referencing.
- If you represent your control algorithm in a test harness as a Model block, specify the name of the control algorithm model in the Model Reference Parameters dialog box.

- A test harness is a model that evaluates a control algorithm. Typically, a harness consists of a unit under test, a test vector source, evaluation and logging, a plant or feedback system, and input and output scaling components.
- The unit under test is the control algorithm being tested.
- The test vector source provides the data that drives the simulation which generates results used for verification.
- During verification, the test harness compares control algorithm simulation results against golden data and logs the results.
- The plant or feedback component of a test harness models the environment that is being controlled.
- When developing a test harness,
  - Scale input and output components.
  - Select input signals to route to the unit under test.
  - Select output signals to route to the plant.
  - Rescale signals between engineering units and units that are writable for the unit under test.
  - Handle rate transitions between the plant and the unit under test.
- Before running simulation or completing verification, consider checking a model with the Model Advisor.

# Configure Model and Generate Code

**In this section...**

“About This Example” on page 47-13

“Configure the Model for Code Generation” on page 47-14

“Save Your Model Configuration as a MATLAB Function” on page 47-15

“Check Model Conditions and Configuration Settings” on page 47-15

“Generate Code for the Model” on page 47-16

“Review the Generated Code” on page 47-16

“Generate an Executable” on page 47-17

“Key Points” on page 47-18

## About This Example

### Learning Objectives

- Configure a model for code generation.
- Apply model checking tools to discover conditions and configuration settings resulting in generation of inaccurate or inefficient code.
- Generate code from a model.
- Locate and identify generated code files.
- Review generated code.

### Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Ability to set model configuration parameters.
- Ability to use the Simulink Model Advisor.
- Ability to read C code.
- An installed, supported C compiler.

### Required Files

rtwdemo\_throttlectrl model file

## Configure the Model for Code Generation

Model configuration parameters determine the method for generating the code and the resulting format.

- 1 Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path. Then, open the **Simulink Coder** app.
- 2 Open the Configuration Parameters dialog box, **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. The following table shows the solver configuration for this example.

Parameter	Setting	Effect on Generated Code
<b>Type</b>	Fixed-step	Maintains a constant (fixed) step size, which is required for code generation
<b>Solver</b>	discrete (no continuous states)	Applies a fixed-step integration technique for computing the state derivative of the model
<b>Fixed-step size</b>	.001	Sets the base rate; must be the lowest common multiple of the rates in the system

- 3 Set model configuration parameter **System target file** to `grt.tlc`.

**Note** The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the `rsim.tlc` system target file supports variable step code generation.

The system target file defines an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a system target file is the value for the CodeFormat TLC variable. The GRT configuration requires a fixed step solver and the `rsim.tlc` supports variable step code generation.

- 4 Set model configuration parameter **Include directories** as follows:

```
"$matlabroot$\toolbox\rtw\rtwdemos\EmbeddedCoderOverview\"
```

This folder includes files that are required to build an executable for the model.

- 5 Close the Model Configuration Parameters dialog box.

## Save Your Model Configuration as a MATLAB Function

You can save the settings of model configuration parameters as a MATLAB function by using the `getActiveConfigSet` function. In the MATLAB Command Window, enter:

```
thcntrlAcs = getActiveConfigSet('throttlecntrl');
thcntrlAcs.saveAs('throttlecntrlModelConfig');
```

You can then use the resulting function (for example, `throttlecntrlModelConfig`) to:

- Archive the model configuration.
- Compare different model configurations by using differencing tools.
- Set the configuration of other models.

For example, you can set the configuration of model `myModel` to match the configuration of the throttle controller model by opening `myModel` and entering:

```
myModelAcs = throttlecntrlModelConfig;
attachConfigSet('myModel', myModelAcs, true);
setActiveConfigSet('myModel', myModelAcs.Name);
```

For more information, see “Save a Configuration Set” (Simulink) and “Load a Saved Configuration Set” (Simulink).

## Check Model Conditions and Configuration Settings

Before generating code for a model, use the Simulink Model Advisor to check the model for conditions and configuration settings. This check finds issues that can result in inaccurate or inefficient code.

- 1 Open model `throttlecntrl`. Then, open the **Simulink Coder** app.
- 2 Start the Model Advisor. In the **C Code** tab, click **C/C++ Code Advisor**. A dialog box opens showing the model system hierarchy.
- 3 Click `rtwdemo_throttlecntrl` and then click **OK**. The Model Advisor window opens.
- 4 In the left pane, select **Run this check**. The report shows a **Run Summary** that flags check warnings.
- 5 Review the report. The warnings highlight issues. At this point, you can ignore them. For more information about reports, see “View Model Advisor Check Reports” (Simulink).

## Generate Code for the Model

- 1 Open `throttlecntrl`. Then, open the **Simulink Coder** app.
- 2 Select model configuration parameter **Generate code only**.
- 3 Select model configuration parameter **Create code generation report** and click **Apply**.
- 4 Generate code.

Messages appear in the Diagnostics Viewer. The code generator produces standard C and header files, and an HTML code generation report. The code generator places the files in a *build folder*, a subfolder named `throttlecntrl_grt_rtw` under your current working folder.

## Review the Generated Code

- 1 In the code generation report, click the link for the generated C model file and review the generated code. Look for these items in the report:
  - Identification, version, timestamp, and configuration comments.
  - Links to help you navigate within and between files
  - Data definitions
  - Scheduler code
  - Controller code
  - Model initialization and termination functions

- Call interface for the GRT system target file — output, update, initialization, start, and terminate
- 2 Save and close model `throttlecntrl`.

Consider examining the following files. In the code generation report **Contents** pane, click the links.

File	Description
<code>throttlecntrl.c</code>	C file that contains the scheduler, controller, initialization, and interface code
<code>throttlecntrl_data.c</code>	C file that assigns values to generated data structures
<code>throttlecntrl.h</code>	Header file that defines data structures
<code>throttlecntrl_private.h</code>	Header file that defines data used only by the generated code
<code>throttlecntrl_types.h</code>	Header file that defines the model data structure

For more information, see “Manage Build Process File Dependencies” (Simulink Coder).

At this point, consider logging data to a MAT-file. For an example, see “Log Data for Analysis” (Simulink Coder).

## Generate an Executable

- 1 Open `throttlecntrl`. Then, open the **Simulink Coder** app.
- 2 Clear model configuration parameter **Generate code only** and click **Apply**.
- 3 Build the model. Watch the messages in the Diagnostics Viewer. The code generator uses a template make file associated with your system target file selection to create an executable file. You can run this program on your workstation, independent of external timing and events.
- 4 Check your working folder for the file `throttlecntrl.exe`.
- 5 Run the executable. In the Command Window, enter `!throttlecntrl`. The `!` character passes the command that follows it to the operating system, which runs the standalone program.

The program produces one line of output in the Command Window:

```
** starting the model **
```

At this point, consider logging data to a MAT-file. For an example, see “Log Data for Analysis” (Simulink Coder).

---

**Tip** For UNIX platforms, run the executable program in the Command Window with the syntax `!./executable_name`. If preferred, run the executable program from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs” (MATLAB).

---

## Key Points

- To generate code, change the model configuration to specify a fixed-step solver then select a system target file. Using the `grt.tlc` file requires a fixed-step solver. If the model contains continuous time blocks, you can use a variable-step solver with the `rsim.tlc` system target file.
- After debugging a model, consider configuring a model with parameter inlining enabled.
- Use the `getActiveConfigSet` function to save a model configuration for future use or to apply it to another model.
- Before generating code, consider checking a model with the Model Advisor.
- The code generator places generated files in a subfolder (`model_grt_rtw`) of your working folder.

# Configure Data Interface

## About This Example

### Learning Objectives

- Configure the data interface for code generated for a model.
- Control the name, data type, and data storage class of signals and parameters in generated code.

### Prerequisites

- Understanding ways to represent and use data and signals in models.
- Familiarity with representing data constructs as data objects.
- Ability to read C code.

### Required File

rtwdemo\_throttlecntrl\_datainterface model file

## Declare Data

Most programming languages require that you declare data before using it. The declaration specifies the following information:

Data Attribute	Description
Scope	The region of the program that has access to the data
Duration	The period during which the data is resident in memory
Data type	The amount of memory allocated for the data
Initialization	An initial value, a pointer to memory, or NULL. If you do not provide an initial value, most compilers assign a zero value or a null pointer.

The following data types are supported for code generation.

## Supported Data Types

Name	Description
double	Double-precision floating point
single	Single-precision floating point
int8	Signed 8-bit integer
uint8	Unsigned 8-bit integer
int16	Signed 16-bit integer
uint16	Unsigned 16-bit integer
int32	Signed 32-bit integer
uint32	Unsigned 32-bit integer
Fixed-point data types	8-, 16-, 32-bit word lengths

A storage class is the scope and duration of a data item. For more information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 33-99.

## Use Data Objects

In Simulink models and Stateflow charts, the following methods are available for declaring data: data objects and direct specification. This example uses the data object method. Both methods allow full control over the data type and storage class. You can mix the two methods in a single model.

In the MATLAB and Simulink environment, you can use data objects in various ways. This example focuses on the following types of data objects:

- Signal
- Parameter
- Bus

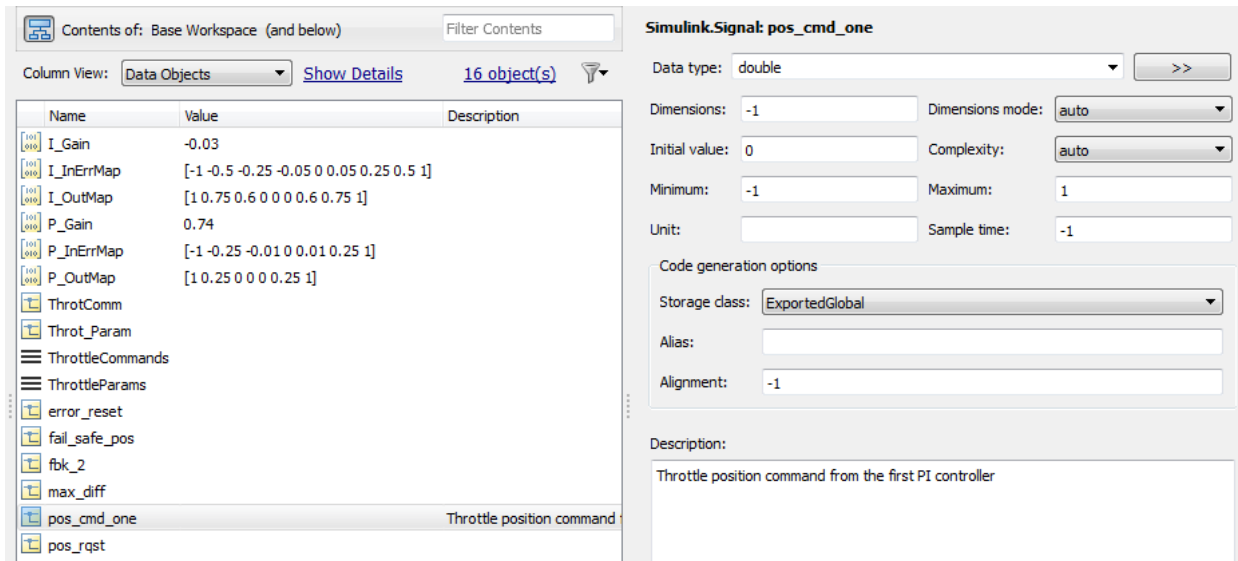

To configure the data interface for your model using the data object method, in the MATLAB base workspace, you define data objects. Then, associate them with your Simulink model or embedded Stateflow chart. When you build your model, the build process uses the associated base workspace data objects in the generated code.

You can set the values of the data object properties, which include:

- Data type
- Storage class
- Value (parameters)
- Initial value (signals)
- Identifier (define a different name in the generated code)
- Dimension (typically inherited for parameters)
- Complexity (inherited for parameters)
- Unit (physical measurement unit)
- Minimum value
- Maximum value
- Description (used to document your data objects — does not affect simulation or code generation)

You can create and inspect base workspace data objects by entering commands in the MATLAB Command Window or by using Model Explorer. To explore base workspace signal data objects, use these steps:

- 1 Open `rtwdemo_throttlecntrl_datainterface` and save a copy as `throttlecntrl_datainterface` in a writable location on your MATLAB path.
- 2 Open Model Explorer.
- 3 Select **Base Workspace**.
- 4 Select the `pos_cmd_one` signal object for viewing.

You can also view the definition of a signal object. In the MATLAB Command Window, enter `pos_cmd_one`:

```
pos_cmd_one =
```

```
Signal with properties:
```

```

CoderInfo: [1x1 Simulink.CoderInfo]
Description: 'Throttle position command from the first PI controller'
DataType: 'double'
Min: -1
Max: 1
Unit: ''
Dimensions: -1
DimensionsMode: 'auto'
Complexity: 'auto'
SampleTime: -1
InitialValue: '0'
```

- 5 To view other signal objects, in Model Explorer, click the object name or in the MATLAB Command Window, enter the object name. This table summarizes object characteristics for some of the data objects in this model.

Object Characteristics	pos_cmd_on_e	pos_rqst	P_InErrMap	ThrotComm*	ThrottleCommands*
Description	Top-level output	Top-level input	Calibration parameter	Top-level output structure	Bus definition
Data type	Double	Double	Auto	Auto	Structure
Storage class	Exported global	Imported extern pointer	Constant	Exported global	None

\* `ThrottleCommands` defines a Bus object; `ThrotComm` is an instantiation of the bus. If the bus is a nonvirtual bus, the signal generates a structure in the C code.

You can use a bus definition (`ThrottleCommands`) to instantiate multiple instances of the structure. In a model diagram, a bus object appears as a wide line with central dashes, as shown.

## Add New Data Objects

You can create data objects for named signals, states, and parameters. To associate a data object with a construct, the construct must have a name.

To find constructs for which you can create data objects, use the Data Object Wizard. This tool finds the constructs and then creates the objects for you. The model includes two signals that are not associated with data objects: `fbk_1` and `pos_cmd_two`.

To find the signals and create data objects for them:

- 1 In the Simulink Editor, in the **Modeling** tab, under **Design**, click **Data Object Wizard**. The Data Object Wizard dialog box opens.
- 2 To find candidate constructs, click **Find**. Constructs `fbk_1` and `pos_cmd_two` appear in the dialog box.

- 3 To select both constructs, click **Select All**.
- 4 In the table, under **Class**, make sure that each proposed data object uses the class `Simulink.Signal`. To change the class of the objects, click **Change Class**.
- 5 To create the data objects, click **Create**. Constructs `fbk_1` and `pos_cmd_two` are removed from the dialog box.
- 6 Close the Data Object Wizard.
- 7 In the **Contents** pane of the Model Explorer, find the newly created objects `fbk_1` and `pos_cmd_two`.

## Enable Data Objects for Generated Code

- 1 Enable a signal to appear in generated code.
  - a In the Simulink Editor, right-click the `pos_cmd_one` signal line and select **Properties**. A Signal Properties dialog box opens.
  - b Make sure that you select the **Signal name must resolve to Simulink signal object** parameter.

- 2 Enable signal object resolution for the signals in the model. In the MATLAB Command Window, enter:
 

```
disableimplicitsignalresolution('throttlectrl_datainterface')
```
- 3 Save and close `throttlectrl_datainterface`.

## Effects of Simulation on Data Typing

In the throttle controller model, the data types are set to `double`. Because Simulink software uses the `double` data type for simulation, do not expect changes in the model behavior when you run the generated code. You verify this effect by running the test harness.

Before you run your test harness, update it to include the `throttlecntrl_datainterface` model.

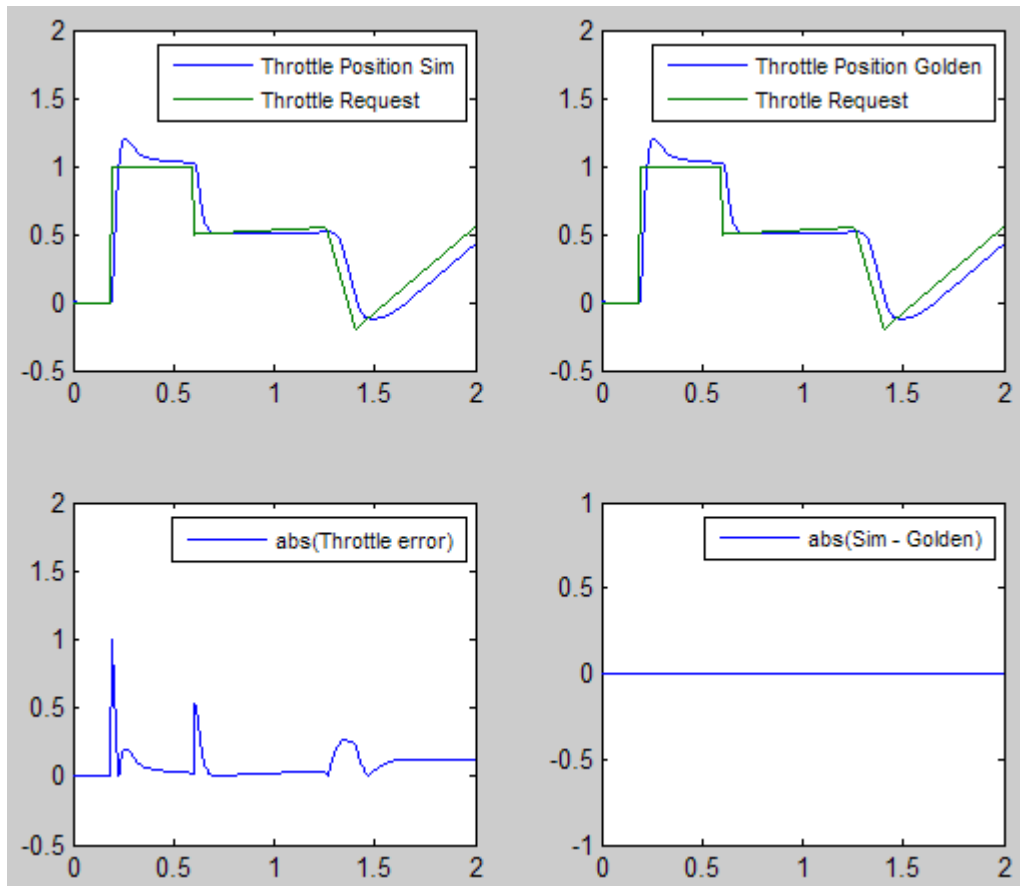

---

**Note** The following procedure requires a Stateflow license.

---

- 1 Open `throttlecntrl_datainterface`.
- 2 Open your copy of test harness, `throttlecntrl_testharness`.
- 3 Right-click the `Unit_Under_Test Model` block and select **Block Parameters (ModelReference)**.
- 4 Set **Model name** to `throttlecntrl_datainterface`. Click **OK**.
- 5 Update the test harness model diagram.
- 6 Simulate the test harness.

The resulting plot shows that the difference between the golden and simulated versions of the model remains zero.

7 Save and close `throttlecntrl_testharness`.

## Manage Data

Data objects exist in a separate file from the model in the base workspace. To save the data manually, in the MATLAB Command Window, enter `save`.

The separation of data from the model provides the following benefits:

- One model, multiple data sets:

- Use of different parameter values to change the behavior of the control algorithm (for example, for reusable components with different calibration values)
- Use of different data types to change targeted hardware (for example, for floating-point and fixed-point targeted hardware)
- Multiple models, one data set:
  - Sharing data between models in a system
  - Sharing data between projects (for example, transmission, engine, and wheel controllers can use the same CAN message data set)

## Key Points

- You can declare data in Simulink models and Stateflow charts by using data objects or direct specification.
- From the Model Explorer or from the command line in the MATLAB Command Window, manage (create, view, configure, and so on) base workspace data.
- The Data Object Wizard provides a quick way to create data objects for constructs such as signals, buses, and parameters.
- Configure data objects explicitly to appear by name in generated code.
- Separation of data from model provides several benefits.

### About This Example

#### Learning Objectives

- Evaluate a C function as part of a model simulation.
- Call an external C function from generated code.

#### Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Ability to set model configuration parameters.
- Ability to read C code.
- An installed, supported C compiler.

#### Required Files

- `rtwdemo_throttlectrl_extfuncall` model file
- `rtwdemo_ValidateLegacyCodeVrsSim` model file
- `/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.c`
- `/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.h`

## Include External C Functions in a Model

Simulink models are one part of Model-Based Design. For many applications, a design also includes a set of pre-existing C functions created, tested (verified), and validated outside of a MATLAB and Simulink environment. You can integrate these functions easily into a model and the generated code. You can use external C code in the generated code to access hardware devices and external data files during rapid simulation runs.

This example shows you how to create a custom block that calls an external C function. When the block is part of the model, you can take advantage of the simulation environment to test the system further.

## Create a Block That Calls a C Function

To specify a call to an external C function, use an S-Function block. You can automate the process of creating the S-Function block by using the Simulink Legacy Code Tool. Using this tool, specify an interface for your external C function. The tool then uses that interface to automate creation of an S-Function block.

- 1 Make copies of the files `SimpleTable.c` and `SimpleTable.h`, located in the folder `matlabroot/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files` (open). Put the copies in your working folder.
- 2 Create an S-Function block that calls the specified function at each time step during simulation:
  - a In the MATLAB Command Window, create a function interface definition structure:

```
def=legacy_code('initialize')
```

The data structure `def` defines the function interface to the external C code.

```
def =
```

```

      SFunctionName: ''
InitializeConditionsFcnSpec: ''
      OutputFcnSpec: ''
      StartFcnSpec: ''
      TerminateFcnSpec: ''
      HeaderFiles: {}
      SourceFiles: {}
      HostLibFiles: {}

```

```
TargetLibFiles: {}  
IncPaths: {}  
SrcPaths: {}  
LibPaths: {}  
SampleTime: 'inherited'  
Options: [1x1 struct]
```

- b** Populate the function interface definition structure by entering the following commands:

```
def.OutputFcnSpec=['double y1 = SimpleTable(double u1,',...  
    'double p1[], double p2[], int16 p3)'];  
def.HeaderFiles = {'SimpleTable.h'};  
def.SourceFiles = {'SimpleTable.c'};  
def.SFunctionName = 'SimpTableWrap';
```

- c** Create the S-function:

```
legacy_code('sfcn_cmex_generate', def)
```

- d** Compile the S-function:

```
legacy_code('compile', def)
```

- e** Create the S-Function block:

```
legacy_code('slblock_generate', def)
```

A new model window opens that contains the `SimpTableWrap` block.

---

**Tip** Creating the S-Function block is a one-time task. Once the block exists, you can reuse it in multiple models.

---

- 3** Save the model to your working folder as: `s_func_simpwrap`.  
**4** Create a Target Language Compiler (TLC) file for the S-Function block:

```
legacy_code('sfcn_tlc_generate', def)
```

The TLC file is the component of an S-function that specifies how the code generator produces the code for a block.

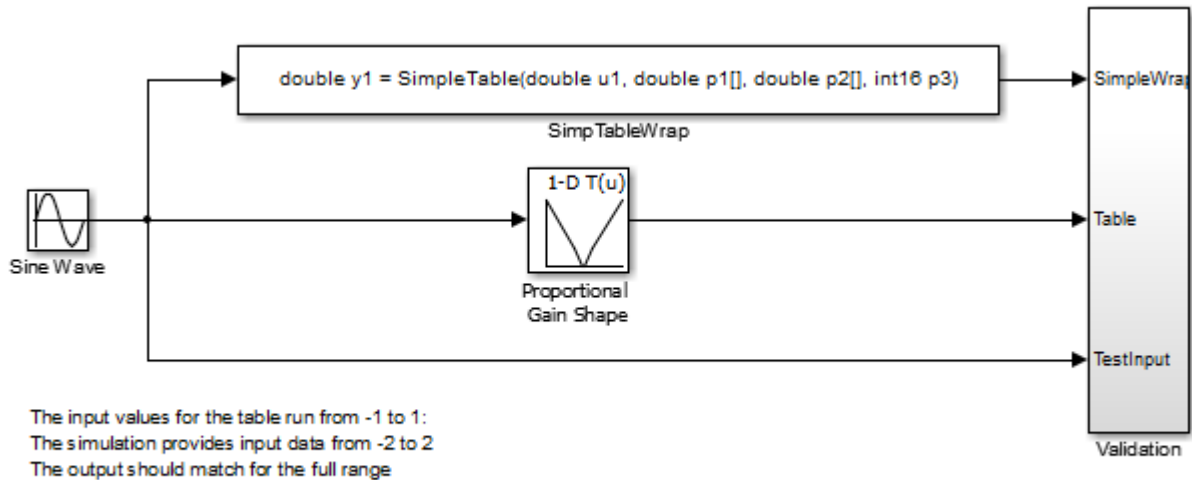

For more information on using the Legacy Code Tool, see:

- “Integrate C Functions Using Legacy Code Tool” (Simulink)
- “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder)

## Validate External Code in the Simulink Environment

When you integrate external C code with a Simulink model, before using the code, validate the functionality of the external C function code as a standalone component.

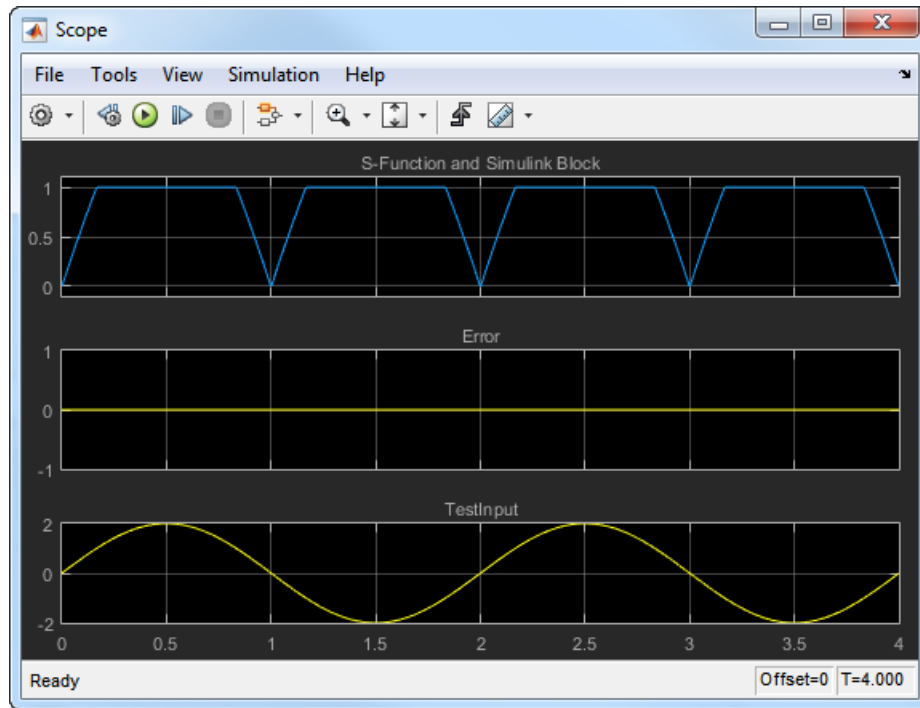

- 1 Open the model `rtwdemo_ValidateLegacyCodeVrsSim`. This model validates the S-function block that you created.

Copyright 2007-2011 The MathWorks, Inc.

- The Sine Wave block produces output values from  $[-2 : 2]$ .
  - The input range of the lookup table is from  $[-1 : 1]$ .
  - The output from the lookup table is the absolute value of the input.
  - The lookup table output clips the output at the input limits.
- 2 Simulate the model.
  - 3 View the validation results by opening the `Validation` subsystem and, in that subsystem, clicking the Scope block.

The following figure shows the validation results. The external C code and the Simulink Lookup table block provide the same output values.

- 4 Close the validation model.

## Validate C Code as Part of a Model

After you validate the functionality of the external C function code as a standalone component, validate the S-function in the model. Use the test harness model to complete the validation.

---

**Note** The following procedure requires a Stateflow license.

---

- 1 Open `rtwdemo_throttlectrl_extfunccall` and save a copy to `throttlectrl_extfunccall` in a writable folder on your MATLAB path.
- 2 Examine the `PI_ctrl_1` and `PI_ctrl_2` subsystems.
  - a Lookup blocks have been replaced with the block you created using the Legacy Code Tool.

- b** Examine the block parameter settings for `SimpTableWrap` and `SimpTableWrap1`.
- c** Close the Block Parameter dialog boxes and the PI subsystem windows.
- 3** Open the test harness model, right-click the `Unit_Under_Test Model` block, and select **Block Parameters (ModelReference)**.
- 4** Set **Model name** to `throttlecntrl_extfunccall`. Click **OK**.
- 5** Update the test harness model diagram.
- 6** Simulate the test harness.

The simulation results match the expected golden values.

- 7** Save and close `throttlecntrl_extfunccall` and `throttlecntrl_testharness`.

## Call a C Function from Generated Code

The code generator uses a TLC file to process the S-Function block. Calls to C code embedded in an S-Function block:

- Can use data objects.
  - Are subject to expression folding, an operation that combines multiple computations into a single output calculation.
- 1 Open `throttlecntrl_extfunccall`.
  - 2 Generate code for the model.
  - 3 Examine the generated code in the file `throttlecntrl_extfunccall.c`.
  - 4 Close `throttlecntrl_extfunccall` and `throttlecntrl_testharness`.

## Key Points

- You can easily integrate external functions into a model and generated code by using the Legacy Code Tool.
- Validate the functionality of external C function code which you integrate into a model as a standalone component.
- After you validate the functionality of external C function code as a standalone component, validate the S-function in the model.

## Reload Generated Code

You can reload the code generated for a model from the Model Explorer.

- 1 Click the **Code for *model*** node in the **Model Hierarchy** pane.
- 2 In the **Code** pane, click the **Refresh** link.

The code generator reloads the code for the model from the build folder.

## Manage Build Process Folders

The build process places generated files from Simulink diagram updates and model builds into a hierarchy of folders that is specified by default. You can change the default specification for build process folders, if, for example:

- Your company does not use the current working folder as the location for the code generation folder or the simulation cache folder.
- You place the code generation folder under version control, but do not place the simulation cache folder under version control.

The MATLAB session parameters `CacheFolder`, `CodeGenFolder`, and `CodeGenFolderStructure` are file generation control parameters that specify the folder locations for the build process. At the start of a MATLAB session, these Simulink preferences determine the values of the parameters:

**Simulation cache folder** (Simulink) - `CacheFolder`

**Code generation folder** (Simulink) - `CodeGenFolder`

**Code generation folder structure** (Simulink) - `CodeGenFolderStructure`

To modify the parameters during a MATLAB session, use `Simulink.fileGenControl`. The parameter values that you set expire at the end of the MATLAB session.

## File Generation Control Parameters

This table provides information about how you can use the parameters to manage build process folders.

<b>MATLAB Session Parameter</b>	<b>Simulink Preference</b>	<b>Description</b>
CacheFolder	<b>Simulation cache folder</b> (Simulink)	<p>The build process places generated files from Simulink diagram updates and model build artifacts for simulation and code generation in the simulation cache folder <i>simulationCacheFolder</i>. The folder is a root folder.</p> <p>By default (<code>CacheFolder = ''</code>), <i>simulationCacheFolder</i> is the current working folder, <code>pwd</code>.</p> <p>You can use the parameter to specify another folder. For example, if you want to:</p> <ul style="list-style-type: none"><li>• Separate generated files from the models and other source material.</li><li>• Reuse or share previously built simulation targets without having to set the current working folder back to a previous working folder.</li></ul>

MATLAB Session Parameter	Simulink Preference	Description
CodeGenFolder	<b>Code generation folder</b> (Simulink)	<p>The build process, which uses system target files to generate production code from a Simulink model, places the production code in the code generation folder <i>codeGenerationFolder</i>. The folder is a root folder.</p> <p>If you choose to generate an executable program file, the build process writes the file <i>model.exe</i> (Windows) or <i>model</i> (UNIX) to the folder.</p> <p>By default (<code>CodeGenFolder = ''</code>), <i>codeGenerationFolder</i> is the current working folder, <code>pwd</code>.</p> <p>You can use the parameter to specify another folder. For example, if you want to separate generated production code from:</p> <ul style="list-style-type: none"> <li>• Models and other source material.</li> <li>• Generated simulation and code generation artifacts.</li> </ul> <p>If you specify the root folder of a drive as the code generation folder, the build process cannot generate code for your model. For example, <code>C:\</code>.</p>
CodeGenFoldersStructure	<b>Code generation folder structure</b> (Simulink)	<p>To specify the folder structure within the code generation folder, use the parameter. For example, if you configure models for different target environments, you can specify a separate subfolder for the generated code from each model.</p>

## Build Process Folders

This table provides information about how `CodeGenFolderStructure` controls the folder structure within the simulation cache folder and the code generation folder.

Folder Name when <code>CodeGenFolderStructure = 'ModelSpecific'</code>	Folder Name when <code>CodeGenFolderStructure = 'TargetEnvironmentSubfolder'</code>	Description
<code>codeGenerationFolder/model_target_rtw</code>  The default for <i>target</i> is the name of the selected system target file, for example, <code>grt</code> , <code>ert</code> , and <code>rsim</code> . You can change <i>target</i> with the <code>rtwgensettings.BuildDirSuffix</code> field in the system target file.	<code>codeGenerationFolder/targetSpecific/model</code>  The build process uses configuration information for the system target file and the hardware device to produce a unique label for the subfolder, <i>targetSpecific</i> .	Build folder, which stores generated source code and other files created by the build process.  Contains the generated code modules, <i>model.c</i> and <i>model.h</i> , and generated makefile, <i>model.mk</i> .  <i>model.mk</i> is for compiling and linking code generated from model components.  <i>model</i> is the name of the source model.
<code>codeGenerationFolder/model_target_rtw/html</code>	<code>codeGenerationFolder/targetSpecific/model/html</code>	Code generation report folder that contains report files generated by the build process.
<code>codeGenerationFolder/slprj/target/model</code>	<code>codeGenerationFolder/targetSpecific/_ref/model</code>	Model reference target files.
<code>codeGenerationFolder/slprj/target/model/referenced_model_includes</code>	<code>codeGenerationFolder/targetSpecific/_ref/model/referenced_model_includes</code>	Header files from models referenced by <i>model</i> .

Folder Name when CodeGenFolderStructure = 'ModelSpecific'	Folder Name when CodeGenFolderStructure = 'TargetEnvironmentSubfolder'	Description
<code>codeGenerationFolder/slprj/target/model/tmwinternal</code>	<code>codeGenerationFolder/targetSpecific/_ref/model/tmwinternal</code>	MAT-files used during code generation.
<code>codeGenerationFolder/slprj/target/_sharedutils</code>	<code>codeGenerationFolder/targetSpecific/_shared</code>	Utility functions for model reference system target files, which are shared across models.  Folder also contains <code>rtwshared.mk</code> for compiling generated shared utility code
<code>simulationCacheFolder/slprj/sim/model</code>	<code>simulationCacheFolder/slprj/sim/model</code>	Simulation target files for referenced models.
<code>simulationCacheFolder/slprj/sim/model/tmwinternal</code>	<code>simulationCacheFolder/slprj/sim/model/tmwinternal</code>	MAT-files used during code generation.
<code>simulationCacheFolder/slprj/sim/_sharedutils</code>	<code>simulationCacheFolder/slprj/sim/_sharedutils</code>	Utility functions for simulation system target files, which are shared across models.

If the system target file is ERT-based, then these model configuration parameters also control the location of shared utility code:

- Shared code placement (Simulink Coder) (`UtilityFuncGeneration`)
- Existing shared code (`ExistingSharedCode`)

You can use `RTW.getBuildDir` to display build folder information for the model.

## Manage Build Process Files

To apply generated code source and header files from the build process, it is helpful to understand the files that the build process generates and the conditions that control file generation. This information provides access to generated code resources, such as:

- Public interface to the model entry points
- Enumerated types corresponding to built-in data types
- Data structures that describe the model signals, states, and parameters

The code generator creates *model*.\* files during the code generation and build process. You can customize the file names for generated header, source, and data files. For more information, see “Customize Generated File Names” on page 50-71. The code generator creates additional folders and dependency files to support shared utilities and model references. For more information about the folders that the build process creates, see “Manage Build Process Folders” (Simulink Coder). For an example that shows how to use a project to manage build process folders, see “Generate Code and Simulate Models in a Project” (Simulink Coder).

Depending on model architectures and code generation options, the build process for a GRT-based system target file can produce files that the build process does not generate for an ERT-based system target file. Also, for ERT-based system target files, the build process packages generated files differently than for GRT-based system target files. See “Manage File Packaging of Generated Code Modules” on page 48-13.

---

**Note** By default, the build process deletes foreign (not generated) source files in the build folder. It is possible to preserve foreign source files in the build folder by following the guidelines in “Preserve External Code Files in Build Folder” (Simulink Coder).

---

The table describes the principal generated files. Within the generated file names shown in the table, the *model* represents the name of the model for which you are generating code. The *subsystem* represents the name of a subsystem within the model. When you select the **Create code generation report** parameter, the code generator produces a set of HTML files. There is one HTML file for each source file plus a *model\_contents.html* index file in the `html` subfolder within your build folder. The source and header files in the table have dependency relationships. For descriptions of other file dependencies, see “Manage Build Process File Dependencies” (Simulink Coder) and “Add Build Process Dependencies” (Simulink Coder).

File	Description
<code>builtin_typeid_types.h</code>	<p>Defines an enumerated type corresponding to built-in data types.</p> <p>A model build generates this file when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• Your model contains a Stateflow chart that uses messages.</li> <li>• Your model configuration enables <b>MAT-file logging</b>.</li> <li>• Your model configuration enables C API options in <b>Code Generation &gt; Interface</b>.</li> </ul>
<code>modelsources.txt</code>	Lists additional sources to include in the compilation.
<code>model.bat</code>	<p>Contains Windows batch file commands that set the compiler environment and invoke the make utility.</p> <p>For more information about using this file, see “model.bat” on page 47-48.</p>
<code>model.c</code> <code>model.cpp</code>	<p>Corresponds to the model file.</p> <p>The Target Language Compiler generates this C or C++ source code file. The file contains:</p> <ul style="list-style-type: none"> <li>• Include files <code>model.h</code> and <code>model_private.h</code></li> <li>• Data, except data placed in <code>model_data.c</code></li> <li>• Model-specific scheduler code</li> <li>• Model-specific solver code</li> <li>• Model registration code</li> <li>• Algorithm code</li> <li>• Optional GRT wrapper functions</li> </ul>
<code>model.exe</code> (Windows platform) <code>model</code> (UNIX and Macintosh platforms)	<p>Executable program file.</p> <p>A model build generates this file unless you explicitly specify that the code generator produce code only. The build generates the executable in the current folder (not the build folder) under control of the make utility of your development system.</p>

File	Description
<i>model.h</i>	<p>Defines model data structures and a public interface to the model entry points and data structures. Provides an interface to the real-time model data structure (<i>model_rtM</i>) via access macros.</p> <p>Subsystem .c or .cpp files in the model include <i>model.h</i>. This file includes:</p> <ul style="list-style-type: none"> <li>• Exported Simulink data symbols</li> <li>• Exported Stateflow machine parented data</li> <li>• Model data structures, including <i>rtM</i></li> <li>• Model entry-point functions</li> </ul> <p>For more information, see “model.h” (Simulink Coder).</p>
<i>model.mk</i>	<p>Generated makefile that controls compiling and linking the generated code into the final binary file by the <i>make</i> utility of your development system.</p> <p>If you set the <i>MAKEFLAGS</i> environment variable, do not select options with this variable that conflict with the current <i>make</i> utility used by the build process.</p>
<i>model.rtw</i>	<p>Represents the compiled model.</p> <p>By default, the build process deletes this ASCII file when the build process is complete. You can choose to retain the file for inspection.</p>
<i>model_capi.h</i> <i>model_capi.c</i>	<p>(optional files) Contain data structures that describe the model signals, states, and parameters without using external mode.</p> <p>For more information, see “Exchange Data Between Generated and External Code Using C API” (Simulink Coder).</p>

File	Description
<i>model_data.c</i>	<p>Contains (if conditionally generated) declarations for the parameters data structure and the constant block I/O data structure, and zero representations for structure data types that the model uses.</p> <p>A model build generates this file when the model uses these data structures. The <code>extern</code> declarations for structures appear in <i>model.h</i>. When present, this file contains:</p> <ul style="list-style-type: none"> <li>• Constant block I/O parameters</li> <li>• Include files <i>model.h</i> and <i>model_private.h</i></li> <li>• Definitions for the zero representations for user-defined structure data types that the model uses</li> <li>• Constant parameters</li> </ul>
<i>model_dt.h</i>	(optional file) Declares structures that contain data type and data type transition information for generated model data structures for supporting external mode.
<i>model_private.h</i>	<p>Contains local <code>define</code> constants and local data for the model and subsystems.</p> <p>The generated source files from the model build include this file. When you interface external code with generated code from a model, include <i>model_private.h</i>. The file contains:</p> <ul style="list-style-type: none"> <li>• Imported Simulink data symbols</li> <li>• Imported Stateflow machine parented data</li> <li>• Stateflow entry points</li> <li>• Simulink Coder details (various macros, enums, and so forth, that are private to the code)</li> </ul> <p>For more information, see “Manage Build Process File Dependencies” (Simulink Coder).</p>
<i>model_reference_types.h</i>	<p>Contains type definitions for timing bridges.</p> <p>A model build generates this file for a referenced model or a model containing model reference blocks.</p>

<b>File</b>	<b>Description</b>
<code>model_targ_data_map.m</code>	(optional file) Contains MATLAB language commands that external mode uses to initialize the external mode connection.
<code>model_types.h</code>	<p>Provides forward declarations for the real-time model data structure and the parameters data structure.</p> <p>The generated header files from the model build include this file. Function declarations of reusable functions can use these structures.</p>
<code>multiword_types.h</code>	<p>Contains type definitions for multiple-word wide data types and their word-size chunks. If your code uses multiword data types, include this header file.</p> <p>A model build generates this file when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• Your model uses multiword data types.</li> <li>• Your model configuration enables <b>MAT-file logging</b>.</li> <li>• Your model configuration enables <b>Code Generation &gt; Interface &gt; External mode</b>.</li> </ul>
<code>rtGetInf.c</code> <code>rtGetInf.h</code> <code>rtGetNaN.c</code> <code>rtGetNaN.h</code> <code>rt_nonfinite.c</code> <code>rt_nonfinite.h</code>	<p>Declares and initializes global nonfinite values for <code>inf</code>, <code>minus inf</code>, and <code>nan</code>. Provides nonfinite comparison functions.</p> <p>A model build generates these files when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• The model contains S-functions.</li> <li>• The generated code from the model requires nonfinite numbers.</li> <li>• Your model configuration enables <b>MAT-file logging</b>.</li> <li>• Your model configuration selects <code>grt.tlc</code> as the <b>System target file</b> and enables the <b>Classic call interface</b>.</li> </ul>
<code>rtmodel.h</code>	<p>Contains <code>#include</code> directives required by static main program modules such as <code>rt_main.c</code>.</p> <p>The build process does not create these modules at code generation time. The modules include <code>rtmodel.h</code> to access model-specific data structures and entry points. If you create your own main program module, make sure to include <code>rtmodel.h</code>.</p>

File	Description
rtwtypes.h	<p>Provides the essential type definitions, #define statements, and enumerations.</p> <p>For GRT-based system target files, rtwtypes.h includes simstruc_types.h which, in turn, includes tmwtypes.h.</p> <p>For ERT-based system target files that do not generate a GRT interface and do not have noninlined S-functions, rtwtypes.h does not include simstruc_types.h.</p> <p>For more information, see “rtwtypes.h” (Simulink Coder) and “Manage Build Process File Dependencies” (Simulink Coder).</p>
rtw_proj.tmw sl_proj.tmw	<p>Marker files.</p> <p>The build process generates these files to help the make utility determine when to recompile and link the generated code.</p>
rt_defines.h	<p>Contains type definitions for special mathematical constants (such as <math>\pi</math> and <math>e</math>) and defines the UNUSED_PARAMETER macro.</p> <p>A model build generates this file when the generated code requires a mathematical constant definition or when the function body does not access a required model function argument.</p>
rt_sfcn_helper.h rt_sfcn_helper.c	<p>(optional files) Provide functions that the noninlined S-functions use in a model.</p> <p>The noninlined S-functions use functions rt_CallSys, rt_enableSys, and rt_DisableSys to call downstream function-call subsystems.</p>
subsystem.c	<p>(optional file) Contains C source code for each noninlined nonvirtual subsystem or copy the code when the subsystem is configured to place code in a separate file.</p>
subsystem.h	<p>(optional file) Contains exported symbols for noninlined nonvirtual subsystems.</p>

## model.bat

This file contains Windows batch file commands that set the compiler environment and invoke the make utility.

If you are using the toolchain approach for the build process, you also can use this batch file to extract information from the generated makefile, *model.mk*. The information includes macro definitions and values that appear in the makefile, such as *CFLAGS* (C compiler flags) and *CPP\_FLAGS* (C++ compiler flags). With the folder containing *model.bat* selected as the current working folder, in the Command Window, type:

```
>> system('model.bat info')
```

On UNIX and Macintosh platforms, the code generator does not create the *model.bat* file. To extract information for toolchain approach builds from the generated makefile on these systems, in the Command Window, type:

```
>> system('gmake -f model.mk info')
```

## model.h

The header file *model.h* declares model data structures and a public interface to the model entry points and data structures. This header file also provides an interface to the real-time model data structure (*model\_M*) by using access macros. If your code interfaces to model functions or model data structures, include *model.h*:

- Exported global signals

```
extern int32_T INPUT;    /* '<Root>/In' */
```

- Global structure definitions

```
/* Block parameters (auto storage) */  
extern Parameters_mymodel mymodel_P;
```

- Real-time model (RTM) macro definitions

```
#ifndef rtmGetSampleTime  
# define rtmGetSampleTime(rtm, idx)  
((rtm)->Timing.sampleTimes[idx])  
#endif
```

- Model entry point functions (ERT example)

```
extern void mymodel_initialize(void);
extern void mymodel_step(void);
extern void mymodel_terminate(void);
```

The `main.c` (or `.cpp`) file includes `model.h`. If the model build generates the `main.c` (or `.cpp`) file from a TLC script, the TLC source can include `model.h`.

```
#include "%<CompiledModel.Name>.h"
```

If `main.c` is a static source file, you can use the fixed header file name `rtmodel.h`. This file includes the `model.h` header file:

```
#include "model.h"      /* If main.c is generated */
```

or

```
#include "rtmodel.h"   /* If static main.c is used */
```

Other external source files can require to include `model.h` to interface to model data, for example exported global parameters or signals. The `model.h` file itself can have additional header dependencies due to requirements of generated code. See “System Header Files” (Simulink Coder) and “Code Generator Header Files” (Simulink Coder).

To reduce dependencies and reduce the number of included header files, see “Manage Build Process File Dependencies” (Simulink Coder).

## rtwtypes.h

The header file `rtwtypes.h` defines data types, structures, and macros required by the generated code. You include `rtwtypes.h` for GRT and ERT system target files, instead of including `tmwtypes.h` or `simstruc_types.h`.

Often, the generated code requires that integer operations overflow or underflow at specific values. For example, when the code expects a 16-bit integer, the code does not accept an 8-bit or a 32-bit integer type. The C language does not set a standard for the number of bits in types such as `char`, `int`, and others. So, there is no universally accepted data type in C to use for sized-integers.

To accommodate this feature of the C language, the generated code uses sized integer types, such as `int8_T`, `uint32_T`, and others, which are not standard C types. In `rtwtypes.h`, the generated code maps these sized-integer types to the corresponding C keyword base type using information in the **Hardware Implementation** pane of the configuration parameters.

The code generator produces the optimized version of `rtwtypes.h` for ERT-based system target files when these conditions apply:

- **Configuration Parameters > Code Generation > Interface > Advanced parameters > Classic call interface** is not selected.
- The model does not contain noninlined S-functions.

Include `rtwtypes.h`. If you include it for GRT system target files, for example, it is easier to use your code with ERT-based system target files.

For GRT and ERT system target files, the location of `rtwtypes.h` depends on whether the build process uses the *shared utilities* location. If it uses a shared location, the code generator places `rtwtypes.h` in `slprj/target/_sharedutils`; otherwise, it places `rtwtypes.h` in the build folder (*model\_target\_rtw*). See “Specify Generated Code Interfaces” (Simulink Coder).

Source files include the `rtwtypes.h` header file when the source files use code generator type names or other code generator definitions. A typical example is for files that declare variables by using a code generator data type, for example, `uint32_T myvar`.

A source file that the code generator and an S-function use can use the preprocessor macro `MATLAB_MEX_FILE`. The macro definition comes from the `mex` function:

```
#ifndef MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
```

A source file for the code generator `main.c` (or `.cpp`) file includes `rtwtypes.h` without preprocessor checks.

```
#include "rtwtypes.h"
```

Custom source files that the Target Language Compiler generates can also emit these `include` statements into their generated file.

See “Control Placement of `rtwtypes.h` for Shared Utility Code” (Simulink Coder).

## Manage Build Process File Dependencies

An important control of the size of generated code is managing the number and size of included files (dependencies). To reduce the number of system header files and generated header files that generated code requires, it is helpful to understand the dependencies that the build process generates and the conditions that lead to dependencies.

The dependency relationships among generated source and header files appear in the figure. Arrows coming from a file point to files it includes. Other dependencies exist, for example, on Simulink header files `tmwtypes.h` and `simstruc_types.h`, plus C or C++ library files. The figure maps inclusion relations between only those files that are generated in the build folder. These files can reference utility and model reference code located in a code generation folder. For more information about the folders and files that the build process creates, see “Manage Build Process Folders” (Simulink Coder) and “Manage Build Process Files” (Simulink Coder).

The two tables identify the conditions that control creation of dependency files for GRT and ERT targets. To manage build-related dependencies, consider how these conditions apply to your model and code generation process. Then, configure model parameters and code generation options to manage build process file dependencies.

Due to differences in file packaging options for code generated with ERT-based system target files, the file dependencies differ slightly from file packaging for code generated with GRT-based system target files. See “Manage File Packaging of Generated Code Modules” on page 48-13.

The parent system header files (`model.h`) include child subsystem header files (`subsystem.h`). In more layered models, subsystems similarly include their children's header files in the model hierarchy. As a consequence, subsystems are able to view recursively into their descendant subsystems and view into the root system because every `subsystem.c` or `subsystem.cpp` includes `model.h` and `model_private.h`.

In the figure, files `model.h`, `model_private.h`, and `subsystem.h` depend on the header file `rtwtypes.h`. If you use system target files that are not based on the ERT system target file, the source files that you generate can have additional dependencies on `tmwtypes.h` and `simstruc_types.h`.

## System Header Files

The system header files make function declarations, type definitions, and macro definitions available to the legacy or external code. Some code generation scenarios require including header files that are specific to the code generator product.

The code generator includes some system header files for broadly defined cases. For example, generated code includes `<stddef.h>` when the model contains a utility function that requires this header file. This approach helps identify header file dependencies:

- 1 Set model configuration parameter **Shared code placement** to 'Shared location' and build the model. The code generator places the utility functions in `__sharedutils` folder.
- 2 Use a find-in-file utility (for example, grep utility) to search the `.c` and `.h` files in the `__sharedutils` folder for `#include`. The search results list the utilities with header file dependencies.

- 3 Use this information to identify utilities to remove from the model and reduce header file dependencies in the generated code.

For more information, see “Generate Shared Utility Code for Fixed-Point Functions” (Simulink Coder).

System Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
<math.h>	<p>Defines math constants</p> <p>GRT—Generated code does not include this file.</p> <p>ERT—Generated code includes this file when the code honors your model configuration for solver <b>Stop time</b> and either:</p> <ul style="list-style-type: none"> <li>• Your model configuration enables parameter <b>MAT-file logging</b>. To omit calls to <code>memset()</code> from model initialization code, select model configuration parameters <b>Remove root level I/O zero initialization</b> and <b>Remove internal data zero initialization</b>.</p>

## Code Generator Header Files

Dependencies in the table for generated header files apply to the system target files `grt.tlc` and `ert.tlc`. System target files derived from these base system target files can have additional header dependencies. Code generation for blocks from blocksets, embedded targets, and custom S-functions can introduce additional header dependencies.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
<code>builtin_typeid_types.h</code>	<p>Defines an enumerated type corresponding to built-in data types</p> <p>GRT and ERT—Generated code includes this file when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• Your model contains a Stateflow chart that uses messages.</li> <li>• Your model configuration enables: <b>MAT-file logging</b>. ## Add Build Process Dependencies

When you specify a system target file for code generation, the code generator can build a standalone executable program that can run on the development computer. To build the executable program, the code generator uses the selected compiler and the makefile generated by the toolchain or template makefile (TMF) build process approach. Part of the makefile generation process is to add source file, header file, and library file information (the dependencies) in the generated makefile for a compilation. Or, for a specific application, you can add the generated files and file dependencies through a configuration management system.

The generated code for a model consists of a small set of files. (See “Manage Build Process Files” (Simulink Coder).) These files have dependencies on other files, which occur due to:

- Header file inclusions
- Macro declarations
- Function calls
- Variable declarations

The model or external code introduces dependencies for various reasons:

- Blocks in a model generate code that makes function calls. These calls can occur in several forms:
  - Included source files (not generated) declare the called functions. In cases such as a blockset, manage these source file dependencies by compiling them into a library file.
  - The generated code makes calls to functions in the run-time library provided by the compiler.
  - Some function dependencies also are generated files, which are referred to as shared utilities. Some examples are fixed-point utilities and non-finite support functions. These dependencies are referred to as shared utilities. The generated functions can appear in files in the build folder for standalone models or in the `_sharedutils` folder under the `slprj` folder for builds that involve model reference.
- Models with continuous time require solver source code files.
- Code generator options such as external mode, C API, and MAT-file logging.

- External code specifies dependencies.

## File Dependency Information for the Build Process

The code generator provides several mechanisms to input file dependency information into the build process. The mechanisms depend on whether your dependencies are block-based or are model- or system target file-based.

For block dependencies, consider using:

- S-functions and blocksets
  - Add folders that contain S-function MEX-files that the model uses to the header include path.
  - Create makefile rules for these folders to allow for finding source code.
  - Specify additional source file names with the S-Function block parameter `SFunctionModules`.
  - Specify additional dependencies with the `rtwmakecfg.m` mechanism. See “Use `rtwmakecfg.m` API to Customize Generated Makefiles” (Simulink Coder).

For more information on applying these approaches to legacy or external code integration, see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder).

- S-Function Builder block, which provides its own UI for specifying dependency information

For model- or system target file-based dependencies, such as external header files, consider using:

- The **Code Generation > Custom Code** pane in the Configuration Parameters dialog box. You can specify additional libraries, source files, and include folders.
- TLC functions `LibAddToCommonIncludes()` and `LibAddToModelSources()`. You can specify dependencies during the TLC phase. See “`LibAddToCommonIncludes(incFileName)`” (Simulink Coder) and “`LibAddSourceFileCustomSection(file, builtInSection, newSection)`” (Simulink Coder). The Embedded Coder product also provides a TLC-based customization template for generating additional source files.

## Generated Makefile Dependencies

For toolchain approach or template makefile (TMF) approach build processes, the code generator generates a makefile. For TMFs, the generated makefile provides token expansion in which the build process expands different tokens in the makefile to include the additional dependency information. The resulting makefile contains the complete dependency information. See “Customize Template Makefiles” (Simulink Coder).

The generated makefile contains:

- Names of the source file dependencies
- Folders where source files are located
- Location of the header files
- Precompiled library dependencies
- Libraries that the make utility compiles and creates

A property of make utilities is that you do not have to specify the specific location for a given source C or C++ file. If a rule exists for that folder and the source file name is a prerequisite in the makefile, the make utility can find the source file and compile it. The C or C++ compiler (preprocessor) does not require absolute paths to the headers. The compiler finds header file with the name of the header file by using an `#include` directive and an include path. The generated C or C++ source code depends on this standard compiler capability.

Libraries are created and linked against, but occlude the specific functions that the program calls.

These properties can make it difficult to determine the minimum list of file dependencies manually. You can use the makefile as a starting point to determine the dependencies in the generated code. For an example that shows how to identify dependencies, see “Relocate Code to Another Development Environment with packNGo” (Simulink Coder).

Another approach to determining the dependencies is using linker information, such as a linker map file, to determine the symbol dependencies. The map file provides the location of code generator and blockset source and header files to help in locating the dependencies.

## Code Generator Static File Dependencies

Several locations in the MATLAB folder tree contain static file dependencies specific to the code generator:

- `matlabroot/rtw/c/src` (open)

This folder has subfolders and contains additional files that must be compiled. Examples include solver functions (for continuous time support), external mode support files, C API support files, and S-function support files. Include source files in this folder into the build process with the SRC variables of the makefile.

- Header files in the folder `matlabroot/rtw/extern/include`
- Header files in the folder `matlabroot/simulink/include`

These folders contain additional header file dependencies such as `tmwtypes.h`, `simstruc_types.h`, and `simstruc.h`.

---

**Note** For ERT-based system target files, you can avoid several header dependencies. ERT-based system target files generate the minimum set of type definitions, macros, and so on, in the file `rtwtypes.h`.

---

### Blockset Static File Dependencies

Blockset products with S-function code apply the `rtwmakecfg.m` mechanism to provide the code generator with dependency information. The `rtwmakecfg.m` file from the blockset contains the list of include path and source path dependencies for the blockset. Typically, blocksets create a library from the source files to which the generated model code can link. The libraries are created and identified when you use the `rtwmakecfg.m` mechanism.

To locate the `rtwmakecfg.m` files for blocksets in your MATLAB installed tree, use the following command:

```
>> which -all rtwmakecfg.m
```

If the model that you are compiling uses one or more of the blocksets listed by the `which` command, you can determine folder and file dependency information from the respective `rtwmakecfg.m` file.

### Folder Dependency Information for the Build Process

You can add `#include` statements to generated code. Such references can come from several sources, including TLC scripts for inlining S-functions, custom storage classes, bus objects, and data type objects. The included files consist of header files for external code or other customizations. You can specify compiler include paths with the `-I`

compiler option. The build process uses the specified paths to search for included header files.

Usage scenarios for the generated code include, but are not limited to, the following:

- A custom build process compiles generated code that requires an environment-specific set of `#include` statements.

In this scenario, the build process invokes the code generator when you select model configuration parameter **Generate code only**. Consider using fully qualified paths, relative paths, or just the header file names in the `#include` statements. Use include paths.

- The build process compiles the generated code.

In this case, you can specify compiler include paths (`-I`) for the build process in several ways:

- Specify additional include paths on the **Code Generation > Custom Code** pane in the Configuration Parameters dialog box. The code generator propagates the include paths into the generated makefile.
- The `rtwmakecfg.m` mechanism allows S-functions to introduce additional include paths into the build process. The code generator propagates the include paths into the generated makefile.
- When building a model that uses a custom system target file and is makefile-based, you can directly add the include paths into the template makefile that the system target file uses.
- Use the `make` command to specify a `USER_INCLUDES` make variable that defines a folder in which the build process searches for included files. For example:

```
make_rtw USER_INCLUDES=-Id:\work\feature1
```

The build process passes the custom includes to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler.

### Use `#include` Statements and Include Paths

Consider the following approaches for using `#include` statements and include paths with the build process to generate code that remains portable and minimizes compatibility problems with future versions.

Assume that additional header files are:

```
c:\work\feature1\foo.h  
c:\work\feature2\bar.h
```

- An approach is to include in the `#include` statements only the file name, such as:

```
#include "foo.h"  
#include "bar.h"
```

Then, the include path passed to the compiler contains folders in which the headers files exist:

```
cc -Ic:\work\feature1 -Ic:\work\feature2    ...
```

- Another approach is to use relative paths in `#include` statements and provide an anchor folder for these relative paths using an include path, for example:

```
#include "feature1\foo.h"  
#include "feature2\bar.h"
```

Then, specify the anchor folder (for example `\work`) to the compiler:

```
cc -Ic:\work    ...
```

## Avoid These Folder Dependencies

When using the build process, avoid dependencies on folders in the build process “Code generation folder” (Simulink), such as the `model_ert_rtw` folder or the `slprj` folder. Do not use paths in `#include` statements that are relative to the location of the generated source file. For example, if your MATLAB code generation folder is `c:\work`, the build process generates the `model.c` source file into a subfolder such as:

```
c:\work\model_ert_rtw\model.c
```

The `model.c` file has `#include` statements of the form:

```
#include "..\feature1\foo.h"  
#include "..\feature2\bar.h"
```

It is preferable to use one of the other suggested approaches because the relative path creates a dependency on the code generator folder structure.

- “Build Process Support for Folder Names with Spaces or Special Characters” (Simulink Coder)
- “Build Process Workflow for Real-Time Systems” (Simulink Coder)

## Build Process Support for Folder Names with Spaces or Special Characters

### Folder Names with Spaces

On a Windows system, the code generator maps a drive corresponding to the MATLAB installation folder for either of these conditions:

- The `matlabroot` folder is a UNC location.
- The path the `matlabroot` folder contains spaces, and the system has no alternative name support.

These folder paths can contain spaces:

- The path to your MATLAB installation folder (`matlabroot`). For example, `C:\Program Files\MATLAB\R2015b`
- The path to the current working folder where you start the build (`pwd`). For example, `C:\Users\username\Documents\My Work`.
- The path to the installation folder for a compiler that the build process uses.

If your work environment includes one or more of the preceding scenarios, use the following support mechanisms for the build process:

- If you are using the toolchain approach to build generated code, the system support for spaces in folder names influences toolchain operation:
  - For Linux systems and Windows systems with 8.3 name creation enabled, the toolchain manages spaces in folder names by using alternative names from the operating system. The toolchain uses the `TransformPathsWithSpaces` attribute to manage these names.

```
addAttribute(toolchainObject, 'TransformPathsWithSpaces', true);
```

The security permissions of drives and folders can determine whether the toolchain transforms the path. For example, if the path contains a folder with a security configuration that forbids 8.3 path transformations, the toolchain does not transform the path and the build process produces a warning.

- For Windows systems with 8.3 name creation disabled, the toolchain manages spaces in folder names by mapping a network drive using a batch file (.bat). This

operation requires adding the `RequiresBatchFile` attribute to the toolchain definition.

```
addAttribute(toolchainObject, 'RequiresBatchFile', true);
```

When developing a toolchain for a Windows system, set both attributes. For more information about the toolchain attributes, see `addAttribute`.

- If you are using the template makefile approach to build generated code, the template makefile (`.tmf`) requires code to manage spaces in folder names. When the alternative folder names (Windows short names) differ from the file system folder names (Windows long names), add this code to the makefile.

```
ALT_MATLAB_ROOT      = |>ALT_MATLAB_ROOT<|
ALT_MATLAB_BIN       = |>ALT_MATLAB_BIN<|
!if "$(MATLAB_ROOT)" != "$(ALT_MATLAB_ROOT)"
MATLAB_ROOT = $(ALT_MATLAB_ROOT)
!endif
!if "$(MATLAB_BIN)" != "$(ALT_MATLAB_BIN)"
MATLAB_BIN = $(ALT_MATLAB_BIN)
!endif
```

When the values of the location tokens are not equal, this code replaces `MATLAB_ROOT` with `ALT_MATLAB_ROOT`. The replacement indicates that the path to your MATLAB installation folder includes spaces. This code applies the same type of replacement for `MATLAB_BIN` with `ALT_MATLAB_BIN`. The preceding code is specific to `nmake`. For platform-specific examples, see the supplied template makefiles.

With either build approach, when there is an issue with support for creation of alternate names (short names), build errors can occur on Windows. If a build generates an error message similar to the following message, see “Troubleshooting Errors When Folder Names Have Spaces” (Simulink Coder).

```
NMAKE : fatal error U1073: don't know how to make ' ...
```

When using operating system commands, such as `system` or `dos`, enclose paths that specify executable files or command parameters in double quotes (" "). For example:

```
system('dir "D:\Applications\Common Files"')
```

This table provides a summary of build folder support and limitations for Windows.

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows
<p>matlabroot folder</p> <p>The matlabroot value is derived from the MATLAB installation location.</p>	<p>During a build, a UNC location such as:</p> <pre>\\networkdrive\matlab\R20xxb</pre> <p>could be remapped as:</p> <pre>T:\</pre> <p>During a build on a Windows system with short file name (8.3) support (default for Windows using NTFS), the build process uses the Windows API <code>getShortPathName( )</code> for the folder location.</p> <p>During a build on a Windows system without short file name (8.3) support (systems using ReFS or using NTFS with 8.3 support disabled), a location with spaces in the path such as:</p> <pre>C:\Program Files\MATLAB\R20xxb</pre> <p>could be remapped as:</p> <pre>T:\R20xxb</pre>	<p>Build process folder support available independent of file system (NTFS or ReFS) or file system configuration for short file name support.</p> <p><b>Limitations:</b></p> <p>On systems that require drive mapping for the installation location, the build process requires that a drive letter is available for mapping.</p> <p>On systems without short file name (8.3) support (using ReFS or using NTFS with 8.3 support disabled), the final folder in the installation location cannot contain spaces. For example, a final folder name:</p> <pre>C:\Program Files\MATLAB\R20xxb sp1</pre> <p>is not supported.</p>
<p>Code generation folder</p> <p>Simulation cache folder</p> <p>Custom code source file locations—among others, these locations</p>	<p>For UNC locations, build process temporarily maps a drive by using the shell commands <code>pushd</code> and <code>popd</code>.</p>	<p>Build process folder support is available independent of file system (NTFS or ReFS) or file system configuration for short path name support.</p>

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows
include folders specified by: <ul style="list-style-type: none"> <li>• rtwmakecfg.m</li> <li>• Model configuration parameter</li> </ul> <b>Additional build information</b> <ul style="list-style-type: none"> <li>• Code replacement library</li> </ul>	For paths with spaces, build process uses the Windows short path name (8.3) by using the Windows API: <code>getShortPathName()</code>	Build process folder support depends on NTFS file system and requires Windows default support. Registry sets value of 2 or 0 for: <code>NtfsDisable8dot3NameCreation</code>  <b>Limitations:</b> Build process does not support spaces in the path to these folders for: <ul style="list-style-type: none"> <li>• NTFS file system with short path name support disabled</li> <li>• ReFS file system (this file system does not support short path names)</li> </ul>

## Folder Names with Special Characters

If a build-related folder path contains a Japanese (multibyte) character where the final byte is equal to the 5C hexadecimal character, the build process might produce an error. The make and compiler tools might incorrectly interpret the final byte as the '\ ' (backslash) character.

## Troubleshooting Errors When Folder Names Have Spaces

On Windows, when there is an issue with support for creation of short file names, build process errors can occur. When this issue affects a build, you see an error message similar to:

```
NMAKE : fatal error U1073: don't know how to make 'C:\Work\My'
```

This message can occur if a space in the folder name (C:\Work\My Models) prevents the build process from finding the model or a file to build. For descriptions of the build-related folders that are sensitive to a space in the folder name or path, see “Folder Names with Spaces” (Simulink Coder).

To avoid issues from folder names with spaces when Windows short file name support for file names is disabled, do not use paths with spaces. For example, install third-party

software to paths without spaces. Do not use paths with spaces for folders containing your models, source files, or libraries.

An issue can occur with builds that use folder names with spaces, because it is possible to disable Windows alternate name support. The build process uses this alternate name support on Windows systems. There are many terms for this file, folder, and path alternate name support:

- 8.3 name
- DOS path
- short file name (SFN, ShortFileName)
- long name alias
- Windows path alias

Verify the type of file system that the drive uses. In Windows Explorer, right-click the drive icon and select properties.

- If the file system is ReFS (Resilient File System), it is an issue. The ReFS does not provide short file name support. Except for the MATLAB installation folder, the build process does not support folder names with spaces for the ReFS file system. If your work environment requires short file name support for the build folder or for additional external code folders, do not use ReFS.
- If the file system is NTFS (New Technology File System), it is possible that the build error is related to a registry setting incompatibility. Continue with troubleshooting steps.

The error could stem from an issue with short file name support on a system using NTFS. Check the Windows registry setting that enables the creation of short names for files, folders, and paths.

- 1 Open the Windows command prompt, running as administrator. For example, from the Windows Start menu, type `cmd`, right-click the `cmd.exe` icon, and select `Run as administrator`.
- 2 Change to the `windows\system32` folder and query the `NtfsDisable8dot3NameCreation` status by typing:  

```
> fsutil 8dot3name query
```
- 3 If the registry state of `NtfsDisable8dot3NameCreation` is not 2, the default (Volume level setting), change the value to 2 by typing:  

```
> fsutil 8dot3name set 2
```

For more information about enabling creation of short names. See <https://technet.microsoft.com/en-us/library/ff621566.aspx>.

Changing the registry setting enables creation of short names only for files and folders that are created after the change.

- 4 To create short names for files created while short name creation was disabled, at the Windows command line, use the `fsutil` utility.

To set the short name, the syntax is:

```
> fsutil file setshortname <FileName> <ShortName>
```

For example, to create the short name `PROGRA~1` for the long name `C:\Program Files`, type:

```
> fsutil file setshortname "C:\Program Files" PROGRA~1
```

The `C:\Program Files` folder name is in quotations because it has spaces.

- 5 To verify that the short name was created, use the `dir` command with `/x` option to show short names.

```
> dir C:\ /x
```

## Code Generation of Matrices and Arrays

MATLAB stores matrix data and arrays (1-D, 2-D, ...) in column-major format as a vector. Simulink and the code generator can store array data in column-major or row-major format. For an array stored in column-major layout, the elements of the columns are contiguous in memory. In row-major layout, the elements of the rows are contiguous. Array layout is also referred to as order, format, and representation. The order in which elements are stored can be important for integration, usability, and performance. Certain algorithms perform better on data stored in a particular order.

Programming languages and environments assume a single array layout for all data. MATLAB and Fortran use column-major layout by default, whereas C and C++ use row-major layout. With Simulink Coder, you can generate C/C++ code that uses row-major layout or column-major layout.

### Array Storage in Computer Memory

Computer memory stores data in terms of one-dimensional arrays. For example, when you declare a 3-by-3 matrix, the software stores this matrix as a one-dimensional array with nine elements. By default, MATLAB stores these elements with a column-major array layout. The elements of each column are contiguous in memory.

Consider the matrix A:

```
A =
    1    2    3
    4    5    6
    7    8    9
```

A translates to an array of length 9 in this order:

```
A(1) = A(1,1) = 1;
A(2) = A(2,1) = 4;
A(3) = A(3,1) = 7;
A(4) = A(1,2) = 2;
A(5) = A(2,2) = 5;
```

and so on.

In column-major format, the next element of an array in memory is accessed by incrementing the first index of the array. For example, these element pairs are stored sequentially in memory:

- $A(i)$  and  $A(i+1)$
- $B(i, j)$  and  $B(i+1, j)$
- $C(i, j, k)$  and  $C(i+1, j, k)$

The matrix A is represented in memory by default with this arrangement:

1      4      7      2      5      8      3      6      9

In row-major array layout, the programming language stores row elements contiguously in memory. In row-major layout, the elements of the array are stored as:

1      2      3      4      5      6      7      8      9

You can store the N-dimensional arrays in column-major or row-major layout. In column-major layout, the elements from the first (leftmost) dimension or index are contiguous in memory. In row-major layout, the elements from the last (rightmost) dimension or index are contiguous.

For more information on the internal representation of MATLAB data, see “MATLAB Data” (MATLAB).

Code generation software uses column-major format by default for several reasons:

- The world of signal and array processing is largely in column-major array layout: MATLAB, LAPack, Fortran90, and DSP libraries.
- A column is equivalent to a channel in frame-based processing. In this case, column-major storage is more efficient.
- A column-major array is self-consistent with its component submatrices:
  - A column-major 2-D array is a simple concatenation of 1-D arrays.
  - A column-major 3-D array is a simple concatenation of 2-D arrays.
  - The stride is the number of memory locations to index to the next element in the same dimension. The stride of the first dimension is one element. The stride of the  $n$ th dimension element is the product of the sizes of the lower dimensions.
  - Row-major  $n$ -D arrays have their stride of 1 for the highest dimension. Submatrix manipulations are typically accessing a scattered data set in memory, which does not allow for efficient indexing.

C uses row-major format. MATLAB and Simulink use column-major format by default. You can configure the code generation software to generate code with a row-major array

layout. If you are integrating external C code with the generated code, see the considerations listed in this table.

Action	Consider
Configure array layout of the model for code generation.	In the Configuration Parameters dialog box, set model configuration parameter <b>Array layout</b> (Simulink Coder) to <b>Column-major</b> or <b>Row-major</b> .
Enable efficient row-major algorithms for simulation and code generation.	Select model configuration parameter <b>Use algorithms optimized for row-major array layout</b> (Simulink).
Integrate external C code functions in row-major array layout with the generated code.	<p>Create S-functions that integrate external code functions with the generated code by using:</p> <ul style="list-style-type: none"> <li>• The SimStruct function <code>ssSetArrayLayoutForCodeGen</code>.</li> <li>• The <b>Array layout</b> (Simulink) setting in the S-Function Builder block.</li> <li>• The Legacy Code Tool option <code>convert2DMatrixToRowMajor</code> in <code>legacy_code</code>. Using <code>convert2DMatrixToRowMajor</code> impacts code efficiency.</li> </ul> <p>Use the C Caller block to call external C functions into Simulink. Specify array layout of custom C functions by using model configuration parameter <b>Default function array layout</b> (Simulink).</p> <p>You can also use <code>coder.ceval</code> in a MATLAB Function block. See “Interface with Row-Major Data in MATLAB Function Block” (Simulink).</p>

## Code Generator Matrix Parameters

The compiled model file, *model*.rtw, represents matrices as character vectors in MATLAB syntax, without an implied storage format. This format enables you to copy the character vector out of an .rtw file, paste it into a MATLAB file, and have MATLAB recognize it.

### Column-Major Layout

For example, the 3-by-3 matrix in the Constant block

```
1  2  3
4  5  6
7  8  9
```

is stored in *model*.rtw as

```
Parameter {
    Identifier           "Constant_Value"
    LogicalSrc           P0
    Protected            no
    Value                [1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0]
    CGTypeIdx            18
    ContainerCGTypeIdx   19
    ReferencedBy         Matrix(1,4)
    GraphicalRef         Matrix(1,2)
    BHMPrmIdx            0
    GraphicalSource      [0, 1]
    OwnerSysIdx          [0, -1]
    VarGroupId           [1, 0]
    WasAccessedAsVariable 1
}
```

The *model\_data.c* file declares the actual storage for the matrix parameter. You can see that the format is in column-major layout.

```
Parameters model_P = {
  /* Expression: [ [1,2,3] ; [4,5,6] ;[7,8,9]]
   * Referenced by: '<Root>/Constant '
   */
  { 1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0 }
};
```

### Row-Major Layout

For example, the 3-by-3 matrix in the Constant block

1	2	3
4	5	6
7	8	9

is stored in *model.rtw* as

```
Parameter {
  Identifier          "Constant_Value"
  LogicalSrc          P0
  Protected           no
  Value               [1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0]
  CGTypeIdx           18
  ContainerCGTypeIdx  19
  ReferencedBy        Matrix(1,4)
  GraphicalRef        Matrix(1,2)
  BHMPrmIdx           0
  GraphicalSource      [0, 1]
  OwnerSysIdx         [0, -1]
  VarGroupIdx         [1, 0]
  WasAccessedAsVariable 1
}
```

The `model_data.h` file declares the actual storage for the matrix parameter. You can see that the format is in row-major layout.

```
Parameters model_P = {
  /* Expression: [ [1,2,3] ; [4,5,6] ;[7,8,9]]
   * Referenced by: '<Root>/Constant '
   */
  { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0 }
};
```

## Internal Data Storage for Complex Number Arrays

Simulink and code generator internal data storage formatting differs from MATLAB internal data storage formatting only in the storage of complex number arrays. In MATLAB, the real and imaginary parts are stored in separate arrays. In Simulink and the code generator, the parts are stored in an interleaved format. The numbers in memory alternate real, imaginary, real, imaginary, and so forth. This convention allows efficient implementations of small signals on Simulink lines, for Mux blocks, and other virtual signal manipulation blocks. For example, the signals do not actively copy their inputs, just the references.

## Unsupported Blocks for Row-Major Code Generation

The code generator does not support these blocks for code generation in row-major array layout.

## Cross-Release Shared Utility Code Reuse

In this section...
“Workflow to Reuse Shared Utility Code” on page 47-86
“Required Editing for Shared Utility Code Reuse” on page 47-87

When you generate code for a model, the code generator by default creates shared utility files that the model requires. When you generate code with different releases, the code generators can produce functionally identical shared files that contain some nonfunctional differences. For example, different comments and different coding style. When you use the same release to generate code for different models in different folders, you can also produce shared files with nonfunctional differences. For example, if you specify different `ParenthesesLevel` or `ExpressionFolding` values for the models, the code generator can produce shared files that contain different comments or different coding styles.

Integrated code that includes functionally identical shared files:

- Is more expensive to verify because each shared file requires verification.
- Produces compilation errors if the shared files define duplicate symbols.

If you have an Embedded Coder license, you can avoid these issues by specifying the reuse of shared code from an existing folder, for example, a read-only library of verified code. In this case, the code generator does not create new shared utility files. The build process uses external code or previously generated shared utility code from the folder. An administrator maintains and updates the read-only library.

### Workflow to Reuse Shared Utility Code

- 1 In the Configuration Parameters dialog box:
  - a In the **Existing shared code** field, enter the full path to your shared code folder.
  - b Verify that the **Use only existing shared code** diagnostic is set to **error** (default).
- 2 Remove the `s\prj` folder or move to a new working folder.
- 3 Build your model. If you do not see an error, your shared code folder contains the required shared utility files.

- 4 If files are missing from the existing shared code folder, you see an error. To continue code generation with a locally generated version of the missing shared utility files:
  - a Set the **Use only existing shared code** diagnostic to warning.
  - b Rebuild your model. The code generation process uses a locally generated version of the missing shared utility files.
  - c Provide the administrator of the verified code library with your model and information about missing shared utility files. With the model, the administrator generates the required shared utility files. Using `sharedCodeUpdate`, the administrator adds the files to the existing shared code folder.

If you require reuse of shared code for a component exported from a previous release, provide the administrator with information about the build folder location for the component. The administrator can use `sharedCodeUpdate` to copy the shared code for the component to the existing shared code folder.

- d When the files are available in the existing shared code folder, repeat steps 1–3.

If the shared utility code is generated from library subsystems that are shared across models (Simulink Coder), you cannot reuse the code *across* releases because the code is release-specific—the symbol name and file name mangling includes the release number. The administrator must add the shared utility code generated for each release to the shared code folder.

The `sharedCodeUpdate` function can add files to the shared code folder that have identical content but different file and function names. This behavior is useful when you have different model components that require their own shared utility functions. Although some code is duplicated, the different model components can access the shared utility functions with which they were verified. To force model components to have their own versions of shared utility functions, configure naming rules to insert the model name into shared utility identifiers (Simulink Coder).

## Required Editing for Shared Utility Code Reuse

For most shared utility code files, you can specify master copies that you can reuse across releases without modifying the files. With some files, for example, `rtwtypes.h`, and `zero_crossing_types.h`, there are situations where manual editing is required to produce master copies that you can use with generated code from different releases. For example:

- The `rtwtypes.h` file generated by releases up to and including R2013a contains a checksum.

```
/* This ID is used to detect inclusion  
  of an incompatible rtwtypes.h */  
#define RTWTYPES_ID_C08S16I32L64N64F0
```

For each version of this `rtwtypes.h` file that you want to include in your integration, copy the corresponding `#define` statement into your master copy of `rtwtypes.h`.

- In R2015a, the zero-crossing definitions moved from `rtwtypes.h` into `zero_crossing_types.h`. To create an `rtwtypes.h` file that is compatible with generated model code from different releases, in your master copy of `rtwtypes.h`, insert this statement.

```
#include "zero_crossing_types.h"
```

Remove definitions from `rtwtypes.h` that `zero_crossing_types.h` provides.

“Compare Simulation Behavior of Model Component in Current Release and Generated Code from Previous Release” on page 47-101

“Import AUTOSAR Code from Previous Releases” on page 47-102

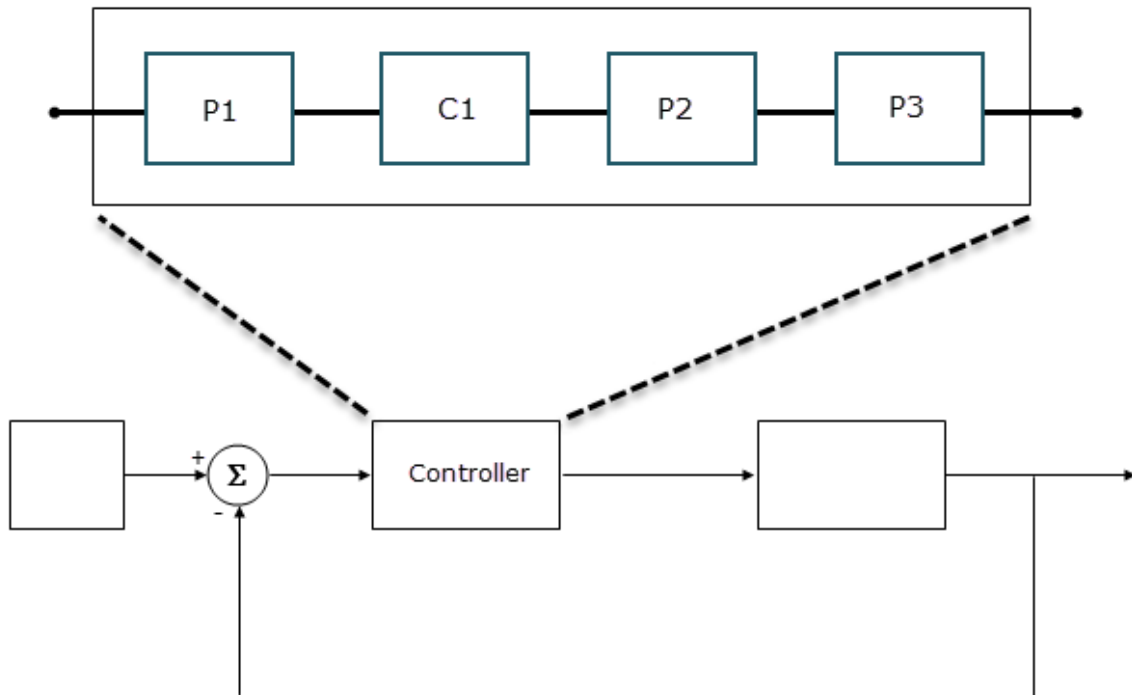

If you have an Embedded Coder license, you can integrate generated C code from previous releases (R2010a and later) with generated code from the current release when the source models are single-rate and the generated C code is from:

- Top-model or subsystem build processes that use the nonreusable function code interface.
- Single or multiple instance model reference build processes that suppress error status monitoring (SuppressErrorStatus is on).

If you can reuse existing code without modification, you can reduce the cost of reverification.

### Workflow

Consider this control system model.

The Controller Model block references a model that consists of three components:

- P1 is a Model block, which references a model developed with a previous release, for example, R2015b. The generated model code, with the standalone code interface, is in the folder P1\_ert\_rtw.
- C1 is a Model block, which references a model that you are developing in the current release.
- P2 is a subsystem block developed with a previous release, for example, R2016a. The generated subsystem code is in the folder P2\_ert\_rtw.

- P3 is a Model block, which references a model developed with a previous release, for example, R2016b. The generated model code, with the model reference code interface, is in the folder `slprj/ert/P3`.

To integrate code from previous releases with generated code from the current release, use this workflow:

### 1 Specify an existing shared code folder

You can specify the reuse of shared code (Simulink Coder) from an existing folder, for example, a library of verified code that an administrator maintains and updates. Specify the shared code folder for model components that require code generation in the current release, for example, `Controller` and `C1`.

In the Configuration Parameters dialog box, in the **Existing shared code** field, enter the full path to the shared code folder.

### 2 Import components into current release

From the current release, import generated component code from previous releases as software-in-the-loop (SIL) blocks or processor-in-the-loop (PIL) blocks. For example:

```
crossReleaseImport(folderPathForP1_ert_rtw,'Controller', ...
'SimulationMode','SIL');
crossReleaseImport(folderPathForP2_ert_rtw,'Controller', ...
'SimulationMode','SIL');
crossReleaseImport(folderPathForP3,'Controller', ...
'SimulationMode','SIL');
```

In the current working folder, the `crossReleaseImport` function creates the `xrel` subfolder that contains software-in-the-loop (SIL) blocks and subfolders:

- `P1_R2015b_sil` and `P1_R2015b_sil_resources`
- `P2_R2016a_sil` and `P2_R2016a_sil_resources`
- `P3_R2016b_sil` and `P3_R2016b_sil_resources`

### 3 Incorporate components into current release model

To replace components with SIL or PIL blocks, use the Simulink Editor or the `pil_block_replace` command. For example, replace:

- P1 with `P1_R2015b_sil`.
- P2 with `P2_R2016a_sil`.

- P3 with P3\_R2016b\_sil.

When you run a model simulation, the simulation runs the previous release code through the SIL or PIL blocks.

When you build the `Controller` model (`rtwbuild('Controller')`), the code generator does not generate new code for the components represented by the SIL or PIL blocks. The model code calls code generated by previous releases.

The Simulink Code Inspector supports call-site validation for a cross-release SIL or PIL block. The block provides a specification of the expected function call, which is derived from the generated code. During analysis, the Simulink Code Inspector compares the expected function call with the block behavior. For information about analysis limitations, see “S-Function” (Simulink Code Inspector).

## Limitations

The cross-release code integration workflow does not support:

- Export-function models for ERT code.
- Simulink Function and Function Caller blocks across the boundaries of ERT code generated by different releases.
- The integration of generated code from releases before R2010a.
- The import of generated code from the current release into a previous release (forward compatibility).
- The export of files located in the MATLAB root folder of the previous release, for example, blockset library files.
- The export and import of generated code from models with noninlined S-functions.
- C-API on page 57-2.

At the end of the model build process, the code generation report displays shared files that are directly used by the integration model, for example, `Controller`. The report does not display shared files used by the components of the model, for example, P1 and P2.

If your model has:

- A cross-release SIL or PIL block, you cannot run rapid accelerator mode simulations.

- A Model block that references a model containing a cross-release SIL or PIL block, you cannot run accelerator mode or rapid accelerator mode simulations.

You can run:

- Top-model SIL simulations of models that contain cross-release SIL or PIL blocks. The models must not contain cross-release AUTOSAR Model blocks.
- Model block SIL simulations of referenced models that contain cross-release SIL or PIL blocks. The referenced models must not contain cross-release AUTOSAR Model blocks.

For information about other cross-release AUTOSAR code integration limitations, see “Import AUTOSAR Code from Previous Releases” on page 47-102.

## Simulink.Bus Support

To use a bus object as a data type in cross-release ERT code integration, use one of these approaches.

Approach	Code Export	Code Import
Automatic	<p>In the previous release, before generating code, set the <code>DataScope</code> property of the <code>Simulink.Bus</code> object to <code>Auto</code>. Do not assign a value to the <code>HeaderFile</code> property.</p> <p>The code generator creates the <code>Simulink.Bus</code> data type definition in the default header file on page 48-17, which is located in the code generation folder for the model.</p>	<p>In the current release, before running <code>crossReleaseImport</code>, set the <code>DataScope</code> property of the <code>Simulink.Bus</code> object to <code>Auto</code>.</p> <p>When you build the integration model, the build process uses the <code>Simulink.Bus</code> data type from the header file in the imported code.</p>

Approach	Code Export	Code Import
Exported bus	<p>In the previous release, before generating code, specify these properties of the <code>Simulink.Bus</code> object:</p> <ul style="list-style-type: none"> <li>• <code>DataScope</code> — Set to <code>Exported</code>.</li> <li>• <code>HeaderFile</code> — Specify a file name, for example, <code>prevRelBusType</code>.</li> </ul> <p>The code generator creates <code>prevRelBusType.h</code> in the shared utility code folder. This header file contains the definition for the <code>Simulink.Bus</code> data type. Use <code>sharedCodeUpdate</code> to add <code>prevRelBusType.h</code> to the shared code folder that <code>ExistingSharedCode</code> specifies.</p> <p>For R2010a and R2010b, the <code>DataScope</code> property is not available. Do not assign a value to the <code>HeaderFile</code> property. The code generator creates the <code>Simulink.Bus</code> data type definition in <code>modelName_types.h</code>, which is located in the code generation folder for the model.</p>	<p>In the current release, before running <code>crossReleaseImport</code>, set the <code>DataScope</code> property of the <code>Simulink.Bus</code> object to <code>Imported</code>.</p> <p>When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the <code>Simulink.Bus</code> data type definition in <code>prevRelBusType.h</code>.</p> <p>If the imported code is from R2010a or R2010b, specify these properties of the <code>Simulink.Bus</code> object:</p> <ul style="list-style-type: none"> <li>• <code>DataScope</code> — Set to <code>Imported</code>.</li> <li>• <code>HeaderFile</code> — Set to file path for <code>modelName_types.h</code>, which is in the imported code folder.</li> </ul> <p>When you build the integration model, the build process uses the <code>Simulink.Bus</code> data type definition in <code>modelName_types.h</code>.</p>

Approach	Code Export	Code Import
Imported bus	<p>In the previous release, before generating code, specify these properties of the <code>Simulink.Bus</code> object:</p> <ul style="list-style-type: none"> <li>• <code>DataScope</code> — Set to <code>Imported</code>.</li> <li>• <code>HeaderFile</code> — Specify a path to a file that contains the <code>Simulink.Bus</code> data type definition, for example, <code>aBusType.h</code>.</li> </ul> <p>For R2010a and R2010b, the <code>DataScope</code> property is not available. For the <code>HeaderFile</code> property, specify a path to a file that contains the <code>Simulink.Bus</code> data type definition, for example, <code>aBusType.h</code>.</p>	<p>In the current release, after importing generated code, you do not have to change the <code>Simulink.Bus</code>.</p> <p>When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the <code>Simulink.Bus</code> data type definition from <code>aBusType.h</code>.</p> <p>If the imported code is from R2010a or R2010b, specify these properties of the <code>Simulink.Bus</code> object:</p> <ul style="list-style-type: none"> <li>• <code>DataScope</code> — Set to <code>Imported</code>.</li> <li>• <code>HeaderFile</code> — Set to <code>aBusType.h</code>.</li> </ul> <p>When you build the integration model, the build process uses the <code>Simulink.Bus</code> data type definition in <code>aBusType.h</code>.</p>

## Root-Level I/O Through Global Variables in Generated Code

When imported ERT code from a previous release implements an input or output port through a global variable, the code that is generated from the integration model depends on the properties of the signal connected to the port in the integration model.

If the integration model signal does not map to a generated code variable that has the same name as the signal in the imported code, the generated code:

- Defines the variable if it is declared but undefined in the imported code.
- Creates additional code to copy data between the variable generated from the integration model and the variable in the imported code.

If the integration model signal maps to a variable with the same name as the signal in the imported code, the variable used by the imported code is also used by the code generated from the integration model. You must use a compatible storage class for the signal.

Storage Class Property	Property Value Support
<b>Type</b>	Unstructured only
<b>Data access</b>	<p>Cannot connect a port implemented as a <code>Pointer</code> variable in the imported code to a signal of the same name that is implemented through a <code>Direct</code> storage class in the integration model</p> <p>Cannot connect a port implemented as a <code>Direct</code> variable in the imported code to a signal of the same name that is implemented as a <code>Pointer</code> in the integration model</p>

Storage Class Property	Property Value Support
<b>Data scope</b>	<p>If the imported code declares but does not define the variable (i.e. code is generated from a signal that uses the Imported value), then one of the following is required:</p> <ul style="list-style-type: none"> <li>• The integration model uses the Exported value.</li> <li>• External code defines the variable.</li> </ul> <p>If the imported code defines the variable (i.e. code is generated from a signal that uses the Exported value):</p> <ul style="list-style-type: none"> <li>• For signals in the integration model that are connected to root-level I/O ports: <ul style="list-style-type: none"> <li>• Set the <code>EnableDataOwnership</code> configuration parameter to <code>on</code>.</li> <li>• Use a custom storage class with these properties: <ul style="list-style-type: none"> <li>• <b>Type</b> - Unstructured</li> <li>• <b>Data access</b> - Direct</li> <li>• <b>Data scope</b> - Exported</li> <li>• <b>Owner</b> - Non-empty value that is not the name of the integration model. For example, the value can be the name of the imported component.</li> </ul> </li> </ul> </li> <li>• For signals in the integration model that are not connected to root-level I/O ports, use a custom storage class with these property values: <ul style="list-style-type: none"> <li>• <b>Data scope</b> - Imported</li> <li>• <b>Data access</b> - Direct</li> </ul> </li> </ul>

## Communicate Between Current and Previous Release Components Through Global Data Stores

Current and previous release components can communicate through global data stores associated with `Simulink.Signal` objects in the MATLAB base workspace or a Simulink data dictionary. The workflow described here applies to cross-release ERT code integration.

### Code Generation Configuration

Before generating model component code in the old release, configure data store memory to use a storage class that imports external code.

If a top-model or subsystem build process generates the code, set the **Storage class** property of the `Simulink.Signal` objects to one of these classes:

- `ImportedExtern`
- `ImportedExternPointer`
- `ImportFromFile` custom storage class

If a model reference build process generates the code, you can also use these classes:

- `ExportedGlobal`
- `ExportToFile` custom storage class

### Import Configuration

In the current release, before you run `crossReleaseImport`, define a `Simulink.Signal` object in the MATLAB base workspace or a Simulink data dictionary for each global data store of the component that you want to import:

- 1 For the object name and the **Data type**, **Complexity**, and **Dimensions** object properties, specify values that match values of the corresponding object in the component that you want to import.
- 2 For the **Storage class** property, specify a value that is compatible. If the previous release value is `ImportedExtern`, specify one of these values for the current release:
  - `ImportedExtern`
  - `ExportedGlobal`

- `ImportFromFile` or `ExportToFile` custom storage class.

If the previous release value is `ImportedExternPointer`, then specify `ImportedExternPointer` for the current release.

- 3 For the **Alias** property, specify a matching value only if the property is specified for the object in the component that you want to import.
- 4 Save the `Simulink.Signal` objects. The objects are required each time you simulate or build the imported SIL or PIL block.

For more information, see “Data Stores in Generated Code” (Simulink Coder).

## Parameter Tuning

The cross-release ERT code integration workflow supports parameter tuning in an integration model that contains component code with tunable parameters from previous releases.

In the current release, before you run `crossReleaseImport`, for each tunable parameter of the component that you want to import:

- 1 Define a `Simulink.Parameter` object in the MATLAB base workspace or a Simulink data dictionary.
- 2 For the object name and the **Data type**, **Complexity**, and **Dimensions** object properties, specify values that match the previous release object values. If the variable in the imported source code does not have the same name as the object, for the **Alias** property, specify a value that matches the variable name.
- 3 If the previous release object uses the `GetSet` custom storage class, specify:
  - A matching value for the **Storage class** object property.
  - The header file that defines the `get` and `set` access functions. For details, see “Control Data Representation by Configuring Storage Class Properties” on page 37-31 and “Access Data Through Functions with Storage Class `GetSet`” on page 37-42.

Support of the `GetSet` custom storage class from a previous release applies only for R2011a and later releases.

For code generated by a top-model or subsystem build process in a previous release, these limitations apply:

- If a tunable parameter specified by a `Simulink.Parameter` object in the previous release has storage class set to `ExportedGlobal` and the storage class of the `Simulink.Parameter` object in the current release is also `ExportedGlobal`, an error occurs when you build the integration model.
- On a Mac operating system, if a tunable parameter specified by a `Simulink.Parameter` object in the previous release has storage class set to `ExportedGlobal`, you cannot build the integration model if the storage class of the `Simulink.Parameter` object in the current release (with the same name or alias) is `ImportedExtern`. To work around this limitation, modify the default settings:

- 1 Get the build tool from the default toolchain.

```
tc = coder.make.getDefaultToolchain;
cComp = tc.getBuildTool('C Compiler');
```

- 2 Extract the C compiler standard options.

```
stdMaps = cComp.SupportedStandard.getLangStandardMaps;
optionValues = stdMaps.getCompilerOptions('*');
```

- 3 Remove `-fno-common` from the standard options for the C and C++ compilers.

```
optionToRemove = '-fno-common';
optionsToKeep = strrep(optionValues, optionToRemove, '');
c_standard_opts_id = '$(C_STANDARD_OPTS)';

custToolChainOpts = get_param(model, 'CustomToolchainOptions');
custToolChainOpts{2} = ...
    strrep(custToolChainOpts{2}, c_standard_opts_id, optionsToKeep);

set_param(model, 'CustomToolchainOptions', custToolChainOpts);
```

## Use Multiple Instances of Code Generated from Reusable Referenced Model

Using a reusable referenced model, you can specify unique model argument values (Simulink) for each instance of the referenced model in a parent model. Import previously generated code for the reusable referenced model into the current release as a parameterized cross-release SIL or PIL block, and then insert multiple instances of the block into an integration model. For each block instance, you can specify unique model argument values.

- 1 Update existing shared code folder.

```
sharedCodeUpdate(sourceFolder, destinationFolder)
```

- 2 Import generated code for the reusable referenced model into the current release as a parameterized cross-release block, for example, a SIL block.

```
handleSILBlock = crossReleaseImport(reusableReferencedModelcodeLocation, ...
    configSetIntegrationModel, 'SimulationMode', 'SIL');
```

- 3 In the integration model, replace, for example, two instances of the referenced model with instances of the cross-release SIL block.

```
open_system(integrationModel);
```

```
blockInstanceName1 = 'refModelInstanceName1';
blockInstanceName2 = 'refModelInstanceName2';
```

```
SILBlockFullName = getfullname(handleSILBlock);
replace_block(integrationModel, 'Name', blockInstanceName1, ...
    SILBlockFullName, 'noprompt');
replace_block(integrationModel, 'Name', blockInstanceName2, ...
    SILBlockFullName, 'noprompt');
```

- 4 Suppose the reusable referenced model has model arguments *paramA* and *paramB*, and the values for the referenced model instances, *refModelInstanceName1* and *refModelInstanceName2*, are workspace variables. In this case, you can specify argument values for the cross-release block instances that are workspace variables.

```
pathToBlockInstanceName1 = [integrationModel, '/', blockInstanceName1];
pathToBlockInstanceName2 = [integrationModel, '/', blockInstanceName2];

set_param(pathToBlockInstanceName1, 'paramA', 'paramA_instName1');
set_param(pathToBlockInstanceName1, 'paramB', 'paramB_instName1');

set_param(pathToBlockInstanceName2, 'paramA', 'paramA_instName2');
set_param(pathToBlockInstanceName2, 'paramB', 'paramB_instName2');
```

- 5 To specify unique model argument values for the block instances in the integration model, assign values to the workspace variables, *paramA\_instName1*, *paramB\_instName1*, *paramA\_instName2*, and *paramB\_instName2*.

## Compare Simulation Behavior of Model Component in Current Release and Generated Code from Previous Release

In a previous release, suppose that you developed a model component, generated code for the component, and tested and deployed the generated code. Now, in the current release, you want to add features to the model component and use the model component in system development and code generation. Before you proceed, you can compare the functional behavior of the model component and the generated code from the previous release.

To test the numerical equivalence between the model component and the generated code from the previous release, use Simulink Test. With the Test Manager (Simulink Test), you can perform back-to-back tests and output comparisons:

- 1 Bring the model component into the current release as a Model block with the **Simulation mode** block parameter set to **Normal**.
- 2 With the Model block, create a top model that specifies test input data.
- 3 Import the code generated in the previous release into the current release as a SIL block.
- 4 With the SIL block, create another top model that specifies the same the test input data.
- 5 In the Test Manager, create an equivalence test case that runs simulations of the top models and compares outputs.
- 6 Run the test case and review results.

For more information, see “Test Two Simulations for Equivalence” (Simulink Test).

---

**Note** If you want to compare the behavior of generated code from the current and previous release, in step 1, specify these Model block parameters:

- Set **Simulation mode** to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**.
  - Set **Code interface** to **Top model**.
- 

## Import AUTOSAR Code from Previous Releases

If you install the Embedded Coder Support Package for AUTOSAR Standard, you can import into the current release AUTOSAR component code that you generated in a previous release.

When you run `crossReleaseImport`, the function imports the AUTOSAR code as a cross-release Model block instead of a SIL or PIL block. The **Simulation mode** parameter of the Model block is set to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**. Incorporate the Model block into the current release model.

These limitations apply:

- The cross-release workflow does not support per-instance memory that accesses NVRAM.
- Tunable parameters must be mapped to AUTOSAR calibration parameters or AUTOSAR internal calibration parameters.
- If the original model uses variants or symbolic dimensions (dimension variants), the imported model can use only the same variant and symbolic dimension configuration that was used when generating the code in the previous release.

## **Integration of Code from Multiple Folders**

To help you to integrate generated code from multiple code generation folders, this table provides information about actions you can take.

Action	Information	Type of Integration Supported
Use consistent configuration parameters across models	<p>If you want to integrate a group of models, aim to use a configuration set that is consistent across the models.</p> <p>For each model, you can create a hash table from the shared utilities checksum file, <code>checksummap.mat</code>. The key-value pairs in the hash table give you information about model parameters. This information can help you to determine the parameter values that you must use across the models. For more information, see “Manage the Shared Utility Code Checksum” on page 6-74</p> <p>To determine whether parameter values are consistent across the models, for each model, you can run checks for compliance with modeling guidelines that specify parameter values. For more information, see “Model Advisor Checks for High-Integrity Modeling Guidelines” (Simulink).</p> <p>You can specify the same configuration parameters for a group of models. For example, for each model, use a configuration reference to access the same configuration set from a data dictionary. When you use the same configuration set, the generated data types for each model are the same and the corresponding <code>rtwtypes.h</code> files are equivalent except for comments. To integrate code from the different models, you can choose a single <code>rtwtypes.h</code> file. For more information, see:</p>	Same-release, cross-release

Action	Information	Type of Integration Supported
	<ul style="list-style-type: none"> <li>• “About Configuration References” (Simulink)</li> <li>• “What Is a Data Dictionary?” (Simulink)</li> </ul>	
Reuse shared utility code	<p>You can reuse data and functions across software components by specifying a shared utilities folder for your models. In the Configuration Parameters dialog box, set <b>Shared code placement</b> to Shared location.</p> <p>If you want software components to share a utilities folder, generate code from a common working folder or specify the same code generation folder through the file generation control parameter, <code>CodeGenFolder</code>. For more information, see “Manage Build Process Folders” on page 47-36.</p> <p>Identically-named utility files generated in different releases are functionally equivalent even if file style or comments differ. For cross-release code integration, you can use the <code>ExistingSharedCode</code> parameter to specify the reuse of shared utility code from an existing folder. For more information, see:</p> <ul style="list-style-type: none"> <li>• “Workflow to Reuse Shared Utility Code” on page 47-86</li> <li>• “Existing shared code”</li> </ul>	Same release, cross-release

Action	Information	Type of Integration Supported
Avoid generated header file updates	<p>In general, when you build a model, existing header files (and source files) in the <code>_sharedutils</code> or <code>_shared</code> folder are not regenerated. However, there are instances when the code generator overwrites existing header files in the folder. The table in “Code Generator Header Files” on page 47-56, which describes header file generation dependencies, provides information about how you can avoid overwriting some header files, for example, <code>rtwtypes.h</code> and <code>multiword_types.h</code>.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• “Build Process Folders” on page 47-39</li> <li>• “Control Placement of <code>rtwtypes.h</code> for Shared Utility Code” on page 6-72</li> </ul>	N/A
Use cross-release SIL or PIL block	<p>You can use the cross-release SIL or PIL block to integrate generated code from previous releases (R2010a and later) with generated code from the current release. For more information, see “Cross-Release Code Integration” on page 47-89.</p>	Same release, cross-release

Action	Information	Type of Integration Supported
Use CRL and ExistingSharedCode	<p>You can use the code replacement library (CRL) and ExistingSharedCode parameter approaches either separately or jointly:</p> <ul style="list-style-type: none"> <li>• The CRL approach supports customization of code generation and eliminates the generation of some shared utility files. You must manage the use of utility files that are not replaced by CRL. For more information, see “Develop a Code Replacement Library” on page 65-27.</li> <li>• The <b>ExistingSharedCode</b> approach, which is based on previously generated utility files, also supports customization and suppresses regeneration of utility files. If customization is not required, the ExistingSharedCode approach is simpler to set up and manage. For more information, see “Cross-Release Shared Utility Code Reuse” on page 47-86.</li> </ul>	Same release, cross-release

## Integrate Generated Code by Using Cross-Release Workflow

This example shows how to reuse previously generated code by creating a cross-release software-in-the-loop (SIL) block and incorporating the block within an integration model. For more information about the workflow, see “Cross-Release Code Integration” on page 47-89.

### Generate Code from a Model

In the cross-release code integration workflow, you create a software-in-the-loop (SIL) or processor-in-the-loop (PIL) block from code that you previously generated.

This example uses generated code from the current release.

```
model = 'rtwdemo_crossrelease_counter';
close_system(model,0)
load_system(model)
set_param(model, 'SimulationCommand', 'update');
open_system(model)
rtwbuild(model);

### Starting build procedure for model: rtwdemo_crossrelease_counter
### Successful completion of code generation for model: rtwdemo_crossrelease_counter
```

Identify the build folder that contains the generated code.

```
buildFolder = RTW.getBuildDir(model).BuildDirectory;
```

Identify the folder that contains code for shared utilities associated with the generated code.

```
previousSharedCodeFolder = RTW.getBuildDir(model).SharedUtilsTgtDir;
```

To reuse generated code from a previous release:

- 1 On the **Simulation** tab, in the **File** section, select **Save > Previous Version**.
- 2 In the **Save as type field**, specify the release and model type.
- 3 Click **Save**.
- 4 Use the previous release to open the saved model, and then generate code.
- 5 Set the value of `buildFolder` to the location of the code generated in the previous release.
- 6 Set the value of `previousSharedCodeFolder` to the location of the shared utilities generated in the previous release.

### Manage Shared Code

Add the generated shared source code files to a repository folder that is used by the integration model.

```
sharedCodeRepo = 'SharedCodeRepo';  
mkdir(sharedCodeRepo);  
sharedCodeUpdate(previousSharedCodeFolder, sharedCodeRepo, 'Interactive', false);
```

The following files will be copied from `slprj\ert\_sharedutils` to `SharedCodeRepo\R2019b`:

```
rtwtypes.h
```

Files copied from `slprj\ert\_sharedutils` to `SharedCodeRepo\R2019b`.

### Import Code

Open the integration model.

```
integrationModel = 'rtwdemo_crossrelease_integration';  
close_system(integrationModel, 0);  
load_system(integrationModel);
```

Modify the Simulink configuration set so that it references the existing shared code library.

```
cs = getActiveConfigSet(integrationModel);
set_param(cs, 'ExistingSharedCode', fullfile(pwd, sharedCodeRepo));
```

Create the cross-release SIL block.

```
blockHandle = crossReleaseImport(buildFolder, cs, 'SimulationMode', 'SIL');

### Starting import process for component: rtwdemo_crossrelease_counter_R2019b
### Starting build process for SIL block: rtwdemo_crossrelease_counter_R2019b
```

### Incorporate Cross-Release SIL Block into Integration Model

To replace a block in the integration model with the cross-release block, use `pil_block_replace`. This function preserves the block size, line connections, and priority.

```
srcBlock = getfullname(blockHandle);
dstBlock = [integrationModel, '/', 'Counter'];
pil_block_replace(srcBlock, dstBlock)
open_system(integrationModel)
```

Successfully swapped the following blocks:

```
untitled/rtwdemo_crossrelease_counter_R2019b_sil
rtwdemo_crossrelease_integration/Counter
```

Copyright 2017-2019 The MathWorks, Inc.

### Simulate Integration Model

Run a simulation of the integration model.

```
sim(integrationModel)
```

```
### Preparing to start SIL block simulation: rtwdemo_crossrelease_integration/Counter
### Starting SIL simulation for component: rtwdemo_crossrelease_counter_R2019b_sil
rtw.connectivity.HostLauncher: started executable with host process identifier 53316
rtw.connectivity.HostLauncher: stopped executable with host process identifier 53316
### Stopping SIL simulation for component: rtwdemo_crossrelease_counter_R2019b_sil
```

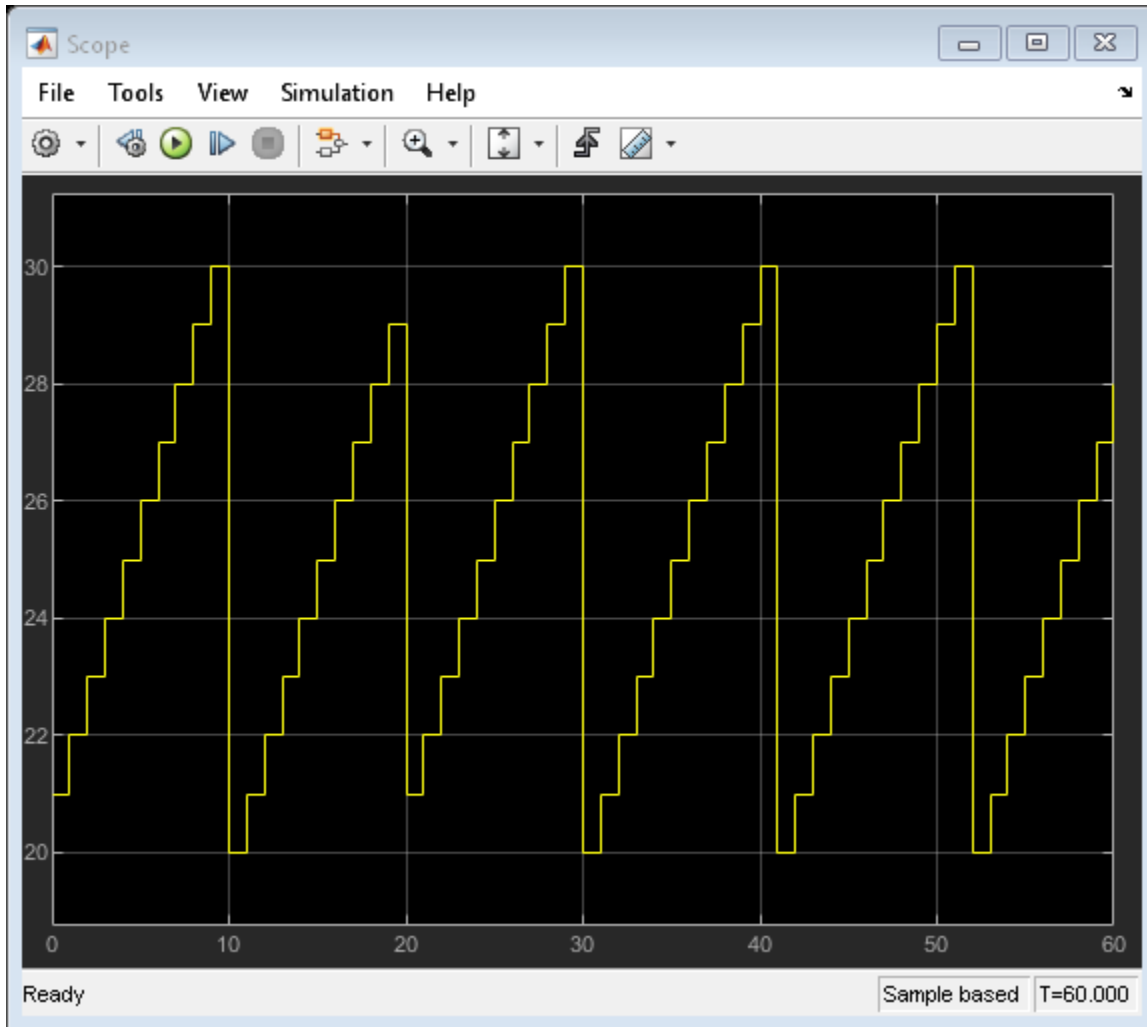

### Tune Parameters

The source model for the cross-release SIL block references two tunable parameters, which are controlled by Simulink.Parameter objects in the base workspace. Use these parameters to modify the behavior of the SIL simulation.

```
countUpper.Value = 30;
countLower.Value = 20;
yout_retuned = sim(integrationModel, 'ReturnWorkspaceOutputs', 'on');

### Preparing to start SIL block simulation: rtwdemo_crossrelease_integration/Counter
### Starting SIL simulation for component: rtwdemo_crossrelease_counter_R2019b_sil
rtw.connectivity.HostLauncher: started executable with host process identifier 43140
rtw.connectivity.HostLauncher: stopped executable with host process identifier 43140
### Stopping SIL simulation for component: rtwdemo_crossrelease_counter_R2019b_sil
```

### Configure Storage Class for Signals in Integration Model

Configure:

- Signal names in the integration model to match the names used in the imported code.
- Complementary storage classes.

In this case, the `ticks` input and `count` output are implemented through the `ImportedExtern` storage class in the imported code. If the storage class for the signals connected to the input and output ports of the cross-release block in the integration model is `ExportedGlobal`, the integration model must provide the definitions for the variables.

If the signal names do not match, the integration model generates additional code to copy data between the signal implemented by the integration model and the signal implemented by the imported code.

```
hLines = get_param(dstBlock, 'LineHandles');  
set(hLines.Inport(1), 'Name', 'ticks', 'StorageClass', 'ExportedGlobal');  
set(hLines.Outport(1), 'Name', 'count', 'StorageClass', 'ExportedGlobal');
```

### **Configure Storage Class for Parameters and Data Store Memory in Integration Model**

The parameters and data stores are implemented through the `ImportedExtern` storage class in the imported code. If you configure the parameters and data stores to use the `ExportedGlobal` storage class, the integration model must provide the definitions for the variables.

```
resetSignal.CoderInfo.StorageClass = 'ExportedGlobal';  
countLower.CoderInfo.StorageClass = 'ExportedGlobal';  
countUpper.CoderInfo.StorageClass = 'ExportedGlobal';
```

### **Generate Code from Integration Model**

Once the required shared code is in the shared code repository, remove the previously generated shared utilities folder.

```
if isfolder(RTW.getBuildDir(integrationModel).SharedUtilsTgtDir)  
    rmdir(RTW.getBuildDir(integrationModel).SharedUtilsTgtDir, 's');  
end
```

Delete the scope and connecting line that do not affect code generation.

```
scopeBlock = [integrationModel, '/', 'Scope'];  
hScopeLines = get_param(scopeBlock, 'LineHandles');  
hScopeLine = hScopeLines.Inport(1);  
assert(strcmp(get(hScopeLine, 'SegmentType'), 'branch'));  
delete_line(hScopeLine);  
delete_block(scopeBlock);
```

Generate code.

```
rtwbuild(integrationModel);
```

```
### Starting build procedure for model: rtwdemo_crossrelease_integration  
### Successful completion of code generation for model: rtwdemo_crossrelease_integration
```

### Examine Call to Imported Code

To examine the cross-release block code within the integration model code, use the `rtwtrace` utility.

```
rtwtrace(dstBlock);
```

### Test Code Generated from Integration Model

Run a top-model software-in-the-loop (SIL) simulation of the integration model. The simulation runs the code generated from the integration model, which calls the imported code.

Log the simulation output in the workspace.

```
set_param(integrationModel, 'SimulationMode', 'software-in-the-loop (sil)');  
yout_SIL = sim(integrationModel, 'ReturnWorkspaceOutputs', 'on');  
plot(yout_SIL.yout{1}.Values);
```

```
### Starting build procedure for model: rtwdemo_crossrelease_integration  
### Successful completion of build procedure for model: rtwdemo_crossrelease_integration  
### Preparing to start SIL simulation ...  
Building with 'Microsoft Visual C++ 2017 (C)'.  
MEX completed successfully.  
### Updating code generation report with SIL files ...  
### Starting SIL simulation for component: rtwdemo_crossrelease_integration  
### Stopping SIL simulation for component: rtwdemo_crossrelease_integration
```

### Compare Simulation Outputs

Compare the outputs from the simulation where only the imported code ran in SIL mode with the outputs from the simulation where the integration model ran as a top-model in SIL mode.

```
max(abs(yout_SIL.yout{1}.Values.Data - yout_retuned.yout{1}.Values.Data))
```

```
ans =
```

```
uint8
```

## Relocate Code to Another Development Environment with packNGo

Use the code generator packNGo option to generate code in one location. After code generation, collect the compiler command-line options, move the generated code to another location, and compile the generated code in combination with custom code.

### Check Platform and Set Up Path and Folders

For this example, you must have the gcc toolchain running on a Linux® platform. After verifying this platform, this example sets up the path, folders, and files.

When you rerun the example, to ease clean up of generated files, the work folders (code\_generation\_area\_dir and build\_area\_dir) are separate from the source files (models\_dir and hand\_code\_dir).

All locations of source file and folders use paths that are relative to the folder containing the example .M file.

```
if ismac
    % Code to run on Mac platform
    disp('Platform (Macintosh) not supported.')
elseif ispc
    % Code to run on Windows platform
    disp('Platform (Windows) not supported.')
elseif isunix

originalFolder = pwd;
thisFilesFullName = mfilename( 'fullpath' );
thisFilesAbsolutePath = fileparts( thisFilesFullName );
modelsFolder = fullfile( thisFilesAbsolutePath, 'models_dir' );
codeGenerationRootFolder = ...
    fullfile( thisFilesAbsolutePath, 'code_generation_area_dir' );
buildAreaRootFolder = ...
    fullfile( thisFilesAbsolutePath, 'build_area_dir' );
handCodeFolder = ...
    fullfile( thisFilesAbsolutePath, 'hand_code_dir' );
```

### Clean Up

To eliminate build artifacts from previously running the example, this example searches for and eliminates folders containing these by-products of previous runs.

```
if( 0 < exist( codeGenerationRootFolder, 'dir' ) )
    clear mex;
    rmdir( codeGenerationRootFolder, 's' );
else
    % No previous codeGenerationRootFolder.
end
mkdir( codeGenerationRootFolder );

if( 0 < exist( buildAreaRootFolder, 'dir' ) )
    clear mex;
    rmdir( buildAreaRootFolder, 's' );
else
    % No previous buildAreaRootFolder.
end
mkdir( buildAreaRootFolder );
if( 0 < exist( modelsFolder, 'dir' ) )
    clear mex;
    rmdir( modelsFolder, 's' );
else
    % No previous modelsFolder.
end
mkdir( modelsFolder );
copyfile((fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'rtwdemo_packngo', 'rtwdemo_packngo_slx')), 'f');
if( 0 < exist( handCodeFolder, 'dir' ) )
    clear mex;
    rmdir( handCodeFolder, 's' );
else
    % No previous handCodeFolder.
end
mkdir( handCodeFolder );
copyfile((fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'rtwdemo_packngo', 'main.c')), 'f');
copyfile((fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'rtwdemo_packngo', 'main.h')), 'f');
directoriesToAddToMatlabPathCellStr = ...
    { ...
      thisFilesAbsolutePath, ...
      modelsFolder ...
    };
for directoryIndex = 1 : numel( directoriesToAddToMatlabPathCellStr )
    currentDirectory = directoriesToAddToMatlabPathCellStr{ directoryIndex };
    addpath( currentDirectory );
end
```

## Generate Code and Output a .zip File with packNGo

In this example, the code generation configuration for the `rtwdemo_packngo` model enables the **Generate code only** parameter (`GenCodeOnly`) and enables the **Package code and artifacts** parameter (`PackageGeneratedCodeAndArtifacts`). These options direct the code generator to create a packNGo archive (.zip file) and stop the build process without compiling the generated code. Compilation occurs later with integrated custom code that replaces the generated `main.c` file.

```
cd( codeGenerationRootFolder );
modelBaseName = 'rtwdemo_packngo';
open_system( modelBaseName );
slbuild( modelBaseName );
close_system( modelBaseName );
```

## Extract Build Information from Makefile

When using the toolchain approach for the build process, you can extract build information from the generated makefile. The information includes source files, dependency files, and macro definitions and values that appear in the makefile. With current working folder set to the folder containing the generated makefile, `rtwdemo_packngo.mk`, in the Command Window, type:

```
cd( 'rtwdemo_packngo_grt_rtw' );
system('gmake -f rtwdemo_packngo.mk info')
```

For information about performing a similar operation on Windows® platforms, see the `model.bat` description in “Manage Build Process Files” (Simulink Coder).

## Move Generated Code and Custom Code to Common Location for Build Process

To integrate the generated code and custom code, this example moves the files to a common location for the build process. The archive from the packNGo option is unzipped.

```
cd( buildAreaRootFolder );
generatedPackNGoArchiveShortName = ...
    [ modelBaseName, '.zip' ];
filesToCopyCellStr = ...
    { ...
        fullfile( codeGenerationRootFolder, generatedPackNGoArchiveShortName ), ...
        fullfile( handCodeFolder, 'main.h' ), ...
        fullfile( handCodeFolder, 'main.c' ) ...
    };
fileCopyFunctionHandle = ...
```

```

    @( sourceFileFullName )copyfile( sourceFileFullName, buildAreaRootFolder );
for sourceFileIndex = 1 : numel( filesToCopyCellStr )
    currentSourceFile = filesToCopyCellStr{ sourceFileIndex };
    fileCopyFunctionHandle( currentSourceFile );
end
generatedPackNGoArchiveDestinationFullName = ...
    fullfile( buildAreaRootFolder, generatedPackNGoArchiveShortName );
unzip( generatedPackNGoArchiveDestinationFullName );

```

### Construct the Build Command

To compile the generated code and integrated custom code, this example constructs a build command for the gcc compiler and tools that:

- Compiles the generated and custom source files
- Specifies the required folders where the preprocessor can locate included header files
- Provides the correct -D arguments for preprocessor macros that the generated code requires

### Identify the Source Files for the Build Command

The generated source files are in a folder extracted from the packNGo archive (.zip file). The file name combines the:

- Model name
- System target file (selected in the model configuration set)
- Original code generation folder

```

generatedCodeSubFolderName = ...
    [ modelBaseName, '_grt_rtw' ];
generatedCodeFolderFullName = ...
    fullfile( buildAreaRootFolder, 'code_generation_area_dir', generatedCodeSubFolderName );
sourceFileFullNamesCellStr = ...
    { ...
        fullfile( buildAreaRootFolder, 'main.c' ), ...
        fullfile( generatedCodeFolderFullName, 'rtwdemo_packngo.c' ) ...
    };

```

### Identify the Header File Folders

The required header file folders include:

- Custom header file locations
- Generated header file locations
- Locations that contain files that the packNGo operation copied from the MATLAB installation folders to the packNGo archive

```
[ ~, matlabReleaseFolderName ] = fileparts( matlabroot() );
headerFileDirectoriesCellStr = ...
    { ...
    buildAreaRootFolder, ...
    generatedCodeFolderFullName, ...
    fullfile( buildAreaRootFolder, matlabReleaseFolderName, 'extern', 'include' ), ...
    fullfile( buildAreaRootFolder, matlabReleaseFolderName, 'simulink', 'include' ) ..
    };
```

### Identify Required Preprocessor Macros

There are a number of preprocessor macros that must be defined to guide conditional compilation in the code. The macro names and values can be copied from the `defines.txt` file in the generated code folder.

```
commandLineDefinesCellStr = ...
    { ...
    'MODEL=rtwdemo_packngo', ...
    'NUMST=1', ...
    'NCSTATES=0', ...
    'HAVESTDIO', ...
    'RT', ...
    'USE_RTMODEL', ...
    'UNIX', ...
    'MAT_FILE=0', ...
    'INTEGER_CODE=0', ...
    'MT=0', ...
    'CLASSIC_INTERFACE=0', ...
    'ALLOCATIONFCN=0', ...
    'ONESTEPFCN=1', ...
    'TERMFCN=1', ...
    'MULTI_INSTANCE_CODE=0', ...
    'TID01EQ=0' ...
    };
```

## Prepare Cell Array Data as Strings

After gathering the source, header, folder, and macro information for the build command into cell array data, this example constructs the build command by reorganizing this data as properly-formed strings. The strings serve as part of a compilation command.

```
commandLineDefinesCompilerArgumentString = ...
    strjoin( strcat( '-D', commandLineDefinesCellStr ), ' ' );
sourceFilesCompilerArgumentString = ...
    [ '' strjoin( sourceFileFullNamesCellStr, ' ' ) '' ];
inclusionDirectoriesCompilerArgumentString = ...
    [ '-I' strjoin( headerFileDirectoriesCellStr, ' -I' ) '' ];
compilationCommandString = ...
    [ ...
        'gcc', ' ', ...
        '-v', ' ', ...
        sourceFilesCompilerArgumentString, ' ', ...
        commandLineDefinesCompilerArgumentString, ' ', ...
        inclusionDirectoriesCompilerArgumentString ...
    ];
```

## Run the Compilation Command

The compilation command is:

```
[ compilationResult, compilationOutput ] = ...
    system( compilationCommandString );
```

## View the Compilation Results

The results use operating system conventions for the return values because "system(...)" returns the results from the operating system. As a result, "0" indicates success, instead of "1"/"true".

```
assert( ( 0 == compilationResult ), compilationOutput );
disp( compilationOutput );
```

## Call the Integrated, Compiled Executable

Running the compile executable produces this output:

```
[ executionResult, executionOutput ] = system( './a.out' );
assert( ( 0 == executionResult ), executionOutput );
disp( executionOutput );
cd( originalFolder );
```

### Considerations for Relocating Code to Other Platforms or Toolchains

This example shows how to use packNGo to relocate code and integrate custom code with generated code. These techniques ease relocating generated code to other platforms (for example, Linux® to Windows®). The sections of this example that show how to construct the build command provide information that supports code relocation.

The build command on the target platform (for example, Microsoft Visual C/C++ MSVC on Windows®) is as close as possible to the build tool flags and definitions in the build command on the source platform (for example, gcc on Linux®). Some flags and definitions are required (for example, list of source and dependency files). Other flags are optional (for example, compiler optimizations vary among compilers).

```
else
    disp('Platform not supported.')
end
```

```
Platform (Windows) not supported.
```

## Generate Code and Simulate Models in a Project

This example shows how to use the code generation template for a new Project. The code generation project template for Project includes multiple models. The project template also provides utilities (.m scripts) that help you generate controller code and run simulations of the harness model.

To see the Project API functions for each operation in this example, view the example code.

### Create a Project

Create a new Project from the code generation project template.

To create this project from the Simulink start page, in the Command Window, type:

```
simulink
```

Select the Code Generation template from the start page, and create the `exampleCodeGen` project.

### Generate Code

Generate controller code for the `feedback_control.slx` model.

To generate controller code, select the **Project Shortcuts** tab and select the **Generate Controller Code** shortcut.

This shortcut runs the `generate_controller_code.m` script in the utilities folder of the project. The script builds the `feedback_control.slx` model in the controller folder of the project.

## Simulate Models

Simulate the top-level harness `feedback_harness.slx` model.

To open the harness model for simulation, select the **Project Shortcuts** tab and select the **Feedback Harness** shortcut. This shortcut opens the `feedback_harness.slx` model in the harnesses folder of the project.

To simulate the model, click **Run**.

Copyright 2012 The MathWorks, Inc.

## Observe Simulation Output

Open the Scope block in the model and observe the simulation output.

To open the scope and observe simulation, in the Simulink window, double-click the Scope block.

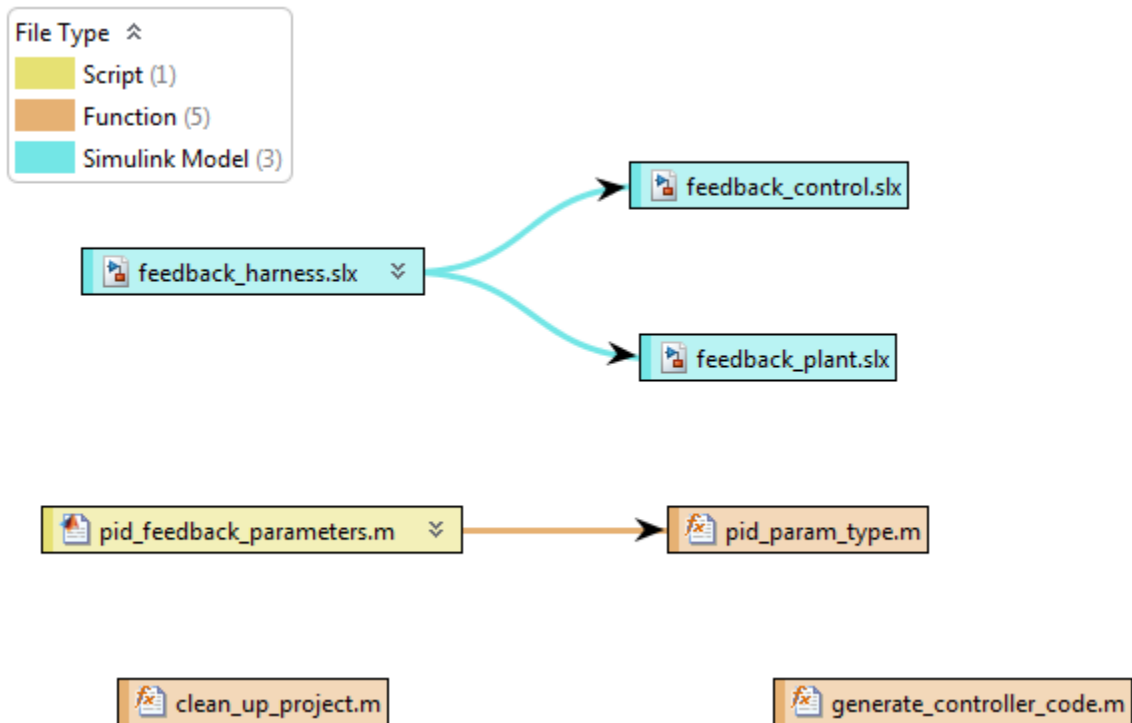

### Use the Dependency Analysis View

To view file dependencies and to open or run files, use the **Dependency Analysis** view of the project.

From the **Dependency Analysis** view, you can:

- Observe file dependencies.
- Use the context menu for each file to open the file, to run .m script files, and run (simulate) model files.

### More Information

- “Work with Project Files” (Simulink)
- `Simulink.createFromTemplate`

## Generate Code and Simulate Models with Project API

This example shows how to add files to a new project, set up project shortcuts, generate code, and simulate the harness model. The models in this example demonstrate some principles of Model-Based Design (MBD).

This example also shows how to use the Project API to perform many project operations.

### **Manage a Model-Based Design Project**

The example models provide a controller that positions a camera fixed to a DC motor that tracks a green ball.

The MBD approach leads to modeling the controller operations:

- Model plant: The plant is a DC motor that rotates to reposition the camera.
- Model controller: The design uses a PID controller with feedback on angular position for positioning the DC motor.
- Model high-level ball tracking scheduler: The scheduler checks for validity of the position of the green ball and the saturation of the reference angle. The scheduler handles the instances of no ball on the screen to track.

The design and Project have the following sections (folders).

**Plant** -- The plant provides:

- Models with continuous-time dynamic systems that use basic Simulink blocks.
- Models with linear time invariant (LTI) systems that use the LTI system block.
- Import and export of simulation data to and from the workspace
- Loading of parameters into the base workspace that use data dictionary and model callbacks.

**Controller** -- The controller provides:

- Models with discrete-time dynamic systems that use basic Simulink blocks.
- Models with discrete-time dynamic systems that use the PID Controller Block.
- Enforcement of signal saturation that use a PWM Conversion subsystem.

**Ball Tracking** -- The ball tracking provides:

- The basic ball tracking algorithm.
- The terminator and ground blocks as placeholders.
- A hybrid controller that generates motor reference angles using Stateflow.

**Harnesses** -- The harnesses provide top-level simulation of the full system.

### Create a Project and Add Files

1. Create a Project from the Blank Project template, then close the project.

To create this project from the Simulink start page:

- In the Command Window, type `simulink`.
- Select the Blank Project template from the start page.
- Create the `modelBasedDesignCodeGenProject` project.

To create this project using the Project API, in the Command Window, type:

```
user_root = userpath;  
checkForFolder = exist(fullfile(user_root, 'user_proj'));  
if (checkForFolder ~= 2)  
    mkdir(user_root, 'user_proj');  
    cd(fullfile(user_root, 'user_proj'));  
else  
    cd(fullfile(user_root, 'user_proj'));  
end  
end
```

Warning: Directory already exists.

```
checkForProject = exist('./ModelBasedDesignCodeGen/ModelBasedDesignCodeGenProject.prj');  
if (checkForProject ~= 2)  
    proj_modelBasedDesignCodeGen = Simulink.createFromTemplate('blank_project.sltx', 'Name');  
else  
    proj_templateCodeGen = simulinkproject('./ModelBasedDesignCodeGen/ModelBasedDesignC');  
end  
end
```

2. Copy the example files to folders within the Project. In the Command Window, type:

```
copyfile(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'slproject_codegen_demo'), ...  
fullfile(pwd), 'f');
```

3. Close the Project from the Project window.

To close this project using the Project API, in the Command Window, type:

```
close(simulinkproject);
```

4. Open the project from the selection on the **Recent Projects** list.

To open this project using the Project API, in the Command Window, type:

```
simulinkproject(fullfile('./ModelBasedDesignCodeGen/ModelBasedDesignCodeGenProject.prj
```

5. To add existing files to the project, click the **Project Files View** button and select **All files View**.

6. Select the folders `ball_tracking`, `controller`, `harnesses`, `plant`, and `utilities`, right-click the icon for one of the folders, and select **Add Folder to Project (Including Child Files)**.

To add these files to the project using the Project API, in the Command Window, type:

```
proj_modelBasedDesignCodeGen = simulinkproject;
if (checkForProject ~= 2)
    addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'ball_tracking');
    addPath(proj_modelBasedDesignCodeGen, 'ball_tracking');
    addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'controller');
    addPath(proj_modelBasedDesignCodeGen, 'controller');
    addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'harnesses');
    addPath(proj_modelBasedDesignCodeGen, 'harnesses');
    addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'plant');
    addPath(proj_modelBasedDesignCodeGen, 'plant');
    addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'utilities');
    addPath(proj_modelBasedDesignCodeGen, 'utilities');
end
```

7. Select the work folder, right-click the icon for one of the folders, and select **Project Path > Add to the Project Path (Including Subfolders)**. If you choose to add this folder to the path, generated files (artifacts) from simulation and code generation are available on the project path. If you choose not to include the generated files in the project, the Dependency Analysis view does not display these files.

To add this folder to the project path using the Project API, in the Command Window, type:

```
if (checkForProject ~= 2)
    addPath(proj_modelBasedDesignCodeGen, 'work');
end
```

**8.** To make the Project more accessible, define and set properties for project shortcuts. Click **All files View** and select **Project Files View**. Open the utilities folder node.

**9.** Select the files `clean_up_project.m`, `generate_controller_code.m`, and `set_up_project.m`, right-click the icon for one of the files, and select **Add Shortcut to > General**. Select the **Shortcut Management** view.

**10.** To set the current working folder, set the simulation cache folder, and run other setup scripts when you open the project:

- Select the `set_up_project.m` script.
- Right-click the file.
- Select **Set Shortcut Action > Startup**.

To add this setup script to project startup using the Project API, in the Command Window, type:

```
if (checkForProject ~= 2)
    addStartupFile(proj_modelBasedDesignCodeGen,fullfile(pwd,'/utilities/set_up_project.m'))
end
```

**11.** To set the restore previous settings and run other clean-up scripts when you close the project:

- Select the `clean_up_project.m` script.
- Right-click the file.
- Select **Set Shortcut Action > Shutdown**.

To add this clean-up script to project shutdown using the Project API, in the Command Window, type:

```
if (checkForProject ~= 2)
    addShutdownFile(proj_modelBasedDesignCodeGen,fullfile(pwd,'/utilities/clean_up_project.m'))
end
```

**12.** Close the project. When you reopen the project, the **Startup** shortcut runs.

To complete these operations using the Project API, in the Command Window, type:

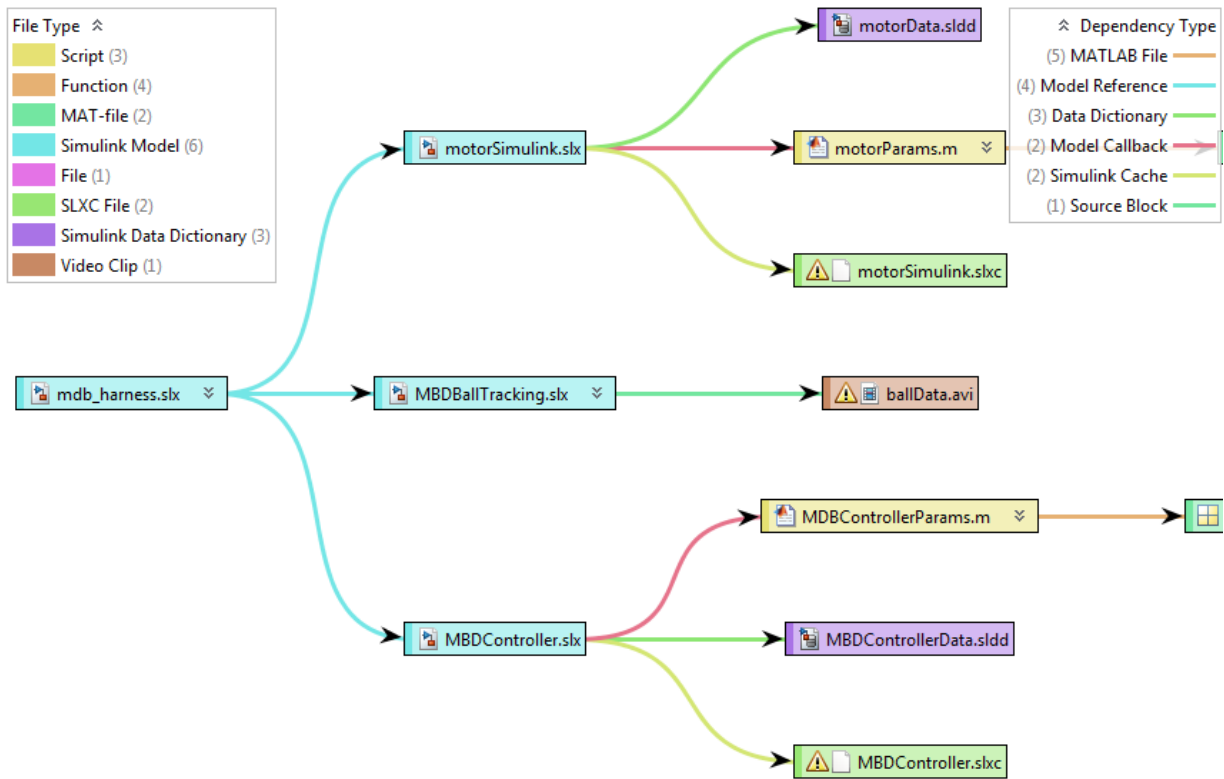

```
close(simulinkproject);
simulinkproject(fullfile('./ModelBasedDesignCodeGen/ModelBasedDesignCodeGenProject.prj'));
run('set_up_project');
```

## Generate Code for the Controller from Dependency Analysis View

1. Open the **Dependency Analysis** view.
2. Click **Analyze**. Project analyzes file dependencies in the project and updates the view of the dependencies.
3. Use the **Zoom** button to zoom into the dependencies map. Use arrow keys or click-drag with the mouse roller wheel to move around in the map.
4. Select the `MBDController.slx` model on the dependency map. Right-click the model and select **Open**.
5. When the model opens in Simulink, click the **Build** button to generate code for the model. Or, use the `generate_controller_code` shortcut in the project to generate code.

```
evalc('rtwbuild(''MBDController'')');
```

6. Observe that the contents of the work folder do not appear in the Dependency Analysis view. This setup simplifies the view to indicate the dependencies in model files and .m script file.

```

bdclose all;
run('clean_up_project');
close(simulinkproject);
clear all;

```

## Generate Code Using Embedded Coder®

This example shows how to select a system target file for a Simulink® model, configure model parameters, generate C code for embedded systems, and view generated files.

The model represents an 8-bit counter that feeds a triggered subsystem that is parameterized by constant blocks INC, LIMIT, and RESET. Input and Output represent I/O for the model. The Amplifier subsystem amplifies the input signal by gain factor K, which updates when signal equal\_to\_count is true.

1. Open the model.

```
model='rtwdemo_rtwecintro';
open_system(model)
```

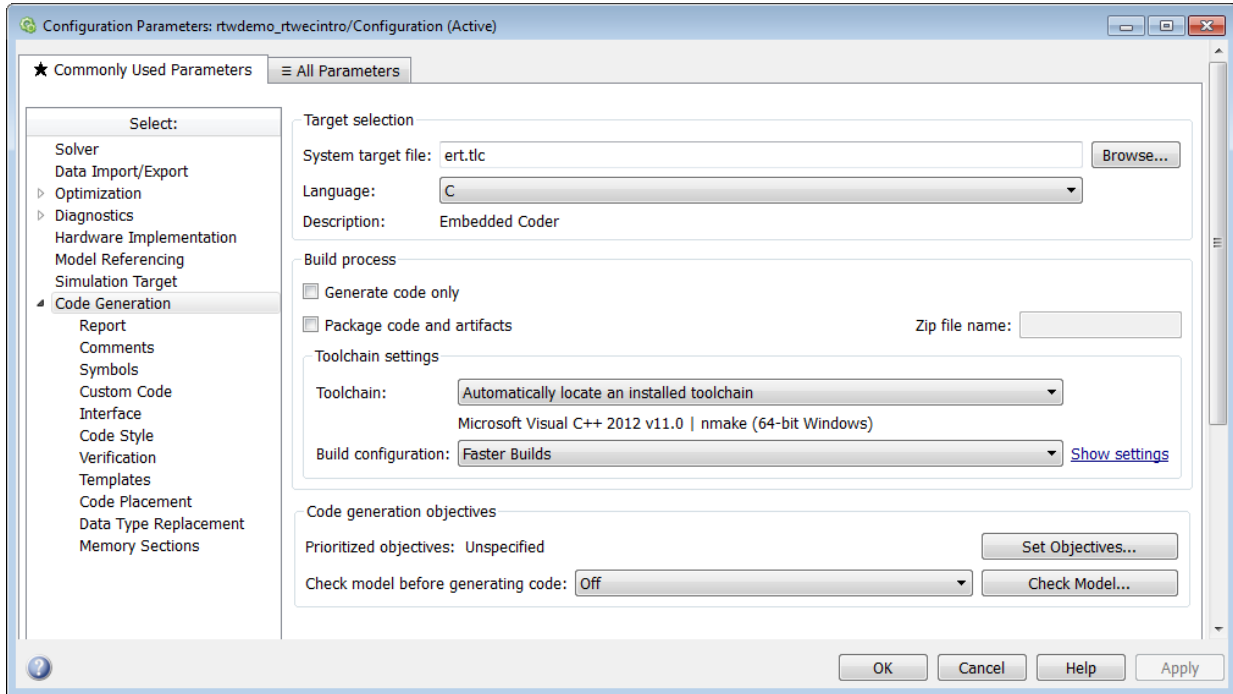

Copyright 1994-2019 The MathWorks, Inc.

2. Open the Model Configuration Parameters dialog box.

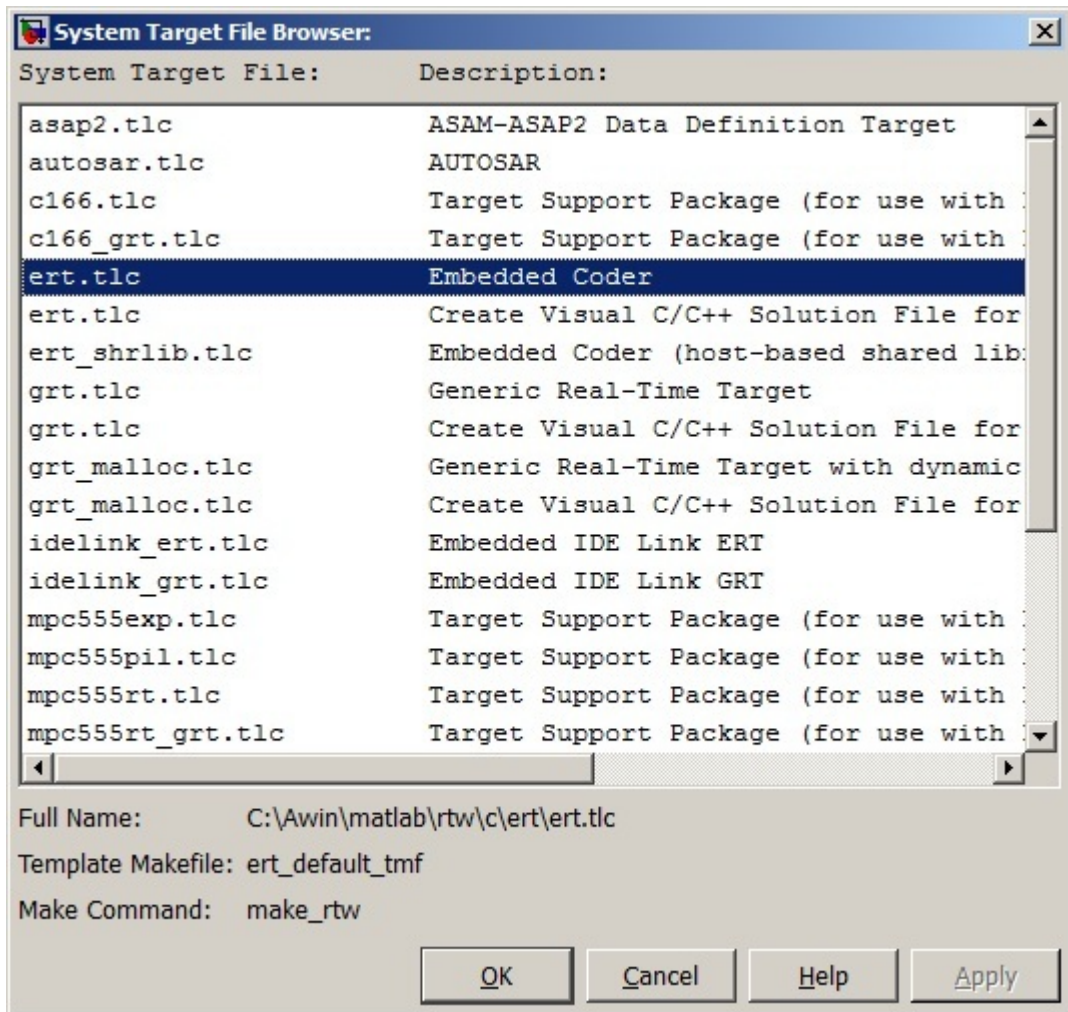

```
cs = getActiveConfigSet(model);
openDialog(cs);
```

### 3. Select the **Code Generation** tab.

4. To select a system target file, in the **Target Selection** pane, click **Browse**. You can generate code for a specific target environment or purpose. Some built-in targeting options are provided by system target files, which control the code generation process for a target environment.

5. Select the **Embedded Real-Time (ERT)** system target file and click **Apply**.

The ERT system target file supports a utility that you can use to specify and prioritize code generation settings based on your application objectives.

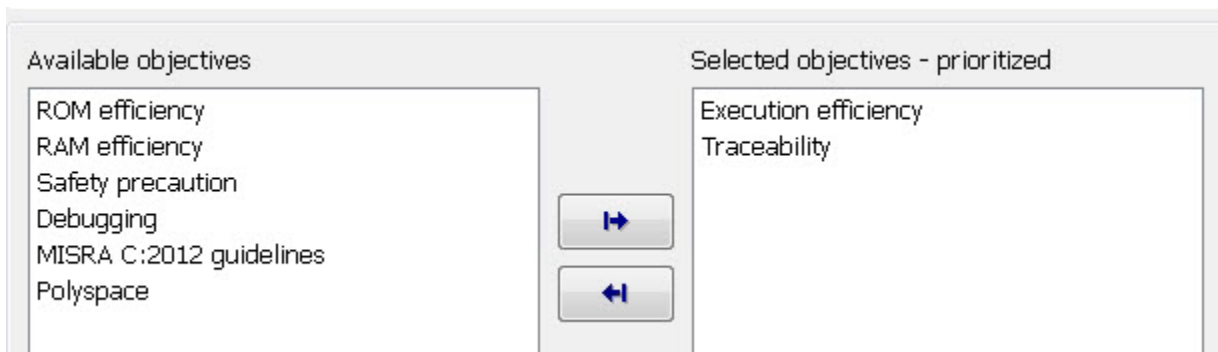

6. In the **Code Generation Advisor** pane, click **Set Objectives**.

You can set and prioritize objectives for the generated code. For example, while code traceability might be a very important criterion for your application, you might not want to prioritize it at the cost of code execution efficiency.

7. In the **Set Objectives** pane, select **Execution efficiency** and **Traceability**. Click **OK**.

You can select and prioritize a combination of objectives before generating code.

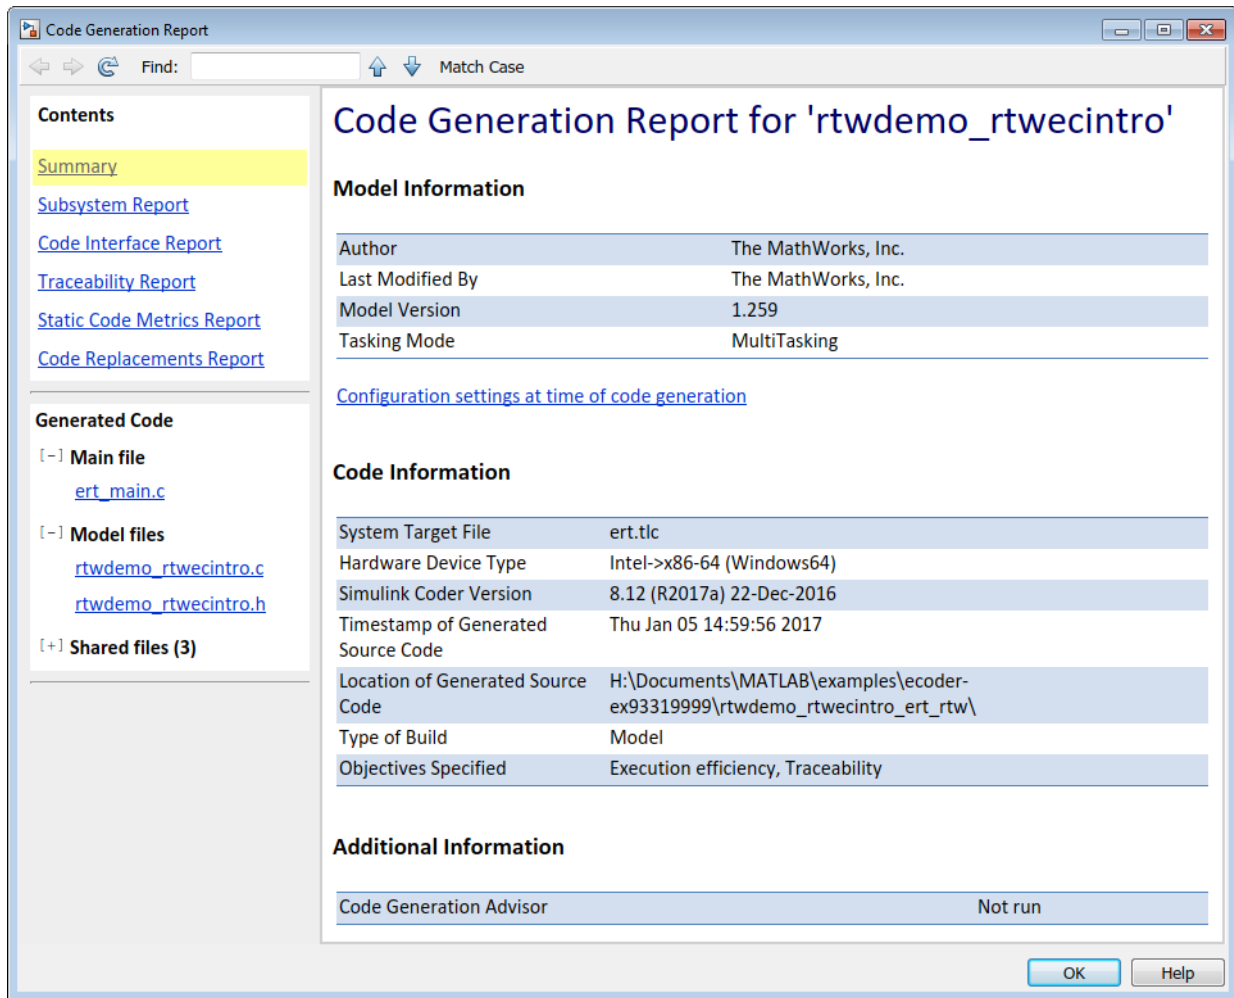

8. In the model window, initiate code generation and the build process for the model by using one of these options:

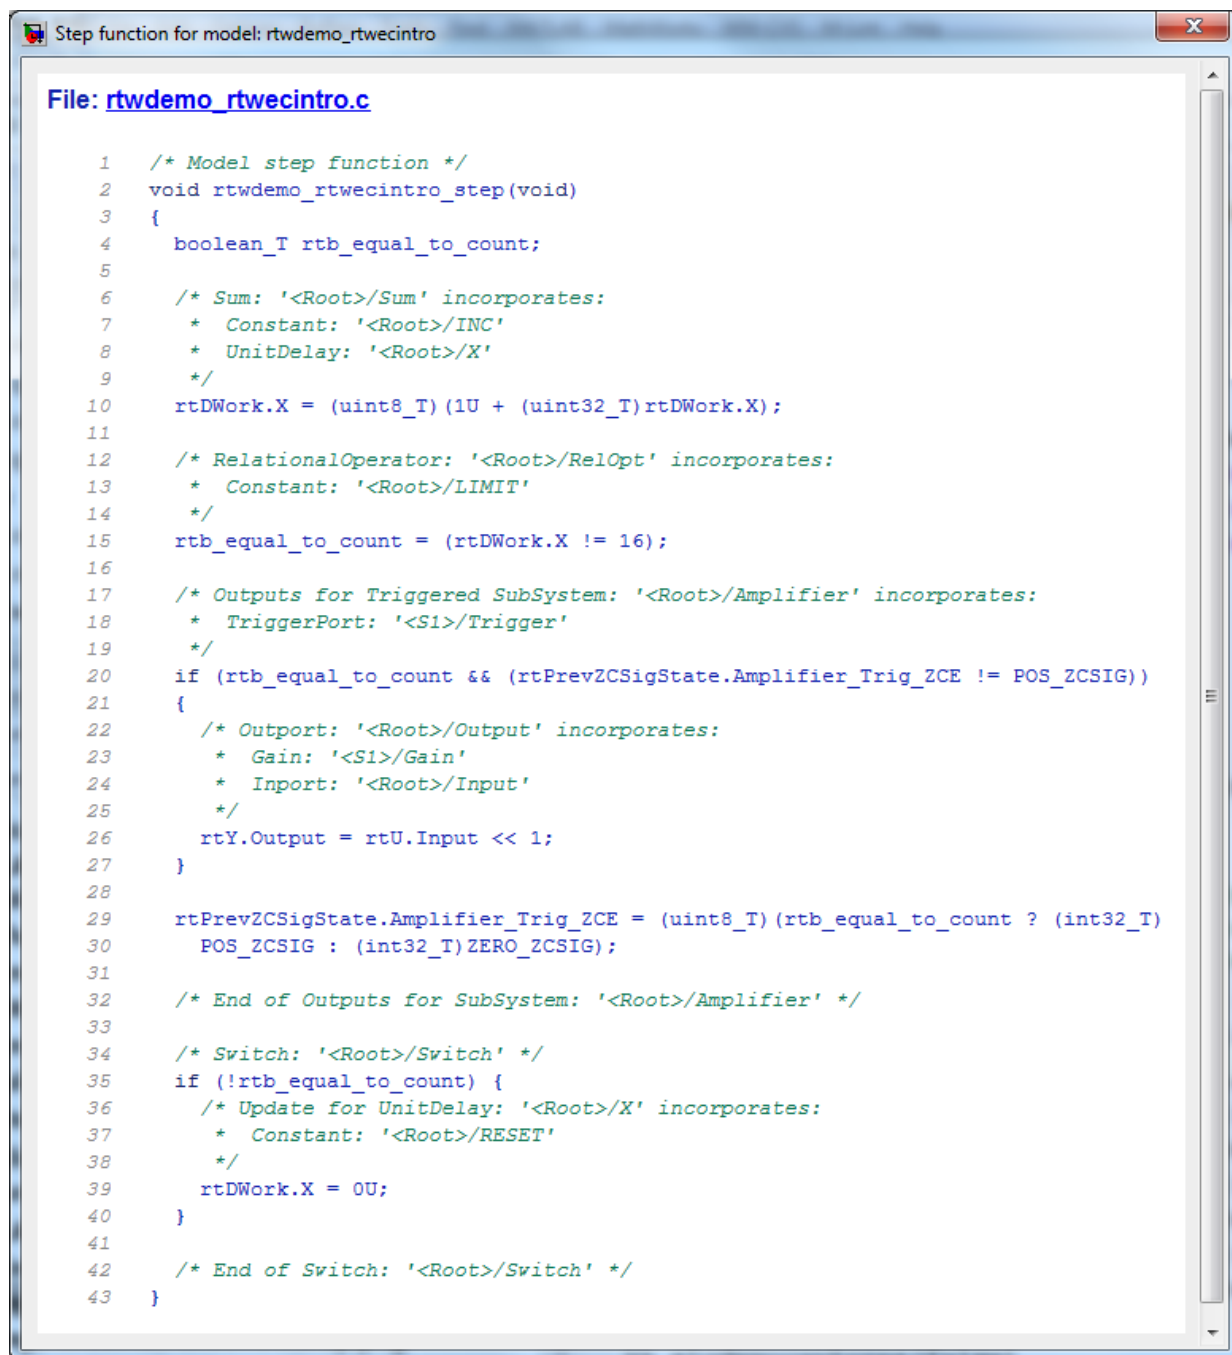

- Click the Build Model button.
- Press **Ctrl+B**.
- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

9. View the code generation report.

The report includes `rtwdemo_rtwecintro.c`, associated utility and header files, and traceability and validation reports.

This figure contains a portion of `rtwdemo_rtwecintro.c`

```
1  /* Model step function */
2  void rtwdemo_rtwecintro_step(void)
3  {
4      boolean_T rtb_equal_to_count;
5
6      /* Sum: '<Root>/Sum' incorporates:
7       * Constant: '<Root>/INC'
8       * UnitDelay: '<Root>/X'
9       */
10     rtDWork.X = (uint8_T)(1U + (uint32_T)rtDWork.X);
11
12     /* RelationalOperator: '<Root>/RelOpt' incorporates:
13      * Constant: '<Root>/LIMIT'
14      */
15     rtb_equal_to_count = (rtDWork.X != 16);
16
17     /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
18      * TriggerPort: '<S1>/Trigger'
19      */
20     if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
21     {
22         /* Output: '<Root>/Output' incorporates:
23          * Gain: '<S1>/Gain'
24          * Inport: '<Root>/Input'
25          */
26         rtY.Output = rtU.Input << 1;
27     }
28
29     rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
30         POS_ZCSIG : (int32_T)ZERO_ZCSIG);
31
32     /* End of Outputs for SubSystem: '<Root>/Amplifier' */
33
34     /* Switch: '<Root>/Switch' */
35     if (!rtb_equal_to_count) {
36         /* Update for UnitDelay: '<Root>/X' incorporates:
37          * Constant: '<Root>/RESET'
38          */
39         rtDWork.X = 0U;
40     }
41
42     /* End of Switch: '<Root>/Switch' */
43 }
```

**10.** Close the model.

```
bdclose(model)  
rtwdemoclean;
```

## Generate Code by Using the Quick Start Tool

The Quick Start tool helps you prepare a model for generating readable, efficient code. To start the tool, open the Embedded Coder app. On the **C Code** tab, click **Quick Start**.

After you start the tool, you must answer these questions about the code that you want to generate:

- What is the model or subsystem for code generation?
- What is the type of code output for your generated code?
- Does your application require reentrant, multi-instance code?
- What is the target hardware processor type?
- What is your primary code generation objective?

The tool validates your choices against the model and presents the parameter changes required to generate code. If you choose to generate code, the tool applies the parameter changes to your configuration set and generates the code. After code generation, you can view the code generation report and find information on building, customizing, optimizing, and packaging the code. To further customize your generated code, click **Finish**, and then use the Embedded Coder app with the Code perspective environment. The Code perspective provides the tools to control the names and representation of the model data and functions in the generated code. For more information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 32-2.

### Quick Start Model Analysis

At each step of the quick start process, the tool validates your model against your selections. The tool checks for model conditions that prevent you from proceeding with code generation. During the analysis step, the tool must also examine your model or subsystem for answers to the following questions. The answers help determine the best configuration for the deployment of your code.

#### **How many sample rates are in your system?**

The Quick Start tool evaluates your model to determine the number of periodic sample rates in your system.

<b>Single rate</b>	Your model has only one periodic sample rate. The generated code has a single-entry point function that runs at the time interval of the sample rate.
<b>Multirate</b>	Your model has more than one periodic sample rate. It is possible that the generated code does not execute at the same time intervals. After the analysis step, you can choose to generate a single-entry point function for each of the sample rates or generate a different entry point function for each sample rate.  If you choose to generate multitasking code, the code generator produces multiple entry-point functions. These functions run as multiple tasks. Each entry-point function is called at an interval defined by the sample rate that is configured in the model.

If your model contains an asynchronous rate, an additional entry-point function is generated to run at the specific interrupt time.

For more information about sample rates, see “Time-Based Scheduling and Code Generation” (Simulink Coder).

**Does your system contain continuous states?**

The Quick Start tool evaluates your model for continuous blocks to determine the correct solver to use.

<b>No</b>	If your system does not contain continuous states, the Quick Start tool configures your model to use a fixed-step discrete solver for code generation if you have not selected one.
<b>Yes</b>	If your system does contain continuous states, the Quick Start tool configures your model to use a fixed-step continuous solver for code generation if you have not selected one. The tool also selects the <code>SupportContinuous</code> configuration parameter.

For more information on solvers, see “Solver Selection Criteria” (Simulink).

**Did you configure your system for export function calls?**

The Quick Start tool evaluates your model to see if scheduler code must be generated.

<b>No</b>	If you did not configure your system for export function calls, the generated code includes code for the system algorithm and the scheduler code.
-----------	---------------------------------------------------------------------------------------------------------------------------------------------------

<b>Yes</b>	If you configured your system for export function calls, the generated code includes code for the system algorithm. You can manually write the scheduler code or generate it from other models.
------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

For more information, see “Export-Function Models Overview” (Simulink).

### **Does your system contain referenced models?**

The Quick Start tool evaluates your model to see if it depends on code from other models.

<b>No</b>	If your system does not contain referenced models, the generated code does not depend on code from other models.
<b>Yes</b>	If your system contains referenced models, the generated code for your model depends on other modules generated from referenced models. The code generator can optimize the generated code because it is aware of the relationship between your model and the referenced models. When the Quick Start tool applies configuration parameter changes to your model, it also applies the changes to the referenced models.

For more information, see “Code Generation of Referenced Models” (Simulink Coder).

## **Configuration Parameter Changes for Models That Have a Configuration Reference**

To apply configuration parameter changes to a model that has an active configuration reference, the Quick Start tool:

- Creates a `Simulink.ConfigSet` object `QuickStart_timestamp` in the workspace or data dictionary that contains the original configuration set. The new object is a copy of the original configuration set that has the parameter changes applied.
- Creates a `Simulink.ConfigSetRef` object that points to the new configuration set object.
- Attaches the new configuration reference to the model and makes it the active configuration.
- If your system contains referenced models that share your original configuration set, the tool attaches the new configuration reference to the referenced models and makes the new configuration reference the active configuration.

To restore the original configuration set, activate the original `Simulink.ConfigSetRef` object.

---

**Note** If the Quick Start tool creates the configuration set object in the MATLAB workspace, you must save the object to preserve the configuration set after the MATLAB session ends. For more information, see “Save a Configuration Set” (Simulink).

---

## Next Steps

After you generate code by using Quick Start tool, possible next steps are:

- “Open Code Generation Report” on page 49-9
- “Preserve Variables in Generated Code” on page 33-3
- “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 44-2
- “Code Appearance”
- “Build Process”
- “Manage a Configuration Set” (Simulink)
- “Build and Run a Program” on page 54-36
- “Relocate Code to Another Development Environment” (Simulink Coder)

To control the names and representation of the model data and functions in the generated code, use the Code Mappings editor and the Model Data Editor in the Embedded Coder app. For more information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 32-2.

## Manage File Packaging of Generated Code Modules

The code generator produces code modules. The file packaging configuration controls where the code generator places code into code modules and header files.

To locate and examine the generated code files, use the **Code** view or the HTML code generation report. The code generation report provides hyperlinks in the comments that you can click to view the generated code in the MATLAB Help browser. For more information, see “Traceability in Generated Code” on page 75-3.

### In this section...

“Generated Code Modules” on page 48-13

“User-Written Code Modules” on page 48-17

“Customize Generated Code Modules” on page 48-17

## Generated Code Modules

The code generator creates a build folder in your working folder to store generated source code. The build folder contains object files, a makefile, and other files created during the code generation process. The default name of the build folder is *model\_ert\_rtw*.

Code Modules and Header Files Affected by File Packaging summarizes the structure of source code that the code generator produces.

You can customize the generated set of files in several ways:

- File packaging formats: Manage the number of source files generated for your model. Select model configuration parameter **File packaging format**. For more information, see “Customize Generated Code Modules” on page 48-17.
- Nonvirtual subsystem code generation: Instruct the code generator to produce separate functions within separate code files for nonvirtual subsystems. You can control the names of the functions and of the code files. For more information, see “Control Generation of Functions for Subsystems” (Simulink Coder).
- Storage classes: Define and use storage classes that partition generated data structures into different files based on file names that you specify. For more information, see “Apply Built-In and Customized Storage Classes to Data Elements” on page 37-19.

- Module packaging: Direct the generated code into a required set of .c or .cpp and .h files, and control the internal organization of the generated files. For details, see “Data, Function, and File Configuration”.

## Code Modules and Header Files Affected by File Packaging

File	Description
<i>model.c</i> or <i>.cpp</i>	Contains entry points for code implementing the model algorithm (for example, <i>model_step</i> , <i>model_initialize</i> , and <i>model_terminate</i> ).
<i>model_private.h</i>	Contains local macros and local data that the model and subsystems require. This file is included in the <i>model.c</i> file as a <code>#include</code> statement. You do not need to include <i>model_private.h</i> when interfacing handwritten code to the generated code of a model.
<i>model.h</i>	<p>Declares model data structures and a public interface to the model entry-points and data structures. Provides an interface to the real-time model data structure (<i>model_M</i>) with accessor macros.</p> <p>The code generator:</p> <ul style="list-style-type: none"> <li>• Produces a separate header file for each Simulink Function block in a model.</li> <li>• Includes <i>model.h</i> in the subsystem <i>.c</i> or <i>.cpp</i> files of a model.</li> </ul> <p>If you interface handwritten code to generated code for one or more models, include <i>model.h</i> for each of those models.</p>
<i>model_data.c</i> or <i>.cpp</i>	Contains (if conditionally generated) the declarations for the parameters data structure, the constant block I/O data structure, and any zero representations for the model structure data types. If the model does not use these data structures and zero representations, <i>model_data.c</i> or <i>.cpp</i> is not generated. These structures and zero representations are declared <code>extern</code> in <i>model.h</i> .
<i>model_types.h</i>	Provides forward declarations for the real-time model data structure and the parameters data structure. Function declarations of reusable functions can require these declarations. Provides type definitions for user-defined types that the model uses.
<i>rtwtypes.h</i>	Defines data types, structures, and macros required by generated code. For more information, see “Control Placement of <i>rtwtypes.h</i> for Shared Utility Code” (Simulink Coder).

File	Description
multiword_types.h	<p>Contains type definitions for wide data types and their chunks. File is generated when multiword data types are used or when you select one or more of these model configuration parameters:</p> <ul style="list-style-type: none"> <li>• <b>MAT-file logging</b></li> <li>• <b>External mode</b></li> </ul>
model_reference_types.h	<p>Contains type definitions for timing bridges. File is generated for a referenced model or a model containing Model blocks.</p>
builtin_typeid_types.h	<p>Defines an enumerated type corresponding to built-in data types. File is generated when your model contains a Stateflow chart that uses messages or when you select one or more of these configuration parameters:</p> <ul style="list-style-type: none"> <li>• <b>MAT-file logging</b></li> <li>• C API model configuratoin parameter</li> </ul>
zero_crossing_types.h	<p>Contains zero-crossing definitions for models with triggered subsystems where the trigger is <i>rising</i>, <i>falling</i>, or <i>either</i>. File is generated only if required by the model.</p>
ert_main.c or .cpp	<p>(optional file) If you select model configuration parameter <b>Generate an example main program</b>, this file is generated. For more information, see “Generate an example main program”.</p>
rtmodel.h	<p>(optional file) If you clear model configuration parameter <b>Generate an example main program</b>, this file is generated. For more information, see “Generate an example main program”.</p> <p>Contains <code>#include</code> directives required by the <code>rt_main.c</code> or <code>rt_cppclass_main.cpp</code> static main program module. Includes <code>rtmodel.h</code> to access model-specific data structures and entry points, because the static main program module is not created at code generation time.</p> <p>For more information, see “Static Main Program Module” on page 63-10.</p>

File	Description
<i>model_capi.c</i> or <i>.cpp</i> <i>model_capi.h</i>	(optional file) Provides data structures that enable a running program to access model signals, states, and parameters without external mode. To learn how to generate and use the <i>model_capi.c</i> or <i>.cpp</i> and <i>.h</i> files, see “Exchange Data Between Generated and External Code Using C API” (Simulink Coder).

## User-Written Code Modules

Code that you write to interface with generated model code usually includes a customized main module. Base this module on a main program produced by the code generator. This customized main module can also include interrupt handlers, device driver blocks and other S-functions, and other supervisory or supporting code. Steps to set up the development environment to support a customized main module include:

- 1 Establish a working folder for your own code modules.
- 2 Put your working folder on the MATLAB path.
- 3 At minimum, inform the build process about the location of your source and object files with model configuration parameter **Additional build information**.
- 4 Your development process could require generating code for a particular microprocessor or development board and deploying the code on target hardware with a cross-development system. To accomplish these goals, make more extensive modifications to the ERT-based system target file.

For information on how to customize your ERT-based system target file for your production requirements, see “Target Development” (Simulink Coder).

## Customize Generated Code Modules

Model configuration parameter **File packaging format** specifies how the code generator packages generated source code into files. You can set the parameter to **Modular**, **Compact (with separate data file)**, and **Compact**. This table describes the generated files and the removed files for each file packaging format.

### Generated Files According to File Packaging Format

File Packaging Format	Generated Files	Removed Files
Modular (default)	<i>model.c</i> subsystem files (optional) <i>model.h</i> <i>model_types.h</i> <i>model_private.h</i> <i>model_data.c</i> (conditional)	None
Compact (with separate data file)	<i>model.c</i> <i>model.h</i> <i>model_data.c</i> (conditional)	<i>model_private.h</i> <i>model_types.h</i> (conditional, see Removed Files According to File Packaging Format)
Compact	<i>model.c</i> <i>model.h</i>	<i>model_data.c</i> <i>model_private.h</i> <i>model_types.h</i> (conditional, see Removed Files According to File Packaging Format)

This table describes content placement from the removed files.

### Removed Files According to File Packaging Format

Removed File	Generated Content In File
<i>model_private.h</i>	<i>model.c</i> and <i>model.h</i>
<i>model_types.h</i>	<i>model.h</i>
<i>model_data.c</i>	<i>model.c</i>

You can specify a different file packaging format for each referenced model.

Model configuration parameter **Shared code placement** interacts with file packaging operations. If you set **Shared code placement** to `Shared location`, the code generator produces separate files for utility code in a shared location, regardless of the file packaging format. If you set **Shared code placement** to `Auto`, the code generator generates code for utilities according to the file packaging format selection.

- **Modular**: Some shared utility files are in the build folder.
- **Compact (with separate data file)**: Utility code is generated in `model.c`.
- **Compact**: Utility code is generated in `model.c`.

File packaging formats `Compact` and `Compact (with separate data file)` generate `model_types.h` for models containing:

- A Variant Subsystem block. The `model_types.h` file includes preprocessor directives defining the variant objects associated with a variant block.
- Storage classes generating a separate header file.

File packaging formats `Compact` and `Compact (with separate data file)` are not compatible with:

- A model containing a subsystem, which is configured to generate separate source files
- A model containing a noninlined S-function
- A model for which **Shared code placement** is set to `Auto`, which uses data objects for which **Data scope** is set to `Exported`

## Generate C Code from a Control Algorithm for an Embedded System

Generate code for a control algorithm model, integrate the generated code with an existing system, and validate simulation and executable results.

### About the Examples

A series of examples are based on a shared model. Each example has a unique version of that model and corresponding data set so that you can use the examples independently. You do not have to run the examples in a specific order. When you transition between examples, you save the current model so that each example captures your modifications to the model and model data.

To recover a model in its original state, delete your local copy of the model and model data. The model data is saved as `PCG_Demo_#_data.mat`.

Use these hyperlinks to navigate to the examples in the series.

- “Configure Data Interface in the Generated Code” on page 48-35
- “Partition Functions in Generated Code” on page 48-48
- “Call External C Code from Model and Generated Code” on page 48-60
- “Build Integrated Code Outside the Simulink Environment” on page 48-66
- “Test Generated Code” on page 48-73
- “Evaluate Performance of the Generated Code” on page 48-83
- “Install and Use Cygwin and Eclipse” on page 48-87

### Third-Party Software

Some of the examples use the Eclipse™ IDE and the Cygwin™/gcc compiler. Instructions to install and use Eclipse™ and Cygwin™/gcc are available in “Install and Use Cygwin and Eclipse” on page 48-87.

### Understand the Model

This example shows and describes the model from behavioral and structural perspectives. The example also shows how to configure a model for code generation and how to generate code. You learn how to:

- Understand the functional behavior of the example model.
- Understand how to validate the model.
- Become familiar with model-checking tools.
- Become familiar with configuration options that affect code generation.
- Generate code from a model.

### **Understand the Functional Design of the Model**

This example uses a simple model of a throttle controller. The model features redundancy, which safety-critical, drive-by-wire applications commonly use. The model highlights a standard model structure and a set of basic blocks in algorithm design.

In the current configuration, the code that the model generates is not configured for a production target system. In this example, you change the target configuration and observe the resulting changes to the format of the generated code.

### **Inspect the Top-Level Model**

Open the example model.

The top-level model consists of:

- Four subsystems: PI\_ctrl\_1, PI\_ctrl\_2, Define\_Throt\_Param, and Pos\_Command\_Arbitration.
- Top-level inputs: pos\_rqst, fbk\_1, and fbk\_2.
- Top-level outputs: pos\_cmd\_one, pos\_cmd\_two, and ThrotComm.
- Signal routing.
- No transformative blocks. Transformative blocks change the value of a signal, for example, Sum and Integrator blocks.

The layout shows a basic model architectural style.

- Separation of calculations from signal routing (lines and buses)
- Partitioning into subsystems

This style suits many types of models.

## Inspect Subsystems

Two subsystems represent PI controllers: `PI_ctrl_1` and `PI_ctrl_2`. The subsystems have identical content and, for now, use identical data. Later, you use the subsystems to learn how the code generator can create reusable functions.

The PI controllers come from a *library*, which is a group of related blocks or models that you intend to reuse. Libraries provide one of two methods for including and reusing models. You see the second method, model referencing, later in this series.

When you use a library block in a model, you cannot edit the instance of the block in the model. Instead, edit the block definition in the library. Then, instances of the block in different models remain consistent.

Open the subsystem `PI_ctrl_1`.

The Stateflow® chart `Pos_Command_Arbitration` performs basic error checking on the two command signals. If the command signals are too far apart, the chart sets the output to a `fail_safe` position.

Open `Pos_Command_Arbitration`.

## Inspect Model Configuration Parameter Settings for Code Generation

To prepare a model for code generation, open the **Embedded Coder** app. Then, set code generation model configuration parameters. The parameters determine the method that the code generator uses to generate the code and the resulting code format.

### Code Generation Objectives

You can manually configure the model configuration parameters. Alternatively, you can choose from predefined objectives to automatically configure the model configuration parameters.

You can choose from these high-level code generation objectives:

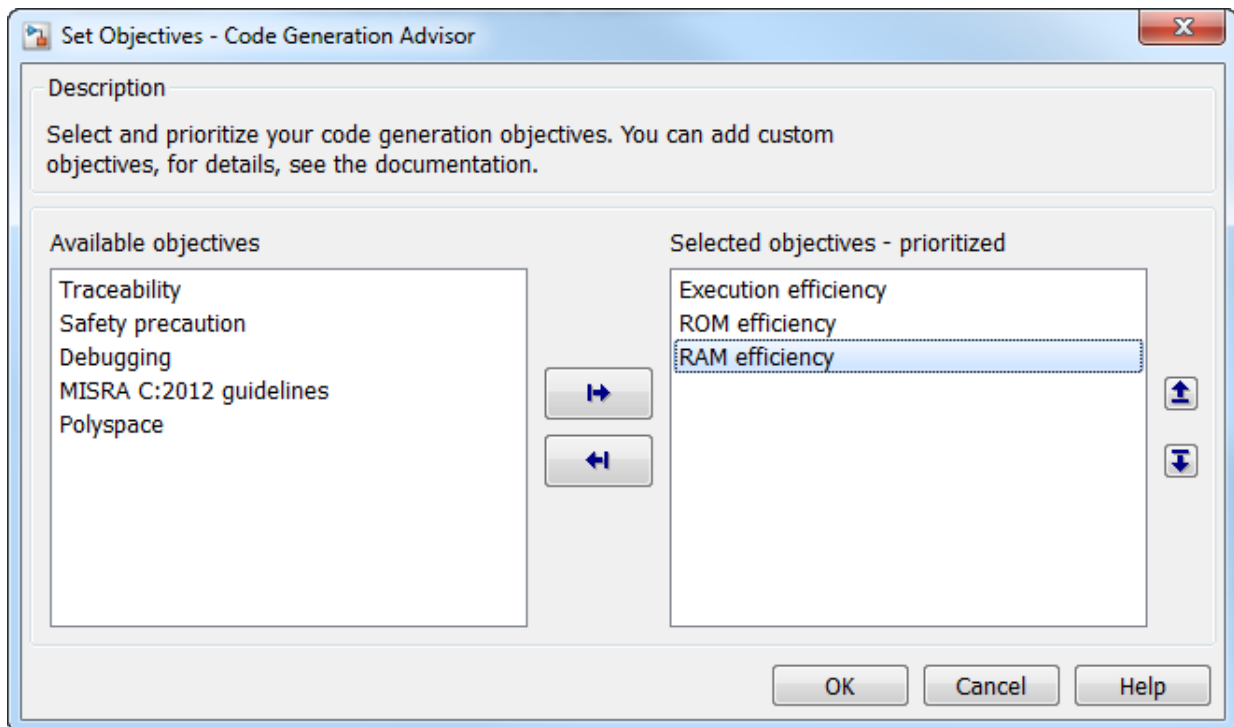

- Execution efficiency
- ROM efficiency
- RAM efficiency
- Traceability
- Safety precaution

- Debugging

Each objective checks the current model configuration parameters against the recommended values of the objectives. Each objective also includes a set of Code Generation Advisor checks. You can use these additional checks to verify that the model configuration parameters are set to create code that meets the objectives.

Some of the recommendations that the objectives make conflict with the Code Generation Advisor checks. The order in which you select objectives determines the result. Simulink® resolves conflicts by satisfying objectives that have a higher priority.

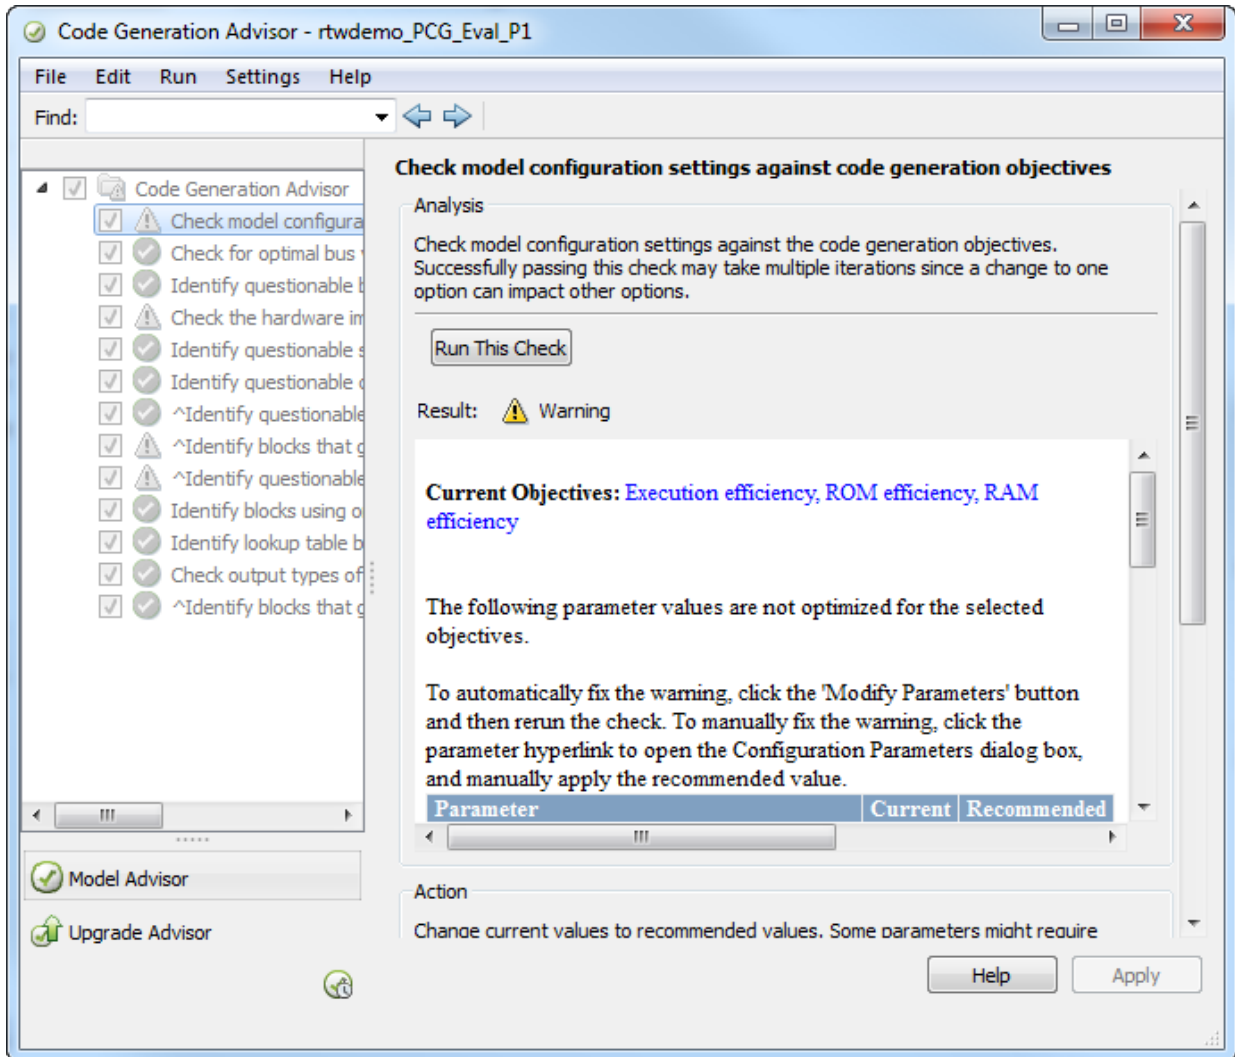

The figure shows how to set the priority to Execution efficiency > ROM efficiency > RAM efficiency. To open the dialog box, in the Configuration Parameters dialog box, select the **Code Generation** pane. Then, click **Set objectives**.

You can run the Code Generation Advisor to check the model based on the specified objectives. To open the Code Generation Advisor, in the **C Code** tab, click **C/C++ Code Advisor**.

The Code Generation Advisor creates a list of checks based on the objectives that you select. The first check reviews current values of the model configuration parameters and suggests alternative values based on the objectives. The check provides an automated method for setting the parameters to recommended values.

### Manual Configuration Options

In the Model Configuration Parameters dialog box, these panes are relevant to code generation:

- Solver

- Hardware Implementation
- Code Generation

### **Solver**

Open the **Solver** pane.

- To generate code for a model, you must set model configuration parameter **Type** to **Fixed-step**.
- Parameter **Fixed-step size** sets the base rate of the system. Set the parameter to the lowest common multiple of rates in the system.
- Parameter **Solver** controls the integration algorithms that the code generator uses.
- To generate an entry-point function for each rate in the system, select parameter **Treat each discrete rate as a separate task**.

### **Hardware Implementation**

Open the **Hardware Implementation** pane.

Use hardware implementation parameters to specify a hardware board. Simulink® adjusts other settings on the pane, including hidden microprocessor device details, based on your board selection. To view or adjust the hidden parameter settings, such as the word size and byte ordering, click **Device details**.

### **Code Generation**

Open the **Code Generation** pane.

Use the **Code Generation** pane to specify the system target file and optimizations. This example uses the Embedded Coder® system target file (`ert.tlc`). You can extend that system target file to create a customized configuration. Some of the basic parameters on the **Code Generation** pane and its subpanes include:

#### **System target file**

- `ert.tlc` - "Base" Embedded Coder®
- `grt.tlc` - "Base" Generic Real-Time Target
- Hardware-specific targets

#### **Make file**

### Code optimizations

- Remove unused branches from the code and control the creation of temporary variables.
- Control which signals have explicit initialization code.
- Enable and disable use of overflow and division-by-zero protection code.

### Code formatting options

- Use of parentheses
- Header file information
- Variable naming conventions

### Inclusion of custom code

- C files
- H files
- Object files
- Folder paths

### Generation of ASAP2 files

#### Save Model Configuration Parameters

You can save the values of model configuration parameters as a MATLAB® function. At the command prompt, enter:

```
hCs = getActiveConfigSet('rtwdemo_PCG_Eval_P1');  
hCs.saveAs('ConfiguredData');
```

The MATLAB® function saves a textual representation of the configuration parameter object. You can use the generated file for archiving or comparing different versions of the files by using traditional diff tools. You can also visually inspect the content of the file.

You can run the function to set the configuration parameters of other models.

```
hCs2 = ConfiguredData;  
attachConfigSet('myModel', hCs2, true);  
setActiveConfigSet('myModel', hCs2.Name);
```

## Understand the Simulation Testing Environment

You test the throttle controller model in a separate model called a *test harness*. A test harness is a model that evaluates the control algorithm. Using a test harness:

- Separates the test data from the control algorithm
- Separates the plant or feedback model from the control algorithm
- Provides a reusable environment for multiple versions of the control algorithm

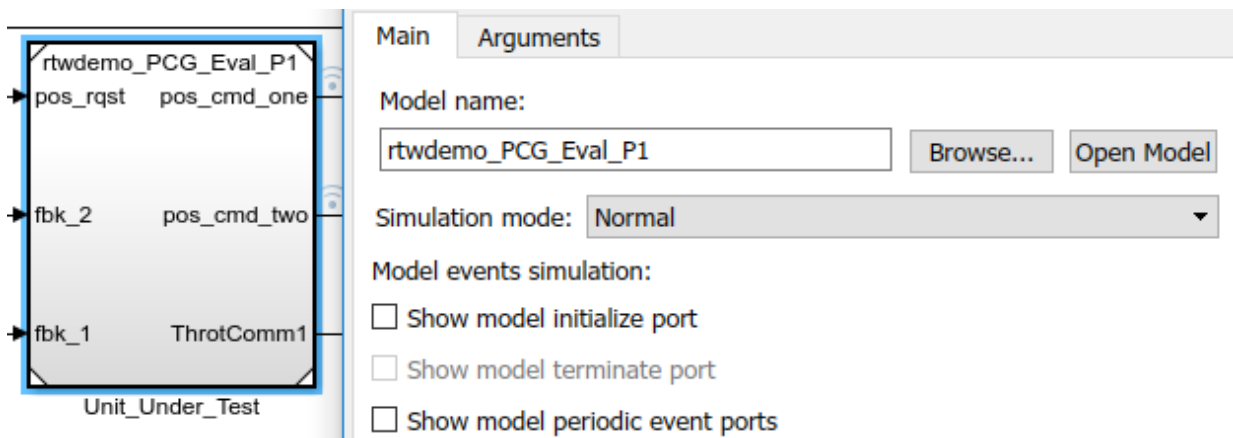

Open the test harness.

A typical simulation testing environment consists of these parts:

- Unit under test
- Test vector source
- Evaluation and logging
- Plant or feedback system
- Input and output scaling

Highlight the unit under test.

The control algorithm is the *unit under test*. The test harness model references the control algorithm through a Model block. With Model blocks, you can reuse components. The Model block refers to the control algorithm by name (`rtwdemo_PCG_Eval_P1`).

The Model block enables inclusion (referencing) of a model in another model as a *compiled function*. By default, Simulink® compiles the referenced model when you change it. Compiled functions have these advantages over libraries:

- Large models simulate faster.
- You can simulate compiled functions directly.
- The simulation requires less memory. When you add multiple instances of the model (multiple Model blocks), only one copy of the compiled model exists in memory.

Highlight the test vector source.

The model uses a Signal Builder block as the test vector source. The block has data that drives the simulation (*pos\_rqst*) and the expected results that the Verification subsystem uses. This example uses only one set of test data, though in a typical application you create a test suite that fully exercises the system.

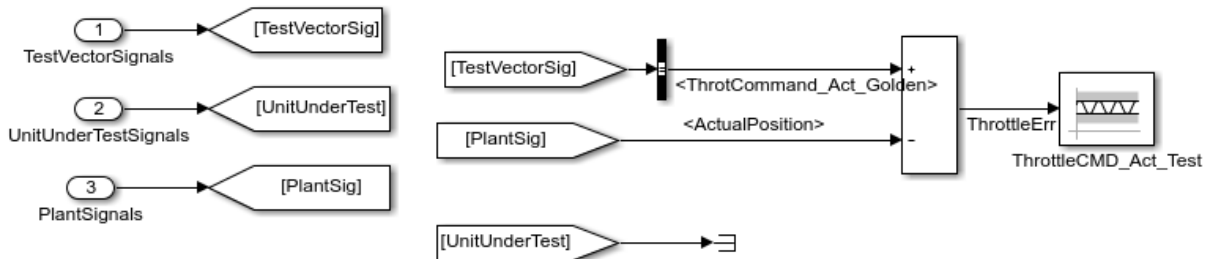

Highlight Verification.

The test harness compares the simulation results against *golden data*, which is a set of test results that indicate the desired behavior for the model. In this model, the V&V Assertion block compares the simulated throttle value position from the plant against the golden value that the test harness provides. If the difference between the two signals is greater than 5%, the test fails and the Assertion block stops the simulation.

Alternatively, you can evaluate the simulation data after the simulation completes execution. You can use either MATLAB® scripts or third-party tools to perform the evaluation. Post-execution evaluation provides greater flexibility in the analysis of the

data, though you must wait until execution finishes. Combining the two methods can yield a highly flexible and efficient test environment.

```
load_system('rtwdemo_PCGEvalHarness')
open_system('rtwdemo_PCGEvalHarness/Verification')
```

Highlight the plant/feedback system.

This example models the throttle dynamics by breaking a transfer function down into a canonical form. You can create plant models to model a specific level of fidelity. Many applications use a different plant model at each stage of testing.

Highlight scaled input and output.

The subsystems that scale input and output perform these primary functions:

- Select signals to route to the unit under test and to the plant.
- Rescale signals between engineering units and units that the unit under test requires.
- Handle rate transitions between the plant and the unit under test.

### Run Simulation Tests

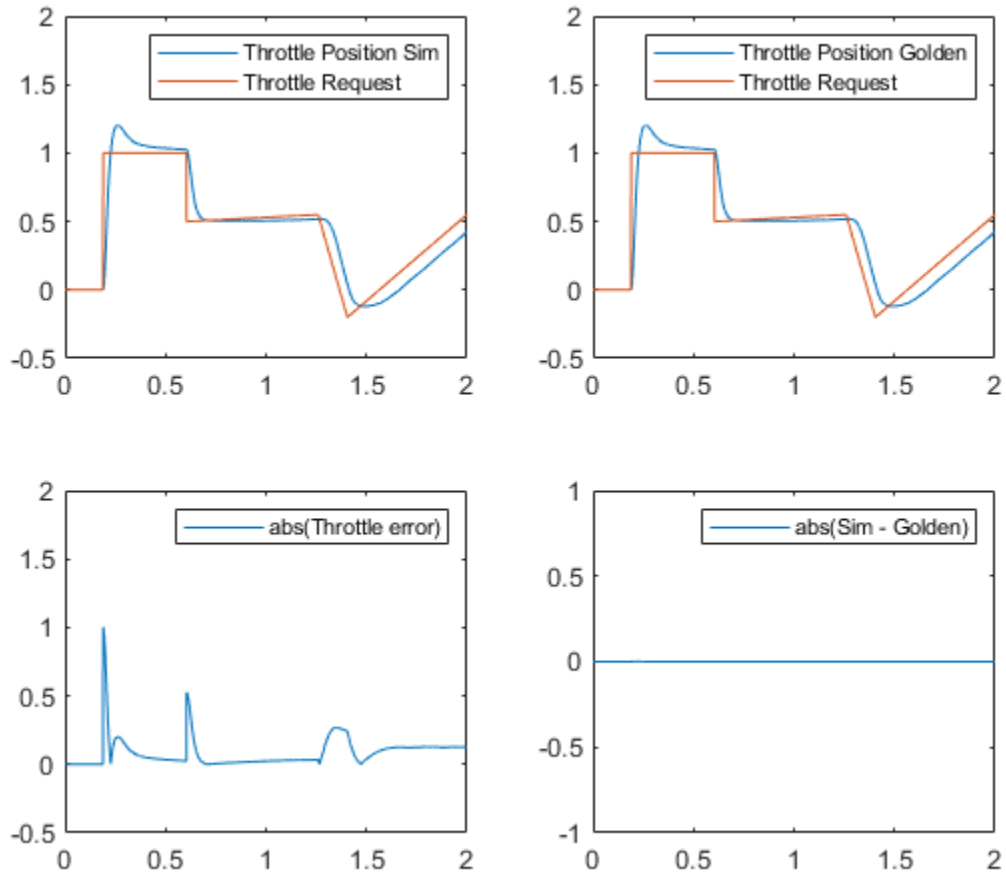

To run the test harness model simulation, click **Start** or click this hyperlink.

Run the test harness.

The first time the test harness runs, Simulink® must compile the referenced model. You can monitor the compilation progress in the Command Window.

When the model simulation is complete, Simulink® displays the results in a plot figure.

```
sim('rtwdemo_PCGEvalHarness')
```

The lower-right plot shows the difference between the expected (golden) throttle position and the throttle position that the plant calculated.

### Generate Code

To generate code, open the **Embedded Coder** app. Then, using one of these techniques:

- In the model, press **Ctrl+B**.

- In the **C Code** tab, select **Build** or **Generate Code**.
- Click this hyperlink:

Generate code for the model.

The code generator produces several files. The resulting code, though computationally efficient, is not yet organized for integration into the production environment.

### Examine the Generated Code

The code generator creates multiple files that you can view from the **Code** view or code generation report. In addition to the standard C definition and header files, the code generator creates a set of HTML files. The HTML files provide hyperlinks between the code and the model.

In the Model Explorer, open the HTML Code Browser.

In the generated code, observe that:

- The controller code exists in one function called *modelName\_step*, which is in the file *rtwdemo\_PCG\_Eval\_P1.c*.
- The code generator folds the operations of multiple blocks into one statement of code.
- The function *modelName\_initialize* initializes variables.
- Data structures define model data (for example, *rtwdemo\_PCG\_Eval\_P1\_U.pos\_rqst*).

```

/* Model step function */
void rtwdemo_PCG_Eval_P1_step(void)
{
    real_T rtb_Sum3;
    real_T rtb_IntegralGainShape;
    real_T Discrete_Time_Integrator1;
    real_T Discrete_Time_Integrator1_i;

    /* Sum: '<S2>/Sum2' incorporates:
     * Inport: '<Root>/fbk_1'
     * Inport: '<Root>/pos_rqst'
     */
    rtb_IntegralGainShape = rtwdemo_PCG_Eval_P1_U.pos_rqst -
        rtwdemo_PCG_Eval_P1_U.fbk_1;
}

```

- rtwdemo\_PCG\_Eval\_P1.c: C file that defines step and initialization functions
- ert\_main.c: Example Main file that includes a simple scheduler
- rtwdemo\_PCG\_Eval\_P1.h: H file that contains type definitions of the Simulink® Coder™ data structures
- PCG\_Eval\_p1\_private.h: File that declares data that only the generated code uses
- rtwdemo\_PCG\_Eval\_P1\_types.h: H file that declares the real-time model data structure

For the next example in this series, see “Configure Data Interface in the Generated Code” on page 48-35.

## Configure Data Interface in the Generated Code

Specify signals, states, and parameters for inclusion in generated code.

Learn how to control these attributes of data in the generated code:

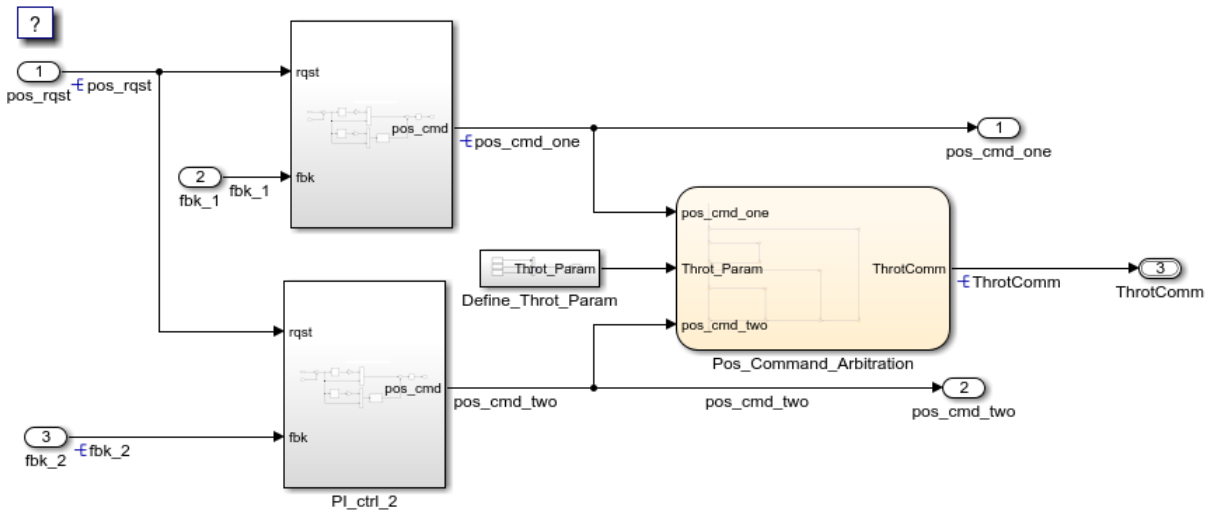

- Name
- Data type
- Data storage class

For information about the example model, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Open Example Model

Open the example model, `rtwdemo_PCG_Eval_P2`.

```
open_system('rtwdemo_PCG_Eval_P2')
```

## Data Declaration

Most programming languages require that you declare data and functions before using them. The declaration specifies:

- **Scope:** The region of the program that has access to the data
- **Duration:** The period during which the data exist in memory
- **Data type:** The amount of memory allocated for the data
- **Initialization:** A value, a pointer to memory, or NULL

The combination of scope and duration is the storage class. If you do not provide an initial value, most compilers assign a zero value or a null pointer.

Supported data types include:

- **double:** Double-precision floating point
- **single:** Single-precision floating point
- **int8:** Signed 8-bit integer
- **uint8:** Unsigned 8-bit integer
- **int16:** Signed 16-bit integer
- **uint16:** Unsigned 16-bit integer
- **int32:** Signed 32-bit integer
- **uint32:** Unsigned 32-bit integer
- **Fixed Point:** 8-, 16-, 32-bit word lengths

With storage classes you can:

- Generate exported files, with custom names, that contain global variable declarations and definitions.
- Import custom header files that contain global variable declarations.
- Generate `const` or `volatile` type qualifiers in declarations.
- Represent a parameter as a macro (`#define` or compiler option).
- Package signals or parameters into flat structures or bit fields.

## Control Data in Simulink® and Stateflow®

This example uses data objects to specify code generation settings for data. Alternatively, you can store the settings in the model by using dialog boxes. Both methods allow full control over the data type and storage class. You can use both methods in a single model.

This example focuses on these types of data objects:

- Signal
- Parameter
- Bus

The code generator uses the objects from the MATLAB base workspace or a Simulink data dictionary. You can create and inspect the objects with commands at the command prompt or in the Model Data Editor or the Model Explorer.

As an example, inspect the definition of the Simulink.Signal object `pos_cmd_one`, which the model created in the base workspace:

- 1 Open the **Embedded Coder** app.
- 2 On the **Modeling** tab, click **Model Data Editor**.
- 3 In the Model Data Editor, inspect the **Signals** tab.
- 4 Click the **Show/refresh additional information** button.
- 5 Set the **Change view** drop-down list to Code.
- 6 Next to the **Filter contents** box, toggle the **Filter using selection** button.
- 7 In the model, select the `pos_cmd_one` signal line. Now, the data table contains two rows: One that corresponds to the signal line in the model and one that corresponds to the signal object in the base workspace. For the row that corresponds to the signal line, the **Resolve** check box is selected, which means the signal line acquires settings from the signal object.
- 8 Optionally, to inspect other properties of the signal object, adjust the setting for the **Change view** drop-down list.

In the Model Data Editor, toggle the **Filter using selection button**. Now, the data table shows these signal lines and signal objects:

- `pos_cmd_one`: Top-level output, Double, Exported Global
- `pos_rqst`: Top-level input, Double, Imported Extern Pointer

- `P_InErrMap`: Calibration parameter, Auto, Constant
- `ThrotComm`: Top-level output structure, Auto, Exported Global

`ThrotComm` is a bus signal, which is an instantiation of the `Simulink.Bus` object `ThrottleCommands`. If a bus signal is nonvirtual, the signal appears as a structure in the C code. Bus objects do not appear in the Model Data Editor. However, you can inspect the object in the Model Explorer (**View > Model Explorer**).

As in C, you can use a bus definition (`ThrottleCommands`) to create multiple instances of the structure. In a model diagram, a bus signal appears as a wide line with central dashes.

A data object has properties that you configure for simulation and for code generation, including:

- `DataType` (numeric data type for storage in the generated code)
- `StorageClass` (storage class for code generation)
- `Value` (parameter value)
- `InitialValue` (initial value for signal)
- `Alias` (alternative name for the data, which the code generator uses)
- `Dimensions` (size and number of dimensions of parameter or signal value)
- `Complexity` (numeric complexity)
- `Unit` (physical units such as cm)
- `Min` (minimum value)
- `Max` (maximum value)

Use the property `Description` to specify custom documentation for data objects.

## Add New Data Objects

You can create data objects for named signals, states, and parameters. To associate a data object with a construct, the construct must have a name.

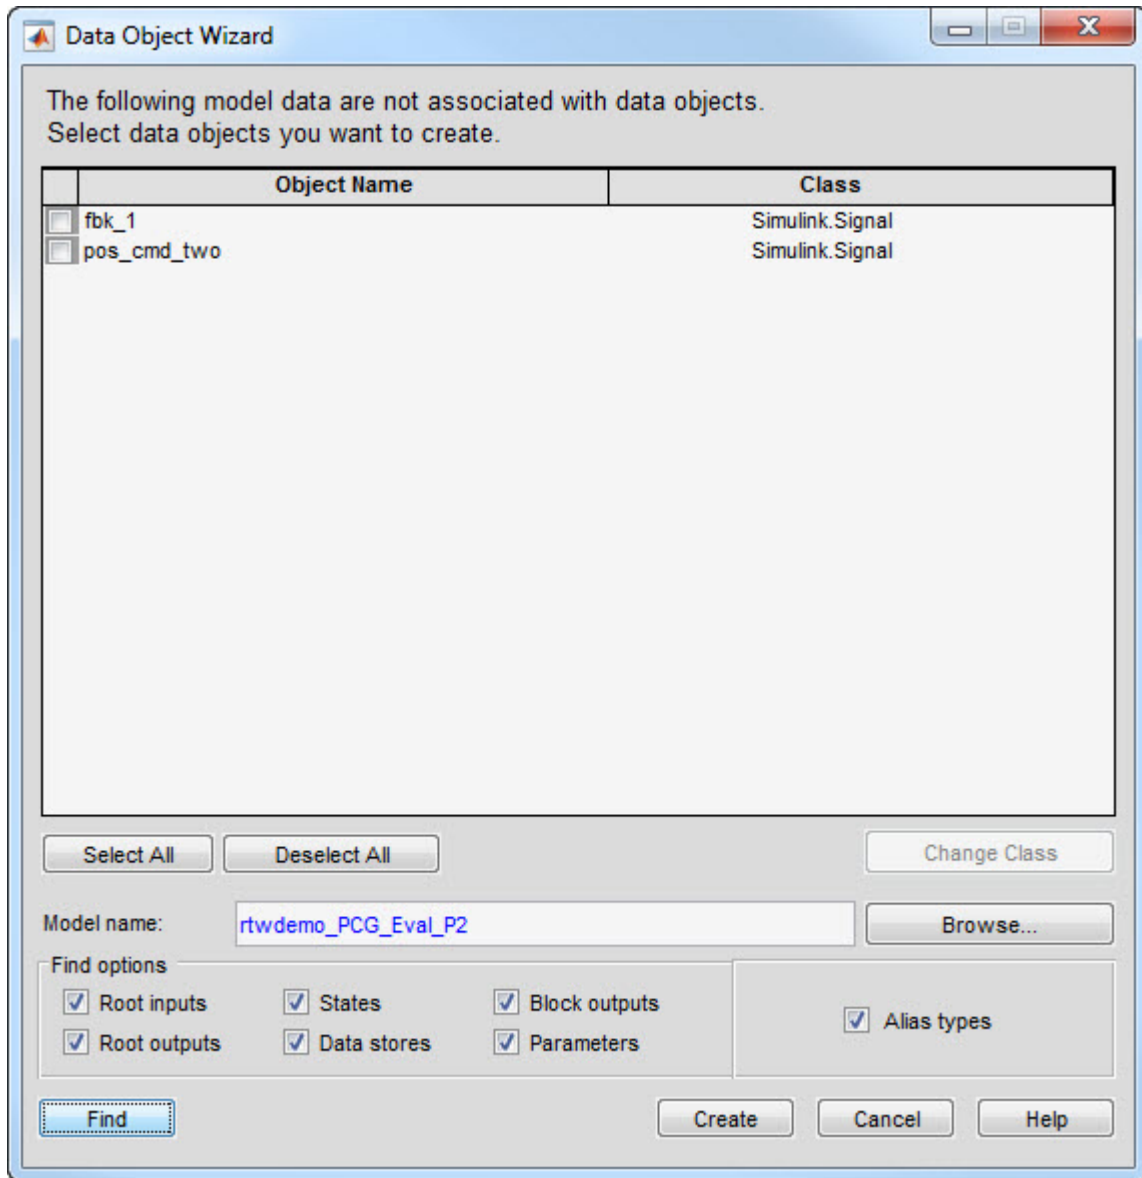

The Data Object Wizard tool finds constructs for which you can create data objects, and then creates the objects for you. The example model includes two signals that are not associated with data objects: `fbk_1` and `pos_cmd_two`.

To find the signals and create data objects for them:

1. Open the Data Object Wizard.

```
dataobjectwizard('rtwdemo_PCG_Eval_P2')
```

2. Click **Find** to find candidate constructs.

3. Click **Select All** to select all candidates.

4. Click **Create** to create the data objects.

The Data Object Wizard performs the equivalent of the following commands:

```
fbk_1 = Simulink.Signal;
fbk_1.Dimensions = 1;
fbk_1.DataType = 'double';
outport = get_param('rtwdemo_PCG_Eval_P2/fbk_1', 'PortHandles');
outport = outport.Outport;
set_param(outport, 'MustResolveToSignalObject', 'on')

pos_cmd_two = Simulink.Signal;
pos_cmd_two.Dimensions = 1;
pos_cmd_two.DataType = 'double';
outport = get_param('rtwdemo_PCG_Eval_P2/PI_ctrl_2', 'PortHandles');
outport = outport.Outport;
set_param(outport, 'MustResolveToSignalObject', 'on')
```

### Configure Data Objects

Set the data type and storage class for each data object. To configure data object properties, inspect the appropriate tab in the Model Data Editor. Use the **Change view** drop-down list to show design properties (such as data type) and code generation settings (such as storage class).

In the Model Data Editor, inspect the **Signals** tab and click the **Show/refresh additional information** button to display information for the signal objects that the Data Object Wizard created. Then, configure these properties for the objects:

- fbk\_1: Data type double, storage class ImportedExtern
- pos\_cmd\_two: Data type double, storage class ExportedGlobal

Alternatively, you can use these commands at the command prompt to configure the objects:

```
fbk_1.DataType = 'double';
fbk_1.StorageClass = 'ImportedExtern';

pos_cmd_two.DataType = 'double';
pos_cmd_two.StorageClass = 'ExportedGlobal';
```

## Control File Placement of Parameter Data

With Embedded Coder®, you can control the file placement of definitions for parameters and constants. The example model writes the parameter definitions to the file `eval_data.c`.

To change the placement of parameter and constant definitions, set the data placement options for the model configuration. In the Configuration Parameters dialog box, configure the options on the **Code Generation > Code Placement** pane.

In the example model, inspect the **Code Placement** pane in the Configuration Parameters dialog box. The model places data definitions in the file `eval_data.c` and declarations in the file `eval_data.h`.

## Declare Block Parameters Tunable or Inlined

You can control the default tunability of block parameters in the generated code by setting model configuration parameter **Default parameter behavior**.

For the example model, the default parameter behavior is set to `Inlined`. By default, block parameters appear in the code as numeric literal values, not as variables stored in memory. You can use `Simulink.Parameter` objects to override inlining and preserve tunability for individual parameters.

## Enable Signal Data Objects in Generated Code

Make sure that the signal data objects (`Simulink.Signal`) appear in the generated code. For individual signal lines in the model, select the option **Signal name must resolve to Simulink signal object** to explicitly resolve the signal name to a `Simulink.Signal` object in a workspace or data dictionary. In the Model Data Editor, set **Change view** to `Code` and select the check box in the **Resolve** column.

Alternatively, you can select the option for all signals in a model. At the command prompt, use the `disableimplicitsignalresolution` function.

## View Data Objects in Generated Code

Generate code from the example model.

```
rtwbuild('rtwdemo_PCG_Eval_P2');  
  
### Starting build procedure for model: rtwdemo_PCG_Eval_P2  
### Successful completion of code generation for model: rtwdemo_PCG_Eval_P2
```

Create a code generation report to more easily view the generated files. In the Simulink Editor, select model configuration parameter **Open Model Report**.

You can access these generated files:

- `rtwdemo_PCG_Eval_P2.c`: Defines the step and initialization functions. Uses the defined data objects.
- `eval_data.c`: Assigns initial values to the defined parameters. The model configuration specifically sets the file name.
- `eval_data.h`: Provides extern declarations of parameter data. The model configuration specifically sets the file name.
- `ert_main.c`: Defines scheduling functions.
- `rtwdemo_PCG_Eval_P2.h`: Contains the type definitions of the default structures that store signal, state, and parameter data. Due to the data object settings, some data appear in `eval_data.c` instead.
- `PCG_Eval_p2_private.h`: Declares private (local) data for the generated functions.
- `rtwdemo_PCG_Eval_P2_types.h`: Declares the real-time model data structure.
- `rtwtypes.h`: Provides mapping to the data types that Simulink® Coder™ defines (typedef). Used for integration with external systems.

For example, view the file `eval_data.c`, which allocates `const` memory for global variables that correspond to the Simulink.Parameter objects in the base workspace.

```
cfile = fullfile('rtwdemo_PCG_Eval_P2_ert_rtw','eval_data.c');
rtwdemodbtype(cfile,'/* Exported data definition */','* [EOF]',1,1)

/* Exported data definition */

/* Const memory section */
/* Definition for custom storage class: Const */
const real_T I_Gain = -0.03;
const real_T I_InErrMap[9] = { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05, 0.25, 0.5,
    1.0 } ;

const real_T I_OutMap[9] = { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6, 0.75, 1.0 } ;

const real_T P_Gain = 0.74;
const real_T P_InErrMap[7] = { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25, 1.0 } ;

const real_T P_OutMap[7] = { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0 } ;
```

```
/*
 * File trailer for generated code.
 *
 * [EOF]
```

View the code algorithm in the model step function in the file `rtwdemo_PCG_Eval_P2.c`. The algorithm uses the data object names directly.

```
cfile = fullfile('rtwdemo_PCG_Eval_P2_ert_rtw','rtwdemo_PCG_Eval_P2.c');
rtwdemodbtype(cfile,'/* Model step function */',...
    '/* Sum: '<S2>/Sum3' incorporates:',1,0);

/* Model step function */
void rtwdemo_PCG_Eval_P2_step(void)
{
    real_T rtb_IntegralGainShape;
    real_T Discrete_Time_Integrator1;
    real_T Discrete_Time_Integrator1_i;

    /* Sum: '<S2>/Sum2' incorporates:
     * Inport: '<Root>/fbk_1'
     * Inport: '<Root>/pos_rqst'
     */
    rtb_IntegralGainShape = *pos_rqst - fbk_1;

    /* DiscreteIntegrator: '<S2>/Discrete_Time_Integrator1' incorporates:
     * Gain: '<S2>/Int Gain1'
     * Lookup_n-D: '<S2>/Integral Gain Shape'
     * Product: '<S2>/Product3'
     */
    if (rtwdemo_PCG_Eval_P2_DWork.Discrete_Time_Integrator1_SYSTE != 0) {
        Discrete_Time_Integrator1 =
            rtwdemo_PCG_Eval_P2_DWork.Discrete_Time_Integrator1_DSTAT;
    } else {
        Discrete_Time_Integrator1 = I_Gain * look1_binlx(rtb_IntegralGainShape,
            (&(I_InErrMap[0])), (&(I_OutMap[0])), 8U) * rtb_IntegralGainShape * 0.001
            + rtwdemo_PCG_Eval_P2_DWork.Discrete_Time_Integrator1_DSTAT;
    }

    /* End of DiscreteIntegrator: '<S2>/Discrete_Time_Integrator1' */
```

Without storage classes and other code generation settings that the data objects specify, the generated code:

- Inlines invariant signals and block parameters when you select these optimizations in the model configuration parameters
- Places model input and output signals, block states, and tunable parameters in global data structures
- Does not create global variables that correspond to MATLAB® variables

In contrast, the example code shows that most of the default data structures have been replaced with user-defined data objects. For example, these signals and parameters appear as global variables in the code:

- `pos_rqst`
- `fbk_1`
- `I_Gain`
- `I_OutMap`
- `I_InErrMap`

However, the local variable `rtb_IntegralGainShape` and the state variable `rtwdemo_PCG_Eval_P2_DWork.Discrete_Time_Integrator1_DSTAT` still use code generator data structures. Data objects do not exist for these entities.

### Store Model Data in Data Dictionary

When you end your MATLAB session, variables that you create in the base workspace do not persist. To permanently store data objects and bus objects, consider linking the model to a data dictionary.

- 1 In the example model, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 2 In the Model Properties dialog box, click **New**.
- 3 In the Create a New Data Dictionary dialog box, set **File name** to `rtwdemo_PCG_Eval_dict` and click **Save**.
- 4 In the Model Properties dialog box, click **Apply**.
- 5 Click **Migrate data**.
- 6 Click **Migrate** in response to message about copying referenced variables.
- 7 Click **OK**.

Alternatively, to manually migrate the objects into a data dictionary, you can use programmatic commands:

```
% Create a list of the variables and objects that the target
% model uses.
usedVars = {Simulink.findVars('rtwdemo_PCG_Eval_P2').Name};
% Create a new data dictionary in your current folder. Link the model to
% this new dictionary.
dictObj = Simulink.data.dictionary.create('rtwdemo_PCG_Eval_dict.sldd');
set_param('rtwdemo_PCG_Eval_P2','DataDictionary','rtwdemo_PCG_Eval_dict.sldd')
% Import only the target variables from the base workspace to the data
% dictionary.
importFromBaseWorkspace(dictObj,'clearWorkspaceVars',true,'varList',usedVars);
```

The data dictionary permanently stores the objects that the model uses. To view the contents of the dictionary, click the model data badge in the lower-left corner of the model, then click the **Data Dictionary** link. In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

The separation of data from the model provides these benefits:

### **One model, multiple data sets**

- Use of different data types to change the targeted hardware (for example, for floating-point and fixed-point targets)
- Use of different parameter values to change the behavior of the control algorithm (for example, for reusable components with different calibration values)

### **Multiple models, one data set**

- Sharing of data between Simulink® models in a system
- Sharing of data between projects (for example, transmission, engine, and wheel controllers might all use the same CAN message data set)

## Partition Functions in Generated Code

This example shows how to associate subsystems in a model with function names and files.

Learn how to:

- Specify function and file names in the generated code.
- Identify the parts of the generated code that are required for integration.
- Generate code for atomic subsystems.
- Identify data that are required to execute a generated function.

For information about the example model and other examples in this series, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Atomic and Virtual Subsystems

The example models in “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20 and “Configure Data Interface in the Generated Code” on page 48-35 use *virtual subsystems*. Virtual subsystems visually organize blocks but do not affect the model functionality. *Atomic subsystems* evaluate the blocks included in a model as a unit. With atomic subsystems, you can specify additional function partitioning information. In a model, atomic subsystems appear with a bold border.

### View Changes in Model Architecture

Open the example model `rtwdemo_PCG_Eval_P3`.

Save a copy of the model to a writable folder.

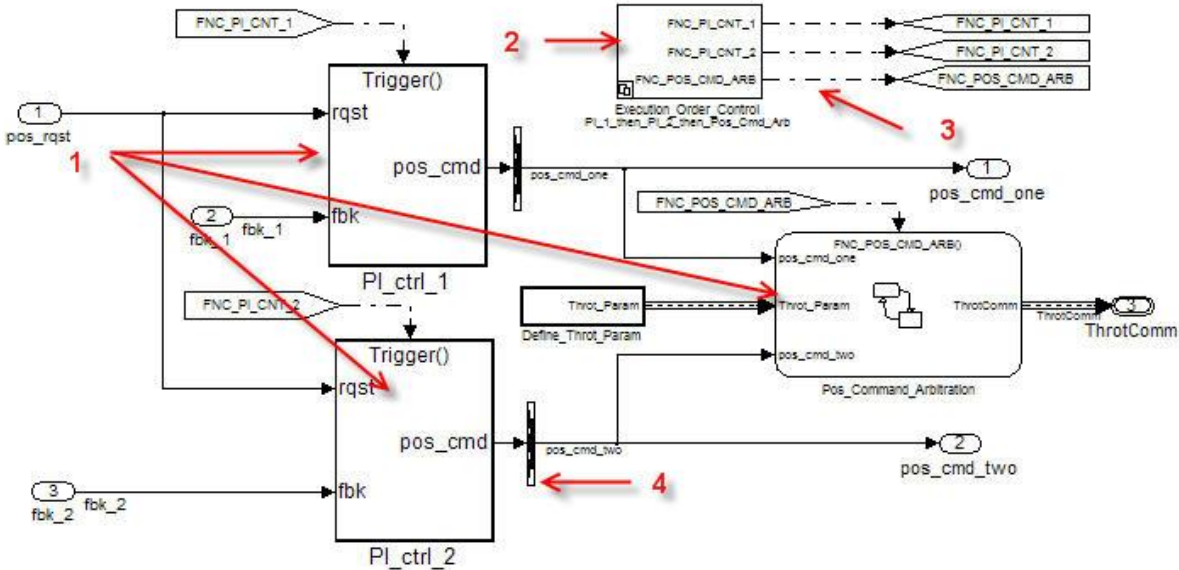

This example shows how to replace the virtual subsystems with *function-call subsystems*. Function-call subsystems:

- Are atomic subsystems
- Enable you to control subsystem execution order
- Execute when a *function call signal* triggers

By controlling the execution order of the subsystems, you can match the model with an existing system that has a specific execution order.

The figure identifies the function call subsystems (1) PI\_ctrl\_1, PI\_ctrl\_2, and Pos\_Command\_Arbitration.

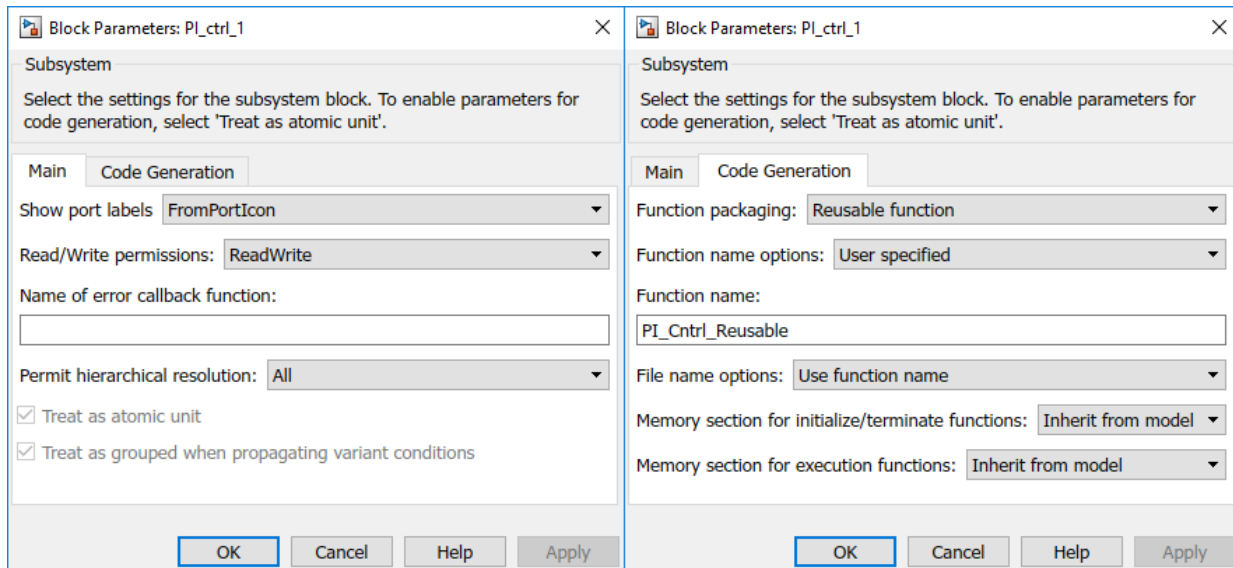

This version of the model contains the new subsystem Execution\_Order\_Control (2), which contains a Stateflow® chart that models the calling functionality of a scheduler. The subsystem controls the execution order of the function call subsystems through function call signals (3). Later in this example, you examine how changing the execution order can change the simulation results.

This version of the model contains new Signal Conversion blocks (4) at the outputs of the PI controllers. With these additional blocks in place, the code generator can generate a single reentrant function for the PI controllers.

**Control Function Location and File Placement in the Generated Code**

In “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20 and “Configure Data Interface in the Generated Code” on page 48-35, the code generator creates a single *model\_step* function that contains the control algorithm code. However, many applications require a greater level of control over the file placement of functions. By modifying the parameters of atomic subsystems, you can specify multiple functions within a single model.

The figure shows the subsystem parameters for PI\_ctrl\_1.

### Treat as atomic unit

- Enables other submenus. For atomic subsystems, this parameter is automatically selected and disabled.

### Sample time

- Specifies a sample time for execution. Not available for function-call subsystems.

### Function packaging options

- **Auto** -- Determines how the subsystem appears in the generated code. This value is the default.
- **Inline** -- Places the subsystem code inline with the rest of the model code.
- **Function** -- Generates the code for the subsystem as a function.
- **Reusable function** -- Generates a reusable (reentrant) function from the subsystem. The function passes all input and output data through formal parameters. The function does not directly access global variables.

### Function name options

- Selecting `Function` or `Reusable` function for **Function packaging** enables function name options.
- `Auto` -- Determines the function.
- `Use subsystem name` -- Bases the function on the subsystem name.
- `User specified` -- Applies the specified file name.

### File name options

- Selecting `Function` or `Reusable` function for **Function packaging** enables file name options.
- `Auto` -- Places the function definition in the module generated for the parent system, or, if the model root is the parent, in `model.c`.
- `Use subsystem name` -- Generates a separate file. The name of the file is the name of the subsystem or library block.
- `Use function name` -- Generates a separate file. The name of the file is the name that you specify with **Function name options**.
- `User specified` -- Applies the specified, unique file name.

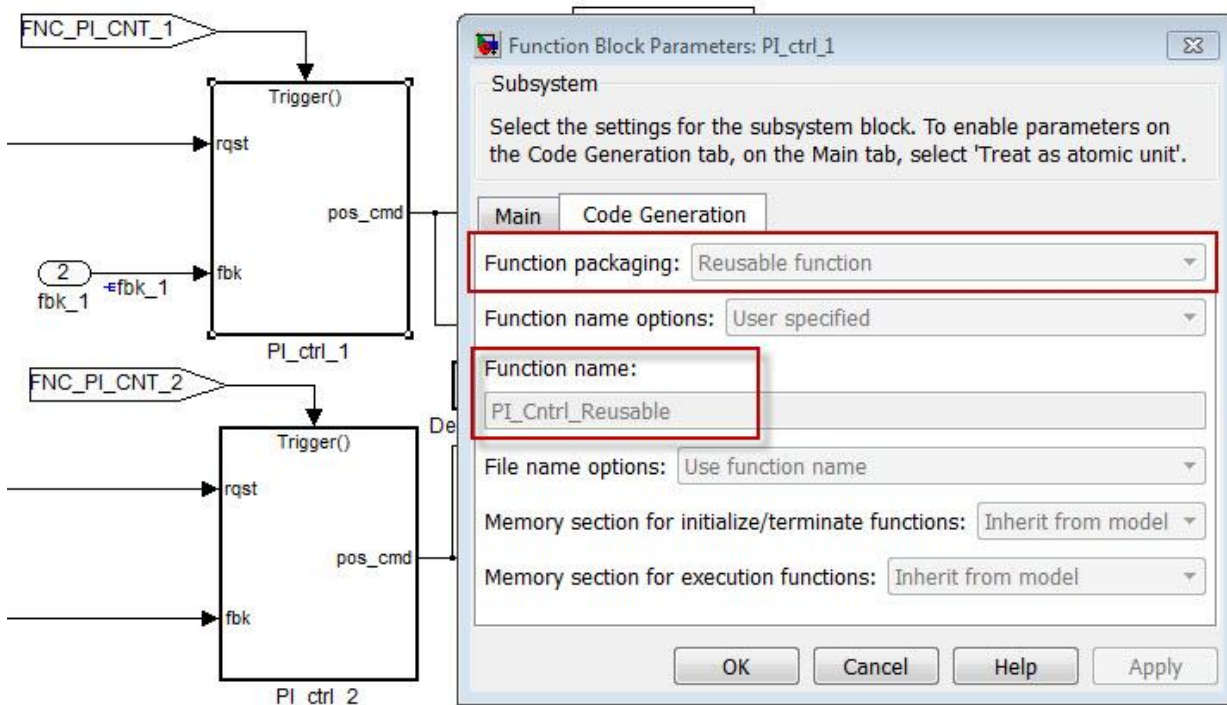

### Function with separate data

- Enabled when you set **Function packaging** to `Function`. When selected, the code generator separates the internal data of the subsystem (for example, signals) from the data of the parent model. The subsystem owns this separate data.

### Generate Reentrant Code

Embedded Coder® supports *reentrant code*. Reentrant code is a reusable programming routine that multiple programs can use simultaneously. Reentrant code is used in operating systems and other system software that uses multithreading to handle concurrent events. Reentrant code does not maintain state data, so there are no persistent variables in the function. Calling programs maintain state variables and must pass the state data into the function. Multiple users or processes can share one copy of a reentrant function.

To generate reentrant code, you must first specify the subsystem as reusable by configuring the subsystem parameter **Function packaging**.

In some cases, the configuration of the model prevents reusable code. The table lists common issues.

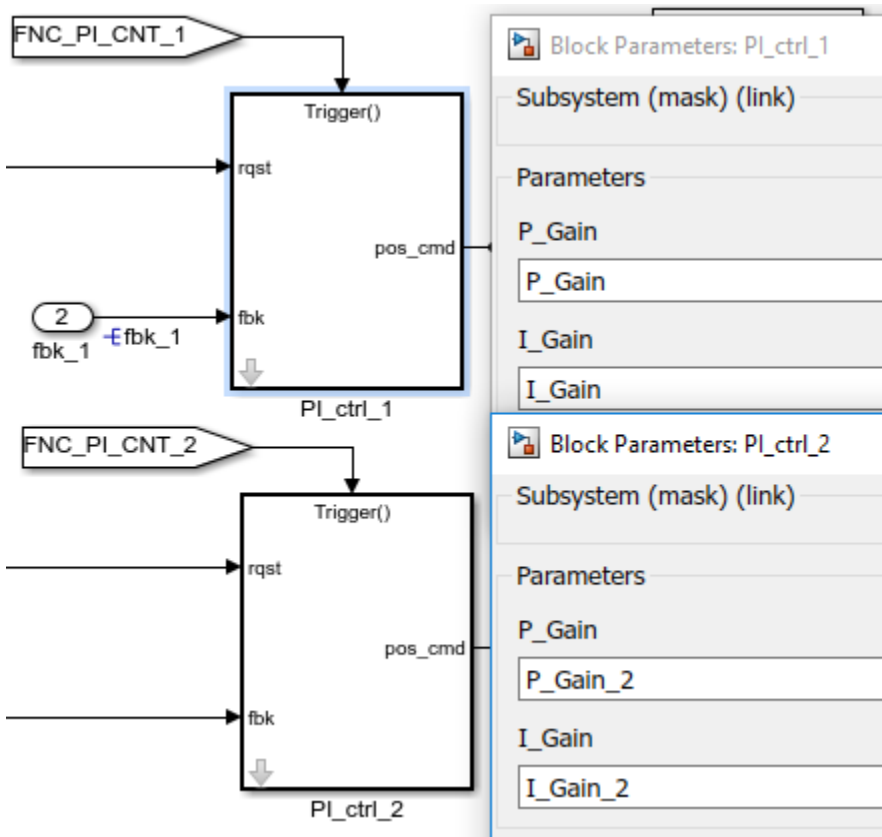

Cause	Solution
Subsystem output feeds global signal data	Add a Signal Conversion block between the subsystem and the global signal.
Generated function receives data (formal parameters) through pointers	Select Configuration Parameters > Model Referencing > Pass fixed-size scalar inputs by value for code generation.
Subsystem uses global signal data in internal algorithm	Use a port to pass the global data in and out of the subsystem.

### Use a Mask to Pass Parameter Values into Library Subsystem

To define algorithmic parameter data (such as a gain or coefficient) outside the scope of a reusable library block or subsystem, you can apply a *mask* to the block or subsystem and

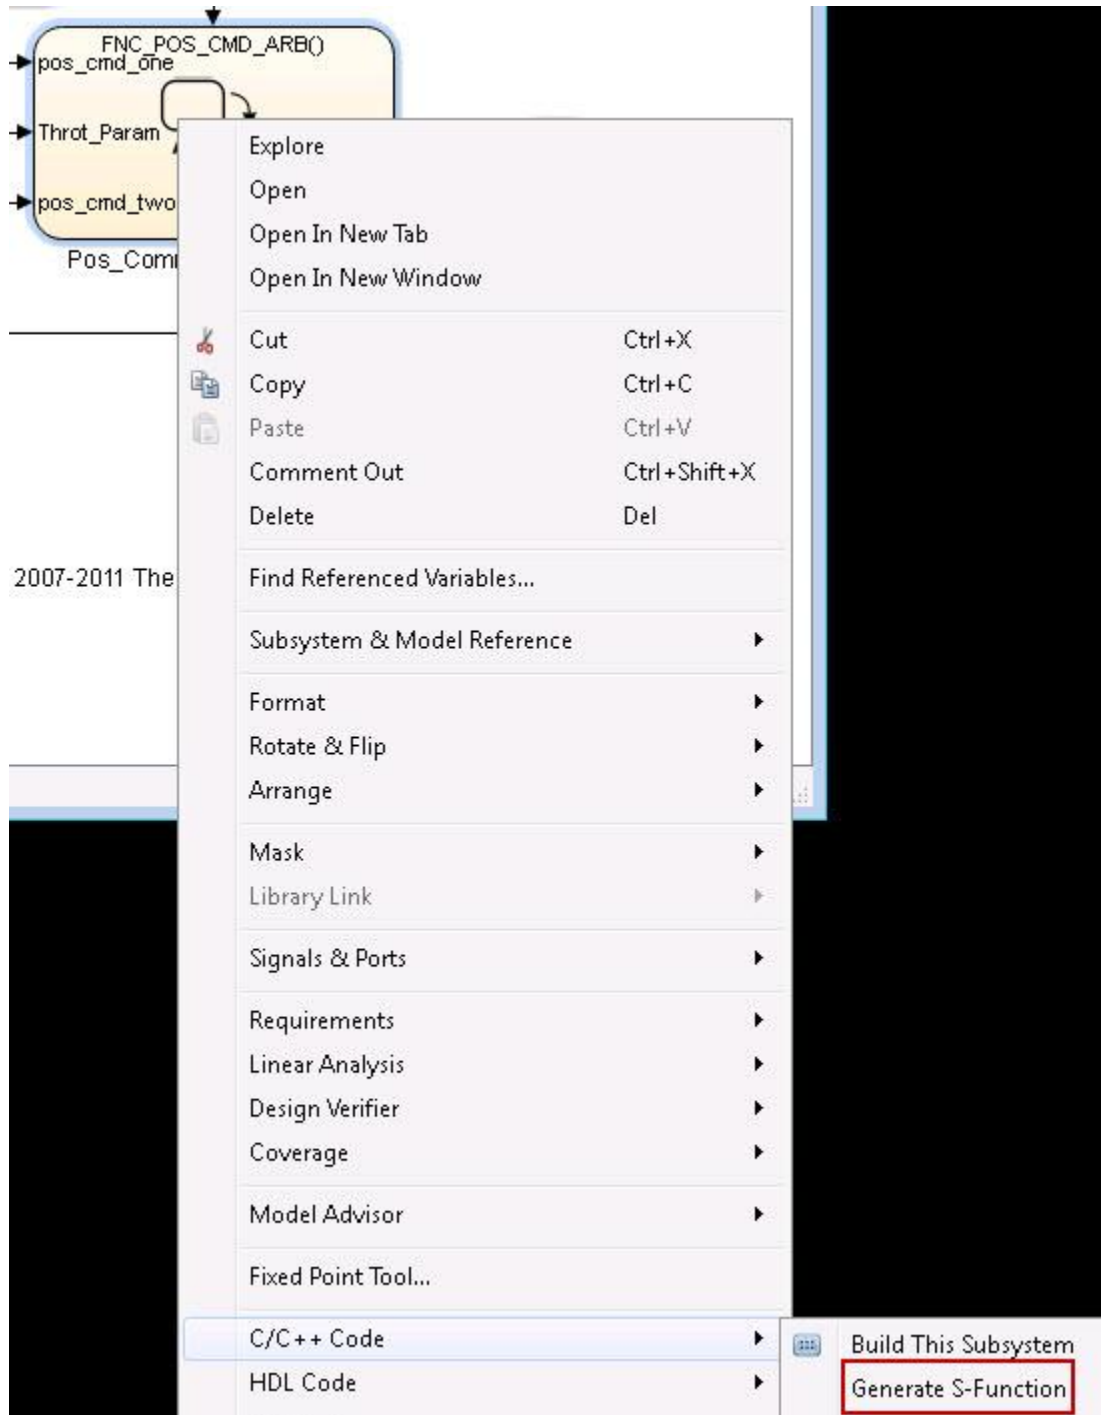

create a mask parameter. You can then specify a different parameter value for each instance of the block or subsystem. Each mask parameter appears in the generated code as a formal parameter of the reentrant function.

In this version of the model, the subsystems PI\_ctrl\_1 and PI\_ctrl\_2 are masked. In each mask, the values of the P and I gains are set by data objects such as I\_Gain\_2 and P\_Gain\_2.

**Generate Code for Atomic Subsystem**

In “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20 and “Configure Data Interface in the Generated Code” on page 48-35, you generate code at the root level of the model. Alternatively, you can build a specific subsystem.

To initiate a subsystem build, use the context menu. You can choose from these options:

- 1 Build This Subsystem:** Treats the subsystem as a separate mode and creates the full set of source C files and header files. This option does not support function-call subsystems.
- 2 Generate S-Function:** Generates C code for the subsystem and creates an S-Function wrapper. You can then simulate the code in the original model. This option does not support function-call subsystems.
- 3 Export Functions:** Generates C code without the scheduling code that comes with the **Build This Subsystem** option. Use this option to build subsystems that use triggers, such as function-call subsystems.

Alternatively, select the subsystem and on the **C Code** tab, click **Build**.

### Examine Generated Code

This example compares the files that are generated for the full system build with the files that are generated for exported functions. You also examine how the masked data appears in the code.

Run the build script for the three options. Then, examine the generated files by clicking the hyperlinks.

- 1 Generate code from the entire model.
- 2 Export the function `PI_ctrl_1`.
- 3 Export the function `Pos_Command_Arbitration`.

#### **rtwdemo\_PCG\_Eval\_P3.c**

- Full Build: Yes, Step function
- `PI_ctrl_1`: No
- `Pos_Command_Arbitration`: No

#### **PI\_ctrl\_1.c**

- Full Build: No
- `PI_ctrl_1`: Yes, Trigger function
- `Pos_Command_Arbitration`: No

#### **Pos\_Command\_Arbitration.c**

- Full Build: No
- PI\_ctrl\_1: No
- Pos\_Command\_Arbitration: Yes, Init and Function

#### **PI\_Ctrl\_Reusable.c**

- Full Build: Yes
- PI\_ctrl\_1: Yes
- Pos\_Command\_Arbitration: No

#### **ert\_main.c**

- Full Build: Yes
- PI\_ctrl\_1: Yes
- Pos\_Command\_Arbitration: Yes

#### **eval\_data.c**

- Full Build: Yes(1)
- PI\_ctrl\_1: Yes(1)
- Pos\_Command\_Arbitration: No, Eval data not used in diagram

(1) `eval_data.c` has different content in the full and export function builds. The full build includes all of the parameters that the model uses. The export function contains only the variables that the subsystem uses.

#### **Masked Data in the Generated Code**

In the file `rtwdemo_PCG_Eval_P3.c`, the call sites of the reentrant function use the data objects `P_Gain`, `I_Gain`, `P_Gain_2`, and `I_Gain_2` as arguments.

```
PI_Cntrl_Reusable(*pos_rqst, fbk_1, &rtwdemo_PCG_Eval_P3_B->PI_ctrl_1,  
                 &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_1, I_Gain, P_Gain);  
PI_Cntrl_Reusable(*pos_rqst, fbk_2, &rtwdemo_PCG_Eval_P3_B->PI_ctrl_2,  
                 &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_2, I_Gain_2, P_Gain_2);
```

#### **Effect of Execution Order on Simulation Results**

By default, Simulink® executes the subsystems in this order:

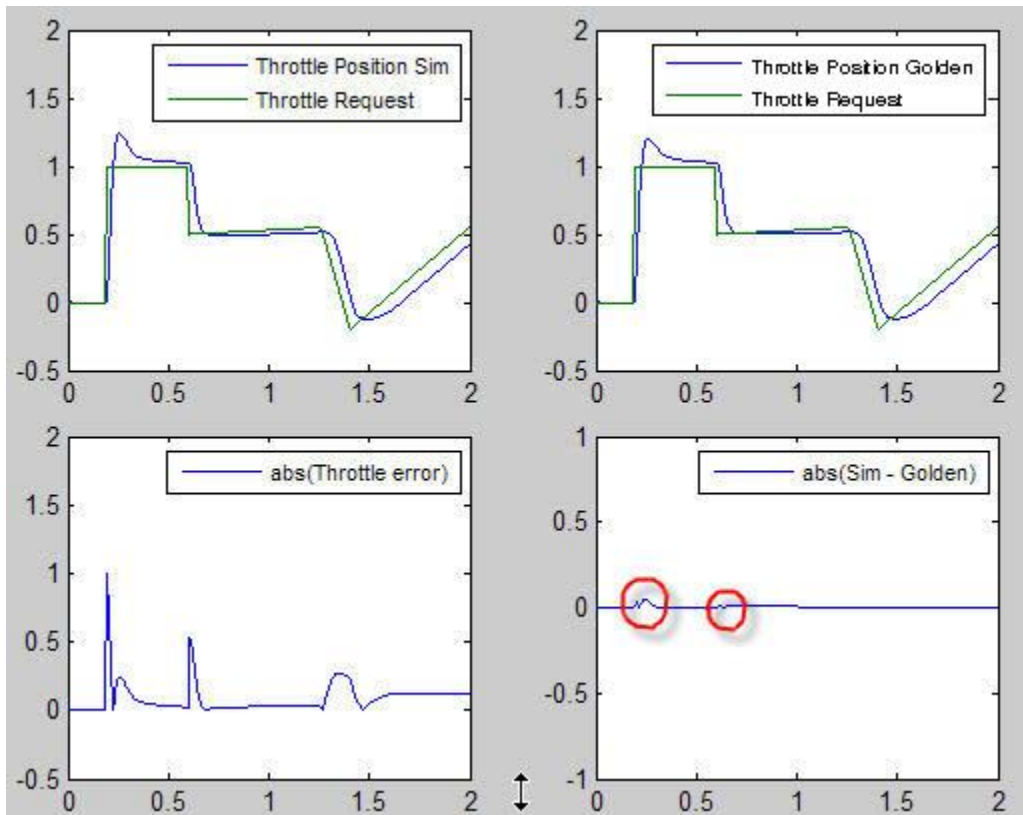

- 1** PI\_ctrl\_1
- 2** PI\_ctrl\_2
- 3** Pos\_Command\_Arbitration

For this example, you can specify one of two alternative orders of execution. You can then use the test harness to observe the effect of the execution order on the simulation results. The subsystem `Execution_Order_Control` has two configurations that control the execution order. To choose a configuration, use the subsystem context menu.

Change the execution order and observe the results.

- 1** Set the execution order to `PI_ctrl_1`, `PI_ctrl_2`, `Pos_Command_Arbitration`.
- 2** Open the test harness.
- 3** Run the test harness.
- 4** Change the execution order to `Pos_Command_Arbitration`, `PI_ctrl_1`, `PI_ctrl_2`.
- 5** Run the test harness.

The simulation results (throttle position over time) vary slightly depending on the order of execution. You can see the difference most clearly when the throttle request changes.

For the next example in this series, see “Call External C Code from Model and Generated Code” on page 48-60.

- “Masking Fundamentals” (Simulink)

## Call External C Code from Model and Generated Code

Call existing, external functions from a simulation or from the generated code by using the Legacy Code Tool.

Learn how to:

- Evaluate a C function as part of a Simulink® model simulation.
- Call a C function from the code that you generate from a model.

For information about the example model, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Replacement Process

Open the example model, `rtwdemo_PCG_Eval_P4`.

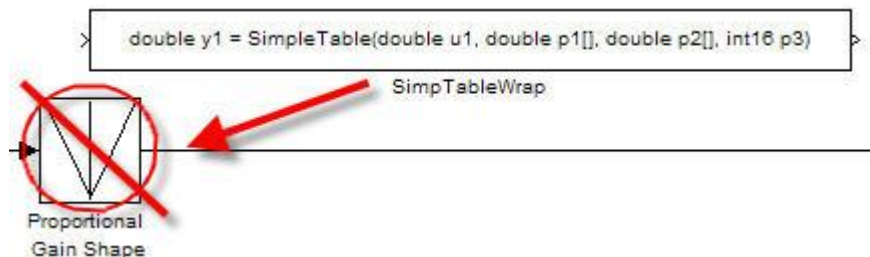

For many Model-Based Design applications, in addition to Simulink® models, a design includes a set of existing C functions that have been tested and validated. You can integrate these functions into a Simulink® model and generate code that uses the functions.

In this example, you create a custom Simulink® block that calls an existing C function. You then include the block in a model and test the overall system through model simulation in Simulink®.

In the example model, you can replace the Lookup blocks (lookup tables) in the PI controllers with calls to an existing C function. The function is defined in files `SimpleTable.c` and `SimpleTable.h`.

View `SimpleTable.c`.

View `SimpleTable.h`.

## Create Block That Calls C Function

To specify a call to an existing C function, use an S-Function block. You can automate the creation of the S-Function block by using the Legacy Code Tool. In the tool, you first specify an interface for your existing C function. The tool then uses that interface to create an S-Function block.

Use the Legacy Code Tool to create an S-Function block for the existing C function in `SimpleTable.c`.

1. Create a structure to contain the definition of the function interface.

```
def = legacy_code('initialize')
```

You can use the structure `def` to define the function interface to the existing C code.

2. Populate the fields of the structure.

```
% Defines the function interface, inputs, return values and parameters
def.OutputFcnSpec = ['double y1 = SimpleTable(double u1,',...
                    'double p1[], double p2[], int16 p3)'];

% the C and H files where the external code is defined
def.HeaderFiles   = {'SimpleTable.h'};
def.SourceFiles   = {'SimpleTable.c'};
% The name of the created S-Function
def.SFunctionName = 'SimpTableWrap';
```

3. Create the S-function.

```
legacy_code('sfcn_cmex_generate',def)
```

4. Compile the S-function.

```
legacy_code('compile',def)
```

5. Create the S-Function block.

```
legacy_code('slblock_generate',def)
```

The generated S-Function block calls the C function in `SimpleTable.c`. You can now use this S-Function block in models.

6. Create the TLC file.

```
legacy_code('sfcn_tlc_generate',def)
```

This command creates a TLC file, which is the component of an S-Function that specifies how to generate code for the block.

### **Validate External Code Through Simulation**

When you integrate existing C code in a Simulink® model, validate the generated S-Function block.

To validate the replacement of the Lookup blocks, compare the simulation results produced by the Lookup blocks with the results produced by the new S-Function block.

1. Open the validation model.

- The Sine Wave block produces output values from [-2 : 2].
- The input range of the lookup table is from [-1 : 1].
- The lookup table outputs the absolute value of the input.
- The lookup table clips the output at the input limits.

2. Run the validation model.

The figure shows the validation results. The existing C code and the Simulink® table block produce the same output values.

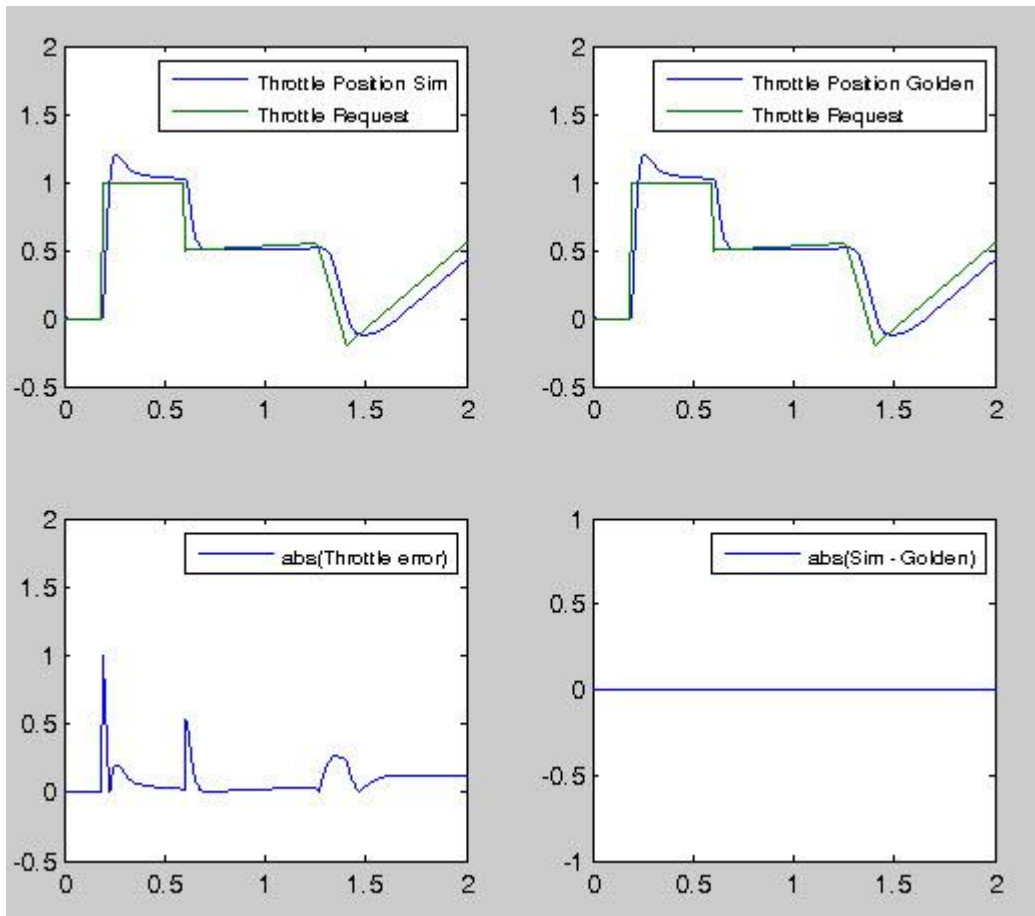

### Validate C Code as Part of Simulink® Model

After validating the existing C function code as a standalone component, validate the S-function in the model. To complete the validation, use a test harness model.

1. Open the test harness.
2. Run the test harness.

The simulation results match the golden values.

### Call C Function from the Generated Code

The code generator uses the TLC file to process the S-Function block like any other block. The code generator can implement *expression folding* with the S-Function block, an operation that combines multiple computations into a single output calculation.

1. Build the full model.
2. Examine the generated code in `PI_Control_Reusable.c`.

The generated code now calls the `SimpleTable` C function.

The figures show the generated code before and after the C code integration. Before the integration, the code calls a generated lookup routine. After the integration, the generated code calls the C function `SimpleTable`.

```
Discrete_Time_Integrator1 = rtp_Masked_I_Gain * look1_bin1x(rtb_Sum2,
  (&(I_InErrMap[0])), (&(I_OutMap[0])), 8U) * rtb_Sum2 * 0.001 +
  localDW->Discrete_Time_Integrator1_DSTAT;

/* DiscreteIntegrator: '<S3>/Discrete Time Integrator1' incorporates:
 * Gain: '<S3>/Int Gain1'
 * Product: '<S3>/Product3'
 * S-Function (SimpTableWrap): '<S3>/SimpTableWrap1'
 */
Discrete_Time_Integrator1 = I_Gain * SimpleTable(rtb_Sum2, (real_T*)
  (&(I_InErrMap[0])), (real_T*)(&(I_OutMap[0])), 7) * rtb_Sum2 * 0.001 +
  localDW->Discrete_Time_Integrator1_DSTAT;
```

## Build Integrated Code Outside the Simulink Environment

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

- Collect files required for building integrated code outside of Simulink®.
- Interface with external variables and functions.

For information about the example model and related examples, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Collect and Build Required Data and Files

The code that Embedded Coder® generates requires support files that MathWorks® provides. To relocate the generated code to another development environment, such as a dedicated build system, you must relocate these support files. You can package these files in a zip file by using the `packNGo` utility. This utility finds and packages the files that you need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a `buildinfo_data` structure, and a `packNGo` function. These files include external files that you identify in the **Code Generation > Custom Code** pane in the Model Configuration Parameters dialog box. The utility saves the `buildinfo` MAT-file in the `model_ert_rtw` folder.

Open the example model, `rtwdemo_PCG_Eval_P5`.

This model is configured to run `packNGo` after code generation.

Generate code from the entire model.

To generate the zip file manually:

- 1 Load the file `buildInfo.mat` (located in the `rtwdemo_PCG_Eval_P5_ert_rtw` subfolder).
- 2 At the command prompt, enter the command `packNGo(buildInfo)`.

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler might require a subset of the files in the zip file. The compiled executable size (RAM/ROM) depends on the linking process. The linker likely includes only the object files that are necessary.

## Integrating the Generated Code into an Existing System

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to integration environments.

### Overview of Integration Environment

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O
- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View `example_main.c`.

```
int_T main(void)
{
    /* Initialize model */
    rt_Pos_Command_Arbitration_Init(); /* Set up the data structures for chart*/
    rtwdemo_PCG_Define_Throt_Param(); /* SubSystem: '<Root>/Define_Throt_Param' */
    defineImportData(); /* Defines the memory and values of inputs */

    do /* This is the "Schedule" loop.
        Functions would be called based on a scheduling algorithm */
    {
        /* HARDWARE I/O */

        /* Call control algorithms */
        PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
            &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
        PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
            &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
        pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
        pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

        rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
            &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
    }
}
```

The file:

- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines extern data.
- Initializes data.
- Calls simulated hardware.
- Calls algorithmic functions.

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.

## Match System Interfaces

Integration requires matching the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

## Connect Input Data

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically comes from other software components or from hardware devices.

View `defineImportedData.c`.

```
/* Define imported data */
#include "rtwtypes.h"
#include "defineImportedData.h"

real_T fbk_1;
real_T fbk_2;
real_T dummy_pos_value = 10.0;
real_T *pos_rqst;
void defineImportData(void)
{
    pos_rqst = &dummy_pos_value;
}
```

View `rtwdemo_PCG_Eval_P5_Private.h`.

```

/* Imported (extern) block signals */
extern real_T fbk_1;          /* '<Root>/fbk_1' */
extern real_T fbk_2;          /* '<Root>/fbk_2' */

/* Imported (extern) pointer block signals */
extern real_T *pos_rqst;     /* '<Root>/pos_rqst' */

```

### Connect Output Data

In this example, you do not access the output data of the system. The example “Test Generated Code” on page 48-73 shows how you can save the output data to a standard log file. You can access the output data by referring to the file `rtwdemo_PCG_Eval_P5.h`.

View `rtwdemo_PCG_Eval_P5.h`.

### Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time

The table lists the common data structures. Depending on the configuration of the model, a combination of these structures appear in the generated code. The data is declared in the file `rtwdemo_PCG_Eval_P5.h`, but in this example, you do not access this data.

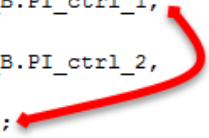

Data Type	Data Name	Data Purpose
Constants	model_cP	Constant parameters
Constants	model_cB	Constant block I/O
Output	model_U	Root and atomic subsystem input
Output	model_Y	Root and atomic subsystem output
Internal data	model_B	Value of block output
Internal data	model_D	State information vectors
Internal data	model_M	Time and other system level data
Internal data	model_Zero	Zero-crossings
Parameters	model_P	Parameters

## Match Function Call Interfaces

By default, functions that the code generator generates have a `void Func(void)` interface. If you configure the model or atomic subsystem to generate reentrant code, the code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with valid input arguments.

```
PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCG_Eval_P5.h`.

## Build Project in Eclipse™ Environment

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:

- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3
- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse” on page 48-87.

You can install the files for this example by clicking this hyperlink:

Set up the build folder.

Alternatively, to install the files manually:

- 1 Create a build folder (Eclipse\_Build\_P5).
- 2 Unzip the file `rtwdemo_PCG_Eval_P5.zip` into the build folder.
- 3 Delete the files `rtwdemo_PCG_Eval_P5.c`, `ert_main.c` and `rt_logging.c`, which are replaced by `example_main.c`.

You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example “Install and Use Cygwin and Eclipse” on page 48-87.

To exercise the model with input data, see “Test Generated Code” on page 48-73.

## Test Generated Code

Validate generated code by using system-level S-functions or by running the code in an external environment.

Learn about:

- Different methods for testing the generated code
- How to test generated code in Simulink®
- How to test generated code outside of Simulink

For information about the example model and other examples in this series, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Validation Methods

Simulink® supports multiple system testing methods for validating the behavior of generated code.

**Windows® run-time executable:** Generate a Microsoft® Windows® executable and run the executable from the command prompt.

- Benefit: Easy to create and enables use of a C debugger to evaluate code
- Drawback: Partial emulation of target hardware

**Software-in-the-loop (SIL) testing:** Use an S-function to include the generated code in the Simulink model.

- Benefit: Easy to create, enables reuse of the Simulink test environment, and enables use of a C debugger to evaluate code
- Drawback: Partial emulation of target hardware

**Processor in the loop (PIL) testing:** Run a non-real-time cosimulation. Simulink executes a portion of the model (typically a plant model) while the target processor runs a different portion of the model (typically a controller). After you download code to the target processor, the processor-in-the-loop technology handles the communication of signals between Simulink and the target during the cosimulation.

- Benefit: Enables reuse of the Simulink test environment, enables use of a C debugger with the simulation, and involves the target processor

- Drawback: Requires additional steps to set up the test environment and the processor does not run in real time

**On-target rapid prototyping:** Run the generated code on the target processor as part of the full system.

- Benefit: You can determine actual hardware constraints and test the component within the full system. The processor runs in real time
- Drawback: Requires hardware and requires additional steps to set up the test environment

**External Mode:** Run the generated code on the target processor as part of the full system.

- Benefit: You can determine actual hardware constraints and test the component within the full system
- Drawback: Requires hardware and requires additional steps to set up the test environment

### **Reuse Test Data Outside of Simulink®**

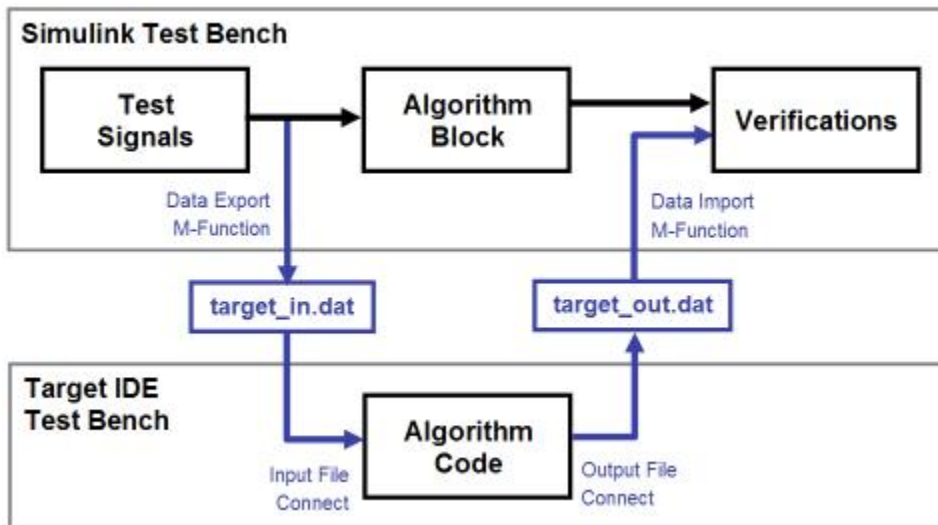

In other examples in this series, you test the system through simulation in Simulink. The test input data come from a Signal Builder block in the test harness model.

To test the system outside of Simulink®, you can reuse the test input data.

- 1 Save the Simulink test data into a file.
- 2 Format the data in a way that the system code can access.
- 3 Read the data file as part of the system code procedures.

To use Simulink to perform verification, you can save the test output data from the external environment in a format that MATLAB® can read.

In this example, the file `hardwareInputs.c` contains the data from the Signal Builder block in the test harness model.

## Test via Software-in-the-Loop (Model Block SIL)

### Create and Configure Model Block for SIL

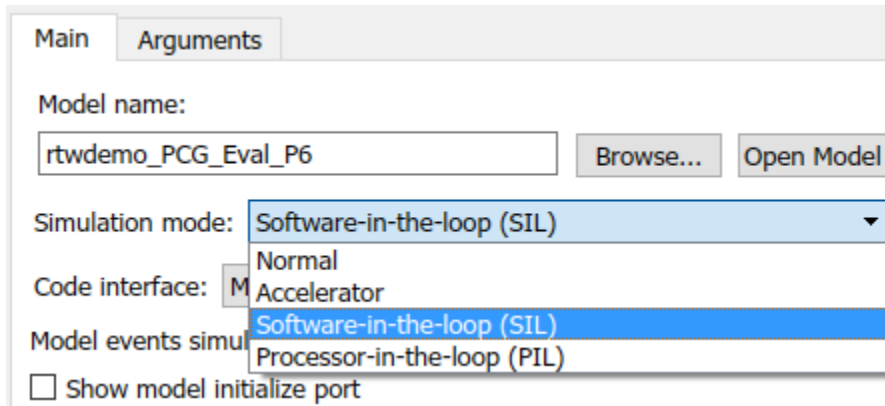

Simulink can generate code from a Model block, wrap the code into an S-Function, and add the S-Function back into the model for software-in-the-loop testing.

Open the example model, `rtwdemo_PCG_Eval_P6`.

Open the test harness model.

The test harness uses a Model block to access the example model. In this example, you run a software-in-the-loop test on the example model.

- 1 Right-click the Model block and select **Block Parameters (ModelReference)**.
- 2 Set **Model name** to the name of the model that you want to test.
- 3 Set **Simulation mode** to Software-in-the-loop (SIL).

The Model block now shows a (SIL) tag.

### Configure Models for SIL

Configure the example model, `rtwdemo_PCG_Eval_P6`, and the test harness model, `rtwdemo_PCGEvalHarnessHTGTSIL`, for SIL simulation by adjusting the hardware implementation parameters.

Open the example model.

For both models, in the Configuration Parameters dialog box, select the **Support long long** check box.

Save a copy of the example model, `rtwdemo_PCG_Eval_P6`, in your current folder.

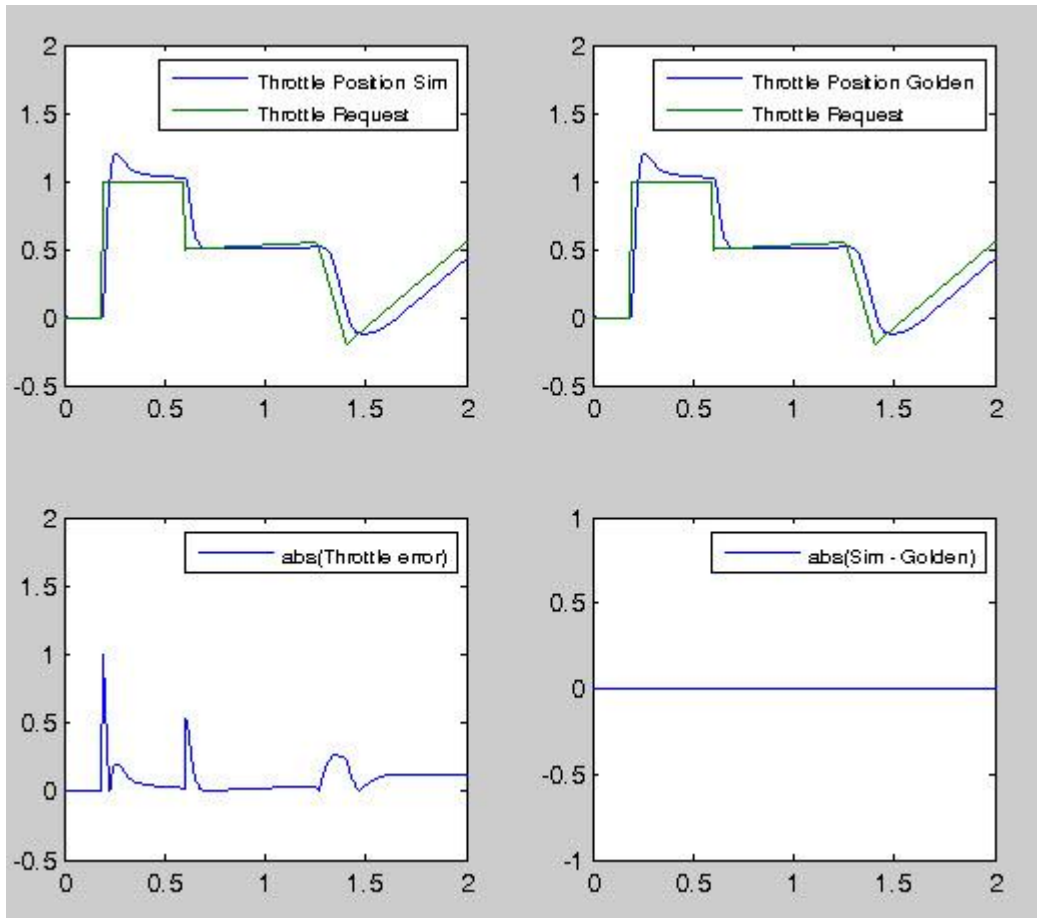

### **Run Model Block SIL**

In this example, the test harness model contains a Model block that is configured for SIL simulation.

Open the test harness.

Run the test harness.

The generated code and the simulation yield the same results.

### Configure System for Testing via Test Vector Import and Export

This example extends the integration example in “Build Integrated Code Outside the Simulink Environment” on page 48-66. In this case, `example_main.c` uses simulated hardware I/O.

The augmented `example_main.c` file now uses this execution order:

1. Initialize data (one time)

```
while < endTime
```

2. Read the simulated hardware inputs
  3. PI\_cnrl\_1
  4. PI\_ctrl\_2
  5. Pos\_Command\_Arbitration
  6. Write the simulated hardware outputs
- end while

View `example_main.c`.

Two functions, `plant` and `hardwareInputs`, supply the input test data.

`Plant.c`: This function, which was generated from the plant portion of the test harness, simulates the throttle body response to throttle commands.

```
void Plant(void)
```

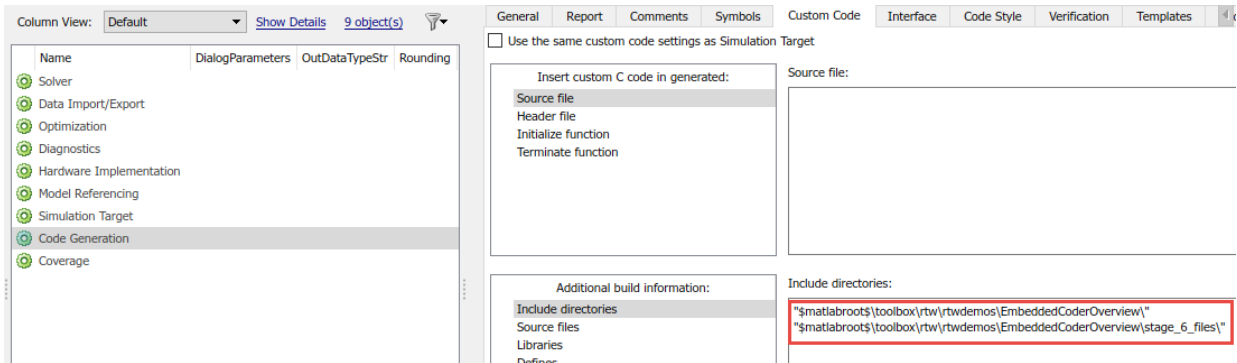

`HardwareInputs.c`: This function provides the `pos_req` signal and adds noise from the `Input_Signal_Scaling` subsystems into the plant feedback signal.

```
void hardwareInputs(void)
```

The handwritten function in `WriteDataForEval.c` logs output data from the test. After the test is finished, the function executes and writes the data to the file `PCG_Eval_ExternSimData.m`. You can run this script file in MATLAB to access the data. You can then compare the data to the simulated data from Simulink®.

To enable these additional files, identify them by using **Configuration Parameters > Code Generation > Custom Code > Additional build information**.

## Test via Test Vector Import and Export (Eclipse™ Environment)

Before building an executable in the Eclipse™ environment, regenerate the code without the S-function interface.

Build C code for integration.

To learn how to install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse” on page 48-87.

To install the files for this example automatically, click the hyperlink.

Automatically set up the build folder.

Alternatively, to manually install the files:

- 1 Create a build folder (Eclipse\_Build\_P6).
- 2 Unzip the file `rtwdemo_PCG_Eval_P6.zip` into the build folder.
- 3 Delete the files `rtwdemo_PCG_Eval_P6.c`, `ert_main.c`, and `rt_logging.c`, which are replaced by `example_main.c`.

Run the control code in Eclipse™. The function in `writeDataForEval.c` creates the file `eclipseData.m`, which contains the output test data. In MATLAB®, load this Eclipse™ data by running the script file. Then, compare this data with the data from the Simulink® test harness model by using `plot`.

For the next example in this series, see “Evaluate Performance of the Generated Code” on page 48-83.

### **See Also**

#### **More About**

- “SIL and PIL Simulations” on page 78-2

## Evaluate Performance of the Generated Code

Learn how characteristics of generated code and RAM/ROM data affect the RAM/ROM metric.

For information about the example model and other examples in this series, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Code Evaluation

You can evaluate the generated code based on two primary metrics: *execution speed* and *memory usage*. In some cases, improvement in one metric implies a sacrifice in the other metric. For example, you can often gain faster execution by consuming more memory.

You can further classify memory usage as ROM (read-only memory) and RAM (random access memory).

- Accessing data from RAM is faster than accessing data from ROM.
- Executables and data must be stored on ROM because RAM does not maintain data between power cycles.

This example evaluates memory requirements and divides the memory usage into function and data components. The example does not evaluate execution speed.

### Compiler Information

This evaluation uses the Freescale™ CodeWarrior® compiler.

- **Compiler:** Freescale™ CodeWarrior®
- **Version:** 5.5.1.1430
- **Target Processor:** Power PC 565

### View Code Metrics

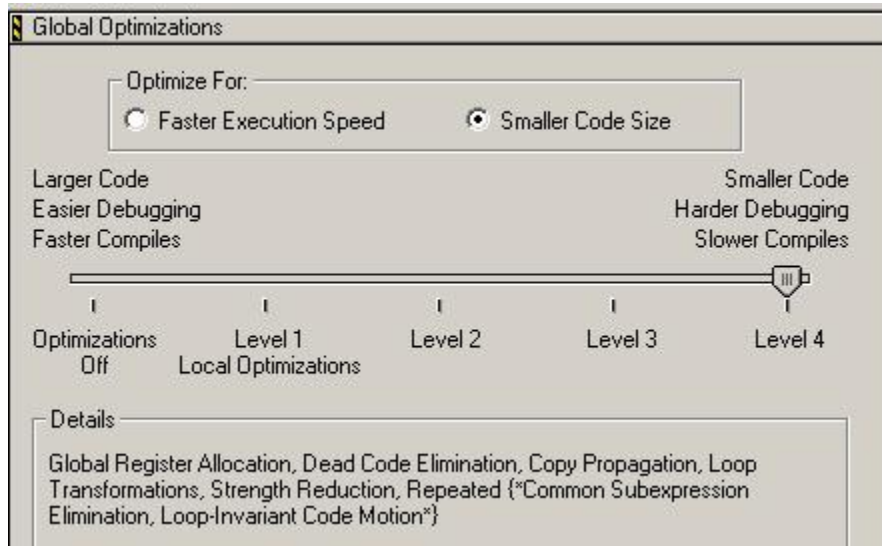

As described in “Build Integrated Code Outside the Simulink Environment” on page 48-66 and “Test Generated Code” on page 48-73, the generated code can require the use of utility functions. The utility functions incur a one-time, fixed cost of memory. Due to this fixed overhead, the data in this example show memory usage for:

- Algorithms: The C code generated from the Simulink® block diagrams plus the data definition functions

- Utilities: Functions that are part of the Simulink® Coder™ library source
- Full: The sum of both the algorithm and utilities

### Build Options Configuration

The three evaluations in this example use the same build configuration. Freescale™ CodeWarrior® was configured to minimize memory usage and apply all applicable optimizations.

### Configuration 1: Reusable Functions with Data Type Double

- **Source files:** PCG\_Eval\_File\_1.zip
- **Data Type:** All doubles
- **Included Data:** The project includes all data that the build requires (including data declared as extern: pos\_rqst, fbk\_1, and fbk\_2)
- **Main Function:** A modified version of example\_main from “Build Integrated Code Outside the Simulink Environment” on page 48-66
- **Function Call Method:** Reusable functions for the PI controllers

defineImportedData.c	12	28	•
defineImportedData.h	0	0	
eval_data.c	0	288	•
eval_data.h	0	0	
example_main.c	260	88	•
PCG_Eval_Fil_Define_Throt_Param.c	52	8	•
PCG_Eval_Fil_Define_Throt_Param.h	0	0	
PCG_Eval_File_1.c	464	92	•
PCG_Eval_File_1.h	0	0	
PCG_Eval_File_1_private.h	0	0	
PCG_Eval_File_1_types.h	0	0	
PI_Cntrl_Reusable.c	384	44	•
PI_Cntrl_Reusable.h	0	0	
rt_look1d.c	220	20	•
rt_look.c	372	20	•

**Utilities** **Func | Data**

## Memory Usage

	Function	Data
Algorithms	1172 bytes	549 bytes
Utilities	592 bytes	40 bytes
Full	1764 bytes	589 bytes

## Configuration 2: Reusable Functions with Data Type Single

In this configuration, the model data use a single-precision floating-point data type instead of double precision.

### Model Configuration

- **Source files:** PCG\_Eval\_File\_2.zip
- **Data Type:** All singles
- **Included Data:** The project includes all data that the build requires (including data declared as extern: pos\_rqst, fbk\_1, and fbk\_2)
- **Main Function:** A modified version of example\_main from “Build Integrated Code Outside the Simulink Environment” on page 48-66
- **Function Call Method:** Reusable functions for the PI controllers

### Memory Usage

	Function	Data
Algorithms	800 bytes	308 bytes
Utilities	592 bytes	40 bytes
Full	1392 bytes	348 bytes

This configuration uses only 56% of the data memory from the first configuration: 308 bytes instead of 549 bytes. This configuration also uses 68% of the function memory: 800 bytes instead of 1172 bytes. For this system, using single precision instead of double precision does not affect the accuracy of the control algorithm, so you can use this configuration to achieve more efficient code.

### Configuration 3: Nonreusable Functions with Data Type Single

- **Source files:** PCG\_Eval\_File\_3.zip
- **Data Type:** All singles
- **Included Data:** The project includes all data that the build requires (including data declared as extern: pos\_rqst, fbk\_1, and fbk\_2)
- **Main Function:** A modified version of `example_main` from “Build Integrated Code Outside the Simulink Environment” on page 48-66
- **Function Call Method:** The function interface is `void void` so data exchange occurs through global variables

### Memory Usage

	Function	Data
Algorithms	948 bytes	348 bytes
Utilities	592 bytes	40 bytes
Full	1540 bytes	388 bytes

This configuration consumes more data and function memory than the previous configuration.

## Install and Use Cygwin and Eclipse

Use Eclipse™ and Cygwin™, a free software integration development environment (IDE) and free compiler, for the examples “Build Integrated Code Outside the Simulink Environment” on page 48-66 and “Test Generated Code” on page 48-73.

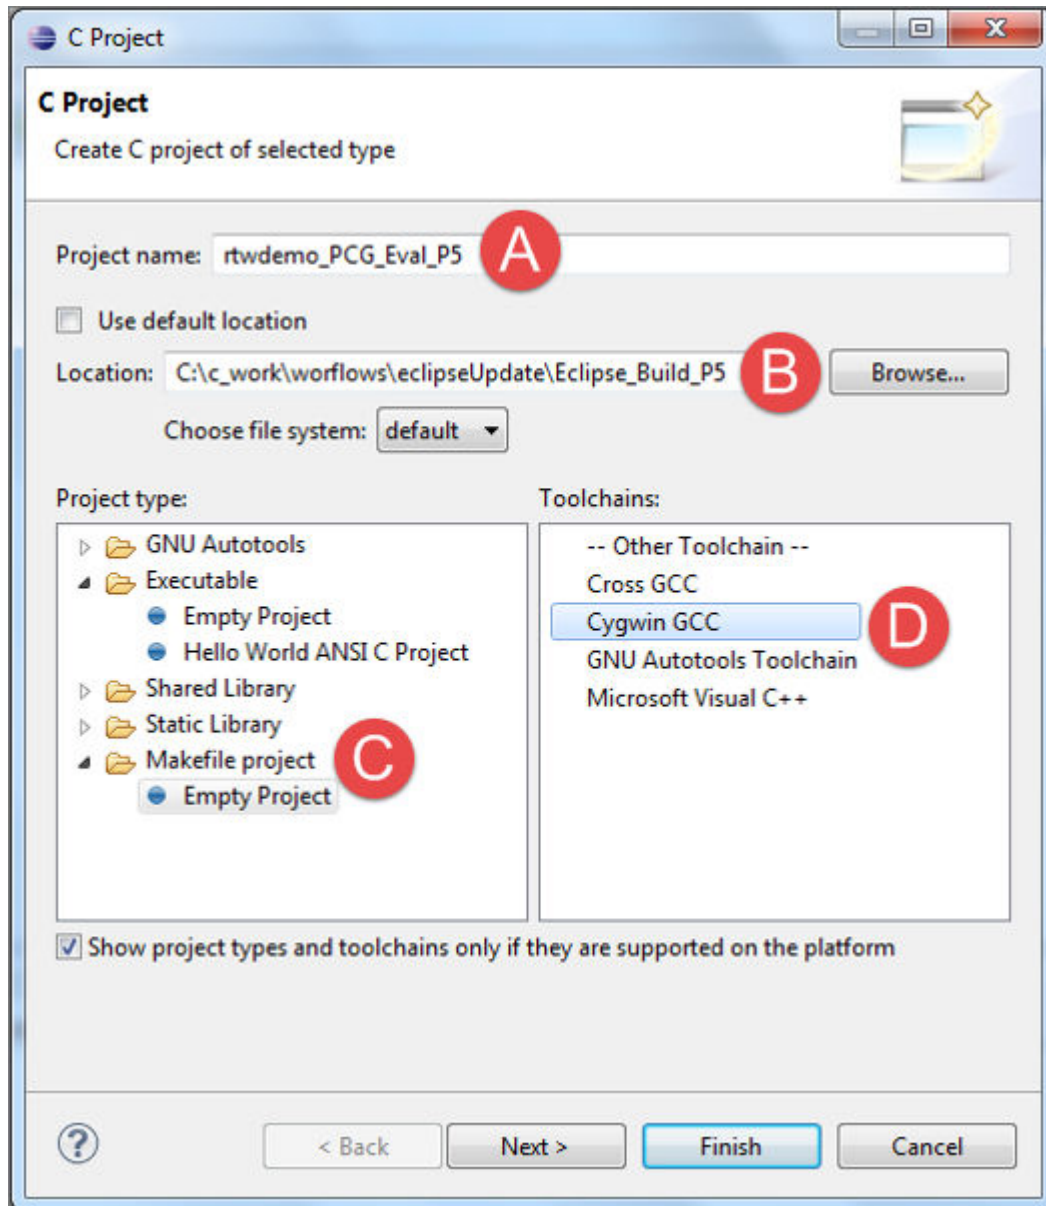

For information about the example model and other examples in this series, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Create an Eclipse CDT Managed Make C Project

1. Open Eclipse.
2. Select **File > New > C Project**.

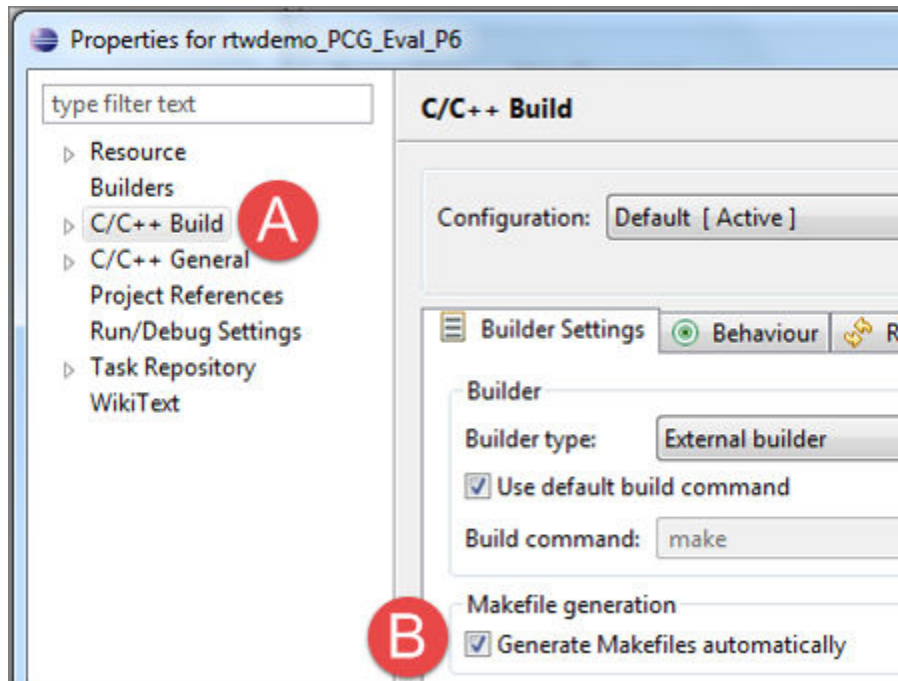

3. Use the **C Project** dialog box to configure the project.
  - a. Specify the project name.
  - b. Select the project location.
  - c. Select the project type as **Makefile**.
  - d. Select the Cygwin GCC toolchain and click **Finish**.

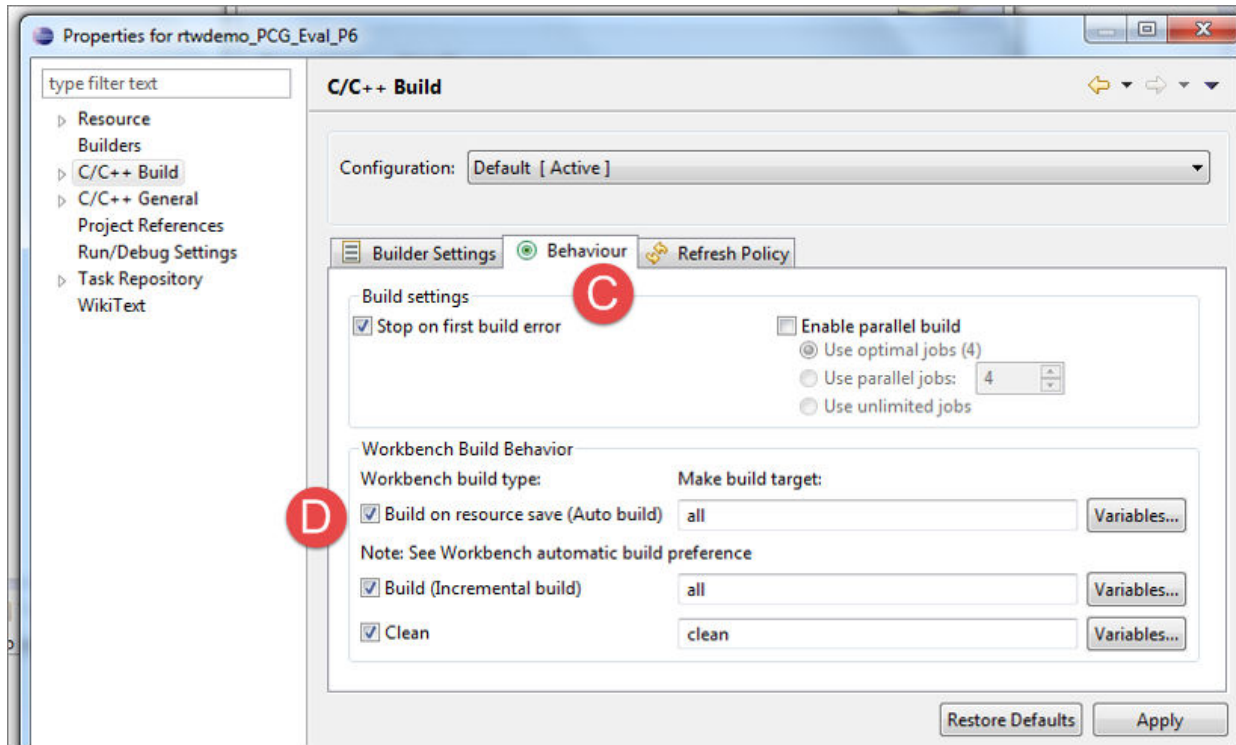

4. Select **Project > Properties**. Use **Advanced settings** to fully configure the project.

- a. Select the **C/C++ Build** properties.
- b. On the **Builder Settings** tab, select **Generate Makefiles automatically**.

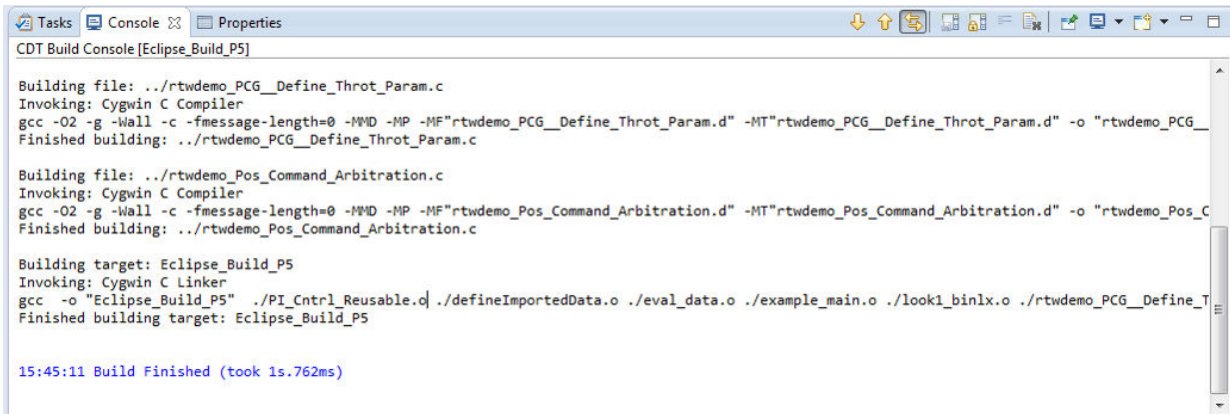

- c. View the **Behaviour** tab.
- d. Select **Build on resource save (Auto build)**.

##### 5. Compile the generated code with Eclipse.

After you define the files, Eclipse determines the main function and builds the project with the managed make environment. The build details appear in the Console window.

```
CDT Build Console [Eclipse_Build_P5]

Building file: ../rtwdemo_PCG_Define_Throt_Param.c
Invoking: Cygwin C Compiler
gcc -O2 -g -Wall -c -fmessage-length=0 -MMD -MP -MF"rtwdemo_PCG_Define_Throt_Param.d" -MT"rtwdemo_PCG_Define_Throt_Param.d" -o "rtwdemo_PCG_
Finished building: ../rtwdemo_PCG_Define_Throt_Param.c

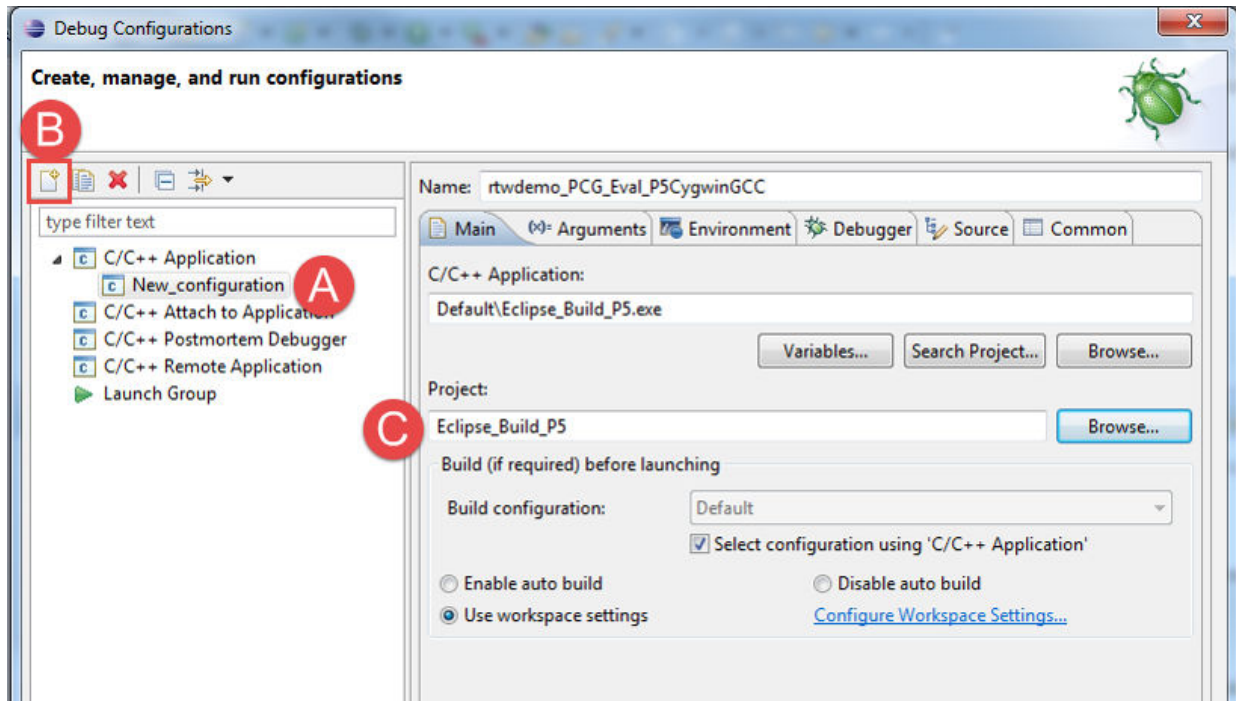

Building file: ../rtwdemo_Pos_Command_Arbitration.c
Invoking: Cygwin C Compiler
gcc -O2 -g -Wall -c -fmessage-length=0 -MMD -MP -MF"rtwdemo_Pos_Command_Arbitration.d" -MT"rtwdemo_Pos_Command_Arbitration.d" -o "rtwdemo_Pos_C
Finished building: ../rtwdemo_Pos_Command_Arbitration.c

Building target: Eclipse_Build_P5

```

## Use Eclipse Debugger with the Generated Code

1. Select **Run > Debug Configurations**.
2. Use the **Debug Configurations** dialog box to configure the debugger.
  - a. Select **C/C++ Application**.
  - b. Click the new configuration button.
  - c. Select the project.

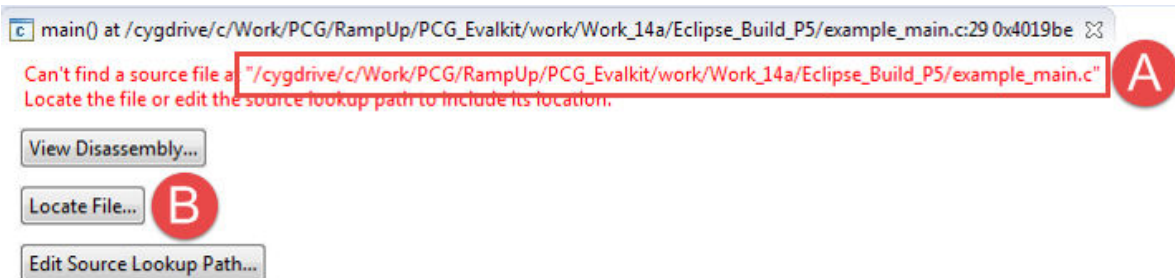

d. Click **Apply**. Do not click **Run**.

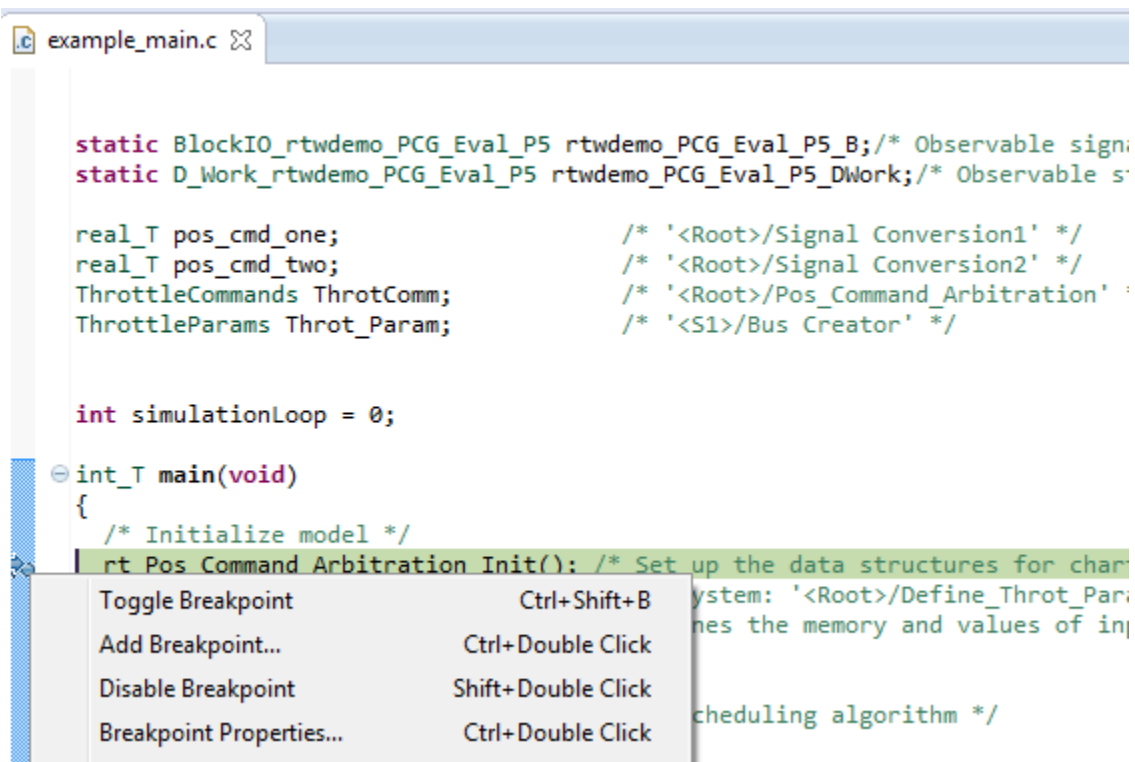

If required, select the executable. Eclipse automatically finds the exe file.

3. To start the debugger, from the primary Eclipse window, select **Run > Debug**.

During the build process, Cygwin creates a virtual drive, `/cygdrive/c/`. To run the debugger, Eclipse either remaps the drive or locates the files. After locating the first file, Eclipse finds the remaining files.

4. Run the debugger on the generated code.

### Use Eclipse Debugger Commands

You can use these commands from the debugger context menu:

- **F5**: Step into
- **F6**: Step over
- **F7**: Step out
- **F8**: Resume
- **Ctrl+Shift+B**: Toggle break point
- **Ctrl+Shift+R**: Run to line
- **Shift+F5**: Use Step Filters

## Reports for Code Generation

### In this section...

“HTML Code Generation Report Location” on page 49-2

“HTML Code Generation Report for Referenced Models” on page 49-3

“HTML Code Generation Report Extensions” on page 49-3

The code generator software produces an HTML code generation report so that you can view and analyze the generated code. When your model is built, the code generation process produces an HTML file that is displayed in an HTML browser or in the Model Explorer. The code generation report includes:

- The **Summary** section that contains model and code information, including **Author**, **Tasking Mode**, **System Target File**, **Hardware Device Type**, and code generation objectives information. The **Configuration settings at the time of code generation** link opens a noneditable view of the Configuration Parameters dialog box. The dialog box shows the Simulink model settings at the time of code generation, including TLC options.
- The **Subsystem Report** section that contains information on nonvirtual subsystems in the model.
- In the **Generated Files** section on the **Contents** pane, you can click the names of source code files generated from your model to view their contents in a MATLAB Web browser window. In the displayed source code, global variables are hypertext that links to their definitions.

For an example, see “Generate a Code Generation Report” on page 49-6.

If you have a Simulink Report Generator license, you can document your code generation project in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. For an example of how to create a Microsoft Word report, see “Document Generated Code with Simulink Report Generator” on page 49-48.

### HTML Code Generation Report Location

The default location for the code generation report files is in the `html` subfolder of the build folder, `model_target_rtw/html/`. `target` is the name of the **System target file** specified on the **Code Generation** pane. The default name for the top-level HTML report file is `model_codegen_rpt.html` or `subsystem_codegen_rpt.html`. For more

information on the location of the build folder, see “Manage Build Process Folders” (Simulink Coder).

## HTML Code Generation Report for Referenced Models

To generate a code generation report for a top model and code generation reports for each referenced model, you need to specify the **Create code generation report** on the **Code Generation > Report** pane for the top model and each referenced model. You can open the code generation report of a referenced model in one of two ways:

- From the top-model code generation report, you can access the referenced model code generation report by clicking a link under **Referenced Models** in the left navigation pane. Clicking a link opens the code generation report for the referenced model in the browser. To navigate back to the top model code generation report, use the **Back** button at the top of the left navigation pane.
- In the referenced model diagram window, on the **C Code** tab, click **Open Report**.

For more information, see “Generate Code for Referenced Models” (Simulink Coder)

## HTML Code Generation Report Extensions

If you have an Embedded Coder license, the code generator enhances the HTML code generation report. Configure your model to include the following sections in the report:

- The **Code Interface Report** section provides information about the generated code interface, including model entry-point functions and input/output data. For more information, see “Analyze the Generated Code Interface” on page 49-18.
- The **Traceability Report** section allows you to account for **Eliminated / Virtual Blocks** that are untraceable versus the listed **Traceable Simulink Blocks / Stateflow Objects / MATLAB Scripts**. This provides a complete mapping between model elements and code. For more information, see “Customize Traceability Reports” on page 75-39.
- The **Static Code Metrics Report** section provides statistics of the generated code. Metrics are estimated from static analysis of the generated code. For more information, see “Static Code Metrics” on page 49-32.
- The **Code Replacements Report** section allows you to account for code replacement library (CRL) functions that were used during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the

replacement. For more information, see “Analyze Code Replacements in Generated Code” on page 49-46.

- The **Coder Assumptions** section provides a list of:
  - Code generation assumptions for your target hardware that you can check.
  - Expected results for the assumption checks.

For more information, see “Check Code Generation Assumptions” on page 53-17.

- The model Web view displays an interactive model diagram within the code generation report and supports traceability between the source code and the model. Therefore, you can share your model and generated code outside of the MATLAB environment. For more information, see “Web View of Model in Code Generation Report” on page 49-14.

On the **Contents** pane, in the **Generated Files** section, you can click the names of source code files generated from your model to view their contents in a MATLAB Web browser window. In the displayed source code:

- If you enable code-to-model traceability, hyperlinks within the displayed source code navigate to the blocks or subsystems from which the code is generated. For more information, see “Code-to-Model Traceability” on page 75-10.
- If you enable model-to-code traceability, you can navigate to the generated code for a block in the model. For more information, see “Model-to-Code Traceability” on page 75-12.
- If you set the **Code coverage tool** parameter on the **Code Generation > Verification** pane, you can view the code coverage data and annotations. For more information, see “Configure Code Coverage with Third-Party Tools” on page 81-12.
- If you select the **Static code metrics** check box on the **Code Generation > Report** pane, you can view code metrics information and navigate to code definitions and declarations in the generated code. For more information, see “View Static Code Metrics and Definitions Within the Generated Code” on page 49-35.

---

**Note** To view the contents of your generated code and navigate between model and code, you can also use the Code view in the Code perspective. In the perspective, click the **Code** tab in the bottom-right corner.

---

### Related Examples

- “Verify Generated Code by Using Code Tracing” on page 75-2

## Generate a Code Generation Report

To generate a code generation report when the model is built:

- 1** On the **C Code** tab, from the **Open Report** list, select **Report Options**. The Configuration Parameters dialog box opens with the **Code Generation > Report** pane visible.
- 2** Select the **Create code generation report** (Simulink Coder) parameter.
- 3** If you want the code generation report to automatically open after generating code, select the **Open report automatically** (Simulink Coder) parameter (which is enabled by selecting **Create code generation report**).
- 4** Generate code.

The build process writes the code generation report files to the `html` subfolder of the build folder (see “HTML Code Generation Report Location” on page 49-2). Next, the build process automatically opens a MATLAB Web browser window and displays the code generation report.

To open an HTML code generation report at any time after a build, see “Open Code Generation Report” on page 49-9 and “Generate Code Generation Report After Build Process” on page 49-7.

## Generate Code Generation Report After Build Process

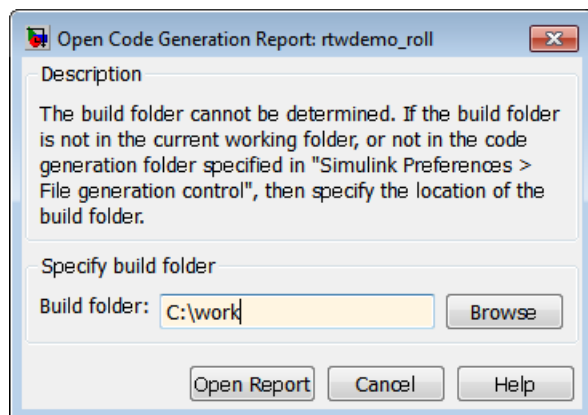

After generating code, if you did not configure your model to create a code generation report, you can generate a code generation report without rebuilding your model.

- 1 In the model diagram window, on the **C Code** tab, select **Open Report**.
- 2 If your current working folder contains the code generation files the following dialog opens.

Click **Generate Report**.

- 3 If the code generation files are not in your current working folder, this dialog box opens.

Enter the full path of the build folder for your model, `../model_target_rtw` and click **Open Report**.

The software generates a report, `model_codgen_rpt.html`, from the code generation files in the build folder you specified.

---

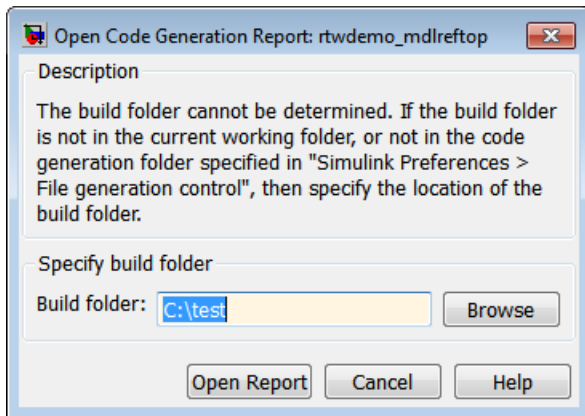

**Note** An alternative method for generating the report after the build process is complete is to configure your model to generate a report and build your model. In this case, the software generates the report without regenerating the code.

---

## Open Code Generation Report

You can refer to existing code generation reports at any time. If you generated a code generation report, in the Simulink Editor, open the report by clicking **Open Report** on the **C Code** tab. A Simulink Coder license is required to view the code generation report. An Embedded Coder license is required to view a code generation report enhanced with Embedded Coder features.

If your current working folder does not contain the code generation files and the code generation report, the following dialog box opens:

Enter the full path of the build folder for your model, `../model_target_rtw` and click **Open Report**.

Alternatively, you can open the code generation report (`model_codegen_rpt.html` or `subsystem_codegen_rpt.html`) manually into a MATLAB Web browser window, or in another Web browser. For the location of the generated report files, see "HTML Code Generation Report Location" on page 49-2.

### Limitation

After building your model or generating the code generation report, if you modify legacy or custom code, you must rebuild your model or regenerate the report for the code generation report to include the updated legacy source files. For example, if you modify your legacy code, and then use the **Open Report** button to open an existing report, the software does not check if the legacy source file is out of date compared to the generated

code. Therefore, the code generation report is not regenerated and the report includes the out-of-date legacy code. This issue also occurs if you open a code generation report using the `coder.report.open` function.

To regenerate the code generation report, do one of the following:

- Rebuild your model.
- Generate the report using the `coder.report.generate` function.

## Generate Code Generation Report Programmatically

At the MATLAB command line, you can generate, open, and close an HTML Code Generation Report with the following functions:

- `coder.report.generate` generates the code generation report for the specified model.
- `coder.report.open` opens an existing code generation report.
- `coder.report.close` closes the code generation report.

## Package and Share the Code Generation Report

### In this section...

“Package the Code Generation Report” on page 49-12

“View the Code Generation Report” on page 49-13

### Package the Code Generation Report

To share the code generation report, you can package the code generation report files and supporting files into a zip file for transfer. The default location for the code generation report files is in two folders:

- /slprj
- html subfolder of the build folder, *model\_target\_rtw*, for example *rtwdemo\_counter\_grt\_rtw/html*

To create a zip file from the MATLAB command window:

- 1 In the Current Folder browser, select the two folders:
  - /slprj
  - Build folder: *model\_target\_rtw*
- 2 Right-click to open the context menu.
- 3 In the context menu, select **Create Zip File**. A file appears in the Current Folder browser.
- 4 Name the zip file.

Alternatively, you can use the MATLAB `zip` command to zip the code generation report files:

```
zip('myzip',{'slprj','rtwdemo_counter_grt_rtw'})
```

---

**Note** If you need to relocate the static and generated code files for a model to another development environment, such as a system or an integrated development environment (IDE) that does not include MATLAB and Simulink products, use the code generator pack-and-go utility. For more information, see “Relocate Code to Another Development Environment” (Simulink Coder).

---

## View the Code Generation Report

To view the code generation report after transfer, unzip the file and save the two folders at the same folder level in the hierarchy. Navigate to the *model\_target\_rtw/html/* folder and open the top-level HTML report file named *model\_codgen\_rpt.html* or *subsystem\_codegen\_rpt.html* in a Web browser.

## Web View of Model in Code Generation Report

### In this section...

“About Model Web View” on page 49-14

“Generate HTML Code Generation Report with Model Web View” on page 49-14

“Model Web View Limitations” on page 49-17

### About Model Web View

To review and analyze the generated code, it is helpful to navigate between the code and model. You can include a Web view of the model within the HTML code generation report. You can then share your model and generated code outside of the MATLAB environment. When you generate the report, the Web view includes the block diagram attributes displayed in the Simulink Editor, such as, block sorted execution order, signal properties, and port data types.

A Simulink Report Generator license is required to include a Web view (Simulink Report Generator) of the model in the code generation report.

### Browser Requirements for Web View

Web view requires a Web browser that supports Scalable Vector Graphics (SVG). Web view uses SVG to render and navigate models.

You can use the following Web browsers:

- Mozilla Firefox Version 1.5 or later, which has native support for SVG. To download the Firefox browser, go to [www.mozilla.com/](http://www.mozilla.com/).
- The Microsoft Internet Explorer® Web browser with the Adobe® SVG Viewer plug-in. To download the Adobe SVG Viewer plug-in, go to [www.adobe.com/svg/](http://www.adobe.com/svg/).
- Apple Safari Web browser

### Generate HTML Code Generation Report with Model Web View

This example shows how to create an HTML code generation report which includes a Web view of the model diagram.

- 1 Open the `rtwdemo_mdltreftop` model.
- 2 Open the Configuration Parameters dialog box and navigate to the **Code Generation** pane.
- 3 Specify `ert.tlc` for the **System target file** parameter.
- 4 Open the **Code Generation > Report** pane.
- 5 Select the following parameters:
  - **Create code generation report**
  - **Open report automatically**
  - **Generate model Web view**
- 6 Select the parameters **Code-to-model** and **Model-to-code**.

---

**Note** These settings specify only the top model, not referenced models.

- 7 Open the Configuration Parameters for the referenced model, `rtwdemo_mdltreftop` and perform steps 3-6.
- 8 Save the models, `rtwdemo_mdltreftop` and `rtwdemo_mdltreftop`.
- 9 From the top model diagram, press `Ctrl+B`. After building the model and generating code, the code generation report for the top model opens in a MATLAB Web browser.
- 10 In the left navigation pane, select a source code file. The corresponding source code is displayed in the right pane and includes hyperlinks.

The screenshot shows the 'Code Generation Report' window. The top pane displays C code for a model step function. The middle pane shows a block diagram of the 'rtwdemo\_mdireftop' model with three referenced blocks: CounterA, CounterB, and CounterC. CounterB is highlighted in green. The bottom right pane shows the 'Parameter Attributes' for the model, including ModelVersion (1.205), LastModifiedDate (Mon Jun 30 11:33:32 2014), and a description of Model Reference.

```

48
49 /* Model step function */
50 void rtwdemo_mdireftop_step(void)
51 {
52     /* local block i/o variables */
53     real_T rtb_output;
54     real_T rtb_output_o;
55     real_T rtb_output_of;
56     real_T rtb_PulseTs01;
57
58     /* DiscretePulseGenerator: '<Root>/Pulse (Ts=0.1)' */
59     rtb_PulseTs01 = ((rtwdemo_mdireftop_DW.clockTickCounter < 1) &&
60                     (rtwdemo_mdireftop_DW.clockTickCounter >= 0));
61     if (rtwdemo_mdireftop_DW.clockTickCounter >= 1) {
62         rtwdemo_mdireftop_DW.clockTickCounter = 0;
63     } else {
64         rtwdemo_mdireftop_DW.clockTickCounter++;
65     }
66
67     /* End of DiscretePulseGenerator: '<Root>/Pulse (Ts=0.1)' */

```

OK Help

- 11 Click a link in the code. The model Web view displays and highlights the corresponding block in the model.
- 12 To highlight the generated code for a referenced model block in your model, click CounterB. The corresponding code is highlighted in the source code pane.

**Note** You cannot open the referenced model diagram in the Web view by double-clicking the referenced model block in the top model.

- 13 To open the code generation report for a referenced model, in the left navigation pane, below **Referenced Models**, click the link, `rtwdemo_mdireftop`. The source files for the referenced model are displayed along with the Web view of the referenced model.

- 14** To go back to the code generation report for the top model, at the top of the left navigation pane, click the **Back** button until the top model's report is displayed.

For more information about exploring a model in a Web view, see “Navigate the Web View” (Simulink Report Generator).

For more information about navigating between the generated code and the model diagram, see “Trace Simulink Model Elements in Generated Code” on page 75-10.

## Model Web View Limitations

The HTML code generation report includes the following limitations when using the model Web view:

- Code is not generated for virtual blocks. In the model Web view of the code generation report, when tracing between the model and the code, when you click a virtual block, it is highlighted yellow.
- In the model Web view, you cannot open a referenced model diagram by double-clicking the referenced model block in the top model. Instead, open the code generation report for the referenced model by clicking a link under **Referenced Models** in the left navigation pane.
- Stateflow truth tables, events, and links to library charts are not supported in the model Web view.
- Searching in the code generation report does not find or highlight text in the model Web view.
- If you navigate from the actual model diagram (not the model Web view in the report), to the source code in the HTML code generation report, the model Web view is disabled and not visible. To enable the model Web view, open the report again, see “Open Code Generation Report” (Simulink Coder).
- For a subsystem build, the traceability hyperlinks of the root level inport and output blocks are disabled.
- “Traceability Limitations” on page 75-8 that apply to tracing between the code and the actual model diagram.

## Analyze the Generated Code Interface

### In this section...

- “Code Interface Report Overview” on page 49-18
- “Generating a Code Interface Report” on page 49-19
- “Navigating Code Interface Report Subsections” on page 49-21
- “Interpreting the Entry-Point Functions Subsection” on page 49-22
- “Interpreting the Inports and Outports Subsections” on page 49-25
- “Interpreting the Interface Parameters Subsection” on page 49-27
- “Interpreting the Data Stores Subsection” on page 49-29
- “Code Interface Report Limitations” on page 49-30

### Code Interface Report Overview

When you select the **Create code generation report** option for an ERT-based model, a **Code Interface Report** section is automatically included in the generated HTML report. The **Code Interface Report** section provides documentation of the generated code interface, including model entry-point functions and interface data, for consumers of the generated code. The information in the report can help facilitate code review and code integration.

The code interface report includes the following subsections:

- **Entry-Point Functions** — interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.
- **Inports and Outports** — interface information about each model inport and output.
- **Interface Parameters** — interface information about tunable parameters that are associated with the model.
- **Data Stores** — interface information about global data stores and data stores with non-auto storage that are associated with the model.

For limitations that apply to code interface reports, see “Code Interface Report Limitations” on page 49-30.

For illustration purposes, this section uses the following models:

- `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window) for examples of report subsections
- `rtwdemo_mrmtbb` for examples of timing information
- `rtwdemo_fcnprotoctrl` for examples of function argument and return value information

## Generating a Code Interface Report

To generate a code interface report for your model:

- 1 Open your model, go to the **Code Generation** pane of the Configuration Parameters dialog box, and select `ert.tlc` or an ERT-based **System target file**, if one is not already selected.
- 2 Go to the **Code Generation > Report** pane of the Configuration Parameters dialog box and select the option **Create code generation report**, if it is not already selected. The `rtwdemo_basicsc`, `rtwdemo_mrmtbb`, and `rtwdemo_fcnprotoctrl` models used in this section select multiple **Report** pane options by default. But selecting only **Create code generation report**, generates a **Code Interface Report** section in the HTML report.

Alternatively, you can programmatically select the option by issuing the following MATLAB command:

```
set_param(bdroot, 'GenerateReport', 'on')
```

If the **Code-to-model** parameter is selected, the generated report contains hyperlinks to the model. Leave this value selected unless you plan to use the report outside the MATLAB environment.

- 3 Build the model. If you selected the **Report** pane option **Open report automatically**, the code generation report opens automatically after the build process is complete. (Otherwise, you can open it manually from within the model build folder.)
- 4 To display the code interface report for your model, go to the **Contents** pane of the HTML report and click the **Code Interface Report** link. For example, here is the generated code interface report for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

## Code Interface Report for rtwdemo\_basicsc

### Table of Contents

- [Interface Parameters](#)
- [Data Stores](#)

### Entry-Point Functions

Function: [rtwdemo\\_basicsc\\_initialize](#)

Prototype	<b>void rtwdemo_basicsc_initialize(void)</b>
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_basicsc.h</a>

Function: [rtwdemo\\_basicsc\\_step](#)

Prototype	<b>void rtwdemo_basicsc_step(void)</b>
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_basicsc.h</a>

### Inports

[-]

Block Name	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/In1</a>	input1	real32_T	1
<a href="#">&lt;Root&gt;/In2</a>	input2	real32_T	1
<a href="#">&lt;Root&gt;/In3</a>	input3	real32_T	1
<a href="#">&lt;Root&gt;/In4</a>	input4	real32_T	1

### Outports

Block Name	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/Out1</a>	output	real32_T	1

### Interface Parameters

[-]

Parameter Source	Code Identifier	Data Type	Dimension
K2	K2	real_T	1
LOWER	LOWER	real32_T	1
T1Break	T1Break	real32_T	[1 11]
T1Data	T1Data	real32_T	[1 11]
T2Break	T2Break	real32_T	[1 3]
T2Data	T2Data	real32_T	[3 3]
UPPER	UPPER	real32_T	1
K1	K1	int8_T	1

### Data Stores

Data Store Source	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/Data Store Memory</a>	mode	boolean_T	1

For help navigating the content of the code interface report subsections, see “Navigating Code Interface Report Subsections” on page 49-21. For help interpreting the content of the code interface report subsections, see the sections beginning with “Interpreting the Entry-Point Functions Subsection” on page 49-22.

## Navigating Code Interface Report Subsections

To help you navigate code interface descriptions, the code interface report provides collapse/expand tokens and hyperlinks, as follows:

- For a large subsection, the report provides [-] and [+] symbols that allow you to collapse or expand that section. In the example in the previous section, the symbols are provided for the **Inports** and **Interface Parameters** sections.
- Several forms of hyperlink navigation are provided in the code interface report. For example:
  - The **Table of Contents** located at the top of the code interface report provides links to each subsection.
  - You can click each function name to go to its definition in *model.c*.
  - You can click each function's header file name to go to the header file source listing.
  - If you selected the **Code-to-model** parameter for your model, to go to the corresponding location in the model display, you can click hyperlinks for any of the following:
    - Function argument
    - Function return value
    - Inport
    - Outport
    - Interface parameter (if the parameter source is a block)
    - Data store (if the data store source is a Data Store Memory block)

For backward and forward navigation within the HTML code generation report, use the **Back** and **Forward** buttons above the **Contents** section in the upper-left corner of the report.

## Interpreting the Entry-Point Functions Subsection

The **Entry-Point Functions** subsection of the code interface report provides the following interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.

Field	Description
<b>Function:</b>	Lists the function name. You can click the function name to go to its definition in <code>model.c</code> .
<b>Prototype</b>	Displays the function prototype, including the function return value, name, and arguments.
<b>Description</b>	Provides a text description of the function's purpose in the application.
<b>Timing</b>	Describes the timing characteristics of the function, such as how many times the function is called, or if it is called periodically, and at what time interval. For a multirate timing example, see the following <code>rtwdemo_mrmtbb</code> report excerpt.
<b>Arguments</b>	If the function has arguments, displays the number, name, data type, and Simulink description for each argument. If you select the <b>Code-to-model</b> parameter for your model, you can click the hyperlink in the description to go to the block corresponding to the argument in the model display. For argument examples, see the <code>rtwdemo_fcncnprotoctrl</code> report excerpt below.
<b>Return value</b>	If the function has a return value, this field displays the return value data type and Simulink description. If you selected the <b>Code-to-model</b> parameter for your model, you can click the hyperlink in the description to go to the block corresponding to the return value in the model display. For a return value example, see the following <code>rtwdemo_fcncnprotoctrl</code> report excerpt.
<b>Header file</b>	Lists the name of the header file for the function. You can click the header file name to go to the header file source listing.

For example, here is the **Entry-Point Functions** subsection for the model `rtwdemo_basicsc`.

**Entry-Point Functions**Function: [rtwdemo\\_basicsc\\_initialize](#)

Prototype	<b>void rtwdemo_basicsc_initialize(void)</b>
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_basicsc.h</a>

Function: [rtwdemo\\_basicsc\\_step](#)

Prototype	<b>void rtwdemo_basicsc_step(void)</b>
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_basicsc.h</a>

To illustrate how timing information might be listed for a multirate model, here are the **Entry-Point Functions** and **Inports** subsections for the model `rtwdemo_mrmtbb`. This multirate, discrete-time, multitasking model contains Inport blocks 1 and 2, which specify 1-second and 2-second sample times, respectively. The sample times are constrained to the specified times by the **Periodic sample time constraint** option on the **Solver** pane of the Configuration Parameters dialog box.

**Entry-Point Functions**

Function: [rtwdemo\\_mrmtbb\\_initialize](#)

Prototype	<b>void rtwdemo_mrmtbb_initialize(void)</b>
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_mrmtbb.h</a>

Function: [rtwdemo\\_mrmtbb\\_step0](#)

Prototype	<b>void rtwdemo_mrmtbb_step0(void)</b>
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_mrmtbb.h</a>

Function: [rtwdemo\\_mrmtbb\\_step1](#)

Prototype	<b>void rtwdemo_mrmtbb_step1(void)</b>
Description	Output entry point of generated code
Timing	Must be called periodically, every 2 seconds
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_mrmtbb.h</a>

**Inports**

Block Name	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/In1_1s</a>	rtU.In1_1s	real_T	1
<a href="#">&lt;Root&gt;/In2_2s</a>	rtU.In2_2s	real_T	1

To illustrate how function arguments and return values are displayed in the report, here is the entry-point function description of the model step function for model `rtwdemo_fcnpctctrl`.

Function: [rtwdemo\\_fcnprotctrl\\_step\\_custom](#)

Prototype	<b>boolean_T</b> <b>rtwdemo_fcnprotctrl_step_custom(const real_T argIn1, const BusObject *const argIn2, BusObject *argOut2, const BusObject *const argIn3, uint8_T *argIn4)</b>		
Description	Output entry point of generated code		
Timing	Can be called at any time		
Arguments	[-]		
	<b># Name</b>	<b>Data Type</b>	<b>Description</b>
	1 argIn1	const real_T	<a href="#">&lt;Root&gt;/In1</a>
	2 argIn2	const BusObject *const	<a href="#">&lt;Root&gt;/In2</a>
	3 argOut2	BusObject *	<a href="#">&lt;Root&gt;/Out2</a>
	4 argIn3	const BusObject *const	<a href="#">&lt;Root&gt;/In3</a>
	5 argIn4	uint8_T *	<a href="#">&lt;Root&gt;/In4</a>
Return value	<b>Data Type</b>	<b>Description</b>	
	<b>boolean_T</b>	<a href="#">&lt;Root&gt;/Out1</a>	
Header file	<a href="#">rtwdemo_fcnprotctrl.h</a>		

## Interpreting the Inports and Outports Subsections

The **Inports** and **Outports** subsections of the code interface report provide the following interface information about each inport and outport in the model.

Field	Description
<b>Block Name</b>	Displays the Simulink block name of the inport or outport. If you selected the <b>Code-to-model</b> parameter for your model, you can click on each inport or outport <b>Block Name</b> value to go to its location in the model display.

Field	Description
<b>Code Identifier</b>	<p>Lists the identifier associated with the inport or output data in the generated code, as follows:</p> <ul style="list-style-type: none"> <li>• If the data is defined in the generated code, the field displays the identifier text.</li> <li>• If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</li> <li>• If the data is neither defined nor declared in the generated code — for example, if model configuration parameter <b>Code interface packaging</b> is set to Reusable function — the field displays the text 'Defined externally'.</li> </ul>
<b>Data Type</b>	Lists the data type of the inport or output.
<b>Scaling</b>	<p>For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation.</p> <hr/> <p><b>Note</b> You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).</p>
<b>Dimension</b>	Lists the dimensions of the inport or output (for example, 1 or [4, 5]).

For example, here are the **Inports** and **Outports** subsections for the model `rtwdemo_basicsc`.

## Inports

[-]

Block Name	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/In1</a>	input1	real32_T	1
<a href="#">&lt;Root&gt;/In2</a>	input2	real32_T	1
<a href="#">&lt;Root&gt;/In3</a>	input3	real32_T	1
<a href="#">&lt;Root&gt;/In4</a>	input4	real32_T	1

## Outputs

Block Name	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/Out1</a>	output	real32_T	1

## Interpreting the Interface Parameters Subsection

The **Interface Parameters** subsection of the code interface report provides the following interface information about tunable parameters that are associated with the model.

Field	Description
<b>Parameter Source</b>	<p>Lists the source of the parameter value, as follows:</p> <ul style="list-style-type: none"> <li>If the source of the parameter value is a block, the field displays the block name, such as &lt;Root&gt;/Gain2 or &lt;S1&gt;/Lookup1. If you selected the <b>Code-to-model</b> parameter for your model, you can click the <b>Parameter Source</b> value to go to the parameter's location in the model display.</li> <li>If the source of the parameter value is a workspace variable, the field displays the name of the workspace variable.</li> </ul>

Field	Description
<b>Code Identifier</b>	<p>Lists the identifier associated with the tunable parameter data in the generated code, as follows:</p> <ul style="list-style-type: none"> <li>• If the data is defined in the generated code, the field displays the identifier text.</li> <li>• If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</li> <li>• If the data is neither defined nor declared in the generated code — for example, if model configuration parameter <b>Code interface packaging</b> is set to <b>Reusable function</b> — the field displays the text 'Defined externally'.</li> </ul>
<b>Data Type</b>	Lists the data type of the tunable parameter.
<b>Scaling</b>	<p>For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation.</p> <hr/> <p><b>Note</b> You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).</p>
<b>Dimension</b>	Lists the dimensions of the tunable parameter (for example, 1 or [4, 5, 6]).

For example, here is the **Interface Parameters** subsection for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

## Interface Parameters

[-]			
Parameter Source	Code Identifier	Data Type	Dimension
K2	K2	real_T	1
LOWER	LOWER	real32_T	1
T1Break	T1Break	real32_T	[1 11]
T1Data	T1Data	real32_T	[1 11]
T2Break	T2Break	real32_T	[1 3]
T2Data	T2Data	real32_T	[3 3]
UPPER	UPPER	real32_T	1
K1	K1	int8_T	1

## Interpreting the Data Stores Subsection

The **Data Stores** subsection of the code interface report provides the following interface information about global data stores and data stores with non-auto storage that are associated with the model.

Field	Description
<b>Data Store Source</b>	<p>Lists the source of the data store memory, as follows:</p> <ul style="list-style-type: none"> <li>If the data store is defined using a Data Store Memory block, the field displays the block name, such as &lt;Root&gt;/DS1. If you selected the <b>Code-to-model</b> parameter for your model, you can click on the <b>Data Store Source</b> value to go to the data store's location in the model display.</li> <li>If the data store is defined using a Simulink.Signal object, the field displays the name of the Simulink.Signal object.</li> </ul>

Field	Description
<b>Code Identifier</b>	<p>Lists the identifier associated with the data store data in the generated code, as follows:</p> <ul style="list-style-type: none"> <li>• If the data is defined in the generated code, the field displays the identifier text.</li> <li>• If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</li> <li>• If the data is neither defined nor declared in the generated code — for example, if model configuration parameter <b>Code interface packaging</b> is set to Reusable function — the field displays the text 'Defined externally'.</li> </ul>
<b>Data Type</b>	Lists the data type of the data store.
<b>Scaling</b>	<p>For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation.</p> <hr/> <p><b>Note</b> You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).</p>
<b>Dimension</b>	Lists the dimensions of the data store (for example, 1 or [1, 2]).

For example, here is the **Data Stores** subsection for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

### Data Stores

Data Store Source	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/Data Store Memory</a>	mode	boolean_T	1

## Code Interface Report Limitations

The following limitations apply to the code interface section of the HTML code generation reports.

- The code interface report does not support the GRT interface with an ERT target or **C++ class** code interface packaging. For these configurations, the code interface report is not generated and does not appear in the HTML code generation report **Contents** pane.
- The code interface report supports data resolved with most storage classes, except when the storage class properties are set in any of the following ways:
  - The storage class property **Type** is set to **FlatStructure**. For example, the **BitField** and **Struct** storage classes in the Simulink package have **Type** set to **FlatStructure**.
  - The storage class property **Type** is set to **Other**. For example, the **GetSet** storage class in the Simulink package has **Type** set to **Other**.
  - The storage class property **Data access** is set to **Pointer**, indicating that imported symbols are declared as pointer variables rather than simple variables. This property is accessible only when the storage class property **Data scope** is set to **Imported** or **Instance-specific**.

In these cases, the report displays empty **Data Type** and **Dimension** fields.

- For outputs, the code interface report cannot describe the associated memory (data type and dimensions) if the memory is optimized. In these cases, the report displays empty **Data Type** and **Dimension** fields.
- The code interface report does not support data type replacement using the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box. The data types listed in the report will link to built-in data types rather than their specified replacement data types.

## Static Code Metrics

### In this section...

“Static Code Metrics” on page 49-32

“Static Code Metrics Analysis” on page 49-33

“View Static Code Metrics and Definitions Within the Generated Code” on page 49-35

“Static Code Metrics Report Limitations” on page 49-36

### Static Code Metrics

The code generator performs static analysis on page 49-33 of the generated C or C++ code and provides these metrics in the **Static Code Metrics Report** section of the HTML Code Generation Report. When you place your cursor over a function or a variable in the generated code, you can also see metrics.

You can use the information in the report to:

- Find the number of files and lines of code in each file.
- Estimate the number of lines of code and stack usage per function.
- Compare the difference in terms of how many files, functions, variables, and lines of code are generated every time you change the model or MATLAB algorithm.
- Determine a target platform and allocation of RAM to the stack, based on the size of global variables plus the estimated stack size.
- Determine possible performance slow points, such as the largest global variables or the most costly call path in terms of stack usage.
- View the cyclomatic complexity of a function, which counts the number of linearly independent paths through a function.
- View the function call tree. Determine the longest call path to estimate the worst case execution timing.
- View how target functions, provided by the selected code replacement library, are used in the generated code.

For examples, see:

- “Generate Static Code Metrics Report for Simulink Model” on page 49-37

- “Generating a Static Code Metrics Report for Code Generated from MATLAB Code” on page 49-42

## Static Code Metrics Analysis

Static analysis of the generated code is performed only on the source code without executing the program. The results of the static code metrics analysis are included in the **Static Code Metrics** section of the HTML Code Generation Report. The report is not available if you generate a MEX function from MATLAB code.

Static analysis of the generated source code files:

- Uses the specified C data types. For Simulink models, you specify these data types in the **Hardware Implementation > Production hardware** pane of the Configuration Parameters dialog box. For code generation from MATLAB code, you specify them in the **Hardware** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. Actual object code metrics might differ due to target-specific compiler and platform settings.
- Includes custom code only if you specify it. For Simulink models, you specify custom code on the **Code Generation > Custom Code** pane in the model configuration. For code generation from MATLAB code, you specify it on the **Debugging** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. An error report is generated if the generated code includes platform-specific files not contained in the standard C run-time library.
- For Simulink models, includes the generated code from referenced models.
- Uses 1-byte alignment for all members of a structure for estimating global and local data structure sizes. The size of a structure is calculated by summing the sizes of all of its fields. This estimation represents the smallest possible size for a structure.
- Calculates the self stack size of a function as the size of local data within a function, excluding input arguments. The accumulated stack size of a function is the self stack size plus the maximum of the accumulated stack sizes of its called functions. For example, if the accumulated stacks sizes for the called functions are represented as `accum_size1...accum_sizeN`, then the accumulated stack size for a function is

```
accumulated_stack_size = self_stack_size + max(accum_size1,...,accum_sizeN)
```

For example consider this piece of generated code:

```

/* Real-time model */
RT_MODEL rtM;
RT_MODEL *const rtM = &rtM;
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
                    rtd_A[6], real_T rtd_B[6]);

```

Now consider the code metrics shown below:

Static Code Metrics reported stack sizes

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code
(-) _local_demo_step	12	0	1
.Debug_b	12	12	6
_local_demo_initialize	0	0	0

The accumulated stack size is 12 bytes because the self stack size of the function `Debug_b` is 12 bytes and the 4 input arguments do not contribute to the calculation of accumulated stack size.

- When estimating the stack size of a function, static analysis stops at the first instance of a recursive call. The **Function Information** table indicates when recursion occurs in a function call path. Code generation generates only recursive code for Stateflow event broadcasting and for graphical functions if it is written as a recursive function.
- Calculates the cyclomatic complexity of a function as the number of decisions plus one:

$$CC = \text{Number of decisions} + 1$$

The following constructs add a decision:

- If statement
- Else-If statement
- Switch statement (1 decision for each case branch)
- Loop statements: While, For, Do-while

---

**Note** Boolean operators in the preceding constructs do not add extra decisions.

---

- Does not include `ert_main.c`, because you have the option to provide your own `main.c`.

## View Static Code Metrics and Definitions Within the Generated Code

- “Code Generation Report” on page 49-35
- “Code View” on page 49-36

### Code Generation Report

When you view code in the code generation report, to access code metrics and definitions:

- On the **Code Generation > Report** pane, if you select the **Static code metrics** check box, you can place your cursor over global variables and functions in the code window to see code metrics information.

```

141 *   UnitDelay: '<Root>/X'
142 */
143 /* Gateway: Chart */
144 if (rtDWork.temporalCounter_i1 < 7U) {
145     rtDWork: Global Variable: rtDWork (19 byte)
146 }
147

```

- In the code window, if you click linked variables or functions, the code inspect window opens. The window provides links to definitions for the variables or functions. On the **Code Generation > Report** pane, if you selected the **Static code metrics** check box, you can also see code metrics information for the variable or function.

```

29 /* Block states (auto storage) */
30 D_Work rtDWork;
31
32 /* External outputs (root outports fed by signals with auto storage) */
33 ExternalOutputs rtY;

```

Global Variable: *rtDWork* (19 byte)  
*rtDWork* defined at [rtwdemo\\_hyperlinks.c line 30](#)

## Code View

When you view code in the Code view of the Code perspective, place your cursor over the ellipsis menu above global variables and functions to see code metrics information.

```

30
31 /* Ex Function defined in rtwdemo\_roll.c (defined by signals with default storage) */
32 ExtY 35 void rtwdemo\_roll\_step\(void\)
33
34 /* Mo stack: 5 byte, total stack: 5 byte
35 void rtwdemo_roll_step(void)
36 {
37     boolean_T rtb_NotEngaged_f;
38     real32_T rtb_Sum1;
--

```

The tooltip provides a link to the definition for the variable or function.

## Static Code Metrics Report Limitations

Static code metrics are not available if the target configuration for a model results in generated code that:

- Includes a header file that is not generated by the model hierarchy and is not a system header file
- Uses a macro that is not recognized

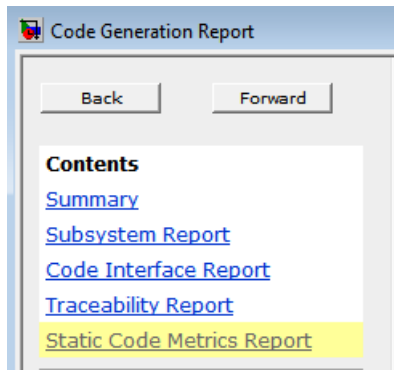

## Generate Static Code Metrics Report for Simulink Model

The **Static Code Metrics Report** is a section included in the HTML Code Generation Report. For more information on the static analysis of the generated code, see “Static Code Metrics Analysis” on page 49-33.

- 1 Before generating the HTML Code Generation Report, open the Configuration Parameters dialog box for your model. On the **Code Generation > Report** pane, select the “Static code metrics” (Simulink Coder) check box.

If your model includes referenced models, select the **Static code metrics** check box in each referenced model’s configuration set. Otherwise, you cannot view a separate static code metrics report for a referenced model.

- 2 Press **Ctrl+B** to build your model and generate the HTML code generation report. For more information, see “Generate a Code Generation Report” on page 49-6.
- 3 If the HTML Code Generation Report is not already open, open the report. On the left navigation pane, in the **Contents** section, select **Static Code Metrics Report**.

- 4 To see the generated files and how many lines of code are generated per file, look at the **File Information** section.

## 1. File Information [\[hide\]](#)

[–] Summary (excludes ert\_main.c)

Number of .c files : 2  
 Number of .h files : 4  
 Lines of code : 1,132  
 Lines : 1,958

[–] File details

File Name	Lines of Code	Lines	Generated On
<a href="#">fuel_rate_control.c</a>	665	1,107	06/10/2016 4:17 PM
<a href="#">fuel_rate_control_data.c</a>	253	342	06/10/2016 4:17 PM
<a href="#">rtwtypes.h</a>	97	177	06/10/2016 4:17 PM
<a href="#">fuel_rate_control.h</a>	88	249	06/10/2016 4:17 PM
<a href="#">fuel_rate_control_types.h</a>	22	52	06/10/2016 4:17 PM
<a href="#">fuel_rate_control_private.h</a>	7	31	06/10/2016 4:17 PM

- 5 Hover your cursor over column titles and some column values to see a description of the corresponding data.
- 6 If your model includes referenced models, the File information section includes a **Referenced Model** column. In this column, click the referenced model name to open its static code metrics report. If the static code metrics report is not available for a referenced model, specify the **Static code metrics** parameter in the referenced model's configuration set and rebuild your model.
- 7 To view the global variables in the generated code, their size, and the number of accesses, see the **Global Variables** section.

## 2. Global Variables [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] <a href="#">fuel_rate_control_DW</a>	23	175	78
[+] <a href="#">fuel_rate_control_B</a>	21	42	26
[+] <a href="#">fuel_rate_control_U</a>	16	27	24
[+] <a href="#">fuel_rate_control_M_</a>	8	0*	0*
[+] <a href="#">fuel_rate_control_Y</a>	4	4	3
<b>Total</b>	<b>72</b>	<b>248</b>	

\* The global variable is not directly used in any function.

The **Reads/Writes** column displays the total number of read and write accesses to the global variable. The **Reads/Writes in a Function** column displays the maximum

number of read and write accesses to the global variable within a function. You use this information to estimate the benefit of turning on optimizations, which reduce the number of global references. For more information, see “Optimize Global Variable Usage” on page 69-2.

Click **[+]** to expand structures.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
<a href="#">[-] fuel_rate_control_DW</a>	23	175	78
DiscreteIntegrator_DSTATE	4	5	4
ThrottleTransient_states	4	4	3
DiscreteFilter_states	4	4	3
DiscreteFilter_states_i	4	4	3
<a href="#">[+] bitsForTIDO</a>	5	156	60
temporalCounter_i1	2	7	5
<a href="#">[-] fuel_rate_control_B</a>	21	42	26
<a href="#">[+] es_o</a>	16	23	18
fuel_mode	4	15	8
O2_normal	1	6	4
<a href="#">[-] fuel_rate_control_U</a>	16	27	24
<a href="#">[+] sensors</a>	16	27	24
<a href="#">[-] fuel_rate_control_M</a>	8	0*	0*
errorStatus	8	0	0
<a href="#">[-] fuel_rate_control_Y</a>	4	4	3
fuel_rate	4	4	3
<b>Total</b>	<b>72</b>	<b>248</b>	

\* The global variable is not directly used in any function.

- 8 To navigate from the report to the source code, click a global variable or function name. These names are hyperlinks to their definitions.
- 9 To view the function call tree of the generated code, in the **Function Information** section, click **Call Tree** at the top of the table.

### 3. Function Information [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: [Call Tree](#) | [Table](#)

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[ - ] <a href="#">fuel_rate_control_step</a>	52	16	272	504	43
<a href="#">look2_iff_linlca</a>	36	36	55	100	12
[ - ] <a href="#">fuel_rate_control_Fail</a>	4	4	67	103	13
<a href="#">fuel_rate_control_Fueling_Mode</a>	0	0	166	240	19
<a href="#">fuel_rate_control_Fueling_Mode</a>	0	0	166	240	19
[ + ] <a href="#">fuel_rate_control_initialize</a>	0	0	43	67	1
<a href="#">fuel_rate_control_terminate</a>	0	0	0	4	1

`ert_main.c` is not included in the code metrics analysis, therefore it is not shown in the call tree format. The **Complexity** column includes the cyclomatic complexity of each function.

**10** To view the functions in a table format, click **Table**.

### 3. Function Information [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: [Call Tree](#) | [Table](#)

Function Name	Called By (number of call sites)	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
<a href="#">fuel_rate_control_Fail</a>	<a href="#">fuel_rate_control_step</a> (9)	4	4	67	103	13
<a href="#">fuel_rate_control_Fueling_Mode</a>	<a href="#">fuel_rate_control_step</a> <a href="#">fuel_rate_control_Fail</a> (2)	0	0	166	240	19
<a href="#">fuel_rate_control_initialize</a>		0	0	43	67	1
<a href="#">fuel_rate_control_step</a>		52	16	272	504	43
<a href="#">fuel_rate_control_terminate</a>		0	0	0	4	1
<a href="#">look2_iff_linlca</a>	<a href="#">fuel_rate_control_step</a> (5)	36	36	55	100	12
<code>memset</code>	<a href="#">fuel_rate_control_initialize</a> (2)	<i>Not available</i>	-	-	-	-

The second column, **Called By**, lists functions that call the function listed in the first column, using the following criteria:

- If a function is called by multiple functions, all functions are listed.
- If a function has no called function, this column is empty.

For example, `Fueling_Mode` is called by `Fail` and `fuel_rate_control_step`. The number of call sites is included in parentheses. `Fail` calls `Fueling_Mode` twice.

## Generating a Static Code Metrics Report for Code Generated from MATLAB Code

The static code metrics report contains the results of static analysis of the generated C/C++ code, including generated file information, number of lines, and memory usage. For more information, see “Static Code Metrics” on page 49-32. To produce a static code metrics report, you must use Embedded Coder to generate standalone C/C++ code and produce a code generation report. See “Code Generation Reports” (MATLAB Coder).

By default, static code metrics analysis does not run at code generation time. Instead, if and when you want to run the analysis and view the results, click **Code Metrics** on the **Summary** tab of the code generation report.

### Example Static Code Metrics Report

This example runs static code metrics analysis and examines a static code metrics report.

Create the example function `averaging_filter`.

```
function y = averaging_filter(x) %#codegen
% Use a persistent variable 'buffer' that represents a sliding window of
% 16 samples at a time.
persistent buffer;
if isempty(buffer)
    buffer = zeros(16,1);
end
y = zeros(size(x), class(x));
for i = 1:numel(x)
    % Scroll the buffer
    buffer(2:end) = buffer(1:end-1);
    % Add a new sample value to the buffer
    buffer(1) = x(i);
    % Compute the current average value of the window and
    % write result
    y(i) = sum(buffer)/numel(buffer);
end
```

Create sample data.

```
v = 0:0.00614:2*pi;
x = sin(v) + 0.3*rand(1,numel(v));
```

Enable production of a code generation report by using a configuration object for standalone code generation (static library, dynamically linked library, or executable program).

```
cfg = coder.config('lib', 'ecoder', true);
cfg.GenerateReport=true;
```

Alternatively, use the `codegen -report` option.

Generate code by using `codegen`. Specify the type of the input argument by providing an example input with the `-args` option. Specify the configuration object by using the `-config` option.

```
codegen averaging_filter -config cfg -args {x}
```

To open the code generation report, click **View report**.

To run the static code metrics analysis and view the code metrics report, on the **Summary** tab of the code generation report, click **Code Metrics**.

Explore the code metrics report.

- 1 To see the generated files and the number of lines of code per file, click **File Information**.

1. File Information [hide]

[ - ] Summary

Number of .c files : 3  
 Number of .h files : 5  
 Lines of code : 86  
 Lines : 281

[ - ] File details

File Name	Lines of Code	Lines
<a href="#">averaging_filter.c</a>	24	65
<a href="#">rtwtypes.h</a>	22	46
<a href="#">averaging_filter.h</a>	9	30
<a href="#">averaging_filter_initialize.h</a>	8	29
<a href="#">averaging_filter_terminate.h</a>	8	29
<a href="#">averaging_filter_initialize.c</a>	6	30
<a href="#">averaging_filter_terminate.c</a>	5	30
<a href="#">averaging_filter_types.h</a>	4	22

- 2 To see the global variables in the generated code, go to the **Global Variables** section.

## 2. Global Variables [\[hide\]](#)

Global variables defined in the generated code

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
<a href="#">buffer</a>	128	5	4
<b>Total</b>	<b>128</b>	<b>5</b>	

To navigate from the report to the source code, click a global variable name.

- To view the function call tree of the generated code, in the **Function Information** section, click **Call Tree**.

## 3. Function Information [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: [Call Tree](#) | [Table](#)

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[+] <a href="#">averaging_filter</a>	136	136	14	24	3
<a href="#">double_to_uint64_helper</a>	8	8	6	8	1
[+] <a href="#">averaging_filter_initialize</a>	0	0	1	4	1
<a href="#">averaging_filter_terminate</a>	0	0	0	4	1

To navigate from the report to the function code, click a function name.

- To view the functions in a table format, click **Table**.

## 3. Function Information [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: [Call Tree](#) | [Table](#)

Function Name	Called By (number of call sites)	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
<a href="#">averaging_filter</a>		136	136	14	24	3
<a href="#">averaging_filter_init</a>	<a href="#">averaging_filter_initialize</a>	0	0	1	4	1
<a href="#">averaging_filter_initialize</a>		0	0	1	4	1
<a href="#">averaging_filter_terminate</a>		0	0	0	4	1

The second column, **Called By**, lists functions that call the function listed in the first column. If multiple functions call that function, all functions are listed. If no functions call that function, this column is empty.

## Requirements for Running Static Code Metrics Analysis After Code Generation

By default, static code metrics analysis does not run at code generation time. Instead, you can run the analysis later by clicking **Code Metrics** in the code generation report. Running static code metrics analysis after code generation has these requirements and limitations:

- You must have Embedded Coder and use the platform that you used for code generation. Once you run the static code metrics analysis, you can open the code metrics report without Embedded Coder or open it on a different platform.
- If you make the code generation report read-only before you run the analysis, each time that you click **Code Metrics**, the analysis runs.

## Running Static Code Metrics at Code Generation Time

If you want the code generator to run static code metrics analysis and produce the code metrics report at code generation time:

- In an Embedded Coder code generation configuration object, set `GenerateCodeMetricsReport` to `true`.
- In the MATLAB Coder app, on the **Debugging** tab, set **Static code metrics** to Yes.

- “Code Generation Reports” (MATLAB Coder)

## Analyze Code Replacements in Generated Code

When you select the check box **Summarize which blocks triggered code replacements** (Simulink Coder) for an ERT-based model, a Code Replacements Report section is automatically included in the generated HTML report. The Code Replacements Report section documents the code replacement library (CRL) functions that were used for code replacements during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the replacement. To enable display of the Simulink block information, select the **Code Generation > Comments** check box **Include comments**. On the same pane, select either the **Simulink block comments** checkbox or the **Simulink block descriptions** check box if present, or both.

You can use the report to:

- Determine which replacement functions were used in the generated code.
- Trace each replacement instance back to the block that triggered the replacement.

The figure below shows a Code Replacements Report generated for the CRL model `rtwdemo_crladdsub`. Each replacement function used is listed with a link to the block that triggered the replacement.

The screenshot shows a window titled "Code Generation Report" with a search bar and "Match Case" option. The left sidebar contains a "Contents" section with links to various reports, with "Code Replacements Report" highlighted. Below it is a "Generated Code" section with a tree view showing files like `ert_main.c`, `rtwdemo_crladdsub.c`, and `rtwdemo_crladdsub_types.h`.

## Code replacements in rtwdemo\_crladdsub

Code replacements for library 'Addition & Subtraction Examples'. The library comprises:

- Addition & Subtraction Examples
  - `crl_table_addsub`

To see the replacements and misses in the Code Replacement Viewer, look [here](#).

### 1. Addition operator replacements [\[hide\]](#)

The following table provides a mapping from the addition operators used from the selected Code Replacement Library to the blocks in the model that triggered the replacement.

Function	Block
<code>s16_add_s16_s16</code>	<code>&lt;S1&gt;:1</code>
<code>u8_add_u8_u8</code>	<code>&lt;Root&gt;/Add8</code>
<code>u16_add_u16_u16</code>	<code>&lt;Root&gt;/Add16</code>

### 2. Subtraction operator replacements [\[hide\]](#)

The following table provides a mapping from the subtraction operators used from the selected Code Replacement Library to the blocks in the model that triggered the replacement.

Function	Block
<code>u32_sub_u32_u32</code>	<code>&lt;Root&gt;/EmbSub32</code>
<code>s8_sub_s8_s8</code>	<code>&lt;Root&gt;/Sub8</code>
<code>s32_sub_s32_s32</code>	<code>&lt;Root&gt;/Sub32</code>

At the bottom of the window are "OK" and "Help" buttons.

If you click a block path in the report, the block that triggered the replacement is highlighted in the model diagram. If the replacement was triggered by a Stateflow chart or a MATLAB function, a window opens to display the chart or function.

For more information, see "Verify Code Replacement Library" on page 65-67.

## Document Generated Code with Simulink Report Generator

In this section...
“Generate Code for the Model” on page 49-49
“Open the Report Generator” on page 49-49
“Set Report Name, Location, and Format” on page 49-51
“Include Models and Subsystems in a Report” on page 49-52
“Customize the Report” on page 49-53
“Generate the Report” on page 49-54

The Simulink Report Generator software creates documentation from your model in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. This example shows one way to document a code generation project in Microsoft Word. The generated report includes:

- System snapshots (model and subsystem diagrams)
- Block execution order list
- Simulink Coder and model version information for generated code
- List of generated files
- Optimization configuration parameter settings
- System target file selection and build process configuration parameter settings
- Subsystem map
- File name, path, and generated code listings for the source code

To adjust Simulink Report Generator settings to include custom code and then generate a report for a model, complete the following tasks:

- 1 “Generate Code for the Model” on page 49-49
- 2 “Open the Report Generator” on page 49-49
- 3 “Set Report Name, Location, and Format” on page 49-51
- 4 “Include Models and Subsystems in a Report” on page 49-52
- 5 “Customize the Report” on page 49-53

## 6 “Generate the Report” on page 49-54

A Simulink Report Generator license is required for the following report formats: PDF, RTF, Microsoft Word, and XML. For more information on generating reports in these formats, see the Simulink Report Generator documentation.

## Generate Code for the Model

Before you use the Report Generator to document your project, generate code for the model.

- 1 In the MATLAB Current Folder browser, navigate to a folder where you have write access.
- 2 Create a working folder from the MATLAB command line by typing:  

```
mkdir report_ex
```
- 3 Make `report_ex` your working folder:  

```
cd report_ex
```
- 4 Open the `slexAircraftExample` model by entering the model name on the MATLAB command line.
- 5 On the **Simulation** tab, in the **Save** list, select **Save as**. Navigate to the working folder, `report_ex`, and save a copy of the `slexAircraftExample` model as `myModel`.
- 6 Open the Configuration Parameters dialog box. Set the **Solver > Solver selection > Type** parameter to **Fixed-step**.
- 7 Select the **Code Generation** pane. Select **Generate code only**.
- 8 Click **Apply**.
- 9 In the model window, press **Ctrl+B**. The build process generates code for the model.

## Open the Report Generator

After you generate the code, open the Report Generator.

- 1 Open the Report Generator app. In the model diagram window, in the **Apps** gallery, click **Report Generator**.
- 2 In the Report Explorer window, in the options pane (center), click the folder **rtw** (**toolbox\rtw**). Click the setup file that it contains, **codegen.rpt**.

- 3 Double-click **codegen.rpt** or select it and click the **Open report** button. The Report Explorer displays the structure of the setup file in the outline pane (left).

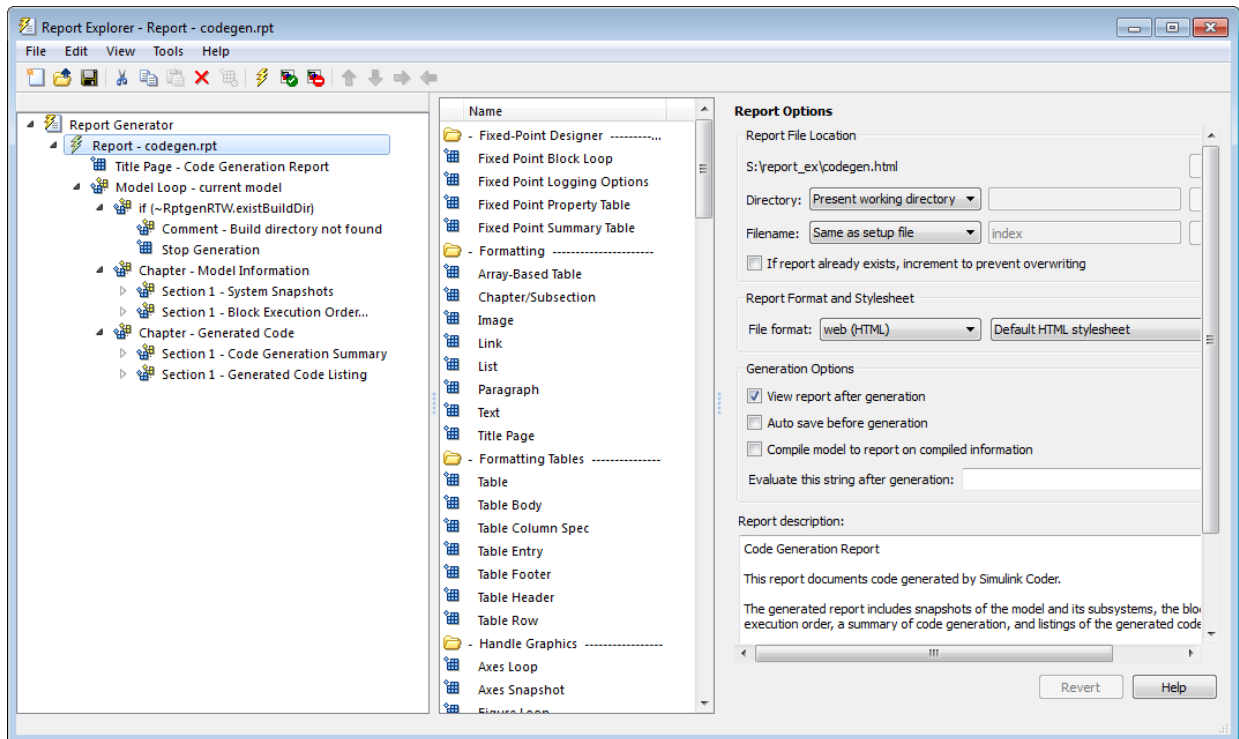

## Set Report Name, Location, and Format

Before generating a report, you can specify report output options, such as the folder, file name, and format. For example, to generate a Microsoft Word report named `MyCGModelReport.rtf`:

- 1 In the properties pane, under **Report Options**, review the options listed.

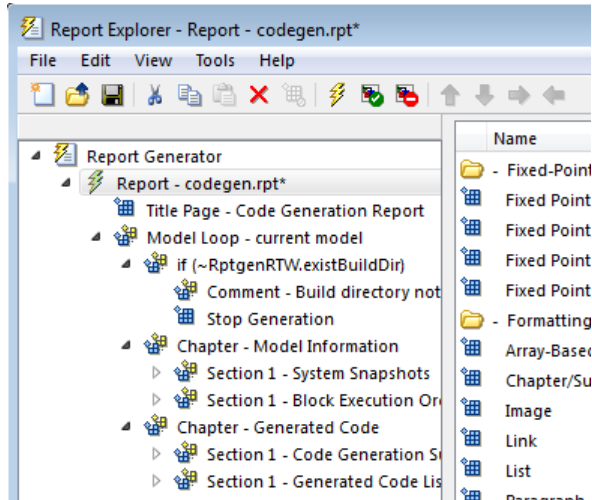

- 2 Leave the **Directory** field set to Present working directory.
- 3 For **Filename**, select Custom: and replace index with the name MyModelCGReport.
- 4 For **File format**, specify Rich Text Format and replace Standard Print with Numbered Chapters & Sections.

## Include Models and Subsystems in a Report

Specify the models and subsystems that you want to include in the generated report by setting options in the Model Loop component.

- 1 In the outline pane (left), select **Model Loop**. Report Generator displays Model Loop component options in the properties pane.
- 2 If not already selected, select Current block diagram for the **Model name** option.

- 3 In the outline pane, click **Report - codegen.rpt\***.

## Customize the Report

After specifying the models and subsystems to include in the report, you can customize the sections included in the report.

- 1 In the outline pane (left), expand the node **Chapter - Generated Code**. By default, the report includes two sections, each containing one of two report components.
- 2 Expand the node **Section 1 – Code Generation Summary**.
- 3 Select **Code Generation Summary**. Options for the component are displayed in the properties pane.
- 4 Click **Help** to review the report customizations that you can make with the Code Generation Summary component. For this example, do not customize the component.
- 5 In the Report Explorer window, expand the node **Section 1 – Generated Code Listing**.
- 6 Select **Import Generated Code**. Options for the component are displayed in the properties pane.
- 7 Click **Help** to review the report customizations that you can make with the Import Generated Code component.

## Generate the Report

After you adjust the report options, from the **Report Explorer** window, generate the report by clicking **File > Report**. A **Message List** dialog box opens, which displays messages that you can monitor as the report is generated. Model snapshots also appear during report generation. The **Message List** dialog box might be hidden behind other dialog boxes.

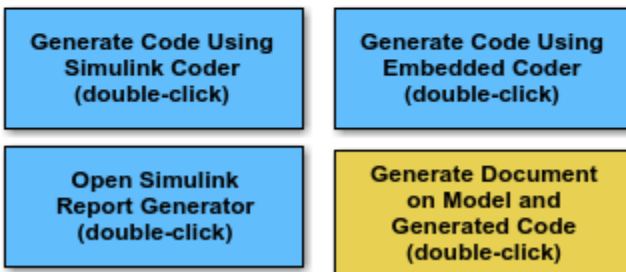

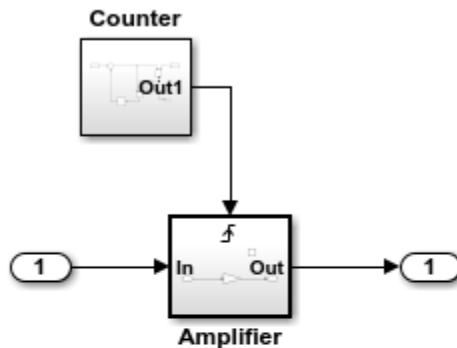

When the report is complete, open the report, `MyModel\CGReport.rtf` in the folder `report_ex` (in this example).

## Document Generated Code

This example shows how to use the Simulink® Report Generator with Simulink® Coder™ to automatically generate documentation for a model and its generated code.

```
model='rtwdemo_codegenrpt';  
open_system(model)
```

Copyright 2006-2019 The MathWorks, Inc.

```
% Cleanup  
rtwdemoclean;  
close_system(model,0)
```

### More About

- “Document Generated Code with Simulink Report Generator” on page 49-48

## Get Code Description of Generated Code

You can use the code descriptor API to obtain meta-information about the generated code. For each model build, the code generator, by default, creates a `codedescriptor.dmr` file in the build folder. When simulating the model in Accelerator and Rapid Accelerator modes, the `codedescriptor.dmr` is not generated.

You can use the code descriptor API once the code is generated. Use the code descriptor API to describe these items in the generated code:

- Data Interfaces: inports, outports, parameters, data stores, and internal data.
- Function Interfaces: initialize, output, update, and terminate.
- Run-time information of the data and function interfaces, such as timing requirements of each interface entity.
- Model hierarchy information and code description of referenced models.

### Get Data Interface Information

The `coder.descriptor.DataInterface` object describes various properties for a specified data interface in the generated code. In the model `rtwdemo_comments`, there are four inports, one outport, and a tunable external parameter. For more information about the data interfaces in your model, use the `coder.codedescriptor.CodeDescriptor` object and its methods.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;  
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_comments');  
evalc('rtwbuild(''rtwdemo_comments'')');
```

- ▶ Simulink Block
- ▶ Stateflow State
- ▶ Stateflow Transition
- ▶ Simulink Signal Object
- ▶ Simulink Parameter Object
- ▶ MPT Signal Object
- ▶ MPT Callback Function

- ▶ Open International Example
- ▶ Open Comments Settings
- ▶ Comments Documentation
- ▶ Customize banners via code templates

Generate Code Using  
Embedded Coder  
(double-click)

DOC  
Text  
History

Copyright 1994-2019 The MathWorks, Inc.

3. Create a `coder.codeDescriptor.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_comments');
```

4. To obtain a list of all the data interface types in the generated code, use the `getDataInterfaceTypes` method.

```
dataInterfaceTypes = codeDescriptor.getDataInterfaceTypes()
```

```
dataInterfaceTypes =
```

```
5x1 cell array
```

```
    {'Inports'      }  
    {'Outports'     }  
    {'Parameters'  }
```

```
{'GlobalParameters'}
{'InternalData' }
```

To obtain a list of all the supported data interfaces, use the `getAllDataInterfaceTypes` method.

5. To obtain more information about a particular data interface type, use the `getDataInterfaces` method.

```
dataInterface = codeDescriptor.getDataInterfaces('Inports');
```

This method returns properties of the Inport blocks in the generated code.

6. Because this model has four inports, `dataInterface` is an array of `coder.descriptor.DataInterface` objects. Obtain the details of the first Inport of the model by accessing the first location in the array.

```
dataInterface(1)
```

```
ans =
```

```
DataInterface with properties:
    Type: [1x1 coder.descriptor.types.Double]
    SID: 'rtwdemo_comments:99'
    GraphicalName: 'In1'
    VariantInfo: [0x0 coder.descriptor.VariantInfo]
    Implementation: [1x1 coder.descriptor.StructExpression]
    Timing: [1x1 coder.descriptor.TimingInterface]
    Unit: ''
    Range: [0x0 coder.descriptor.Range]
```

## Get Function Interface Information

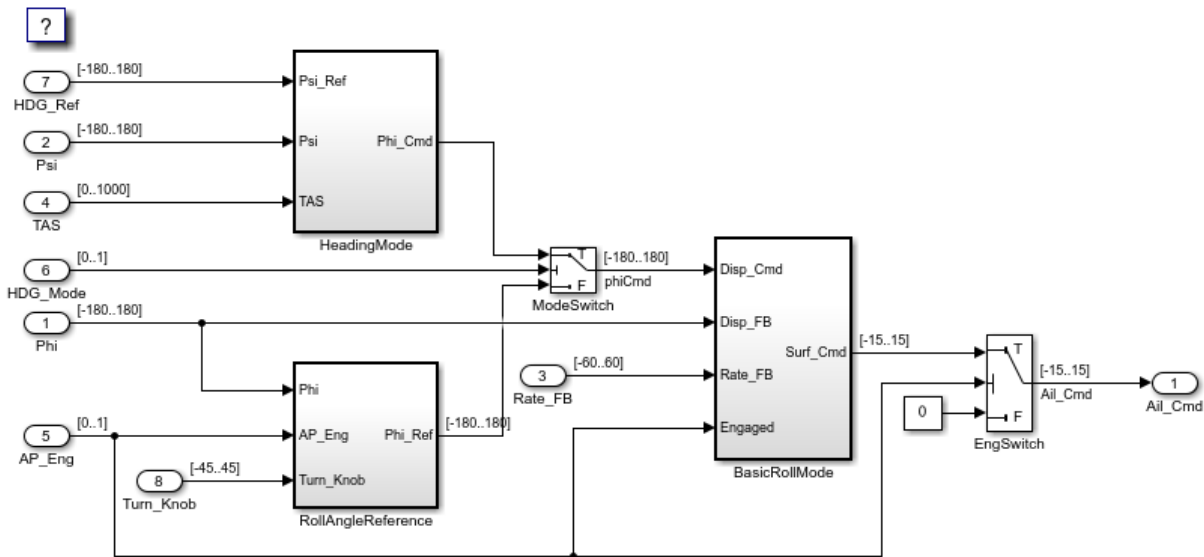

The function interfaces are the entry-point functions in the generated code. In the model `rtwdemo_roll`, the entry-point functions are `model_initialize`, `model_step`, and `model_terminate`. For more information about the function interfaces in your model, use the `coder.descriptor.FunctionInterface` object.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_roll');
evalc('rtwbuild(''rtwdemo_roll'')');
```

Copyright 1990-2019 The MathWorks, Inc.

3. Create a `coder.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_roll');
```

4. To obtain a list of all the function interface types in the generated code, use the `getFunctionInterfaceTypes` method.

```
functionInterfaceTypes = codeDescriptor.getFunctionInterfaceTypes()
```

```
functionInterfaceTypes =
```

```
2x1 cell array
```

```
{'Initialize'}
```

```
{'Output' }
```

To obtain a list of all the supported function interfaces, use the `getAllFunctionInterfaceTypes` method.

5. To obtain more information about a particular function interface type, use the `getFunctionInterfaces` method.

```
functionInterface = codeDescriptor.getFunctionInterfaces('Initialize')
```

```
functionInterface =
```

```
FunctionInterface with properties:
  Prototype: [1x1 coder.descriptor.types.Prototype]
  ActualReturn: [0x0 coder.descriptor.DataInterface]
  VariantInfo: [0x0 coder.descriptor.VariantInfo]
  FunctionOwner: [0x0 coder.descriptor.TypedRegion]
  Timing: [1x1 coder.descriptor.TimingInterface]
  ActualArgs: [1x0 coder.descriptor.DataInterface List]
```

6. You can further expand on the properties to obtain detailed information. To get the function return value, name, and arguments:

```
functionInterface.Prototype
```

```
ans =
```

```
Prototype with properties:
  Name: 'rtwdemo_roll_initialize'
  Return: [0x0 coder.descriptor.types.Argument]
  HeaderFile: 'rtwdemo_roll.h'
  SourceFile: 'rtwdemo_roll.c'
  Arguments: [1x0 coder.descriptor.types.Argument List]
```

## Get Model Hierarchy Information

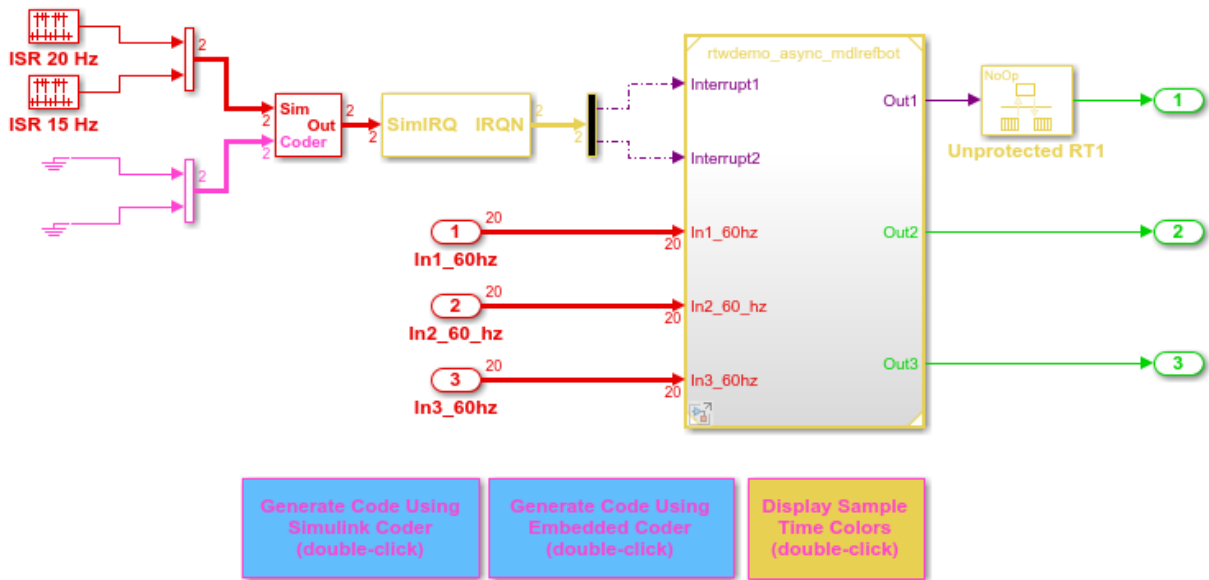

Use the `coder.codedescriptor.CodeDescriptor` object to get the entire model hierarchy information. The model `rtwdemo_async_mdltreftop` has model `rtwdemo_async_mdltreftop` as the referenced model.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_async_mdrefbot');
evalc('rtwbuild(''rtwdemo_async_mdrefbot'')');
```

Copyright 2010-2019 The MathWorks, Inc.

3. Create a `coder.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_async_mdrefbot');
```

4. Get a list of all the referenced models by using the `getReferencedModelNames` method.

```
refModels = codeDescriptor.getReferencedModelNames()
```

```
refModels =  
  
    1x1 cell array  
  
    {'rtwdemo_async mdlrefbot'}
```

5. To obtain the `coder.codedescriptor.CodeDescriptor` object for the referenced model, use the `getReferencedModelCodeDescriptor` method.

```
refCodeDescriptor = codeDescriptor.getReferencedModelCodeDescriptor('rtwdemo_async mdlrefbot')
```

You can now use the `refCodeDescriptor` object to obtain more information about the referenced model by using all the available methods in the Code Descriptor API.

### More About

- “Model Configuration Parameters: Comments”

## Add Custom Comments for Variables in the Generated Code

To control code generation options for signals, states, and parameters in a model, you can create data objects in a workspace or data dictionary. You can generate comments in the code that help you to document the purpose and properties of the data in each object. Associate handwritten comments with each object, or write a function that generates comments based on the properties of the object.

For more information about data objects, see “Data Objects” (Simulink).

### Embed Handwritten Comments for Signals or Parameters

To embed handwritten comments in the generated code near the definition of a signal, state, or parameter:

- 1 Open a Simulink model.

```
model='ex_param_array';
open_system(model)
```

- 2 Create a data object to represent a signal, state, or parameter. You can use a data object from any package such as Simulink. For example, use a data object of the classes `Simulink.Signal` or `Simulink.Parameter`, which are defined in the package `Simulink`.

```
myParam = Simulink.Parameter(15.23);
```

- 3 In the model, under the **PREPARE** section select **Property Inspector**. Click the target Gain block. Set its parameter value to `myParam`.
- 4 Set the storage class of the data object so that optimizations do not eliminate the signal or parameter from the generated code. For example, use the storage class `ExportedGlobal`.

```
myParam.StorageClass = 'ExportedGlobal';
```

- 5 Set the **Description** property of the object. The description that you specify appears in the generated code as lines of comments.

```
myParam.Description = 'This parameter represents multiplication';
```

- 6 In the **Model Configuration Parameters** select **Simulink data object descriptions**.
- 7 Generate code from the model. In the code, the data object description appears near the definition of the corresponding variable.

```
/* Exported block parameters */
real_T myParam = 15.23;      /* Variable: myParam
                             * Referenced by: '<S1>/Gain'
                             * This parameter represents multiplication.
                             */
```

## Generate Dynamic Comments Based on Data Properties

You can generate dynamic comments that include the properties of a data object such as data type, units, and dimensions. If you change the properties of the data object in Simulink, the code generator maintains the accuracy of the comments. For example, this comment displays some of the property values for a data object named MAP for the Simulink model in the previous example:

- 1 Create a data object from the package `mpt` and apply a custom storage class to the object. The default storage class is the custom storage class `Global (Custom)`.

```
myParam = mpt.Parameter;
```

To generate dynamic comments, you must use a data object from the package `mpt` and you must apply a custom storage class to the object.

- 2 Write a MATLAB or TLC function that generates the comment text. For an example MATLAB function, see the function `matlabroot/toolbox/rtw/rtwdemos/rtwdemo_comments_mptfun.m`.

The function must accept three input arguments that correspond to `objectName`, `modelName`, and `request`. If you write a TLC file, you can use the library function `LibGetSLDataObjectInfo` to get the property values of the data object.

- 3 Save the function as a MATLAB file or a TLC file. Place the file in a folder that is on your MATLAB path.
- 4 In the **Model Configuration Parameters** select **Custom comments (MPT objects only)** i.

- 5 Set **Custom comments function** to the name of the MATLAB file or TLC file that you created.
- 6 Generate code from the model. The comments that your function generates appear near the code that represents each data object.

```
/* Object: myParam - user description:  
   DataType -- auto  
   Units    --  
   CSC      -- Global */
```

### Limitations

- To generate comments by using the **Custom comments (MPT objects only)** and **Custom comments function** options, you must create data objects from the package `mpt`. The data objects must use a custom storage class.
- Only the custom storage classes from the `mpt` package that create unstructured variables support the custom comments function.

## See Also

### Related Examples

## Add Global Comments in the Generated Code

In this section...
“Use a Simulink DocBlock to Add a Comment” on page 50-8
“Use a Simulink Annotation to Add a Comment” on page 50-12
“Use Sorted Notes to Add Comments” on page 50-12

These examples show how to add a global comment to a Simulink model so that the comment text appears in the generated file or files. Specify a template symbol name with a Simulink DocBlock, a Simulink annotation, or a Stateflow note. You can also use a sorted-notes capability that works with Simulink annotations or Stateflow notes, but not DocBlocks. For more information about template symbols, see “Template Symbols and Rules” on page 50-98.

---

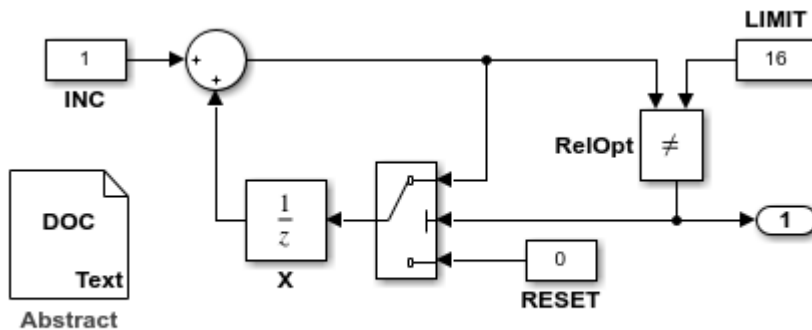

**Note** Template symbol names `Description` and `Model Information` are fields in the **Property Inspector** dialog box. If you use one of these symbol names for global comment text and its **Property Inspector** fields also has text in it, both names appear in the generated files.

---

### Use a Simulink DocBlock to Add a Comment

- 1 Open a Simulink model.

```
model='rtwdemo_codetemplate';  
open_system(model)
```

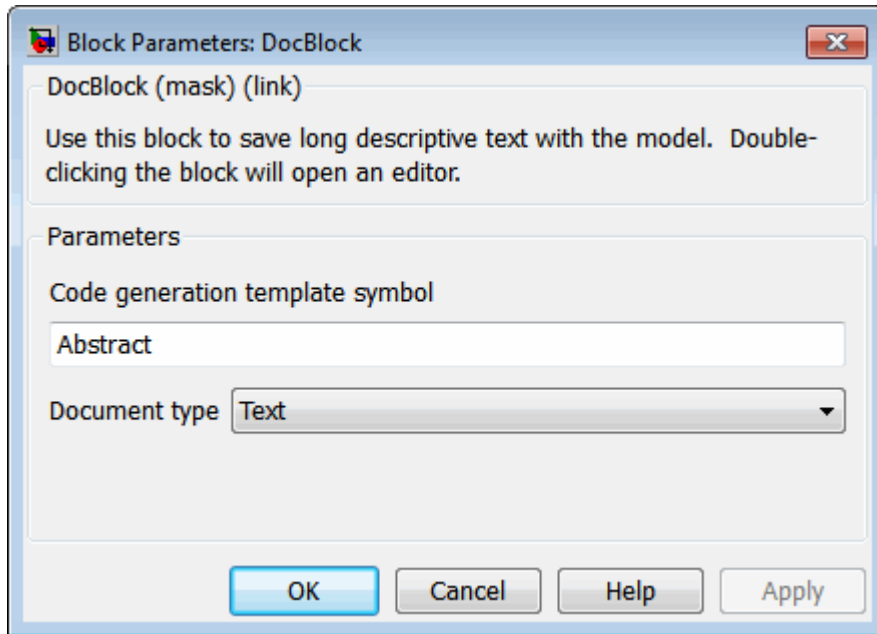

<S:Note>This Simulink annotation maps to the code template %<Note> symbol.

- 2 Under Configuration Parameters, set the **Code templates** to `rtwdemocodetemplate.cgt`. This code template contains the necessary customizations to generate global comments.
- 3 Right-click the DocBlock and select **Mask > Mask Parameters**.
- 4 In the **Code generation template symbol** box, type one of the following:
  - Abstract
  - Description
  - History
  - ModifiedHistory
  - Notes

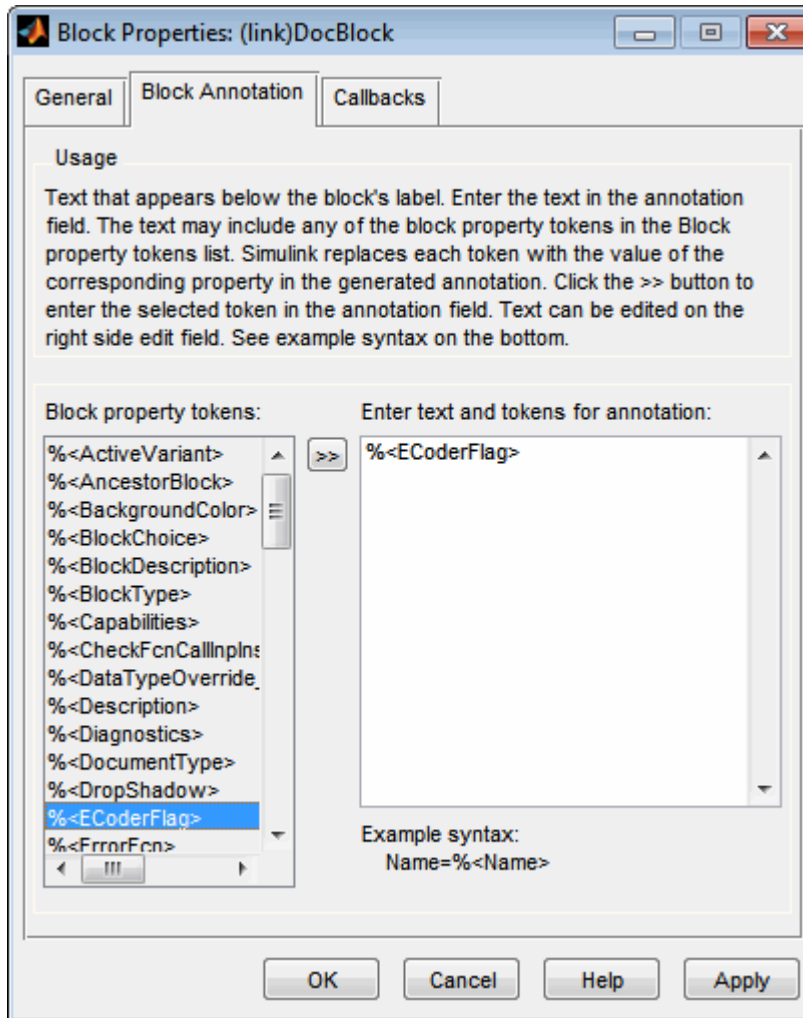

Click **OK**. Template symbol names are case-sensitive.

If you are using a DocBlock to add comments to your code, set the **Document type** to Text. If you set **Document type** to RTF or HTML, your comments do not appear in the code.

- 5 In the Block Properties dialog box, on the **Block Annotation** tab, select %<ECode rFlag> and click **OK**. The symbol name that you typed in the previous step now appears under the DocBlock in the model.

- 6 Save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you designated. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.

The relevant fragment from the generated file for this model is:

```
*  
* ABSTRACT:  
* This text maps to the code template %<Abstract> symbol.
```

- 7 To add more comments to the generated files, repeat steps 2-6.

## Use a Simulink Annotation to Add a Comment

- 1 Open the model `rtwdemo_codetemplate`.
- 2 Double-click the unoccupied area on the model where you want to place the comment. See “Describe Models Using Annotations” (Simulink).
- 3 Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:
  - `Abstract`
  - `Description`
  - `History`
  - `ModifiedHistory`
  - `Notes`

For example, type `<S:Description>This is the description I want`. Template symbol names are case-sensitive. If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 50-12.

- 4 Click outside the annotation rectangle and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you assigned. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file. If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 50-12.
- 5 To add one or more other comments to the generated files, repeat steps 2-4.

## Use Sorted Notes to Add Comments

The sorted-notes capability enables you to add sorted comments to the generated files. The code generator places these comments in each generated file at the location that corresponds to where the `Notes` symbol is located in the template file.

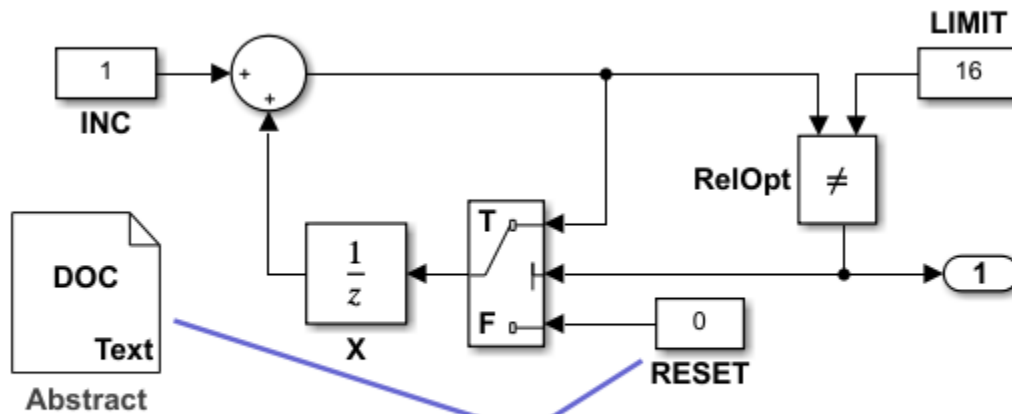

The code generator uses this sorting order:

- Numbers before letters.
- Among numbers, zero is placed first.
- Among letters, uppercase letters are placed before lowercase letters.

You can use sorted notes for a Simulink annotation or a Stateflow note, but not with a DocBlock.

- In the Simulink annotation or the Stateflow note, type `<S:NoteY>` followed by the first comment. Y is a number or a letter.
- Repeat this process for as many additional comments you want. Replace Y with a subsequent number or letter.

This figure illustrates sorted notes on a model. It shows where the code generator places each note in a generated file.

`<S:Note>`This Simulink annotation maps to the code template `%<Note>` symbol.

`<S:Note1>`Another Simulink annotation .

The relevant fragment from the generated file for this model is:

```
*  
* NOTES:  
* Note: This Simulink annotation maps to the code template %<Note> symbol.  
* Note1: Another Simulink annotation .  
*
```

## Customize Generated Identifier Naming Rules

### In this section...

“Apply Naming Rules to Identifiers Globally” on page 50-15

“Apply Naming Rules to Simulink Data Objects” on page 50-17

For GRT and RSim targets, the code generator constructs identifiers for variables and functions in the generated code. For ERT targets, you can customize the naming of identifiers in the generated code by specifying parameters on the **Code Generation > Identifiers** pane in the Configuration Parameters dialog box. You can also specify parameters that control identifiers generated from Simulink data objects. For detailed information about these parameters, see “Model Configuration Parameters: Code Generation Identifiers” (Simulink Coder).

### Apply Naming Rules to Identifiers Globally

Goal	Specify
Set the maximum number of characters that the code generator uses for function, typedef, and variable names (default 31).	An integer value for the “Maximum identifier length” (Simulink Coder) parameter. For more information, see “Specify Identifier Length to Avoid Naming Collisions” (Simulink Coder). If you expect your model to generate lengthy identifiers (due to use of long signal or parameter names, for example), or if identifiers are mangled more than you expect, increase the value of this parameter.

Goal	Specify
<p>Define a macro that specifies certain text included within generated identifiers for:</p> <ul style="list-style-type: none"> <li>• Global variables</li> <li>• Global types</li> <li>• Field names of global types</li> <li>• Subsystem methods</li> <li>• Subsystem method arguments</li> <li>• Local temporary variables</li> <li>• Local block output variables</li> <li>• Constant macros</li> <li>• Shared utilities identifier format</li> </ul>	<p>A macro for the <b>Identifier format control</b> parameters. For more information, see “Identifier Format Control” on page 50-22. See also “Exceptions to Identifier Formatting Conventions” on page 50-35 and “Identifier Format Control Parameters Limitations” on page 50-36.</p>
<p>Set the minimum number of characters that the code generator uses for the mangling text.</p>	<p>An integer value for the “Minimum mangle length” (Simulink Coder) parameter. For more information, see “Control Name Mangling in Generated Identifiers” on page 50-30</p>
<p>Control whether the software uses shortened names for system-generated identifiers.</p>	<p><b>Shortened</b> for the “System-generated identifiers” (Simulink Coder) parameter. This setting:</p> <ul style="list-style-type: none"> <li>• Provides more space for user names.</li> <li>• Provides a more predictable and consistent naming system that uses camel case.</li> <li>• Does not include underscores or plurals.</li> <li>• Provides consistent abbreviations for both a type and a variable.</li> </ul>

Goal	Specify
Control whether the generated code expresses scalar inlined parameter values as literal values or as macros.	<p>The value <code>Literals</code> or <code>Macros</code> for the “Generate scalar inlined parameters as” (Simulink Coder) parameter.</p> <ul style="list-style-type: none"> <li>• <b>Literals:</b> If you set <b>Default parameter behavior</b> to <code>Inlined</code>, parameters are expressed as numeric constants.</li> <li>• <b>Macros:</b> Parameters are expressed as variables (with <code>#define</code> macros). This setting makes code more readable.</li> </ul>

## Apply Naming Rules to Simulink Data Objects

When your model uses Simulink data objects from the Simulink package, identifiers in generated code copy the names of the objects by default. For example, a Simulink.Signal object named Speed appears as the identifier Speed in generated code.

You can control these identifiers by specifying naming rules that are specific to Simulink data objects. On the **Code Generation > Identifiers** pane of the Configuration Parameters dialog box, adjust the settings in the **Simulink data object naming rules** section.

When you specify naming rules for generated code, follow ANSI C<sup>5</sup>/C++ rules for naming identifiers.

### Specify Naming Rule Using a Function

This example shows how to customize identifiers in generated code by defining a MATLAB function.

- 1 Write a MATLAB function that returns an identifier by modifying a data object name, and save the function in your working folder. For example, the following function returns an identifier name by appending the text `_param` to a data object name.

```
function revisedName = append_text(name, object)
% APPEND_TEXT: Returns an identifier for generated
% code by appending text to a data object name.
```

5. ANSI is a registered trademark of the American National Standards Institute, Inc.

```

%
% Input arguments:
% name: data object name as spelled in model
% object: target data object
%
% Output arguments:
% revisedName: altered identifier returned for use in
% generated code.
%
%
text = '_param';

```

```
revisedName = [name,text];
```

- 2 Open the model `rtwdemo_namerules`.
- 3 Double-click the yellow box labeled **View Symbols Configuration** to open the **Code Generation > Identifiers** pane in the Configuration Parameters dialog box.
- 4 From the **Parameter naming** (Simulink Coder) drop-down list, select **Custom M-function**.

- 5 In the **M-function** field, type the name of the file that defines the MATLAB function, `append_text.m`.
- 6 Click **Apply**.
- 7 Generate code for the model.
- 8 Inspect the code generation report to confirm the parameter object naming rule. For example, the generated file `rtwdemo_namerules.h` represents the parameter objects G1, G2, and G3 with the variables G1\_param, G2\_param, and G3\_param.

### Specify Naming Rule for Storage Class Define

You can specify a naming rule that applies only to Simulink data objects whose storage class you set to **Define**. For these data objects, the specified naming rule overrides the other parameter and signal object naming rules. On the **Code Generation > Identifiers**

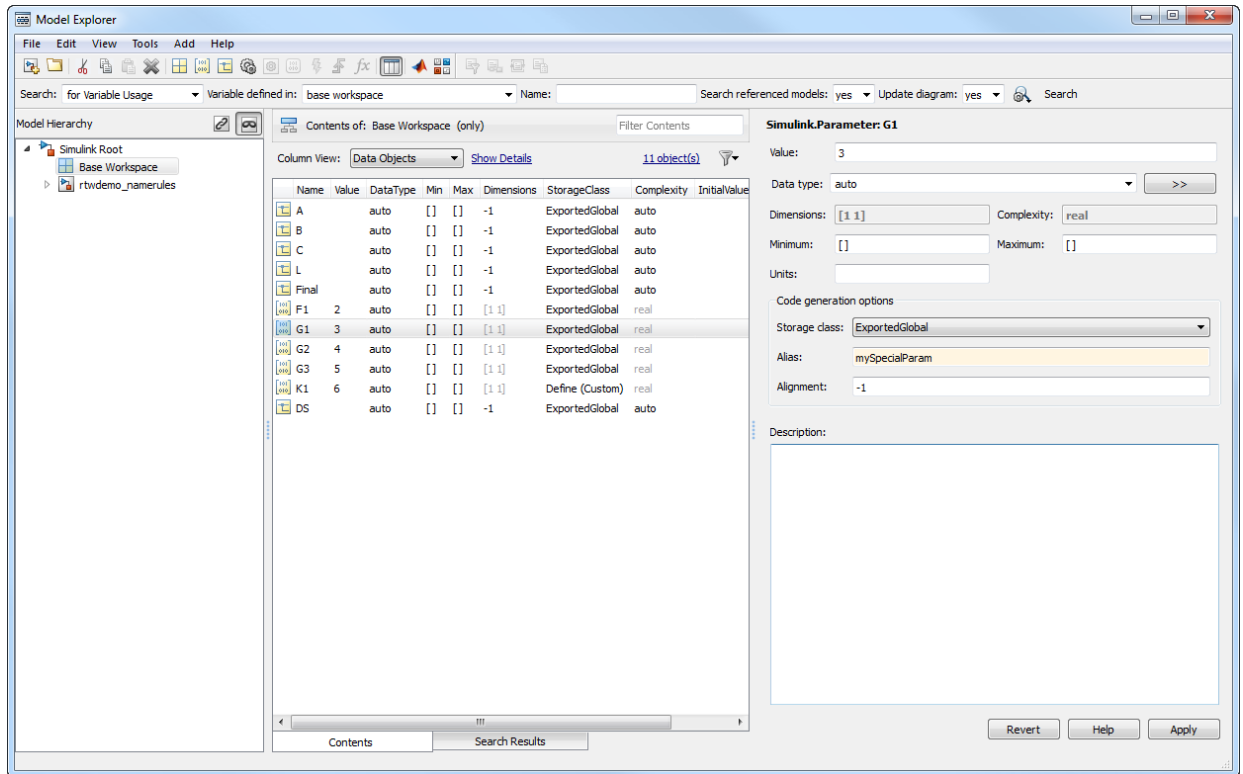

pane in the Configuration Parameters dialog box, adjust the **#define naming** (Simulink Coder) setting.

### Override Data Object Naming Rules

This example shows how to override a data object naming rule for a single data object.

You can override data object naming rules by specifying the `Alias` property of an individual Simulink data object. Generated code uses the text that you specify as the identifier to represent the data object, regardless of naming rules.

- 1 Open the model `rtwdemo_namerules`.
- 2 On the **Modeling** tab, click **Model Data Editor**.
- 3 In the Model Data Editor, on the **Parameters** tab, click the **Show/refresh additional information** button.
- 4 In the data table, find the row that corresponds to the `Simulink.Parameter` object `G1`, which resides in the base workspace.
- 5 In the row, double-click the parameter icon .
- 6 In the Model Explorer Dialog pane (the right pane), for `G1`, specify the `Alias` property as `mySpecialParam`. Click **Apply**.

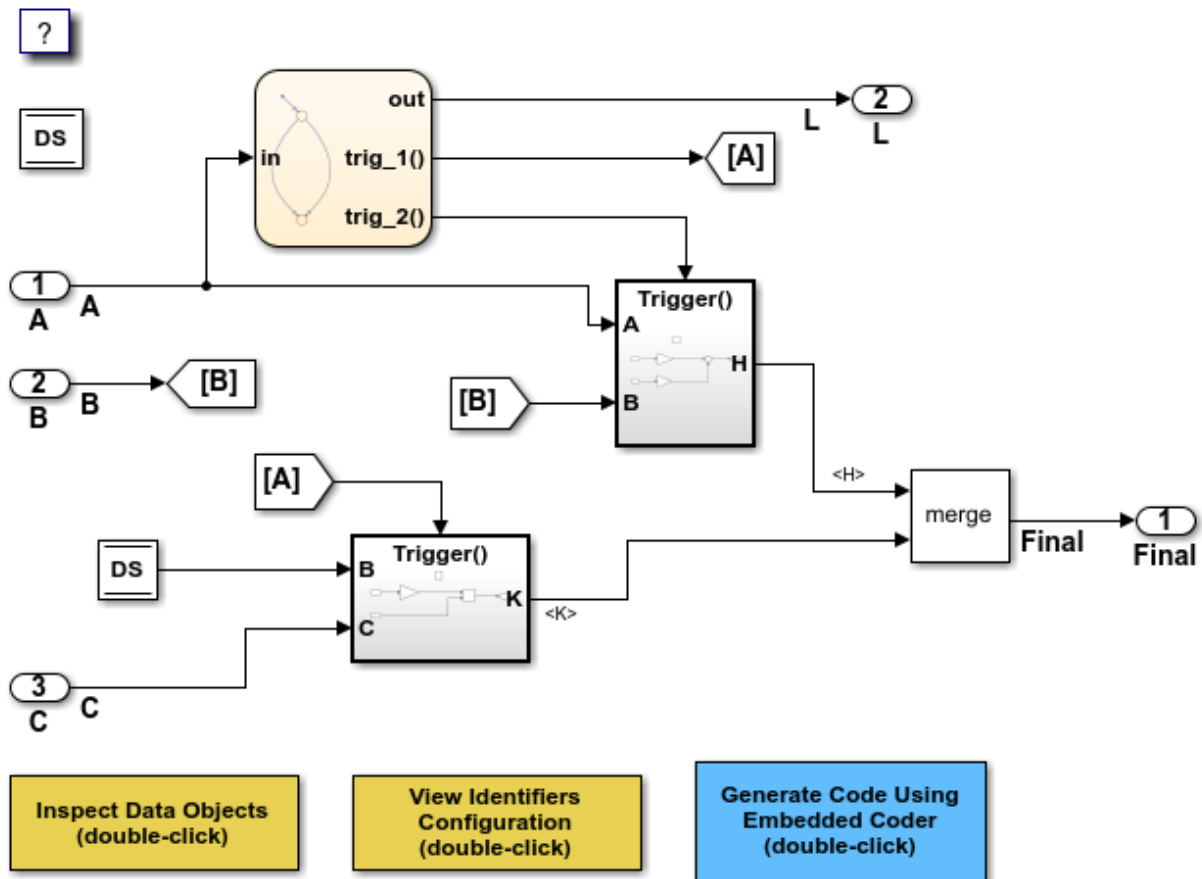

- 7 Generate code for the model.
- 8 In the code generation report, confirm the alias for the parameter object G1. The generated file `rtwdemo_namerules.h` represents G1 with the variable `mySpecialParam`.

### Apply Custom Naming Conventions to Identifiers

This example shows how to apply uniform naming rules for Simulink® data objects, including signals, parameters, and data store memory variables.

```
model='rtwdemo_namerules';
open_system(model)
```

Copyright 1994-2019 The MathWorks, Inc.

```
% Cleanup
rtwdemoclean;
close_system(model,0)
```

## Identifier Format Control

You can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Identifiers** pane in the Configuration Parameters dialog box. For each parameter, you can enter a macro that specifies whether, and in what order, certain text is included within generated identifiers. For example, you can specify that the root model name be inserted into each identifier using the \$R token.

The macro can include:

- Valid tokens, which are listed in Identifier Format Tokens. You can use or omit tokens depending on what you want to include in the identifier name. The **Shared utilities identifier format** parameter requires you to specify the checksum token, \$C. The other parameters require the mangling token, \$M. For more information, see “Control Name Mangling in Generated Identifiers” on page 50-30. The mangling token is subject to the use and ordering restrictions noted in Identifier Format Control Parameter Values.
- Token decorators, which are listed in “Control Case with Token Decorators” on page 50-27. You can use token decorators to control the case of generated identifiers for each token.
- Valid C or C++ language identifier characters (a-z, A-Z, \_ , 0-9).

The build process generates each identifier by expanding tokens and inserting the resultant text into the identifier. The tokens are expanded in the order listed in Identifier Format Tokens. Groups of characters are inserted in the positions that you specify around tokens directly into the identifier. Contiguous token expansions are separated by the underscore (\_) character.

## Identifier Format Tokens

Token	Description
\$C	This token is required for <b>Shared utilities identifier format</b> . If the identifier exceeds the <b>Maximum identifier length</b> , the code generator inserts an 8-character checksum to avoid naming collisions. The position of the \$C token in the <b>Identifier format control</b> parameter specification determines the position of the checksum in the generated identifier. For example, if you use the specification \$N\$C, the checksum is appended to the end of the identifier. This token is available only for shared utilities.
\$M	This token is required. If necessary, the code generator inserts name-mangling text to avoid naming collisions. Modify checksum character length by using <b>Shared checksum length</b> parameter. The position of the \$M token in the <b>Identifier format control</b> parameter specification determines the position of the name-mangling text in the generated identifier. For example, if you use the specification \$R\$N\$M, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Control Name Mangling in Generated Identifiers” on page 50-30.
\$U	Insert text that you specify for the \$U token. Use the <b>Custom token text</b> parameter to specify this text.
\$F	Insert method name (for example, <code>_Update</code> for update method). This token is available only for subsystem methods.
\$N	Insert name of object (block, signal or signal object, state, parameter, shared utility function or parameter object) for which identifier is being generated.
\$R	<p>Insert root model name into identifier, replacing unsupported characters with the underscore (<code>_</code>) character. When you use referenced models, this token is required in addition to \$M (see “Avoid Identifier Name Collisions with Referenced Models” on page 50-32).</p> <p><b>Note:</b> This token replaces the <b>Prefix model name to global identifiers</b> option in previous releases.</p>

Token	Description
\$H	<p>Insert tag indicating system hierarchy level. For root-level blocks, the tag is the text <code>root_</code>. For blocks at the subsystem level, the tag is of the form <code>sN_</code>. N is a unique system number assigned by the Simulink software. This token is available only for subsystem methods and field names of global types.</p> <p><b>Note:</b> This token replaces the <b>Include System Hierarchy Number in Identifiers</b> option in previous releases.</p>
\$A	<p>Insert data type acronym (for example, <code>i32</code> for integers) to signal and work vector identifiers. This token is available for local block output variables, local temporary variables, and field names of global types.</p> <p><b>Note:</b> This token replaces the <b>Include data type acronym in identifier</b> option in previous releases.</p>
\$I	<ul style="list-style-type: none"> <li>• Insert <code>u</code> if the argument is an input.</li> <li>• Insert <code>y</code> if the argument is an output.</li> <li>• Insert <code>uy</code> if the argument is an input and output.</li> </ul> <p>For example, <code>rtu_</code> for an input argument, <code>rty_</code> for an output argument, and <code>rtuy_</code> for an input and output argument. This token is available only for subsystem method arguments.</p>
\$G	<p>Insert the name of a storage class that is associated with the data item. This token is also available in the naming rule that you specify for the <b>Header File</b> for a storage class in the Embedded Coder Dictionary.</p>
\$E	<p>Insert the file type. \$E represents these instances of file types:</p> <ul style="list-style-type: none"> <li>• <code>capi</code></li> <li>• <code>capi_host</code></li> <li>• <code>dt</code></li> <li>• <code>testinterface</code></li> <li>• <code>private</code></li> <li>• <code>types</code></li> </ul> <p>This token is required for <b>Header files</b> and <b>Source files</b>.</p>

Identifier Format Control Parameter Values lists the default macro value, the supported tokens, and the applicable restrictions for each **Identifier format control** parameter.

## Identifier Format Control Parameter Values

Parameter	Default Value	Supported Tokens	Restrictions
<b>Global variables</b> (Simulink Coder)	\$R\$N\$M	\$M, \$R, \$G,\$N,\$U	\$F, \$H, \$A, \$E, and \$I are not allowed.
<b>Global types</b> (Simulink Coder)	\$N\$R\$M_T	\$M, \$R, \$G,\$N,\$U	\$F, \$H, \$A, \$E, and \$I are not allowed.
<b>Field name of global types</b> (Simulink Coder)	\$N\$M	\$M, \$N, \$H, \$A, \$U	\$R, \$F, \$G, \$E, and \$I are not allowed.
<b>Subsystem methods</b> (Simulink Coder)	\$R\$N\$M\$F	\$M, \$R, \$N, \$H, \$F, \$U	\$F and \$H are empty for Stateflow functions; \$A, \$G, \$E, and \$I are not allowed.
<b>Subsystem method arguments</b> (Simulink Coder)	rt\$I\$N\$M	\$M, \$N, \$I, \$U	\$R, \$F, \$H, \$G, \$E, and \$A are not allowed.
<b>Local temporary variables</b> (Simulink Coder)	\$N\$M	\$M, \$R, \$N, \$A, \$U	\$F, \$H, \$G, \$E, and \$I are not allowed.
<b>Local block output variables</b> (Simulink Coder)	rtb_ \$N\$M	\$M, \$N, \$A, \$U	\$R, \$F, \$H, \$G, \$E, and \$I are not allowed.
<b>Constant macros</b> (Simulink Coder)	\$R\$N\$M	\$M, \$R, \$N, \$U	\$F, \$H, \$A, \$G, \$E, and \$I are not allowed.
<b>Shared utilities identifier format</b> (Simulink Coder)	\$N\$C	\$N, \$C, \$R, \$U	\$C is required. \$M, \$F, \$H, \$A, \$G, \$E, and \$I are not allowed.
<b>EMX array utility functions identifier format</b> (Simulink Coder)	emx\$M\$N	\$M, \$N,\$R	\$C, \$U, \$F, \$H, \$A, \$G, \$E, and \$I are not allowed.
<b>EMX array types identifier format</b> (Simulink Coder)	emxArray_ \$M\$N	\$M, \$N,\$R	\$C, \$U, \$F, \$H, \$A, \$G, \$E, and \$I are not allowed.

Parameter	Default Value	Supported Tokens	Restrictions
<b>Header files</b>	\$R\$E	\$R,\$U,\$E	\$C, \$M, \$N, \$F, \$H, \$A, \$G, and \$I are not allowed.
<b>Source files</b>	\$R\$E	\$R,\$U,\$E	\$C, \$M, \$N, \$F, \$H, \$A, \$G, and \$I are not allowed.
<b>Data files</b>	\$R_data	\$R,\$U	\$C, \$M, \$N, \$F, \$H, \$A, \$G, \$E, and \$I are not allowed.

Non-ERT-based targets (such as the GRT target) implicitly use a default \$R\$N\$M specification. This default specification consists of the root model name, followed by the name of the generating object (signal, parameter, state, and so on), followed by name-mangling text.

For limitations that apply to **Identifier format control** parameters, see “Exceptions to Identifier Formatting Conventions” on page 50-35 and “Identifier Format Control Parameters Limitations” on page 50-36.

## Control Case with Token Decorators

On the **Code Generation > Identifiers** pane, you can use token decorators to control the case of generated identifiers. Place a decorator immediately after the target token and enclose the decorator in square brackets [ ]. For example, you can set **Global variables** to \$R[uL]\$N\$M, which capitalizes the first letter of the model name and forces the remaining characters in the model name to lowercase.

The table shows how to manipulate the expansion of the \$R token for a model whose name is modelName.

Desired Expansion	Description	Token and Decorator
ModelName	First letter of model name is uppercase. Remaining characters are not modified.	\$R[u]
Modelname	First letter of model name is uppercase. Remaining characters are lowercase.	\$R[uL]

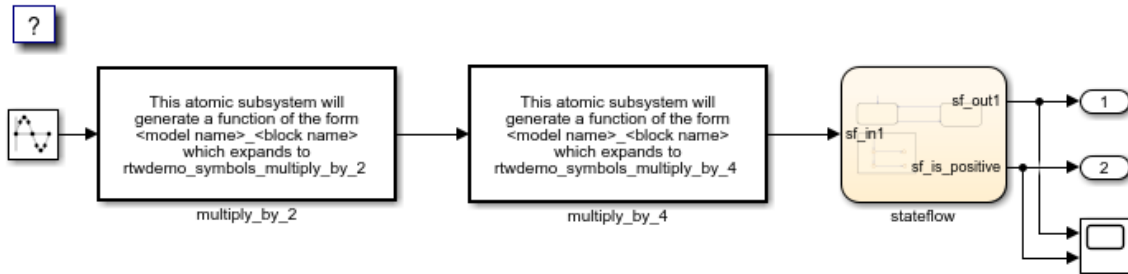

Desired Expansion	Description	Token and Decorator
MODELNAME	All characters are uppercase.	\$R[U]
modelname	All characters are lowercase.	\$R[L]
mODELNAME	First letter of model name is lowercase. Remaining characters are uppercase.	\$R[LU]
modelName	First letter of model name is lowercase. Remaining characters are not modified.	\$R[l]

When you use a decorator, the code generator removes the underscore character ( `_` ) that appears between tokens by default. However, you can append each decorator with an underscore: `$R[U_] $N`. For example, if you set the **Global variables** parameter to `$R[u_] $N[uL] $M` for a model named `modelName` and a `DWork` structure represented by `DW`, the result is `modelName_Dw`.

## Control Formatting of Identifiers

This example shows how you can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Identifiers** pane in the Configuration Parameters dialog box.

```
model='rtwdemo_symbols';
open_system(model)
```

▶ Double-click to view identifier format

▶ Double-click to view mangle settings

▶ Double-click to view identifier format help

▶ Double-click to view traceability help

```

## Control Name Mangling in Generated Identifiers

The position of the \$M token in the **Identifier format control** parameter specification determines the position of the name-mangling text in the generated identifiers. For example, if you use the specification \$R\$N\$M, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Identifier Format Control” on page 50-22.

### Name-Mangling Text Per Object

Object Type	Source of Mangling Text
Block diagram	Name of block diagram
Simulink block	Simulink identifier (for details, see “Locate Diagram Components Using Simulink Identifiers” (Simulink))
Simulink parameter	Full name of parameter owner (model or block) and parameter name
Simulink signal	Signal name, full name of source block, and port number
Stateflow objects	Complete path to Stateflow block and Stateflow computed name (unique within chart)

The length of the name-mangling text is specified by the **Minimum mangle length** (Simulink Coder) parameter. The default value is 1, but this automatically increases during code generation as a function of the number of collisions. To minimize disturbance to the generated code during development, specify a larger **Minimum mangle length**. A **Minimum mangle length** of 4 is a conservative value. A value of 4 allows for over 1.5 million collisions for a particular identifier before the mangle length is increased.

### Minimize Name Mangling

The length of generated identifiers is limited by the **Maximum identifier length** (Simulink Coder) parameter. When a name collision exists, the \$M token is expanded to the minimum number of characters required to avoid the collision. Other tokens are expanded in the order listed in Identifier Format Tokens. If the **Maximum identifier length** is not large enough to accommodate full expansions of the other tokens, partial expansions are used. To avoid partial expansions, it is good practice to:

- Avoid name collisions. One way to avoid name collisions is to not use default block names (for example, Gain1, Gain2...) when there are many blocks of the same type in the model.

- Where possible, increase the **Maximum identifier length** to accommodate the length of the identifiers that you expect to generate.
- Set the **Maximum identifier length** parameter to reserve at least three characters for the name-mangling text. The length of the name-mangling text increases as the number of name collisions increases.

If changes to the model create more or fewer collisions, existing name-mangling text increases or decreases in length. If the length of the name-mangling text increases, additional characters are appended to the existing text. For example, the mangling text 'xyz' can change to 'xyzQ'. For fewer collisions, the name-mangling text 'xyz' changes to 'xy'.

## Avoid Identifier Name Collisions with Referenced Models

Within a model that uses referenced models, collisions between the names of the models are not allowed. When generating code from a model that uses model referencing:

- You must include the \$R token in the **Identifier format control** parameter specifications (in addition to the \$M token).
- The **Maximum identifier length** (Simulink Coder) must be large enough to accommodate full expansions of the \$R and \$M tokens. If **Maximum identifier length** is too small, a code generation error occurs.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

If your model contains two referenced models with the same input or output port names, and one of the referenced models contains an atomic subsystem with “Function packaging” (Simulink) set to `Nonreusable function`, a name conflict can occur and the build process produces an error.

## Use Model Advisor to Detect Identifier Names Changed During Code Generation

For a referenced model, if the following parameters do not have specifications that do not contain a \$R token (which represents the name of the reference model), code generation prepends the \$R token to the identifier format.

- **Global variables** (Simulink Coder)
- **Global types** (Simulink Coder)
- **Subsystem methods** (Simulink Coder)
- **Constant macros** (Simulink Coder)

You can use the Model Advisor to identify referenced models in a model referencing hierarchy for which code generation changes these configuration parameter settings.

- 1 In the **Modeling** tab, click **Model Advisor**.
- 2 Select **By Task**.

- 3 Run the **Check code generation identifier formats used for model reference** check.

## See Also

### Related Examples

- “Identifier Format Control” on page 50-22
- “Specify Identifier Length to Avoid Naming Collisions” on page 43-36

## Maintain Traceability for Generated Identifiers

To verify your model, you can trace back and forth between generated identifiers and corresponding entities within the model. To maintain traceability, it is important that incremental revisions to a model have minimal impact on the identifier names that appear in generated code. There are two ways to minimally impact the identifier names:

- Choose unique names for Simulink objects (blocks, signals, states, and so on) as much as possible.
- Use name mangling when conflicts cannot be avoided.

The position of the name-mangling text is specified by the placement of the `$M` token in the **Identifier format control** parameters. Mangle characters consist of alphanumeric characters that are unique to each object. For more information, see “Control Name Mangling in Generated Identifiers” on page 50-30.

## Exceptions to Identifier Formatting Conventions

There are some exceptions to the identifier formatting conventions described in “Identifier Format Control” on page 50-22.

- Type name generation: name mangling conventions do not apply to type names (that is, `typedef` statements) generated for global data types. If the `$R` token is included in the **Identifier format control** parameter specification, the model name is included in the `typedef`. When generating type definitions, the **Maximum identifier length** parameter is not respected.
- Non-Auto storage classes: the **Identifier format control** parameters specification does not affect objects (such as signals and parameters) that have a storage class other than `Auto` (such as `ImportedExtern` or `ExportedGlobal`).
- For shared utilities, code generation inserts the checksum specified by `$C` to prevent name collisions in the following situations:
  - `$C` is specified without `$N`.
  - The length of `$N` plus the length of the text that you specify exceeds the **Maximum identifier length**. Code generation truncates `$N` and inserts an 8-character checksum where you specified `$C` in the formatting scheme.

## Identifier Format Control Parameters Limitations

The following limitations apply to the **Identifier format control** parameters:

- The following autogenerated identifiers currently do not fully comply with the setting of the **Maximum identifier length** parameter on the **Code Generation > Identifiers** pane of the Configuration Parameters dialog box.
  - Model methods
    - The applicable format scheme is  $\$R\$F$ , and the longest  $\$F$  is `_derivatives`, which is 12 characters long. The model name can be up to 19 characters without exceeding the default **Maximum identifier length** of 31.
  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - DW identifiers generated by S-functions in referenced models
  - Fixed-point shared utility macros or shared utility functions
  - Simulink `rtm` macros
    - Most are within the default **Maximum identifier length** of 31, but some exceed the limit. Examples are `RTMSpecAccsGetStopRequestedValStoredAsPtr`, `RTMSpecAccsGetErrorStatusPointer`, and `RTMSpecAccsGetErrorStatusPointerPointer`.
  - Define protection guard macros
    - Header file guards, such as `_RTW_HEADER_$(filename)_h_`, which can exceed the default **Maximum identifier length** of 31 given a filename such as `$R_private.h`.
    - Include file guards, such as `_$R_COMMON_INCLUDES_`.
    - typedef guards, such as `_CSCI_$R_CHARTSTRUCT_`.
- In some situations, the following identifiers potentially can conflict with others.
  - Model methods
  - Reentrant model function arguments

- Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
- Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
- Fixed-point shared utility macros or shared utility functions
- Include header guard macros
- The following external identifiers that are unknown to the Simulink software might conflict with autogenerated identifiers.
  - Identifiers defined in custom code
  - Identifiers defined in custom header files
  - Identifiers introduced through a non-ANSI C standard library
  - Identifiers defined by custom TLC code
- Identifiers generated for simulation targets might exceed the **Maximum identifier length**. Simulation targets include the model reference simulation target, the accelerated simulation target, the RSim target, and the S-function target.
- Identifiers generated using a model name and bus object data type name, which are both long names, might exceed the **Maximum identifier length**. For example, a ground value variable name is generated as `<model_name>_rtZ<bus_name>`. If the *model\_name* and *bus\_name* are close to the maximum identifier length, the name exceeds the maximum identifier length.

## Control Parentheses in Generated Code

C code contains some syntactically required parentheses, and can contain additional parentheses that change semantics by overriding default operator precedence. C code can also contain optional parentheses that have no functional significance, but only increase the readability of the code. Optional C parentheses vary between two stylistic extremes:

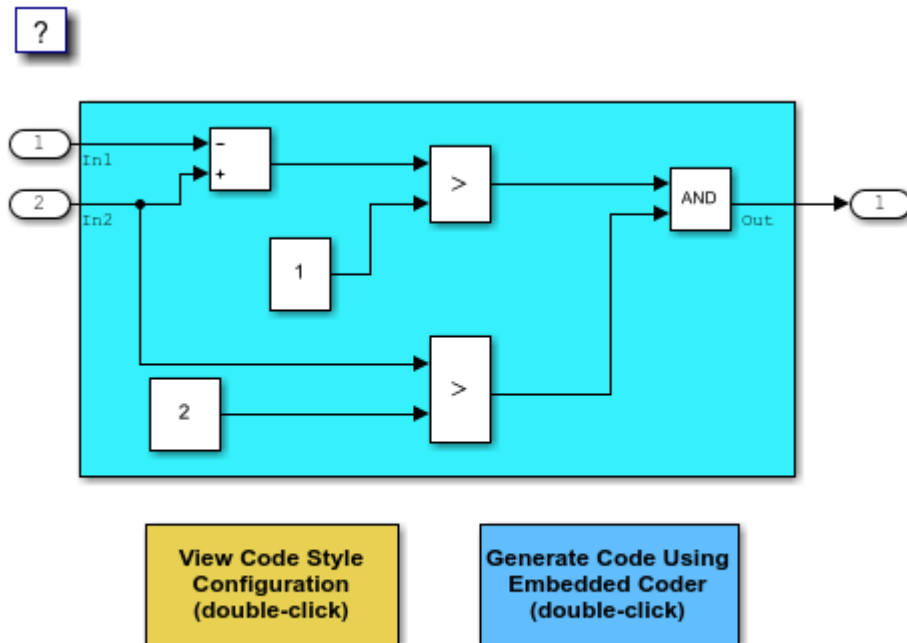

- Include the minimum parentheses required by C syntax and precedence overrides so that C precedence rules specify all semantics unless overridden by parentheses.
- Include the maximum parentheses that can exist without duplication so that C precedence rules become irrelevant. Parentheses alone completely specify all semantics.

Understanding code with minimum parentheses can require applying nonobvious precedence rules. Maximum parentheses can hinder code reading by belaboring obvious precedence rules. Various parenthesization standards exist that specify one or the other extreme, or define an intermediate style useful to people who read code.

### Control Use of Parentheses

This example shows that Embedded Coder® provides three levels of control for parentheses in the generated code.

```
model='rtwdemo_parentheses';  
open_system(model)
```

Copyright 2006-2019 The MathWorks, Inc.

```
rtwdemoclean;
close_system(model,0)
```

## Optimize Code by Reordering Commutable Operands

This example shows how to reorder commutable operands to make expressions left-recursive. Left-recursive reordering saves stack space in memory. This optimization improves code efficiency.

### Example Model

To reorder commutable operands, create this model and name it `operand_order`. The output signal is the result of multiplying the signal from Inport block In1 by the sum of the signals from Inport blocks In2 and In3.

### Generate Code

- 1 Open the Model Configuration Parameters dialog box. On the **Code Style** tab, select the **Preserve operand order in expression** parameter.
- 2 Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains this code:

```
operand_order_Y.Out1 = operand_order_U.In1 * (operand_order_U.In2 +
    operand_order_U.In3);
```

The code generator preserves the specified expression order in the model, which increases the readability of the code for code traceability.

## Generate Code with Optimization

- 1 Open the Model Configuration Parameters dialog box. On the **Code Style** tab, clear the **Preserve operand order in expression** parameter.
- 2 Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains this code:

```
operand_order_Y.Out1 = (operand_order_U.In2 + operand_order_U.In3) *  
    operand_order_U.In1;
```

The code generator optimizes the code by reordering the commutable operands to make the expression left-recursive, which improve code efficiency.

## Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements

This example shows how to specify whether to generate default cases for switch-case statements in the code for Stateflow charts. Generated code that does not contain default cases conserves ROM consumption and enables better code coverage because every branch in the generated code is falsifiable.

Some coding standards, such as MISRA, require the default case for switch-case statements. If you want to increase your chances of producing MISRA C compliant code, generate default cases for unreachable Stateflow switch statements.

### Example

Figures 1, 2, and 3 show relevant portions of the `sldemo_fuelsys` model, a closed-loop system containing a plant and controller. The Air-fuel rate controller logic is a Stateflow chart that specifies the different operation modes.

### Fault-Tolerant Fuel Control System

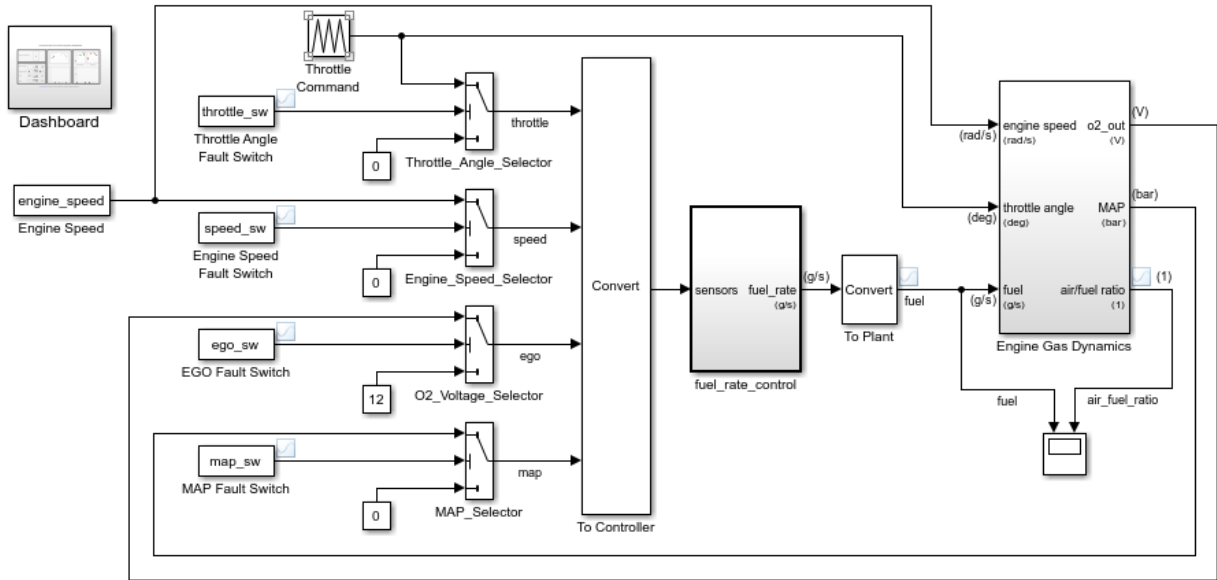

Figure 1: Top-level model of the plant and controller

### Fuel Rate Control Subsystem

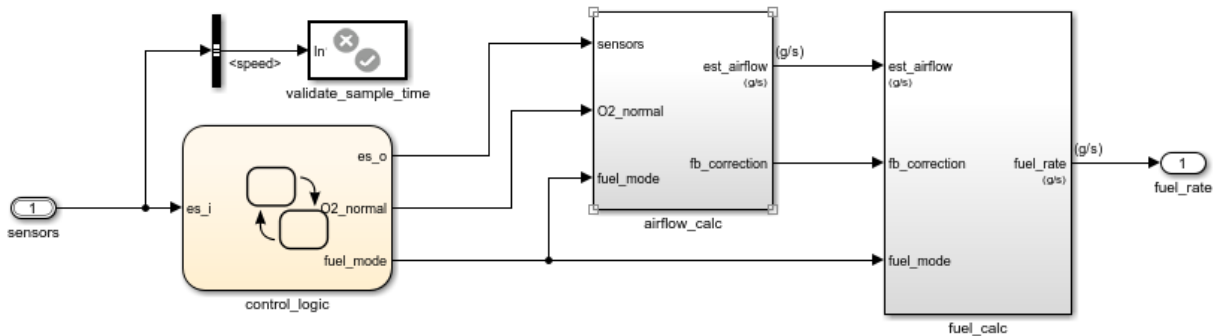

Figure 2: Fuel rate controller subsystem

Figure 3: Fuel rate controller logic

## Generate Code with Default Cases for Unreachable Stateflow Switch Statements

- 1 In the MATLAB Command Window, to open `sldemo_fuelsys` via `rtwdemo_fuelsys` enter:

```
rtwdemo_fuelsys
```

- 2 Open the Model Configuration parameters dialog box. On the **Code Generation > Code Style** tab, clear the **Suppress generation of default cases for Stateflow switch statements if unreachable** parameter.
- 3 In the MATLAB Command Window, to build the model, enter:

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
```

For the different operation modes, the `fuel_rate_control.c` file contains default cases for unreachable switch statements. For example, for the Shutdown operation mode, the generated code contains this default statement:

```
default:
/* Unreachable state, for coverage only */
rtDWork.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
break;
```

For the Warmup operation mode, the generated code contains this default statement:

```
default:
/* Unreachable state, for coverage only */
rtDWork.bitsForTID0.is_Low_Emissions = IN_NO_ACTIVE_CHILD;
break;
```

## Suppress Default Cases for Unreachable Stateflow Switch Statements

- 1 Open the Configuration Parameters dialog box. On the **Code Generation > Code Style** tab, select the **Suppress generation of default cases for Stateflow statements if unreachable** parameter.
- 2 Build the model.

Read through the `fuel_rate_control.c` file. The default cases for unreachable switch statements are not in the generated code.

## Replace Multiplication by Powers of Two with Signed Bitwise Shifts

This example shows how to generate code that replaces multiplication by powers of two with signed bitwise shifts. Code that contains bitwise shifts executes faster than the code containing multiplication by powers of two.

Some coding standards, such as MISRA, do not allow bitwise operations on signed integers. If you want to increase your chances of producing MISRA C compliant code, do not replace multiplication by powers of two with bitwise shifts.

### Example

To replace multiplication by powers of two with bitwise shifts, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift > Direction** parameter is set to Left. The **Bits to shift > Number** parameter is set to 3. This parameter corresponds to a value of 8, or raising 2 to the power of 3.

### Generate Code with Signed Bitwise Shifts

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Replace multiplications by powers of two with signed bitwise shifts** parameter is on by default.
- 2 Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 << 3);
```

The signed integer, `bitwise_multiplication_U.In1`, is shifted three bits to the left.

## Generate Code with Multiplication by Powers of Two

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab.
- 2 Clear the **Replace multiplications by powers of two with signed bitwise shifts** parameter.
- 3 Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 * 8);
```

The signed integer `bitwise_multiplication_U.In1` is multiplied by 8.

## See Also

- “Replace multiplications by powers of two with signed bitwise shifts”
- “Model Configuration Parameters: Code Style”

## Generate Code Containing Right Shifts on Signed Integers

This example shows how to control whether the generated code contains right shifts on signed integers. Generated code that does not contain right shifts on signed integers first casts the signed integers to unsigned integers, and then right shifts the unsigned integers.

Some coding standards, such as MISRA, do not allow right shifts on signed integers because different hardware can store negative integers differently. For negative integers, you can get different answers depending on the hardware. If you want to increase your chances of producing MISRA C compliant code, do not allow right shifts on signed integers.

### Example Model

To generate code with right shifts on signed integers, create this model. A signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift > Direction** parameter is set to Right. The **Bits to shift > Number** parameter is set to 3.

### Generate Code Containing Right Shifts on Signed Integers

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Allow right shifts on signed integers** parameter is on by default.
- 2 Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)(rightshift_U.In1 >> 3);
```

The signed integer `rightshift_U.In1` is shifted three bits to the right.

## Generate Code That Does Not Allow Right Shifts on Signed Integers

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. Clear the **Allow right shifts on signed integers** parameter.
- 2 Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)asr_s32(rightshift_U.In1, 3U);
```

When you clear the **Allow right shifts on signed integers** parameter, the generated code contains a function call instead of a right shift on a signed integer. The function `asr_s32` contains this code:

```
int32_T asr_s32(int32_T u, uint32_T n)
{
    int32_T y;
    if (u >= 0) {
        y = (int32_T)((uint32_T)u >> n);
    } else {
        y = -(int32_T)((uint32_T)-(u + 1) >> n) - 1;
    }

    return y;
}
```

The `asr_s32` function casts a signed integer to an unsigned integer, and then right shifts the unsigned integer.

## Control Cast Expressions in Generated Code

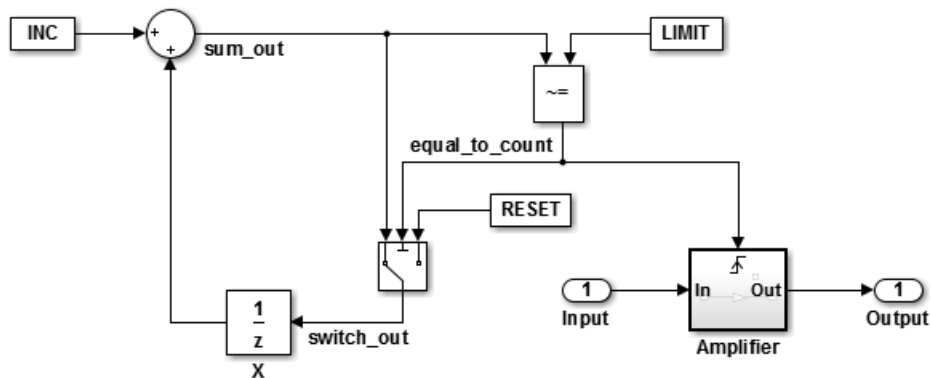

You can choose how the code generator specifies data type casts in the generated code. In the Configuration Parameters dialog box, select **Code Generation > Code Style**. From the **Casting modes** drop-down list, three parameter options control how the code generator casts data types.

- **Nominal** instructs the code generator to generate code that has minimal data type casting. When you do not have special data type information requirements, choose **Nominal**.
- **Standards Compliant** instructs the code generator to cast data types to conform to MISRA standards when it generates code. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations.

For more information, see “MISRA C Guidelines” on page 22-6.

- **Explicit** instructs the code generator to cast data type values explicitly when it generates code. You can see how a value is stored, which tells you how much memory space the code uses for the variable. The data type informs you how much precision is possible in calculations involving the variable.

Open the example model `rtwdemo_rtwecintro`.

## Enable Nominal Casting Mode and Generate Code

When you choose Nominal casting mode, the code generator does not create data type casts for variables in the generated code.

- 1 On the **Code Generation > Code Style** pane, from the **Casting modes** drop-down list, select **Nominal**.
- 2 On the **Code Generation > Report** pane, select **Create code generation report**.
- 3 On the **Code Generation** pane, select **Generate code only**.
- 4 Click **Apply**.
- 5 In the model window, press **Ctrl+B** to generate code.
- 6 In the Code Generation report left pane, click `rtwdemo_rtwecontrol.c` to see the code.

```

/* Model step function */
void rtwdemo_rtwecontrol_step(void)
{
    boolean_T rtb_equal_to_count;

    /* Sum: 'XRootX/Sum' incorporates:
     * Constant: 'XRootX/INC'
     * UnitDelay: 'XRootX/X'
     */
    rtDWork.X++;

    /* RelationalOperator: 'XRootX/RelOpt' incorporates:
     * Constant: 'XRootX/LIMIT'
     */
    rtb_equal_to_count = (rtDWork.X != 16);

    /* Outputs for Triggered SubSystem: 'XRootX/Amplifier' incorporates:
     * TriggerPort: 'XS1X/Trigger'
     */
    if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
    {
        /* Outputport: 'XRootX/Output' incorporates:
         * Gain: 'XS1X/Gain'
         * Inport: 'XRootX/Input'
         */
        rtY.Output = rtU.Input << 1;
    }

    rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
        POS_ZCSIG : (int32_T)ZERO_ZCSIG);

    /* End of Outputs for SubSystem: 'XRootX/Amplifier' */

    /* Switch: 'XRootX/Switch' */
    if (!rtb_equal_to_count) {
        /* Update for UnitDelay: 'XRootX/X' incorporates:
         * Constant: 'XRootX/RESET'
         */
        rtDWork.X = 0U;
    }
}

```

```

    }
    /* End of Switch: 'XRootX/Switch' */
}

```

## Enable Standards Compliant Casting Mode and Generate Code

When you choose **Standards Compliant** casting mode, the code generator creates MISRA standards compliant data type casts for variables in the generated code.

- 1 On the **Code Style** pane, from the **Casting modes** drop-down list, select **Standards Compliant**.
- 2 On the **Code Generation** pane, click **Apply**.
- 3 In the model window, press **Ctrl+B** to generate code.
- 4 In the Code Generation report left pane, click `rtwdemo_rtweccintro.c` to see the code.

```

void rtwdemo_rtweccintro_step(void)
{
    boolean_T rtb_equal_to_count;

    /* Sum: '<Root>/Sum' incorporates:
     * Constant: '<Root>/INC'
     * UnitDelay: '<Root>/X'
     */
    rtDWork.X++;

    /* RelationalOperator: '<Root>/RelOpt' incorporates:
     * Constant: '<Root>/LIMIT'
     */
    rtb_equal_to_count = (boolean_T)(int32_T)((int32_T)rtDWork.X != (int32_T)16);

    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
     * TriggerPort: '<S1>/Trigger'
     */
    if (((int32_T)rtb_equal_to_count) && (rtPrevZCSigState.Amplifier_Trig_ZCE !=
        POS_ZCSIG)) {
        /* Output: '<Root>/Output' incorporates:
         * Gain: '<S1>/Gain'
         * Inport: '<Root>/Input'
         */
        rtY.Output = (int32_T)(uint32_T)((uint32_T)rtU.Input << (uint32_T)(int8_T)1);
    }

    rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(int32_T)(rtb_equal_to_count ?
        (int32_T)(uint8_T)POS_ZCSIG : (int32_T)(uint8_T)ZERO_ZCSIG);

    /* End of Outputs for SubSystem: '<Root>/Amplifier' */

    /* Switch: '<Root>/Switch' */
    if (!rtb_equal_to_count) {
        /* Update for UnitDelay: '<Root>/X' incorporates:
         * Constant: '<Root>/RESET'
         */
    }
}

```

```

    rtDWork.X = 0U;
}

/* End of Switch: '<Root>/Switch' */
}

```

## Enable Explicit Casting Mode and Generate Code

When you choose `Explicit` casting mode, the code generator creates explicit data type casts for variables in the generated code.

- 1 On the **Code Style** pane, from the **Casting modes** drop-down list, select `Explicit`.
- 2 On the **Code Generation** pane, click **Apply**.
- 3 In the model window, press **Ctrl+B** to generate code.
- 4 In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```

/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
    boolean_T rtb_equal_to_count;

    /* Sum: '<Root>/Sum' incorporates:
     * Constant: '<Root>/INC'
     * UnitDelay: '<Root>/X'
     */
    rtDWork.X = (uint8_T)(1U + (uint32_T)(int32_T)rtDWork.X);

    /* RelationalOperator: '<Root>/RelOpt' incorporates:
     * Constant: '<Root>/LIMIT'
     */
    rtb_equal_to_count = (boolean_T)((int32_T)rtDWork.X != 16);

    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
     * TriggerPort: '<S1>/Trigger'
     */
    if (((int32_T)rtb_equal_to_count) && ((int32_T)((int32_T)
        rtPrevZCSigState.Amplifier_Trig_ZCE != (int32_T)POS_ZCSIG))) {
        /* Output: '<Root>/Output' incorporates:
         * Gain: '<S1>/Gain'
         * Inport: '<Root>/Input'
         */
        rtY.Output = rtU.Input << 1;
    }

    rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
        POS_ZCSIG : (int32_T)ZERO_ZCSIG);

    /* End of Outputs for SubSystem: '<Root>/Amplifier' */

    /* Switch: '<Root>/Switch' */
    if (!(int32_T)rtb_equal_to_count) {
        /* Update for UnitDelay: '<Root>/X' incorporates:
         * Constant: '<Root>/RESET'
         */

```

```
    rtDWork.X = 0U;
  }
  /* End of Switch: '<Root>/Switch' */
}
```

## Customize Code Organization and Format

### In this section...

“Custom File Processing Components” on page 50-55

“Custom File Processing Configuration” on page 50-56

Custom file processing (CFP) tools allow you to customize the organization and formatting of generated code. With these tools, you can:

- Generate a source (.c or .cpp) or header (.h) file. If you configure the **Code interface packaging** for a model to be `Reusable function` or `Nonreuseable function` (not C++ `class`), you can use a *custom file processing template* to control how the code generator:
  - Emits code to standard generated files---*model.c* or *.cpp* and *model.h*
  - Produces files that are independent of model code
- Organize generated code into sections (such as includes, typedefs, functions, and more). Your CFP template can emit code (for example, functions), directives (such as `#define` or `#include` statements), or comments into each section.
- Generate custom *file banners* (comment sections) at the start and end of generated code files and custom *function banners* that precede functions in the generated code.
- Generate code to call model functions, such as *model\_initialize*, *model\_step*, and so on.
- Generate code to read and write model inputs and outputs.
- Generate a main program module.
- Obtain information about the model and the generated files from the model.

### Custom File Processing Components

The custom file processing features are based on the following interrelated components:

- *Code generation template* (CGT) files: a CGT file defines the top-level organization and formatting of generated code. See “Code Generation Template (CGT) Files” on page 50-59.
- The *code template API*: a high-level Target Language Compiler (TLC) API that provides functions with which you can organize code into named sections and subsections of

generated source and header files. The code template API also provides utilities that return information about generated files, generate standard model calls, and perform other functions. See “Code Template API Summary” on page 50-86.

- *Custom file processing (CFP) templates*: a CFP template is a TLC file that manages the process of custom code generation. A CFP template assembles code to be generated into buffers. A CFP template also calls the code template API to emit the buffered code into specified sections of generated source and header files. A CFP template interacts with a CGT file, which defines the ordering of major sections of the generated code. See “Custom File Processing (CFP) Templates” on page 50-66.

To use CFP templates, you must understand TLC programming, for more information, see “Target Language Compiler” (Simulink Coder).

## Custom File Processing Configuration

Customize generated code by specifying code and data templates on the **Code Generation > Templates** pane:

Goal	Action
Specify a template that defines the top-level organization and formatting of generated source code (.c or .cpp) files	Enter a code generation template (CGT) file for the <b>Source file (*.c) template</b> parameter.
Specify a template that defines the top-level organization and formatting of generated header (.h) files	Enter a CGT file for the <b>Header file (*.h) template</b> parameter. This template file can be the same template file that you specify for <b>Source file (.c) template</b> . If you use the same template file, source and header files contain identical banners. The default template is <code>matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt</code> .
Specify a template that organizes generated code into sections (such as includes, typedefs, functions, and more)	Enter a custom file processing (CFP) template file for the “File customization template” parameter. A CFP template can emit code, directives, or comments into each section. For more information, see “Custom File Processing (CFP) Templates” on page 50-66.
Generate a model-specific example main program module	Select <b>Generate an example main program</b> . For more information, see “Generate a Standalone Program” on page 63-2.

---

**Note** Place the template files that you specify on the MATLAB path.

---

## Specify Templates For Code Generation

To use custom file processing features, create CGT files and CFP templates. These files are based on default templates provided by the code generation software. Once you have created your templates, you must integrate them into the code generation process.

Select and edit CGT files and CFP templates, and specify their use in the code generation process in the **Code Generation > Templates** pane of a model configuration set. The following figure shows options configured for their defaults.

The options related to custom file processing are:

- The **Source file (.c) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating source (.c or .cpp) files. You must place this file on the MATLAB path.
- The **Header file (.h) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating header (.h) files. You must place this file on the MATLAB path.

By default, the template for both source and header files is `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

- The **File customization template** edit field in the **Custom templates** section. This field specifies the name of a CFP template file to use when generating code files. You must place this file on the MATLAB path. The default CFP template is `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`.

In each of these fields, click **Browse** to navigate to and select an existing CFP template or CGT file. Click **Edit** to open the specified file into the MATLAB editor where you can customize it.

## Code Generation Template (CGT) Files

Code Generation Template (CGT) files define the top-level organization and formatting of generated source code and header files. CGT files have the following applications:

- Generation of custom banners (comments sections) in code files. See “Generate Custom File and Function Banners” on page 50-90.
- Generation of custom code using a CFP template requires a CGT file. To use CFP templates, you must understand the CGT file structure. In many cases, however, you can use the default CGT file without modifying it.

### Default CGT file

The code generation software provides a default CGT file, *matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt*. Base your custom CGT files on the default file.

### CGT File Structure

A CGT file consists of one required section and four optional sections:

#### Code Insertion Section

(Required) This section contains tokens that define an ordered partitioning of the generated code into a number of sections (such as `Includes` and `Defines` sections). Tokens have the form of:

```
%<SectionName>
```

For example,

```
%<Includes>
```

The code generation software defines a minimal set of required tokens. These tokens generate C or C++ source or header code. They are *built-in* tokens (see “Built-In Tokens and Sections” on page 50-60). You can also define custom tokens on page 50-81 and custom sections on page 50-79.

Each token functions as a placeholder for a corresponding section of generated code. The ordering of the tokens defines the order in which the corresponding sections appear in

the generated code. If you do not include a token, then the corresponding section is not generated. To generate code into a given section, explicitly call the code template API from a CFP template, as described in “Custom File Processing (CFP) Templates” on page 50-66.

The CGT tokens define the high-level organization of generated code. Using the code template API, you can partition each code section into named subsections, as described in “Subsections” on page 50-62.

In the code insertion section, you can also insert C or C++ comments between tokens. Such comments emit directly into the generated code.

### **File Banner Section**

(Optional) This section contains comments and tokens you use in generating a custom file banner.

### **Function Banner Section**

(Optional) This section contains comments and tokens for use in generating a custom function banner.

### **Shared Utility Function Banner Section**

(Optional) This section contains comments and tokens for use in generating a custom shared utility function banner.

### **File Trailer Section**

(Optional) This section contains comments for use in generating a custom trailer banner.

For more information on these sections, see “Generate Custom File and Function Banners” on page 50-90.

## **Built-In Tokens and Sections**

The following code extract shows the required code insertion section of the default CGT file with the required built-in tokens.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%  
%% Code insertion section (required)  
%% These are required tokens. You can insert comments and other tokens in  
%% between them, but do not change their order or remove them.
```

```
%%  
%<Includes>  
%<Defines>  
%<Types>  
%<Enums>  
%<Definitions>  
%<Declarations>  
%<Functions>
```

Note the following requirements for customizing a CGT file:

- Do not remove required built-in tokens.
- Built-in tokens must appear in the order shown because each successive section has dependencies on previous sections.
- Only one token per line.
- Do not repeat tokens.
- You can add custom tokens and comments to the code insertion section as long as you do not violate the previous requirements.

---

**Note** If you modify a CGT file and then rebuild your model, the code generation process does not force a top model build. To regenerate the code, see “Force Regeneration of Top Model Code” (Simulink Coder).

---

The following table summarizes the built-in tokens and corresponding section names, and describes the code sections.

### Built-In CGT Tokens and Corresponding Code Sections

Token and Section Name	Description
Includes	<code>#include</code> directives section
Defines	<code>#define</code> directives section
Types	<code>typedef</code> section. Typedefs can depend on a previously defined type
Enums	Enumerated types section
Definitions	Data definitions (for example, <code>double x = 3.0;</code> )
Declarations	Data declarations (for example, <code>extern double x;</code> )
Functions	C or C++ functions

### Subsections

You can define one or more named subsections for any section. Some of the built-in sections have predefined subsections summarized in table Subsections Defined for Built-In Sections.

---

**Note** Sections and subsections emit to the source or header file in the order listed in the CGT file.

---

Using the custom section feature, you can define additional sections. See “Generate a Custom Section” on page 50-79.

**Subsections Defined for Built-In Sections**

<b>Section</b>	<b>Subsections</b>	<b>Subsection Description</b>
Includes	N/A	
Defines	N/A	
Types	IntrinsicTypes	Intrinsic typedef section. Intrinsic types depend only on intrinsic C or C++ types.
Types	PrimitiveTypedefs	Primitive typedef section. Primitive typedefs depend only on intrinsic C or C++ types and on typedefs previously defined in the IntrinsicTypes section.
Types	UserTop	You can place any type of code in this section, including code that has dependencies on the previous sections.
Types	Typedefs	typedef section. Typedefs can depend on previously defined types
Enums	N/A	
Definitions	N/A	
Declarations	N/A	
Functions		C or C++ functions
Functions	CompilerErrors	#error directives
Functions	CompilerWarnings	#warning directives
Functions	Documentation	Documentation (comment) section
Functions	UserBottom	You can place any code in this section.

## Format Generated Code Files by Using Templates

This example shows how to use code generation templates to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files.

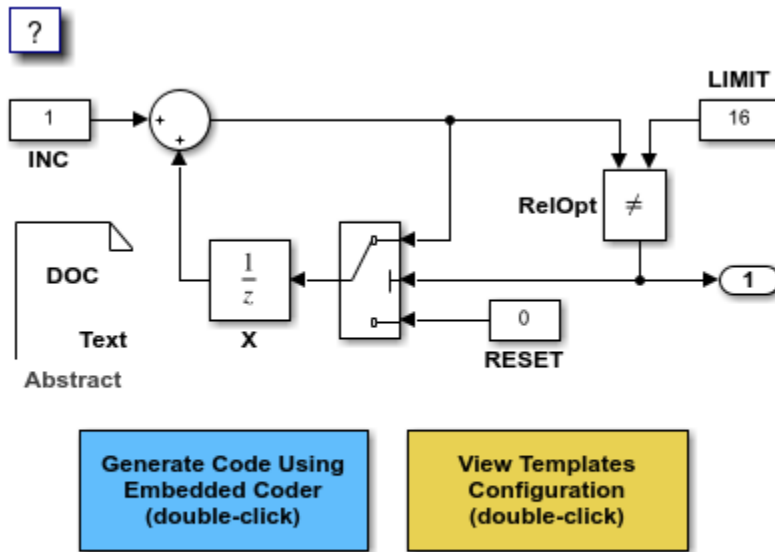

The model extracts text from the Model Description, a DOC block, and a Simulink annotation. The Simulink annotation maps to the code template %<Note> symbol.

The templates provide consistent file layout and elaboration for your organization's coding standards. Embedded Coder provides extensible code generation templates for formatting generated code. The layout and format of the code template file controls the output of the generated code.

Code generation templates (.cgt files) enable you to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into the generated code files. Code generation templates are imported automatically from the MATLAB path. For this model, the code generation template `rtwdemocodetemplate.cgt` is used.

1. Open model `rtwdemo_codetemplate`.

```
model='rtwdemo_codetemplate';  
open_system(model)
```

Copyright 1994-2019 The MathWorks, Inc.

2. In the Configuration Parameters dialog box, open **Code Generation > Templates** pane.
3. In the **Code templates** section, click the **Edit** button beside **Source file template**. The `rtwdemocodetemplate.cgt` template opens in the MATLAB Command Window. Inspect the code template.
4. Build the model and generate code. On the **C Code** tab, click **Build**.
5. Open `rtwdemo_codetemplate.c` to inspect the generated code.

```
rtwdemoclean;
close_system(model,0)
```

## Custom File Processing (CFP) Templates

The files provided to support custom file processing are:

- `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc`: A TLC function library that implements the code template API. `codetemplatelib.tlc` also provides the comprehensive documentation of the API in the comments headers preceding each function.
- `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`: An example custom file processing (CFP) template, which you should use as the starting point for creating your own CFP templates. Guidelines and examples for creating a CFP template are provided in “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 50-74.
- TLC files supporting generation of single-rate and multirate main program modules (see “Customizing Main Program Module Generation” on page 50-78).

Once you have created a CFP template, you must integrate it into the code generation process, using the **File customization template** edit field. See “Specify Templates For Code Generation” on page 50-58.

### Custom File Processing (CFP) Template Structure

A custom file processing (CFP) template imposes a simple structure on the code generation process. The template, a code generation template (CGT) file, partitions the code generated for each file into a number of sections. These sections are summarized in Built-In CGT Tokens and Corresponding Code Sections and Subsections Defined for Built-In Sections.

Code for each section is assembled in buffers and then emitted, in the order listed, to the file being generated.

To generate a file section, your CFP template must first assemble the code to be generated into a buffer. Then, to emit the section, your template calls the TLC function

```
LibSetSourceFileSection(fileH, section, tmpBuf)
```

where

- `fileH` is a file reference to a file being generated.

- `section` is the code section or subsection to which code is to be emitted. `section` must be one of the section or subsection names listed in Subsections Defined for Built-In Sections.

Determine the `section` argument as follows:

- If Subsections Defined for Built-In Sections does not define subsections for a given section, use the section name as the `section` argument.
- If Subsections Defined for Built-In Sections defines one or more subsections for a given section, you can use either the section name or a subsection name as the `section` argument.
- If you have defined a custom token denoting a custom section, do not call `LibSetSourceFileSection`. Special API calls are provided for custom sections (see “Generate a Custom Section” on page 50-79).
- `tmpBuf` is the buffer containing the code to be emitted.

There is no requirement to generate all of the available sections. Your template need only generate the sections you require in a particular file.

Note that legality or syntax checking is not performed on the custom code within each section.

See “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 50-74, for typical usage examples.

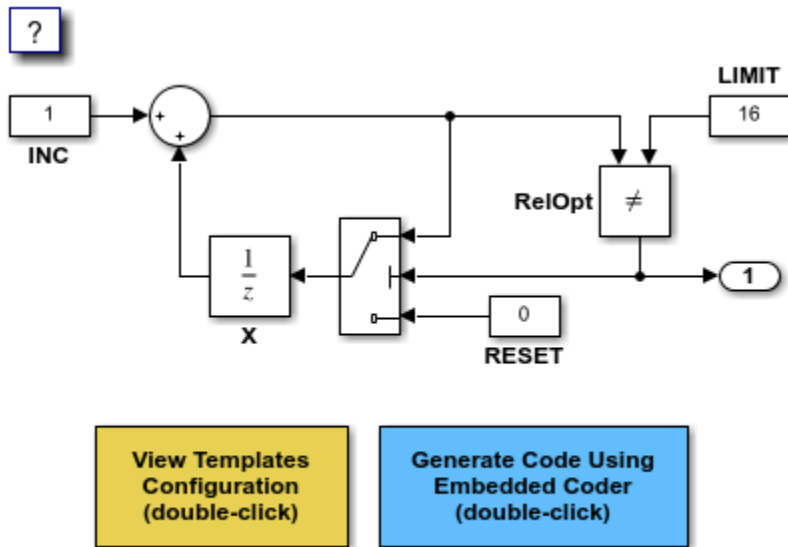

## Generate Additional Files Required to Interface with an Application

Embedded Coder® provides an extensible API to augment generated code and to generate additional files. The model configuration parameter **File customization template** specifies a custom Target Language Compiler (TLC) script that executes at the end of the code generation process. Using this script, you can generate additional code to interface with application code.

In this example, the TLC script file `rtwdemofileprocess.tlc` creates an additional entry-point function, `rtwdemo_fileprocess`, which calls the step function and initializes the model, if necessary. The initialization function is transparent to the caller.

1. Open the example model `rtwdemo_fileprocess`.

```
open_system('rtwdemo_fileprocess');
```

Copyright 1994-2019 The MathWorks, Inc.

2. Verify the model configuration parameter **File customization template** is set to `rtwdemofileprocess.tlc` by double-clicking the yellow button labeled **View Templates Configuration**.

3. Generate code.

4. Inspect the generated code. An additional function, `rtwdemo_fileprocess`, appears at the end of the generated file `rtwdemo_fileprocess.c`. The entry point is declared `extern` in `rtwdemo_fileprocess.h` as the `rtwdemofileprocess.tlc` script specifies.

## Change the Organization of a Generated File

The files created during code generation are organized according to the general code generation template. This template has the filename `ert_code_template.cgt`, and is specified by default in **Code Generation > Templates** pane of the Configuration Parameters dialog box.

The following fragment shows the `rtwdemo_basicsc.c` file header that is generated using this default template:

```
/*
 * File: rtwdemo_basicsc.c
 *
 * Code generated for Simulink model 'rtwdemo_basicsc'.
 *
 * Model version           : 1.299
 * Simulink Coder version  : 8.11 (R2017a) 01-Aug-2016
 * C/C++ source code generated on : Fri Aug 19 12:45:59 2016
 *
 * Target selection: ert.tlc
 * Embedded hardware selection: Intel->x86-64 (Windows64)
 * Code generation objectives: Unspecified
 * Validation result: Not run
 */
```

You can change the organization of generated files using code templates and data templates. Code templates organize the files that contain functions, primarily. Data templates organize the files that contain identifiers. In this procedure, you organize the generated files, using the supplied code and data templates:

- 1 Display the active **Templates** configuration parameters.
- 2 In the **Code templates** section of the **Templates** pane, type `code_c_template.cgt` into the **Source file (\*.c) templates** text box.
- 3 Type `code_h_template.cgt` into the **Header file (\*.h) templates** text box.
- 4 In the **Data templates** section, type `data_c_template.cgt` into the **Source file (\*.c) templates** text box.
- 5 Type `data_h_template.cgt` into the **Header file (\*.h) templates** text box, and click **Apply**.
- 6 In the model window, press **Ctrl+B**. Now the files are organized using the templates you specified. For example, the `rtwdemo_basicsc.c` file header now is organized like this:

```
/**
*****
** FILE INFORMATION:
** Filename:          rtwdemo_basicsc.c
** File Creation Date: 19-Aug-2016
**
** ABSTRACT:
**
**
** NOTES:
**
**
** MODEL INFORMATION:
** Model Name:        rtwdemo_basicsc
** Model Description: Specifying Storage Class Within a Diagram

    This model shows how to define data storage class as part of
    the diagram.

```

## Customize Generated File Names

The code generator creates *model.\** files during the code generation and build process. When you generate C/C++ code for ERT-based models, you can customize the names of the generated header, source, and data files. Custom file names enable you to:

- Comply with naming standards of the company or industry.
- Integrate with external code.

In the Configuration Parameters dialog box, on the **Code Generation > Code Placement** pane, use the **Auto-generated file naming rules** group to customize the names of generated files. When you use Modular or Compact(with separate date file) file packaging, you can specify custom names for generated header, source, and data files. When you use Compact file packaging, you can specify custom names for generated header and source files.

- 1 Open any ERT-based model, for example, `rtwdemo_dynamicio`. In the Configuration Parameters dialog box, change the **System target file** to `ert.tlc`.
- 2 On the **Code Generation > Code Placement** pane, select **File packaging format** as Compact(with separate date file).
- 3 Specify custom file names by using the naming rules for these parameters:
  - **Header files:** `$R$E_header`
  - **Source files:** `$R$E_source`
  - **Data files:** `$R_data`

`$E` is mandatory for **Header files** and **Source files**. `$E` represents these instances of file types:

- `capi`
  - `capi_host`
  - `dt`
  - `testinterface`
  - `private`
  - `types`
- 4 To build the model, press **Ctrl + B**. In the code generation report, the generated files are listed on the left pane under **Model files** and **Data files** section.

**Generated Code**[-] **Main file**[ert\\_main.c](#)[-] **Model files**[rtwdemo\\_dynamicio\\_header.h](#)[rtwdemo\\_dynamicio\\_private\\_header.h](#)[rtwdemo\\_dynamicio\\_source.c](#)[rtwdemo\\_dynamicio\\_types\\_header.h](#)[-] **Data files**[rtwdemo\\_dynamicio\\_data.c](#)

In this example, \$E resolves to `private` and `types`. The generated header files resolve to the model name with the value for \$E and custom text header. The generated source files resolve to the model name with custom text source. The generated data file resolves to the model name with custom text data. Here is a summary of naming rules applied and the corresponding generated files:

Type of File	Token Specification	Custom Text	Generated File Name
Header file	\$R\$E	header	rtwdemo_dynamicio_header.h
Header file	\$R\$E	header	rtwdemo_dynamicio_private_header.h
Source file	\$R\$E	source	rtwdemo_dynamicio_source.c
Header file	\$R\$E	header	rtwdemo_dynamicio_types_header.h

---

Type of File	Token Specification	Custom Text	Generated File Name
Data file	\$R	data	rtwdemo_dynami cio_data.c

## Generate Source and Header Files with a Custom File Processing (CFP) Template

### In this section...

“Generate Code with a CFP Template” on page 50-74

“Analysis of the Example CFP Template and Generated Code” on page 50-76

“Generate a Custom Section” on page 50-79

“Custom Tokens” on page 50-81

This example shows you the process of generating a simple source (.c or .cpp) and header (.h) file using the example CFP template. Then, it examines the template and the code generated by the template.

The example CFP template, *matlabroot/toolbox/rtw/targets/ecoder/example\_file\_process.tlc*, demonstrates some of the capabilities of the code template API, including

- Generation of simple source (.c or .cpp) and header (.h) files
- Use of buffers to generate file sections for includes, functions, and so on
- Generation of includes, defines, into the standard generated files (for example, *model.h*)
- Generation of a main program module

### Generate Code with a CFP Template

This section sets up a CFP template and configures a model to use the template in code generation. The template generates (in addition to the standard model files) a source file (*timestwo.c* or *.cpp*) and a header file (*timestwo.h*).

Follow the steps below to become acquainted with the use of CFP templates:

- 1 Copy the example CFP template, *matlabroot/toolbox/rtw/targets/ecoder/example\_file\_process.tlc*, to a folder outside of the MATLAB folder structure (that is, not under *matlabroot*). If the folder is not on the MATLAB path or the TLC path, then add it to the MATLAB path. It is good practice to locate the CFP template in the same folder as your system target file, which is on the TLC path.

- 2 Rename the copied `example_file_process.tlc` to `test_example_file_process.tlc`.
- 3 Open `test_example_file_process.tlc` into the MATLAB editor.
- 4 Uncomment the following line:

```
%% %assign ERTCustomFileTest = TLC_TRUE
```

It now reads:

```
%assign ERTCustomFileTest = TLC_TRUE
```

If `ERTCustomFileTest` is not assigned as shown, the CFP template is ignored in code generation.

- 5 Save your changes to the file. Keep `test_example_file_process.tlc` open, so you can refer to it later.
- 6 Open the `rtwdemo_udt` model.
- 7 Open the Simulink Model Explorer. Select the active configuration set of the model, and open the **Code Generation** pane of the active configuration set.
- 8 On the **Templates** tab, in the **File customization template** field, specify `test_example_file_process.tlc`. This is the file you previously edited and is now the specified CFP template for your model.
- 9 On the **General** tab, select the **Generate code only** check box.
- 10 Click **Apply**.
- 11 In the model window, press **Ctrl+B**. During code generation, notice the following message in the **Diagnostic Viewer**:

```
Warning: Overriding example ert_main.c!
```

This message is displayed because `test_example_file_process.tlc` generates the main program module, overriding the default action of the ERT target. This is explained in greater detail below.

- 12 The `rtwdemo_udt` model is configured to generate an HTML code generation report. After code generation is complete, view the report.

Notice that the **Generated Code** list contains the following files:

- Under **Main file**, `ert_main.c`.
- Under **Other files**, `timestwo.c` and `timestwo.h`.

The files were generated by the CFP template. The next section examines the template to learn how this was done.

- 13 Keep the model, the code generation report, and the `test_example_file_process.tlc` file open so you can refer to them in the next section.

## Analysis of the Example CFP Template and Generated Code

This section examines excerpts from `test_example_file_process.tlc` and some of the code it generates. Refer to the comments in `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc` while reading the following discussion.

### Generating Code Files

Source (.c or .cpp) and header (.h) files are created by calling `LibCreateSourceFile`, as in the following excerpts:

```
%assign cFile = LibCreateSourceFile("Source", "Custom", "timestwo")
...
%assign hFile = LibCreateSourceFile("Header", "Custom", "timestwo")
```

Subsequent code refers to the files by the file reference returned from `LibCreateSourceFile`.

### File Sections and Buffers

The code template API lets you partition the code generated to each file into sections, tagged as `Definitions`, `Includes`, `Functions`, `Banner`, and so on. You can append code to each section as many times as required. This technique gives you a great deal of flexibility in the formatting of your custom code files.

`Subsections Defined for Built-In Sections` describes the available file sections and their order in the generated file.

For each section of a generated file, use `%openfile` and `%closefile` to store the text for that section in temporary buffers. Then, to write (append) the buffer contents to a file section, call `LibSetSourceFileSection`, passing in the desired section tag and file reference. For example, the following code uses two buffers (`typesBuf` and `tmpBuf`) to generate two sections (tagged "Includes" and "Functions") of the source file `timestwo.c` or `.cpp` (referenced as `cFile`):

```
%openfile typesBuf
```

```

#include "rtwtypes.h"

%closefile typesBuf

%<LibSetSourceFileSection(cFile,"Includes",typesBuf)>

%openfile tmpBuf

/* Times two function */
real_T timestwofcn(real_T input) {
    return (input * 2.0);
}

%closefile tmpBuf

%<LibSetSourceFileSection(cFile,"Functions",tmpBuf)>

```

These two sections generate the entire `timestwo.c` or `.cpp` file:

```

#include "rtwtypes.h"

/* Times two function */
FLOAT64 timestwofcn(FLOAT64 input)
{
    return (input * 2.0);
}

```

### Adding Code to Standard Generated Files

The `timestwo.c` or `.cpp` file generated in the previous example was independent of the standard code files generated from a model (for example, `model.c` or `.cpp`, `model.h`, and so on). You can use similar techniques to generate custom code within the model files. The code template API includes functions to obtain the names of the standard models files and other model-related information. The following excerpt calls `LibGetMdlPubHdrBaseName` to obtain the name for the `model.h` file. It then obtains a file reference and generates a definition in the `Defines` section of `model.h`:

```

%% Add a #define to the model's public header file model.h

%assign pubName = LibGetMdlPubHdrBaseName()
%assign modelH = LibCreateSourceFile("Header", "Simulink", pubName)

%openfile tmpBuf

#define ACCELERATION 9.81

```

```
%closefile tmpBuf
%<LibSetSourceFileSection(modelH, "Defines", tmpBuf)>
```

Examine the generated `rtwdemo_udt.h` file to see the generated `#define` directive.

### Customizing Main Program Module Generation

Normally, the ERT target determines whether and how to generate an `ert_main.c` or `.cpp` module based on the settings of the **Generate an example main program** and **Target operating system** options on the **Templates** pane of the Configuration Parameters dialog box. You can use a CFP template to override the normal behavior and generate a main program module customized for your target environment.

To support generation of main program modules, two TLC files are provided:

- `bareboard_srmain.tlc`: TLC code to generate an example single-rate main program module for a bareboard target environment. Code is generated by a single TLC function, `FcnSingleTaskingMain`.
- `bareboard_mrmain.tlc`: TLC code to generate a multirate main program module for a bareboard target environment. Code is generated by a single TLC function, `FcnMultiTaskingMain`.

In the example CFP template file `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, the following code generates either a single- or multitasking `ert_main.c` or `.cpp` module. The logic depends on information obtained from the code template API calls `LibIsSingleRateModel` and `LibIsSingleTasking`:

```
%% Create a simple main. Files are located in MATLAB/rtw/c/tlc/mw.
%if LibIsSingleRateModel() || LibIsSingleTasking()
%include "bareboard_srmain.tlc"
%<FcnSingleTaskingMain()>
%else
%include "bareboard_mrmain.tlc"
%<FcnMultiTaskingMain()>
%endif
```

Note that `bareboard_srmain.tlc` and `bareboard_mrmain.tlc` use the code template API to generate `ert_main.c` or `.cpp`.

When generating your own main program module, you disable the default generation of `ert_main.c` or `.cpp`. The TLC variable `GenerateSampleERTMain` controls generation of `ert_main.c` or `.cpp`. You can directly force this variable to `TLC_FALSE`. The examples `bareboard_mrmain.tlc` and `bareboard_srmain.tlc` use this technique, as shown in the following excerpt from `bareboard_srmain.tlc`.

```
%if GenerateSampleERTMain
    %assign CompiledModel.GenerateSampleERTMain = TLC_FALSE
    %warning Overriding example ert_main.c!
%endif
```

Alternatively, you can implement a `SelectCallback` function for your target. A `SelectCallback` function is a MATLAB function that is triggered when you:

- Load the model.
- Update any configuration settings in the Configuration Parameters dialog box.
- Build the model.

Your `SelectCallback` function should deselect and disable the **Generate an example main program** option. This prevents the TLC variable `GenerateSampleERTMain` from being set to `TLC_TRUE`.

See the “`rtwgensettings` Structure” (Simulink Coder) section for information on creating a `SelectCallback` function.

The following code illustrates how to deselect and disable the **Generate an example main program** option in the context of a `SelectCallback` function.

```
slConfigUISetVal(hDlg, hSrc, 'GenerateSampleERTMain', 'off');
slConfigUISetEnabled(hDlg, hSrc, 'GenerateSampleERTMain', 0);
```

---

**Note** Creation of a main program for your target environment requires some customization; for example, in a bareboard environment you need to attach `rt_OneStep` to a timer interrupt. It is expected that you will customize either the generated code, the generating TLC code, or both. See “Guidelines for Modifying the Main Program” on page 63-4 and “Guidelines for Modifying `rt_OneStep`” on page 63-9 for further information.

---

## Generate a Custom Section

You can define custom tokens on page 50-81 in a CGT file and direct generated code into an associated built-in section. This feature gives you additional control over the formatting of code within each built-in section. For example, you could add subsections to built-in sections that do not already define subsections. Custom sections must be associated with one of the built-in sections: `Includes`, `Defines`, `Types`, `Enums`, `Definitions`, `Declarations`, or `Functions`. To create custom sections, you must

- Add a custom token to the code insertion section of your CGT file.
- In your CFP file:
  - Assemble code to be generated to the custom section into a buffer.
  - Declare an association between the custom section and a built-in section, with the code template API function `LibAddSourceFileCustomSection`.
  - Emit code to the custom section with the code template API function `LibSetSourceFileCustomSection`.

The following code examples illustrate the addition of a custom token, `Myincludes`, to a CGT file, and the subsequent association of the custom section `Myincludes` with the built-in section `Includes` in a CFP file.

---

**Note** If you have not already created custom CGT and CFP files for your model, copy the default template files `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt` and `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc` to a work folder that is outside the MATLAB folder structure but on the MATLAB or TLC path, rename them (for example, add the prefix `test_` to each file), and update the **Templates** pane of the Configuration Parameters dialog box to reference them.

---

First, add the token `Myincludes` to the code insertion section of your CGT file. For example:

```
%<Includes>
%<Myincludes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Next, in the CFP file, add code to generate `include` directives into a buffer. For example, in your copy of the example CFP file, you could insert the following section between the `Includes` section and the `Create a simple main` section:

```
%% Add a custom section to the model's C file model.c

%openfile tmpBuf
```

```
#include "moretables1.h"
#include "moretables2.h"
%closefile tmpBuf

%<LibAddSourceFileCustomSection(modelC,"Includes","Myincludes")>
%<LibSetSourceFileCustomSection(modelC,"Myincludes",tmpBuf)>
```

The `LibAddSourceFileCustomSection` function call declares an association between the built-in section `Includes` and the custom section `Myincludes`. `Myincludes` is a subsection of `Includes`. The `LibSetSourceFileCustomSection` function call directs the code in the `tmpBuf` buffer to the `Myincludes` section of the generated file. `LibSetSourceFileCustomSection` is syntactically identical to `LibSetSourceFileSection`.

In the generated code, the include directives generated to the custom section appear after other code directed to `Includes`.

```
#include "rtwdemo_udt.h"
#include "rtwdemo_udt_private.h"

/* #include "mytables.h" */
#include "moretables1.h"
#include "moretables2.h"
```

---

**Note** The placement of the custom token in this example CGT file is arbitrary. By locating `%<Myincludes>` after `%<Includes>`, the CGT file specifies only that the `Myincludes` code appears after `Includes` code.

---

## Custom Tokens

Custom tokens are automatically translated to TLC syntax as a part of the build process. To escape a token, that is to prepare it for normal TLC expansion, use the `'!` character. For example, the token `%<!TokenName>` is expanded to `%<TokenName>` by the template conversion program. You can specify valid TLC code, including TLC function calls: `%<!MyTLCFcn()>`.

## Comparison of a Template and Its Generated File

This figure shows part of a user-modified custom file processing (CFP) template and the resulting generated code. The figure illustrates how you can use a template to:

- Define what code the code generation software should add to the generated file
- Control the location of code in the file
- Optionally insert comments in the generated file

Notice `%<Includes>`, for example, on the template. The term `Includes` is a symbol name. A percent sign and brackets (`%< >`) must enclose every symbol name. You can add the desired symbol name (within the `%< >` delimiter) at a particular location in the template. This is how you control where the code generator places an item in the generated file.

## Template and Generated File

### Mapping Template Specification to Code Generation

This part of the template...		Generates in the file...		Explanation
		Line	Description	
(1)	<code>/*#INCLUDES*/ %&lt;Includes&gt;</code>	26-28	An <code>/*#INCLUDES*/</code> comment, followed by <code>#include</code> statements	The code generator adds the C/C++ comment as a header, and then interprets the <code>%&lt;Includes&gt;</code> template symbol to list the required <code>#include</code> statements in the file. This code is first in this section of the file because the template entries are first.
(2)	<code>/*#DEFINES*/ %&lt;Defines&gt;</code>	30	A <code>/*#DEFINES*/</code> comment, but no <code>#define</code> statements	Next, the code generator places the comment as a header for <code>#define</code> statements, but the file does not need <code>#define</code> . No code is added.
(3)	<code>#pragma string1</code>	31	<code>#pragma</code> statements	While the code generator requires <code>%&lt;&gt;</code> delimiters for template symbols, it can also interpret C/C++ statements in the template without delimiters. In this case, the generator adds the specified statements to the code, following the order in which the statements appear in the template.
(5)	<code>#pragma string2</code>	42		
(4)	<code>/*DEFINITIONS*/ %&lt;Definitions&gt;</code>	32-41	<code>/*DEFINITIONS*/</code> comment, followed by definitions	The code generator places the comment and definitions in the file between the <code>#pragma</code> statements, according to the order in the template. It also inserts comments (lines 33 and 36) that are preset in the model's Configuration Parameters dialog box.

This part of the template...		Generates in the file...		Explanation
		Line	Description	
(6)	%<Declarations>	43	No declarations	The file needs no declarations, so the code generator does not generate declarations for this file. The template does not have a comment to provide a header. Line 43 is left blank.
(7)	%<Functions>	44-74	Functions	Finally, the code generator adds functions from the model, plus comments that are preset in the Configuration Parameters dialog box. But it adds no comments as a header for the functions, because the template does not have one. This code is last because the template entry is last.

For a list of template symbols and the rules for using them, see “Template Symbol Groups” on page 50-99, “Template Symbols” on page 50-102, and “Rules for Modifying or Creating a Template” on page 50-105. To set comment options, in the Configuration Parameters dialog box, select the **Code Generation > Comments** pane. For details, see “Configure Code Comments” (Simulink Coder).

## Code Template API Summary

Code Template API Functions summarizes the code template API. See the source code in *matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc* for detailed information on the arguments, return values, and operation of these calls.

**Code Template API Functions**

<b>Function</b>	<b>Description</b>
LibClearFileSectionContents	Clears a file section with custom values before writing file to disk.
LibGetNumSourceFiles	Returns the number of created source files (.c or .cpp and .h).
LibGetSourceFileTag	Returns <filename>_h and <filename>_c for header and source files, respectively, where filename is the name of the model file.
LibCreateSourceFile	Creates a new C or C++ file and returns its reference. If the file already exists, simply returns its reference.
LibGetFileRecordName	Returns a model file name (including the path) without the extension.
LibGetSourceFileFromIdx	Returns a model file reference based on its index. This is useful for a common operation on all files, such as to set the leading file banner of all files.
LibSetSourceFileSection	Adds to the contents of a specified section within a specified file (see also “Custom File Processing (CFP) Template Structure” on page 50-66).
LibIndentSourceFile	Indents a file (from within the TLC environment).
LibCallModelInitialize	Returns code for calling the model's <i>model_initialize</i> function (valid for ERT only).
LibCallModelStep	Returns code for calling the model's <i>model_step</i> function (valid for ERT only).
LibCallModelTerminate	Returns code for calling the model's <i>model_terminate</i> function (valid for ERT only).

Function	Description
LibCallSetEventForThisBaseStep	Returns code for calling the model's set events function (valid for ERT only).
LibWriteModelData	Returns data for the model (valid for ERT only).
LibSetRTModelErrorStatus	Returns the code to set the model error status.
LibGetRTModelErrorStatus	Returns the code to get the model error status.
LibIsSingleRateModel	Returns true if model is single rate and false otherwise.
LibGetModelName	Returns name of the model (without an extension).
LibGetMdlSrcBaseName	Returns the name of model's main source file (for example, <i>model.c</i> or <i>.cpp</i> ).
LibGetMdlPubHdrBaseName	Returns the name of model's public header file (for example, <i>model.h</i> ).
LibGetMdlPrvHdrBaseName	Returns the name of the model's private header file (for example, <i>model_private.h</i> ).
LibIsSingleTasking	Returns true if the model is configured for single-tasking execution.
LibWriteModelInput	Returns the code to write to a particular root input (that is, a model inport block). (valid for ERT only).
LibWriteModelOutput	Returns the code to write to a particular root output (that is, a model outport block). (valid for ERT only).
LibWriteModelInputs	Returns the code to write to root inputs (that is, all model inport blocks). (valid for ERT only)
LibWriteModelOutputs	Returns the code to write to root outputs (that is, all model outport blocks). (valid for ERT only).

<b>Function</b>	<b>Description</b>
<code>LibNumDiscreteSampleTimes</code>	Returns the number of discrete sample times in the model.
<code>LibSetSourceFileCodeTemplate</code>	Set the code template to be used for generating a specified source file.
<code>LibSetSourceFileOutputDirectory</code>	Set the folder into which a specified source file is to be generated.
<code>LibAddSourceFileCustomSection</code>	Add a custom section to a source file. The custom section must be associated with one of the built-in (required) sections: <b>Includes, Defines, Types, Enums, Definitions, Declarations, or Functions.</b>
<code>LibSetSourceFileCustomSection</code>	Adds to the contents of a specified custom section within a specified file. The custom section must have been previously created with <code>LibAddSourceFileCustomSection</code> .

## Generate Custom File and Function Banners

Using code generation template (CGT) files, you can specify custom file banners and function banners for the generated code files. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. Use these banners to add a company copyright statement, specify a special version symbol for your configuration management system, remove time stamps, and for many other purposes. These banners can contain characters, which propagate to the generated code.

To specify banners, create a custom CGT file with customized banner sections. The build process creates an executable TLC file from the CGT file. The code generation process then invokes the TLC file.

You do not need to be familiar with TLC programming to generate custom banners. You can modify example files that are supplied with the ERT target.

---

**Note** Prior releases supported direct use of customized TLC files as banner templates. You specified these with the **Source file (.c) banner template** and **Header file (.h) banner template** options of the ERT target. You can still use a custom TLC file banner template, however, you can now use CGT files instead.

---

ERT template options on the **Code Generation > Templates** pane of a configuration set, in the **Code templates** section, support banner generation.

The options for function and file banner generation are:

- “Code templates: Source file (\*.c) template”: CGT file to use when generating source (.c or .cpp) files. Place this file on the MATLAB path.
- “Code templates: Header file (\*.h) template”: CGT file to use when generating header (.h) files. You must place this file on the MATLAB path. This file can be the same template specified in the **Code templates: Source file (\*.c) template** field, in which case identical banners are generated in source and header files.

By default, the template for both source and header files is `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

- In each of these fields, click **Browse** to navigate to and select an existing CGT file for use as a template. Click **Edit** to open the specified file into the MATLAB editor, where you can customize it.

## Create a Custom File and Function Banner Template

To customize a CGT file for custom banner generation, make a local copy of the default code template and edit it, as follows:

- 1 Activate the configuration set that you want to work with.
- 2 Open the **Code Generation** pane of the active configuration set.
- 3 Click the **Templates** tab.
- 4 By default, the code template specified in the **Code templates: Source file (\*.c) template** and **Code templates: Header file (\*.h) template** fields is `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.
- 5 If you want to use a different template as your starting point, click **Browse** to locate and select a CGT file.
- 6 Click **Edit** button to open the CGT file into the MATLAB editor.
- 7 Save a local copy of the CGT file. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If required, add the folder to the MATLAB path.
- 8 If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder.
- 9 Rename your local copy of the CGT file. When you rename the CGT file, update the associated **Code templates: Source file (\*.c) template** or **Code templates: Header file (\*.h) template** field to match the new file name.
- 10 Edit and customize the local copy of the CGT file for banner generation, using the information provided in “Customize a Code Generation Template (CGT) File for File and Function Banner Generation” on page 50-92.
- 11 Save your changes to the CGT file.
- 12 Click **Apply** to update the configuration set.
- 13 Save your model.
- 14 Generate code. Examine the generated source and header files to confirm that they contain the banners specified by the template or templates.

## Customize a Code Generation Template (CGT) File for File and Function Banner Generation

This section describes how to edit a CGT file for custom file and function banner generation. For a description of CGT files, see “Code Generation Template (CGT) Files” on page 50-59.

### Components of the File and Function Banner Sections in the CGT file

In a CGT file, you can modify the following sections: file banner, function banner, shared utility function banner, and file trailer. Each section is defined by open and close tags. The tags specific to each section are shown in the following table.

CGT File Section	Open Tag	Close Tag
File Banner on page 50-94	<FileBanner>	</FileBanner>
Function Banner on page 50-96	<FunctionBanner>	</FunctionBanner>
Shared-utility Banner on page 50-96	<SharedUtilityBanner>	</SharedUtilityBanner>
File Trailer on page 50-97	<FileTrailer>	</FileTrailer>

You can customize your banners by including tokens and comments between the open and close tag for each section. Tokens are typically TLC variables, for example <ModelVersion>, which are replaced with values in the generated code.

---

**Note** Including C comment indicators, `'/*'` or `'*/'`, in the contents of your banner might introduce an error in the generated code.

---

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- **width**: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- **style**: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is as follows:

```
<OpenTag style = "style_value" width = "num_width">
```

---

**Note** If the **Configuration Parameters > Code Generation > Language** parameter is set to C++, to select a comment style that uses C comment notation (`/* . . . */`), you must also set the **Configuration Parameters > Comments > Comment style** parameter to **Multi-line**.

---

The built-in style options for the `style` attribute are:

- `classic`

```
/* single line comments */
/*
 * multiple line comments
 * second line
 */
```

- `classic_cpp`

```
// single line comments
//
// multiple line comments
// second line
//
```

- `box`

```
/******
 * banner contents
 ******
```

- `box_cpp`

```
////////////////////////////////////
// banner contents
////////////////////////////////////
```

- `open_box`

```
/******
 * banner contents
 ******
```

- `open_box_cpp`

```
////////////////////////////////////  
// banner contents  
////////////////////////////////////
```

- `doxygen`

```
/** single line comments */  
  
/**  
 * multiple line comments  
 * second line  
 */
```

- `doxygen_cpp`

```
/// single line comments  
  
///  
/// multiple line comments  
/// second line  
///
```

- `doxygen_qt`

```
/*! single line comments */  
  
/*!  
 * multiple line comments  
 * second line  
 */
```

- `doxygen_qt_cpp`

```
//! single line comments  
  
//!  
//! multiple line comments  
//! second line  
//!
```

### **File Banner**

This section contains comments and tokens for use in generating a custom file banner. The file banner precedes C or C++ code generated by the model. If you omit the file banner section from the CGT file, then no file banner emits to the generated code.

---

**Note** If you customize your file banner, the software does not emit the customized banner for the file `const_params.c`.

---

The following section is the file banner section provided with the default CGT file, `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file banner section (optional)
%%
<FileBanner style="classic">
File: %<FileName>

Code generated for Simulink model %<ModelName>.

Model version                : %<ModelVersion>
Simulink Code version        : %<RTWFileVersion>
TLC version                  : %<TLCVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
%<CodeGenSettings>
</FileBanner>

```

### Summary of Tokens for File Banner Generation

FileName	Name of the generated file (for example, "rtwdemo_udt.c").
FileType	Either "source" or "header". Designates whether generated file is a .c or .cpp file or an .h file.
FileTag	Given file names file.c or .cpp and file.h; the file tags are "file_c" and "file_h", respectively.
ModelName	Name of generating model.
ModelVersion	Version number of model.
RTWFileVersion	Version number of <code>model.rtw</code> file.
RTWFileGeneratedOn	Timestamp of <code>model.rtw</code> file.
TLCVersion	Version of Target Language Compiler.
SourceGeneratedOn	Timestamp of generated file.
CodeGenSettings	Code generation settings for model: target language, target selection, production hardware selection, test hardware selection, code generation objectives (in priority order), and Code Generation Advisor validation result.

### Function Banner

This section contains comments and tokens for use in generating a custom function banner. The function banner precedes C or C++ function generated during the build process. If you omit the function banner section from the CGT file, the default function banner emits to the generated code. The following section is the default function banner section provided with the default CGT file, *matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt*.

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom function banner section (optional)
%%   Customize function banners by using the following predefined tokens:
%%   %<ModelName>, %<FunctionName>, %<FunctionDescription>, %<Arguments>,
%%   %<ReturnType>, %<GeneratedFor>, %<BlockDescription>.
%%
<FunctionBanner style="classic">
%<FunctionDescription>
%<BlockDescription>
</FunctionBanner>

```

### Summary of Tokens for Function Banner Generation

FunctionName	Name of function
Arguments	List of function arguments
ReturnType	Return type of function
ModelName	Name of generating model
FunctionDescription	Short abstract about the function
GeneratedFor	Full block path for the generated function
BlockDescription	User input from the <b>Block Description</b> parameter of the block properties dialog box. <b>BlockDescription</b> contains an optional token attribute, <b>style</b> . The only valid value for <b>style</b> is <b>content_only</b> , which is case-sensitive and enclosed in double quotes. Use the <b>content_only</b> style when you want to include only the block description content that you entered in the block parameter dialog. The syntax for the token attribute <b>style</b> is:  %<BlockDescription style = "content_only">

### Shared Utility Function Banner

The shared utility function banner section contains comments and tokens for use in generating a custom shared utility function banner. The shared utility function banner

precedes C or C++ shared utility function generated during the build process. If you omit the shared utility function banner section from the CGT file, the default shared utility function banner emits to the generated code. The following section is the default shared utility function banner section provided with the default CGT file, *matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt*.

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom shared utility function banner section (optional)
%%   Customize banners for functions generated in shared location by using the
%%   following predefined tokens: %<FunctionName>, %<FunctionDescription>,
%%   %<Arguments>, %<ReturnType>.
%%
<SharedUtilityBanner style="classic">
%<FunctionDescription>
</SharedUtilityBanner>

```

### Summary of Tokens for Shared Utility Function Banner Generation

FunctionName	Name of function
Arguments	List of function arguments
ReturnType	Return type of function
FunctionDescription	Short abstract about function

### File Trailer

The file trailer section contains comments for generating a custom file trailer. The file trailer follows C or C++ code generated from the model. If you omit the file trailer section from the CGT file, no file trailer emits to the generated code. The following section is the default file trailer provided in the default CGT file.

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file trailer section (optional)
%%
<FileTrailer style="classic">
File trailer for generated code.

[EOF]
</FileTrailer>

```

Tokens available for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

## Template Symbols and Rules

In this section...
“Introduction” on page 50-98
“Template Symbol Groups” on page 50-99
“Template Symbols” on page 50-102
“Rules for Modifying or Creating a Template” on page 50-105

### Introduction

“Template Symbol Groups” on page 50-99 and “Template Symbols” on page 50-102 describe custom file processing (CFP) template symbols and rules for using them. The location of a symbol in one of the supplied template files (`code_c_template.cgt`, `code_h_template.cgt`, `data_c_template.cgt`, or `data_h_template.cgt`) determines where the items associated with that symbol are located in the corresponding generated file. “Template Symbol Groups” on page 50-99 identifies the symbol groups, starting with the parent (“Base”) group, followed by the children of each parent. “Template Symbols” on page 50-102 lists the symbols alphabetically.

---

**Note** If you are using custom CGT sections, for files generated to the `_sharedutils` folder, you can only use symbol names in the Base symbol group.

---

## Template Symbol Groups

Symbol Group	Symbol Names in This Group
Base (Parents)	Declarations Defines Definitions Documentation Enums Functions Includes Types
Declarations	ExternalCalibrationLookup1D ExternalCalibrationLookup2D ExternalCalibrationScalar ExternalVariableScalar
Defines	LocalDefines LocalMacros

Symbol Group	Symbol Names in This Group
Documentation	Abstract Banner Created Creator Date Description FileName History LastModifiedDate LastModifiedBy ModelName ModelVersion ModifiedBy ModifiedComment ModifiedHistory
	Notes ToolVersion
Functions	CFunctionCode
Types	This parent has no children.

## Template Symbols

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
Abstract	Documentation	N/A	User-supplied description of the model or file. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
Banner	Documentation	N/A	Comments located near top of the file. Contains information that includes model and software versions, and date file was generated.
CFunctionCode	Functions	File	C/C++ functions. Must be at the bottom of the template.
Created	Documentation	N/A	Date when model was created. From <b>Created on</b> field on Model Properties dialog box.
Creator	Documentation	N/A	User who created model. From <b>Created by</b> field on Model Properties dialog box.
Date	Documentation	N/A	Date file was generated. Taken from computer clock.
Declarations	Base		Data declaration of a signal or parameter. For example, <code>extern real_T globalvar;</code>
Defines	Base	File	Required <code>#defines</code> of .h files.
Definitions	Base	File	Data definitions of signals or parameters.
Description	Documentation	N/A	Description of model. From <b>Model description</b> field on Model Properties dialog box.**

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
Documentation	Base	N/A	Comments about how to interpret the generated files.
Enums	Base	File	Enumerated data type definitions.
ExternalCalibrationLookup1D	Declarations	External	***
ExternalCalibrationLookup2D	Declarations	External	***
ExternalCalibrationScalar	Declarations	External	***
ExternalVariableScalar	Declarations	External	***
FileName	Documentation	N/A	Name of the generated file.
FilescopeCalibrationLookup1D	Definitions	File	***
FilescopeCalibrationLookup2D	Definitions	File	***
FilescopeCalibrationScalar	Definitions	File	***
FilescopeVariableScalar	Definitions	File	***
Functions	Base	File	Generated function code.
GlobalCalibrationLookup1D	Definitions	Global	***
GlobalCalibrationLookup2D	Definitions	Global	***
GlobalCalibrationScalar	Definitions	Global	***
GlobalVariableScalar	Definitions	Global	***
History	Documentation	N/A	User-supplied revision history of the generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
Includes	Base	File	<code>#include</code> preprocessor directives.

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
LastModifiedDate	Documentation	N/A	Date when model was last saved. From <b>Last saved on</b> field on Model Properties dialog box.
LastModifiedBy	Documentation	N/A	User who last saved model. From <b>Last saved by</b> field on Model Properties dialog box.
LocalDefines	Defines	File	<b>#define</b> preprocessor directives from code-generation data objects.
LocalMacros	Defines	File	C/C++ macros local to the file.
ModelName	Documentation	N/A	Name of the model.
ModelVersion	Documentation	N/A	Version number of the Simulink model. From <b>Model version</b> field on Model Properties dialog box.
ModifiedBy	Documentation	N/A	Name of user who last modified the model.
ModifiedComment	Documentation	N/A	Comment user enters in the <b>Modified Comment</b> field on the Log Change dialog box. For more information, see “Log Comments History” (Simulink).
ModifiedHistory	Documentation	N/A	Text from <b>Model history</b> field on Model Properties dialog box.**
Notes	Documentation	N/A	User-supplied miscellaneous notes about the model or generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
ToolVersion	Documentation	N/A	A list of the versions of the toolboxes used in generating the code.
Types	Base		Data types of generated code.

\* Symbol names must be enclosed between %< >. For example, %<Functions>.

\*\* This symbol can be used to add a comment to the generated files. See “Add Global Comments in the Generated Code” on page 50-8. The code generator places the comment in each generated file whose template has this symbol name. The code generator places the comment at the location that corresponds to where the symbol name is located in the template file.

\*\*\* The description can be deduced from the symbol name. For example, GlobalCalibrationScalar is a symbol that identifies a scalar. It contains data of global scope that you can calibrate.

## Rules for Modifying or Creating a Template

The following are the rules for creating an MPF template. “Comparison of a Template and Its Generated File” on page 50-82 illustrates several of these rules.

- 1 Place a symbol on a template within the %< > delimiter. For example, the symbol named Includes should look like this on a template: %<Includes>. *Note that symbol names are case-sensitive.*
- 2 Place a symbol on a template where desired. Its location on the template determines where the item associated with this symbol is located in the generated file. If no item is associated with it, the symbol is ignored.
- 3 Place a C/C++ statement outside of the %< > delimiter, and on a different line than a %< > delimiter, for that statement to appear in the generated file. For example, #pragma message ("my text") in the template results in #pragma message ("my text") at the corresponding location in the generated file. Note that the statement must be compatible with your C/C++ compiler.
- 4 Use the .cgt extension for every template filename. ("cgt" stands for code generation template.)

- 5** Note that %% \$Revision: 1.1.4.10.4.1 \$ appears at the top of the MathWorks supplied templates. This is for internal MathWorks use only. It does not need to be placed on a user-defined template and does not show in a generated file.
- 6** Place a comment on the template between /\* \*/ as in standard ANSI C<sup>6</sup>. This results in /\*comment\*/ on the generated file.
- 7** Each MPF template must have all of the Base group symbols, in predefined order. They are listed in “Template Symbol Groups” on page 50-99. Each symbol in the Base group is a parent. For example, Declarations is a parent symbol.
- 8** Each symbol in a non-Base group is a child. For example, LocalMacros is a child.
- 9** Except for Documentation children, children must be placed after their parent, before the next parent, and before the Functions symbol.
- 10** Documentation children can be located before or after their parent in any order anywhere in the template.
- 11** If a non-Documentation child is missing from the template, the code generator places the information associated with this child at its parent location in the generated file.
- 12** If a Documentation child is missing from the template, the code generator omits the information associated with that child from the generated file.

---

## Annotate Code for Justifying Polyspace Checks

This example shows how to turn on comments in the generated code that suppress error detection through Polyspace.

### Polyspace Checks

With the Polyspace Code Prover software you can apply Polyspace verification to Embedded Coder generated code. The software detects run-time errors in the generated code and helps you to locate and fix model faults. Polyspace might highlight overflows for certain operations that are legitimate because of the way the code generator implements these operations. These legitimate overflows should not be flagged by Polyspace. Generate comments in the code that suppress this error detection.

### Code Generation

1. Open the example Simulink model mSatAddSub.

```
model='mSatAddSub';
open_system(model);
```

2. In the Embedded Coder app on the the **Configuration Parameters** dialog box, turn off **Operator annotations**.

```
set_param('mSatAddSub', 'OperatorAnnotations', 'off');
```

3. To build the model and generate code, press **Ctrl+B**.

```
evalc('rtwbuild(''mSatAddSub'')');
```

*%The generated code is:*

```
file = fullfile('mSatAddSub_ert_rtw', 'mSatAddSub.c');
rtwdemodbtype(file, '/* Model step function */', ...
    'End of Sum', 1, 1);
```

```
/* Model step function */
void mSatAddSub_step(void)
{
    uint32_T qY;

    /* Sum: '<Root>/SubUnsigned' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     */
    qY = U1 - U2;
    if (qY > U1) {
        qY = 0U;
    }

    USub = qY;
}
```

4. Run the Polyspace check. The code generator recognizes that the largest built-in data type is 32-bit. It is not possible to saturate all the results of the subtractions using 0U and a bigger single-word integer data type. Instead the software detects the results overflow and the direction of the overflow, and saturates the result. The operation is flagged by Polyspace because it fails to recognize the saturation.

5. In the Embedded Coder app on the the **Configuration Parameters** dialog box, turn off **Operator annotations**.

```
set_param('mSatAddSub', 'OperatorAnnotations', "on");
evalc('rtwbuild(''mSatAddSub'')');
```

6. The generated code is:

```
file = fullfile('mSatAddSub_ert_rtw', 'mSatAddSub.c');
rtwdemodbtype(file, '/* Model step function */', ...
    'End of Sum', 1, 1);
```

```
/* Model step function */
void mSatAddSub_step(void)
{
    uint32_T qY;

    /* Sum: '<Root>/SubUnsigned' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     */
}
```

```
*/  
qY = U1 - /*MW:0vSat0k*/ U2;  
if (qY > U1) {  
    qY = 0U;  
}  
  
USub = qY;
```

The code generator inserts the `/*MW:0vSat0k*/` comment that suppresses the error detected by Polyspace.

7. Close the model.

```
bdclose(model)  
rtwdemoclean;
```

## Enhance Readability of Code for Flow Charts

<b>In this section...</b>
“Appearance of Generated Code for Flow Charts” on page 50-110
“Convert If-Elseif-Else Code to Switch-Case Statements” on page 50-113
“Example of Converting Code to Switch-Case Statements” on page 50-115

### Appearance of Generated Code for Flow Charts

If you have Embedded Coder and you generate code for models that include Stateflow objects, the code from a flow chart resembles the samples that follow.

The following characteristics apply:

- By default, the generated code uses `if-elseif-else` statements to represent `switch` patterns. To convert the code to use `switch-case` statements, see “Convert If-Elseif-Else Code to Switch-Case Statements” on page 50-113.
- By default, variables that appear in the flow chart do not retain their names in the generated code. Modified identifiers make sure that no naming conflicts occur.
- Traceability comments for the transitions appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Trace Stateflow Elements in Generated Code” on page 75-15.

```

if (modelname_U.In1 == 1.0) {
  /* Transition: '<S1>:11' */
  /* Transition: '<S1>:12' */
  modelname_Y.Out1 = 10.0;

  /* Transition: '<S1>:15' */
  /* Transition: '<S1>:16' */
} else {
  /* Transition: '<S1>:10' */
  if (modelname_U.In1 == 2.0) {
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    modelname_Y.Out1 = 20.0;

    /* Transition: '<S1>:16' */
  } else {
    /* Transition: '<S1>:17' */
    modelname_Y.Out1 = 30.0;
  }
}
}

```

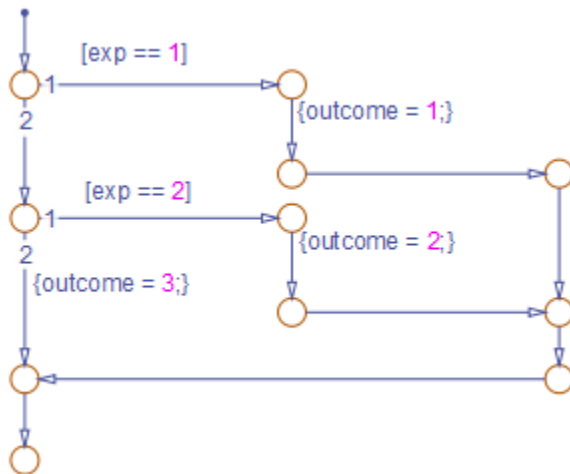

### Sample Code for a Decision Logic Pattern

```
for (sf_i = 0; sf_i < 10; sf_i++) {
  /* Transition: '<S1>:40' */
  /* Transition: '<S1>:41' */
  modelname_B.y = modelname_B.y +
    modelname_U.In1;

  /* Transition: '<S1>:39' */
}
```

**Sample Code for an Iterative Loop Pattern**

```
if (modelname_U.In1 == 1.0) {
    /* Transition: '<S1>:149' */
    /* Transition: '<S1>:150' */
    modelname_Y.Out1 = 1.0;

    /* Transition: '<S1>:151' */
    /* Transition: '<S1>:152' */
    /* Transition: '<S1>:158' */
    /* Transition: '<S1>:159' */
} else {
    /* Transition: '<S1>:156' */
    if (modelname_U.In1 == 2.0) {
        /* Transition: '<S1>:153' */
        /* Transition: '<S1>:154' */
        modelname_Y.Out1 = 2.0;

        /* Transition: '<S1>:155' */
        /* Transition: '<S1>:158' */
        /* Transition: '<S1>:159' */
    } else {
        /* Transition: '<S1>:161' */
        modelname_Y.Out1 = 3.0;
    }
}
```

### Sample Code for a Switch Pattern

## Convert If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` code to `switch-case` statements. This conversion can enhance readability of the code. For example, when a flow chart contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

### How to Convert If-Elseif-Else Code to Switch-Case Statements

Step	Task	Reference
1	Verify that your flow chart follows the rules for conversion.	“Verify the Contents of the Flow Chart” on page 50-117
2	Enable the conversion and generate code for your model.	“Enable the Conversion” on page 50-118
3	Troubleshoot the generated code. <ul style="list-style-type: none"> <li>• If you see <code>switch-case</code> statements for your flow chart, you can stop.</li> <li>• If you see <code>if-elseif-else</code> statements for your flow chart, update the chart and repeat the previous step.</li> </ul>	“Troubleshoot the Generated Code” on page 50-118

### Rules of Conversion

For the conversion to occur, following these guidelines. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
Flow chart	Must have a default and two or more <i>unique</i> conditions. For more information, see “Duplicate Conditions” on page 50-115.
Each condition	Must test equality only. Must use the same variable or expression for the LHS. You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression. Cannot be a constant. Must have an integer or enumerated data type. Cannot have any side effects on simulation. For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant or a parameter. Must have an integer or enumerated data type.

### Duplicate Conditions

If a flow chart has duplicate conditions, the conversion preserves only the first condition. The code discards the other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. If not, the conversion does not occur and the code contains all duplicate conditions.

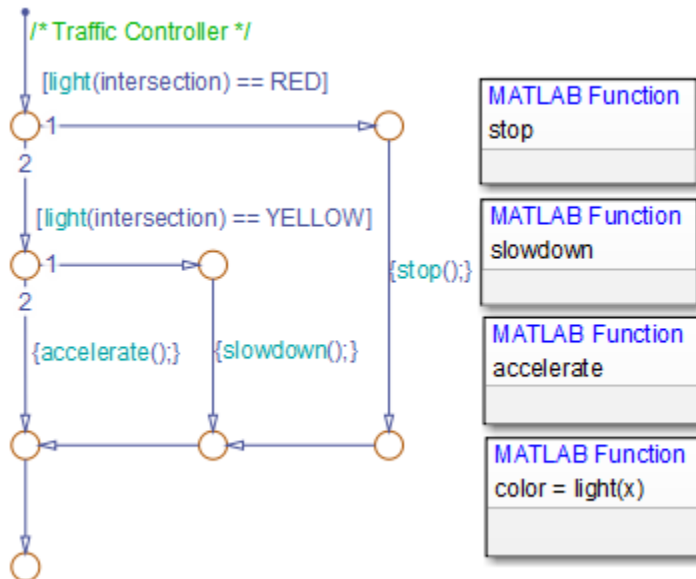

Example of Generated Code	Code After Conversion
<pre>if (x == 1) {     block1 } else if (x == 2) {     block2 } else if (x == 1) { // duplicate     block3 } else if (x == 3) {     block4 } else if (x == 1) { // duplicate     block5 } else {     block6 }</pre>	<pre>switch (x) {     case 1:         block1; break;     case 2:         block2; break;     case 3:         block4; break;     default:         block6; break; }</pre>
<pre>if (x == 1) {     block1 } else if (x == 1) { // duplicate     block2 } else {     block3 }</pre>	<p>No change, because only one unique condition exists</p>

### Example of Converting Code to Switch-Case Statements

Suppose that you have this model containing a single chart.

The chart contains a flow chart and four MATLAB functions.

The MATLAB functions in the chart contain the code listed in the table. In each case, the **Function Inline Option** is Auto. For more information about function inlining, see “Specify Graphical Function Properties” (Stateflow).

MATLAB Function	Code
stop	function stop %#codegen coder.extrinsic('disp'); disp('Not moving.')
slowdown	function slowdown %#codegen coder.extrinsic('disp') disp('Slowing down.')
accelerate	function accelerate %#codegen coder.extrinsic('disp'); disp('Accelerating.')
color = light(x)	function color = light(x) %#codegen coder.extrinsic('disp'); disp('Light color: ' + x);

MATLAB Function	Code
accelerate	<pre>function accelerate %#codegen coder.extrinsic('disp'); disp('Moving along.')</pre> <pre>traffic_speed = 2;</pre>
light	<pre>function color = light(x) %#codegen if (x &lt; 20)     color = TrafficLights.GREEN; elseif (x &gt;= 20 &amp;&amp; x &lt; 25)     color = TrafficLights.YELLOW; else     color = TrafficLights.RED; end</pre>

The output `color` of the function `light` uses the enumerated type `TrafficLights`. The enumerated type definition in `TrafficLights.m` is:

```
classdef TrafficLights < Simulink.IntEnumType
    enumeration
        RED(0)
        YELLOW(5)
        GREEN(10)
    end
end
```

For more information, see “Define Enumerated Data Types” (Stateflow).

### Verify the Contents of the Flow Chart

Check that the flow chart in your Stateflow chart follows the rules in “Rules of Conversion” on page 50-114.

Construct	How the Construct Follows the Rules
Flow chart	<p>A default condition and two unique conditions exist:</p> <ul style="list-style-type: none"> <li>[light(intersection) == RED]</li> <li>[light(intersection) == YELLOW]</li> </ul>

Construct	How the Construct Follows the Rules
Each condition	Each condition: <ul style="list-style-type: none"> <li>• Tests equality</li> <li>• Uses the same function call <code>light(intersection)</code> for the LHS</li> </ul>
Each LHS	Each LHS: <ul style="list-style-type: none"> <li>• Contains a single expression</li> <li>• Is the output of a function call, not a constant</li> <li>• Is of enumerated type <code>TrafficLights</code>, which you define in <code>TrafficLights.m</code> on the MATLAB path. See “Define Enumerated Data Types” (Stateflow).</li> <li>• Uses a function call that does not have side effects</li> </ul>
Each RHS	Each RHS: <ul style="list-style-type: none"> <li>• Is an enumerated value and therefore a constant</li> <li>• Is of enumerated type <code>TrafficLights</code></li> </ul>

### Enable the Conversion

- 1 Open the Model Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, select `ert.tlc` for the **System target file** for an ERT-based target for your model.
- 3 In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

If you select this check box, the conversion applies to:

- Flow charts in all charts of a model
  - MATLAB functions in all charts of a model
  - All MATLAB Function blocks in that model
- 4 In the model, on the **C Code** tab, click **Build** to generate source code from the model.

### Troubleshoot the Generated Code

The generated code for the flow chart appears like this code:

```

if (sf_color == RED) {
    /* Transition: '<S1>:11' */
    /* Transition: '<S1>:12' */
    /* MATLAB Function 'stop': '<S1>:23' */
    /* '<S1>:23:6' */
    rtb_traffic_speed = 0;

    /* Transition: '<S1>:15' */
    /* Transition: '<S1>:16' */
} else {
    /* Transition: '<S1>:10' */
    /* MATLAB Function 'light': '<S1>:19' */
    if (ifelse_using_enums_U.In1 < 20.0) {
        /* '<S1>:19:3' */
        /* '<S1>:19:4' */
        sf_color = GREEN;
    } else if ((ifelse_using_enums_U.In1 >= 20.0) &&
               (ifelse_using_enums_U.In1 < 25.0)) {
        /* '<S1>:19:5' */
        /* '<S1>:19:6' */
        sf_color = YELLOW;
    } else {
        /* '<S1>:19:8' */
        sf_color = RED;
    }
}

if (sf_color == YELLOW) {
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    /* MATLAB Function 'slowdown': '<S1>:24' */
    /* '<S1>:24:6' */
    rtb_traffic_speed = 1;

    /* Transition: '<S1>:16' */
} else {
    /* Transition: '<S1>:17' */
    /* MATLAB Function 'accelerate': '<S1>:25' */
    /* '<S1>:25:6' */
    rtb_traffic_speed = 2;
}
}

```

Because the MATLAB function `light` appears inlined, inequality comparisons appear in these lines of code:

```
if (ifelse_using_enums_U.In1 < 20.0) {  
    ....  
} else if ((ifelse_using_enums_U.In1 >= 20.0) &&  
           (ifelse_using_enums_U.In1 < 25.0)) {  
    ....  
}
```

Because inequalities appear in the body of the `if-elseif-else` code for the flow chart, the conversion to `switch-case` statements does not occur. Do one of the following:

- Specify that the function `light` does not appear inlined. See “Change the Inlining Property for the Function” on page 50-120.
- Modify the flow chart. See “Modify the Flow Chart to Ensure Switch-Case Statements” on page 50-121.

### Change the Inlining Property for the Function

If you do not want to modify your flow chart, change the inlining property for the function `light`:

- 1 Right-click the function box for `light` and select **Properties**.
- 2 In the properties dialog box, for **Function Inline Option**, select **Function**.
- 3 Click **OK** to close the dialog box.

---

**Note** You do not have to change the inlining property for the other three MATLAB functions in the chart. Because the flow chart does not call those functions during evaluation of conditions, the inlining property for those functions can remain **Auto**.

---

When you regenerate code for your model, the code for the flow chart now appears like this code:

```
switch (ifelse_using_enums_light(ifelse_using_enums_U.In1)) {  
    case RED:  
        /* Transition: '<S1>:11' */  
        /* Transition: '<S1>:12' */  
        /* MATLAB Function 'stop': '<S1>:23' */  
        /* '<S1>:23:6' */  
        ifelse_using_enums_Y.Out1 = 0.0;  
  
        /* Transition: '<S1>:15' */  
        /* Transition: '<S1>:16' */  
        break;  
}
```

```

case YELLOW:
    /* Transition: '<S1>:10' */
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    /* MATLAB Function 'slowdown': '<S1>:24' */
    /* '<S1>:24:6' */
    ifelse_using_enums_Y.Out1 = 1.0;

    /* Transition: '<S1>:16' */
    break;

default:
    /* Transition: '<S1>:17' */
    /* MATLAB Function 'accelerate': '<S1>:25' */
    /* '<S1>:25:6' */
    ifelse_using_enums_Y.Out1 = 2.0;
    break;
}

```

Because the MATLAB function `light` no longer appears inlined, the conversion to switch-case statements occurs. To enhance readability, the switch-case statements provide these benefits:

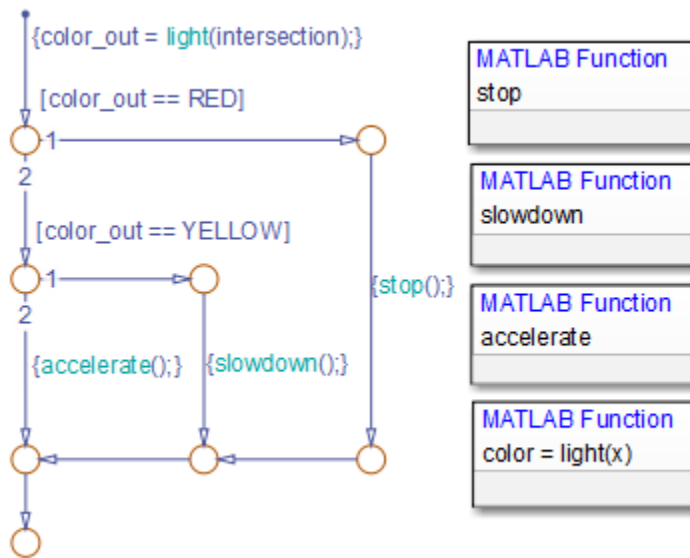

- The code reduces the use of parentheses and braces.
- The LHS expression `ifelse_using_enums_light(ifelse_using_enums_U.In1)` appears only once, minimizing repetition in the code.

### Modify the Flow Chart to Ensure Switch-Case Statements

If you do not want to change the inlining property for the function `light`, modify your flow chart:

- 1 Add chart local data `color_out` with the enumerated type `TrafficLights`.
- 2 Replace each instance of `light(intersection)` with `color_out`.
- 3 Add the action `{color_out = light(intersection)}` to the default transition of the flow chart.

The chart now looks similar to this chart:

When you regenerate code for your model, the code for the flow chart uses switch-case statements.

# Enhance Code Readability for MATLAB Function Blocks

**In this section...**

“Requirements for Using Readability Optimizations” on page 50-123

“Converting If-Elseif-Else Code to Switch-Case Statements” on page 50-123

“Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements” on page 50-125

## Requirements for Using Readability Optimizations

To use readability optimizations in your code, you must have an Embedded Coder license. These optimizations appear only in code that you generate for an embedded real-time (ert) target.

---

**Note** These optimizations do not apply to MATLAB files that you call from the MATLAB Function block.

---

For more information, see “Configure a System Target File” on page 45-2.

## Converting If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` decision logic to `switch-case` statements. This conversion can enhance readability of the code.

For example, when a MATLAB Function block contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

### How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the MATLAB Function block from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your block follows the rules for conversion.	“Verifying the Contents of the Block” on page 50-127
2	Enable the conversion.	“Enabling the Conversion” on page 50-128
3	Generate code for your model.	“Generating Code for Your Model” on page 50-129

### Rules for Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
MATLAB Function block	<p>Must have two or more <i>unique</i> conditions, in addition to a default.</p> <p>For more information, see “How the Conversion Handles Duplicate Conditions” on page 50-125.</p>
Each condition	<p>Must test equality only.</p> <p>Must use the same variable or expression for the LHS.</p> <hr/> <p><b>Note</b> You can reverse the LHS and RHS.</p>
Each LHS	<p>Must be a single variable or expression, not a compound statement.</p> <p>Cannot be a constant.</p> <p>Must have an integer or enumerated data type.</p> <p>Must not have side effects on simulation.</p> <p>For example, the LHS can read from but not write to global variables.</p>
Each RHS	<p>Must be a constant.</p> <p>Must have an integer or enumerated data type.</p>

## How the Conversion Handles Duplicate Conditions

If a MATLAB Function block has duplicate conditions, the conversion preserves only the first condition. The generated code discards other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. Otherwise, a conversion does not occur and the generated code contains instances of duplicate conditions.

The following examples show how the conversion handles duplicate conditions.

Example of Generated Code	Code After Conversion
<pre>if (x == 1) {     block1 } else if (x == 2) {     block2 } else if (x == 1) { // duplicate     block3 } else if (x == 3) {     block4 } else if (x == 1) { // duplicate     block5 } else {     block6 }</pre>	<pre>switch (x) {     case 1:         block1; break;     case 2:         block2; break;     case 3:         block4; break;     default:         block6; break; }</pre>
<pre>if (x == 1) {     block1 } else if (x == 1) { // duplicate     block2 } else {     block3 }</pre>	<p>Does not change, because only one unique condition exists</p>

## Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements

Suppose that you have the following model with a MATLAB Function block. Assume that the output data type is `double` and the input data type is `Controller`, an enumerated type that you define.

The block contains the following code:

```
function system = fcn(type)
%#codegen

if (type == Controller.P)
    system = 0;
elseif (type == Controller.I)
    system = 1;
elseif (type == Controller.PD)
    system = 2;
elseif (type == Controller.PI)
    system = 3;
elseif (type == Controller.PID)
    system = 4;
else
    system = 10;
end
```

The enumerated type definition in `Controller.m` is:

```
classdef Controller < Simulink.IntEnumType
    enumeration
        P(0)
        I(1)
        PD(2)
        PI(3)
        PID(4)
        UNKNOWN(10)
    end
end
```

If you generate code for an embedded real-time target using default settings, you see something like this:

```

if (if_to_switch_eml_blocks_U.In1 == P) {
    /* '<S1>:1:4' */
    /* '<S1>:1:5' */
    if_to_switch_eml_blocks_Y.Out1 = 0.0;
} else if (if_to_switch_eml_blocks_U.In1 == I) {
    /* '<S1>:1:6' */
    /* '<S1>:1:7' */
    if_to_switch_eml_blocks_Y.Out1 = 1.0;
} else if (if_to_switch_eml_blocks_U.In1 == PD) {
    /* '<S1>:1:8' */
    /* '<S1>:1:9' */
    if_to_switch_eml_blocks_Y.Out1 = 2.0;
} else if (if_to_switch_eml_blocks_U.In1 == PI) {
    /* '<S1>:1:10' */
    /* '<S1>:1:11' */
    if_to_switch_eml_blocks_Y.Out1 = 3.0;
} else if (if_to_switch_eml_blocks_U.In1 == PID) {
    /* '<S1>:1:12' */
    /* '<S1>:1:13' */
    if_to_switch_eml_blocks_Y.Out1 = 4.0;
} else {
    /* '<S1>:1:15' */
    if_to_switch_eml_blocks_Y.Out1 = 10.0;
}

```

The LHS variable `if_to_switch_eml_blocks_U.In1` appears multiple times in the generated code.

---

**Note** By default, variables that appear in the block do not retain their names in the generated code. Modified identifiers prevent naming conflicts.

---

Traceability comments appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Use Traceability in MATLAB Function Blocks” on page 75-45.

### Verifying the Contents of the Block

Check that the block follows the rules in “Rules for Conversion” on page 50-124.

Construct	How the Construct Follows the Rules
MATLAB Function block	Five unique conditions exist, in addition to the default: <ul style="list-style-type: none"> <li>• (type == Controller.P)</li> <li>• (type == Controller.I)</li> <li>• (type == Controller.PD)</li> <li>• (type == Controller.PI)</li> <li>• (type == Controller.PID)</li> </ul>
Each condition	Each condition: <ul style="list-style-type: none"> <li>• Tests equality</li> <li>• Uses the same input for the LHS</li> </ul>
Each LHS	Each LHS: <ul style="list-style-type: none"> <li>• Contains a single variable</li> <li>• Is the input to the block and therefore not a constant</li> <li>• Is of enumerated type <code>Controller</code>, which you define in <code>Controller.m</code> on the MATLAB path</li> <li>• Does not impact simulation</li> </ul>
Each RHS	Each RHS: <ul style="list-style-type: none"> <li>• Is an enumerated value and therefore a constant</li> <li>• Is of enumerated type <code>Controller</code></li> </ul>

### Enabling the Conversion

- 1 Open the Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

This step specifies an embedded real-time target for your model.

- 3 In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

**Tip** This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- MATLAB Function blocks in a model
- MATLAB functions in Stateflow charts of that model
- Flow charts in Stateflow charts of that model

For more information, see “Enhance Readability of Code for Flow Charts” on page 50-110.

---

## Generating Code for Your Model

In the model window, press **Ctrl+B**.

The code for the MATLAB Function block uses `switch-case` statements instead of `if-elseif-else` code:

```
switch (if_to_switch_eml_blocks_U.In1) {
  case P:
    /* '<S1>:1:4' */
    /* '<S1>:1:5' */
    if_to_switch_eml_blocks_Y.Out1 = 0.0;
    break;

  case I:
    /* '<S1>:1:6' */
    /* '<S1>:1:7' */
    if_to_switch_eml_blocks_Y.Out1 = 1.0;
    break;

  case PD:
    /* '<S1>:1:8' */
    /* '<S1>:1:9' */
    if_to_switch_eml_blocks_Y.Out1 = 2.0;
    break;

  case PI:
    /* '<S1>:1:10' */
    /* '<S1>:1:11' */
    if_to_switch_eml_blocks_Y.Out1 = 3.0;
    break;

  case PID:
    /* '<S1>:1:12' */
    /* '<S1>:1:13' */
    if_to_switch_eml_blocks_Y.Out1 = 4.0;
```

```
        break;

    default:
        /* '<S1>:1:15' */
        if_to_switch_eml_blocks_Y.Out1 = 10.0;
        break;
}
```

The `switch-case` statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS variable `if_to_switch_eml_blocks_U.In1` appears only once, minimizing repetition in the code.

### More About

- “Use Traceability in MATLAB Function Blocks” on page 75-45
- “Code Generation for Enumerations” (Simulink)
- “Model Configuration Parameters: Code Style”

## Generate Inlined Subsystem Code

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, the **Function packaging** parameter specifies the format of the subsystem's generated code. This parameter has four settings: `Auto`, `Inline`, `Nonreusable function`, and `Reusable function`. The code generator can generate inlined code for the `Auto` or `Inline` settings.

The `Inline` setting explicitly directs the code generator to inline the subsystem code unconditionally.

The default `Auto` setting directs the code generator to generate the most efficient code for the subsystem based on the type and number of instances of the subsystem that exist in the model. When there is only one instance of a subsystem, the `Auto` setting inlines the subsystem code. When there are multiple instances of a subsystem, that is not too complex, the `Auto` setting inlines the code for each subsystem. Otherwise, the `Auto` setting generates a single copy of the function (as a reusable function). For a function-call subsystem with multiple callers, the `Auto` setting generates subsystem code that is consistent with the `Nonreusable function` setting.

### Configure Subsystem to Inline Code

To configure your subsystem for inlining:

- 1 Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
- 2 In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.
- 3 Click the **Code Generation** tab and select `Auto` or `Inline` from the **Function packaging** parameter.
- 4 Click **Apply** and close the dialog box.

The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within `model.c` or `model.cpp` (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

## Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though you select the `InLine` setting.

- If a noninlined S-function calls a function-call subsystem, the code generator ignores the `InLine` setting. Because noninlined S-functions use function pointers to make function calls, the code generator must generate a function with all arguments present.
- In a feedback loop involving function-call subsystems, the code generator generates a function instead of inlined code for one of the subsystems. Based on the internal, sorted order of the subsystems, the code generator selects which subsystem to generate a function.
- If an S-function, an Async Interrupt, or a Task Sync block with the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` set to `TRUE` calls a subsystem, the code generator generates a function instead of inlined code for the subsystem. The VxWorks block library (`vxlib1`), contains the user-defined Async Interrupt and Task Sync blocks.<sup>7</sup>

## Improve Data Coherency in Generated Code

For models containing read and write operations for Data Store Memory blocks, you can generate code that contains a single variable to hold the value for each Data Store Read and Write operation. Generating one variable for each operation improves data access coherency.

### Example Model

The `data_store_latching` model contains a single Data Store Memory block that is accessed by two different Data Store Memory Read and two Data Store Memory Write blocks. Two Sum blocks perform addition on the input generated by the Data Store Read blocks and output the data to the Data Store Write blocks.

### Generate Code Without Parameter Enabled

Building the model with the **Implement each data store block as a unique access point** parameter turned off by default, generates this code:

```
void data_store_latching_step(void)
{
    /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
     * DataStoreRead: '<Root>/Data Store Read'
     * Sum: '<Root>/Add'
     */
    data_store_latching_DW.A += data_store_latching_DW.A +
        data_store_latching_DW.A;

    /* DataStoreWrite: '<Root>/Data Store Write1' incorporates:
     * DataStoreRead: '<Root>/Data Store Read1'
     * Sum: '<Root>/Add1'
     */
    data_store_latching_DW.A += data_store_latching_DW.A +
        data_store_latching_DW.A;
}
```

For both data read and write operations, the code contains the global variable `data_store_latching_DW.A`.

## Generate Code With Parameter Enabled

In the Configuration Parameters dialog box, on the **Interface** pane, select the **Implement each data store block as a unique access point** parameter. Click **Apply**.

The generated code is now:

```
void data_store_latching_step(void)
{
    real_T rtb_DataStoreRead;
    real_T rtb_DataStoreRead1;

    /* DataStoreRead: '<Root>/Data Store Read' */
    rtb_DataStoreRead = data_store_latching_DW.A;

    /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
     * Sum: '<Root>/Add'
     */
    data_store_latching_DW.A = (rtb_DataStoreRead + rtb_DataStoreRead) +
        rtb_DataStoreRead;

    /* DataStoreRead: '<Root>/Data Store Read1' */
    rtb_DataStoreRead1 = data_store_latching_DW.A;

    /* DataStoreWrite: '<Root>/Data Store Write1' incorporates:
     * Sum: '<Root>/Add1'
     */
    data_store_latching_DW.A = (rtb_DataStoreRead1 + rtb_DataStoreRead1) +
```

```
    rtb_DataStoreRead1;  
}
```

For each data store read operation, the code contains a variable. The variables are `rtb_DataStoreRead` and `rtb_DataStoreRead1`. These separate variables improve data access coherency.

# Code Replacement in Simulink Coder

---

- “What Is Code Replacement?” on page 51-2
- “Choose a Code Replacement Library” on page 51-8
- “Replace Code Generated from Simulink Models” on page 51-10

## What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

### Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for

a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

Table Entry Component	Description
Conceptual representation	<p>Identifies the table entry and contains match criteria for the code generator. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'cos' and operator key 'RTW_OP_ADD'.</li> <li>• Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</li> <li>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</li> </ul>

Table Entry Component	Description
Implementation representation	<p>Specifies replacement code. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name. For example, 'cos_dbl' or 'u8_add_u8_u8'.</li> <li>• Implementation arguments, with corresponding I/O types (output or input) and data types.</li> <li>• Parameters that provide additional implementation details, such as header and source file names and paths of build resources.</li> </ul>
Priority	<p>Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.</p>

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

## Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.

Term	Definition
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.

Term	Definition
Conceptual representation	<p>Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of:</p> <ul style="list-style-type: none"> <li>• Function or operator name or key</li> <li>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</li> <li>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</li> </ul>
Implementation argument	<p>Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.</p>
Implementation representation	<p>Specifies C or C++ replacement function prototype. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name (for example, 'cos_dbl' or 'u8_add_u8_u8')</li> <li>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</li> <li>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</li> </ul>
Key	<p>Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.</p>

Term	Definition
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

## Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

## Choose a Code Replacement Library

### In this section...

“About Choosing a Code Replacement Library” on page 51-8

“Explore Available Code Replacement Libraries” on page 51-8

“Explore Code Replacement Library Contents” on page 51-8

### About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

- 1 Explore available libraries. Identify one that best meets your application needs.
  - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 52-2.
  - See “Explore Available Code Replacement Libraries” on page 51-8.
- 2 Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 51-8.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

### Explore Available Code Replacement Libraries

Select the “Code replacement library” (Simulink Coder) to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane (Simulink Coder). To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

### Explore Code Replacement Library Contents

Use the **Code Replacement Viewer** to explore the content of a code replacement library.

- 1 At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

- 2 In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
- 3 In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
- 4 In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TfLCOperationEntryGenerator` or `RTW.TfLCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

## Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as elimination of `math.h`, system header files, or calls to `memcpy` or `memset`, or use of BLAS.

### Prepare for Code Replacement

1. Make sure that MATLAB®, Simulink®, Simulink Coder™, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can require Embedded Coder®.

To install MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

2. Identify an existing Simulink model or create a model for which you want the code generator to replace code.

### Choose a Code Replacement Library

By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks® provides and that you create and register by using the Embedded Coder® product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder® product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

### **Configure Code Generator to Use Code Replacement Library**

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation > Interface** pane, select a library for the “Code replacement library” (Simulink Coder) parameter.
- Set the `CodeReplacementLibrary` parameter at the command line or programmatically.

2. Configure the code generator to produce code only (not build an executable program) so you can verify your code replacements before building an executable program. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only” (Simulink Coder).
- Set the `GenCodeOnly` parameter at the command line or programmatically.

### **Include Code Replacement Information in Code Generation Report**

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report” (Simulink Coder). Consider having the report open automatically. Select **Open report automatically**.

2. Include the code replacement section in the report. Select “Summarize which blocks triggered code replacements” (Simulink Coder).

### Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

### Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

# Code Replacement for Simulink Models in Embedded Coder

---

- “What Is Code Replacement?” on page 52-2
- “Choose a Code Replacement Library” on page 52-8
- “Replace Code Generated from Simulink Models” on page 52-10

## What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

### Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for

a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

Table Entry Component	Description
Conceptual representation	<p>Identifies the table entry and contains match criteria for the code generator. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'cos' and operator key 'RTW_OP_ADD'.</li> <li>• Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</li> <li>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</li> </ul>

Table Entry Component	Description
Implementation representation	<p>Specifies replacement code. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name. For example, 'cos_dbl' or 'u8_add_u8_u8'.</li> <li>• Implementation arguments, with corresponding I/O types (output or input) and data types.</li> <li>• Parameters that provide additional implementation details, such as header and source file names and paths of build resources.</li> </ul>
Priority	<p>Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.</p>

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

## Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.

Term	Definition
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.

Term	Definition
Conceptual representation	<p>Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of:</p> <ul style="list-style-type: none"> <li>• Function or operator name or key</li> <li>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</li> <li>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</li> </ul>
Implementation argument	<p>Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.</p>
Implementation representation	<p>Specifies C or C++ replacement function prototype. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name (for example, 'cos_dbl' or 'u8_add_u8_u8')</li> <li>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</li> <li>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</li> </ul>
Key	<p>Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.</p>

Term	Definition
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

## Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

### In this section...

“About Choosing a Code Replacement Library” on page 52-8

“Explore Available Code Replacement Libraries” on page 52-8

“Explore Code Replacement Library Contents” on page 52-8

### About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

- 1 Explore available libraries. Identify one that best meets your application needs.
  - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 52-2.
  - See “Explore Available Code Replacement Libraries” on page 52-8.
- 2 Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 52-8.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

### Explore Available Code Replacement Libraries

Select the “Code replacement library” (Simulink Coder) to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane (Simulink Coder). To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

### Explore Code Replacement Library Contents

Use the **Code Replacement Viewer** to explore the content of a code replacement library.

- 1 At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

- 2 In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
- 3 In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
- 4 In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TfLCOperationEntryGenerator` or `RTW.TfLCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

## Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as elimination of `math.h`, system header files, or calls to `memcpy` or `memset`, or use of BLAS.

### Prepare for Code Replacement

1. Make sure that MATLAB®, Simulink®, Simulink Coder™, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can require Embedded Coder®.

To install MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

2. Identify an existing Simulink model or create a model for which you want the code generator to replace code.

### Choose a Code Replacement Library

By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks® provides and that you create and register by using the Embedded Coder® product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder® product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

### **Configure Code Generator to Use Code Replacement Library**

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation > Interface** pane, select a library for the “Code replacement library” (Simulink Coder) parameter.
- Set the `CodeReplacementLibrary` parameter at the command line or programmatically.

2. Configure the code generator to produce code only (not build an executable program) so you can verify your code replacements before building an executable program. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only” (Simulink Coder).
- Set the `GenCodeOnly` parameter at the command line or programmatically.

### **Include Code Replacement Information in Code Generation Report**

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report” (Simulink Coder). Consider having the report open automatically. Select Open report automatically.

2. Include the code replacement section in the report. Select “Summarize which blocks triggered code replacements” (Simulink Coder).

### Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

### Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

# Deployment

# External Code Integration in Simulink Coder

---

The code generator includes multiple approaches for integrating legacy or custom code with generated code. Legacy code is existing handwritten code or code for environments that you integrate with code produced by the code generator. Custom code is legacy code or other user-specified lines of code that you include in the code generator build process. Collectively, legacy and custom code are called external code.

You integrate external code by importing existing external code into code produced by the code generator, exporting generated code into an existing external code base, or you can do both. For example, you can import code by calling an external function, by using the Legacy Code Tool, or place external code at specific locations in generated code by including Custom Code blocks in a model. When you import external code, the resulting generated code interfaces with generated scheduling code.

You can export generated code as a plug-in function for use in an external development environment. When you export generated code, you intend to interface that code manually with a scheduling mechanism in your application run-time environment.

For guidance on choosing an approach based on your application, see “Choose an External Code Integration Workflow” (Simulink Coder) .

- “What Is External Code Integration?” on page 53-3

- “Exchange Data Between External Calling Code and Generated Code” on page 53-107
- “Generate Code That Matches Appearance of External Code” on page 53-110

## What Is External Code Integration?

Software projects typically involve combining code from multiple sources. A typical system structure for a code generation application consists of a framework that combines code from multiple sources, including external code and code generated from Simulink models.

This figure shows an application that requires integration of existing driver code for hardware devices. The core software algorithms and logic can be a combination of code modules for external reusable algorithms integrated into the Simulink environment and code generated as part of an overall model design.

Several workflows and tools are available for you to integrate external and generated code. Each workflow identifies tooling for generating code that aligns interfaces, code appearance, and other factors, such as optimization between external and generated code.

## Choose an External Code Integration Workflow

In this section...
“Choose a Software Execution Framework for Scheduling Code Execution” on page 53-5
“Evaluate Characteristics of External Code” on page 53-7
“Identify Integration Requirements” on page 53-8
“Choose a Workflow” on page 53-10

Completing these tasks helps you choose external code integration workflows and tooling that align with your project.

Task	Action	More Information
1	Partition your application, map algorithms to components, and identify integration points.	“Design Models for Generated Embedded Code Deployment” on page 1-2
2	Determine whether you can rely on scheduling code that the code generator produces, or whether you must integrate generated code with scheduling mechanisms that are specific to your run-time environment.	“Choose a Software Execution Framework for Scheduling Code Execution” on page 53-5
3	Evaluate the characteristics of the external code that you are importing or to which you are exporting generated code.	“Evaluate Characteristics of External Code” on page 53-7
4	Identify integration requirements, which assists with choosing optimal tooling for your integration.	“Identify Integration Requirements” on page 53-8
5	Based on the results of tasks 1-4, choose a workflow.	“Choose a Workflow” on page 53-10

## Choose a Software Execution Framework for Scheduling Code Execution

The code generator supports two types of software execution frameworks—single top model and multiple top-level, as described in “Design Models for Generated Embedded Code Deployment” on page 1-2. The first question to answer concerns which of the two frameworks meets the scheduling and other needs of your project. For example, you can import external code into a single, rate-based top model. You can export code from a single top model or multiple top-level models for integration with custom (external) scheduling mechanisms.

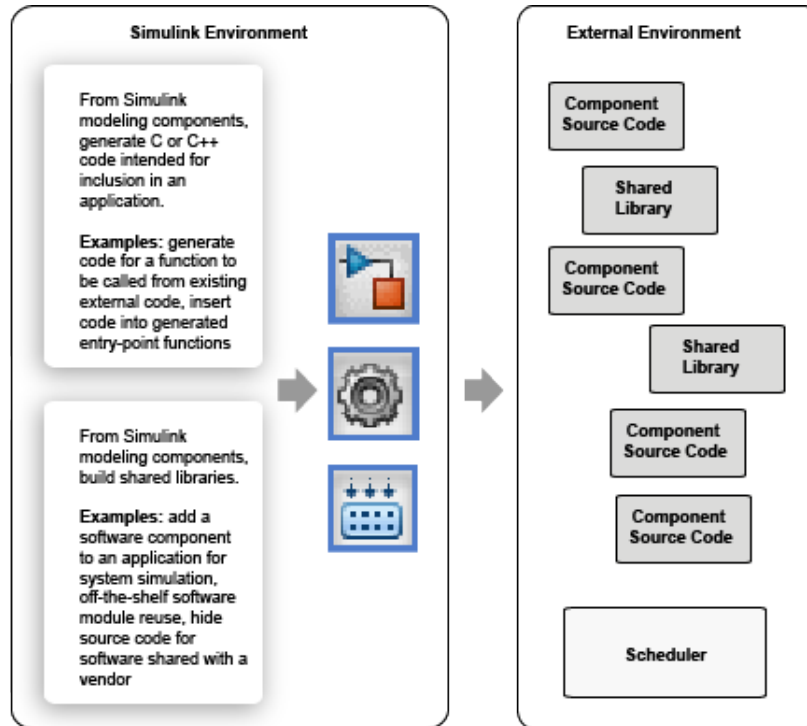

- Single top model

Generate one set of application code files from external code and code that the Simulink C/C++ code generator produces. The generated code includes a scheduler. In this case, you *import* code into the Simulink code generation environment.

- Single top model or multiple top-level models

Integrate C or C++ code that the code generator produces from model components with external application code and an external scheduler. You *export* generated code from the Simulink code generation environment.

Importing calls to external device driver code into a model and generating code for that model for export involves importing and exporting code.

Based on goals and requirements, external code integration is characterized in several ways, requiring different workflows and integration tooling:

- Import existing external code into generated code.
  - Call reusable external algorithm code for simulation and code generation.
  - Place external C/C++ code in generated code.

- Call external device drivers.
- Apply function and operator code replacements.
- Interface with external timer interrupt or scheduler.
- Generate replacement code for specific run-time environment.
- Export generated code for inclusion in external code base.
  - Generate component source code for export.
  - Generate shared library for export.

Next, see “Evaluate Characteristics of External Code” on page 53-7.

## Evaluate Characteristics of External Code

Before choosing an external integration workflow, evaluate these characteristics of the external code. To interface with external code, generated C or C++ code handles one or more of the external code characteristics. An understanding of these characteristics and your requirements for modeling, simulation, and code generation helps you choose the optimal workflow for your integration scenario. (See “Identify Integration Requirements” on page 53-8.)

Characteristic	What to Consider
Hardware dependency	<p>Is the external code hardware-dependent? Utility functions, lookup tables, and filters are examples of hardware-independent code.</p> <p>Device drivers interact directly with hardware. They depend on characteristics of the hardware. For example, a device driver for an analog-to-digital converter initializes, reads data from, and writes data to hardware registers. Hardware differences and dependencies concern data type size, endianness, shift operations, compiler directives, and optimized function and operator support. Other code interfaces with device drivers by using an API and data mapped to specific memory addresses. Typically, simulation on a development computer is not possible. Reading from and writing to a register during simulation on a development computer produces unexpected and unwanted results.</p>

Characteristic	What to Consider
Reusable	Is the external code a reusable software module? Examples include utility functions, lookup tables, filters, specialized integrators, and proportional-integral-derivative (PID) control modules.
Dependency on data persistence between function calls	Does the external code require persistent data? For example, a call to a first order filter function uses the output of the previous call to the function to calculate a new output value. You have the option of defining the data as global or using shared memory outside the context of the function.
Data typing and interface	How complex is the data that the external code uses? What does the data interface look like? It consists of arguments, a return value, global variables, and access functions. What data types does the code use? Are the types limited to basic ANSI C integers, floating-point types, arrays of integers or floating-point types, and pointers to these types? Does the interface include structures or pointers to structures?
Fixed-point code	Is the external code designed to run on integer-only processors? If yes, the code exchanges and uses data represented as integers only. Data can be associated with fixed-point scaling or offsets.
External resource dependencies	Does the external code use data, functions, or macros defined outside the scope of the code? For example, the function can use a standard ANSI function, a shared library, or predefined constants. In these cases, you must inform the compiler and linker of the paths and file names of the external resources.
External solver required	Are you using the external function for advanced development or rapid prototyping to describe a system with a continuous transfer function or a set of differential equations? If yes, the external code relies on an external solver.

Next, see “Identify Integration Requirements” on page 53-8.

## Identify Integration Requirements

Before choosing an external integration workflow, review these integration requirements. An understanding of these requirements and the characteristics of your external code helps you choose the optimal workflow for your integration scenario. (See “Evaluate Characteristics of External Code” on page 53-7.)

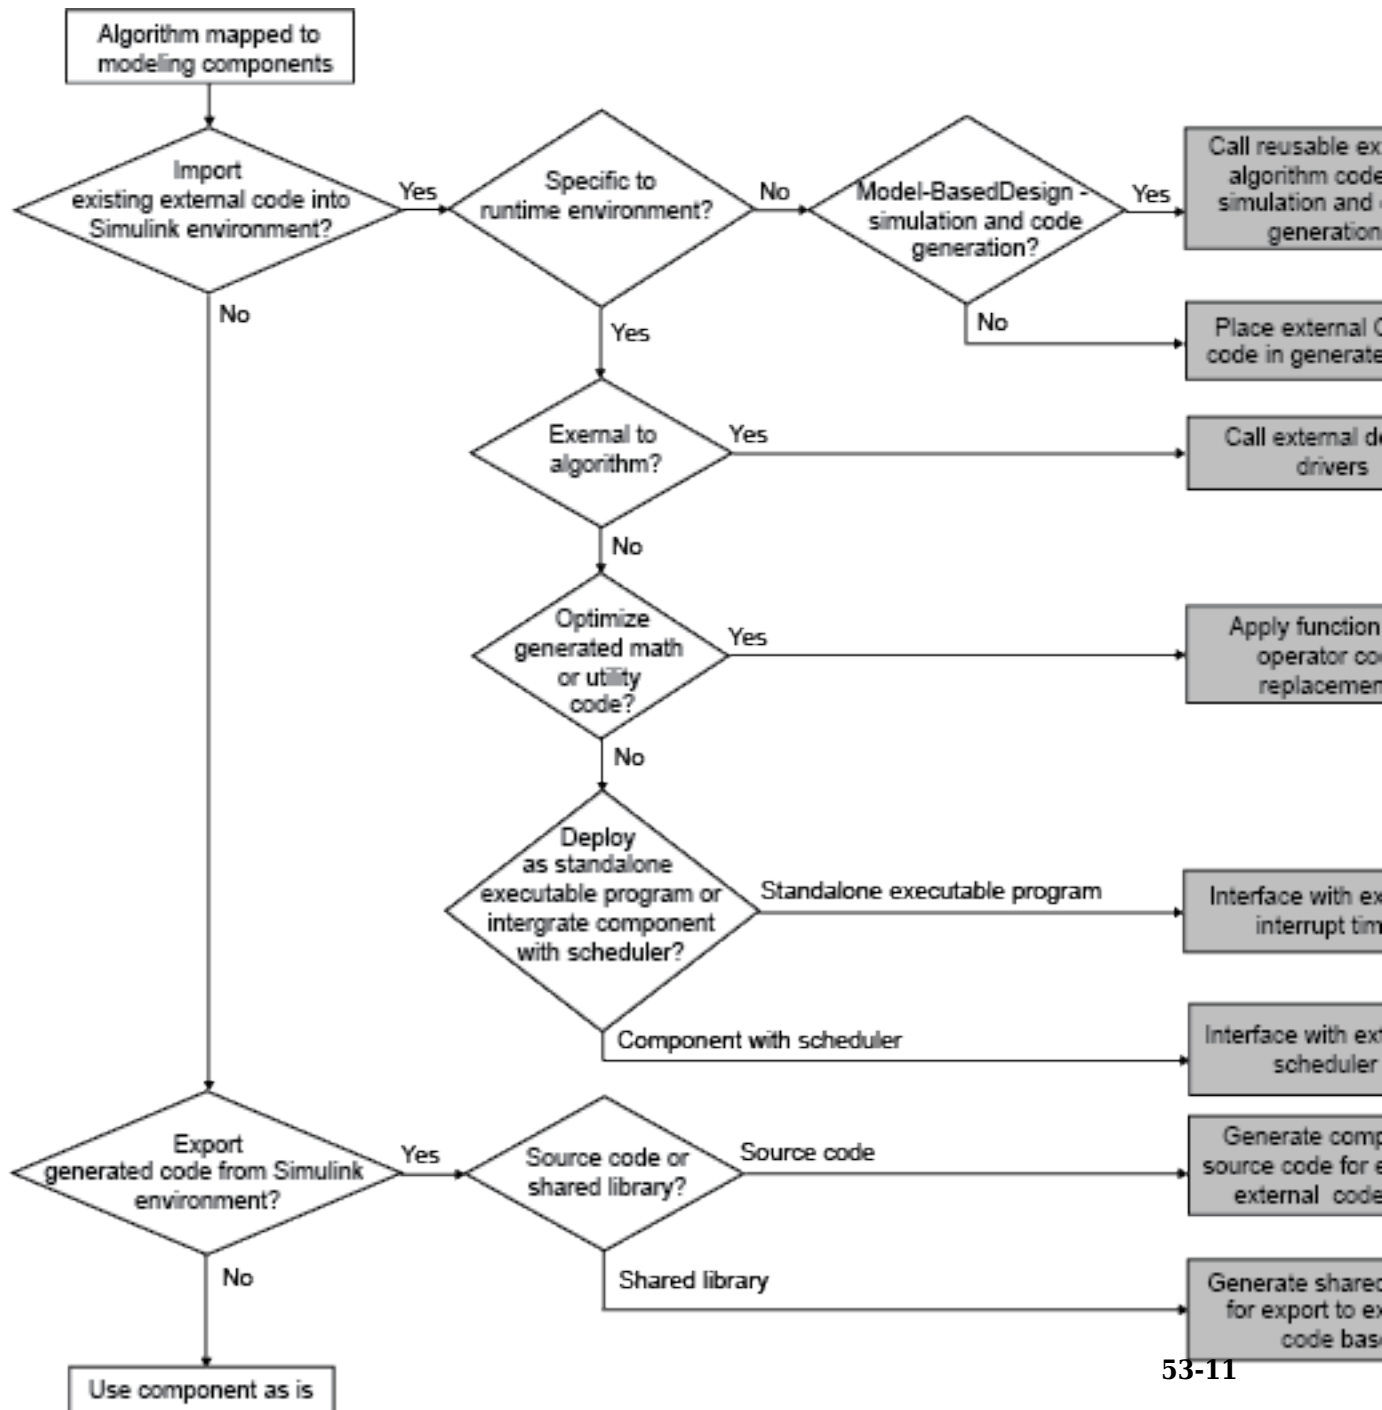

Requirement	What to Consider
Effort	What level of effort is planned for the integration project—low, medium, or high?
Learning effort	What is the programming experience of assigned project resources? How much experience do assigned resources have with Simulink and MathWorks C/C++ code generation products?
Simulation and code generation behaviors	Do you want to take advantage of Model-Based Design? To take full advantage of Model-Based Design, convert code to modeling elements, which you can then use in the Simulink and Stateflow simulation environment. Then, simulate and generate code for the integrated component. Use software-in-the-loop (SIL) or processor-in-the-loop (PIL) testing to verify whether algorithm behavior is the same in both environments.
Data interface and typing	<ul style="list-style-type: none"> <li>• Does your model or generated code need to exchange data with the external function? If so, map inputs, outputs, and parameters to the external function interface. Typical function interfaces involve function arguments and return values, global variables, and access functions, such as <code>getRPM</code>.</li> <li>• Do you want to represent arrays, structures, or enumerated types? In the Simulink environment, you can represent these types as vectors, buses, and <code>IntEnum</code>, respectively.</li> <li>• Is fixed-point support required? If you use the Simulink fixed-point interface, you can scale and specify offsets.</li> <li>• Does the external code use company-specific data types? If yes and you have Embedded Coder software, create alias types to represent those external types. The code generator uses the alias types in the code that it produces. For example, once defined, you can specify an alias type in a function prototype, for a temporary variable, or for block output.</li> <li>• Does the code exchange data with shared memory? If yes, define and use memory sections.</li> </ul>
Direct function call	Do you want to call C external code directly from a model? You can choose from mechanisms, such as the Legacy Code Tool, Stateflow external code interface and chart action language, and the MATLAB Function block.

Requirement	What to Consider
Insertion of external code into generated code	Do you want to control the placement of external code within generated code? Do you want to insert code into generated entry-point functions? You can place code within generated code by using model configuration parameters or custom code blocks.
Code generation optimization support	Do you want to optimize the code that the code generator produces? If so, you can configure the model for the code generator to optimize the code it produces based on application objectives, such as execution, ROM, and RAM efficiency. You also have the option of using code replacement libraries.
Files required	Do you want to minimize the number of files that you maintain? Some external code integration tools require that you maintain separate files for defining simulation and code generation.

Next, see “Choose a Workflow” on page 53-10.

## Choose a Workflow

To choose a workflow for each integration point, use the following flow diagram . The gray boxes identify common workflows and provide links to more information. Click the gray box that best addresses the requirements of an integration point.

## Configure Target Hardware Characteristics

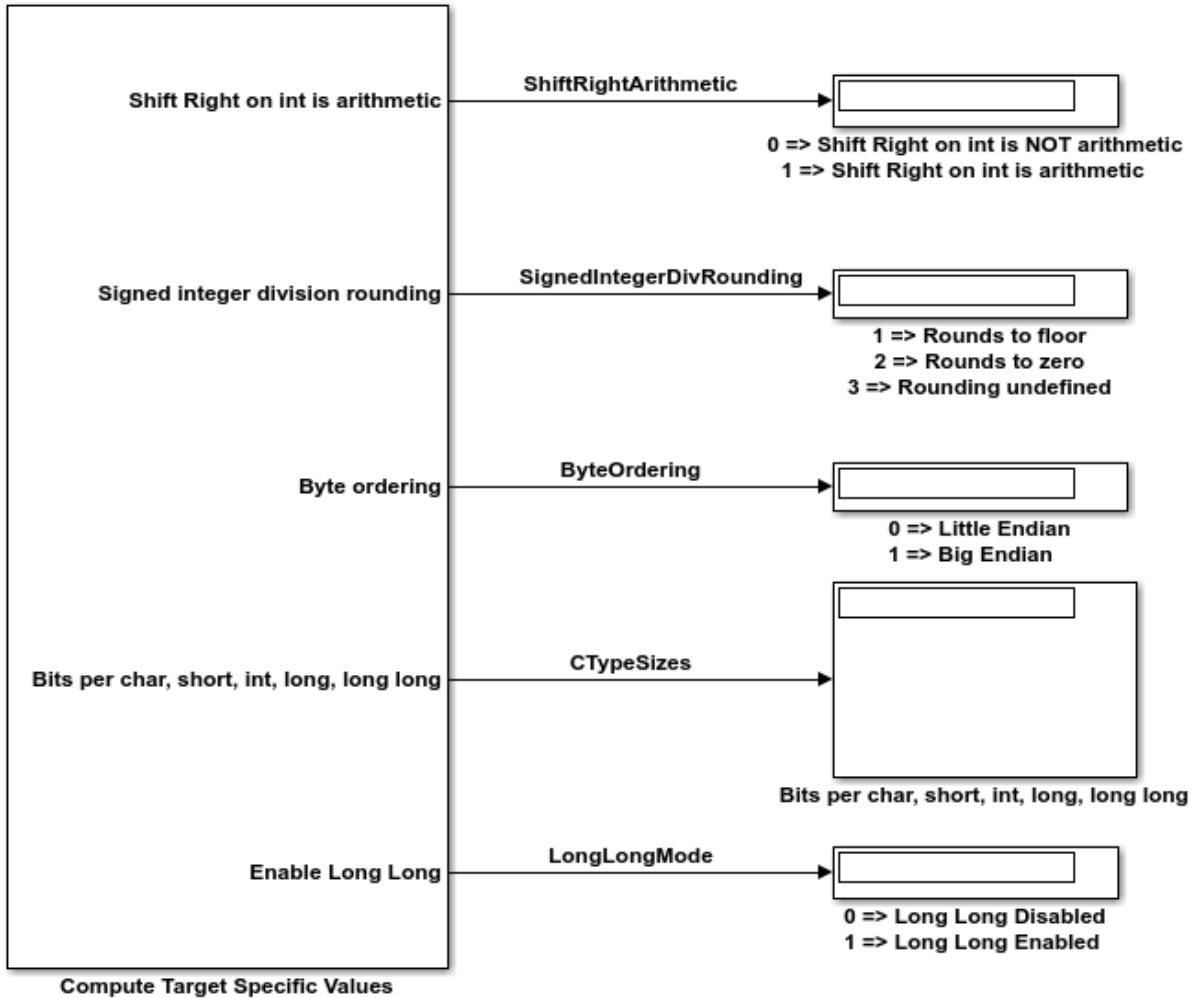

Simulink® allows you to configure the hardware implementation characteristics of your target system. Failure to do so can result in code that is incorrect or inefficient.

### **Open Example Model**

Open the example model `rtwdemo_targetsettings`.

```
open_system('rtwdemo_targetsettings');
```

?

View Hardware Configuration (double-click)

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

My microprocessor is not listed ...

Open the **Hardware Implementation** pane of the Configuration Parameters dialog box by double-clicking the yellow button in the model.

### Hardware Board Configuration

By default, the model is configured for the code generator to determine the hardware board configuration based on the specified system target file. The default system target file setting is `grt.tlc`.

If you have installed support for a hardware board, that board should appear in the **Hardware board** menu. If you select it, the dialog box displays parameters that are relevant to your hardware board.

### My Hardware Board is Not Listed

If you are using a hardware board that is not listed, add it to the menu by installing the corresponding target support package. Start the Support Package Installer by setting **Hardware board** to `Get hardware Support Packages`, or by entering `supportPackageInstaller` in the MATLAB® Command Window.

After installing support for a hardware board, reopen the Configuration Parameters dialog box and select the hardware board.

### Cross-Development Systems that Include Source Level Debuggers

If you use a cross-development system that includes a source level debugger:

1. Configure the model for your hardware board.
2. Generate code and build an executable using your target development system. For details about retrieving file and path information, see the documentation on the Simulink Coder® Build Information API.
3. Download the executable to the target hardware and set breakpoints at the model output code for each output of the model.
4. Run a debugging session and observe the behavior of the code as it executes on the target hardware. As you step through the code, it computes the values for target hardware device characteristics.

If your target development system does not support source level debugging, generate code and add `printf` statements or other code that gets the results.

5. On the **Hardware Implementation** pane of the Configuration Parameters dialog box, set **Device vendor** to `Custom processor`, click the **Device details** arrow, and adjust the microprocessor device settings manually.

## Check Code Generation Assumptions

The code generator implements assumptions that depend, for example, on the hardware implementation settings for your model. It is important to check that the assumptions are valid for your target hardware. Use the `buildStandaloneCoderAssumptions` function to create an application that performs assumption checks on your target hardware.

When you configure your model, try to specify hardware implementation and build configuration settings that match your target hardware. Then, to check code generator assumptions for your target hardware, use this workflow:

- 1 With `GenerateReport` set to 'on', build (**Ctrl+B**) your model.
- 2 To view the list of code generator assumptions that you can check, open the code generation report and click the **Coder Assumptions** link.

For more information, see “Coder Assumptions List” on page 53-19.

- 3 Run `buildStandaloneCoderAssumptions`, which uses the generated code in the build folder to create an application that runs code generation assumption checks.
- 4 Download the application onto the target hardware or target environment, and then run the application.
- 5 While the application runs, use a debug tool to view check results that are in a data structure.

### Check Code Generator Assumptions for Development Computer

If the target hardware is, for example, your Windows development computer, you can use Microsoft Visual Studio® to run and debug the application:

- 1 To open a model, in the Command Window, enter `rtwdemo_sil_topmodel`.
- 2 In the Model Configuration Parameters dialog box, in the **Hardware Implementation** pane, specify settings to match the target hardware. For example, for a 64-bit Windows computer specify these parameter settings:
  - **Device vendor** -- Intel
  - **Device type** -- x86-64 (Windows 64)
- 3 Clear model configuration parameter **Enable portable word sizes**.

- 4 Build the model (**Ctrl+B**).
- 5 To view the list of code generator assumptions, open the code generation report and click the **Coder Assumptions** link.
- 6 From the Command Window, in the working folder, run:
 

```
buildStandaloneCoderAssumptions('rtwdemo_sil_topmodel_ert_rtw')
```

In the build folder, the function creates the `coderassumptions\standalone` subfolder, which contains the target application, `rtwdemo_sil_topmodel_ca`.
- 7 Open Microsoft Visual Studio and select **File > Open > Project/Solution**
- 8 Using the Open Project dialog box, navigate to the `coderassumptions\standalone` subfolder and select `rtwdemo_sil_topmodel_ca`. Then, click **Open**.
- 9 Select **File > Open > File**. Using the Open File dialog box, select `coderassumptions\standalone\rtwdemo_sil_topmodel_ca.c`
- 10 At the return statement, insert a break point.
- 11 Select **Debug > Start Debugging**.
- 12 To verify code generator assumptions, use a Watch window to inspect the `Results` data structure:
  - a In the `rtwdemo_sil_topmodel_ca.c` code, right-click `Results`.
  - b From the context menu, select **Add Watch**.

The variables in the data structure contain:

- Check outcomes (`TestResults`)
- Target hardware truths (`ActualValues`)
- Code generator assumptions (`ExpectedValues`)

For example, if the code generator assumption for `bitsPerChar` is accurate, you see the `CA_PASS` value in the `status` variable.

Name	Value
Results	{TestResults=0x00007ff749ba7560 {rtwdemo_si 0x00007ff749ba7560 {rtwdemo_sil_topmodel_c
TestResults	{status=CA_PASS (2) msg=CA_NO_MSG (0) }
bitsPerChar	{status=CA_PASS (2) msg=CA_NO_MSG (0) }
status	CA_PASS (2)
msg	CA_NO_MSG (0)
bitsPerShort	{status=CA_PASS (2) msg=CA_NO_MSG (0) }
bitsPerInt	{status=CA_PASS (2) msg=CA_NO_MSG (0) }
bitsPerLong	{status=CA_PASS (2) msg=CA_NO_MSG (0) }

## Coder Assumptions List

The contents section of the code generation report has a link to the Coder Assumptions page. The page provides a list of:

- Code generation assumptions that you can check
- Expected results for the assumption checks

This table describes the labels that you see in the list.

Category	Label	Assumption You Can Check
C/C++ Language Configuration for Target Hardware or Development Computer	BitPerChar	Number of bits per char (ProdBitPerChar)
	BitPerShort	Number of bits per short (ProdBitPerShort)
	BitPerInt	Number of bits per int (ProdBitPerInt)
	BitPerLong	Number of bits per long (ProdBitPerLong)
	BitPerFloat	Size of float (Only if PurelyIntegerCode is 'off')
	BitPerDouble	Size of double (Only if PurelyIntegerCode is 'off')
	BitPerPointer	Number of bits per pointer (ProdBitPerPointer)
	BitPerSizeT	Number of bits per size_t (ProdBitPerSizeT)
	BitPerPtrDiffT	Number of bits per ptrdiff_t (ProdBitPerPtrDiffT)
	Endianness	Byte ordering (ProdEndianness)
	Shift right for signed integer is arithmetic shift	Sign bit behavior (ProdShiftRightIntArith)
	Signed integer division rounds to	Rounding behavior for integer division (ProdIntDivRoundTo)

Category	Label	Assumption You Can Check
C/C++ Language Standard	Initial value of a global integer variable is zero	Zero initialization of memory (ZeroExternalMemoryAtStartup and ZeroInternalMemoryAtStartup)
Floating-Point Numbers	Flush-to-zero computed subnormal values (FTZ)	Flush-to-zero subnormal number processing
	Flush-to-zero incoming subnormal values (DAZ)	Denormals-are-zero subnormal number processing

## Call Reusable External Algorithm Code for Simulation and Code Generation

Code reuse offers business and technological advantages. From a business perspective, code reuse saves time and resources. From a technological perspective, code reuse promotes consistency and reduces memory requirements. Other considerations include:

- Modularizing an application
- Reusing an optimized algorithm
- Interfacing with a predefined dataset
- Developing application variants

Examples of reusable hardware-independent algorithmic code to consider importing into the Simulink environment for simulation and code generation include:

- Utility functions
- Lookup tables
- Digital filters
- Specialized integrators
- Proportional-integral-derivative (PID) control modules

### Workflow

To call reusable external algorithm code for simulation and code generation, iterate through the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 53-4
2	Based on the programming language of the external code, choose an integration approach to add the external code to a Simulink model.	“Choose an Integration Approach” on page 53-22

Task	Action	More Information
3	Verify algorithm behavior and performance by simulating the model.	“Simulation” (Simulink)
4	Define the representation of model data for code generation.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 53-95
5	Configure the model for code generation.	“Generate Code That Matches Appearance of External Code” on page 53-110 and “Model Configuration”
6	Generate code and a code generation report.	“Code Generation”
7	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 49-18 and “Static Code Metrics” on page 49-32
8	Build an executable program from the model.	“Build Integrated Code Within the Simulink Environment” on page 53-54
9	Verify that executable program behaves as expected.	“Numerical Equivalence Testing”
10	Verify that executable program performs as expected.	“Code Execution Profiling”

## Choose an Integration Approach

Several approaches are available for integrating reusable algorithmic code into the Simulink environment for code generation. Some approaches integrate external code directly. Other approaches convert the external code to Simulink or Stateflow modeling elements for simulation, and later for code generation from the modeled design. The integration approach that you choose depends on:

- Programming language of the external code — MATLAB, C, C++, or Fortran
- Your programming language experience and preference
- Performance requirements
- Whether the algorithm must model continuous time dynamics or you are integrating the algorithm into an application that uses discrete and continuous time

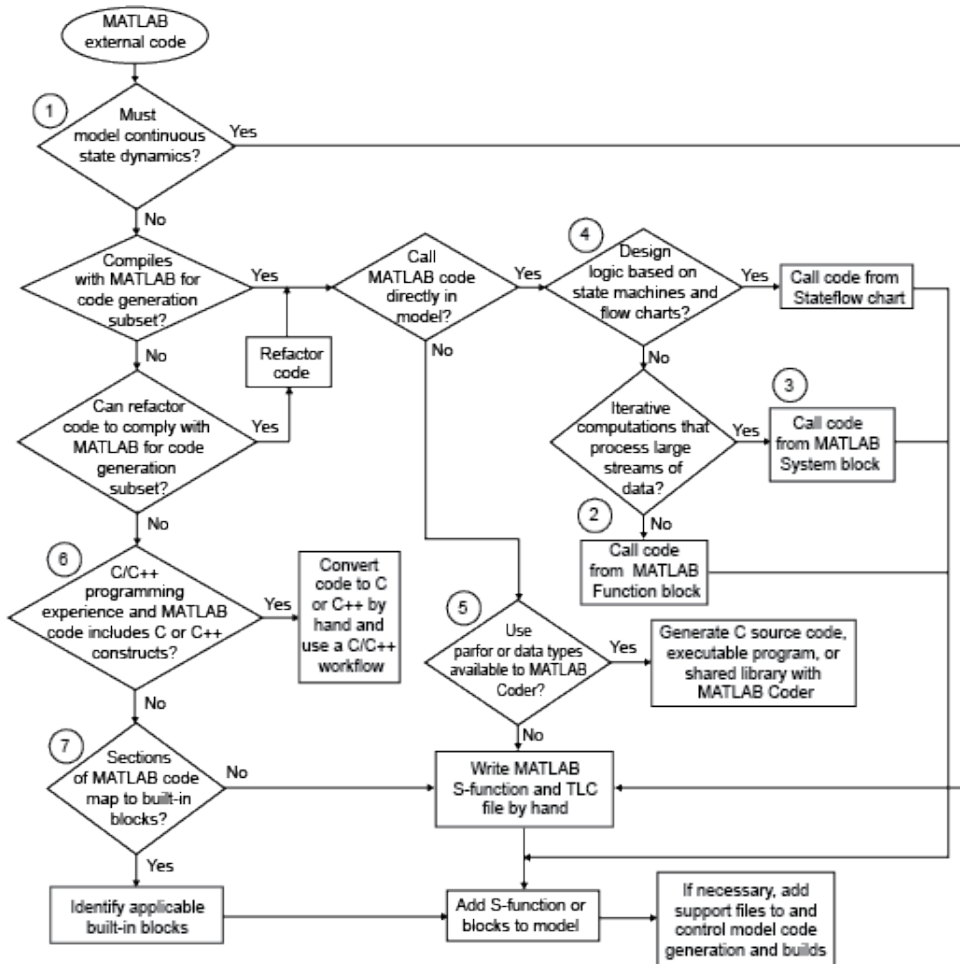

- Whether you want to take advantage of Model-Based Design
- Level of control required over the code that the code generator produces

To choose an approach for a reusable algorithm, see the subsection that matches the programming language of your external algorithm code.

- “Integration Approaches for External MATLAB Code” on page 53-23
- “Integration Approaches for External C or C++ Code” on page 53-26
- “Integration Approaches for External Fortran Code” on page 53-32

### **Integration Approaches for External MATLAB Code**

Multiple approaches are available for integrating external MATLAB code into the Simulink environment. The following diagram and table help you choose the best integration approach for your application based on integration requirements.

	Condition or Requirement	Action	More Information
1	The algorithm must model continuous state dynamics.	Write a MATLAB S-function and, for generating code, a corresponding TLC file for the algorithm. Add the S-function to your model.	<ul style="list-style-type: none"> <li>“Create and Configure MATLAB S-Functions” (Simulink)</li> <li>“S-Functions” (Simulink Coder)</li> <li>“Target Language Compiler” (Simulink Coder)</li> </ul>

	<b>Condition or Requirement</b>	<b>Action</b>	<b>More Information</b>
2	External code complies with the MATLAB code for code generation subset and you want to call MATLAB code from a Simulink model.	Add a MATLAB Function block to the model. Embed the MATLAB code in that block.	<ul style="list-style-type: none"> <li>• “Integrate C Code Using the MATLAB Function Block” (Simulink)</li> <li>• MATLAB Function</li> </ul>
3	External code complies with the MATLAB code for code generation subset, you want to call MATLAB code from a Simulink model, and your algorithm includes iterative computations that process large streams of data.	Add a MATLAB System block to the model. Embed the MATLAB code in that block as a System object™.	<ul style="list-style-type: none"> <li>• “Integrate C Code Using the MATLAB Function Block” (Simulink)</li> <li>• MATLAB System</li> </ul>
4	External code complies with the MATLAB code for code generation subset, you want to call MATLAB code from a Simulink model, and your algorithm includes design logic that is based on state machines and flow charts.	Add a Stateflow chart to the model. Call the external code from the chart, using MATLAB as the action language.	<ul style="list-style-type: none"> <li>• “Chart Programming Basics” (Stateflow)</li> <li>• “Insert External Code into Stateflow Charts” on page 53-32</li> </ul>

	Condition or Requirement	Action	More Information
5	You want to use the <code>parfor</code> function for parallel computing or interface data types that are available to MATLAB Coder, Simulink Coder, and Embedded Coder. To use <code>parfor</code> , Parallel Computing Toolbox must be installed.	Use software to generate C code. Then, call that generated code as external C code.	<ul style="list-style-type: none"> <li>• “Generate C Code by Using the MATLAB Coder App” (MATLAB Coder)</li> <li>• “Getting Started with MATLAB Coder” (MATLAB Coder)</li> </ul>
6	You have C or C++ programming experience and the external MATLAB code is compact and primarily uses C or C++ constructs.	Manually convert the MATLAB code to C or C++ code. Choose an integration approach for C or C++ code.	“Integration Approaches for External C or C++ Code” on page 53-26
7	Sections of the external MATLAB code map to built-in blocks.	Develop the algorithm in the context of a model, using the applicable built-in blocks.	<ul style="list-style-type: none"> <li>• “Interactive Model Editing” (Simulink) and “Project Management” (Simulink)</li> <li>• “Blocks and Products Supported for Code Generation” (Simulink Coder)</li> </ul>

To embed external MATLAB code in a MATLAB Function block or generate C or C++ code from MATLAB code with the MATLAB Coder software, the MATLAB code must use functions and classes supported for C/C++ code generation.

- “Functions and Objects Supported for C/C++ Code Generation” (MATLAB Coder)

### Integration Approaches for External C or C++ Code

Under most circumstances, you can integrate external code written in C or C++ into the Simulink environment by generating S-functions and TLC files with the Legacy Code Tool. This tool uses specifications that you supply as MATLAB code to transform existing MATLAB functions into C MEX S-functions that you can include in Simulink models and call from generated code. For details, see “Implement Algorithms Using Legacy Code

Tool” (Simulink) and “Import Calls to External Code into Generated Code with Legacy Code Tool” on page 12-7.

In comparison to alternative approaches, Legacy Code Tool is the most optimal choice for generating code optimized enough for embedded systems. Consider alternative approaches if one or more of the following conditions exist:

- The external code uses global variables to exchange data.
- Programming experience is limited.
- The algorithm must model discrete and continuous state dynamics.
- You want to include the integrated external code in a Stateflow chart.
- The external code requires a fixed-point interface.
- You want maximum flexibility for controlling what code the code generator produces.
- You quickly want to embed a call to the external code in a call to the `coder.ceval` function that is embedded in the MATLAB Function block, and performance is not an issue.

This diagram and table help you choose the best integration approach based on your integration requirements.

	<b>Condition or Requirement</b>	<b>Action</b>	<b>More Information</b>
1	You want to integrate external C code with generated C++ code or conversely	Match the language choice for the generated code by modifying the language of the external code.	"Modify Programming Language of External Code to Match Generated Code" on page 53-31
2	Your algorithm includes design logic that is based on state machines and flow charts. Or, a function that you want to integrate must exchange data with a model by using global variables. The function defines the global variables and uses them to write output rather than returning a value (return) or writing output to an argument.	Add a Stateflow chart to the model. Call the external code from the chart, using C as the action language. In the chart, write code that calls the external function and reads from and writes to the global variables. To perform calculations with output of the external code, the model must read from the global variable during execution.	"Insert External Code into Stateflow Charts" on page 53-32
3	You want to include external C or C++ code in a Stateflow chart for simulation and code generation.	Configure the model that contains the chart to apply the external C or C++ code.	<ul style="list-style-type: none"> <li>• "Custom Code" (Stateflow)</li> <li>• "Call C Library Functions in C Charts" (Stateflow)</li> <li>• "Insert External Code into Stateflow Charts" on page 53-32</li> </ul>
4	You quickly want to embed a call to external C or C++ code in a model. Performance is not an issue.	Call the C or C++ code with the <code>coder.ceval</code> function from within a MATLAB Function block.	<ul style="list-style-type: none"> <li>• <code>coder.ceval</code> function</li> <li>• "Integrate C Code Using the MATLAB Function Block" (Simulink)</li> <li>• MATLAB Function block</li> </ul>

	<b>Condition or Requirement</b>	<b>Action</b>	<b>More Information</b>
5	The application requires more entry-point functions than the code generator typically produces—for example, more than <i>model_step</i> , <i>model_initialize</i> , and <i>model_terminate</i> . You want maximum flexibility for controlling what code the code generator produces.	Manually write an S-function and TLC file.	<ul style="list-style-type: none"> <li>• “C/C++ S-Function Basics” (Simulink)</li> <li>• “S-Functions and Code Generation” on page 12-2</li> <li>• “C S-Function Examples” (Simulink) and “C++ S-Function Examples” (Simulink)</li> </ul>
6	You want to simulate and generate external code for a discrete time application. Optimizing generated code is essential. You want ease of use with moderate flexibility for controlling what code the code generator produces. You have C or C++ programming experience, but you prefer to generate the files for adding the code to a model.	<p>Generate S-function and TLC files by using the Legacy Code Tool. If necessary, refine the generated code manually to meet application requirements. (If you change the generated code, you lose the changes if you regenerate the S-function and TLC files.)</p> <p>For simple algorithms written in C, consider using the Simulink C Caller block.</p>	<ul style="list-style-type: none"> <li>• “Integrate C Functions Using Legacy Code Tool” (Simulink)</li> <li>• “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder)</li> <li>• “Integrate C Code Using C Caller Blocks” (Simulink)</li> </ul>

	Condition or Requirement	Action	More Information
7	The algorithm must model discrete and continuous state dynamics for simulation and rapid prototyping. The external code requires a fixed-point interface. Programming experience is limited. You want ease of use with basic flexibility for controlling what code the code generator produces for rapid prototyping.	Generate S-function and TLC files by using the S-Function Builder. If necessary, refine the generated code manually to meet application requirements. (If you change the generated code, you lose the changes if you regenerate the S-function and TLC files.)	<ul style="list-style-type: none"> <li>• “Build S-Functions Automatically” (Simulink)</li> <li>• “Generate S-Function from Subsystem” on page 12-81</li> </ul>

### Modify Programming Language of External Code to Match Generated Code

To integrate external C code with generated C++ code or conversely, modify the language of the external code to match the programming language choice for the generated code. Options for making the programming language match include:

- Writing or rewriting the external code in the language choice for the generated code.
- If you are generating C++ code and the external code is C code, for each C function, create a header file that prototypes the function. Use this format:

```
#ifdef __cplusplus
extern "C" {
#endif
int my_c_function_wrapper();
#ifdef __cplusplus
}
#endif
```

The prototype serves as a function wrapper. If your compiler supports C++ code, the value `__cplusplus` is defined. The linkage specification `extern "C"` specifies C linkage without name mangling.

- If you are generating C code and the external code is C++ code, include an `extern "C"` linkage specification in each `.cpp` file. For example, the following example shows C++ code in the file `my_func.cpp`:

```
extern "C" {
    int my_cpp_function()
    {
        ...
    }
}
```

## Integration Approaches for External Fortran Code

To integrate external Fortran code, write an S-function and corresponding TLC file.

See “C/C++ S-Function Basics” (Simulink), “Implement Algorithms Using Fortran Code” (Simulink), “S-Functions and Code Generation” on page 12-2, and “Fortran S-Function Examples” (Simulink).

## Insert External Code into Stateflow Charts

- “Integrate External Code for Library Charts” on page 53-32
- “Integrate External Code for All Charts” on page 53-33
- “Call External C Code from Model and Generated Code” on page 53-33

### Integrate External Code for Library Charts

To integrate external code that applies only to Stateflow library charts for code generation, for each library model that contributes a chart to your main model, complete these steps. Then, generate code.

- 1 In the Stateflow Editor, open the Model Configurations dialog box. Select parameter **Use local custom code settings (do not inherit from main model)**,

The library model retains its own custom code settings during code generation.

- 2 Specify your custom code in the subpanes.

Follow the guidelines in “Specify Relative Paths to Your Custom Code” (Stateflow).

If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

- 3 Click **OK**.

After completing these steps for each library model, generate code.

### **Integrate External Code for All Charts**

To integrate external code that applies to all charts for code generation:

- 1 Specify custom code options for code generation of your main model.
  - a In the Model Configuration Parameters dialog box, select **Code Generation > Custom Code**.
  - b In the custom code text fields, specify your custom code.

Follow the guidelines in “Specify Relative Paths to Your Custom Code” (Stateflow).

If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

- 2 Configure code generation for each library model that contributes a chart to your main model. In the Stateflow Editor, open the Model Configuration dialog box. Clear parameter **Use local custom code settings (do not inherit from main model)**. The library charts inherit the custom code settings of your main model. Click **OK**.
- 3 Generate code.

### **Call External C Code from Model and Generated Code**

Call existing, external functions from a simulation or from the generated code by using the Legacy Code Tool.

Learn how to:

- Evaluate a C function as part of a Simulink® model simulation.
- Call a C function from the code that you generate from a model.

For information about the example model, see “Generate C Code from a Control Algorithm for an Embedded System” on page 48-20.

### Replacement Process

Open the example model, `rtwdemo_PCG_Eval_P4`.

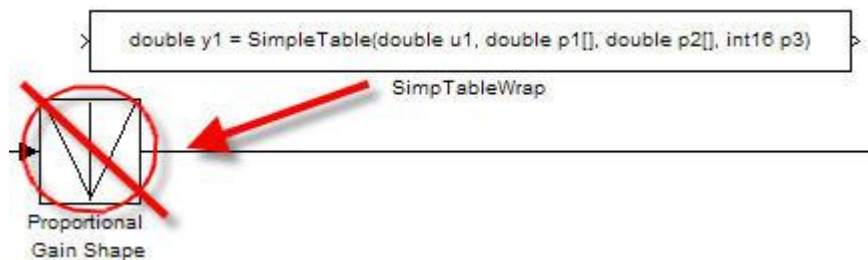

For many Model-Based Design applications, in addition to Simulink® models, a design includes a set of existing C functions that have been tested and validated. You can integrate these functions into a Simulink® model and generate code that uses the functions.

In this example, you create a custom Simulink® block that calls an existing C function. You then include the block in a model and test the overall system through model simulation in Simulink®.

In the example model, you can replace the Lookup blocks (lookup tables) in the PI controllers with calls to an existing C function. The function is defined in files `SimpleTable.c` and `SimpleTable.h`.

View `SimpleTable.c`.

View `SimpleTable.h`.

### Create Block That Calls C Function

To specify a call to an existing C function, use an S-Function block. You can automate the creation of the S-Function block by using the Legacy Code Tool. In the tool, you first specify an interface for your existing C function. The tool then uses that interface to create an S-Function block.

Use the Legacy Code Tool to create an S-Function block for the existing C function in `SimpleTable.c`.

1. Create a structure to contain the definition of the function interface.

```
def = legacy_code('initialize')
```

You can use the structure `def` to define the function interface to the existing C code.

2. Populate the fields of the structure.

```
% Defines the function interface, inputs, return values and parameters
def.OutputFcnSpec = ['double y1 = SimpleTable(double u1,',...
                    'double p1[], double p2[], int16 p3)'];

% the C and H files where the external code is defined
def.HeaderFiles    = {'SimpleTable.h'};
def.SourceFiles    = {'SimpleTable.c'};
% The name of the created S-Function
def.SFunctionName = 'SimpTableWrap';
```

3. Create the S-function.

```
legacy_code('sfcn_cmex_generate',def)
```

4. Compile the S-function.

```
legacy_code('compile',def)
```

5. Create the S-Function block.

```
legacy_code('slblock_generate',def)
```

The generated S-Function block calls the C function in `SimpleTable.c`. You can now use this S-Function block in models.

6. Create the TLC file.

```
legacy_code('sfcn_tlc_generate',def)
```

This command creates a TLC file, which is the component of an S-Function that specifies how to generate code for the block.

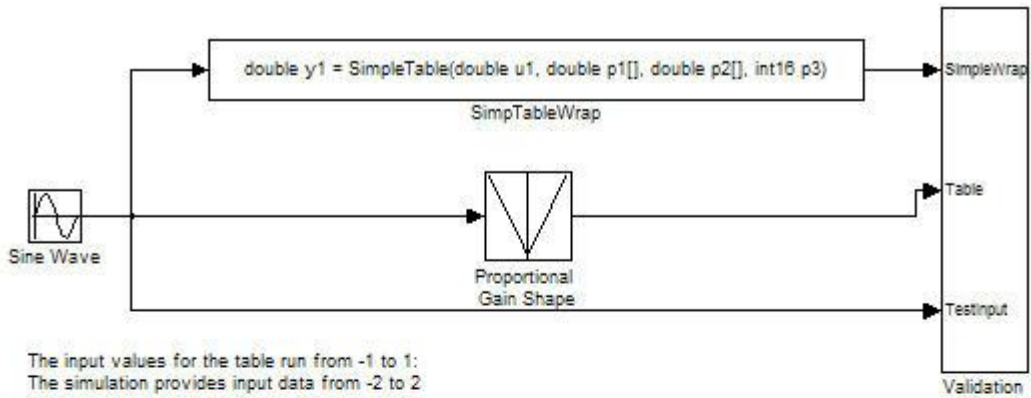

### **Validate External Code Through Simulation**

When you integrate existing C code in a Simulink® model, validate the generated S-Function block.

To validate the replacement of the Lookup blocks, compare the simulation results produced by the Lookup blocks with the results produced by the new S-Function block.

1. Open the validation model.
  - The Sine Wave block produces output values from [-2 : 2].
  - The input range of the lookup table is from [-1 : 1].
  - The lookup table outputs the absolute value of the input.
  - The lookup table clips the output at the input limits.
2. Run the validation model.

The figure shows the validation results. The existing C code and the Simulink® table block produce the same output values.

### Validate C Code as Part of Simulink® Model

After validating the existing C function code as a standalone component, validate the S-function in the model. To complete the validation, use a test harness model.

1. Open the test harness.
2. Run the test harness.

The simulation results match the golden values.

### Call C Function from the Generated Code

The code generator uses the TLC file to process the S-Function block like any other block. The code generator can implement *expression folding* with the S-Function block, an operation that combines multiple computations into a single output calculation.

1. Build the full model.
2. Examine the generated code in `PI_Control_Reusable.c`.

The generated code now calls the `SimpleTable` C function.

The figures show the generated code before and after the C code integration. Before the integration, the code calls a generated lookup routine. After the integration, the generated code calls the C function `SimpleTable`.

```
Discrete_Time_Integrator1 = rtp_Masked_I_Gain * look1_binlx(rtb_Sum2,
  (&(I_InErrMap[0])), (&(I_OutMap[0])), 8U) * rtb_Sum2 * 0.001 +
  localDW->Discrete_Time_Integrator1_DSTAT;

/* DiscreteIntegrator: '<S3>/Discrete_Time_Integrator1' incorporates:
 * Gain: '<S3>/Int Gain1'
 * Product: '<S3>/Product3'
 * S-Function (SimpTableWrap): '<S3>/SimpTableWrap1'
 */
Discrete_Time_Integrator1 = I_Gain * SimpleTable(rtb_Sum2, (real_T*)
  (&(I_InErrMap[0])), (real_T*)&(I_OutMap[0])), 7) * rtb_Sum2 * 0.001 +
  localDW->Discrete_Time_Integrator1_DSTAT;
```

## Place External C/C++ Code in Generated Code

### In this section...

“Workflow” on page 53-40

“Choose an Integration Approach” on page 53-41

“Integrate External Code by Using Custom Code Blocks” on page 53-43

“Integrate External Code by Using Model Configuration Parameters” on page 53-46

“Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 53-48

You can customize code that the code generator produces for a model by specifying external code with custom code blocks or model configuration parameters.

- Place code at the start and end of the generated code for the root model.
- Place declaration, body, and exit code in generated function code for blocks in the root model or nonvirtual subsystems.

The functions that you can augment with external code depends on the functions that the code generator produces for blocks that are in the model. For example, if a model or atomic subsystem includes blocks that have states, you can specify code for a disable function. Likewise, if you need the code for a block to save data, free memory, or reset target hardware, specify code for a terminate function. For more information, see “Block Target File Methods” (Simulink Coder).

### Workflow

To place external C or C++ code at specific locations in code that the code generator produces for root models and subsystems, iterate through the tasks listed in this table.

Task	Action	More Information
1	If you want to integrate external C code with generated C++ code or conversely, modify the language of the external code to match the language choice for the generated code.	“Modify Programming Language of External Code to Match Generated Code” (Simulink Coder)

Task	Action	More Information
2	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 53-4
3	If necessary, rewrite code in C or C++.	
4	Choose an integration approach to add the external code to a Simulink model.	“Choose an Integration Approach” on page 53-41
5	Define the representation of model data for code generation.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 53-95
6	Configure the model for code generation.	“Generate Code That Matches Appearance of External Code” on page 53-110 and “Model Configuration”
7	Generate code and a code generation report.	“Code Generation”
8	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 49-18 and “Static Code Metrics” on page 49-32
9	Build an executable program from the model.	“Build Integrated Code Within the Simulink Environment” on page 53-54
10	Verify that executable program performs as expected.	“Numerical Equivalence Testing” and “Code Execution Profiling”

## Choose an Integration Approach

Within the Simulink modeling environment, two approaches are available for placing external C or C++ code into sections of code that the code generator produces:

- Add blocks from the Custom Code library to a root model or atomic subsystem.
- Set model configuration parameters on the **Code Generation > Custom Code** pane.

The following table compares the two approaches. Choose the approach that aligns best with your integration requirements. For more information about how to apply each

approach, see “Integrate External Code by Using Custom Code Blocks” on page 53-43 and “Integrate External Code by Using Model Configuration Parameters” on page 53-46.

<b>Requirement</b>	<b>Blocks</b>	<b>Model Configuration Parameters</b>
Include a representation of your external code in the modeling canvas	✓	
Place code in functions generated for root models	✓	✓
Place code in functions generated for atomic subsystems	✓	
Save code placement in a model configuration set		✓
Place code at the top and bottom of the header and source files generated for a model	✓	✓
Place code within declaration, execution, and exit sections of the <code>SystemInitialize</code> and <code>SystemTerminate</code> functions that the code generator creates	✓	✓
Place code within declaration, execution, and exit sections of the <code>SystemStart</code> , <code>SystemEnable</code> , <code>SystemDisable</code> , <code>SystemOutputs</code> , <code>SystemUpdate</code> , or <code>SystemDerivatives</code> functions that the code generator creates	✓	
Add preprocessor macro definitions to generated code		✓
Use the custom code settings that are specified for the simulation target		✓
Configure a library model to use custom code settings of the parent model to which the library is linked		✓

## Integrate External Code by Using Custom Code Blocks

- “Custom Code Block Library” on page 53-43
- “Add Custom Code Blocks to the Modeling Canvas” on page 53-44
- “Add External Code to Generated Start Function” on page 53-44

### Custom Code Block Library

The Custom Code block library contains blocks that you can use to place external C or C++ code into specific locations and functions within code that the code generator produces. The library consists of 10 blocks that add your code to the model header (*model.h*) and source (*model.c* or *model.cpp*) files that the code generator produces.

The Model Header and Model Source blocks add external code at the top and bottom of header and source files that the code generator produces for a root model. These blocks display two text fields into which you can type or paste code. One field specifies code that you want to place at the top of the generated header or source file. The second field specifies code that you want to place at the bottom of the file.

The remaining blocks add external code to functions that the code generator produces for the root model or atomic subsystem that contains the block. The blocks display text fields into which you can type or paste code that customizes functions that the code generator produces. The text fields correspond to the declaration, execution, and exit sections of code for a given function.

To Customize Code That	Use This Block
Computes continuous states	System Derivatives
Disables state	System Disable
Enables state	System Enable
Resets state	System Initialize
Produces output	System Outputs
Executes once	System Start
Saves data, free memory, reset target hardware	System Terminate
Requires updates at each major time step	System Update

The block and its location within a model determines where the code generator places the external code. For example, if the System Outputs block is at the root model level, the

code generator places the code in the model `Outputs` function. If the block resides in a triggered or enabled subsystem, the code generator places the code in the subsystem `Outputs` function.

If the code generator does not need to generate a function that corresponds to a Custom Code block that you include in a model, the code generator does one of the following:

- Omits the external code that you specify in the Custom Code block.
- Returns an error, indicating that the model does not include a relevant block. In this case, remove the Custom Code block from the model.

For more information, see “Block Target File Methods” (Simulink Coder).

---

**Note** To avoid a potential mismatch between simulation and code generation results, do not use custom code blocks to read from and write to global Simulink data (signals, states, and block parameters). Instead, use the proper modeling pattern (for example, Data Store Read, Data Store Write, State Reader, and State Writer blocks.)

---

### **Add Custom Code Blocks to the Modeling Canvas**

To add the Custom Code library blocks to a model:

- 1** In the Simulink Library Browser, open the Custom Code block library.
- 2** Drag the blocks that you want into your model or subsystem. Drag Model Header and Model Source blocks into root models only. Drag function-based Custom Code blocks into root models or atomic subsystems.

You can use models that contain Custom Code blocks as referenced models. The code generator ignores the blocks when producing code for a simulation target. When producing code for a code generation target, the code generator includes and compiles the custom code.

### **Add External Code to Generated Start Function**

This example shows how to use the System Start block to place external C code in the code that the code generator produces for a model that includes a discrete filter.

- 1** Create the following model.

- 2 Configure the model for code generation.
- 3 Double-click the System Start block.
- 4 In the block parameters dialog box, in the **System Start Function Declaration Code** field, enter this code:
 

```
unsigned int *ptr = 0xFFEE;
```
- 5 In the **System Start Function Execution Code** field, enter this code:
 

```
/* Initialize hardware */
*ptr = 0;
```
- 6 Click **OK**.
- 7 Generate code and a code generation report.
- 8 View the generated *model.c* file. Search for the string `start` function. You should find the following code, which includes the external code that you entered in steps 4 and 5.

```
{
  {
    /* user code (Start function Header) */
    /* System '<Root>' */
    unsigned int *ptr = 0xFFEE;

    /* user code (Start function Body) */
    /* System '<Root>' */
    /* Initialize hardware */
    *ptr = 0;
  }
}
```

For another example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 53-48.

## Integrate External Code by Using Model Configuration Parameters

Model configuration parameters provide a way to place external C or C++ code into specific locations and functions within code that the code generator produces.

To	Select
Insert external code near the top of the generated <i>model.c</i> or <i>model.cpp</i> file	<p><b>Source file</b>, and enter the external code to insert.</p> <p>If you generate subsystem code into separate files, that code does not have access to external code that you specify with the <b>Source file</b> parameter. For example, if you specify an include file as a <b>Source file</b> setting, the code generator inserts the <code>#include</code> near the top of the <i>model.c</i> or <i>model.cpp</i> file. The subsystem code that the code generator places in a separate file does not have access to declarations inside your included file. In this case, consider specifying your external code with the <b>Header file</b> parameter.</p>
Insert external code near the top of the generated <i>model.h</i> file	<b>Header file</b> , and enter the external code to insert.
Insert external code inside the model initialize function in the <i>model.c</i> or <i>model.cpp</i> file	<b>Initialize function</b> , and enter the external code to insert.
Insert external code inside the model terminate function in the <i>model.c</i> or <i>model.cpp</i> file	<b>Terminate function</b> , and enter the external code to insert. Also select the <b>Terminate function required</b> parameter on the <b>Interface</b> pane.
Add preprocessor macro definitions	<b>Defines</b> , and enter a space-separated list of preprocessor macro definitions to add to the generated code. The list can include simple definitions (for example, <code>-DEF1</code> ) and definitions with a value (for example, <code>-DDEF2=1</code> ). Definitions can omit the <code>-D</code> (for example, <code>-DF00=1</code> and <code>F00=1</code> are equivalent). If a definition includes <code>-D</code> , the toolchain can override the flag if the toolchain uses a different flag for defines.

To	Select
Use the same custom code parameter settings as the settings specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	<p><b>Use the same custom code settings as Simulation Target</b></p> <p>This parameter refers to the <b>Simulation Target</b> pane in the Configuration Parameters dialog box.</p>
Enable a library model to use custom code settings unique from the parent model to which the library is linked	<p><b>Use local custom code settings (do not inherit from main model)</b></p> <p>This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.</p>

To include a header file in an external header file, add `#ifndef` code. Using this code avoids multiple inclusions. For example, in `rtwtypes.h`, the following `#include` guards are added:

```
#ifndef RTW_HEADER_rtwtypes_h_
#define RTW_HEADER_rtwtypes_h_
...
#endif /* RTW_HEADER_rtwtypes_h_ */
```

For more information on how to add files names and locations of header, source, and shared library files to the build process, see “Build Integrated Code Within the Simulink Environment” on page 53-54.

---

**Note** The code generator includes external code that you include in a configuration set when generating code for software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations. However, the code generator ignores external code that you include in a configuration set when producing code with the S-function, rapid simulation, or simulation system target file.

---

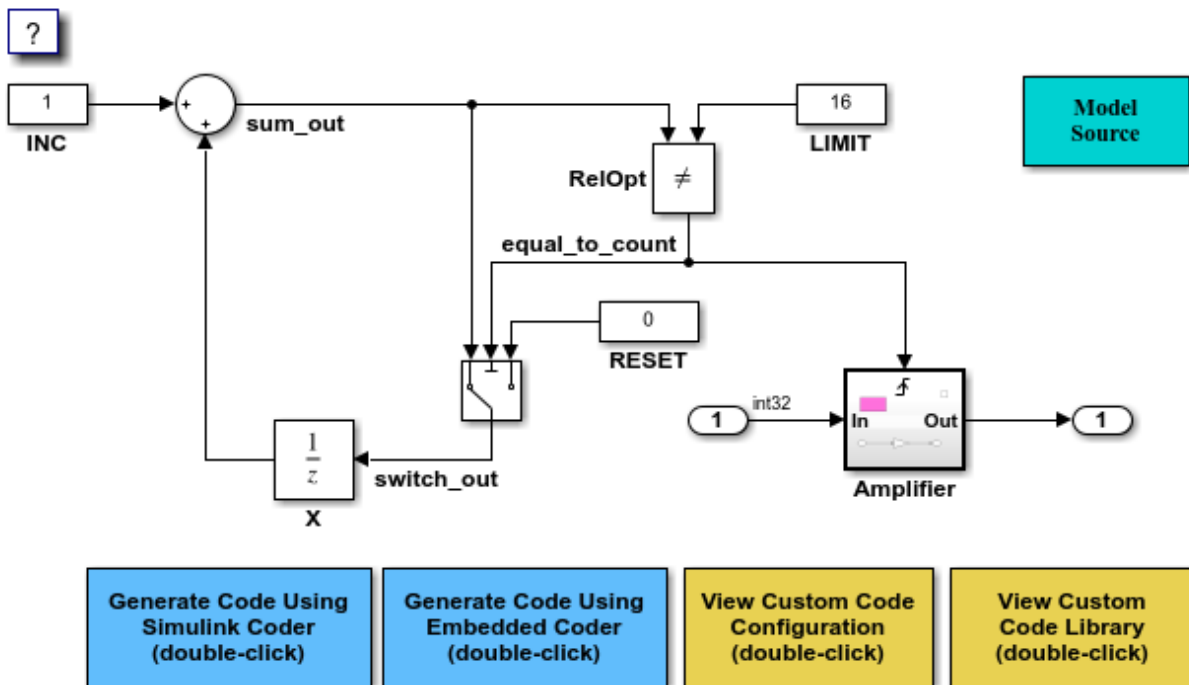

For more information about **Custom Code** parameters, see “Model Configuration Parameters: Code Generation Custom Code” (Simulink Coder). For an example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 53-48.

## Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```

Copyright 1994-2019 The MathWorks, Inc.

2. Open the **Simulink Coder** or **Embedded Coder** app.

3. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

4. Examine the settings for model configuration parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable GLOBAL\_INT2 to -1.
- **Initialize function** initializes the variable GLOBAL\_INT2 to 1.

5. Close the dialog box.

6. Double-click the Model Source block. Block parameter **Top of Model Source** specifies that the code generator declare the variable GLOBAL\_INT1 and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

7. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:

- Declares the pointer variable `*intPtr` and initializes it with the value of variable GLOBAL\_INT1.
- Sets the pointer variable to -1 during execution.
- Resets the pointer variable to 0 before exiting.

8. Generate code and a code generation report.

9. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;
```

```
int_T GLOBAL_INT1 = 0;
```

The Output function for the **Amplifier** subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the **Amplifier** subsystem.

```
int_T *intPtr = &GLOBAL_INT1;
```

```
*intPtr = -1;
```

```
rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;  
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

```
GLOBAL_INT2 = 1;
```

## Call External Device Drivers

Device drivers for protocols and target hardware are essential to many real-time development projects. For example, you can have a working device driver that you want to integrate with algorithmic code that has to read data from and write data to the I/O device that the driver supports. The code generator can produce a single set of application source files from an algorithm model and integrated driver code written in C or C++.

To call external device driver code from the Simulink environment, iterate through the tasks in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	"Choose an External Code Integration Workflow" on page 53-4

## Apply Function and Operator Code Replacements

If your generated code must use functions and operators that are consistent with external code, configure the code generator to use a code replacement library (CRL). By default, the code generator does not apply a code replacement library. You can choose from several libraries that MathWorks provides, including GNU C99 extensions, AUTOSAR 4.0, and several Intel® platform-specific IPP and IPP/SSE libraries. Depending on the products that you have, other libraries might be available. If you have Embedded Coder software, you can view and choose from additional libraries and you can create custom code replacement libraries.

## Build Integrated Code Within the Simulink Environment

### Workflow

To build executable programs that integrate generated code and external C or C++ code, iterate through the tasks in this table.

Task	Action	More Information
1	Choose whether to use the toolchain approach or template makefile approach build process.	<p>“Choose Build Approach and Configure Build Process” on page 54-14</p> <p>For an example, see “Build Process Workflow for Real-Time Systems” on page 54-32.</p>
2	Configure build process support for your external code.	“Configure Parameters for Integrated Code Build Process” on page 53-55
3	Configure S-Function build support for your external code.	<p>“Build Support for S-Functions” on page 53-57</p> <p>“Use makecfg to Customize Generated Makefiles for S-Functions” on page 84-20</p> <p>For examples, see “Call External C Code from Model and Generated Code” on page 48-60 and “Call Reusable External Algorithm Code for Simulation and Code Generation” on page 53-21.</p>
4	Configure build process to find the external code source, library, and header files.	<p>“Manage Build Process File Dependencies” on page 47-52</p> <p>“Control Library Location and Naming During Build” on page 84-4</p>

Task	Action	More Information
5	Set up custom build processing required for your external code integration.	<p>For the build process customization workflow, see “Customize Post-Code-Generation Build Processing” on page 84-10.</p> <p>To automate applying build customizations to a toolchain approach build, see “Customize Build Process with sl_customization.m” on page 84-51.</p> <p>To automate applying build customizations to a template makefile approach build, see “Customize Build Process with STF_make_rtw_hook File” on page 84-46.</p>

## Configure Parameters for Integrated Code Build Process

The table provides a guide to model configuration parameters on **Code Generation > Custom Code** pane of the Model Configuration Parameters dialog box that support the build process for external code integration. For information about folders for your external code, see “Manage Build Process Folders” on page 47-36. If you choose to place your external code in the “Code generation folder” (Simulink), see “Preserve External Code Files in Build Folder” on page 53-56.

To	Select
Add include folders, which contain header files, to the build process	<p><b>Additional build information &gt; Include directories</b>, and enter the absolute or relative paths to the folders.</p> <p>If you specify relative paths, the paths must be relative to the folder containing your model files, not relative to the build folder. The order in which you specify the folders is the order in which they are searched for header, source, and library files.</p>

To	Select
Add source files to be compiled and linked	<p><b>Additional build information &gt; Source files</b>, and enter the full paths or just the file names for the files.</p> <p>Enter just the file name if the file is in the current MATLAB folder or in one of the include folders. For each additional source that you specify, the build process expands a generic rule in the template makefile for the folder in which the source file is located. For example, if a source file is located in folder <code>inc</code>, the build process adds a rule similar to the following:</p> <pre>%.obj: builddir\inc\%.c     \$(CC) -c -Fo\$(@F) \$(CFLAGS) \$&lt;</pre> <p>The build process adds the rules in the order that you list the source files.</p>
Add libraries to be linked	<p><b>Additional build information &gt; Libraries</b>, and enter the full paths or just the file names for the libraries.</p> <p>Enter just the file name if the library is located in the current MATLAB folder or in one of the include folders.</p>
Use the same custom code settings as those specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	<p><b>Use the same custom code settings as Simulation Target</b></p> <p>This parameter refers to the <b>Simulation Target</b> pane in the Configuration Parameters dialog box.</p>
Enable a library model to use custom code settings unique from the parent model to which the library is linked	<p><b>Use local custom code settings (do not inherit from main model)</b></p> <p>This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.</p>

## Preserve External Code Files in Build Folder

By default, the build process deletes foreign source files. You can preserve foreign source files by following these guidelines.

If you put a `.c/.cpp` or `.h` source file in a build folder, and you want to prevent the code generator from deleting it during the TLC code generation process, insert the text `target specific file` in the first line of the `.c/.cpp` or `.h` file. For example:

```
/* COMPANY-NAME target specific file
 *
 * This file is created for use with the
 * COMPANY-NAME target.
 * It is used for ...
 */
...
```

Make sure that you spell the text “target specific file” as shown in the preceding example, and that the text is in the first line of the source file. Other text can appear before or after this text.

Flagging user files in this manner prevents postprocessing these files to indent them with generated source files. Auto-indenting occurred in previous releases to build folder files with names having the pattern `model_*.c/.cpp` (where `*` was text). The indenting is harmless, but can cause differences detected by source control software that can potentially trigger unnecessary updates.

## Build Support for S-Functions

User-written S-Function blocks provide a powerful way to incorporate external code into the Simulink development environment. In most cases, you use S-functions to integrate existing external code with generated code. Several approaches to writing S-functions are available:

- “Write Noninlined S-Function” on page 12-114
- “Write Wrapper S-Function and TLC Files” on page 12-117
- “Write Fully Inlined S-Functions” on page 12-126
- “Write Fully Inlined S-Functions with mdlRTW Routine” on page 12-128
- “S-Functions That Support Code Reuse” on page 12-106
- “S-Functions for Multirate Multitasking Environments” on page 12-107

S-functions also provide the most flexible and capable way of including build information for legacy and custom code files in the build process.

There are different ways of adding S-functions to the build process.

## Implicit Build Support

When building models with S-functions, the build process adds rules, include paths, and source file names to the generated makefile. The source files (.h, .c, and .cpp) for the S-function must be in the same folder as the S-function MEX-file. Whether using the toolchain approach or template makefile approach for builds, the build process propagates this information through the toolchain or template makefile.

- If the file *sfcname.h* exists in the same folder as the S-function MEX-file (for example, *sfcname.mexext*), the folder is added to the include path.
- If the file *sfcname.c* or *sfcname.cpp* exists in the same folder as the S-function MEX-file, the build process adds a makefile rule for compiling files from that folder.
- When an S-function is not inlined with a TLC file, the build process must compile the S-function source file. To determine the name of the source file to add to the list of files to compile, the build process searches for *sfcname.cpp* on the MATLAB path. If the source file is found, the build process adds the source file name to the makefile. If *sfcname.cpp* is not found on the path, the build process adds the file name *sfcname.c* to the makefile, whether or not it is on the MATLAB path.

---

**Note** For the Simulink engine to find the MEX-file for simulation and code generation, it must exist on the MATLAB path or exist in our current MATLAB working folder.

---

## Specify Additional Source Files for an S-Function

If your S-function has additional source file dependencies, you must add the names of the additional modules to the build process. Specify the file names:

- In the **S-function modules** field in the S-Function block parameter dialog box
- With the `SFunctionModules` parameter in a call to the `set_param` function

For example, suppose you build your S-function with multiple modules.

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then add the modules to the build process by doing one of the following:

- In the S-function block dialog box, specify `sfun_main`, `sfun_module1`, and `sfun_module2` in the **S-function modules** field.
- At the MATLAB command prompt, enter:

```
set_param(sfun_block, 'SFunctionModules', 'sfun_module1 sfun_module2')
```

Alternatively, you can define a variable to represent the parameter value.

```
modules = 'sfun_module1 sfun_module2'  
set_param(sfun_block, 'SFunctionModules', modules)
```

The **S-function modules** field and `SFunctionModules` parameter do not support complete source file path specifications. To use the parameter, the code generator must find the additional source files when executing the makefile. For the code generator to locate the additional files, place them in the same folder as the S-function MEX-file. You can then leverage the implicit build support described in “Implicit Build Support” on page 53-58.

When you are ready to generate code, force the code generator to rebuild the top model, as described in “Control Regeneration of Top Model Code” (Simulink Coder).

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 84-22.

### Use TLC Library Functions

If you inline your S-function by writing a TLC file, you can add source file names to the build process by using the TLC library function `LibAddToModelSources`. For details, see “`LibAddSourceFileCustomSection(file, builtInSection, newSection)`” (Simulink Coder).

---

**Note** This function does not support complete source file path specifications. The function assumes that the code generator can find the additional source files when executing the makefile.

---

Another useful TLC library function is `LibAddToCommonIncludes`. Use this function in a `#include` statement to include S-function header files in the generated `model.h` header file. For details, see “`LibAddToCommonIncludes(incFileName)`” (Simulink Coder).

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 84-22.

### Precompile S-Function Libraries

You can precompile new or updated S-function libraries (MEX-files) for a model by using the MATLAB language function `rtw_precompile_libs`. Using a specified model and a

library build specification, this function builds and places the libraries in a precompiled library folder.

By precompiling S-function libraries, you can optimize system builds. Once your precompiled libraries exist, the build process can omit library compilation from subsequent builds. For models that use numerous libraries, the time savings for build processing can be significant.

To use `rtw_precompile_libs`:

- 1 Set the library file suffix, including the file type extension, based on your system platform.

Consider determining the type of platform, and then use the `TargetLibSuffix` parameter to set the library suffix accordingly. For example, when applying a suffix for a GRT target, you can set the suffix to `_std.a` for a UNIX platform and `_vcx64.lib` for a Windows platform.

```

if isunix
    suffix = '_std.a';
else
    suffix = '_vcx64.lib';
end

set_param(my_model, 'TargetLibSuffix', suffix);

```

There are a number of factors that influence the precompiled library suffix and extension. The following table provides examples for typical selections of system target file, the compiler toolchain, and other options that affect your choice of suffix and extension. For more information, examine the template make files in the `matlab/rtw/c/grt` folder or `matlab/rtw/c/ert` folder.

TMF File	COMPILER _TOOL_CHAIN Value	Precompiler Libraries (PRECOMP_LIBRARIES)			
		Library Suffix S-Function (EXPAND _LIBRARY _NAME Value)	Library Suffix Integer- Only Code (EXPAND _LIBRARY _NAME Value)	Library Suffix Optimize for Speed (EXPAND _LIBRARY _NAME Value)	Library Extension (EXPAND _LIBRARY _NAME Value)
ert_lcc64.tmf	lcc	_rtwsfcn_lcc	_int_ert_lcc	_ert_lcc	.lib
ert_vcx64.tmf	vcx64	_rtwsfcn_vcx64	_int_ert_vcx64	_ert_vcx64	.lib

TMF File	COMPILER _TOOL_CHAIN Value	Precompiler Libraries (PRECOMP_LIBRARIES)			
		Library Suffix S-Function (EXPAND _LIBRARY _NAME Value)	Library Suffix Integer- Only Code (EXPAND _LIBRARY _NAME Value)	Library Suffix Optimize for Speed (EXPAND _LIBRARY _NAME Value)	Library Extension (EXPAND _LIBRARY _NAME Value)
ert_unix.tmf	unix	_rtwscfn	_int_ert	_ert	.a
grt_lcc64.tmf	lcc	n/a	n/a	_lcc	.lib
grt_vcx64.tmf	vcx64	n/a	n/a	_vcx64	.lib
grt_unix.tmf	unix	n/a	n/a	_std	.a

## 2 Set the precompiled library folder.

Use one of the following methods to set the precompiled library folder:

- Set the `TargetPreCompLibLocation` parameter, as described in “Specify the Location of Precompiled Libraries” on page 84-5.
- Set the `makeInfo.precompile` field in an `rtwmakecfg.m` function file. (For more information, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 84-22.)

If you set `TargetPreCompLibLocation` and `makeInfo.precompile`, the setting for `TargetPreCompLibLocation` takes precedence.

The following command sets the precompiled library folder for model `my_model` to folder `lib` under the current working folder.

```
set_param(my_model, 'TargetPreCompLibLocation', fullfile(pwd, 'lib'));
```

---

**Note** If you set both the target folder for the precompiled library files and a target library file suffix, the build process detects whether any precompiled library files are missing while processing builds.

---

## 3 Define a build specification.

Set up a structure that defines a build specification. The following table describes fields that you can define in the structure. These fields are optional, except for `rtwmakecfgDirs`.

Field	Description
<code>rtwmakecfgDirs</code>	<p>A cell array of character vectors that name the folders containing <code>rtwmakecfg</code> files for libraries to be precompiled. The function uses the <code>Name</code> and <code>Location</code> elements of <code>makeInfo.library</code>, as returned by <code>rtwmakecfg</code>, to specify the name and location of the precompiled libraries. If you set the <code>TargetPreCompLibLocation</code> parameter to specify the library folder, that setting overrides the <code>makeInfo.library.Location</code> setting.</p> <p><b>Note:</b> The specified model must contain blocks that use precompiled libraries specified by the <code>rtwmakecfg</code> files because the TMF-to-makefile conversion generates the library rules only if the build process uses the libraries.</p>
<code>libSuffix</code>	<p>A character vector that specifies the suffix, including the file type extension, to be appended to the name of each library (for example, <code>.a</code> or <code>_vc.lib</code>). The character vector must include a period (<code>.</code>). You must set the suffix with either this field or the <code>TargetLibSuffix</code> parameter. If you specify a suffix with both mechanisms, the <code>TargetLibSuffix</code> setting overrides the setting of this field.</p>
<code>intOnlyBuild</code>	<p>A Boolean flag. When set to true, the flag indicates the libraries are to be optimized such that they are compiled from integer code only. This field applies to ERT targets only.</p>
<code>makeOpts</code>	<p>A character vector that specifies an option to be included in the <code>rtwMake</code> command line.</p>
<code>addLibs</code>	<p>A cell array of structures that specify libraries to be built that are not specified by an <code>rtwmakecfg</code> function. Each structure must be defined with two fields that are character arrays:</p> <ul style="list-style-type: none"> <li><code>libName</code> — the name of the library without a suffix</li> <li><code>libLoc</code> — the location for the precompiled library</li> </ul> <p>The target makefile (TMF) can specify other libraries and how those libraries are built. Use this field to precompile those libraries.</p>

The following commands set up build specification `build_spec`, which indicates that the files to be compiled are in folder `src` under the current working folder.

```
build_spec = [];
build_spec.rtwmakecfgDirs = {fullfile(pwd,'src')};
```

#### 4 Issue a call to `rtw_precompile_libs`.

The call must specify the model for which you want to build the precompiled libraries and the build specification. For example:

```
rtw_precompile_libs(my_model,build_spec);
```

“Generate C Function Code for Export-Function Model” on page 53-70

“Generate C++ Function and Class Code for Export-Function Model” on page 53-76

“Generate Code for Export-Function Subsystems” on page 53-81

If you have Embedded Coder software, you can generate function source code from modeling components to use in an external code base. The generated code does not include supporting scheduling code (for example, a step function). Controlling logic outside of the Simulink environment invokes the generated function code.

### Modeling Options

You can generate function code to export for these modeling components:

- Export-function models (model containing functional blocks that consist exclusively of function-call subsystems, function-call model blocks, or other export-function models, as described in “Export-Function Models Overview” (Simulink))
- Export-function subsystems (virtual subsystem that contains function-call subsystems)

To export code that the code generator produces for these modeling components, the modeling components must meet specific requirements on page 53-65.

For models designed in earlier releases, the code generator can export functions from triggered subsystems. The requirements stated for export-function subsystems also apply to exporting functions from triggered subsystems, with the following exceptions:

- Encapsulate triggered subsystems from which you intend to export functions in a top-level virtual subsystem.

- Triggered subsystems do not have to meet requirements and limitations identified for virtual subsystems that contain function-call subsystem.
- “Export Functions That Use Absolute or Elapsed Time” on page 53-66 does not apply to exporting functions from triggered subsystems.

## Requirements

- Model solver must be a fixed-step discrete solver.
- You must configure each root-level Inport block that triggers a function-call subsystem to output a function-call trigger. These Inport blocks cannot connect to an Asynchronous Task Specification block.
- Model or subsystem, must contain only the following blocks at the root level:
  - Function-call blocks (such as Function-Call Subsystem, Simulink Function, S-Functions, and Function-Call Model blocks at the root level if the solver model configuration parameter **Tasking and sample time options > Periodic sample time constraint** is set to Ensure sample time independent)
  - Inport and Outport blocks (ports)
  - Constant blocks (including blocks that resolve to constants, such as Add)
  - Blocks with a sample time of Inf
  - Merge and data store memory blocks
  - Virtual connection blocks (such as, Function-Call Split, Mux, Demux, Bus Creator, Bus Selector, Signal Specification, and virtual subsystems that contain these blocks)
  - Signal-viewer blocks, such as Scope blocks (export-function subsystems only)
- When a constant block appears at the top level of the model or subsystem, you must set the model configuration parameter **Optimization > Default parameter behavior** for the model or containing model to Inlined.
- Blocks inside the model or subsystem must support code generation.
- Blocks that use absolute or elapsed time must be inside a periodic function-call subsystem with a discrete sample time specified on the corresponding function-call root-level Inport block. See “Export Functions That Use Absolute or Elapsed Time” on page 53-66.
- Data signals that cross the boundary of an exported system cannot be a virtual bus and cannot be implemented as a Goto-From connection. Data signals that cross the export boundary must be scalar, muxed, or a nonvirtual bus.

In addition, for export-function models, you cannot generate code for a rate-based model that includes multiple instances of an export-function model. For example, you cannot generate code for a test harness model that you use for scheduling reusable export-function models during simulation.

For export-function subsystems, the following additional requirements apply:

- A trigger signal that crosses the boundary of an export-function subsystem must be scalar. Input and output data signals that do not act as triggers do not have to be scalar.
- When a constant signal drives an output port of an export-function subsystem, the signal must specify a storage class.

### Export Functions That Use Absolute or Elapsed Time

If you want to export function code for a modeling component with blocks that use absolute or elapsed time, those blocks must be inside a function-call subsystem that:

- You configure for periodic execution
- You configure the root-level Inport block with a discrete sample time

To configure a function-call subsystem for periodic execution:

- 1 In the function-call subsystem, right-click the Trigger block and choose **Block Parameters** from the context menu.
- 2 Set parameter **Sample time type** to **periodic**.
- 3 Set **Sample time** to the same granularity specified (directly or by inheritance) in the function-call initiator.
- 4 Click **OK** or **Apply**.

For more information, see “Absolute and Elapsed Time Computation” (Simulink Coder).

### Limitations for Export-Function Subsystems

- Subsystem block parameters do not control the names of the files containing the generated code. The file names begin with the name of the exported subsystem.
- Subsystem block parameters do not control the names of top-level functions in the generated code. Each function name reflects the name of the signal that triggers the function or (for an unnamed signal) reflects the block from which the signal originates.

- You can export function-call systems for the C++ class code interface packaging only when its function specification is set to **Default step method**. See “Customize Generated C++ Class Interfaces” on page 40-27. The exported function is compatible with single-threaded execution. To avoid potential data race conditions for shared signals, invoke all members for the class from the same execution thread.
- The code generator supports a SIL or PIL block in accelerator mode only if its function-call initiator is noninlined in accelerator mode. Examples of noninlined initiators include Stateflow charts.
- A Level-2 S-function initiator block, such as a Stateflow chart or the built-in Function-Call Generator block, must drive a SIL block.
- You can export an asynchronous (sample-time) function-call system, but the software does not support the SIL or PIL block for an asynchronous system.
- The use of the TLC function `LibIsFirstInit` has been removed for export-function subsystems.

## Workflow

To generate code for an exported function, iterate through the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 53-4
2	Verify that the model or subsystem that you are exporting satisfies function exporting requirements.	“Requirements” on page 53-65
3	Address data interface requirements by modifying the model or subsystem.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 53-95
4	If necessary, configure function prototype.	“Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 40-18 and, for fixed-step rate-based models, “Customize Generated C Function Interfaces” on page 40-2 or “Customize Generated C++ Class Interfaces” on page 40-27

<b>Task</b>	<b>Action</b>	<b>More Information</b>
5	If necessary , update the model to place external application-specific code in generated system functions.	“Place External C/C++ Code in Generated Code” on page 53-40
6	Verify that the functions behave and perform as expected during simulation by creating and using a test harness model. The test harness model schedules execution of the functions during simulation.	“Configure Model, Generate Code, and Simulate” on page 47-2 and, if you have Simulink Test software, “Test Authoring” (Simulink Test)
7	Configure the model or subsystem for code generation.	“Generate Code Using Embedded Coder®” on page 48-2, “Generate Code That Matches Appearance of External Code” on page 53-110, and “Model Configuration”
8	Generate code and a code generation report.	“Code Generation”
9	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 49-18 and “Static Code Metrics” on page 49-32
10	Build an executable program that includes the exported function code.	“Build Integrated Code Outside the Simulink Environment” on page 48-66
11	Verify that executable program behaves and performs as expected.	

## Choose an Integration Approach

Multiple approaches are available for generating function code for export to an external development environment. The following table compares approaches. Choose the approach that aligns best with your integration requirements. For more information on how to create export-function models, see “Export-Function Models Overview” (Simulink). For more information on generating code for function call subsystems, see “Generate Component Source Code for Export to External Code Base” on page 53-64.

## Generate C Function Code for Export-Function Model

This example shows how to generate function code for individual Simulink function blocks and function-call subsystems in a model without generating scheduling code.

To generate function code for export:

- 1 Create a model that contains the functions for export.
- 2 Create a test harness model that schedules execution of the functions during simulation.
- 3 Simulate the model that contains the functions by using the test harness model.
- 4 Generate code for the model that contains the functions.

## Create Model That Contains Functions for Export

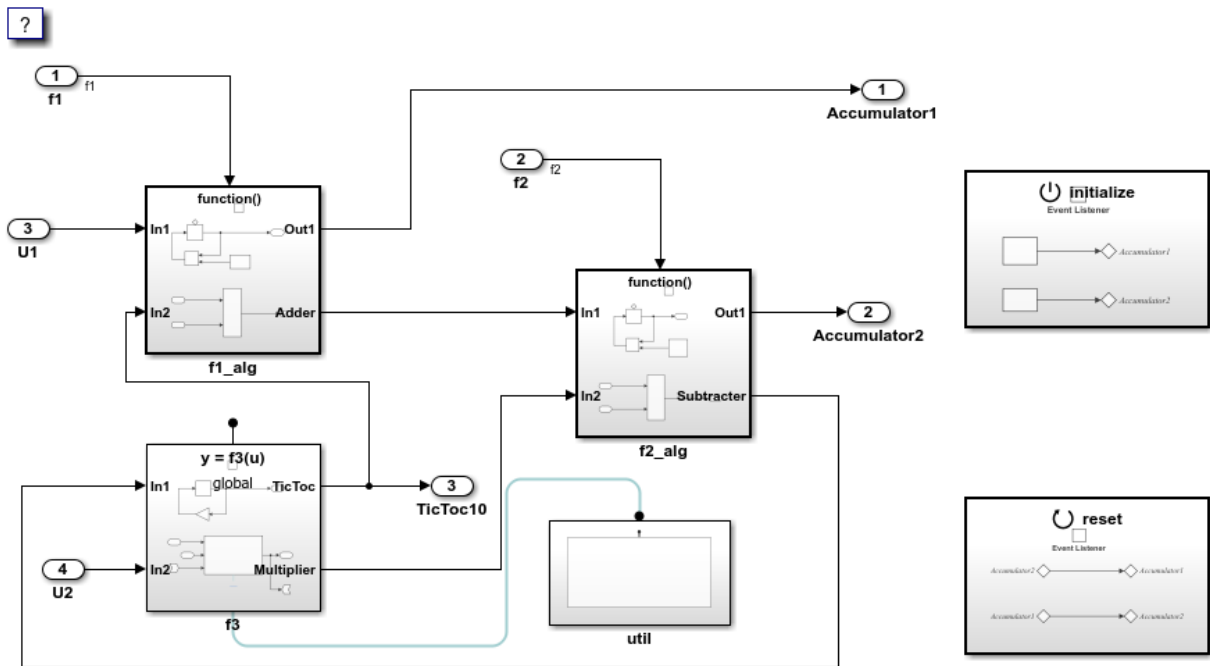

The model with functions for export must satisfy architectural constraints at the model root level. At the root level, valid blocks are:

- Inport
- Outport
- Function-Call Subsystem
- Simulink Function
- Goto
- From
- Merge

The code generator produces function code for Function-Call Subsystem and Simulink Function blocks and Initialize and Reset Function blocks. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives. A Simulink Function block is executed in response to the execution of a corresponding Function Caller block or Stateflow chart. An Initialize Function block is executed on a model initialize event and a Reset Function block is executed on a user-defined reset event.

For exporting functions, model `rtwdemo_functions` contains two function-call subsystems (`f1_alg` and `f2_alg`) and a Simulink Function block (`f3`) for exporting functions. The model also contains an Initialize Function block (`Initialize Function`) and a Reset Function block (`Reset Function`). To calculate initial conditions for blocks with state in other parts of the model, the State Writer blocks are used inside the Initialize and Reset Function blocks.

```
open_system('rtwdemo_functions')
```

Copyright 2014-2018 The MathWorks, Inc.

## Create Model That Contains Function Caller Block

Use a Function Caller block to invoke a Simulink Function block. The Function Caller block can be in the same model or in a different model as the Simulink Function block.

Multiple Function Caller blocks can invoke a Simulink Function block. You can place the Function Caller block inside a function-call subsystem. During code generation, the code generator exports a function from the function-call subsystem.

The model `rtwdemo_caller` exports a function-call subsystem that contains a Function Caller block.

```
open_system('rtwdemo_caller')
```

Copyright 2014-2018 The MathWorks, Inc.

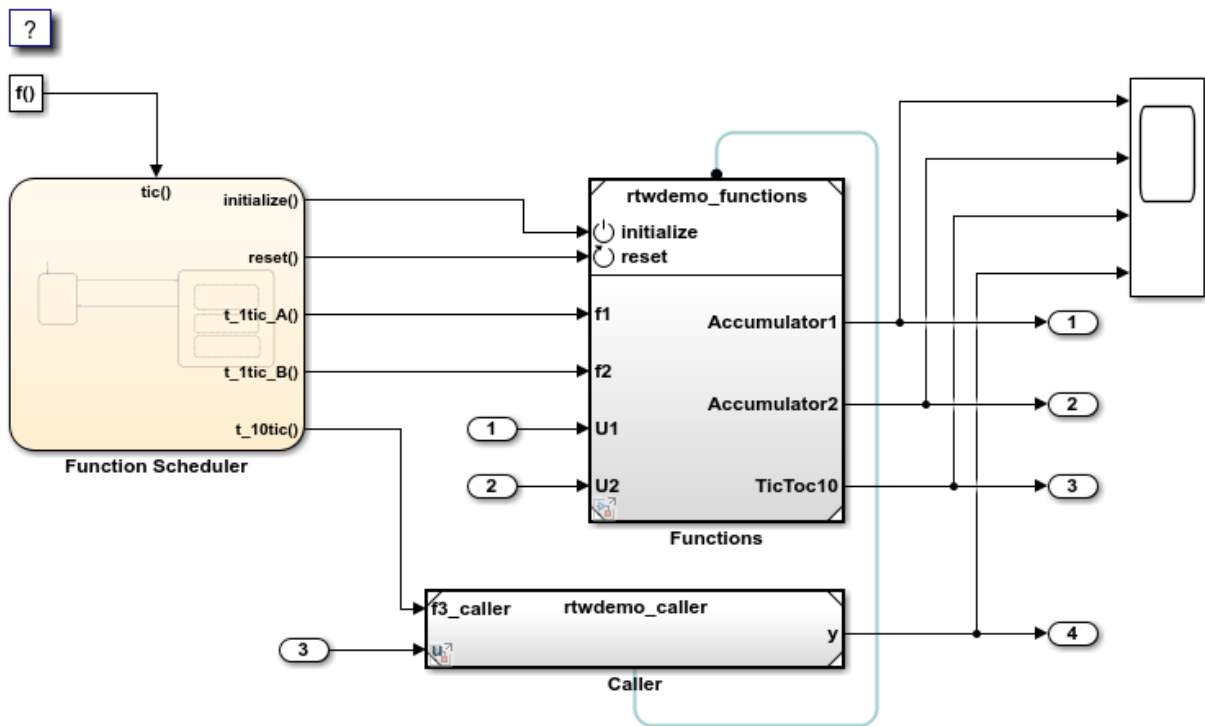

### Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_export_functions` is a test harness. The model:

- Schedules the Simulink Function block with the Function Caller block in `rtwdemo_caller`.
- Provides function-call signals to other models in this example to schedule the model contents, including the model initialize and reset events.

```
open_system('rtwdemo_export_functions')
```

Copyright 2014-2019 The MathWorks, Inc.

### Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_export_functions`.

```
sim('rtwdemo_export_functions')
```

### Generate Function Code and Report

Open the **Embedded Coder** app. Then, generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_functions`.

```
rtwbuild('rtwdemo_functions')
```

```
### Starting build procedure for model: rtwdemo_functions  
### Successful completion of code generation for model: rtwdemo_functions
```

## Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_functions.c` calls the initialization function, including `Initialize Function`, and exported functions for model components `f1_alg`, `f2_alg`, and `f3`.
- `rtwdemo_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `f3.h` is a shared file that declares the call interface for the Simulink function `f3`.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

## Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

- 1 Include the generated header files by adding directives `#include rtwdemo_functions.h`, `#include f3.h`, and `#include rtwtypes.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.U1` of type `real_T` with dimension 1
- `rtU.U2` of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_functions_initialize(void)`. At startup, call this function once.
- Reset entry-point function, `void rtwdemo_functions_reset(void)`. Call this function as needed.

- Exported function, void f1(void). Call this function as needed.
- Exported function, void f2(void). Call this function as needed.
- Simulink function, void f3(real\_T rtu\_u, real\_T \*rty\_y). Call this function as needed.

Output ports:

- rtY.Accumulator1 of type int8\_T with dimension [2]
- rtY.Accumulator2 of type int8\_T with dimension [2]
- rtY.TicToc10 of type int8\_T with dimension 1

- “Generate Code for a Simulink Function and Function Caller” (Simulink Coder)

### Close Example Models

```
bdclose('rtwdemo_export_functions')  
bdclose('rtwdemo_functions')  
bdclose('rtwdemo_caller')
```

## Generate C++ Function and Class Code for Export-Function Model

This example shows how to generate function code for an export-function model that includes a function-call subsystem. The code generator produces function and class code that does not include scheduling code.

To generate function code for export:

- 1 Create a model that contains the functions for export.
- 2 Create a test harness model that schedules execution of the functions during simulation.

- 3 Simulate the model that contains the functions by using the test harness model.
- 4 Generate code for the model that contains the functions.

### **Create Model That Contains Functions and C++ Class Interface for Export**

The model with functions for export with a C++ model class interface must satisfy architectural constraints at the model root level. For C++ class generation, blocks that are valid at the root level are:

- Inport
- Outport
- Function-Call Subsystem
- Goto
- From
- Merge

**Note:** Export Function-Call Subsystem with C++ class interface does not support Simulink Function blocks.

The code generator produces function code for the Function-Call Subsystem block. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives.

Model `rtwdemo_cppclass_functions` contains function-call subsystems `f1`, `f2`, and `f3` for exporting functions.

```
open_system('rtwdemo_cppclass_functions')
```

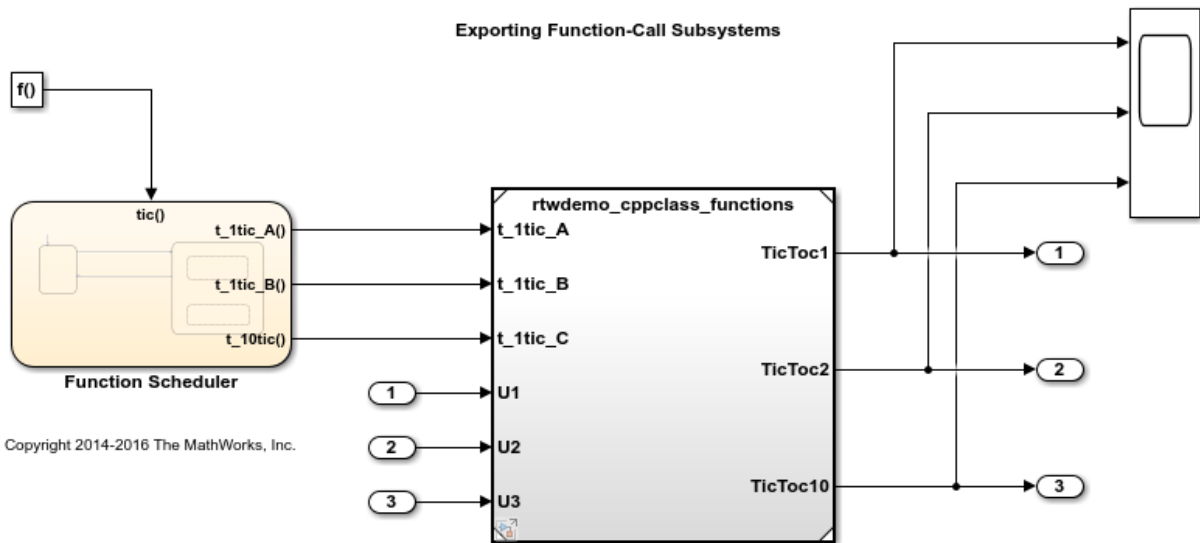

Copyright 2016 The MathWorks, Inc.

### Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_cppclass_export_functions` is a test harness. The model provides function-call signals to other models in this example to schedule the model contents.

```
open_system('rtwdemo_cppclass_export_functions')
```

### Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_cppclass_export_functions`.

```
sim('rtwdemo_cppclass_export_functions')
```

### Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_cppclass_functions`.

```
rtwbuild('rtwdemo_cppclass_functions')
```

```
### Starting build procedure for model: rtwdemo_cppclass_functions
### Successful completion of build procedure for model: rtwdemo_cppclass_functions
```

### Review Generated Code

From the code generation report, review the generated code.

- `ert_main.cpp` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_cppclass_functions.cpp` calls the initialization function, including `Initialize Function`, and exported functions for model subsystem components `f1`, `f2`, and `f3`.
- `rtwdemo_cppclass_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

### Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

- 1 Include the generated header files by adding directives `#include rtwdemo_cppclass_functions.h` and `#include rtwtypes.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.U1` of type `real_T` with dimension 1
- `rtU.U2` of type `real_T` with dimension 1
- `rtU.U3` of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void initialize(void)`. At startup, call this function once.
- Exported function, `void t_ltic_A(void)`. Call this function as needed.
- Exported function, `void t_ltic_B(void)`. Call this function as needed.
- Exported function, `void t_ltic_C(void)`. Call this function as needed.

Output ports:

- `rtY.TicToc1` of type `int8_T` with dimension [2]
- `rtY.TicToc2` of type `int8_T` with dimension [2]
- `rtY.TicToc10` of type `int8_T` with dimension 1

### Close Example Models

```
bdclose('rtwdemo_cppclass_export_functions')  
bdclose('rtwdemo_cppclass_functions')
```

## Generate Code for Export-Function Subsystems

- “Specify a Custom Initialize Function Name” on page 53-82
- “Specify a Custom Description” on page 53-82
- “Optimize Code Generated for Export-Function Subsystems” on page 53-83

To generate code for an export-function subsystem:

- 1 Verify that the subsystem for which you are generating code satisfies exporting requirements on page 53-65.
- 2 In the Configuration Parameters dialog box:
  - a Set the parameter **System target file** to an ERT-based system target file, such as `ert.tlc`.
  - b If you want a SIL block with the generated code, for verification purposes, set model configuration parameter **Create block** to SIL.
  - c Click **OK** or **Apply**.
- 3 Right-click the subsystem block and select **C/C++ Code > Export Functions** from the context menu.

The operation creates a new model, *subsystem.slx*, that contains the content of the original subsystem and creates a `ScratchModel` that contains a Model block. This block references the newly created *subsystem.slx* model.

The **Build code for subsystem: *Subsystem*** dialog box opens. This dialog box is not specific to export-function subsystems. Generating code does not require entering information in the dialog box.

- 4 Click **Build** to build the newly created *subsystem.slx* model.

The code generator produces code and places it in the working folder.

If you set **Create block** to SIL in step 2b, Simulink opens a new window that contains an S-function block that represents the generated code. This block has the same size, shape, and connectors as the original subsystem.

Code generation and optional block creation are now complete. You can test and use the code and optional block as you do for generated ERT code and S-function block. For optional workflow tasks, see “Specify a Custom Initialize Function Name” on page 53-82 and “Specify a Custom Description” on page 53-82.

### Specify a Custom Initialize Function Name

You can specify a custom name for the initialize function of your exported function as an argument to the `rtwbuild` command. The command takes the following form:

```
blockHandle = rtwbuild('subsystem', 'Mode', 'ExportFunctionCalls',...  
                    'ExportFunctionInitializeFunctionName', 'fcname')
```

*fcname* specifies the function name. For example, if you specify the name 'myinitfcn', the build process emits code similar to:

```
/* Model initialize function */  
void myinitfcn(void){  
    ...  
}
```

### Specify a Custom Description

You can enter a custom description for an exported function by using the Block Properties dialog box of an Inport block.

- 1 Right-click the Inport block that drives the control port of the subsystem for which you are exporting code.

- 2 Select **Properties**.
- 3 In the **General** tab, in the **Description** field, enter your descriptive text.

During function export, the text you enter is emitted to the generated code in the header for the Inport block. For example, if you open the example program `rtwdemo_exporting_functions` and enter a description in the Block Properties dialog box for port `t_ltic_A`, the code generator produces code that is similar to:

```
/*  
 * Output and update for exported function: t_ltic_A  
 *  
 * My custom description of the exported function  
 */  
void t_ltic_A(void)  
{  
    ...  
}
```

### Optimize Code Generated for Export-Function Subsystems

To optimize the code generated for an export-function subsystem, specify a separate storage class for each input signal and output signal that crosses the boundary of the subsystem.

For each function-call subsystem that you are exporting:

- 1 Right-click the subsystem.
- 2 From the context menu, choose **Block Parameters (Subsystem)**.
- 3 Select the **Code Generation** tab.
- 4 Set **Function packaging** to Auto.
- 5 Click **OK** or **Apply**.

# Generate Shared Library for Export to External Code Base

## In this section...

“About Generated Shared Libraries” on page 53-85

“Workflow” on page 53-85

“Generate Shared Libraries” on page 53-86

“Create Application Code That Uses Generated Shared Libraries” on page 53-87

“Limitations” on page 53-90

## About Generated Shared Libraries

If you have Embedded Coder software, you can generate a shared library—Windows dynamic link library (.dll), UNIX shared object (.so), or Macintosh OS X dynamic library (.dylib)— from a model component. You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. Uses of shared libraries include:

- Adding a software component to an application for system simulation
- Reusing software modules among applications on a development computer
- Hiding intellectual property associated with software that you share with vendors

When producing a shared library, the code generator exports:

- Variables and signals of type `ExportedGlobal` as data
- Real-time model structure (*model\_M*) as data
- Functions essential to executing the model code

## Workflow

To generate a shared library from a model component and use the library, complete the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	<ul style="list-style-type: none"> <li>• “Choose an External Code Integration Workflow” on page 53-4</li> <li>• “Shared Library Limitations” on page 61-7</li> </ul>
2	Configure the model for code generation.	“Generate Code That Matches Appearance of External Code” on page 53-110 and “Model Configuration”
3	Configure the model for the code generator to produce a shared library and initiate code generation.	“Generate Shared Libraries” on page 53-86
4	<p>Verify that the generated shared library meets requirements. For example, review the code generation report and view the list of symbols in the library.</p> <ul style="list-style-type: none"> <li>• On Windows, use the Dependency Walker utility, downloadable from <a href="http://www.dependencywalker.com">www.dependencywalker.com</a></li> <li>• On UNIX, use <code>nm -D model.so</code></li> <li>• On Macintosh OS X, use <code>nm -g model.dylib</code></li> </ul>	
5	Use the shared library in application code.	“Create Application Code That Uses Generated Shared Libraries” on page 53-87
6	Compile and link application code that loads and uses the generated shared library.	“Build Integrated Code Within the Simulink Environment” on page 53-54
7	Verify that executable program behaves and performs as expected.	

## Generate Shared Libraries

- 1 When configuring the model for code generation, select the system target file `ert_shrlib.tlc`.

- 2 Build the model. The code generator produces source code for the model and a shared library version of the code. The code generator places the source code in the code generation folder and the shared library (.dll, .so, or .dylib file) in your current working folder. The code generator also produces and retains a .lib file to support implicit linking.

## Create Application Code That Uses Generated Shared Libraries

This example application code is generated for the example “Interface to a Development Computer Simulator By Using a Shared Library” on page 53-92.

- 1 Create an application header file that contains type declarations for model external input and output. For example:

```
#ifndef _APP_MAIN_HEADER_
#define _APP_MAIN_HEADER_

typedef struct {
    int32_T Input;
} ExternalInputs_rtwdemo_shrlib;

typedef struct {
    int32_T Output;
} ExternalOutputs_rtwdemo_shrlib;

#endif /*_APP_MAIN_HEADER_*/
```

- 2 In the application C source code, dynamically load the shared library. Use preprocessing conditional statements to invoke platform-specific commands. For example:

```
#if (defined(_WIN32)||defined(_WIN64)) /* WINDOWS */
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#else /* UNIX */
#include <dlfcn.h>
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose
```

```

#endif

int main()
{
    void* handleLib;
    ...
    #if defined(_WIN64)
        handleLib = LOADLIB("./rtwdemo_shrplib_win64.dll");
    #else #if defined(_WIN32)
        handleLib = LOADLIB("./rtwdemo_shrplib_win32.dll");
    #else /* UNIX */
        handleLib = LOADLIB("./rtwdemo_shrplib.so", RTLD_LAZY);
    #endif
    #endif
    ...
    return(CLOSELIB(handleLib));
}

```

- 3 From the application C source code, access exported data and functions generated from the model. The code uses hooks to add user-defined initialization, step, and termination code.

```

    int32_T i;
    ...
    void (*mdl_initialize)(boolean_T);
    void (*mdl_step)(void);
    void (*mdl_terminate)(void);

    ExternalInputs_rtwdemo_shrplib (*mdl_Uptr);
    ExternalOutputs_rtwdemo_shrplib (*mdl_Yptr);

    uint8_T (*sum_outptr);
    ...
    #if (defined(LCCDLL)||defined(BORLANDCDLL))
        /* Exported symbols contain leading underscores
           when DLL is linked with LCC or BORLANDC */
        mdl_initialize =
            (void*)(boolean_T)GETSYMBOLADDR(handleLib ,
            "_rtwdemo_shrplib_initialize");
        mdl_step =
            (void*)(void)GETSYMBOLADDR(handleLib ,
            "_rtwdemo_shrplib_step");
        mdl_terminate =
            (void*)(void)GETSYMBOLADDR(handleLib ,

```

```

        "_rtwdemo_shrplib_terminate");
mdl_Uptr =
    (ExternalInputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
    "_rtwdemo_shrplib_U");
mdl_Yptr =
    (ExternalOutputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
    "_rtwdemo_shrplib_Y");
sum_outptr =
    (uint8_T*)GETSYMBOLADDR(handleLib , "_sum_out");
#else
mdl_initialize =
    (void*)(boolean_T)GETSYMBOLADDR(handleLib ,
    "rtwdemo_shrplib_initialize");
mdl_step =
    (void*)(void)GETSYMBOLADDR(handleLib ,
    "rtwdemo_shrplib_step");
mdl_terminate =
    (void*)(void)GETSYMBOLADDR(handleLib ,
    "rtwdemo_shrplib_terminate");
mdl_Uptr =
    (ExternalInputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
    "rtwdemo_shrplib_U");
mdl_Yptr =
    (ExternalOutputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
    "rtwdemo_shrplib_Y");
sum_outptr =
    (uint8_T*)GETSYMBOLADDR(handleLib , "sum_out");
#endif

if ((mdl_initialize &&
    mdl_step &&
    mdl_terminate &&
    mdl_Uptr &&
    mdl_Yptr &&
    sum_outptr)) {
    /* user application
    initialization function */
    mdl_initialize(1);
    /* insert other user defined
    application initialization code here */

    /* user application
    step function */
    for(i=0;i<=12;i++){

```

```

        mdl_Uptr->Input = i;
        mdl_step();
        printf("Counter out(sum_out):
               %d\tAmplifier in(Input):
               %d\tout(Output):
               %d\n", *sum_outptr, i,
               mdl_Yptr->Output);
        /* insert other user defined
           application step function
           code here */
    }

    /* user application
       terminate function */
    mdl_terminate();
    /* insert other user defined
       application termination
       code here */
}
else {
    printf("Cannot locate the specified
           reference(s) in the shared library.\n");
    return(-1);
}
}

```

## Limitations

- Code generation for the `ert_shrlib.tlc` system target file exports the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (*model\_M*)
- Code generation for the `ert_shrlib.tlc` system target file supports the C language only (not C++). When you select `ert_shrlib.tlc`, language selection is unavailable on the **Code Generation** pane in the Configuration Parameters dialog box.
- To reconstruct a model simulation by using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing must be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables model configuration parameters **Support: continuous time** and **Single output/update function**. For more information, see Single output/update function (Simulink Coder) dependencies.

## Interface to a Development Computer Simulator By Using a Shared Library

This example generates a shared library for interfacing to a simulator that runs on your development computer. Generate the shared library by using the system target file `ert_shrLib.tlc`.

To build a shared library from the model and use the library in an application:

1. Develop your model. For this example, open the model `rtwdemo_shrLib`. Save a copy of the model to a writable location.

```
open_system('rtwdemo_shrLib');
```

**View Code  
Generation  
Configuration  
(double-click)**

matlabroot\toolbox\rtw\rtwdemos\shrlib\_demo\rtwdemo\_shrlib\_app.h

matlabroot\toolbox\rtw\rtwdemos\shrlib\_demo\rtwdemo\_shrlib\_app.c

matlabroot\toolbox\rtw\rtwdemos\shrlib\_demo\run\_rtwdemo\_shrlib\_app.m

Run script run\_rtwdemo\_shrlib\_app.m (double-click)

Copyright 2006-2019 The MathWorks, Inc.

The model is a single-rate, discrete-time model. An 8-bit counter feeds the triggered subsystem named `Amplifier`. Parameters `INC`, `LIMIT`, and `RESET` are set to constant values 1, 4, and 0, respectively. When signal `equal_to_count` is true, the subsystem amplifies its input signal by a gain factor  $K=3$  and the output signal is updated.

2. Open the **Embedded Coder** app.
3. Set model configuration parameter **System target file** to `ert_shrlib.tlc`.

4. Build the shared library file. The file that the code generator produces depends on your development platform. For example, on a Windows system, the code generator produces the library file `rtwdemo_shrlib_win64.dll`.

5. Create application code that uses the shared library. This example uses application code that is available in these files:

```
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.h  
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.c
```

To view the source code in these files, in the model, click the white buttons for the `.h` and `.c` files.

6. Compile and link the file application and shared library files to produce an executable program. The following script compiles, builds, and runs the program.

```
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\run_rtwdemo_shrlib_app.m
```

To view the script code, in the model, click the white button for the `.m` file.

To build the model and run the application that uses the generated shared library, in the model, double-click the blue button.

For more information about using a shared library, see “Package Generated Code as Shared Libraries” on page 61-2.

### More About

- “Generate Shared Library for Export to External Code Base” on page 53-85

## Exchange Data Between External C/C++ Code and Simulink Model or Generated Code

Whether you import your external code into a Simulink model (for example, by using the Legacy Code Tool) or export the generated code to an external environment, the model or the generated code typically exchange data (signals, states, and parameters) with your code.

Functions in C or C++ code, including your external functions, can exchange data with a caller or a called function through:

- Arguments (formal parameters) of functions. When a function exchanges data through arguments, an application can call the function multiple times. Each instance of the called function can manipulate its own independent set of data so that the instances do not interfere with each other.
- Direct access to global variables. Global variables can:
  - Enable different algorithms (functions) and instances of the same algorithm to share data such as calibration parameters and error status.
  - Enable the different rates (functions) of a multitasking system to exchange data.
  - Enable different algorithms to exchange data asynchronously.

In Simulink, you can organize and configure data so that a model uses these exchange mechanisms to provide, extract, and share data with your code.

Before you attempt to match data interfaces, to choose an overall integration approach, see “Choose an External Code Integration Workflow” on page 53-4.

### Import External Code into Model

To exchange data between your model and your external function, choose an exchange mechanism based on the technique that you chose to integrate the function.

- To exchange data through the arguments of your external function, construct and configure your model to create and package the data according to the data types of the arguments. Then, you connect and configure the block that calls or represents your function to accept, produce, or refer to the data from the model.

For example, if you use the Legacy Code Tool to generate an S-Function block that calls your function, the ports and parameters of the block correspond to the

arguments of the function. You connect the output signals of upstream blocks to the input ports and set parameter values in the block mask. Then, you can create signal lines from the output ports of the block and connect those signals to downstream blocks.

- To exchange data through global variables that your external code already defines, a best practice is to use a Stateflow chart to call your function and to access the variables. You write algorithmic C code in the chart so that during simulation or execution of the generated code, the model reads and writes to the variables.

To use such a global variable as an item of parameter data (not signal or state data) elsewhere in a model, you can create a numeric MATLAB variable or `Simulink.Parameter` object that represents the variable. If you change the value of the C-code variable in between simulation runs, you must manually synchronize the value of the Simulink variable or object. If your algorithmic code (function) changes the value of the C-code variable during simulation, the corresponding Simulink variable or object does not change.

If you choose to create a Simulink representation of the C-code variable, you can configure the Simulink representation so that the generated code reads and writes to the variable but does not duplicate the variable definition. Apply a storage class to the Simulink representation.

<b>Technique for Integrating External Function</b>	<b>Mechanism to Exchange Data with Model</b>	<b>Examples and More Information</b>
S-Function block	Function arguments	To call your function through an S-function that you create by using the Legacy Code Tool, see “Integrate C Functions into Simulink Models with Legacy Code Tool” (Simulink).
Stateflow chart	Function arguments and direct access to global variables	To call your function and access global variables in a Stateflow chart, see “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow). For information about creating data items in a chart (which you can pass to your function as arguments), see “Add Stateflow Data” (Stateflow).

<b>Technique for Integrating External Function</b>	<b>Mechanism to Exchange Data with Model</b>	<b>Examples and More Information</b>
coder.ceval in MATLAB Function block	Function arguments	To call your function in a MATLAB Function block by using <code>coder.ceval</code> , see “Integrate C Code Using the MATLAB Function Block” (Simulink). For information about creating data items in a MATLAB Function block (which you can pass to your function as arguments), see “Ports and Data Manager” (Simulink).

## Export Generated Code to External Environment

To export the generated code into your external code, see “Exchange Data Between External Calling Code and Generated Code” (Simulink Coder).

## Simulink Representations of C Data Types and Constructs

To model and reuse your custom C data such as structures, enumerations, and typedef aliases, use the information in these tables.

### Modeling Patterns for Matching Data in External C Code

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Primitive type alias (typedef)	typedef float mySinglePrec_T;	<p>Create a <code>Simulink.AliasType</code> object. Use the object to:</p> <ul style="list-style-type: none"> <li>• Set the data types of signals and block parameters in a model.</li> <li>• Configure data type replacements for code generation.</li> </ul> <p>Generating code that uses an alias data type requires Embedded Coder.</p>	<p>For information about defining custom data types for your model, see <code>Simulink.AliasType</code> and “Control Data Type Names in Generated Code” on page 35-2.</p> <p>For an example that shows how to export the generated code into your external code, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-27.</p>

<b>C Data Type or Construct</b>	<b>Example C Code</b>	<b>Simulink Equivalent</b>	<b>More Information</b>
Array	<code>int myArray[6];</code>	<p>Specify signal and parameter dimensions as described in “Signal Dimensions” (Simulink).</p> <p>The generated code defines and accesses multidimensional data, including matrices, as column-major serialized vectors. If your external code uses a different format, consider using alternative techniques to integrate the generated code. See “Code Generation of Matrices and Arrays” on page 47-79.</p>	<p>For information about how the generated code stores nonscalar data (including limitations), see “Code Generation of Matrices and Arrays” (Simulink Coder).</p> <p>For an example that shows how to export the generated code into your external code, see “Reuse Parameter Data from External Code in the Generated Code” on page 37-2.</p> <p>To model lookup tables, see <code>Simulink.LookupTable</code>.</p>

<b>C Data Type or Construct</b>	<b>Example C Code</b>	<b>Simulink Equivalent</b>	<b>More Information</b>
Enumeration	<pre>typedef enum myColorsType {     Red = 0,     Yellow,     Blue } myColorsType;</pre>	Define a Simulink enumeration that corresponds to your enumeration definition. Use the Simulink enumeration to set data types in a model.	<p>To use enumerated data in a Simulink model, see “Use Enumerated Data in Simulink Models” (Simulink).</p> <p>For an example that shows how to generate enumerated parameter data, see “Enumeration” on page 24-25.</p> <p>For an example that shows how to export the generated code into your external code by exchanging enumerated data, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-34.</p>

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Structure	<pre>typedef struct myStructType {     int count;     double coeff; } myStructType;</pre>	<p>Create a <code>Simulink.Bus</code> object that corresponds to your structure type.</p> <p>To create structured signal or state data, package multiple signal lines in a model into a single nonvirtual bus signal.</p> <p>To create structured parameter data, create a parameter object (such as <code>Simulink.Parameter</code>) that stores a MATLAB structure. Use the bus object as the data type of the parameter object.</p> <p>To package lookup table data into a structure, use <code>Simulink.LookupTable</code> and, optionally, <code>Simulink.Breakpoint</code> objects.</p>	<p>For information about bus signals, see “Getting Started with Buses” (Simulink).</p> <p>For information about structures of parameters, see “Organize Related Block Parameter Definitions in Structures” (Simulink).</p> <p>For an example that shows how to import your external code into a model by using the Legacy Code Tool, see “Integrate C Function Whose Arguments Are Pointers to Structures” (Simulink).</p> <p>For examples that show how to export the generated code into your external code, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-34 and “Access Structured Data Through a Pointer That External</p>

<b>C Data Type or Construct</b>	<b>Example C Code</b>	<b>Simulink Equivalent</b>	<b>More Information</b>
			<p>Code Defines” on page 37-12.</p> <p>To package lookup table data into a structure, <code>Simulink.LookupTable</code>.</p> <p>For general information about creating structures in the generated code, see “Organize Data into Structures in Generated Code” (Simulink Coder).</p>

**Additional Modeling Patterns for Code Generation (Embedded Coder)**

<b>C Data Type or Construct</b>	<b>Example C Code</b>	<b>Simulink Equivalent</b>	<b>More Information</b>
Macro	<code>#define myParam 9.8</code>	<p>Apply the storage classes <code>Define</code> and <code>ImportedDefine</code> to parameters. With macros, you can reuse a parameter value in multiple locations in an algorithm and change the parameter value between code compilations without consuming memory to store the value. Typically, macros represent engineering constants that you do not expect to change during code execution.</p> <p>This technique requires Embedded Coder.</p>	“Macro Definitions ( <code>#define</code> )” on page 24-70
Storage type qualifiers such as <code>const</code> and <code>volatile</code>	<code>const myParam = 9.8;</code>	Apply the storage classes <code>Const</code> , <code>Volatile</code> , and <code>ConstVolatile</code> to data items.	“Protect Global Data with Keywords <code>const</code> and <code>volatile</code> ” (Simulink Coder)

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Bit field	<pre>typedef struct myBitFields {     unsigned short int MODE : 1;     unsigned short int FAIL : 1;     unsigned short int OK : 1; } myBitFields</pre>	<ul style="list-style-type: none"> <li>Apply the storage class <code>BitFields</code> to signals, states, and parameters whose data type is <code>boolean</code>.</li> <li>Use a model configuration parameter to aggregate <code>Boolean</code> data into bit fields.</li> </ul> <p>These techniques require <code>Embedded Coder</code>.</p>	<p>“Bitfields” on page 24-88</p> <p>“Optimize Generated Code By Packing Boolean Data Into Bitfields” on page 71-12</p>
Call to custom external function that reads or writes to data	<p>External code:</p> <pre>/* Call this function to acquire the value of the signal. */ double get_inSig(void) {     return myBigGlobalStruct.inSig; }</pre> <p>Generated algorithmic code:</p> <pre>algorithmInput = get_inSig();</pre>	<p>Apply the storage class <code>GetSet</code> to signals, states, and parameters. Each data item appears in the generated code as a call to your custom functions that read and write to the target data.</p> <p>This technique requires <code>Embedded Coder</code>.</p>	<p>“Access Data Through Functions with Storage Class <code>GetSet</code>” on page 37-42</p>

## Considerations for Other Modeling Goals

Goal	Considerations and More Information
Use Simulink to run and interact with the generated code	<p>You can use SIL, PIL, and external mode simulations to connect your model to the corresponding generated application for simulation. When you import parameter data from your external code:</p> <ul style="list-style-type: none"> <li>• At the time that you begin an external mode simulation, the external executable uses the value that your code uses to initialize the parameter data. However, when you change the corresponding value in Simulink during the simulation (for example by modifying the <code>Value</code> property of the corresponding parameter object), Simulink downloads the new value to the executable.</li> <li>• SIL and PIL simulations do not import the parameter value from your code. Instead, the simulations use the parameter value from Simulink. If you include your external code in the Simulink Coder build process, duplicate data definitions can prevent the generated code from compiling.</li> </ul> <p>For information about SIL and PIL, see “Choose a SIL or PIL Approach” on page 78-14. For information about external mode simulation, see “Host-Target Communication with External Mode Simulation” (Simulink Coder).</p>
Generate code comments that describe attributes of exported data including physical units, real-world initial value, and data type	Generating these comments can help you match data interfaces while handwriting integration code. See “Add Custom Comments for Variables in the Generated Code” on page 50-5.

- “Generate Code That Dereferences Data from a Literal Memory Address” on page 63-21

## Exchange Data Between External Calling Code and Generated Code

To export the generated code into your external code, you configure the generated code to match the data interface of your external code. For example, if your external code defines a global variable for storing output data and you need the generated code to read that data as input, you can configure a corresponding Inport block so that the generated code interacts with the existing variable.

- You can generate reentrant code from a model. The generated entry-point functions typically accept data through arguments. Your calling code passes data through these arguments. You can call the functions multiple times in a single application—the application can maintain multiple instances of the model. See “Data Exchange for Reentrant Generated Code” (Simulink Coder).
- When you generate nonreentrant code, by default, the entry-point functions exchange data between the generated code and your code through global variables. You can generate variable definitions for your code to use or you can share and reuse existing variables that your code already defines. See “Data Exchange for Nonreentrant Generated Code” (Simulink Coder).

Alternatively, you can configure the entry-point functions to exchange system inputs and outputs (root-level Inport and Outport blocks) through arguments instead of global variables. Apply function prototype control to the model, which requires Embedded Coder. For more information about function prototype control, see “Customize Generated C Function Interfaces” on page 40-2.

For general information about exchanging data between generated and external code, including how to match specific C code patterns, see “Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” (Simulink Coder).

### Data Exchange for Reentrant Generated Code

When you generate reentrant code, the model entry-point functions exchange data through arguments. You can control some of the characteristics of the arguments. For more information, see “Control Data and Function Interface in Generated Code” (Simulink Coder).

For information about creating a separate set of data for each call site in your external code, see “Modify Static Main to Allocate and Access Model Instance Data” on page 63-14.

## Data Exchange for Nonreentrant Generated Code

To make the generated code read or write to an item of signal, state, or parameter data as a global variable, apply a storage class to the data in the model. The storage class also determines whether the generated code exports the variable definition to your external code or imports the definition from your code. For general information about controlling the data interface of a model that you configure to generate nonreentrant code, see “Control Data Interface for Nonreentrant Code” (Simulink Coder). For examples, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder) and “Integrate External Application Code with Code Generated from PID Controller” on page 37-68.

When you generate code that defines (allocates memory for) global data, the generated code exports that data. When your external code defines data, the generated code imports that data. Typically, storage classes that import data have the word **Import** in the storage class name, for example, `ImportedExternPointer`.

### Control File Placement of Exported Global Data (Embedded Coder)

When you export data from the generated code by using storage classes, the code generator creates an `extern` declaration. By default, this declaration typically appears in the generated header file `model.h`. You can include (`#include`) this header file in your external code.

By default, the definition (memory allocation) of exported data typically appears in `model.c`.

You can control the file placement of the declarations and definitions to:

- Create separate object files that store only global parameter data.
- Modularize the generated code by organizing declarations into separate files.

For more information about controlling file placement of declarations and definitions, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2. For an example, see “Definition, Initialization, and Declaration of Parameter Data” on page 24-7.

### Prevent Duplicate Initialization Code for Global Variables

When your external code defines global variables, you can generate code that interacts with those variables. For example, use the storage class `ImportFromFile` (see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder)).

For imported variables that represent signal or state data, the code generator can produce initialization code as described in “Initialization of Signal, State, and Parameter Data in the Generated Code” (Simulink Coder). If your code already initializes a variable, consider preventing the generation of duplicate initialization code. Create your own storage class and, for that storage class, set **Data initialization** to None. For information about creating and applying your own storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2.

### **Protect Global Data with Keywords `const` and `volatile`**

When your external code and the generated code exchange data through global variables, you can generate code that uses C type qualifiers `const` and `volatile` to protect data integrity and improve the safety of your application. For example:

- Apply `const` to a calibration parameter.
- Apply `volatile` to a global variable that stores the output of a hardware device operating asynchronously.
- Apply `const` and `volatile` to signals, states, and parameters that represent data defined by your external code. Then, the generated code declares and interacts with the external data by using the corresponding storage type qualifiers.

You must have Embedded Coder. For more information, see “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 41-17.

## Generate Code That Matches Appearance of External Code

A key aspect of code integration, especially for larger projects, is adherence to guidelines and standards for code appearance. If code appearance requirements apply to your project, review the requirements in this table. To learn more, see the relevant information.

Requirement	More Information
Thoroughly document code or document code in a specific way.	<ul style="list-style-type: none"> <li>• “Configure Code Comments” on page 43-27</li> <li>• “Annotate Code for Justifying Polyspace Checks” on page 50-107</li> <li>• “Add Custom Comments for Variables in the Generated Code” on page 50-5</li> <li>• “Add Global Comments in the Generated Code” on page 50-8</li> </ul>

## Select C or C++ Programming Language

The default programming language selection for code generation is C language. In the code generation workflow, after the steps in “Select a Solver That Supports Code Generation” (Simulink Coder) and “Select a System Target File from STF Browser” (Simulink Coder), an optional step is to change the programming language selection for code generation.

To change the programming language setting:

- 1 In the Configuration Parameters dialog box, from the **Language** list, select C or C++. Alternatively, set the `TargetLang` parameter at the command line.

The code generator produces `.c` or `.cpp` files, depending on your selection, and places the generated files in your build folder.

For more information, see “Language” (Simulink Coder).

- 2 Check whether you must choose and configure a compiler. If you select C++, you must choose and configure a compiler. For details, see “Select and Configure C or C++ Compiler” (Simulink Coder).
- 3 Check whether the standard math library is configured for your compiler. By default, the code generator uses the ISO/IEC 9899:1999 C (C99 (ISO)) library for the C language and the ISO/IEC 14882:2003 C++ (C++03 (ISO)) library for the C++ language.

For more information, see “Standard math library” (Simulink Coder).

### More About

- “Select and Configure C or C++ Compiler” (Simulink Coder)
- “Troubleshoot Compiler Issues” (Simulink Coder)

## Select and Configure C or C++ Compiler

The build process requires a supported compiler. *Compiler*, in this context, refers to a development environment containing a linker and make utility, and a high-level language compiler. For details on supported compiler versions, see:

[https://www.mathworks.com/support/compilers/current\\_release](https://www.mathworks.com/support/compilers/current_release)

When creating an executable program, the build process must be able to access a supported compiler. The build process can find a compiler to use based on your default MEX compiler.

The build process also requires the selection of a toolchain or template makefile. The toolchain or template makefile determines which compiler runs, during the make phase of the build. For more information, see “Choose Build Approach and Configure Build Process” (Simulink Coder)

To determine which templates makefiles are available for your compiler and system target file, see “Compare System Target File Support Across Products” (Simulink Coder).

For both generated files and user-supplied files, the file extension, `.c` or `.cpp`, determines whether the build process uses a C or a C++ compiler. If the file extension is `.c`, the build process uses C compiler to compile the file, and the symbols use the C linkage convention. If the file extension is `.cpp`, the build process uses a C++ compiler to compile the file, and the symbols use the C++ linkage specification.

### Language Standards Compliance

The code generator produces code that is compliant with the following standards:

Language	Supported Standard
C	ISO/IEC 9899:1990, also known as C89/C90
C++	ISO/IEC 14882:2003

Code that the code generator produces from these sources is ANSI C/C++ compliant:

- Simulink built-in block algorithmic code
- Generated system-level code (task ID [TID] checks, management, functions, and so on)
- Code from other blocksets, including the Fixed-Point Designer product and the Communications Toolbox product

- Code from other code generators, such as MATLAB functions

Also, the code generator can incorporate code from:

- Embedded system target files (for example, startup code, device driver blocks)
- Custom S-functions or TLC files

---

**Note** Coding standards for these two sources are beyond the control of the code generator. These standards can be a source for compliance problems, such as code that uses C99 features not supported in the ANSI C, C89/C90 subset.

---

## Programming Language Considerations

The code generator produces C and C++ code. Consider the following as you choose a programming language:

- Does your project require you to configure the code generator to use a specific compiler? C/C++ code generation on Windows requires this selection.
- Does your project require you to change the default language configuration setting for the model? See “Select C or C++ Programming Language” on page 54-2.
- Does your project require you to integrate legacy or custom code with generated code? For a summary of integration options, see “What Is External Code Integration?” on page 53-3.
- Does your project require you to integrate C and C++ code? If so, see “What Is External Code Integration?” on page 53-3.

---

**Note** You can mix C and C++ code when integrating generated code with custom code. However, you must be aware of the differences between C and default C++ linkage conventions, and add the `extern "C"` linkage specifier where required. For the details of the differing linkage conventions and how to apply `extern "C"`, refer to a C++ programming language reference book.

---

- Does your project require code generation support from other products? See “C++ Language Support Limitations” on page 54-5.

For C++ code generation examples with Stateflow, see the `sfcdemo_cppcount` model or `sf_cpp` model.

## C++ Language Support Limitations

To use C++ language support, you could need to configure the code generator to use a specific compiler. For example, if a supported compiler is not installed on your Microsoft Windows computer, the default compiler is the `gcc` C compiler shipped with the MATLAB product. This compiler does not support C++. If you do not configure the code generator to use a C++ compiler before you specify C++ for code generation, the software produces an error message.

Code generator limitations on C++ support include:

- The code generator does not support C++ code generation for the following:
  - Simscape Driveline
  - Simscape Multibody First Generation (Simscape Multibody Second Generation is supported)
  - Simscape Electrical Power Systems
  - Simulink Real-Time
- For ERT and ERT-based system target files with **Code interface packaging** set to `Nonreusable` function, the following fields currently do not support the `.cpp` extension.
  - **Data definition filename**
  - **Definition file** for a data object, which is an object of the `Simulink.Signal` or `Simulink.Parameter` classes or their subclasses.

If you specify a file name with a `.c` extension or with no extension and specify C++ for the code generation language, the code generator produces a `.cpp` file.

## Code Generator Assumes Wrap on Signed Integer Overflows

The code generator reduces memory usage and enhances generated code execution by assuming signed integer C operations wrap on overflow. A signed integer overflow occurs when the result of an arithmetic operation is outside the range of values that the output data type can represent. The C programming language does not define the results of such operations. Some C compilers aggressively optimize signed operations for in-range values at the expense of overflow conditions. Other compilers preserve the full wrap-on-overflow behavior. For example, the `gcc` and `MinGW` compilers provide an option to wrap on overflow reliably for signed integer overflows. The generated program image for a model can produce results that differ from model simulation results because the handling of overflows varies, depending on your compiler.

When you generate code, if you use a supported compiler with the default options configured by the code generator, the compiler preserves the full wrap-on-overflow behavior. If you change the compiler options or compile the code in another development environment, it is possible that the compiler does not preserve the full wrap-on-overflow behavior. In this case, the executable program can produce unpredictable results.

If this issue is a concern for your application, consider one or more of the following actions:

- Verify that the compiled code produces expected results.
- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, configure the build process to use the compiler option `-fwrapv`.
- Choose a compiler that wraps on integer overflow.
- If you have Embedded Coder installed, develop and apply a custom code replacement library to replace code generated for signed integers. For more information, see “Code Replacement Customization”.

## Choose and Configure Compiler

To view the installed compilers and select the default compiler, in the Command Window, type:

```
mex -setup
```

On a Windows computer, you can install supported compilers and select a default compiler.

On a UNIX platform, the default compiler is GNU `gcc/g++` for GNU or Xcode for Mac.

Unless the build approach configuration selects a specific compiler, the code generator uses the default compiler for the build process.

Primarily, the specified system target file determines the compiler that the code generator requires:

- If you select a toolchain-based system target file such as `grt.tlc` (Generic Real-Time Target), `ert.tlc` (Embedded Coder), or `autosar.tlc` (Embedded Coder for AUTOSAR), the **Build process** subpane displays configuration parameters for the build process. Use the **Toolchain** configuration parameter to select a compiler and

associated tools for your model build. To validate the selected toolchain, click the **Validate Toolchain**.

- If you select a template makefile (TMF) based system target file, such as `rsim.tlc`, the **Build process** subpane displays template makefile parameters for configuring the build process. The **Template makefile** parameter displays the default TMF file for the selected system target file. If the system target file supports compiler-specific template makefiles (for example, Rapid Simulation or S-Function system target files), you can set **Template makefile** to a compiler-specific TMF, such as `rsim_lcc.tmf` or `rsim_unix.tmf`. (See “Compare System Target File Support Across Products” (Simulink Coder) for valid TMF names.)

If the generated code exceeds the 2 Gb static memory limit, a compiler error occurs. To resolve this issue:

- For GRT-based system target files, set model configuration parameter **Code interface packaging** to `Reusable function`.
- For ERT-based system target files, set model configuration parameter **Code interface packaging** to `Reusable function` and select parameter **Use dynamic memory allocation for model initialization**.

## Include S-Function Source Code

When the code generator builds models with S-functions, source code for the S-functions can be either in the current folder or in the same folder as their MEX-file. The code generator adds an include path to the generated makefiles whenever it finds a file named `sfcnname.h` in the same folder as the S-function MEX-file. This folder must be on the MATLAB path.

Similarly, the code generator adds a rule for the folder when it finds a file `sfcnname.c` (or `.cpp`) in the same folder as the S-function MEX-file is in.

### Compiler Version Mismatch Errors

#### Description

The build process produces a compiler version mismatch error.

#### Action

- 1 Check the list of supported and compatible compilers available at [www.mathworks.com/support/compilers/current\\_release/](http://www.mathworks.com/support/compilers/current_release/).
- 2 Upgrade or change your compiler. For more information, see “Choose and Configure Compiler” on page 54-6.
- 3 Rebuild the model.

### Results for Model Simulation and Program Execution Differ

#### Description

The program generated for the model produces different results from model simulation results. The generated source code includes an arithmetic operation that produces a signed integer overflow. It is possible that your compiler does not implement wrapping behavior for signed integer overflow conditions. Or, if you are using a compiler that supports wrapping, it is possible that you did not configure it to use the `-fwrapv` option.

For more information, see “Code Generator Relies on Undefined Behavior of C Language for Integer Overflows.”

**Action**

- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, specify the compiler option `-fwrapv`.
- Choose a compiler that checks for integer overflows.
- If you have Embedded Coder, develop and apply a code replacement library to replace code generated for signed integers.

**Generates Expected Code and Produces Unexpected Results****Description**

The build process generates expected source code, but the executable program produces unexpected results. The generated source code appears as expected. However, the executable program produces unexpected results.

**Action**

Do one of the following:

- Lower the compiler optimization level.
  - 1** Set the **Compiler optimization level** configuration parameter to Custom.
  - 2** In the **Custom compiler optimization flags** field, specify a lower optimization level.
  - 3** Rebuild the model.
- Disable compiler optimizations.
  - 1** Set **Compiler optimization level** to Optimizations off (faster builds).
  - 2** Rebuild the model.

For more information, see “Control Compiler Optimizations” (Simulink Coder) and your compiler documentation.

## Compile-Time Issues

Issue	Action
Error is present in the compiler configuration.	Make sure that MATLAB supports the compiler and version that you want to use. For a list of currently supported and compatible compilers, see <a href="http://www.mathworks.com/support/compilers/current_release/">www.mathworks.com/support/compilers/current_release/</a> . If necessary, upgrade or change your compiler (see “Choose and Configure Compiler” on page 54-6 or “Choose and Configure Compiler” on page 54-6).
Environment variables are incorrectly set up for your make utility, compiler, or linker. For example, installation of Cygwin tools on a Windows platform affects environment variables used by other compilers.	Review the environment variable settings for your system by using the <code>set</code> command on a Windows platform or <code>setenv</code> on a Linux platform. Make sure that the settings match what is required for the tools you are using.
Error is present in custom code specified as an S-Function block or in <b>Custom Code</b> . For example, the code refers to a header file that the compiler cannot find.	To isolate the source of the problem, remove the custom code from the model, debug, and rebuild the model.
The model includes a block, such as a device driver block, which is not intended for use with the currently selected system target file.	Remove the system target file-specific block or configure the model for use with another system target file.

Issue	Action
<p>A linker error about an undefined reference to the data appears when the model build generates an executable program from the model reference hierarchy and these conditions are true:</p> <ul style="list-style-type: none"> <li>• You represent signal, state, or parameter data by creating a data object such as <code>Simulink.Signal</code>. You use the object in a model reference hierarchy.</li> <li>• You use a custom storage class with the data object. Custom storage classes require Embedded Coder.</li> <li>• You set the owner of the object to a model that does not directly access the data.</li> <li>• You use the toolchain <code>lcc-win64</code>.</li> </ul>	<p>To resolve the issue, choose one of these methods:</p> <ul style="list-style-type: none"> <li>• In the data object, clear the <code>Owner</code> property. Alternatively, set the owner to a model that directly accesses the data.</li> <li>• Use a different toolchain, such as <code>gcc</code>, instead of <code>lcc</code>.</li> </ul>

## LCC Compiler Does Not Support Ampersands in Source Folder Paths

### Description

If you use the LCC compiler and your model folder path contains an ampersand (&), the build process produces an error.

### Action

Remove the ampersand from the model folder path. Then, rebuild the model.

## LCC Compiler Might Not Support Line Lengths of Rapid Accelerator Code

### Description

If you are compiling Rapid Accelerator code, the LCC compiler might produce an error related to line limits. Rapid Accelerator code can have longer line lengths due to obfuscation.

### Action

Compile your Rapid Accelerator code using a compiler that supports longer code lines.

## Choose Build Approach and Configure Build Process

The code generator supports these approaches for building (compiling and linking) code that you generate from Simulink models:

- Toolchain — A build process that generates makefiles and supports custom toolchains. This approach:
  - Provides control of your build process with toolchain information objects. You can define these objects using MATLAB scripts.
  - Supports model referencing, SIL, and PIL.
  - Supports Simulink Coder, Embedded Coder, and MATLAB Coder.
- Template makefile — A build process that uses a template makefile with a toolchain that you specify. This approach:
  - Optionally uses a toolchain information object.
  - Supports model referencing, SIL, and PIL.
  - Supports Simulink Coder and Embedded Coder.

You can use the “System target file” (Simulink Coder) configuration parameter to select the build process for a model. When you set the **System target file** to:

- `ert.tlc`, `ert_shrlib.tlc`, `grt.tlc`, or any toolchain-compliant system target file, the build process uses the toolchain approach on page 54-14 by default.
- Any non-toolchain-compliant system target file, the build process uses the template makefile approach on page 54-20.

You can switch from the toolchain approach to the template makefile approach with this command:

```
set_param(model, 'MakeCommand', 'make_rtw TMF=1')
```

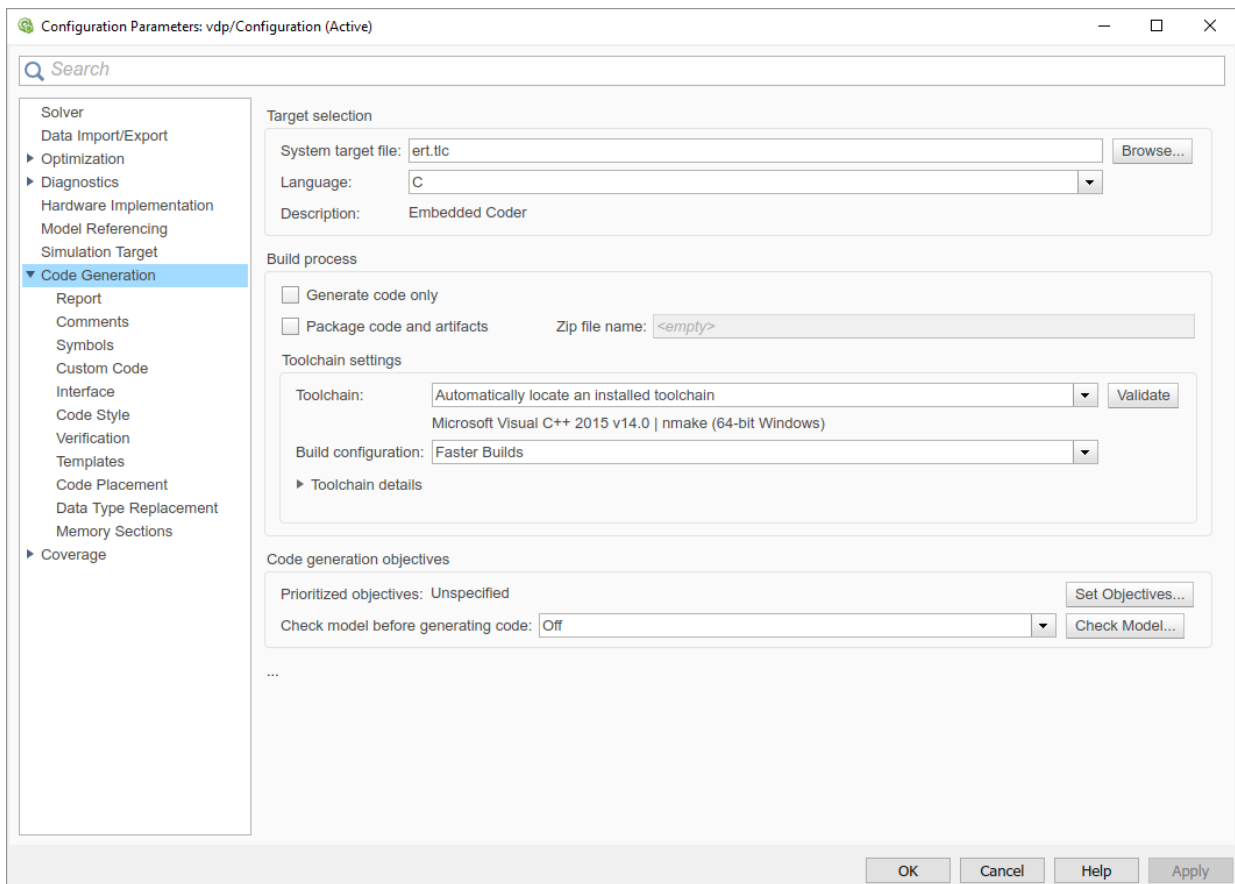

### Toolchain Approach

**Toolchain settings** appear under **Build process** when you set **System target file** to:

- `grt.tlc` – Generic Real-Time Target
- `ert.tlc` – Embedded Coder (requires the Embedded Coder product)

- `ert_shrlib.tlc` – Embedded Coder (host-based shared library target) (requires Embedded Coder)
- Any toolchain-compliant system target file (If ERT-based, requires Embedded Coder)

For more information about toolchain-compliant system target files, see “Support Toolchain Approach with Custom Target” (Simulink Coder).

The **Toolchain settings** include these configuration parameters:

- “Toolchain” (Simulink Coder) -- Specifies the collection of third-party software tools that builds the generated code. A toolchain can include a compiler, linker, archiver,

and other prebuild or postbuild tools that download and run the executable file on the target hardware.

The default value of **Toolchain** is Automatically locate an installed toolchain. The **Toolchain** parameter displays name of the located toolchain just below Automatically locate an installed toolchain.

Click the **Validate Toolchain** button to check that the toolchain is present and validate that the code generator has the information required to use the toolchain. The resulting Validation Report gives a pass/fail for the selected toolchain, and identifies issues to resolve.

- “Build configuration” (Simulink Coder) -- Specifies the optimization settings. By default, **Build Configuration** is set to **Faster Builds**. You can also select **Faster Runs**, **Debug**, and **Specify**. If you select **Specify**, you can customize the options for the toolchain. When you click **Apply**, the custom toolchain settings apply to the current model.

---

**Note** The following system target files, which use the template makefile approach, have the same names but different descriptions from system target files that use the toolchain approach:

- `ert.tlc` – Create Visual C/C++ Solution File for Embedded Coder
- `grt.tlc` – Create Visual C/C++ Solution File for Simulink Coder

To avoid confusion, click **Browse** to select the system target file and look at the description of each file.

---

## Upgrade Model to Use Toolchain Approach

When you open a model created before R2013b that uses the following system target files, the software tries to upgrade the model. The upgrade changes the configuration from using template makefile settings to using the toolchain settings:

- `ert.tlc` – Embedded Coder
- `ert_shrplib.tlc` – Embedded Coder (host-based shared library target)
- `grt.tlc` – Generic Real-Time Target

---

**Note** To upgrade models using a custom system target file to use the toolchain approach, see “Support Toolchain Approach with Custom Target” on page 85-80.

---

Some model configuration parameter values prevent the software from upgrading a model to use toolchain settings. The following instructions show you ways to complete the upgrade process.

Consider upgrading your models and use the toolchain build approach. Doing so is not required. You can continue generating code from a model that has not been upgraded.

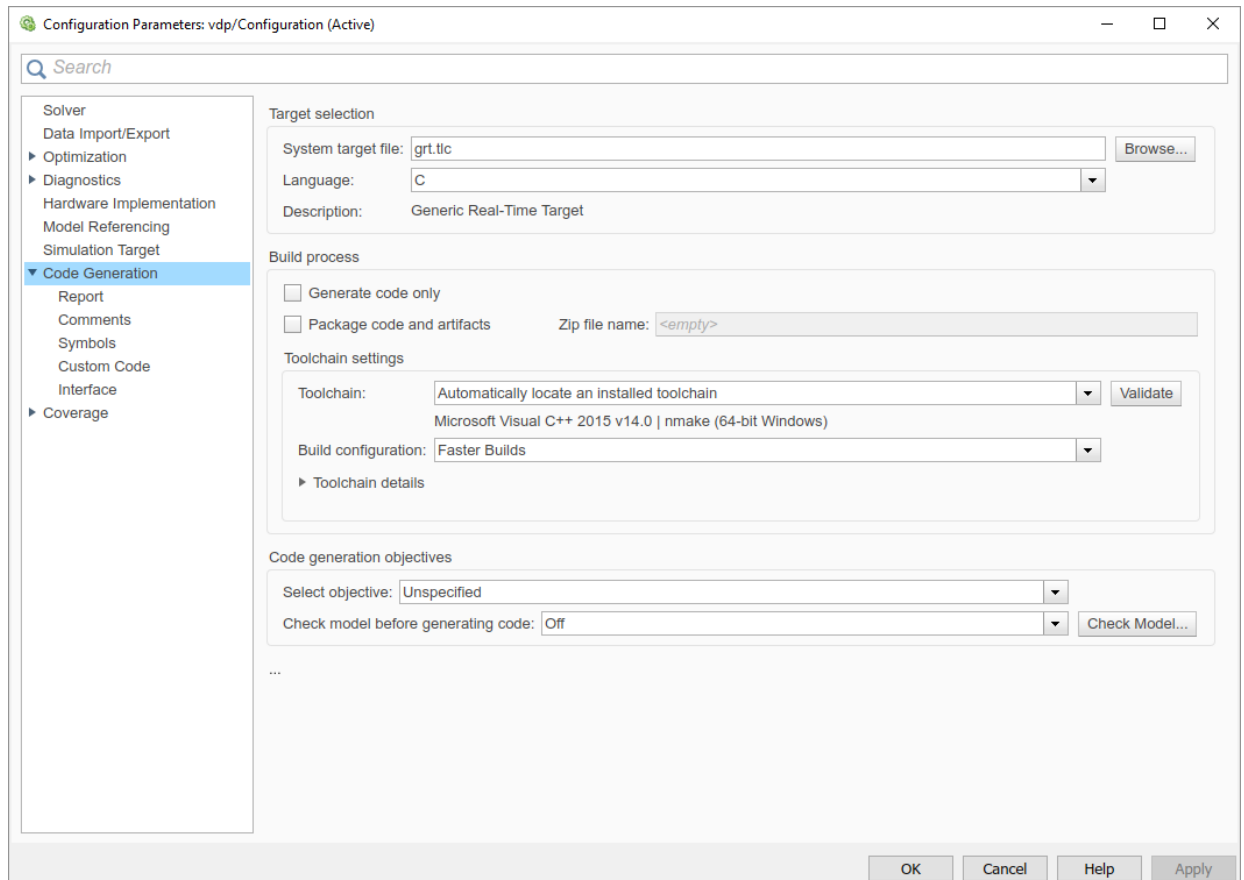

---

**Note** The software does not upgrade models that use the following system target files:

- `ert.tlc` – Create Visual C/C++ Solution File for Embedded Coder
  - `grt.tlc` – Create Visual C/C++ Solution File for Simulink Coder
- 

To see if a model has been upgraded:

- 1 If the **Toolchain** and **Build configuration** configuration parameters are specified, the model has been upgraded.

If makefile configuration parameters such as **Generate makefile**, **Make command**, and **Template makefile** are specified, the model has not been upgraded.

Start by creating a working copy of the model using **File > Save As**. This action preserves the original model and configuration parameters for reference.

Try to upgrade the model using Upgrade Advisor:

- 1 On the **Modeling** tab, in the **Evaluate & Manage** section, select **Upgrade Advisor**.
- 2 In Upgrade Advisor, select **Check and update model to use toolchain approach to build generated code** and click **Run This Check**.

**3** Perform the suggested actions and/or click **Update Model**.

When you cannot upgrade the model using Upgrade Advisor, one or more of the following parameters is not set to its default value, shown here:

- **Compiler optimization level** — Optimizations off (faster builds)
- **Generate makefile** — Enabled
- **Template makefile** — System target file-specific template makefile
- **Make command** — make\_rtw without arguments

Sometimes, a model cannot be upgraded. Try the following procedure:

- If **Generate makefile** is disabled, this case cannot be upgradable. However, you can try enabling it and try upgrading the model using Upgrade Advisor.
- If **Compiler optimization level** is set to Optimizations on (faster runs):
  - 1** Set **Compiler optimization level** is to Optimizations off (faster builds).
  - 2** Upgrade the model using Upgrade Advisor.
  - 3** Set **Build configuration** to Faster Runs.
- If **Compiler optimization level** is set to Custom:
  - 1** Copy the **Custom compiler optimization flags** to a text file.
  - 2** Set **Compiler optimization level** to Optimizations off (faster builds).
  - 3** Upgrade the model using Upgrade Advisor.
  - 4** Set **Build configuration** to Specify.
  - 5** To perform the same optimizations, edit the compiler options.
- If **Template makefile** uses a customized template makefile, this case cannot be upgradable. However, you can try the following:
  - 1** Update **Template makefile** to use the default makefile for the system target file.

---

**Note** To get the default makefile name, change the **System target file**, click **Apply**, change it back, and click **Apply** again.

---

- 2** Upgrade the model using Upgrade Advisor.
- 3** If the template makefile contains build tool options, such as compiler optimization flags, set **Build configuration** to Specify and update the options.

- 4 If the template makefile uses custom build tools, create and register a custom toolchain, as described in “Custom Toolchain Registration” (MATLAB Coder) . Then, set the **Toolchain** parameter to use the custom toolchain.

---

**Note** After registering the custom toolchain, update **Toolchain** to use the custom toolchain.

---

- 5 If the template makefile contains custom rules and logic, these customizations cannot be applied to the upgraded model.

## Template Makefile Approach

When the **System target file** is set to a `tlc` file that uses the template makefile approach, the software displays **Compiler optimization level**, **Generate makefile**, **Make command**, and **Template makefile** parameters.

## Specify Whether to Generate a Makefile

The **Generate makefile** option specifies whether the build process is to generate a makefile for a model. By default, the build process generates a makefile. Suppress generation of a makefile, for example in support of custom build processing that is not based on makefiles, by clearing **Generate makefile**. When you clear this parameter:

- The **Make command** and **Template makefile** options are unavailable.
- Set up post code generation build processing using a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” (Simulink Coder).

## Specify a Make Command

Each template makefile-based system target file has an associated `make` command. The code generator uses this internal MATLAB command to control the build process. The command appears in the **Make command** field and runs when you start a build.

Most system target files use the default command, `make_rtw`. Third-party system target files could supply another `make` command. See the documentation from the vendor.

In addition to the name of the `make` command, you can supply makefile options in the **Make command** field. These options could include compiler-specific options, include paths, and other parameters. When the build process invokes the `make` utility, these options are passed on the `make` command line, which adds them to the overall flags passed to the compiler.

“Template Makefiles and Make Options” on page 54-26 lists the **Make command** options you can use with each supported compiler.

## Specify the Template Makefile

The **Template makefile** field has these functions:

- If you selected a system target file with the System Target File Browser, this field displays the name of a MATLAB language file that selects a template makefile for your development environment. For example, in “Model Configuration Parameters: Code Generation” (Simulink Coder), the **Template makefile** field displays `grt_default_tmf`, indicating that the build process invokes `grt_default_tmf.m`.

“Template Makefiles and Make Options” on page 54-26 gives a detailed description of the logic by which the build process selects a template makefile.

- Alternatively, you can explicitly enter the name of a specific template makefile (including the extension) or a MATLAB language file that returns a template makefile in this field. Use this approach if you are using a system target file that does not appear in the System Target File Browser. For example, use this approach if you have written your own template makefile for a custom system target file.

If you specify your own template makefile, be sure to include the file name extension. If you omit the extension, the build process attempts to find and execute a file with the extension `.m` (that is, a MATLAB language file). The template make file (or a MATLAB language file that returns a template make file) must be on the MATLAB path. To determine whether the file is on the MATLAB path, enter the following command in the MATLAB Command Window:

which `tmf_filename`

## Associate the Template Makefile with a Toolchain

Specify a toolchain for the template makefile build process. This example provides a definition for a minimal toolchain and shows how you can associate the toolchain with a template makefile that is a copy of `ert_unix.tmf` or `ert_vcx64.tmf`.

Use this code for the toolchain definition file.

```
function tc = minimalToolchainForTMF
% Create a toolchain object
tc = coder.make.ToolchainInfo('Name', 'Minimal Toolchain for TMF Build');

% Specify that the linker requires a response file instead of
% including all object file modules on the linker command line
tc.addAttribute('RequiresCommandFile', true);

if ispc
    objExt = '.obj';
else
    objExt = '.o';
end

% Specify source file and object file extension used by the C compiler
tool = tc.getBuildTool('C Compiler');
tool.setFileExtension('Source', '.c');
tool.setFileExtension('Header', '.h');
tool.setFileExtension('Object', objExt);

% Specify source file and object file extension used by the C++ compiler
tool = tc.getBuildTool('C++ Compiler');
tool.setFileExtension('Source', '.cpp');
tool.setFileExtension('Header', '.hpp');
tool.setFileExtension('Object', objExt);
```

Use a copy of `ert_unix.tmf` or `ert_vcx64.tmf` as the template makefile.

```
copyfile(fullfile(matlabroot, 'rtw', 'c', 'ert', 'ert_vcx64.tmf'), 'ert_copy.tmf')
```

In the template makefile, i.e. `ert_copy.tmf`, edit the `TOOLCHAIN_NAME` macro.

```
TOOLCHAIN_NAME = "Minimal Toolchain for TMF Build"
```

Associate the toolchain with the template make file.

- 1 Run the toolchain definition file, which generates a `ToolchainInfo` object, `tc`.
 

```
tc = minimalToolchainForTMF;
```
- 2 Save the `ToolchainInfo` object to a MAT file.

```
save('tcMinimal','tc')
```

**3** Register the toolchain in RTW.TargetRegistry.

- a** Place this code in an `rtwTargetInfo.m` file.

```
function rtwTargetInfo(tr)
tr.registerTargetInfo(@loc_createToolchain);
end

function config = loc_createToolchain
config(1) = coder.make.ToolchainInfoRegistry;
config(1).Name = 'Minimal Toolchain for TMF Build';
config(1).FileName = fullfile(fileparts(mfilename('fullpath')),...
    'tcMinimal.mat');
config(1).TargetHWDeviceType = {'*'};
config(1).Platform = {computer('arch')};
end
```

- b** Save the file in the current working folder or in a folder that is on the MATLAB search path.
- c** Reset the TargetRegistry.

```
RTW.TargetRegistry.getInstance('reset');
```

Associate the template makefile with your model and build the model.

```
set_param(model, 'TemplateMakefile', 'ert_copy.tmf');
rtwbuild(model);
```

## Specify TLC for Code Generation

Target Language Compiler (TLC) is an integral part of the code generator. It enables you to customize generated code. Through customization, you can produce platform-specific code, or you can incorporate your own algorithmic changes for execution speed, code size, or compatibility with existing methods that you prefer to maintain. For additional information, see “Target Language Compiler Overview” (Simulink Coder).

TLC options that you specify for code generation appear in the summary section of the generated HTML code generation report.

---

**Note** Specifying TLC command-line options does not add flags to the make command line.

---

You can specify Target Language Compiler (TLC) command-line options and arguments for code generation using the model parameter `TLCOptions` in a `set_param` function call. For example,

```
>> set_param(gcs,'TLCOptions','-p0 -aWarnNonSaturatedBlocks=0')
```

Some common uses of TLC options include the following:

- `-aVarName=1` to declare a TLC variable and/or assign a value to it
- `-IC:\Work` to specify an include path
- `-v` to obtain verbose output from TLC processing (for example, when debugging)

- “Executable Program Generation” on page 54-67

## Template Makefiles and Make Options

The code generator includes a set of built-in template makefiles that build programs for specific system target files.

### Types of Template Makefiles

There are two types of template makefiles:

- *Compiler-specific* template makefiles are for a particular compiler or development system.

By convention, compiler-specific template makefiles names correspond to the system target file and compiler (or development system). For example, `grt_vcx64.tmf` is the template makefile for building a generic real-time program under the Visual C++ compiler; `ert_lcc.tmf` is the template makefile for building an Embedded Coder program under the `lcc` compiler.

- *Default* template makefiles make your model designs more portable, by choosing the compiler-specific makefile and compiler for your installation. “Select and Configure C or C++ Compiler” on page 54-3 describes the operation of default template makefiles in detail.

Default template makefiles have names that follow the pattern `target_default_tmf`. They are MATLAB language files that, when run, select the TMF for the specified system target file configuration. For example, `grt_default_tmf` is the default template makefile for building a generic real-time program; `ert_default_tmf` is the default template makefile for building an Embedded Coder program.

For details on the structure of template makefiles, see “Customize Template Makefiles” on page 85-62. This section describes compiler-specific template makefiles and common options you can use with each.

### Specify Template Makefile Options

You can specify template makefile options through the **Make command** configuration parameter. Append the options after `make_rtw` (or other make command), as in the following example:

```
make_rtw OPTS="-DMYDEFINE=1"
```

The syntax for make command options differs slightly for different compilers.

---

**Note** To control compiler optimizations for a makefile build, use the **Compiler optimization level** configuration parameter, which provides:

- System target file-independent values `Optimizations on` (faster runs) and `Optimizations off` (faster builds), which easily allow you to toggle compiler optimizations on and off during code development
- The value `Custom` for entering custom compiler optimization flags at Simulink GUI level (rather than at other levels of the build process)

If you specify compiler options for your makefile build using `OPT_OPTS`, `MEX_OPTS` (except `MEX_OPTS="-v"`), or `MEX_OPT_FILE`, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

---

## Template Makefiles for UNIX Platforms

The template makefiles for UNIX platforms are for the Free Software Foundation's GNU Make. These makefiles conform to the guidelines specified in the IEEE<sup>8</sup> Std 1003.2-1992 (POSIX) standard.

- `ert_unix.tmf`
- `grt_unix.tmf`
- `rsim_unix.tmf`
- `rtwsfcn_unix.tmf`

You can supply options to makefiles through the **Make command** configuration parameter. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,  
`OPTS="-DMYDEFINE=1"`
- `OPT_OPTS`— Optimization options. Default is `-O`. To enable debugging, specify the option as `OPT_OPTS=-g`. Because of optimization problems in `IBM_RS`, the default is to not optimize.

---

8. IEEE is a registered trademark of The Institute of Electrical and Electronics Engineers, Inc.

- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,  
`USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"`
- `DEBUG_BUILD` — Add debug information to generated code, for example,  
`DEBUG_BUILD=1`

These options are also documented in the comments at the head of the respective template makefiles.

## Template Makefiles for the Microsoft Visual C++ Compiler

- “Visual C++ Executable Build” on page 54-28
- “Visual C++ Code Generation Only” on page 54-29

### Visual C++ Executable Build

To build an executable using the Visual C++ compiler within the build process, use one of the `target_vcx64.tmf` template makefiles:

- `ert_vcx64.tmf`
- `grt_vcx64.tmf`
- `rsim_vcx64.tmf`
- `rtwsfcn_vcx64.tmf`

You can supply options to makefiles through the **Make command** configuration parameter. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPT_OPTS` — Optimization option. Default is `-O2`. To enable debugging, specify the option as `OPT_OPTS=-Zi`.
- `OPTS` — User-specific options.
- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,

```
USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
```

- `DEBUG_BUILD` — Add debug information to generated code, for example,

```
DEBUG_BUILD=1
```

These options are also documented in the comments at the head of the respective template makefiles.

### Visual C++ Code Generation Only

To create a Visual C++ project makefile (*model.mak*) without building an executable, use one of the *target\_msvc.tmf* template makefiles:

- `ert_msvc.tmf`
- `grt_msvc.tmf`

These template makefiles are for `nmake`, which is bundled with the Visual C++ compiler.

You can supply options to makefiles through the **Make command** configuration parameter. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,

```
OPTS="/D MYDEFINE=1"
```

- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,

```
USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
```

- `DEBUG_BUILD` — Add debug information to generated code, for example,

```
DEBUG_BUILD=1
```

These options are also documented in the comments at the head of the respective template makefiles.

### Template Makefiles for the LCC Compiler

The code generator provides template makefiles to create an executable for the Windows platform using Lcc compiler Version 2.4 and GNU Make (`gmake`).

- ert\_lcc.tmf
- grt\_lcc.tmf
- rsim\_lcc.tmf
- rtwsfcn\_lcc.tmf

You can supply options to makefiles by using the **Make command** configuration parameter. Options specified in the **Make command** field are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- **OPTS** — User-specific options, for example,  

```
OPTS=" -DMYDEFINE=1 "
```
- **OPT\_OPTS** — Optimization options. Default is to not use options. To enable debugging, specify `-g4`:

```
OPT_OPTS=" -g4 "
```

- **CPP\_OPTS** — C++ compiler options.
- **USER\_SRCS** — Additional user sources, such as files used by S-functions.
- **USER\_INCLUDES** — Additional include paths. For example:

```
USER_INCLUDES=" -Iwhere-ever -Iwhere-ever2 "
```

For `lcc`, use `/` as file separator before the file name instead of `\`, for example, `d:\work\proj1\myfile.c`.

- **DEBUG\_BUILD** — Add debug information to generated code, for example,

```
DEBUG_BUILD=1
```

These options are also documented in the comments at the head of the respective template makefiles.

- “Customize System Target Files” (Simulink Coder)
- “Associate the Template Makefile with a Toolchain” on page 54-23

## Build Process Workflow for Real-Time Systems

The building process includes generating code in C or C++ from a model and building an executable program from the generated code. This example can use a generic real-time (GRT) or an embedded real-time (ERT) system target file (STF) for code generation. The resulting standalone program runs on your development computer, independent of external timing and events.

### Working Folder

This example uses a local copy of the `slexAircraftExample` model, stored in its own folder, `aircraftexample`. Set up your *working folder* as follows:

- 1 In the MATLAB Current Folder browser, navigate to a folder to which you have write access.
- 2 To create the working folder, enter the following MATLAB command:

```
mkdir aircraftexample
```

- 3 Make `aircraftexample` your working folder:

```
cd aircraftexample
```

- 4 Open the `slexAircraftExample` model:

```
slexAircraftExample
```

The model appears in the Simulink Editor model window.

- 5 In the model window, choose **File > Save As**. Navigate to your working folder, `aircraftexample`. Save a copy of the `slexAircraftExample` model as `myAircraftExample`.

### Build Folder and Code Generation Folders

While producing code, the code generator creates a *build folder* within your working folder. The build folder name is `model_target_rtw`, derived from the name of the source model and the chosen system target file. The build folder stores generated source code and other files created during the build process. Examine the build folder contents at the end of this example.

When a model contains Model blocks (references to other models), the model build creates special subfolders in your “Code generation folder” (Simulink) to organize code

for the referenced models. These code generation folders exist alongside product build folders and are named `slprj`. “Generate Code for Referenced Models” on page 4-4 describes navigating code generation folder structures in Model Explorer.

Under the `slprj` folder, a subfolder named `_sharedutils` contains generated code that can be shared between models.

## Set Model Parameters for Code Generation

To generate code from your model, you must change some of the model configuration parameters. In particular, the generic real-time (GRT) system target file and most other system target files require that the model specifies a fixed-step solver.

---

**Note** For models that specify variable-step solvers, the code generator produces code only if the models also specify rapid simulation (`rsim`) or S-function system target files.

---

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 In the Configuration Parameters dialog box, specify configuration parameter values for the solver:
  - **Start time:** 0.0
  - **Stop time:** 60
  - **Type:** Fixed-step
  - **Solver:** ode5 (Dormand-Prince)
  - **Fixed step size (fundamental sample time):** 0.1
  - **Treat each discrete rate as a separate task:** Off
- 3 Click **Apply**.
- 4 Save the model.

## Configure Build Process

To configure the build process for your model, choose a system target file, a toolchain or template makefile, and a `make` command.

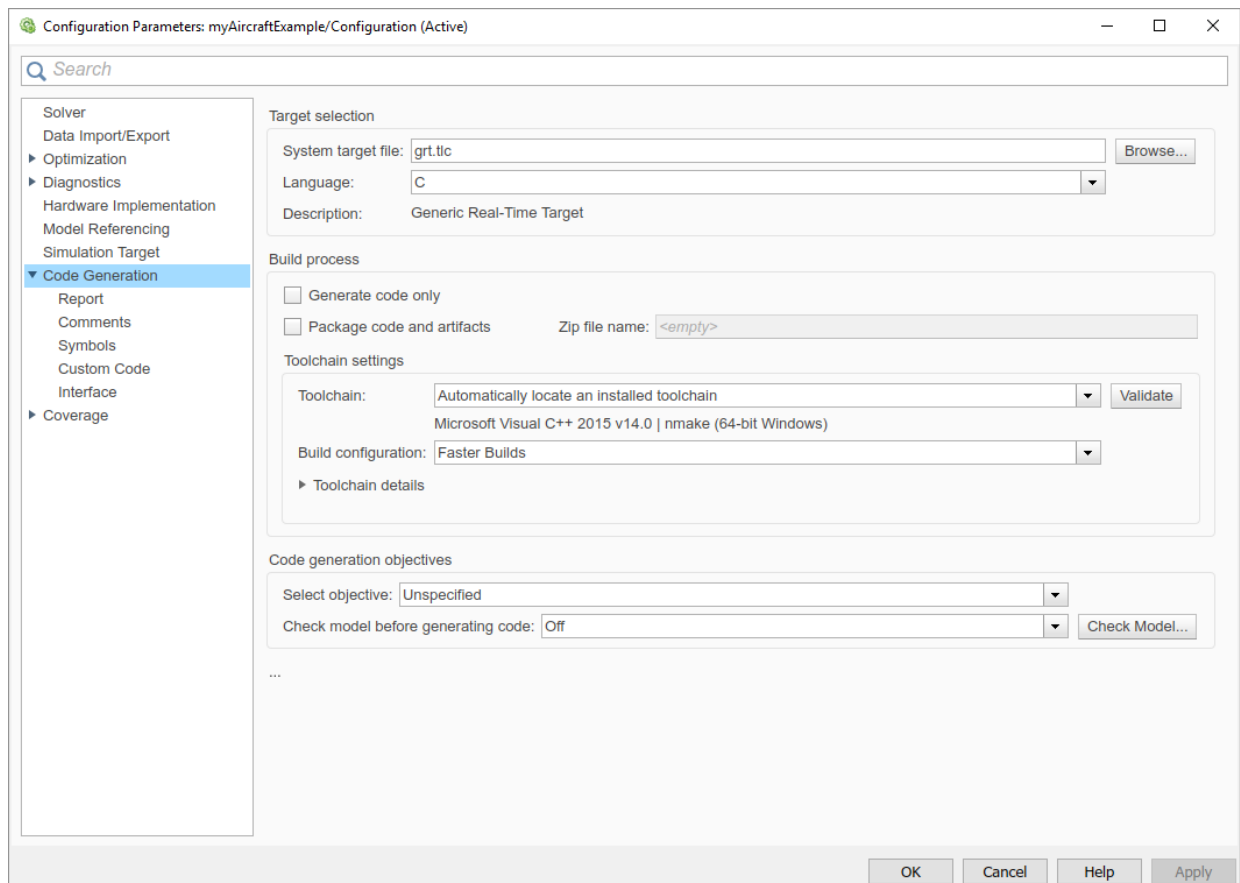

In these examples and in most applications, you do not need to specify these parameters individually. The examples use the ready-to-run generic real-time target (GRT)

configuration. The GRT system target file builds a standalone executable program that runs on your desktop computer.

To select the GRT system target file:

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 In the Configuration Parameters dialog box, in the **System target file** field, enter `grt.tlc`. Then click **Apply**.

You see selections for **Toolchain** (Automatically locate an installed toolchain), and **Build Configuration** (Faster Builds).

- 3 Save the model.

---

**Note** If you click **Browse**, a System Target File Browser opens and displays the system target files on the MATLAB path. Some system target files require additional products. For example, `ert.tlc` requires Embedded Coder.

---

## Set Code Generation Parameters

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 In the Configuration Parameters dialog box, specify settings:
  - a These **Code Generation** parameters control build verbosity and debugging:
    - **Verbose build** (RTWVerbose)
    - **Retain .rtw file** (RetainRTWFile)
    - **Profile TLC** (ProfileTLC)
    - **Start TLC debugger when generating code** (TLCDebug)
    - **Start TLC coverage when generating code** (TLCCoverage)
    - **Enable TLC assertion** (TLCAssert)

Use the default settings.
  - b Use the default **Code Generation > Comments** settings.
  - c The **Code Generation > Identifiers** options control the look and feel of generated code. Use the default settings.
  - d Select **Code Generation > Interface**.
    - i From the **Shared code placement** list, select `Shared` location. The build process places generated code for utilities in a subfolder within your “Code generation folder” (Simulink).
    - ii Clear the **Classic call interface** check box.
  - e In **Code Generation > Report**, select the **Create code generation report** check box. This action enables the software to create and display a code generation report for the `myAircraftExample` model.
- 3 Click **Apply** and save the model.

## Build and Run a Program

The build process generates C code from the model. It then compiles and links the generated program to create an executable image. To build and run the program:

1 With the `myAircraftExample` model open, perform one of these actions:

- On the **C Code** tab, click **Build**.
- Press **Ctrl+B**.
- Run the `rtwbuild` command from the MATLAB command line.
- Run the `slbuild` command from the MATLAB command line.

You see code generation and compilation messages in the Command Window. The initial message is:

```
### Starting build procedure for model: myAircraftExample
```

The contents of many of the succeeding messages depends on your compiler and operating system. The final messages include:

```
### Created executable myAircraftExample.exe
### Successful completion of build procedure for model: myAircraftExample
### Creating HTML report file myAircraftExample_codegen_rpt.html
```

The code generation folder now contains an executable, `myAircraftExample.exe` (Microsoft Windows platforms) or `myAircraftExample` (UNIX platforms). In addition, the build process has created an `slprj` folder and a `myAircraftExample_grt_rtw` folder in your “Code generation folder” (Simulink).

---

**Note** After generating the code for the `myAircraftExample` model, the build process displays a code generation report. See “Report Generation” (Simulink Coder) for more information about how to create and use a code generation report.

---

2 To see the contents of the working folder after the build, enter the `dir` or `ls` command:

```
>> dir

.                myAircraftExample.slx          slprj
..               myAircraftExample.slx.autosave
myAircraftExample.exe  myAircraftExample_grt_rtw
```

3 To run the executable from the Command Window, type `!myAircraftExample`. The `!` character passes the command that follows it to the operating system, which runs the standalone `myAircraftExample` program.

```
>> !myAircraftExample

** starting the model **
** created myAircraftExample.mat **
```

- 4 To see the files created in the build folder, use the `dir` or `ls` command again. The exact list of files produced varies among MATLAB platforms and versions. Here is a sample list from a Windows platform:

```
>> dir myAircraftExample_grt_rtw

.                rt_main.obj                myAircraftExample_data.c
..               rtmodel.h                myAircraftExample_data.obj
buildInfo.mat    rtw_proj.tmw                myAircraftExample_private.h
codeInfo.mat     myAircraftExample.bat      myAircraftExample_ref.rsp
defines.txt      myAircraftExample.c        myAircraftExample_types.h
html             myAircraftExample.h
modelsources.txt myAircraftExample.mk
rt_logging.obj   myAircraftExample.obj
```

## Contents of the Build Folder

The build process creates a build folder and names it `model_target_rtw`, where `model` is the name of the source model and `target` is the system target file selected for the model. In this example, the build folder is named `myAircraftExample_grt_rtw`.

The build folder includes the following generated files.

File	Description
<code>myAircraftExample.c</code>	Standalone C code that implements the model
<code>myAircraftExample.h</code>	An include header file containing definitions of parameters and state variables
<code>myAircraftExample_private.h</code>	Header file containing common include definitions
<code>myAircraftExample_types.h</code>	Forward declarations of data types used in the code
<code>rtmodel.h</code>	Master header file for including generated code in the static main program (its name does not change, and it simply includes <code>myAircraftExample.h</code> )

The code generation report that you created for the `myAircraftExample` model displays a link for each of these files. You can click the link explore the file contents.

The build folder contains other files used in the build process. They include:

- `myAircraftExample.mk` — Makefile for building executable using the specified Toolchain.
- Object (`.obj`) files
- `myAircraftExample.bat` — Batch control file
- `rtw_proj.tmw` — Marker file
- `buildInfo.mat` — Build information for relocating generated code to another development environment
- `defines.txt` — Preprocessor definitions required for compiling the generated code
- `myAircraftExample_ref.rsp` — Data to include as command-line arguments to `mex` (Windows systems only)

The build folder also contains a subfolder, `html`, which contains the files that make up the code generation report. For more information, see “Reports for Code Generation” (Simulink Coder).

## Customized Makefile Generation

After producing code, the code generator produces a customized makefile, `model.mk`. The generated makefile instructs the `make` system utility to compile and link source code generated from the model, any required harness program, libraries, or user-provided modules. The code generator produces the file `model.mk` regardless of the approach that you use for build process control:

- If you use the toolchain approach, the code generator creates `model.mk` based on the model **Toolchain settings**. You can modify generation of the makefile through the `rtwmakecfg.m` API.
- If you use the template makefile approach, the code generator creates `model.mk` from a system template file, `system.tmf` (where *system* stands for the selected system target file name). The system template makefile is designed for your system target file. You can modify the template makefile to specify compilers, compiler options, and additional information for the creation of the executable.

For more information, see “Choose Build Approach and Configure Build Process” on page 54-14.

## Build Models from a Windows Command Prompt Window

This example shows how to build models by using a batch file, entering commands at the Command Prompt in Windows.

### About MATLAB Command-Line (Start Up) Arguments

When you start MATLAB from a Command Prompt in Windows (as done in a batch file), you can control MATLAB start up with a number of command-line arguments.

For a description of these command-line arguments, in the Command Prompt window, type `matlab -help`.

To start MATLAB from a Command Prompt window, use these steps:

- 1 From the Windows Start menu, open a Command Prompt window.
- 2 From the Windows Command Prompt, type: `matlab`.

**Tip:** To display the path to the MATLAB root folder, at the MATLAB command prompt type: `matlabroot`.

### Run MATLAB with a Batch File

When you run MATLAB with a batch file, you can:

- Control MATLAB start up with command-line arguments
- Run a series of operating system commands (such as source control checkout/commit)
- Run a series of MATLAB scripts

A batch approach also lets you automate your overall build process. Such a process can generate code from one or more Simulink models, then use your makefile to compile custom code and generated code.

This batch file sets the `MATLABROOT` environment variable, sets the `PATH` environment variable to include `MATLABROOT`, and starts MATLAB with an input script argument `%1` and a logfile argument.

**Note:** Customize the `MATLABROOT` value in the batch file to match your system. The batch file assumes that a `c:\temp` folder exists on your system.

### Create a batch file named `mat.bat`

```
SET MATLABROOT="C:\Program Files\MATLAB\R2019a"  
PATH=%MATLABROOT%;%PATH%  
START matlab.exe -batch %1 -logfile c:\temp\logfile  
PAUSE
```

### Create a MATLAB script `myFilesToBuild.m`

```
my_rtwdemo_counter_builder  
my_rtwdemo_rtwinintro_builder  
exit
```

### Create a MATLAB script `my_rtwdemo_counter_builder.m`

```
open_system('rtwdemo_counter');  
save_system('rtwdemo_counter','my_rtwdemo_counter')  
rtwbuild('my_rtwdemo_counter');  
close_system('my_rtwdemo_counter');
```

### Create a MATLAB script `my_rtwdemo_rtwinintro_builder.m`

```
open_system('rtwdemo_rtwinintro');  
save_system('rtwdemo_rtwinintro','my_rtwdemo_rtwinintro')  
rtwbuild('my_rtwdemo_rtwinintro');  
close_system('my_rtwdemo_rtwinintro');
```

### Run the batch file

From the Windows Start menu, open a Command Prompt window, change folders to the folder containing the batch file, and type:

```
mat myFilesToBuild
```

When you run the batch file with the input MATLAB script, the batch file runs MATLAB and loads, builds, and closes each of the example Simulink models.

### Observe the log of MATLAB operations

After the batch file runs, view the `c:\temp\logfile` file.

**Tip:** Omitting the semicolon (;) from the `rtwbuild` line in each script provides more build information in the log file.

## Optimize Your Batch File

Use the MATLAB command-line arguments to optimize the batch file. Some options to consider include:

- Suppress the MATLAB splash screen on startup with the `-nosplash` argument.
- Provide command-line input to the input script or function selected with the `-batch` argument.

For example, you can call a function `myfile.m`, which accepts two arguments:

```
matlab -batch myfile(arg1,arg2)
```

To pass numeric values into `myfile.m`, replace `arg1` and `arg2` with numeric values.

To pass string or character values into `myfile.m`, replace `arg1` and `arg2` with the string or character values surrounded in single quotes. For example, to pass the string values `hello` and `world` into `myfile.m`, in the Command Prompt window, type:

```
matlab -batch myfile('hello','world')
```

## Rebuild a Model

If you update generated source code or makefiles manually to add customizations, you can rebuild the files with the `rtwrebuild` command. This command recompiles the modified files by invoking the generated makefile. Alternatively, you can rebuild from the Model Explorer:

- 1 Open the Model Explorer
- 2 In the **Model Hierarchy** pane, expand the node for the model.
- 3 Click the **Code for *model*** node.
- 4 In the **Code** pane, next to **Code Recompile Command**, click **rebuild generated code**.

- `rtwrebuild`
- “Build Process Workflow for Real-Time Systems” (Simulink Coder)

## Control Regeneration of Top Model Code

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. The model build regenerates top model code if any of the following conditions is true:

- The structural checksum of the model has changed.
- The top-model-only checksum has changed. The top-model-only checksum provides information about top model parameters, such as application lifespan, maximum stack size, make command, verbose and `.rtw` file debug settings, and `TLCOptions`.
- Any of the following TLC debugging configuration parameters is selected:
  - **Start TLC debugger when generating code** (`TLCDebug`)
  - **Start TLC coverage when generating code** (`TLCCoverage`)
  - **Enable TLC assertion** (`TLCAssert`)
  - **Profile TLC** (`ProfileTLC`)

Whether the top model code is regenerated, the build process calls the build process hooks and reruns the makefile. The hooks include the `STF_make_rtw_hook` functions and the post code generation command. This process recompiles and links the external dependencies.

System target file authors can perform actions related to code regeneration in the `STF_make_rtw_hook` functions that the build process calls. These actions include forcing or reacting to code regeneration. For more information, see “Control Code Regeneration Using `STF_make_rtw_hook.m`” on page 84-49.

### Regeneration of Top Model Code

If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. An example check is whether previously generated code is not current due to a model update.

The build process omits regeneration of the top model code when the checks indicate both:

- The top model generated code is current for the model.

- Model settings do not require full regeneration.

This omission can significantly reduce model build times.

With an Embedded Coder license, if you modify a code generation template (CGT) file then rebuild your model, the code generation process does not force a top model build. In this case, see “Force Regeneration of Top Model Code” on page 54-46.

## Force Regeneration of Top Model Code

If you want to control or override the default top model build behavior, use one of the following command-line options:

- To ignore the checksum and force regeneration of the top model code:
  - `rtwbuild(model, 'ForceTopModelBuild', true)`
  - `slbuild(model, 'StandaloneCoderTarget', 'ForceTopModelBuild', true)`
- To clean the model build area enough to trigger regeneration of the top model code at the next build (slbuild only):  
`slbuild(model, 'CleanTopModel')`

You can force regeneration of the top model code by deleting the `slprj` folder or the generated model code folder from the “Code generation folder” (Simulink) .

- “Rebuild a Model” on page 54-43
- “Reduce Build Time for Referenced Models by Using Parallel Builds” on page 54-47

## Reduce Build Time for Referenced Models by Using Parallel Builds

In a parallel computing environment, you can increase the speed of code generation and compilation for models containing large model reference hierarchies. Achieve the speed by building referenced models in parallel whenever conditions allow. For example, if you have Parallel Computing Toolbox software, code generation and compilation for each referenced model can be distributed across the cores of a multicore host computer. If you also have MATLAB Parallel Server™ software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Parallel Server configuration.

### Parallel Building for Large Model Reference Hierarchies

The execution speed improvement realized by using parallel builds for referenced models depends on several factors. These factors include how many models can be built in parallel for a given model referencing hierarchy, the size of the referenced models, and parallel computing resources. The resources include the number of local and/or remote workers available and the hardware attributes of the local and remote machines. Examples of hardware attributes are the amount of RAM and number of cores.

Simulink cache (.slxc) files are generated for the entire model reference hierarchy during a parallel build. For more information, see “Simulink Cache Files for Incremental Code Generation” (Simulink Coder).

For configuration requirements that could apply to your parallel computing environment, see “Parallel Building Configuration Requirements” on page 54-48.

For a description of the general workflow for building referenced models in parallel whenever conditions allow, see “Build Models in a Parallel Computing Environment” on page 54-48.

For information on how to configure a custom embedded system target file to support parallel builds, see “Support Model Referencing” (Simulink Coder).

---

**Note** In a MATLAB Parallel Server parallel computing configuration, parallel building is designed to work interactively with the software. You can initiate builds from the Simulink user interface or from the MATLAB Command Window using commands such as `slbuild`. You cannot initiate builds using `batch` or other batch mode workflows.

---

## Parallel Building Configuration Requirements

The following requirements apply to configuring your parallel computing environment for building model reference hierarchies in parallel whenever conditions allow:

- For local pools, the host machine must have enough RAM to support the number of local workers (MATLAB sessions) that you plan to use. For example, using `parpool(4)` to create a parallel pool with four workers results in five MATLAB sessions on your machine. Each pool uses the amount of memory required for MATLAB and the code generator at startup. For memory requirements, see System Requirements for MATLAB & Simulink.
- Remote MATLAB Parallel Server workers participating in a parallel build and the client machine must use a common platform and compiler.
- A consistent MATLAB environment must be set up in each MATLAB worker session as in the MATLAB client session — for example, shared base workspace variables, MATLAB path settings, and so forth. One approach is to use the `PreLoadFcn` callback of the top model. If you configure your model to load the top model with each MATLAB worker session, its preload function can be used for any MATLAB worker session setup.
- It is possible to cause a build error by relying on callbacks to load variables when executing an incremental parallel build (referenced model hierarchy build). To avoid this issue during parallel builds, use one of these options:
  - Do not rely on callback to manage workspace variable of referenced models,
  - Between builds, run the commands `spmd, bdclose all, end` to close all models on the parallel build workers.
  - Between builds, restart the parallel pool.

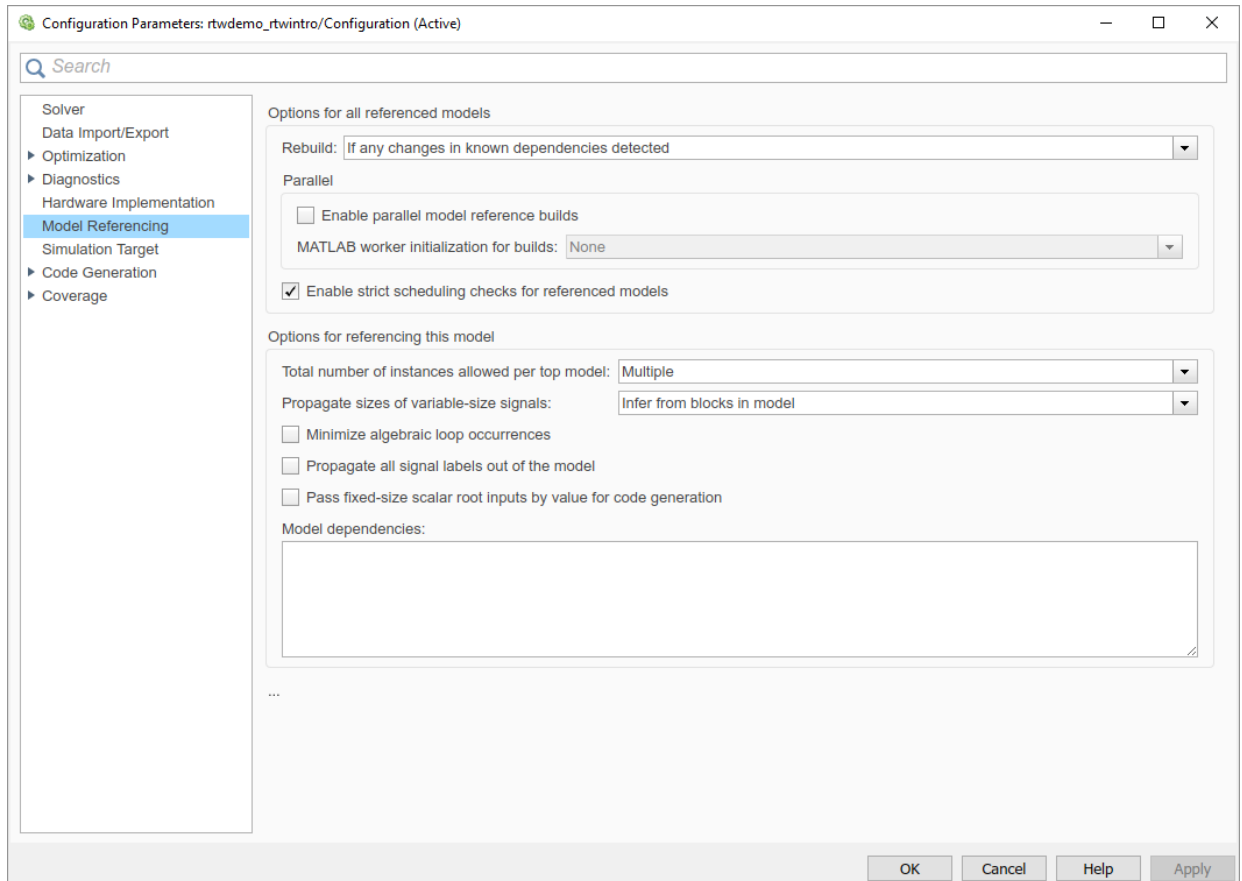

## Build Models in a Parallel Computing Environment

To take advantage of parallel building for a model reference hierarchy:

- 1 Set up a pool of local and/or remote MATLAB workers in your parallel computing environment.
  - a Make sure that Parallel Computing Toolbox software is licensed and installed.
  - b To use remote workers, make sure that MATLAB Parallel Server software is licensed and installed.

- c Issue MATLAB commands to set up the parallel pool, for example, `parpool(4)`.
- 2 From the top model of the model reference hierarchy, open the Configuration Parameters dialog box. Select the **Enable parallel model reference builds** (Simulink) check box. This selection enables the parameter **MATLAB worker initialization for builds** (Simulink).

For **MATLAB worker initialization for builds**, select one of the following values:

- **None** if it is preferable that the software does not perform special worker initialization. Specify this value if the child models in the model reference hierarchy do not rely on anything in the base workspace beyond what they explicitly set up. An example is a model load function.

- `Copy base workspace` if it is preferable that the software attempts to copy the base workspace to each worker. Specify this value if you use a setup script to prepare the base workspace for multiple models to use.
- `Load top model` if it is preferable that the software loads the top model on each worker. Specify this value if the top model in the model reference hierarchy handles the base workspace setup. An example is a model load function.

---

**Note** Only set **Enable parallel model reference builds** for the top model of the model reference hierarchy to which it applies.

---

- 3 Optionally, turn on verbose messages for simulation builds, code generation builds, or both. If you select verbose builds, the build messages report the progress of each parallel build with the name of the model. To produce build messages, select these configuration parameters:

- **Verbose accelerator builds.**
- **Verbose build**

You can see the build messages in the MATLAB Command Window and in parallel build log files.

- 4 Optionally, inspect the model reference hierarchy to determine, based on model dependencies, which models are built in parallel. You can use the Model Dependency Viewer. On the **Modeling** tab, in the **Evaluate & Manage** section, select **Dependencies > Referenced Model Instances**.
- 5 Build your model. Messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. The order in which referenced models build is nondeterministic. They could build in a different order each time the model is built.

If you need more information about a parallel build, for example, if a build fails, see “Locate Parallel Build Logs” on page 54-50.

## Locate Parallel Build Logs

If verbose builds are turned on when you build a model for which referenced models are built in parallel, messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. For example,

```
### Initializing parallel workers for parallel model reference build.  
### Parallel worker initialization complete.
```

```

### Starting parallel model reference SIM build for 'bot_model001'
### Starting parallel model reference SIM build for 'bot_model002'
### Starting parallel model reference SIM build for 'bot_model003'
### Starting parallel model reference SIM build for 'bot_model004'
### Finished parallel model reference SIM build for 'bot_model001'
### Finished parallel model reference SIM build for 'bot_model002'
### Finished parallel model reference SIM build for 'bot_model003'
### Finished parallel model reference SIM build for 'bot_model004'
### Starting parallel model reference RTW build for 'bot_model001'
### Starting parallel model reference RTW build for 'bot_model002'
### Starting parallel model reference RTW build for 'bot_model003'
### Starting parallel model reference RTW build for 'bot_model004'
### Finished parallel model reference RTW build for 'bot_model001'
### Finished parallel model reference RTW build for 'bot_model002'
### Finished parallel model reference RTW build for 'bot_model003'
### Finished parallel model reference RTW build for 'bot_model004'

```

To obtain more detailed information about a parallel build, you can examine the parallel build log. For each referenced model built in parallel, the build process generates a file named *model\_buildlog.txt*, where *model* is the name of the referenced model. This file contains the full build log for that model.

If a parallel build completes, you can find the build log file in the build subfolder corresponding to the referenced model. For example, for a build of referenced model *bot\_model004*, look for the build log file *bot\_model004\_buildlog.txt* in a referenced model subfolder such as *build\_folder/slprj/grt/bot\_model004*, *build\_folder/slprj/ert/bot\_model004*, or *build\_folder/slprj/sim/bot\_model004*. The build log (diagnostic viewer) provides a relative path to the location of each build log file.

If a parallel builds fails, you could see output similar to the following:

```

### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
...
### Starting parallel model reference RTW build for 'bot_model002'
### Starting parallel model reference RTW build for 'bot_model003'
### Finished parallel model reference RTW build for 'bot_model002'
### Finished parallel model reference RTW build for 'bot_model003'
### Starting parallel model reference RTW build for 'bot_model001'
### Starting parallel model reference RTW build for 'bot_model004'
### Finished parallel model reference RTW build for 'bot_model004'
### The following error occurred during the parallel model reference RTW build for
'bot_model001':

Error(s) encountered while building model "bot_model001"

### Cleaning up parallel workers.

```

If a parallel build fails, you can find the build log file in a referenced model subfolder under the build subfolder */par\_md\_l\_ref/model*. For example, for a failed parallel build

of model `bot_model001`, look for the build log file `bot_model001_buildlog.txt` in a subfolder such as `build_folder/par_md1_ref/bot_model001/slprj/grt/bot_model001`, `build_folder/par_md1_ref/bot_model001/slprj/ert/bot_model001`, or `build_folder/par_md1_ref/bot_model001/slprj/sim/bot_model001`.

## View Build Process Status

The **Build Process Status** window lets you view in-progress build status or cancel in-progress parallel builds of models. After completing a model build, you can view the completion status by using the **Build Process Status** window. For more information, see “Apply Build Process Status to Improve Parallel Builds” on page 54-53.

---

**Note** The **Build Process Status** window support parallel builds of referenced model hierarchies. Do not use the **Build Process Status** window for sequential (non-parallel) builds.

---

To open the **Build Process Status** window, use any of these options:

- To open the **Build Process Status** window for a *model*, in the command window, type:

```
coder.buildstatus.open('model')
```

- To open the **Build Process Status** window for a *model* with the `rtwbuild` function, in the command window, type:

```
rtwbuild('model', ...  
        'OpenBuildStatusAutomatically',true)
```

- To open the **Build Process Status** window for a *model* with the `slbuild` function, in the command window, type:

```
slbuild('model','StandaloneCoderTarget', ...  
        'OpenBuildStatusAutomatically',true)
```

To cancel an in-progress model build, the **Build Process Status** window provides a **Cancel** button. This button cancels the build after completion of the current model or referenced model build. Using cancel to stop a build ends a build process without creating out-dated build artifacts that require post-build clean up.

## Apply Build Process Status to Improve Parallel Builds

The **Build Process Status** window lets you view in-progress build status or cancel in-progress parallel builds of models. For more information, see “View Build Process Status” on page 54-52.

This example shows how apply build process status from parallel builds. The status information can help you identify ways to improve parallel builds by modifying the referenced model hierarchy.

- 1 Open a parallel pool for the build process and add the model folder to the path for all workers.

```
parpool('local', 2)
addpath(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'rtwdemo_parallelbuild'))
spmd
addpath(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'rtwdemo_parallelbuild'))
end
```

- 2 Open the top-level model in a reference model hierarchy. The `rtwdemo_parabuild_a_1` model refers to a number of referenced models.

```
open_system('rtwdemo_parabuild_a_1')
```

- 3 View the model dependencies with the Model Dependency Viewer. On the **Modeling** tab, in the **Evaluate & Manage** section, select **Dependencies > Referenced Model Instances**.

During the build process, the Build Process Status window displays the progress of the code generator as it works its way up the referenced model hierarchy. The code generator builds the referenced models in the order that they block building of models further up the dependency tree.

- 4 Start a parallel build of the referenced model hierarchy and open the Build Process Status window.

```
rtwbuild('rtwdemo_parabuild_a_1','OpenBuildStatusAutomatically',true)
```

- 5 As the build progresses, the Build Process Status window displays the status for each referenced model.

**BUILD STATUS**

Cancel Build

ACTIONS

Simulation Targets | Code Generation Targets

Elapsed Time: 00:00:32 | 1 of 4  
 Number of Active Workers: 1 of 2  
 Optimal Pool Size: Pending

Completed Models

Model Name	Status	Elapsed Time
rtwdemo_parabuild_a_1	Blocked	-
rtwdemo_parabuild_b_1	Building	-
rtwdemo_parabuild_b_2	Completed	00:00:25
rtwdemo_parabuild_b_3	Building	-

The table describes the types of build status.

<b>Build Process Status</b>	<b>Description</b>
<b>Blocked</b>	The code generator cannot schedule the model build because the build is blocked by dependencies. For example, another model build must complete before the blocked build can be scheduled.
<b>Scheduled</b>	For parallel build processes, the code generator schedules the model build when it is not blocked by dependencies. The model build waits at the scheduled status until a parallel core is available to process the model build.
<b>Building</b>	The code generator is executing the build process for the model.
<b>Completed</b> or <b>Error</b>	When the build process exits successfully, the status is Completed. When the build process is not success, the status is Error.
<b>Up To Date</b>	When the build process detects that it does not need to generate code (for example, generated code is current with the model), the status is Up to Date.
<b>Canceling</b> or <b>Canceled</b>	When you use the <b>Cancel Build</b> button, the build process changes the status of incomplete builds to Canceling. After processing the Canceling operation, the build process changes the status of these builds to Canceled.

The elapse time shows you where the build process spends time. Use the dependency tree of the model hierarchy and the elapse time of reference model builds to identify locations where the build process spends the most time and restricts the build progress. Some options for reducing the parallel build time include:

- Restructure the referenced model hierarchy to reduce build time for individual models.
- Provide sufficient parallel workers in the pool to match the number of referenced model dependencies being built.

## Relocate Code to Another Development Environment

If you require relocating the static and generated code files for a model to another development environment, use the pack-and-go utility. This condition occurs when your system or integrated development environment (IDE) does not include MATLAB and Simulink products.

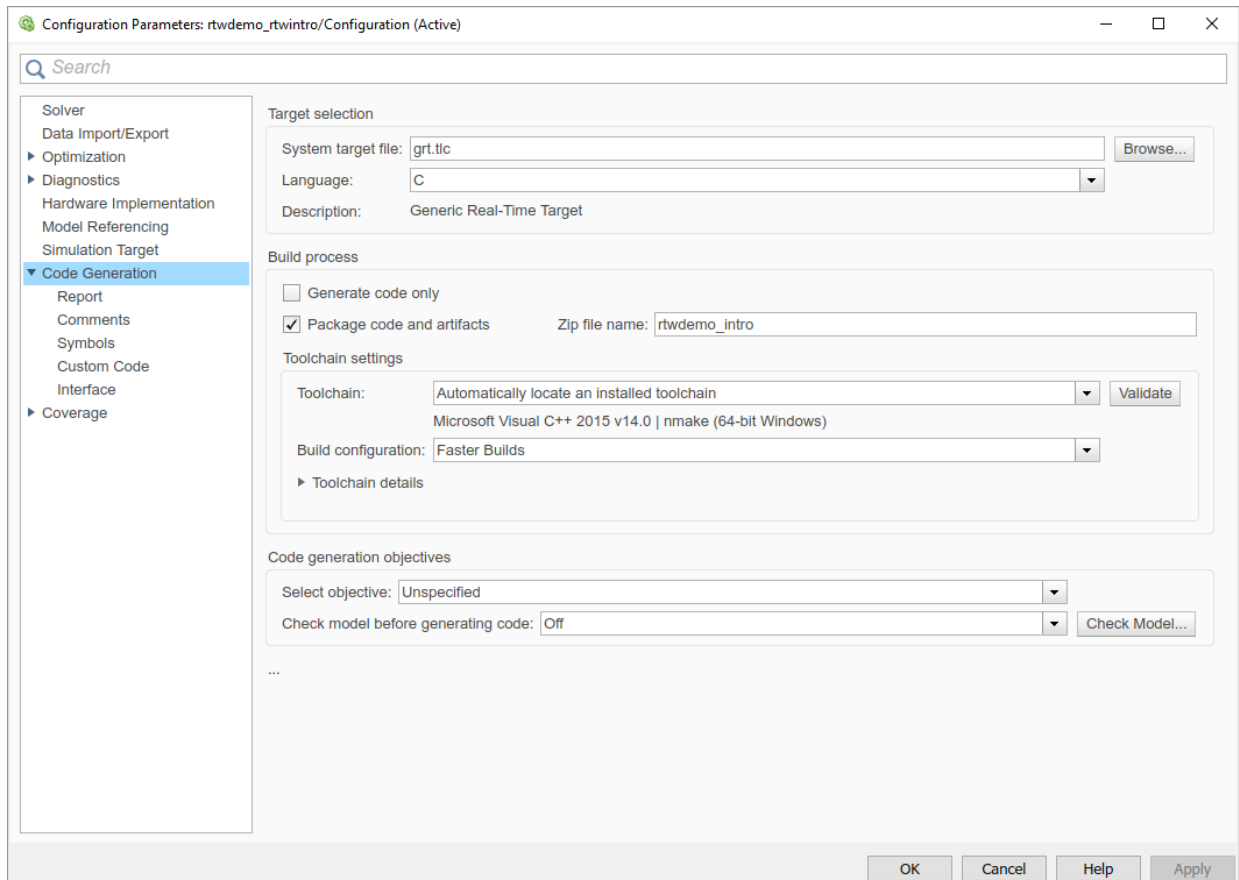

### Code Relocation

The pack-n-go utility uses the tools for customizing the build process after code generation and a `packNGo` function to find and package files for building an executable image. The files are packaged in a compressed file that you can relocate and unpack using a standard `zip` utility.

### Package Code Using the User Interface

To package and relocate code for your model using the user interface:

- 1 In the Configuration Parameters dialog box, select **Package code and artifacts** (Simulink Coder). This option configures the build process to run the `packNGo` function after code generation to package generated code and artifacts for relocation.
- 2 In the **Zip file name** (Simulink Coder) field, enter the name of the `zip` file in which to package generated code and artifacts for relocation. You can specify the file name with or without the `.zip` extension. If you do not specify an extension or an extension other than `.zip`, the `zip` utility adds the `.zip` extension. If you do not specify a value, the build process uses the name `model.zip`, where *model* is the name of the top model for which code is being generated.

- 3 Apply changes and generate code for your model. To verify that it is ready for relocation, inspect the resulting zip file. Depending on the zip tool that you use, you could be able to open and inspect the file without unpacking it.
- 4 Relocate the zip file to the destination development environment and unpack the file.

## Package Code Using the Command-Line Interface

To package and relocate code for your model using the command-line interface:

- 1 Select a structure for the zip file. on page 54-61

- 2 Select a name for the zip file. on page 54-61
- 3 Package the model code files in the zip file. on page 54-62
- 4 Inspect the generated zip file. on page 54-63
- 5 Relocate and unpack the zip file. on page 54-63

### Select a Structure for the Zip File

Before you generate and package the files for a model build, decide whether you want the files to be packaged in a flat or hierarchical folder structure. By default, the `packNGo` function packages the files in a single, flat folder structure.

If...	Then Use a...
You are relocating files to an IDE that does not use the generated makefile, or the code is not dependent on the relative location of required static files	Single, flat folder structure
The destination development environment must maintain the folder structure of the source environment because it uses the generated makefile, or the code depends on the relative location of files	Hierarchical structure

If you use a hierarchical structure, the `packNGo` function creates two levels of zip files, a primary zip file, which in turn contains the following secondary zip files:

- `mlrFiles.zip` — files in your *matlabroot* folder tree
- `sDirFiles.zip` — files in and under your build folder where you initiated code generation for the model
- `otherFiles.zip` — required files not in the *matlabroot* or *start* folder trees

Paths for the secondary zip files are relative to the root folder of the primary zip file, maintaining the source development folder structure.

### Select a Name for the Zip File

By default, the `packNGo` function names the primary zip file *model*. You have the option of specifying a different name. If you specify a file name and omit the file type extension, the function appends `.zip` to the name that you specify.

## Package Model Code in a Zip File

Package model code files by using the `PostCodeGenCommand` configuration parameter, `packNGo` function, and build information object for the model. You can set up the packaging operation to use:

- A system generated build information object.

In this case, before generating the model code, use `set_param` to set the configuration parameter `PostCodeGenCommand` to an explicit call to the `packNGo` function. For example:

```
set_param(bdroot, 'PostCodeGenCommand', 'packNGo(buildInfo);');
```

After generating and writing the model code to disk and before generating a makefile, this command instructs the build process to evaluate the call to `packNGo`. This command uses the system generated build information object for the currently selected model.

- A build information object that you construct programmatically.

In this case, you could use other build information functions to include paths and files selectively in the build information object that you then specify with the `packNGo` function. For example:

```
.
.
.
myModelBuildInfo = RTW.BuildInfo;
addSourceFiles(myModelBuildInfo, {'test1.c' 'test2.c' 'driver.c'});
.
.
.
packNGo(myModelBuildInfo);
```

The following examples show how you can change the default behavior of `packNGo`.

To...	Specify...
Change the structure of the file packaging to hierarchical	<code>packNGo(buildInfo, {'packType' 'hierarchical'});</code>
Rename the primary zip file	<code>packNGo(buildInfo, {'fileName' 'zippedsrcs'});</code>

To...	Specify...
Change the structure of the file packaging to hierarchical and rename the primary zip file	<code>packNGo(buildInfo, {'packType' 'hierarchical'... 'fileName' 'zippedsrcs'});</code>
Include header files found on the include path in the zip file	<code>packNGo(buildInfo, {'minimalHeaders' false});</code>
Generate warnings for parse errors and missing files	<code>packNGo(buildInfo, {'ignoreParseError' true... 'ignoreFileMissing' true});</code>

---

**Note** The `packNGo` function can potentially modify the build information passed in the first `packNGo` argument. As part of packaging model code, `packNGo` could find additional files from source and include paths recorded in build information for the model and add them to the build information.

---

### Inspect a Generated Zip File

To verify that it is ready for relocation, inspect the generated zip file. Depending on the zip tool that you use, you could be able to open and inspect the file without unpacking it. If unpacking the file and you packaged the model code files as a hierarchical structure, unpacking requires you to unpack the primary and secondary zip files. When you unpack the secondary zip files, relative paths of the files are preserved.

### Relocate and Unpack a Zip File

Relocate the generated zip file to the destination development environment and unpack the file.

### Code Packaging Example

This example shows how to package code files generated for the example model `rtwdemo_rtwintr` using the command-line interface:

- 1 Set your working folder to a writable folder.
- 2 Open the model `rtwdemo_rtwintr` and save a copy to your working folder.
- 3 Enter the following MATLAB command:

```
set_param('rtwdemo_rtwintr', 'PostCodeGenCommand',...
'packNGo(buildInfo, {'packType' 'hierarchical'})');
```

You must double the single-quotes due to the nesting of character arrays 'packType' and 'hierarchical' within the character array that specifies the call to packNGo.

- 4 Generate code for the model.
- 5 Inspect the generated zip file, `rtwdemo_rtwintro.zip`. The zip file contains the two secondary zip files, `mlrFiles.zip` and `sDirFiles.zip`.
- 6 Inspect the zip files `mlrFiles.zip` and `sDirFiles.zip`.
- 7 Relocate the zip file to a destination environment and unpack it.

## Limitations

### packNGo Function

For information about limitations that apply to this function, see `packNGo`.

### Executable File with Nondefault Extension

If a build process uses the template makefile approach, then `packNGo` uses the executable file extension specified by the linker tool to determine binary artifacts that require packaging.

If you generate an executable file with an extension that is not a default value, check that the extension is saved in the toolchain associated with the template makefile. For more information, see “Associate the Template Makefile with a Toolchain” (Simulink Coder).

If the build process generates an executable file with an extension that is different from the extension saved in the toolchain, `packNGo` does not package the executable file.

# Compile and Debug Generated C Code with Microsoft® Visual Studio®

This example shows how to generate code from a model and produce a Visual Studio Solution. For the base example, see `rtwdemo_counter`.

## About This Example

Building this example model generates a Visual Studio Solution. These model configuration parameter settings control this code generation:

- Set **System target file** to `grt.tlc`.
- Set **Template makefile** to `RTW.MSVCCBuild`.

When you build the model with this configuration, Simulink Coder generates code in a Visual Studio Solution. Add this solution to a Visual Studio C/C++ project to integrate generated code with your custom Visual Studio code.

## Before You Start

- This example builds code for Microsoft Visual Studio running on Microsoft Windows® platforms.
- This example works with Microsoft Visual Studio, but not with Visual Studio Express.
- Simulink Coder uses the GRT code format, which is intended for rapid prototyping.
- Embedded Coder uses the ERT code format, which is intended for production deployment.

## Example Steps

- 1 Open the example model `rtwdemo_counter_msvc`. In the Command Window, type: `open_system('rtwdemo_counter_msvc');`
- 2 To generate debug output in the generated Visual Studio Solution, set the model configuration parameter **Make command** to `make_rtw DEBUG_BUILD=1`. (Omit this step if debug output is not required in the solution.)
- 3 To generate code and build a program executable, initiate the build process.
- 4 After the build process is complete, you can see a Visual Studio Solution was generated and placed in the `msvc` folder under folder `rtwdemo_counter_msvc_grt_rtw`.

- 5 In Microsoft Visual Studio, open the `rtwdemo_counter_msvc.sln` solution file. Use the solution to build and debug the generated code in Visual Studio.

## Executable Program Generation

The following figure shows how the process for program building.

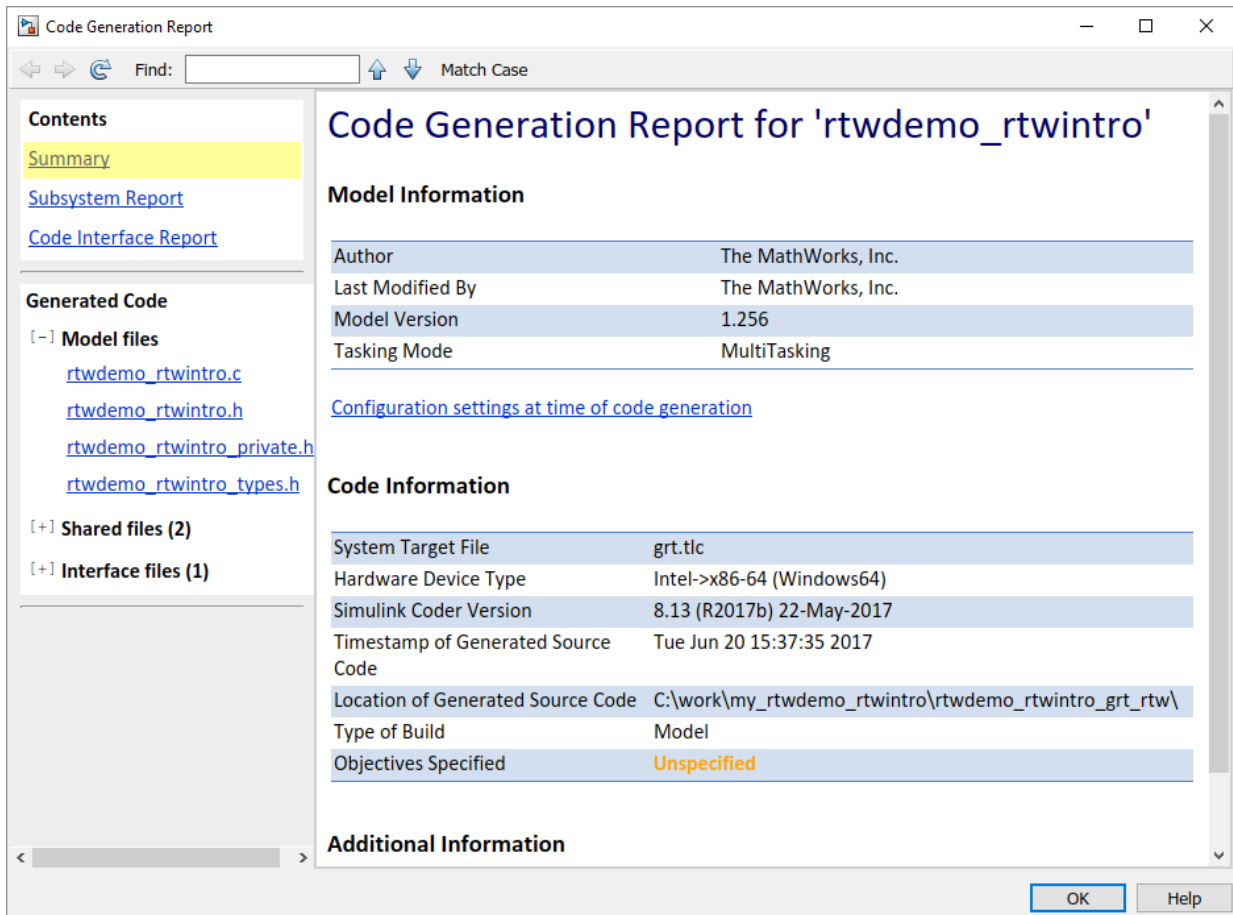

During the final stage of processing, the build process invokes the generated makefile, *model.mk*, which in turn compiles and links the generated code. On PC platforms, a batch file is created to invoke the generated makefile. The batch file sets up the environment for invoking the make utility and related compiler tools. To avoid recompiling C files, the make utility performs date checking on the dependencies between the object and C files; only out-of-date source files are compiled. Optionally, the makefile can download the resulting executable image to your target hardware.

This stage is optional, as illustrated by the control logic in the preceding figure. You could choose to omit this stage (for example, if you are targeting an embedded microcontroller board).

To omit this stage of processing, in the Configuration Parameters dialog box, select the **Generate code only** check box. You can then cross-compile your code and download it to your target hardware.

If you also select the **Create code generation report** check box, the code generator produces an HTML report. To view the report, on the **C Code** tab, select **Open Latest Report**. This example is a code generation report for a generic real-time (GRT) system target file.

## Profile Code Execution Speed

By profiling the execution speed of generated code, you can help verify that the code meets execution speed requirements.

Profiling can be especially important early in the development cycle for identifying potential architectural issues that can be more expensive to address later in the process. Profiling can also identify bottlenecks and procedural issues that indicate a need for optimization, for example, with an inner loop or inline code.

---

**Note** If you have an Embedded Coder license, see “Code Execution Profiling” for an alternative and simpler approach based on software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations.

---

### Use the Profile Hook Function Interface

You can profile code generated with code generation technology by using a Target Language Compiler (TLC) hook function interface.

To use the profile hook function interface:

- 1 For your system target file, create a TLC file that defines the following hook functions. Write the functions so that they specify profiling code. The code generator adds the hook function code to code generated for atomic systems in the model.

Function	Input Arguments	Output Type	Description
ProfilerHeaders	void	Array of header file names	Return an array of the header file names to be included in the generated code.
ProfilerTypedefs	void	typedefs	Generate code statements for profiler type definitions.
ProfilerGlobal-Data	system	Global data for the specified system	Generate code statements that declare global data.

Function	Input Arguments	Output Type	Description
ProfilerExtern-DataDecls	system	extern declarations for the specified system	Generate code statements that create global extern declarations.
ProfilerSystem-Decls	system, functionType	Declarations for the specified system for the specified functionType	Generate code for required variable declarations within the scope of an atomic subsystem Output, Update, OutputUpdate, or Derivatives function.
ProfilerSystem-Start	system, functionType	Profiler start commands for the specified system and functionType	Generate code that starts the profiler within the scope of an atomic subsystem Output, Update, OutputUpdate, or Derivatives function.
ProfilerSystem-Finish	system, functionType	Profiler end commands for the specified system and functionType	Generate code that stops the profiler within the scope of the Output, Update, OutputUpdate, or Derivatives functions of an atomic subsystem.
ProfilerSystem-Terminate	system	Profiler termination code for the specified system	Generate code that terminates profiling (and possibly reports results) for an atomic subsystem.

2 In your *target.tlc* file, define the following global variables.

Define...	To Be...
ProfileGenCode	TLC_TRUE or 1 to turn on profiling (TLC_FALSE or 0 to turn off profiling)
ProfilerTLC	The name of the TLC file that you created in step 1

A quick way to define global variables is to define the parameters with the `-a` option. You can apply this option by using the `set_param` command to set the model configuration parameter `TLCOptions`. For example,

```
>> set_param(gcs,'TLCOptions', ...
    '-aProfileGenCode=1 -aProfilerTLC="rtwdemo_profile_hook.tlc"')
```

- 3 Consider setting configuration parameters for generating a code generation report. You can then examine the profiling code in the context of the code generated for the model.
- 4 Build the model. The build process embeds the profiling code in the hook function locations in the generated code for the model.
- 5 Run the generated executable file. In the MATLAB Command Window, enter `!model-name`. You see the profiling report you programmed in the profiling TLC file that you created. For example, a profile report could list the number of calls made to each system in a model and the number of CPU cycles spent in each system.

For details on programming a `.tlc` file and defining TLC configuration variables, see “Target Language Compiler” (Simulink Coder).

## Profile Hook Function Interface Limitation

The TLC hook function interface for profiling code execution speed does not support the S-function system target file (`rtwsfcn.tlc`).

## Host-Target Communication with External Mode Simulation

You can use external mode simulations for rapid prototyping. An external mode simulation establishes a communication channel between Simulink on your development computer (host) and the target hardware that runs the executable file created by the code generation and build process.

Through the communication channel, you can:

- Modify or tune block parameters in real time. When you change parameters in the model, Simulink downloads the new values to the executing target application.
- Monitor and save signal data from the executing target application.

The low-level transport layer of the channel handles the physical transmission of messages. Simulink and the generated model code are independent of this layer. The transport layer and its interface code are isolated in separate modules that format, transmit, and receive messages and data packets.

## Communication Mechanisms for External Mode

Simulink supports two communication mechanisms for external mode simulation. To decide which mechanism to use, see the information in this table .

Communication Mechanism	Supported By	Why Select
<p>XCP, the Universal Measurement and Calibration Protocol</p>	<p>ERT and GRT system target files.</p> <p>Some Simulink support packages. For details, see <a href="https://www.mathworks.com/hardware-support.html?q=&amp;page=1">https://www.mathworks.com/hardware-support.html?q=&amp;page=1</a>.</p>	<p>XCP external mode:</p> <ul style="list-style-type: none"> <li>• Uses a standard communication protocol.</li> <li>• Requires only a lightweight communication software stack on the target hardware.</li> <li>• Supports signal logging and streaming for Dashboard blocks and the Simulation Data Inspector. You can stream signals from within a referenced model hierarchy.</li> <li>• Provides documented <code>ext_mode.h</code> API for external mode target connectivity.</li> <li>• Supports streaming of execution-time metrics to the Simulation Data Inspector for host-based and support package external mode simulations.</li> </ul> <p>For information about running XCP external mode simulations, see:</p> <ul style="list-style-type: none"> <li>• “External Mode Simulation by Using XCP Communication” on page 55-9</li> <li>• “Customize XCP Slave Software” on page 55-26</li> </ul>

Communication Mechanism	Supported By	Why Select
TCP/IP and serial (RS-232)	ERT, GRT, and RSim system target files.  Simulink support packages.	<p>You do not use the Simulation Data Inspector for visualizing, exporting, and saving data.</p> <p>You want to use signal triggering.</p> <p>For information about running TCP/IP and serial external mode simulations, see:</p> <ul style="list-style-type: none"> <li>• “External Mode Simulation with TCP/IP or Serial Communication” on page 55-39</li> <li>• “Create a Transport Layer for TCP/IP or Serial External Mode Communication” on page 55-89</li> </ul>

## Simulink Feature Support for External Mode

This table summarizes feature support for both forms of external mode simulations.

Feature		XCP Support	TCP/IP and Serial Support
Parameter tuning	With Dashboard blocks	Yes	Yes
	Of tunable (Simulink) block parameters	Yes	Yes
Simulation Data Inspector		Yes. Includes signals within referenced models.	No

Feature		XCP Support	TCP/IP and Serial Support
Logic Analyzer		Yes. Includes signals within referenced models.	No
Blocks that receive and display signals from target application	Dashboard	Yes	No
	Floating Scope, Scope	Yes, provided signal logging is enabled for block input.	Yes
	Spectrum Analyzer, Time Scope (DSP System Toolbox)	Yes, provided signal logging is enabled for block input.	Yes
	Display	Yes, provided signal logging is enabled for block input.	Yes
	To Workspace	Yes, provided signal logging is enabled for block input.	Yes
	User-written S-Function. A method, which enables user-written blocks to support external mode, is built into the S-function API.  See <i>matlabroot/simulink/include/simstruc.h</i> .	Yes, provided signal logging is enabled for block input.	Yes
	XY Graph	Yes, provided signal logging is enabled for block input.	Yes
